B. Anorexia and vomiting also possible
II. Physical examination findings
A. Similar to those of an uncomplicated diabetic
B. Dehydration
C. Depression and weakness
D. Acetone breath
E. Tachypnea

Diagnosis

I. Diagnostic findings are similar to DM, but ketonuria (or ketosis) and acidosis are also present.
II. Additional diagnostics are mandatory in DKA.
A. CBC, serum biochemistry profile
B. UA, urine C & S
C. Canine or feline pancreatic lipase immunoreactivity
D. Amylase, lipase (dogs)
E. Serum thyroxine concentration (cats and dogs) and serum thyroid hormone-stimulating concentration (dogs)

Differential Diagnosis

I. Ketosis
A. Starvation
B. Low-carbohydrate diet
C. Persistent hypoglycemia
D. Persistent fever
E. Pregnancy
II. Acidosis
A. Renal failure
B. Lactic acidosis
C. Toxin exposure
D. Severe tissue destruction
E. Severe diarrhea
F. Chronic vomiting

Treatment

I. Intravenous fluid therapy is the most important component of DKA treatment.
II. Correction of electrolyte abnormalities is imperative.
A. Add potassium to IV fluids and administer at a rate not to exceed 0.5 mEq/kg/hr (Box 44-1).
B. Correct hypophosphatemia with potassium phosphate (potassium 4.4 mEq/mL, phosphate 3 mM/mL) at 0.03 mM phosphate/kg/hr with IV fluids, calculating for concurrent administration of potassium.

Box 44-1

Potassium Supplementation in Hypokalemic Animals*

Serum potassium concentration (mmol/L)	Potassium (mEq) added to 250-mL fluid bag
6-2	20
1-2.5	15
6-3.0	10
1-3.5	7

*Not to exceed 0.5 mEq/kg/hr IV.

TABLE 44-2

Administration of Intravenous Insulin in Animals with Diabetic Ketoacidosis*

BLOOD GLUCOSE CONCENTRATION (mg/dL)	FLUID COMPOSITION	RATE OF ADMINISTRATION (mL/hr)
>250	0.9% NaCl	10
200-250	0.45% NaCl + 2.5% dextrose	7
150-200	0.45% NaCl + 2.5% dextrose	5
100-150	0.45% NaCl + 5% dextrose	5
<100	0.45% NaCl + 5% dextrose	Stop fluid administration

*Give 2.2 U/kg of regular crystalline insulin added to 250 mL of NaCl solution.

C. Correct hyponatremia with IV saline diuresis (0.9% saline).
D. Correct hypomagnesemia with magnesium sulfate (4 mEq/mL) at 1 mEq/kg/24 hr IV.

III. Correction of hyperglycemia is undertaken with insulin therapy.
A. Insulin is only administered IV (Table 44-2) or IM in animals with DKA.
B. IM insulin administration is as follows:
1. Give regular crystalline insulin IM every hour.
2. Begin with 0.2 U/kg insulin.
3. Then give 0.1 U/kg IM 1 hour later.
4. Treatment with IM regular insulin is continued based on blood glucose concentration
a. Give 0.05 U/kg/hr if blood glucose drops >75 mg/dL/hr.
b. Give 0.1 U/kg/hr if blood glucose drops 50 to 75 mg/dL/hr.
c. Give 0.2 U/kg/hr if blood glucose drops <50 mg/dL/hr.

IV. Acidosis is usually corrected with IV fluid administration and insulin therapy alone.
A. Bicarbonate is not needed for treatment of acidosis in most dogs and cats with DKA.
B. The use of bicarbonate for correction of acidosis is controversial and may be harmful.
C. If venous pH remains <7.1 after 1 hour of fluid therapy, consider administering sodium bicarbonate at one third to half the calculated bicarbonate need (0.3 × body weight × negative base excess) over 20 minutes and monitor venous pH every 1 hour until venous pH is ≥7.1.

V. Treat concurrent diseases to help decrease secretion of diabetogenic hormones and lessen insulin resistance.

Monitoring of Animal

I. Monitor hydration status continuously.
II. Monitor blood glucose every 2 hours.
III. Monitor electrolytes and venous pH every 4 hours.
IV. Monitor ketonuria once daily.
V. Continue monitoring as for DM once the ketoacidotic crisis resolves.

HYPEROSMOLAR NONKETOTIC DIABETES MELLITUS

Definition

I. A severe nonketotic form of complicated DM
II. Characterized by hyperosmolarity (>350 mOsm/kg)
III. A medical emergency

Cause and Pathophysiology

I. Severe hyperglycemia contributes to hyperosmolarity.
II. Ketosis may be prevented by residual insulin activity.
III. Increased plasma osmolarity results in movement of fluid from within the cells to the extracellular fluid space.

Clinical Signs

I. Similar to DKA without acetone breath or tachypnea
II. Possible mental obtundation, coma, and death

Diagnosis

I. Diagnostic findings are the same as for DKA except that animals are severely hyperglycemic and hyperosmolar (>350 mOsm/kg).
II. The animal may not be ketoacidotic.

Treatment

I. Similar to DKA, but use 0.45% NaCl to decrease serum sodium concentration; use 0.9% saline if the animal is in shock.
II. Rapid correction of hyperosmolarity is potentially fatal.

Monitoring of Animal

I. Monitoring is similar to DKA, with additional monitoring of osmolarity every 4 hours.
II. Mental status is monitored continuously.

NEOPLASIA

Insulinoma

See Chapters 45 and 73.

Glucagonoma

See Table 44-3 and Chapter 73.

Gastrinoma

See Table 44-3.

TABLE 44-3

Uncommon Tumors of the Pancreas

TUMOR TYPE	CELL ORIGIN	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Glucagonoma	Pancreatic alpha cells	Middle-aged to older dogs	Presence of a pancreatic tumor containing glucagon and hyperglucagonemia	Surgical excision of pancreatic tumor Somatostatin (octreotide): 10-40 μg SC BID-TID
		Necrolytic migratory erythema	Painful crusting and erosions of foot pads Erythema and ulceration of muzzle, mucocutaneous junctions	Treatment of skin disease (Byrne, 1999)
		Diabetes mellitus or small amount of intestinal diarrhea possible	See text	Treatment of small-bowel diarrhea: see Chapter 33 Poor prognosis
Gastrinoma	Residual fetal delta cells or delta cells that revert back to their fetal function of gastrin secretion	Vomiting/hematemesis, diarrhea/hematochezia, melena, weight loss, anorexia, abdominal pain, polydipsia, lethargy, depression, regurgitation, steatorrhea, dehydration, tachycardia, fever, palpable pancreatic mass	Documentation of hypergastrinemia is necessary, but not solely sufficient for a diagnosis of gastrinoma Secretin stimulation test Calcium stimulation test A gastrin-containing pancreatic mass aids the diagnosis	Surgical excision of pancreatic tumor Somatostatin (octreotide): 10-40 μg SC BID-TID H_2-histaminergic blockers: cimetidine, ranitidine H^+ pump inhibitor: omeprazole Sucralfate, misoprostol

CHAPTER 45

Diseases of the Adrenal Gland

Deborah S. Greco

HYPOADRENOCORTICISM

Definition

Hypoadrenocorticism (Addison's disease) arises from deficient secretion of mineralocorticoids (aldosterone) and glucocorticoids by the adrenal gland.

Causes and Pathophysiology

I. Naturally occurring, primary hypoadrenocorticism is usually caused by immune-mediated destruction of the adrenal cortex in cats and dogs.
II. Lymphoma of the adrenal glands is a cause of Addison's disease in cats.
III. Secondary hypoadrenocorticism results when the pituitary gland produces inadequate amounts of adrenocorticotropic hormone (ACTH).
  A. Secondary to chronic steroid therapy
  B. Associated with tumors, trauma, or congenital defects of the pituitary gland
IV. Hypoadrenocorticism associated with glucocorticoid deficiency only is termed *atypical Addison's disease.*
  A. Secondary hypoadrenocorticism is always atypical.
  B. Primary hypoadrenocorticism is atypical in the early stages of the disease, before destruction of the zona glomerulosa.

Clinical Signs

I. Signalment (Kintzer and Peterson, 1997)
  A. Young female dogs (70%) of any breed
  B. Reported in families of Leonbergers and standard poodles (Smallwood and Barsanti, 1995)
  C. Young cats of any breed or sex
II. Historical findings (Table 45-1)
  A. Gastrointestinal (GI) signs: intermittent vomiting, anorexia, diarrhea, melena, weight loss
  B. General signs: lethargy, depression, weakness
  C. Miscellaneous signs: hair loss, polyuria/polydipsia (PU/PD), waxing and waning course
  D. Hypoadrenal crisis: any of the GI, general, and miscellaneous signs plus collapse, hypothermia, shaking
III. Physical examination findings (Box 45-1)
  A. Acute addisonian crisis
    1. Weak pulses
    2. Bradycardia
    3. Prolonged capillary refill time
    4. Severe mental depression
    5. Profound muscle weakness
  B. Features increasing the index of suspicion of hypoadrenocorticism
    1. Normal or slow heart rate in the presence of circulatory shock
    2. Previous response to corticosteroid or fluid therapy
    3. Waxing and waning course of disease before collapse

Diagnosis

I. Serum biochemical abnormalities
  A. Classic electrolyte abnormalities: hyponatremia, hyperkalemia, hypochloremia
  B. Sodium: potassium ratios <27:1 suggestive
  C. Prerenal azotemia and hyperphosphatemia
  D. Hypercalcemia in 30% of cases (Peterson and Feinman, 1982)
  E. Metabolic acidosis
  F. Animals with glucocorticoid deficiency only
    1. No classic electrolyte imbalances
    2. Possible hypoglycemia
II. Complete blood count (CBC)
  A. Mild normocytic normochromic (nonregenerative) anemia (masked by dehydration)
  B. The absence of a stress leukogram
    1. Important feature of atypical hypoadrenocorticism
    2. Atypical hypoadrenocorticism likely with increased eosinophil or lymphocyte count
III. Urinalysis
  A. Urine specific gravity is frequently low owing to medullary washout and decreased medullary blood flow.
  B. Hormonal assays are required to differentiate between hypoadrenocorticism and renal failure.
IV. Electrocardiography (ECG) and radiography
  A. ECG findings: prolonged QRS complex, decreased R wave amplitude, increased T wave amplitude ("spiked" T waves), prolonged or absent P waves, heart block, and sinoatrial standstill
  B. Thoracic radiography: microcardia, narrowed vena cava, hypoperfused lungs, rarely megaesophagus
V. Dynamic adrenal testing (Table 45-2)

TABLE 45-1

Clinical Signs and Abnormal Laboratory Findings in Dogs and Cats with Primary Hypoadrenocorticism (Addison's Disease)

	CATS (%) (*n* = 10)	DOGS (%) (*n* = 225)
Clinical Signs		
Lethargy	100	95
Anorexia	100	90
Weight loss	100	50
Dehydration	88	45
Weakness	75	75
Slow capillary refill time	63	30
Weak pulses	50	20
Vomiting	25	75
Polyuria/polydipsia	25	25
Bradycardia	13	18
Diarrhea	—	40
Waxing/waning course	—	40
Previous response to therapy	—	35
Hypothermia	—	35
Shaking	—	27
Melena	—	15
Painful abdomen	—	8
Hair loss	—	5
Laboratory Findings		
Hyperkalemia	100	95
Hyponatremia	100	80
Hypochloremia	100	40
Azotemia	100	85
Hyperphosphatemia	88	85
Metabolic acidosis	—	40
Increased ALT/AST	—	30
Hyperbilirubinemia	—	20
Hypercalcemia	13	30
Hypoglycemia	—	17
Anemia	25	25
Eosinophilia	20	13
Lymphocytosis	38	10
Urine specific gravity < 1.030	—	75

Data from Kintzer PP, Peterson ME: Treatment and long-term follow-up of 205 dogs with hypoadrenocorticism. J Vet Intern Med 11:43, 1997; Peterson ME, Greco DS, Orth DR: Hypoadrenocorticism in ten cats. J Vet Intern Med 3:55, 1989.

ALT, Alanine transaminase; *AST,* aspartate transaminase.

Box 45-1

Comparison of the Clinical Features of Typical and Atypical Hypoadrenocorticism

Typical Hypoadrenocorticism	Atypical Hypoadrenocorticism
Pathogenesis	
Late primary adrenal insufficiency	Early primary adrenal insufficiency
Secondary adrenal insufficiency (ACTH deficiency)	
Signalment	
Young (<5 years)	Young (<5 years)
Dogs: female; cats: either sex	Dogs: female
Standard poodles, Leonbergers	Any breed
Clinical Signs	
Weakness	Anorexia
Lethargy	Lethargy
Depression	Depression
Vomiting	Vomiting
Diarrhea	Chronic diarrhea
Anorexia	Waxing and waning course
Previous response to therapy	Previous response to therapy
Collapse	Hair loss
Shock	
Hypothermia	
Shaking	
Polydipsia/polyuria	
Painful abdomen	
Melena	
Hair loss	
Laboratory Findings	
Lack of stress leukogram	Lack of stress leukogram
Eosinophilia	Eosinophilia
Hyponatrema	Lymphocytosis
Hyperkalemia	Hypoglycemia
Hypochloremia	
Na^+:K^+ ratio < 27	
Azotemia	
Hypercalcemia	
Metabolic acidosis	
Hypoglycemia	
Endocrine Testing	
Decreased cortisol before and after ACTH	Decreased cortisol before and after ACTH
High endogenous ACTH	Secondary: low endogenous ACTH

ACTH, Adrenocorticotropin hormone.

A. With ACTH response test serum samples are obtained before and at 30 minutes (cats) and 1 hour (cats and dogs) after IV administration of synthetic ACTH (cosyntropin 0.5 mg/kg IV, IM).
B. Baseline and post-ACTH cortisol concentrations are usually low or undetectable.

VI. Endogenous plasma ACTH

A. Collect blood in an ethylenediamine tetraacetic acid (EDTA) tube, separate, and store in plastic before the administration of any corticosteroids.
B. Primary hypoadrenocorticism has endogenous ACTH concentrations usually >100 pg/mL as a result of loss of negative feedback to the pituitary gland.

TABLE 45-2

Protocols for Dynamic Adrenal Function Testing in Dogs and Cats

SCREENING TEST	PROTOCOL	NORMAL VALUES
Corticotropin (ACTH) stimulation test		
Cosyntropin	Dog: 0.5 U/kg aqueous corticotropin IV, IM Serum samples at 0 and 1 hr Cat: 1/2 vial aqueous corticotropin IV, IM Serum samples at 0, 30, 60 min	Pre: 1-4 µg/dL (28-110 nmol/L) Post-ACTH: <20 µg/dL (550 nmol/L)
ACTH gel*	2.2 U/kg corticotropin gel IM (max 20 U in dog) Serum samples at 0 and 2 hr in dog Serum samples at 0, 1, 2 hr in cat	Same as for Cosyntropin
Endogenous ACTH	Single plasma sample (may be collected before screening test and frozen for later analysis) Collect in EDTA Vacutainer (with aprotinin) Centrifuge and store in plastic Ship at 4° C (or frozen if not collected in aprotinin)	20-80 pg/mL (4.4-17.6 pmol/L)

ACTH, Adrenocorticotropic hormone; *max,* maximum; *EDTA,* ethylenediamine tetraacetic acid.

*Efficacy of compounded gels vary (Kemppainen RJ, Behrend EN, Busch KA: Use of compounded adrenocorticotropin hormone (ACTH) for adrenal function testing in dogs. J Am Anim Hosp Assoc 41:368, 2005).

C. Secondary hypoadrenocorticism demonstrates the following:
   1. Decreased endogenous ACTH concentrations (<20 pg/mL)
   2. Diminished exogenous ACTH response
   3. Possibly normal baseline cortisol and post-ACTH cortisol concentrations

Differential Diagnosis

I. Inflammatory bowel disease
II. Intestinal parasitism: *Trichuris vulpis*
III. Bilious vomiting syndrome
IV. Acute renal failure
V. Other causes of hypercalcemia
VI. Postrenal azotemia

Treatment

I. Therapy of acute adrenal crisis
   A. Fluid therapy and stabilization of electrolytes with 0.9% NaCl at shock doses (see Chapter 132)
   B. Glucocorticoid replacement
      1. Dexamethasone sodium phosphate 2 to 4 mg/kg IV (no interference with the cortisol assay)
      2. Prednisolone sodium succinate 15 to 20 mg/kg IV
   C. Correction of life-threatening hyperkalemia
      1. Regular insulin (0.06 to 0.12 U/kg IV) and glucose (4 mL of 50% dextrose/unit insulin IV)
      2. 10% calcium gluconate 0.4 to 1.0 mL/kg IV over 10 to 20 minutes; maximum 10 mL
   D. Prevention and treatment of GI hemorrhage
      1. Treat shock aggressively, because GI hemorrhage occurs after poor intestinal perfusion.
      2. Treatment includes blood transfusion and GI protectants, such as sucralfate 0.5 to 1 g/25 kg PO TID to QID (dogs).
   E. Correction of metabolic acidosis
      1. Metabolic acidosis often resolves after fluid therapy.
      2. Severe acidosis (pH <7.1) is treated with sodium bicarbonate 0.5 mEq/kg IV for 1 to 2 doses.
   F. Treatment of any hypoglycemia: slow IV bolus of 50% dextrose (0.5 to 1.0 mL/kg)
II. Maintenance therapy
   A. Mineralocorticoid supplementation
      1. Oral fludrocortisone acetate 0.02 mg/kg PO SID
      2. Desoxycorticosterone pivalate (DOCP) 1.5 to 2.2 mg/kg IM, SC every 25 days
   B. Prednisone supplementation (0.22 mg/kg) with DOCP
      1. Administer 0.2 to 0.4 mg/kg PO SID to QOD to dogs on fludrocortisone.
      2. When DOCP is used, give 50% of prednisone dose required by fludrocortisone-treated dogs.
      3. Provide additional prednisone (double dose) during periods of stress.
   C. Injectable medication for affected cats
      1. Methylprednisolone acetate (Depo-Medrol) 10 mg IM every 3 to 4 weeks
      2. DOCP 12.5 mg IM every 3 to 4 weeks

Monitoring of Animal

I. Measure serum electrolytes every 3 weeks until optimum dosage and interval of administration are determined.
II. DOCP injections are usually required every 25 to 40 days in dogs, and every 30 days in cats.
III. Serum potassium often remains slightly elevated (4.5 to 5.2 mEq/L) in clinically controlled animals.

HYPERADRENOCORTICISM

Definition

The clinical syndrome of hyperadrenocorticism, or Cushing's syndrome, arises with chronic and/or excessive exposure to glucocorticoids.

Causes and Pathophysiology

I. Pituitary-dependent hyperadrenocorticism (PDH) (Feldman and Nelson, 1996)
   A. Approximately 85% of affected dogs and 90% of affected cats have PDH.
   B. Pituitary microadenomas (70%) and macroadenomas (30%) cause excessive endogenous ACTH secretion, with secondary adrenal hyperplasia.
II. Adrenal tumors (Feldman and Nelson, 1996)
   A. Approximately 15% of animals with hyperadrenocorticism have adrenal tumors.
   B. Of those tumors, 50% are malignant.
III. Iatrogenic hyperadrenocorticism
   A. Prolonged or excessive glucocorticoid administration
   B. Results in chronic negative feedback to the pituitary, decreased endogenous ACTH, and secondary adrenal atrophy

Clinical Signs

I. Signalment
   A. Middle-aged to older dogs or cats (7 to 12 years)
   B. PDH: miniature poodle, dachshund, boxer, Boston terrier, beagle
   C. Adrenal tumors: large-breed dogs, female (3:1) predilection
II. Common historical and clinical signs
   A. PU/PD
   B. Polyphagia, pica
   C. Heat intolerance, panting
   D. Lethargy, muscle weakness
   E. Obesity, abdominal enlargement or "pot belly" appearance
   F. Recurrent urinary tract infections
   G. Cutaneous manifestations (see Chapter 87)
III. Uncommon clinical manifestations of hyperadrenocorticism
   A. Hypertension
   B. Pulmonary thromboembolism
   C. Testicular atrophy in males, clitoral hypertrophy in females
   D. Congestive heart failure
   E. Prostatomegaly in castrated male dogs
   F. Perianal adenoma in a female or castrated male dog
   G. Bronchial calcification
   H. Corneal ulceration (nonhealing)
   I. Cranial cruciate rupture (small dog)
   J. Blindness
   K. Behavior changes: "steroid rage" in cats
   L. Pseudomyotonia
   M. Polyneuropathy and myopathy

Diagnosis

I. Minimum database
   A. Serum biochemistry profile
      1. Increased serum alkaline phosphatase (SAP), usually >1000 IU/L (except in cats)
      2. Increased alanine transaminase
      3. Hypercholesterolemia
      4. Hyperglycemia
      5. Decreased blood urea nitrogen
   B. CBC changes
      1. Nucleated red blood cells
      2. Erythrocytosis
      3. Stress leukogram
      4. Basophilia
   C. Urinalysis findings
      1. Bacteriuria without pyuria
      2. ± Glycosuria
      3. Hyposthenuria or minimally concentrated urine
      4. ± Proteinuria
II. Screening tests (Table 45-3)
   A. Low-dose dexamethasone suppression (LDDS) test
      1. The LDDS is an extremely sensitive test (92% to 95%) (Feldman, 1983a).
      2. Only 5% to 8% of dogs with PDH exhibit suppressed cortisol concentrations at 8 hours (i.e., 5% to 10% false negatives).
      3. Some (30%) dogs with PDH exhibit suppression at 3 to 4 hours, followed by "escape" of suppression at 8 hours; this pattern is diagnostic for PDH, and makes further testing unnecessary.
      4. The major disadvantage of the LDDS test is the lack of specificity in dogs with nonadrenal illness; over 50% of dogs with nonadrenal illness have a positive LDDS test (Box 45-2) (Kaplan and Peterson, 1995).
   B. Modified high-dose dexamethasone suppression (HDDS) test
      1. Dexamethasone 0.1 mg/kg IV
      2. Used to screen cats for hyperadrenocorticism
   C. ACTH (corticotropin) stimulation test
      1. ACTH stimulation test has a sensitivity of approximately 80% to 85% for the diagnosis of naturally occurring hyperadrenocorticism (Peterson et al., 1982).
      2. Specificity is higher than the LDDS test, and only 15% of dogs with nonadrenal disease showed an exaggerated response to ACTH stimulation.
      3. Adrenal tumors are difficult to diagnose using the ACTH stimulation test.
      4. Cortisol samples are collected at 30 and 60 minutes post-ACTH injection in cats.
   D. Urine cortisol: creatinine ratio (UCCR)
      1. The UCCR is a highly sensitive (99%) screening test with few false-negative results (Feldman and Mack, 1992; Mack et al., 1994).
      2. The test is not specific for hyperadrenocorticism, because dogs with moderate to severe nonadrenal illness may also have elevated ratios.

TABLE 45-3

Protocols for Screening and Differentiation Tests for Hyperadrenocorticism

	PROTOCOL	NORMAL VALUES
Screening Tests		
Low-dose dexamethasone suppression test	1. 0.015 mg/kg dexamethasone solution *(Azium)* IV, IM 2. 0.01 mg/kg dexamethasone sodium phosphate IV Samples at 0, 3-4 and 8 hr	Pre: 1-4 µg/dL (28-110 nmol/L) 3 hr: < 1.5 µg/dL (40 nmol/L) 8 hr: < 1.5 µg/dL (40 nmol/L)
Corticotropin (ACTH) stimulation test	1. 0.5 U/kg aqueous corticotropin IV Samples at 0 and 1 hr 2. 2.2 U/kg corticotropin gel IM (max 20 U in dogs) Samples at 0 and 2 hr	Pre: 1-4 µg/dL (28-110 nmol/L) Post-ACTH: <20 µg/dL (550 nmol/L)
Urine cortisol: creatinine ratio	Single urine sample, voided or collected by cystocentesis	Dependent on laboratory
Alkaline phosphatase isoenzyme	Single serum sample SAP should be at least 2-3 times greater than normal	< 150 U/L
Differentiation Tests		
High-dose dexamethasone suppression test	1. 1 mg/kg dexamethasone sodium IV 2. 0.1 mg/kg dexamethasone sodium phosphate IV Samples at 0 and 8 hr	Suppression to < 1.5 µg/dL (40 nmol/L) at 8 hr
Endogenous ACTH	Single plasma sample (may be collected before screening test and frozen for later analysis) Collect in EDTA Vacutainer (with aprotinin) Centrifuge and store in plastic Ship at 4° C (or frozen if not collected in aprotinin)	20-80 pg/mL (4.4-17.6 pmol/L)

ACTH, Adrenocorticotropin; *max,* maximum; *SAP,* serum alkaline phosphatase; *EDTA,* ethylenediamine tetraacetic acid.

3. Collect three samples at home to decrease the probability of stress-associated false-positive results.
4. An increased UCCR is followed by an ACTH stimulation test or an LDDS test.

E. SAP isoenzyme
1. Advantages of SAP isoenzyme determination: wide availability, low cost
2. Disadvantages
   a. Elevations possibly induced by small amounts of exogenous steroids (e.g., ocular preparations)
   b. Low specificity (<44%)
   c. Affected by stress and nonadrenal diseases
   d. Questionable quality of some assays
   e. No differentiation between endogenous and iatrogenic hyperadrenocorticism

F. Dogs suffering from adrenal sex steroid excess may have negative ACTH stimulation and LDDS tests because serum cortisol concentrations are normal.
1. Excessive cortisol precursors may be present.
2. Increases in progesterone, 17-OH-progesterone, androstenedione, testosterone, and estrogens may require dynamic adrenal testing using the ACTH stimulation test and measurement of sex steroids (in addition to cortisol).

III. Differentiation tests (see Table 45-3)

A. HDDS
1. ACTH secretion is suppressed maximally in dogs with functioning adrenal tumors; therefore, serum cortisol concentrations remain elevated.
2. In dogs with PDH, high doses of dexamethasone suppress ACTH and cortisol secretion.
3. Some animals with pituitary macroadenomas (15% to 50% of dogs with PDH) do not suppress on the HDDS test (Mack and Feldman, 1990).

B. Endogenous plasma ACTH concentrations
1. Reliable method of discriminating between PDH and adrenal tumors
2. Tumors: low to undetectable ACTH concentrations
3. PDH: normal to elevated ACTH concentrations

C. Diagnostic imaging of the pituitary and/or the adrenal glands
1. Survey radiographs of 30% to 50% of dogs with adrenal tumors show a mineralized adrenal mass (Pennick et al., 1988).
2. Abdominal ultrasonography is a more sensitive method of identifying tumors, liver metastasis, or vena caval invasion.
3. Abdominal ultrasonography helps to identify adrenomegaly in dogs with PDH.
4. Computed tomography and/or magnetic resonance imaging of the brain and/or abdominal cavity may demonstrate unilateral or bilateral adrenal enlargement and pituitary adenomas (Box 45-3).

Differential Diagnosis

I. Cutaneous lesions (see Chapter 87)
A. Hypothyroidism
B. Adrenal sex steroid excess

Box 45-2

Comparison of Screening Tests for Hyperadrenocorticism

Advantages	Disadvantages
Low-Dose Dexamethasone Suppression Test	
Easy to perform	Lower specificity than ACTH stimulation, especially in stressed dogs (56% false positives)
Reliable	Requires 8 hours of testing
High sensitivity (92% to 95%)	Three samples required
May be diagnostic for PDH if suppression and escape are noted	
Corticotropin Stimulation Test	
Easy to perform, reliable	Lower sensitivity overall than LDDS (85%), especially for AT (50% to 60%)
Higher specificity that LDDS (85%)	Laboratory variation in normal range
Fewer serum samples required	Does not differentiate PDH from AT
Hospitalization not required	
1- or 2-hour test	
Differentiates iatrogenic versus endogenous hyperadrenocorticism	
Provides baseline for therapy	
Urine Cortisol:Creatine Ratio	
Highly sensitive	Low specificity (24%)
Single voided urine sample	Must confirm positive result with an LDDS or ACTH stimulation test
Increased convenience to owner	
Decreased cost: single sample	
Alkaline Phosphate Isoenzyme	
Widely available	Not diagnostic for iatrogenic hyperadrenocorticism
Inexpensive	Affected by stress
Single serum sample	Confirm with LDDS or ACTH stimulation
	Questionable results on some assays

PDH, Pituitary-dependent hyperadrenocorticism; *ACTH*, adrenocorticotropic hormone; *LDDS*, low-dose dexamethasone suppression test; *AT*, adrenal tumor.

Box 45-3

Comparison of Tests and Techniques for Differentiation of Pituitary versus Adrenal Hyperadrenocorticism

Advantages	Disadvantages
High-dose Dexamethasone Suppression Test	
Does not require special facilities	Inconvenient
Inexpensive	8-hour sampling period
	Pituitary macroadenomas may not suppress
Endogenous Adrenocorticotropin Measurement	
Single plasma sample	Expensive
May be collected before screening tests and frozen for later analysis	Analysis restricted to certain laboratories
More reliable than HDDS	Special handling required
Ultrasonography of Adrenals	
Differentiates tumors from PDH	Requires adequate equipment
Noninvasive	Requires skilled ultrasonographer
Relatively inexpensive and widely available	
Computed Tomography/Magnetic Resonance Imaging	
Noninvasive	Expensive
Identifies pituitary tumor	Requires sophisticated equipment
Estimates size of tumor	Not universally available

HDDS, High-dose dexamethasone suppression test; *PDH*, pituitary-dependent hyperadrenocorticism.

C. Growth hormone deficiency

II. PU/PD
- A. Renal disease
- B. Liver disease
- C. Pyometra
- D. Hypoadrenocorticism
- E. Hypercalcemia
- F. Diabetes mellitus
- G. Diabetes insipidus: central, nephrogenic

Treatment and Monitoring

I. Mitotane *(Lysodren)* for PDH
- A. Normal induction protocol
  1. Dosage is 25 to 50 mg/kg/day PO for 5 to 10 days.
  2. Monitor appetite and water consumption.
  3. Discontinue if adverse effects occur (e.g., vomiting, anorexia, weakness).
  4. Assess effectiveness using ACTH stimulation tests (Figure 45-1).
- B. Production of hypoadrenocorticism
  1. Mitotane 50 mg/kg/day PO for 30 days causes complete destruction of the adrenal cortex; then the animal is managed as an Addisonian case.
  2. Physiological doses of prednisolone at 0.2 mg/kg day PO SID are subsequently given.
- C. Slow induction protocol
  1. For cases with dermatological conditions only
  2. Low dose of mitotane 25 mg/kg PO weekly for 1 month
- D. Monitor mitotane therapy with ACTH response tests
  1. Goal is for post-ACTH cortisol concentrations to be in the normal range (1 to 5 μg/dL, or 25 to 150 nmol/L)
  2. Measure at termination of the induction period (7 to 10 days).
  3. Monitor electrolytes weekly for evidence of mineralocorticoid deficiency (hypoadrenocorticism).
  4. Measure at the end of 1 month if the reduced dosage protocol is used.
- E. Maintenance therapy

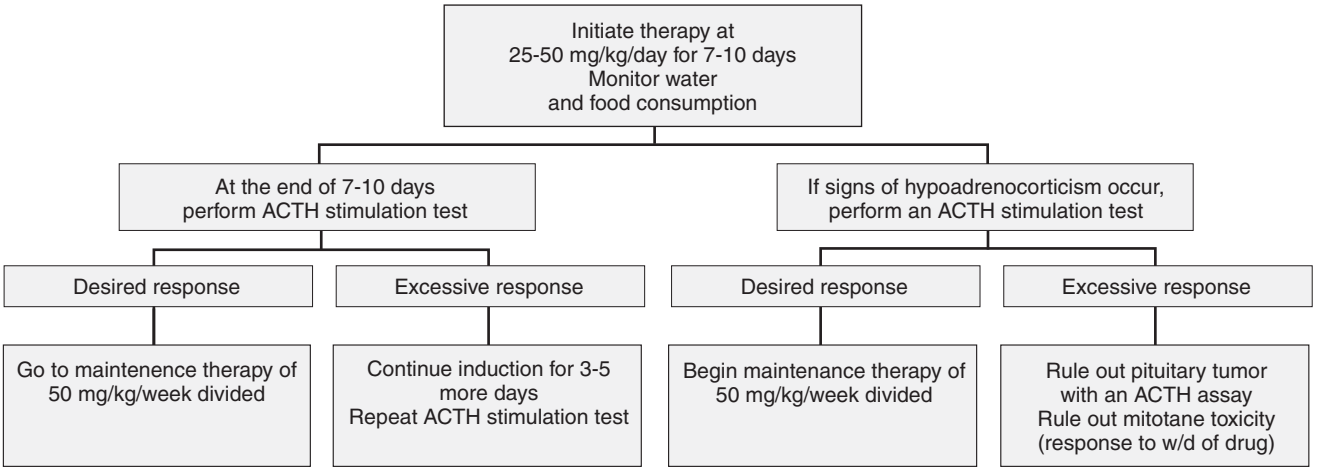

FIGURE 45-1 Outline for the treatment of hyperadrenocorticism with oral mitotane. *ACTH,* Adrenocorticotropic hormone; *w/d,* withdrawal.

1. Mitotane 50 mg/kg/wk PO is divided into two doses, 3 to 4 days apart.
2. ACTH stimulation tests are performed every 4 months.
3. Relapses are common within 12 months of initiating maintenance therapy.

F. Prolonged effects
1. Mitotane causes adrenal necrosis and effects persist for several days.
2. Withdrawal does not result in immediate improvement of side effects.

II. Trilostane

A. It is a competitive 3β-hydroxysteroid dehydrogenase inhibitor that affects both the production of glucocorticoids and aldosterone.
B. Duration of effect is approximately 20 hours in the dog, which is a major advantage in comparison to mitotane.
C. It has been used primarily for PDH, but it has also been used in a few dogs with functional adrenal tumors (Eastwood et al., 2001, 2003).
D. Some dogs respond to once daily administration.
1. Starting dose is 6 mg/kg PO SID.
2. ACTH response tests are performed 4 to 6 hours after administration, which is thought to be the time of peak activity.
3. Goal for post-ACTH cortisol concentrations is 1 to 5 μg/dL (Alenza et al., 2006).

E. Some dogs do better on twice-daily administration.
1. Clinical signs persist in some dogs on SID therapy, probably because cortisol values rise toward the end of the day.
2. Starting dose is 3 mg/kg PO BID.
3. ACTH response tests are performed 8 to 12 hours post-pill to evaluate the drug's duration and effects on cortisol reserves (Alenza et al., 2006).
4. Goal for post-ACTH cortisol concentrations is 2 to 10 μg/dL (Alenza et al., 2006).
5. Yorkshire terriers may require higher doses (Alenza et al., 2006).
6. Although BID administration is more expensive, side effects may be fewer.

F. ACTH response tests are performed 7 days, and 1, 3, and 6 months (or as needed) after starting therapy and dosage adjustments (Alenza et al., 2006).
G. Because of its inhibition of aldosterone synthesis, hyperkalemia is a common side effect, and electrolytes must be monitored in addition to ACTH response tests.
H. Other adverse effects include rare cases of acute death and prolonged hypoadrenocorticism (Eastwood and Elwood, 2003).

III. Ketoconazole

A. Ketoconazole is a steroid inhibitor with a transient effect in dogs.
B. Initial dosage is 7.5 mg/kg PO BID.
C. Increase dose slowly (over 3 weeks) to 15 mg/kg PO BID.
D. Ketoconazole is not often used, owing to its expense and possible severe anorexia.
E. Use is primarily before surgical adrenalectomy or radiation therapy.
F. Goal is for post-ACTH cortisol concentrations of 1 to 5 μg/dL (25 to 150 nmol/L).

IV. L-Deprenyl *(Anipryl)*

A. Monoamine oxidase B inhibitor that increases hypothalamic dopamine concentrations
B. Initial dosage: 1 mg/kg/day PO
C. Used for PDH only; questionable effectiveness
D. Indications
1. Mild hyperadrenocorticism: skin disease only
2. Intolerance to other therapies

E. Laboratory monitoring unnecessary
1. ACTH response tests do not return to normal.
2. Use clinical response as a guide to therapy.

V. Surgical therapy

A. Surgical treatment consists of unilateral (dogs with unilateral tumors) or bilateral (cats with PDH) adrenalectomy (Anderson et al., 2001).

B. Medical management during the intra- and postoperative periods is critical.
C. Mineralocorticoid (DOCP 2.2 mg/kg IM, SC every 25 days) and glucocorticoid (prednisone 0.2 mg/kg/day PO) supplementation are initiated immediately after adrenalectomy.
D. Complications following adrenalectomy are as follows:
1. Dehiscence, poor wound healing
2. Addisonian crisis
3. Pituitary tumor enlargement with subsequent blindness or seizures (Nelson's syndrome)

VI. Radiation therapy of pituitary tumors
A. Effective method of treatment with low morbidity
B. Requires several months for PDH to subside
C. Expensive and time consuming (3 weeks)
D. Good long-term results

PHEOCHROMOCYTOMA

Definition and Cause

I. Pheochromocytoma is a tumor arising from chromaffin cells of the adrenal medulla that hypersecretes catecholamines.
II. Actual cause of the tumor is unknown.

Pathophysiology

I. Cats secrete predominantly norepinephrine; dogs secrete primarily epinephrine from the adrenal medulla.
II. Clinical signs result from overproduction of catecholamines and from direct invasion of adjacent organs and structures.
III. This tumor is uncommon in dogs and extremely rare in cats.

Clinical Signs and Diagnosis

I. Signalment (Feldman and Nelson, 1996)
A. Older dogs (mean age = 11 years)
B. No sex predilection
C. Boxers, miniature poodles, and German shepherd dogs predisposed

II. Historical findings
A. Signs may be chronic (present for >1 year) or acute (often fatal).
B. Thirty percent are identified at necropsy (Feldman and Nelson, 1996).
C. Signs include dyspnea, whining, shaking, shivering, and pacing.
D. Signs may be constant or paroxysmal.

III. Physical examination findings
A. Tachyarrhythmias, weakness, systolic murmur
B. ± Rales from pulmonary edema
C. Possible weight loss secondary to hypermetabolism
D. Ascites, edema, abdominal mass and pain from the tumor, local metastases, or both
E. Anorexia, vomiting, weight loss, diarrhea
F. Hypertension from α_1-mediated increased peripheral vascular resistance
G. Epistaxis, pale mucous membranes, blindness, and hyperemic mucous membranes from hypertension

IV. Clinical pathology
A. CBC: nonregenerative anemia, hemoconcentration, leukocytosis
B. Serum biochemistries
1. Mild hyperglycemia, carbohydrate intolerance, and occasionally overt diabetes mellitus may occur from stimulation of hepatic glycogenolysis and gluconeogenesis, inhibition of insulin secretion, and peripheral insulin resistance.
2. Other possible laboratory abnormalities include mild uremia, increased liver enzyme activity, hypoalbuminemia, and hypocalcemia.
C. Proteinuria: variable

V. Radiographic and ultrasonographic findings
A. Presence of abdominal mass on plain radiography: 30% of cases (Feldman and Nelson, 1996)
B. Ultrasonography superior to radiography for identification of adrenal glands
C. Calcification of adrenal mass
D. Abnormal renal contour, displacement
E. Generalized cardiomegaly
F. Possibly pulmonary edema

VI. Arterial blood pressures
A. Normal canine values
1. Systolic: 148 ± 16 mm Hg (unstressed)
2. Diastolic: 87 ± 8 mm Hg
3. Mean: 102 ± 9 mm Hg
B. Hypertension: systolic >180 or diastolic >95 mm Hg in a nonazotemic, relaxed dog
C. Detectable hypertension in only 50%, owing to the episodic secretion of some tumors (Feldman and Nelson, 1996)

VII. Other diagnostic testing
A. Plasma catecholamines levels >2000 pg/mL are diagnostic.
B. On a clonidine suppression test, clonidine suppresses catecholamine levels in normal animals, but not in those with pheochromocytomas (see Chapter 2).
C. Total excretion of urinary catecholamine and catecholamine metabolites for 24 hours may be determined.
1. Normal vanillylmandelic acid: <7.0 mg/day
2. Normal metanephrine/normetanephrine: <1.3 mg/day
3. Normal total urinary catecholamines: <250 mg/day

Treatment

I. Surgical removal of tumor
A. It is the treatment of choice but is technically demanding.
B. Metastasis is present in 33% of cases at the time of surgery (Feldman and Nelson, 1996).

II. Anesthetic management
A. Phenoxybenzamine 0.2 to 1.5 mg/kg PO BID for 1 to 2 weeks before surgery
B. Propranolol 0.15 mg/kg PO TID, for tachycardia and severe hypertension, with phenoxybenzamine

C. Drugs to avoid: phenothiazines (hypotension), atropine (tachycardia), barbiturates for induction (arrhythmias), halothane (arrhythmias)

III. Medical, palliative therapy
   A. Phenoxybenzamine 0.2 to 1.5 mg/kg PO BID
   B. Addition of propranolol for tachyarrhythmias

Monitoring of Animal

I. If hypertension does not resolve with excision of the mass, suspect an additional tumor.
II. In general, prognosis is fair to poor owing to difficulties commonly associated with surgery and the likelihood of metastases.

CHAPTER 46

Miscellaneous Endocrine Disorders

Stephanie A. Smith

HYPERLIPIDEMIA

Definition

I. Hyperlipidemia is an increased level of lipid in the blood and is only physiologically relevant when it occurs in the fasted state.
   A. *Hypertriglyceridemia* is defined as a triglyceride concentration >150 mg/dL in dogs and >100 mg/dL in cats.
   B. *Hypercholesterolemia* is defined as a cholesterol concentration >300 mg/dL in dogs and >200 mg/dL in cats.
   C. *Hyperchylomicronemia* is defined as an excessive concentration of chylomicrons (see later).

II. Visible lipemia is apparent when triglycerides are >400 mg/dL and the resulting opacity interferes with various laboratory evaluations, depending on the method used.
   A. Total solids via refractometer: falsely increased
   B. Albumin and bilirubin: falsely increased
   C. Bile acids, alkaline phosphatase, alanine transaminase, and aspartate transaminase: ± erroneously increased
   D. Sodium: falsely decreased
   E. Amylase: falsely decreased
   F. Mean corpuscular hemoglobin (MCH) concentration: falsely increased (possibly marked)
   G. Also causes in vitro hemolysis

Causes and Pathophysiology

I. Normal lipid metabolism
   A. Lipids are water insoluble and are transported in the blood by lipid-protein complexes.
   B. Types of lipoproteins include the following:
      1. Chylomicrons, which are formed in intestines and hydrolyzed in the circulation to triglyceride (available for tissue use and storage) and cholesteryl-ester remnants (taken up by the liver)
      2. Very-low-density lipoproteins, which are synthesized in the liver and transport endogenous triglyceride to muscles or fat
      3. Low-density lipoproteins, which are formed in the circulation and transport cholesterol to tissues
      4. High-density lipoproteins, which are the major cholesterol carrier in dogs and cats
         a. Synthesized in the intestine and liver
         b. Transport excess cholesterol to the liver for biliary excretion

II. Relationship of hyperlipidemia to diet
   A. Postprandial
      1. Persistent hyperchylomicronemia up to 12 hours after a meal
      2. Most common cause of lipemia
   B. Diet type
      1. In normal animals: fasting hyperlipidemia possible with extremely high dietary fat content (>55%)
      2. Hypertriglyceridemia or hypercholesterolemia also possible

III. Secondary hyperlipidemia: see Table 46-1

IV. Primary hyperlipidemia associated with inherited metabolic abnormalities: see Table 46-2

Clinical Signs

I. Clinical signs with secondary hyperlipidemia
   A. Signs associated with hypertriglyceridemia
      1. Abdominal pain or discomfort: chronic, acute, or episodic
      2. Possible seizures with marked hypertriglyceridemia
      3. Nonspecific gastrointestinal (GI) signs: vomiting, diarrhea, lethargy, anorexia
      4. Visible lipemia of the vessels of the bulbar conjunctiva, episclera, and retina (lipemia retinalis)
      5. Lipid deposition in abnormal locations
         a. Cutaneous xanthomas: deposits in macrophages forming granulomas
         b. Arcus lipoides: corneal lipid deposits
         c. Lipemic aqueous: lipid in the aqueous humor
   B. Signs from hypercholesterolemia
      1. Atherosclerosis with accompanying thrombosis and/or loss of vascular supply, seen particularly with hypothyroidism and diabetes mellitus
      2. Arcus lipoides

II. Signs possible with primary hyperlipidemia
   A. Idiopathic schnauzer hyperlipidemia
      1. May be clinically asymptomatic
      2. Nonspecific signs of discomfort or GI disturbances, similar to secondary hypertriglyceridemia
      3. Possible polydipsia
      4. Acute pancreatitis as a secondary complication (not well documented but suspected)
   B. Briard hypercholesterolemia: usually no clinical signs

TABLE 46-1

Causes of Secondary Hyperlipidemia

DISORDER	HYPERCHOLESTEROLEMIA	HYPERTRIGLYCERIDEMIA	PATHOGENESIS	NOTES	SEE CHAPTER
Hypothyroidism	Occurs in 2/3 canine cases Degree: mild to marked	Possible Degree: mild	Not clearly defined	Possible atherosclerosis if cholesterol > 750 mg/dL	42
Diabetes mellitus	Possible Degree: mild to moderate	Common Degree: may be marked	Increase fatty acid mobilization from peripheral fat stores causing increased hepatic VLDL synthesis Decreased production of lipoprotein lipase as a result of hypoinsulinemia	Possible atherosclerosis	44
Pancreatitis	Possible Degree: mild	Common Degree: mild to marked	Likely caused by decreased lipoprotein lipase excretion from the pancreas, or inhibition of lipoprotein lipase by inflammatory mediators	Hyperlipidemia or impaired lipid metabolism may be the cause of pancreatitis in some animals, rather than an effect of pancreatitis (speculative)	36
Hyperadrenocorticism	Common Degree: mild to marked	Possible Degree: mild	Peripheral insulin resistance induced by hypercortisolemia Peripheral lipolysis stimulated by glucocorticoids	Not generally associated with atherosclerosis	45
Cholestatic hepatic disease	In some cases	Not present	Decreased cholesterol excretion through the biliary tract Increased cholesterol synthesis possible in some biliary diseases		37
Nephrotic syndrome	Common	Not present	Likely associated with decreased lipoprotein lipase activity resulting from any of the following: • Production of an inhibitor substance • Renal secondary hyperparathyroidism suppressing insulin release • Changes in apolipoprotein synthesis and release		48
Drugs: Glucocorticoids Progestogens			Decreased lipoprotein lipase activity through insulin antagonism Iatrogenic or associated with diestrus in the bitch Progesterones also increase growth hormone secretion, which has an antiinsulin effect	Megestrol acetate, particularly in cats	

VLDL, Very low density lipoproteins.

TABLE 46-2

Primary Hyperlipidemia Associated with Inherited Metabolic Abnormalities

DISORDER	REPORTED BREEDS	TYPE OF HYPERLIPIDEMIA	ADVERSE EFFECTS	NOTES
Idiopathic hyperlipidemia	Frequent in miniature schnauzers Occasionally in beagles and Shetland sheepdogs	Marked hypertriglyceridemia Cholesterol usually normal or mildly elevated, rarely markedly elevated	May be associated with increased risk for pancreatitis	
Hypercholesterolemia	Briards Rough collie (one family)	Triglycerides normal Cholesterol elevated	Not associated with any pathologic accumulation of cholesterol May be linked to development of retinal pigment epithelial dystrophy in the briard Corneal lipidosis in the collie	Likely caused by increased apoprotein E containing high-density lipoprotein
Hyperchylomicronemia	Domestic cats (20 related cats in New Zealand) Sporadic in some breeds and domestic cats Single 4-week-old mixed-breed puppy Two related Brittany spaniels	Fasting lipemia, hypertriglyceridemia, and hypercholesterolemia	Lipid deposition in eye Lipid granulomas in abdomen and skin Peripheral neuropathies	Suspected autosomal recessive inheritance causing deficient lipoprotein lipase activity Affected cats may not show signs until maturity

C. Rough collie hypercholesterolemia: may be associated with corneal lipidosis
D. Inherited hyperchylomicronemia
   1. Inappropriate lipid deposition in skin, eye, and other soft tissues
   2. Peripheral neuropathies (Horner's syndrome, radial or tibial palsy) owing to nearby compression from xanthomas

Diagnosis and Differential Diagnosis

I. Postprandial hyperlipidemia
   A. Confirmed by evaluating triglyceride and cholesterol levels following a ≥12-hour fast
   B. Duration of fast important
II. Secondary hyperlipidemia
   A. History of signs suggestive of underlying disease process
   B. Minimum database
      1. Complete blood count (CBC)
      2. Serum biochemistry panel with pancreatic enzymes
      3. Urinalysis (UA)
   C. Additional tests to consider
      1. Total thyroxine (thyroid concentration) ± other thyroid testing (see Chapter 42)
      2. Adrenocorticotropin (ACTH) stimulation or dexamethasone suppression test (see Chapter 45)
      3. Urine protein: creatinine ratio if proteinuric (see Chapter 48)
      4. For suspected pancreatic disease: abdominal ultrasonography, possibly pancreatic lipase immunoreactivity (cPLI)
      5. For suspected cholestatic liver disease and/or bile duct obstruction (icteric animal): abdominal ultrasonography
III. Primary hyperlipidemia
   A. Exclude all causes of secondary hyperlipidemia.
   B. Measure fasting serum triglycerides and cholesterol.
   C. Consider lipoprotein electrophoresis for further characterization of idiopathic schnauzer hyperlipidemia and inherited chylomicronemia.
   D. No further testing needed for hypercholesterolemia of briard or rough collies.

Treatment

I. Secondary hyperlipidemia
   A. Manage any diagnosed underlying disorder.
   B. Provide nutritional support by selecting a fat-restricted enteral or parenteral diet.
II. Primary hyperlipidemia
   A. Intervention is indicated when hyperlipidemia is associated with clinical signs.

TABLE 46-3

Fat-Restricted Commercial Pet Foods

	% kcal FROM FAT
Canine Diets	
Canned Hill's Prescription Diet w/d	31.0
Canned Purina CNM-OM	28.1
Dry Iams Less Active	28.0
Dry Purina ProPlan Reduced Calorie	24.1
Dry Hill's Prescription Diet r/d	24.0
Canned Hill's Prescription Diet r/d	24.0
Canned Iams Less Active	23.1
Dry Hill's Prescription Diet w/d	23.0
Dry Eukanuba Reduced Fat Formula	23.0
Dry Waltham/Pedigree Calorie Control	22.7
Canned Hill's Science Diet Maintenance Light	22.0
Dry Purina One Reduced Calorie	20.4
Dry Purina CNM-OM	17.7
Dry Purina Fit and Trim	17.4
Dry Eukanuba Restricted Calorie	15.0
Feline Diets	
Canned Hill's Prescription Diet w/d	38.0
Dry Iams Less Active	29.0
Canned Hill's Prescription Diet r/d	24.0
Dry Hill's Prescription Diet r/d	24.0
Dry Purina ProPlan Reduced Calorie	23.4
Dry Hill's Prescription Diet w/d	23.0
Dry Eukanuba Restricted Calorie	23.0
Dry Hill's Science Diet Maintenance Light	22.0

B. Dietary management with fat restriction is the mainstay of treatment.
   1. Keep fasting triglyceride <500 mg/dL and cholesterol <400 mg/dL.
   2. See Table 46-3 for fat-restricted diet information.
C. Lipid-lowering drugs have not been well evaluated in the dog and cat, and are used with caution.
   1. Dogs: gemfibrozil 200 mg/day PO
   2. Dogs: niacin 100 mg/day PO
   3. Dogs: fish oil (eicosapentaenoic, docosahexaenoic acid) 200 mg/kg/day PO

Monitoring of Animal

I. Secondary hyperlipidemia
   A. Most secondary hyperlipidemias resolve with proper management of the primary disorder.
   B. Reevaluate for lipemia once the underlying disease is well controlled, and consider instituting dietary fat restriction if needed.
II. Primary hyperlipidemia
   A. Evaluate fasting serum triglycerides and cholesterol 4 to 6 weeks after dietary change and every 3 to 4 months thereafter.
   B. Primary disorders are much more difficult to treat.

ERYTHROPOIETIN ABNORMALITIES

Definition

I. Erythropoietin (EPO) is a glycoprotein produced by renal interstitial cells that stimulates red blood cell (RBC) production in the bone marrow.
II. Abnormal EPO concentrations cause abnormal circulating RBC mass.

Causes and Pathophysiology

I. Decreased EPO production
   A. Chronic renal failure
      1. As senescent RBCs are removed from the circulation, renal hypoxia triggers EPO production.
      2. Nephron loss prevents adequate response to decreasing RBC mass, resulting in gradual development of anemia.
   B. Polycythemia vera (primary polycythemia)
      1. Myeloproliferative disease with clonal proliferation of erythroid progenitors leads to increased peripheral RBC mass.
      2. Marrow production of RBCs is autonomous and not subject to EPO-negative feedback.
      3. EPO production is appropriately decreased.
II. Appropriately increased EPO production from renal stimulus
   A. Decreased renal perfusion associated with aberrant renal blood vasculature or compression of blood flow
      1. Renal neoplasia
      2. Parenchymal disease
         a. Cystic kidneys: polycystic or single renal cysts
         b. Hydronephrosis
      3. Congenital abnormality of renal vasculature
      4. Compressive neoplasm
      5. Thrombus obstructing renal arterial flow
   B. Decreased renal oxygen delivery
      1. Anemia
      2. Hemoglobinopathy
   C. Hypoxemia (decreased blood oxygen)
      1. Right-to-left cardiovascular shunting, particularly reversed patent ductus arteriosus
      2. Chronic pulmonary disease
      3. High altitudes: decreased inspired oxygen content
      4. Hypothalamic disease: depressed respiration
III. Autonomous secretion of EPO or EPO-like substances by tumors
   A. Renal neoplasia
      1. Lymphosarcoma
      2. Renal carcinoma
   B. Extrarenal neoplasia (paraneoplastic effect)
      1. Hepatoma
      2. Uterine or cecal leiomyosarcoma
      3. Ovarian carcinoma
      4. Nasal fibrosarcoma
      5. Pheochromocytoma and other adrenal tumors
      6. Granular cell tumor
      7. Schwannoma

Clinical Signs

I. Anemia and decreased tissue oxygen delivery: weakness, collapse, exercise intolerance, pallor, ± soft heart murmur (see Chapter 64)
II. Polycythemia (primary or secondary): hyperemia of mucous membranes, skin, sclera, signs of hyperviscosity (see Chapter 64)

Diagnosis and Differential Diagnosis

I. Anemia of EPO deficiency
  A. Evaluate for chronic renal failure.
  B. See Chapter 48 for discussion of appropriate laboratory tests.
II. Polycythemia
  A. Confirm increased RBC mass to rule out relative polycythemia from dehydration.
  B. Investigate causes of hypoxemia causing excessive EPO secretion.
    1. Confirm hypoxemia.
      a. Pulse oximetry: arterial oxygen saturation <90% on room air
      b. Arterial blood gas: Pao_2 <80 mm Hg on room air
    2. Evaluate cardiopulmonary status.
      a. Thoracic radiography
      b. Echocardiography
      c. Electrocardiography
    3. Measure serum EPO concentration (should be normal to increased).
  C. Normal oxygenation with excessive EPO secretion warrants investigation for renal disease or masses.
    1. CBC, serum biochemistry profile, UA, radiographs, abdominal ultrasonography
    2. Serum EPO concentration: normal or high despite polycythemia
  D. Polycythemia vera is a diagnosis of exclusion.
    1. Dyserythropoiesis on bone marrow evaluation
    2. Low serum EPO concentration

Treatment

I. Anemia of EPO deficiency: see Chapter 48
II. Polycythemia from excessive EPO secretion
  A. Therapeutic phlebotomy is indicated for polycythemic animals experiencing clinical signs associated with hyperviscosity.
    1. Place a peripheral and jugular IV catheter or large-bore butterfly catheter.
    2. Slowly withdraw 10% to 25% blood volume from the jugular catheter, with a goal of reducing packed cell volume (PCV) to 55% to 60%.
    3. Replace removed blood volume with a similar volume of IV crystalloid fluids via the peripheral catheter.
    4. Possible complications include catheter clotting, acute hypotension, and volume overload.
  B. Treatment of EPO secretion associated with hypoxemia requires management of the underlying cardiopulmonary disease.
  C. Elevated EPO secretion from renal disease may require the following:
    1. If only one kidney is abnormal (cysts, neoplasia, vascular disorder), surgical removal of the affected kidney is indicated.
    2. Chemotherapy may be tried for bilateral renal lymphosarcoma.
  D. EPO secretion caused by extrarenal neoplasia may improve with surgical removal of the neoplasm.

Monitoring of Animal

I. Anemia of EPO deficiency with chronic renal failure (see Chapter 48)
  A. Deficiency is life-long, so continued EPO administration is required.
  B. Prognosis is guarded but depends on the rate of advancement of renal failure.
II. Polycythemia from excessive EPO secretion
  A. Complications from recurring hyperviscosity include neurological signs, hemorrhage, and stroke.
  B. PCV is monitored weekly to biweekly initially, but long-term observation is based on rapidity of recurrence of polycythemia.
  C. Hypoxemia-induced secondary polycythemia is highly manageable with use of intermittent phlebotomy, with prognosis and monitoring dependent on the underlying cardiopulmonary disorder.
  D. When renal disease is present, monitoring is dependent on the underlying cause.
    1. Prognosis is good for resolution of polycythemia if a cyst or tumor is completely resected or remission is induced with chemotherapy.
    2. Prognosis is guarded with nonresectable disease.
  E. With extrarenal neoplasia, monitoring and prognosis vary with the etiology.
    1. Monitoring depends on tumor type, with a good prognosis if the tumor is completely resectable and guarded prognosis if it is nonresectable.
    2. If polycythemia recurs postoperatively (suggesting recurrence and/or metastasis), the prognosis is worse.

HYPOGLYCEMIA

Definition

I. In the normal dog and cat, blood glucose (BG) is maintained within a fairly small normal range.
II. Unlike people, normal dogs and cats do not become hypoglycemic even in the face of fasting or starvation.
III. Hypoglycemia is defined as resting serum glucose <60 mg/dL, but varies slightly depending on the laboratory methodology.
IV. Hypoglycemia is defined as low serum BG on repeated assays, rather than a single assay.

Causes

I. Spurious hypoglycemia
  A. Serum not promptly separated from cells
  B. Poor technique or poor quality control of in-house analyzers

C. Underestimation of BG by cage-side glucometers measuring whole BG instead of serum glucose

II. Neonatal and toy-breed juvenile hypoglycemia
  A. Insufficient muscle mass glycogen reserves and body fat stores to provide substrate for glycogenolysis and gluconeogenesis
  B. Difficulty maintaining euglycemia
    1. Nutritional stressors, such as inadequate nursing, fasting, and poor diet
    2. Physiological stressors, such as parasitism, diarrhea, and hypothermia

III. Ingestion of oral hypoglycemic agents
  A. Ingestion may be accidental or intentional.
  B. Sulfonylureas (glipizide, glyburide) cause hypoglycemia by stimulating increased release of insulin from β cells.
  C. Xylitol sweetened products (sugar-free gum and foods) promote insulin release in dogs.

IV. Hypoadrenocorticism (cortisol deficiency) (see Chapter 45)
  A. Cortisol is the main hormonal antagonist to insulin.
  B. Cortisol deficiency (with or without aldosterone deficiency) may lead to hypoglycemia.

V. Iatrogenic insulin administration (see Chapter 44)
  A. Otherwise well-regulated diabetics may become hypoglycemic from the following:
    1. Accidental insulin overdose
    2. Excessive exercise
    3. Lack of food ingestion
    4. Effects of a concurrent illness
  B. Insulin needs may vary considerably in some poorly regulated diabetics, with hypoglycemia being a frequent complication.
  C. Diabetic cats occasionally revert from insulin-dependent to non–insulin-dependent, so insulin administration results in hypoglycemia.

VI. Insulinoma (see Chapter 73)
  A. This is a functional β cell tumor of the pancreas that secretes insulin.
  B. Increased BG may provoke insulin release.
  C. Hypoglycemia does *not* suppress insulin release from neoplastic β cells.
  D. Clinical signs of hypoglycemia are often precipitated by fasting, eating, excitement, or exercise.

VII. Paraneoplastic hypoglycemia (see Chapter 73)
  A. Nonpancreatic neoplasms may cause hypoglycemia as a paraneoplastic effect through secretion of polypeptides that behave like insulin.
  B. Possible tumor types include hepatocellular carcinoma, renal adenocarcinoma, hepatoma, leiomyoma, and leiomyosarcoma, although any tumor has the potential to cause hypoglycemia.

VIII. Glycogen storage diseases
  A. Inherited errors in the glycogenolytic pathway inhibit normal glucose homeostasis secondary to a lack of production of glucose from glycogen.
  B. Deficiencies of glucose-6-phosphatase or α-1,4-glucosidase lead to hypoglycemia and abnormal deposition of glycogen in soft tissues.

IX. Sepsis
  A. Gluconeogenesis may become impaired with overwhelming sepsis through poorly understood mechanisms.
  B. Sepsis is also associated with increased peripheral glucose utilization associated with a hypermetabolic state.

X. Hepatic failure (see Chapter 37)
  A. Markedly decreased hepatic function (>70% lost) can lead to hypoglycemia from impaired gluconeogenesis.
  B. When hypoglycemia is present, other substances synthesized in the liver (albumin, cholesterol, and blood urea nitrogen [BUN]) are also decreased.

XI. Hunting dog (exertional) hypoglycemia
  A. Active, lean-bodied hunting dogs may become hypoglycemic after extreme exercise.
  B. Exertional hypoglycemia occurs from depletion of stored glycogen or increased glucose utilization.

Pathophysiology

I. Maintenance of normal BG is a balance between absorption, production, and utilization of glucose.
  A. Glucose from dietary intake is absorbed from the intestine.
  B. Glucose can be synthesized or released from degradation of stored carbohydrate.
    1. Substrates for gluconeogenesis: amino acids (especially alanine), fatty acids, and lactate
    2. Conversion of stored hepatic and muscular glycogen to glucose via glycogenolysis
  C. Glucose uptake and utilization by most peripheral tissues is dependent on insulin.

II. Insulin is a hypoglycemic hormone.
  A. Secreted by pancreatic islet β cells in response to hyperglycemia
  B. Impairs glycogenolysis
  C. Impairs gluconeogenesis directly by inhibition of enzymes necessary for amino acid mobilization
  D. Suppresses glucagon secretion
  E. Suppression of adipocyte lipolysis and increased fatty acid esterification via lipoprotein lipase
  F. Stimulates uptake and utilization of glucose
  G. Tissues dependent on insulin for glucose uptake: brain, RBCs, leukocytes, hepatocytes, renal tubular cells, and pancreatic β cells

III. Other hyperglycemic hormones include the following:
  A. Glucagon
    1. Actions directly opposed to those of insulin
    2. Secreted by pancreatic islet β cells in response to hypoglycemia
    3. Increases hepatic glycogenolysis
    4. Dramatically increases hepatic gluconeogenesis
  B. Cortisol
    1. Secreted by zona fasciculata of the adrenal cortex in response to stimulation by ACTH from the pituitary gland
    2. Stimulates hepatic gluconeogenesis
    3. Decreases the uptake and utilization of glucose by peripheral tissues

C. Epinephrine
   1. Increases hepatic and muscle glycogenolysis
   2. Promotes lipolysis
D. Growth hormone
   1. Promotes lipolysis
   2. Decreases peripheral tissue uptake and utilization of glucose

Clinical Signs

I. The severity of clinical signs is dependent on the degree of hypoglycemia, duration of hypoglycemia, and rapidity of the decline in BG.
   A. Episodic signs of neuroglycopenia (inadequate central nervous system glucose) occur.
   B. Apparent lack of clinical signs occurs from neural adaptation to chronic hypoglycemia.
   C. Lack of mental abnormalities in a profoundly hypoglycemic animal suggests previous episodes or chronic occurrence of low BG.
II. Neuroglycopenia occurs because brain cells are profoundly affected by hypoglycemia, owing to their inability to store glycogen and requirement for glucose as an energy source.
   A. Signs include tremors, seizures, depression or mental dullness, weakness, collapse, increased appetite, and bizarre behavior.
   B. Severe or prolonged neuroglycopenia causes brain injury and alterations in nervous system function that persist beyond the correction of the hypoglycemia.
      1. Temporary or permanent cortical blindness
      2. Chronic seizures following neural hypoxic injury
      3. Peripheral nerve demyelination

Diagnosis and Differential Diagnosis

I. Suggestive clinical signs and history
II. Laboratory confirmation
   A. Evaluate BG immediately with rapid whole-blood glucometer assessment.
   B. Confirm hypoglycemia on serum biochemical analyzer.
III. Definitive diagnosis of hypoglycemia via Whipple's triad
   A. Clinical signs of hypoglycemia
   B. Laboratory confirmation of hypoglycemia
   C. Resolution of signs with dextrose administration
IV. Further assessment of underlying cause
   A. History: known administration or accidental exposure to insulin or oral hypoglycemic agents
   B. CBC
      1. Sepsis: marked inflammatory leukogram
      2. Cortisol deficiency: eosinophilia, lymphocytosis, or lack of stress leukogram
   C. Serum biochemistry profile
      1. Hepatic failure: decreased albumin, BUN, or cholesterol; or increased hepatic enzyme activity
      2. Hypoadrenocorticism: hyponatremia with hyperkalemia
   D. Serum insulin concentration
      1. A sample for insulin evaluation is collected during confirmed hypoglycemia.
      2. If hypoglycemia is present, normal or increased insulin concentration confirms hyperinsulinism.
         a. Iatrogenic administration must be ruled out.
         b. Hyperinsulinism may develop with insulin secretion by either pancreatic or extrapancreatic neoplasms.
   E. Miscellaneous secondary testing
      1. Urinalysis
      2. ACTH stimulation test to rule out cortisol deficiency
      3. Bile acids to assess hepatobiliary function
      4. Thoracic or abdominal radiography, or both, to search for neoplasia or metastatic disease
      5. Abdominal ultrasonography to identify a pancreatic mass, although β cell neoplasms often small and not identifiable
      6. Abdominal computed tomography for detection and localization of pancreatic or metastatic masses
      7. Exploratory laparotomy for positive identification of a cause in hyperinsulinism where other tests are inconclusive

Treatment

I. Neuroglycopenic crisis
   A. Feed animal.
   B. Give enteral glucose.
      1. Apply a monosaccharide (50% dextrose, corn syrup, fruit juice, or honey) to the oral cavity.
      2. Perform orogastric intubation and give 10 to 20 mL/kg of 20% dextrose to the neonate or tractable animal when IV access is limited.
   C. Give dextrose IV.
      1. Dextrose 50% via central IV line
      2. Dextrose ≤20% for peripheral vein administration
      3. Initial dose: 0.5 g/kg dextrose or 1 mL/kg of a 50% solution
      4. Administration of a constant-rate infusion (CRI) of 2.5% to 10% dextrose until resolution of signs or cause
   D. Consider glucagon CRI.
      1. Indicated for iatrogenic insulin shock unresponsive to dextrose infusion, or prevention of rebound hypoglycemia with hyperinsulinism and paraneoplastic hypoglycemia.
      2. Add contents of a 1-mg reconstituted vial of glucagon to 1 L of 0.9% NaCl to make a 1000 ng/mL solution.
      3. Administer glucagon as an initial bolus of 50 ng/kg IV, then a CRI of 10 to 15 ng/kg/min IV to maintain euglycemia.
   E. Monitor BG frequently.
II. Treatment of specific underlying causes
   A. Juvenile hypoglycemia and hunting dog (exertional) hypoglycemia: frequent feeding
   B. Accidental or intentional ingestion of oral hypoglycemic agents: maintenance of glucose support as needed until drug has been completely metabolized
   C. Hypoadrenocorticism (see Chapter 45)

D. Iatrogenic insulin administration
   1. Maintain glucose support as needed until drug has been completely metabolized.
   2. Adjust insulin protocol (see Chapter 44).
E. Insulinoma
   1. Surgical resection
   2. Frequent feeding of small meals
   3. Prednisone
      a. A dosage of 0.5 to 1.0 mg/kg/day PO temporarily counteracts the insulin effects.
      b. The dose may be gradually increased to 4 mg/kg/day PO, but expect adverse effects.
   4. Diazoxide
      a. Inhibits secretion of insulin from pancreatic β cells
      b. Inhibits peripheral uptake of glucose
      c. Dose: 5 to 10 mg/kg PO BID initially, then increased to 20 mg/kg PO BID
      d. Limited availability, expensive
      e. Possible adverse effects: anorexia, vomiting, diarrhea, tachycardia, hematological changes
   5. Streptozocin
      a. Cytotoxic to pancreatic β cells
      b. Indication: known metastatic disease or nonresectable tumors
      c. Seven-hour administration protocol
         (1) Pretreatment fluid diuresis for 3 hours with NaCl 18.3 mL/kg/hr 0.9% IV
         (2) Streptozocin at 500 mg/m^2 mixed into NaCl 36.6 mL/kg 0.9% and administered at 18.3 mL/kg/hr over 2 hours IV
         (3) Posttreatment fluid diuresis for 2 hours with NaCl 18.3 mL/kg/hr 0.9% IV
         (4) Posttreatment butorphanol 0.4 mg/kg IM as needed for emesis
      d. Adverse effects
         (1) Transient anorexia and/or vomiting for 24 hours after dose: common
         (2) Mild neutropenia: rare
         (3) Nephrotoxicity: extremely rare with diuresis protocol
         (4) Secondary diabetes mellitus: transient or permanent, in up to 33% of treated dogs
   6. Octreotide: use and efficacy not well documented
F. Paraneoplastic hypoglycemia
   1. Surgical resection of tumor whenever possible
   2. Prednisone and frequent feeding, as noted previously
G. Glycogen storage diseases: no specific therapy
H. Sepsis
   1. Nutritional support: enteral or total parenteral
   2. CRI of dextrose
   3. Elimination of underlying cause of sepsis with surgery and/or antibiotics
I. Hepatic failure
   1. Nutritional support: enteral or total parenteral
   2. CRI of dextrose
   3. Treatment of specific underlying hepatic disease

Monitoring of Animal

I. Neuroglycopenic crisis
   A. Monitor vital signs every 1 to 2 hours until clinically alert and stable.
   B. Monitor BG every 1 to 2 hours until euglycemia is established and maintained for >4 hours.
   C. Monitor neurological status hourly.
   D. If seizure activity recurs once euglycemic, diazepam or phenobarbital is indicated (see Chapter 22).
II. Specific monitoring for postoperative insulinoma cases
   A. Measure BG intraoperatively, immediately postoperatively, and every 2 to 4 hours thereafter until stable euglycemia is maintained for >12 hours.
   B. If animal is persistently hypoglycemic postoperatively, tumor was incompletely resected and other therapy (described earlier) is warranted.
   C. If animal becomes hyperglycemic postoperatively, transient regular insulin therapy 0.5 U/kg SC, IM is indicated, and continue to monitor BG every 2 to 4 hours.
   D. Discharge animal when clinically stable, euglycemic, and eating.
   E. Recheck for metastatic disease with fasting BG evaluated monthly.

CHAPTER 47

Introduction

Cathy E. Langston

ASSESSMENT OF RENAL FUNCTION

Azotemia

Definition

I. Azotemia is elevation of blood urea nitrogen (BUN) or creatinine.
II. Uremia is the constellation of clinical signs associated with renal failure.

Creatinine

I. Creatinine concentration is a more reliable measure of renal function than BUN.
II. Extensive variation between laboratories makes comparisons difficult (Boozer et al., 2002).
III. Creatinine concentration correlates poorly with glomerular filtration rate (GFR) at low levels of dysfunction.
   A. Major changes in GFR may cause very minor changes in creatinine.
   B. When GFR is markedly reduced, small changes in GFR cause large changes in creatinine (DiBartola, 2005).

Blood Urea Nitrogen

I. Increased by ingestion of high-protein diet, gastrointestinal hemorrhage, and prerenal factors (e.g., dehydration, hypotension, decreased cardiac output)
II. Decreased by low-protein diet, hepatic dysfunction

Glomerular Filtration Rate

I. GFR provides a more accurate assessment of renal function than creatinine or BUN, but measurement is more involved.
II. Multiple methods are available (Kerl and Cook, 2005).
III. Urinary clearance methods involve collecting urine over a specified time, as well as a blood sample at the midpoint of the collection period.
   A. Endogenous or exogenous creatinine or inulin is measured.
   B. The substance must be at steady state during the collection period.
IV. Plasma clearance methods involve collecting multiple blood samples after injection of a test substance.
   A. Exogenous creatinine, iohexol, inulin, Tc99m-diethylenetriamine pentaacetic acid (Tc-99m-DTPA) are measured.
   B. Iohexol is readily available and can be assayed (by Michigan State University Toxicology Section, www.animalhealth.msu.edu).
V. Renal scintigraphy involves measuring clearance of radiolabeled Tc-99m-DTPA.
   A. Requires special equipment (gamma camera)
   B. Only method that can determine left or right kidney function separately

Tubular Function

I. Hypersthenuria: urine specific gravity (USG) ≥1.030 in dogs or ≥1.035 in cats
II. Minimally concentrated urine: USG of 1.013 to 1.029 in dogs or 1.013 to 1.034 in cats
III. Isosthenuria: USG of 1.008 to 1.012 (or urine osmolality of 250 to 350 mOsm/kg) in dogs and cats
IV. Hyposthenuria: USG ≤1.007 in dogs and cats

Proteinuria

Definition

I. Prerenal proteinuria: induced by exposure to extreme heat or cold, seizures, fever, pathologic protein disorders (e.g., Bence Jones proteins, hemoglobinuria, myoglobinuria)
II. Renal proteinuria: glomerular, tubular, renal parenchymal inflammation (e.g., pyelonephritis, renal tumor)
III. Postrenal proteinuria: induced by lower urinary tract inflammation (e.g., bacterial cystitis, cystic calculi, neoplasia)

Measurement

I. Urine dipstick: semiquantitative assessment
  A. Dipsticks primarily measure albumin present in concentrations >30 mg/dL.
  B. Trace to 1+ with USG <1.020 or ≥2+ at any USG is likely significant.
  C. Consider postrenal sources if urine sediment is consistent with inflammation (pyuria, hematuria, bacteriuria).
II. Sulfosalicylic acid (SSA) protein precipitation test
  A. Recommended to confirm any positive dipstick tests
  B. No false-positive results with alkaline or highly concentrated urine (as occurs with dipstick assay)
III. Urine protein:creatinine ratio (UPC)
  A. It standardizes protein measurement despite differences in urine concentration.
  B. It is a reliable substitute for 24-hour urine collection.
  C. Results of serial samples must differ by ≥40% to conclude magnitude of proteinuria has changed.
IV. Microalbuminuria
  A. Defined as albumin concentration in urine between 1 to 30 mg/dL
  B. Commercially available test for dogs and cats (ERD HealthScreen; Heska Co., Fort Collins, Colo.)

Evaluation for Proteinuria

I. Any animal with illness serious enough to prompt complete blood count (CBC) and serum biochemical profile (Lees et al., 2005)
II. Any healthy animal undergoing a routine evaluation that includes a CBC and serum biochemical profile
III. Animals with chronic illness that may be associated with proteinuria (monitor at ≥6-month intervals)
IV. Azotemic animals

Evaluation for Microalbuminuria

I. Animals with serious illness (especially those associated with proteinuria) when standard proteinuria testing is negative (Lees et al., 2005)
II. Apparently healthy dogs >6 years old and cats >8 years old when standard proteinuria testing is negative and sensitive testing desired
III. Dogs or cats at risk for developing glomerular disease (predisposed breeds) when early detection is desired

Response to Proteinuria

I. Monitoring is recommended in the following instances:
  A. Nonazotemic dogs and cats with UPC ≥0.5
  B. Nonazotemic dogs and cats with persistent microalbuminuria
II. Diagnostic evaluation to find an underlying disease is combined with continued monitoring in the following cases:
  A. Nonazotemic dogs and cats with rising proteinuria
  B. Nonazotemic dogs and cats with UPC ≥1.0
  C. Azotemic dogs with UPC <0.5
  D. Azotemic cats with UCP <0.4
III. Therapeutic intervention (diet and/or drugs) is recommended after investigation and treatment of underlying disease in the following:
  A. Nonazotemic dogs and cats with UPC ≥2.0
  B. Azotemic dogs with UPC ≥0.5
  C. Azotemic cats with UPC ≥0.4

STAGING OF CHRONIC RENAL FAILURE

Definition

I. International Renal Interest Society (IRIS) has proposed a staging system for chronic renal failure.
II. System was developed to help design and apply clinical practice guidelines for therapy and prognosis (Polzin et al., 2005).

Criteria

I. They are intended to be used after diagnosis of chronic renal failure.
II. Renal function should be stable for 2 weeks for accurate categorization.
III. Four stages of disease are recognized.
  A. Stage I
    1. Kidney disease present but no azotemia
    2. Markers of kidney disease present: proteinuria, renal cysts
  B. Stage II
    1. Mild azotemia
    2. Clinical signs (except polyuria/polydipsia) absent or minimal
  C. Stage III
    1. Moderate azotemia
    2. Clinical signs generally present
  D. Stage IV
    1. Severe azotemia: chronic kidney failure
    2. Uremic syndrome present
IV. Three categories may be considered.
  A. Level of azotemia (Table 47-1)
  B. Presence of proteinuria: proteinuric (p), nonproteinuric (np), borderline proteinuria (bp)
  C. Presence of hypertension (see Chapter 48)
    1. Hypertensive with complications (hc)
    2. Hypertensive with no complications (hnc)

TABLE 47-1

Staging Scheme for Chronic Renal Failure

STAGE OF DISEASE	SERUM CREATININE (mg/dL)	
	Cats	Dogs
I	<1.6	<1.4
II	1.6-2.8	1.4-2.0
III	2.8-5.0	2.1-5.0
IV	>5.0	>5.0

3. Not hypertensive (nh)
4. Borderline hypertensive (bh)
5. Hypertension not determined (hnd)

CHAPTER 48

Diseases of the Kidney

Cathy E. Langston | Lauren Boyd

CONGENITAL/DEVELOPMENTAL DISORDERS

See Tables 48-1 and 48-2.

DEGENERATIVE DISORDERS

Feline Perinephric Pseudocysts

Definition and Cause

I. Perinephric pseudocysts (perirenal cysts) are accumulations of fluid in fibrous sacs around the kidney.
II. These are not true cysts, because they are not lined by epithelium and the cyst wall is thought to be the renal capsule.
III. Affected cats have the following characteristics:
  A. Generally older (>11 years), but may occur in younger cats (Ochoa et al., 1999)
  B. No gender or breed predisposition
IV. The cause is unknown.

Clinical Signs

I. Abdominal enlargement or detection of an abdominal mass
II. Signs of uremia
  A. The majority of affected cats have chronic renal failure (CRF).
  B. Pseudocysts may be unilateral or bilateral.

Diagnosis

I. On abdominal ultrasonography, anechoic fluid accumulation is seen between the renal capsule and parenchyma.
II. The kidney is often smaller than normal with changes consistent with CRF.
III. Fluid analysis is not necessary for diagnosis but generally reveals a transudate or modified transudate.
  A. Cell count and protein content are low.
  B. Fluid urea nitrogen or creatinine concentrations are lower than serum concentrations.
  C. Occasionally blood contamination is present.
  D. Fluid is generally sterile.
IV. Affected cats have a higher incidence of urinary tract infection (UTI).

Differential Diagnosis

I. Hydronephrosis
II. Renal lymphosarcoma, other renal neoplasia
III. Polycystic kidney disease (PKD)

TABLE 48-1

Congenital Renal Diseases

DISORDER	DEFECT	CLINICAL SIGNS	DIAGNOSIS	TREATMENT
Renal dysplasia	Disorganized development of renal parenchyma	Polyuria, polydipsia, azotemia Age of onset usually <5 years	Considered a possibility from early age of onset of CRF, ± small kidneys Diagnosed by renal biopsy	See Treatment of CRF
X-linked nephropathy	Complete absence of type IV collagen in the basement membrane	Male dogs: severe, rapidly progressive nephropathy with proteinuria Carrier (heterozygous) female dogs: slower progression to CRF at >5 years	Considered a possibility with proteinuria before 6 months of age Definitive diagnosis: immunofluorescent staining of the epidermal basement membranes for type IV collagen	Therapy as for other types of glomerulonephritis: ACE inhibitors, dietary restriction of protein, lipid, calcium, and phosphorus Treatment does not prevent progression of disease but delays onset

CRF, Chronic renal failure; *ACE,* angiotensin converting enzyme.

Treatment

I. Small fluid accumulations may need no specific therapy.
II. Treatment is recommended if abdominal distention is severe enough to cause abdominal pain or other clinical signs.
   A. Laparoscopic or surgical excision of the capsule without nephrectomy
   B. Concurrent nephrectomy (associated with shorter survival times)
   C. Ultrasound-guided drainage
III. Most pseudocysts recur over time.
IV. Drainage does not appear to improve renal function.

Monitoring of Animal

I. Serial abdominal ultrasounds are used to monitor changes in pseudocyst size over time and after drainage procedures.
II. Monitoring appropriate for the stage of CRF present (see Chronic Renal Failure) is also done.

Polycystic Kidney Disease

Definition

I. PKD is an inherited degeneration of the renal parenchyma, with development of multiple cysts throughout the kidney.
   A. Affected cats may also have hepatic and pancreatic cysts.
   B. About 40% of Persian cats genetically carry the PKD trait (DiBartola, 2000).
II. Persian-related cats, other longhaired breeds, and shorthaired cats may also be affected, although incidence in non-Persian cats is 14% (DiBartola, 2000).

TABLE 48-2

Familial Renal Diseases in Dogs and Cats

BREED	DISEASE	AGE OF ONSET (yr)	CLINICAL FINDINGS
Basenji	Fanconi's syndrome: proximal tubular defect	1-5	Glucosuria, metabolic acidosis, aminoaciduria
Beagle	Amyloidosis	5-11	Azotemia, proteinuria
Beagle	Membranoproliferative glomerulonephritis (GN)	2-8	Azotemia, proteinuria
Bernese mountain dog	Membranoproliferative GN	2-5	Azotemia, proteinuria
Brittany spaniel	Membranoproliferative GN: complement 3 deficiency	4-9	Recurrent bacterial infections, ± azotemia, proteinuria
Bullmastiff	GN	1-11	Azotemia, proteinuria
Bull terrier	Polycystic kidneys	0-2	Azotemia, ± cardiac disease
Bull terrier	Basement membrane disorder	0-10	Azotemia, proteinuria, ± hematuria
Cairn terrier	Polycystic kidneys	6 wk	Abdominal distention, hepatic cysts
Doberman pinscher	Basement membrane disorder	0-6	Azotemia, proteinuria
English cocker spaniel	Basement membrane disorder	0-2	Azotemia, proteinuria
English foxhound	Amyloidosis	5-8	Azotemia, proteinuria, renomegaly
Norwegian elkhound	Periglomerular fibrosis	0-5	Azotemia
Norwegian elkhound	Tubular dysfunction	Not reported	Glucosuria, ± azotemia
Rottweiler	Glomerular disease	0-1	Azotemia, proteinuria
Samoyed	Basement membrane disorder	0-1	Azotemia, proteinuria
Shar-pei	Amyloidosis	1-6	Azotemia, proteinuria, ± hepatic involvement, ± fever, joint swelling
Soft-coated Wheaten terrier	Membranoproliferative GN	2-11	Azotemia, proteinuria
Welsh corgi, Pembroke	Telangiectasia	≥5	Hematuria, anemia
West Highland white terrier	Polycystic kidneys	5 wk	Hepatic failure
Abyssinian cat	Amyloidosis	1-5	Azotemia, ± proteinuria
Oriental shorthair cat	Amyloidosis	0-5	Azotemia, ± hepatic involvement
Persian cat	Polycystic kidney disease	3-10	Azotemia, renomegaly, ± hepatic cysts
Siamese cat	Amyloidosis	0-5	Azotemia, ± hepatic involvement

Modified from Abraham LA, Beck C, Slocombe RF: Renal dysplasia and urinary tract infection in a bull mastiff puppy. Aust Vet J 81:336, 2003; Casal ML, Dambach DM, Meister T et al: Familial glomerulonephropathy in the bullmastiff. Vet Pathol 41:319, 2004; DiBartola SP: Familial renal disease in dogs and cats. p. 1819. In Ettinger SJ, Feldman EC (eds): Textbook of Veterinary Internal Medicine. 6th Ed. Elsevier Saunders, St. Louis, 2005.

III. An inherited form has also been described in bull terriers in Australia.

Causes and Pathophysiology

I. A mutation of the PKD1 gene causes autosomal dominant PKD (Lyons et al., 2004).
II. Excessive apoptosis (programmed cell death) destroys the renal parenchyma, allowing cystic epithelial cells to proliferate, which creates multiple and often large cysts.
III. In addition to the inherited genetic defect, an acquired somatic mutation may also be necessary for cyst development.

Clinical Signs

I. Clinical signs may not be present until late in the course when uremia occurs.
II. Palpation or radiographic imaging may detect abnormal renal size and shape.
III. Clinical signs of uremia may prompt investigation of affected cats.
IV. Age at onset of renal failure ranges from 3 to 10 years, with an average of 7 years (DiBartola, 2000).

Diagnosis

I. Screening tests
  A. Abdominal ultrasonography is 75% sensitive and 100% specific in cats <16 weeks of age, and sensitivity increases to 91% at 36 weeks (Biller et al., 1996).
  B. Genetic testing of cats >8 weeks of age is available using cheek swabs (www.vgl.ucdavis.edu).
II. Symptomatic cats with renal failure
  A. Perform diagnostic testing recommended for CRF.
  B. Abdominal ultrasonography reveals multiple, variably sized cysts in the renal parenchyma.

Treatment

I. Cats with PKD are removed from the breeding population.
II. Cats with CRF from PKD are treated as appropriate for the stage (see Chronic Renal Failure).

Monitoring of Animal

I. Onset of renal failure is variable.
II. Routine annual monitoring of adult cats known to have PKD for renal failure is prudent.
III. Once renal failure is apparent, monitor as appropriate for stage present.

INFECTIOUS AND INFLAMMATORY DISEASES

Leptospirosis

Definition and Causes

I. Leptospirosis is a bacterial zoonotic disease of particular importance in dogs that can cause acute or subacute hepatic and/or renal failure.
II. More than 200 serovars have been identified.
  A. The most common serovars causing clinical disease in dogs include *Leptospira kirschneri* serovar *grippotyphosa* and *Leptospira interrogans* serovars *bratislava*, *icterohaemorrhagiae, canicola, pomona,* and *autumnalis* (Birnbaum et al., 1998; Goldstein et al., 2006).
  B. The individual pathogenic significance of other serovars is unknown.
III. Cats are less susceptible than dogs.

Pathophysiology

I. Shedding by infected animals occurs primarily through the urine.
  A. The most common mode of transmission is via stagnant or slow-moving water contaminated with leptospires.
  B. The spirochete may live for several months in optimal environmental conditions.
II. Once the organism enters the host, it replicates in the kidney, liver, spleen, central nervous system (CNS), eyes, and genital tract.
III. The incubation period is usually 5 to 7 days but may vary.
IV. Antibody production appears around day 7 or 8, and the organism is cleared from most organs except the kidneys.
V. The organism replicates and persists in renal tubular epithelial cells, causing shedding for weeks to months after infection.

Clinical Signs

I. Severity of clinical signs varies based on the age and immunity of the host, environmental factors affecting the organism, and virulence of the infecting serovar (Greene et al., 2006).
II. Acute and subacute infections may affect many organs (see Chapter 113).
III. Acute urogenital signs include renal pain, renomegaly, oliguria; anuria with renal failure; and polyuria/polydipsia, with or without renal failure.
IV. Chronic infections may result in CRF, chronic active hepatitis, or hepatic fibrosis.
V. Dogs may be subclinically infected and have prolonged shedding of the organism but exhibit no clinical signs.

Diagnosis

I. Suggestive history and clinical signs
  A. Potential exposure to stagnant water, host animals (e.g., rats, raccoons, deer, cattle), wooded areas, lack of prior vaccination, fever, and renal and/or hepatic dysfunction are suggestive.
  B. Increased risk factors have been identified for leptospirosis.
    1. Middle-aged dogs
    2. Large breed, mixed breed, and hound dogs (Adin and Cowgill, 2000; Ward et al., 2002)
    3. Male dogs
    4. Dogs living in recently urbanized areas
II. Laboratory findings
  A. Hematology
    1. Leukopenia during leptospiremia: subsequent development of leukocytosis, with or without a left shift

2. Thrombocytopenia: may progress to disseminated intravascular coagulation (DIC)
3. Normocytic normochromic anemia

B. Serum biochemistry profile
1. Azotemia, hyperphosphatemia, hypercalcemia
2. Severe vomiting: hyponatremia, hypochloremia, hypokalemia
3. Hyperkalemia with oliguria or anuria
4. Hypoalbuminemia with hypocalcemia
5. Evidence of hepatic involvement
a. Elevated alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, and total bilirubin concentrations, with hypoglycemia
b. May lag behind azotemia by 6 to 8 days

C. Urinalysis
1. Tubular or glomerular proteinuria with an elevated urine protein:creatinine ratio (UPC)
2. Bilirubinuria
3. Hematuria with pyuria
4. Granular casts

III. Specific testing
A. Microscopic agglutination test (MAT): most common method
1. A fourfold increase in titers over a 2- to 4-week period, or a single test result of 1:800 or higher, is diagnostic.
2. It may take 10 days or more for antibody titers to develop (Brown et al., 1996).
3. It has a poor predictive value for shedding leptospires in the urine (Harkin et al., 2003).
4. It cannot distinguish between vaccinal and natural antibodies.

B. Polymerase chain reaction (PCR) assay
1. It becomes positive before seroconversion, so earlier diagnosis is possible.
2. Sensitivity (100%) and specificity (83%) are high (Harkin et al., 2003).
3. Sensitivity may result in false-positive results.

C. Enzyme-linked immunosorbent assay (ELISA)
1. Distinguishes between immunoglobulin (Ig) M (acute) and IgG (chronic) antibody titers
2. May be more sensitive than MAT in subacute infections
3. Paired IgM and IgG titers best to distinguish infection from vaccinal titers
4. Not widely available for clinical use

D. Other test options (see Chapters 2 and 113)

Differential Diagnosis

I. Other causes of acute renal failure (ARF)
A. Ethylene glycol, other renal toxins
B. Acute pyelonephritis
C. Borreliosis, other tick borne diseases

II. Other causes of acute hepatitis
A. Infectious canine hepatitis
B. Other bacterial infections
C. Hepatic toxins

Treatment

I. Supportive care and fluid therapy (see Acute Renal Failure)

II. Elimination of leptospiremia
A. Initially give parenteral penicillins, then switch to oral forms once the animal stops vomiting.
B. IV route has the most consistent absorption and is preferred.
C. Appropriate antibiotics include the following:
1. Ampicillin 22 mg/kg IV, SC QID for 2 weeks
2. Amoxicillin 22 mg/kg PO TID to BID for 2 weeks
3. Penicillin G 25,000 to 40,000 U/kg IM, SC BID for 2 weeks

III. Elimination of the carrier state
A. Treatment is started when animal is discharged from hospital.
B. Appropriate antibiotics include the following:
1. Doxycycline 5 mg/kg PO, IV BID for 2 weeks
2. Tetracycline 22 mg/kg PO TID for 2 weeks (infrequently used)
3. Azithromycin 20 mg/kg PO SID for 1 week

Monitoring of Animal

I. Renal function is monitored as described later for ARF.

II. Serum MAT titers are measured initially and repeated in 2 to 4 weeks.

III. To determine elimination of the carrier state, perform PCR assay 2 to 4 weeks after treatment with doxycycline or azithromycin.

IV. Dogs are immunized after recovery to prevent infection by a different serovar.

Borreliosis

See Chapter 113.

Pyelonephritis

Definition and Causes

I. Pyelonephritis is inflammation of the renal pelvis and parenchyma.
A. Usually associated with bacterial infections
B. Renal medulla more susceptible to infection than renal cortex

II. Common bacterial pathogens include (in descending order of incidence) *Escherichia coli*, *Staphylococcus aureus*, *Proteus mirabilis*, and *Streptococcus* spp. (Barsanti et al., 1994; Barsanti, 2006).
A. Less common are *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, and *Enterobacter* spp. (Barsanti et al., 1994)
B. Occasionally caused by fungal agents, usually *Candida* spp.

Pathophysiology

I. Route of infection may be ascending or hematogenous.
A. Ascending infection is believed to be the most common route.
B. Hematogenous infection is uncommon, owing to the resistance of the renal cortex to infection (Greene et al., 2006).

II. Abnormalities of the urinary tract may enhance renal susceptibility to infection.
  A. Congenital anomalies: ectopic ureters, vaginal strictures, recessed vulva, bladder diverticuli
  B. Acquired abnormalities: urolithiasis, neoplasia, granulomatous disease, fibrous scar tissue of renal parenchyma
  C. Functional and metabolic abnormalities
    1. Vesicoureteral reflux
    2. Disorders of micturition: decreased detrusor contractility, increased outflow resistance, decreased sphincter competence
    3. Diabetes mellitus
    4. Hyperadrenocorticism
    5. Systemic immunosuppression
  D. Urinary catheterization
    1. Associated with both temporary and indwelling catheters
    2. Risk of infection increases with duration of catheterization
III. Pyelonephritis occurs when lower UTI exists along with factors that predispose the kidney to colonization.
IV. Pyelonephritis may be a progressive disease.
  A. Chronic pyelonephritis may exist without progression to renal failure, especially in the absence of underlying renal disease (e.g., nephroliths).
  B. In acute infections, renal tubular cells produce inflammatory mediators (e.g., cytokines, nitrous oxide) that induce renal injury by recruiting neutrophils and macrophages.
  C. Renal scarring and atrophy may lead to end-stage kidney disease.

Clinical Signs

I. Acute pyelonephritis
  A. Fever, depression, anorexia, vomiting
  B. Renal pain
  C. Polyuria, polydipsia
II. Chronic pyelonephritis
  A. Polyuria, polydipsia
  B. Nonspecific signs of anorexia, lethargy, weight loss
  C. May be asymptomatic

Diagnosis

I. Suspicious history and physical examination findings
II. Complete blood count (CBC)
  A. May have a neutrophilic leukocytosis, with or without a left shift (especially in acute or complicated chronic pyelonephritis)
  B. May be normal
III. Serum biochemistry profile
  A. ± Azotemia, hyperphosphatemia with bilateral pyelonephritis
  B. Hyperglobulinemia possible with chronic infections
  C. May be normal
IV. Urinalysis
  A. Bacteriuria, pyuria, hematuria
  B. Possibly cellular or granular casts
  C. Isosthenuria
  D. Glucosuria with normoglycemia
V. Urine culture
  A. Pyelocentesis is definitive for pyelonephritis but is technically difficult if dilation is minimal.
  B. Ultrasound-guided percutaneous nephropyelocentesis may be done to retrieve urine for culture.
  C. Urine culture is best obtained by cystocentesis.
  D. Positive culture on cystocentesis does not localize infection to a site in the urinary tract.
VI. Radiographic imaging
  A. Excretory urography findings that are compatible with pyelonephritis include the following:
    1. Renal pelvic and/or proximal ureteral dilation
    2. Decreased opacity of the vascular nephrogram
    3. Blunting or distortion of renal pelvic diverticula
    4. Prolonged retention of contrast media in the renal pelvis
    5. May be normal
  B. Ultrasound findings that are compatible with pyelonephritis are as follows:
    1. Dilatation of the renal pelvis and proximal ureter
    2. Generalized hyperechoic renal cortex
    3. Increased prominence of the pelvic and ureteral mucosa
    4. Poor corticomedullary distinction
    5. Renal asymmetry

Differential Diagnosis

I. Other causes of fever, leukocytosis, and painful abdomen: peritonitis, pancreatitis, early gastrointestinal (GI) distention or torsion
II. Nephrolithiasis, ureterolithiasis, stricture
III. Lower UTI
IV. Bacterial prostatitis

Treatment and Monitoring

I. Correct any underlying predisposing factors.
II. Antibiotic therapy is selected based on bacterial culture and sensitivity.
  A. Antibiotics that penetrate renal tissue (specifically medulla) are preferred.
    1. Fluoroquinolones: enrofloxacin, marbofloxacin, orbifloxacin, difloxacin
    2. Ampicillin, amoxicillin, amoxicillin-clavulanic acid
    3. Cephalosporins
    4. Trimethoprim-sulfa drugs
      a. Sulfonamides do not reach effective intrarenal concentrations.
      b. Only the trimethoprim component is effective (Bergeron, 1995).
    5. Aminoglycosides as a last resort because of their potential nephrotoxicity
  B. Antibiotic therapy is continued for a total of 6 weeks.
  C. Repeat culture 1 week after completion of antibiotics.
  D. Fluconazole is the antifungal agent of choice, because it is excreted in urine in the active form (Pressler et al., 2003).
  E. Avoid indwelling urinary catheters.

III. Increase water intake to prevent urine stasis and encourage diuresis.
IV. Treat ARF or CRF, if present.

RENAL PARASITES

See Table 48-3.

NEPHROTOXICOSIS

Definition and Causes

I. Nephrotoxins are chemicals or drugs that produce acute tubular injury ranging from sublethal cell injury to cellular necrosis and apoptosis.
II. Toxins can also decrease renal blood flow and induce hypoxia that results in cell injury or death.
III. Nephrotoxins are a major cause of ARF in animals.
IV. For a list of causes, see Table 48-4.

Pathophysiology

I. Acute tubular injury is the most common sequela of a toxic insult to the kidney.
   A. Acute tubular injury can result in either sublethal cell damage or cell death.
   B. In nephrotoxic ARF, tubular injury is characterized by patchy distribution of degenerative or necrotic foci of tubular epithelium, with little or no evidence of interstitial inflammation (Cowgill and Francey, 2005).
II. Nephrotoxic injury to the glomerulus can be caused by loss of capillary surface area (aminoglycosides), disruption of endothelial cell integrity (doxorubicin), and mesangial cell proliferation and hypertrophy (azathioprine) (Brown and Grauer, 2002).
III. Duration of exposure, quantity and type of nephrotoxicant, and predisposing factors determine the severity and reversibility of renal damage.
IV. Predisposing factors can potentiate the damage caused by nephrotoxicosis.
   A. Hypotension
   B. Preexisting renal insufficiency
   C. Fever, sepsis
   D. Dehydration
   E. Hypokalemia (Brinker et al., 1981)
   F. Liver disease and dysfunction
   G. Decreased protein intake (Grauer et al., 1994)
   H. Concurrent use of two or more substances with nephrotoxic potential

Clinical Signs

I. Clinical signs are consistent with ARF.
   A. Polyuria, oliguria, or anuria
   B. Depression, lethargy, anorexia
   C. Vomiting and diarrhea, with or without melena
   D. Uremic breath
   E. Evidence of platelet dysfunction: petechiae, excessive bleeding
II. Laboratory findings may include the following:
   A. Metabolic acidosis
   B. Hyperkalemia or hypokalemia
   C. Azotemia
   D. Hyperphosphatemia
   E. Normoglycemic glucosuria
   F. Proteinuria

TABLE 48-3

Renal Parasites

PARASITE	INTERMEDIATE HOSTS	CLINICAL SIGNS	DIAGNOSIS	TREATMENT
Capillaria plica (cats and dogs)	Earthworm	Ova in urine often incidental finding Possible dysuria, pollakiuria, hematuria	Double operculated ova in urine False-positive results from *Trichuris* spp. with fecal contamination	Spontaneous resolution within 3-4 months in some animals Fenbendazole 50 mg/kg/day PO for 5-10 days Ivermectin 200 µg/kg PO once (not safe in collie-type dogs)
Capillaria feliscati (cats)	Earthworm	Same as for previous parasite	Same as for previous parasite	Fenbendazole 22 mg/kg PO BID for 3-10 days
Dioctophyma renale	Worms ingested by fish or frogs Raw fish or frogs then ingested by dogs or cats	May be asymptomatic Uremia if bilateral Hematuria or signs of ureteral obstruction	Ova in urine or abdominal fluid Adult nematodes seen on ultrasonography or at surgery	Surgical removal of adult worm or nephrectomy Possible aberrant migration in peritoneal cavity

TABLE 48-4

Potential Nephrotoxins in Dogs and Cats

CLASS OF AGENT	EXAMPLES
Antimicrobials	Aminoglycosides, cephalosporins, penicillins, sulfonamides, quinolones, tetracyclines, vancomycin, carbapenems, aztreonam, rifampin, nafcillin
Antiprotozoals	Trimethoprim-sulfamethoxazole, sulfadiazine, thiacetarsamide, pentamidine, dapsone
Antifungals	Amphotericin B
Antivirals	Acyclovir, foscarnet
Chemotherapeutics	Cisplatin, carboplatin, doxorubicin, methotrexate
Immunosuppressives	Cyclosporine, azathioprine, interleukin 2
Nonsteroidal anti-inflammatory drugs	All
Angiotensin-converting enzyme inhibitors	All
Diuretics	All
Radiocontrast agents	Hyperosmolar ionic water-soluble contrast media
Miscellaneous therapeutics	Allopurinol, cimetidine, apomorphine, dextran 40, penicillamine, streptokinase, methoxyflurane, tricyclic antidepressants, lipid-lowering agents, calcium antagonists
Heavy metals	Mercury, uranium, lead, bismuth salts, chromium, arsenic, gold, cadmium, thallium, copper, silver, nickel, antimony
Organic compounds	Ethylene glycol, chloroform, pesticides, herbicides, solvents, carbon tetrachloride
Other exogenous toxins	Gallium nitrate, disphosphonates, mushrooms, grapes, raisins, snake venom, bee venom, lilies, vitamin D_3-containing rodenticides
Endogenous toxins	Hemoglobin, myoglobin, hypercalcemia

G. Urine sediment: renal epithelial cells, granular casts, red blood cells (RBCs) or white blood cells (WBCs) secondary to tubular cell necrosis

Diagnosis and Differential Diagnosis

I. Known potential exposure to nephrotoxin increases suspicion.
II. Clinical signs and laboratory findings are consistent with ARF.
III. Presence of granular casts in the urine or urine enzyme: creatinine excretion ratios may be early markers of gentamicin-induced nephrotoxicity (Grauer et al., 1995).
IV. Severe hypercalcemia may lead to increased suspicion of vitamin D_3 intoxication.
V. Confirmation of ethylene glycol toxicosis involves the following:
   A. High anion gap, metabolic acidosis
   B. Ethylene glycol test kit to confirm exposure
      1. It can detect levels as early as 30 minutes and for up to 12 hours after exposure.
      2. Negative test after 12 hours does not rule out exposure.
      3. It tests for the parent compound, not toxic metabolites.
      4. Most widely used test kit (PRN Pharmacal, Pensacola, FL) may not be sensitive enough to detect levels that are lethal to cats.
      5. Newer test has lower (20 parts per million [ppm] vs 50 ppm) detection limits (Kacey, Asheville, NC).
      6. Toxicology laboratories can quantify concentrations (vs qualitative results with test kits).
   C. Evidence of CNS abnormalities (e.g., seizures, ataxia, disorientation), polyuria, polydipsia
   D. Monohydrate calcium oxalate crystalluria
   E. Supportive ultrasonographic findings
      1. ± Normal kidneys
      2. Increased corticomedullary echogenicity consistent with renal mineralization or deposition of calcium oxalate crystals
   F. Renal biopsy
      1. Confirms acute tubular injury and presence of calcium oxalate crystals
      2. Helps determine prognosis

Treatment and Monitoring

I. Therapy includes measures to resolve ARF and supportive care (see Acute Renal Failure).
II. Resolution of electrolyte abnormalities is important.
III. Therapy for ethylene glycol ingestion includes hemodialysis or administering specific antidotes.
   A. Hemodialysis is the therapy of choice, because it can completely remove ethylene glycol and its metabolites and may prevent renal damage if performed within 5 to 6 hours of ingestion.
   B. If the animal arrives at the clinic within 2 hours of ingestion, then treatment with an emetic followed by activated charcoal and a cathartic is indicated (see Chapter 128).
   C. If the animal arrives at the clinic more than 2 hours after ingestion, then treatment with ethanol or 4-methyl-pyrazole (4-MP) is indicated to inhibit further ethylene glycol metabolism (Dorman and Dye, 2005).
      1. 4-MP is the preferred treatment in dogs (not effective in cats).
      2. The initial dose of 4-MP is 20 mg/kg IV, followed by 15 mg/kg IV at 12 hours, again at 24 hours, and then 5 mg/kg IV at 36 hours.

3. Additional doses of 3 mg/kg IV BID may be necessary if the dog is not fully recovered or if ethylene glycol levels are still detectable in the blood.

D. If 4-MP is not available, then ethanol is administered IV to produce CNS depression but not a comatose state.
   1. In dogs, administer a 20% solution in 0.9% saline at a dose of 5.5 mL/kg IV every 4 hours for five treatments and then QID for four treatments.
   2. In cats, 20% ethanol is given at 5 mL/kg IV QID for five treatments, then TID for four treatments (Langston, 2005).

IV. Dialyzable toxins include ethylene glycol, methanol, salicylate, lithium, ethanol, phenobarbital, acetaminophen, aminoglycosides, and tricyclic antidepressants.

V. Prognosis for most nephrotoxicants is guarded, and removal of the toxin may or may not result in restoration of renal function.

IMMUNE-MEDIATED DISEASES

Glomerular Diseases

Definition

I. Glomerulonephritis (GN) is inflammation of the glomerulus.
   A. More common in middle-aged to older dogs
   B. Uncommon in cats

II. Glomerulopathies do not have an inflammatory component and include hereditary nephritis and some renal diseases classically considered to be forms of GN (membranous nephropathy).

III. Amyloidosis is deposition of fibrils of protein in the glomerulus (most common), medulla, or possibly other organs.
   A. The Chinese shar-pei is predisposed to medullary amyloidosis, and affected dogs may have a history of tibiotarsal swelling and fever (shar-pei fever).
   B. Abyssinian and Siamese cats are predisposed to medullary amyloidosis.

IV. Protein-losing nephropathy includes GN, glomerulopathy, and amyloidosis.

Causes and Pathophysiology

I. GN is caused by immune complex deposition in the glomerulus.
   A. Antigen excess or large numbers of circulating antigen-antibody complexes lodge in the glomerular membrane, eliciting an immune response characterized by inflammatory cell influx, complement activation, and cellular damage.
   B. The renal response is cellular and mesangial matrix proliferation, as well as thickening of the glomerular basement membrane.
   C. Approximately 50% of GN in dogs is primary or idiopathic.
   D. Multiple secondary causes of GN have been identified (Table 48-5).

TABLE 48-5

Diseases Associated with Glomerulonephritis in Dogs

CAUSES	EXAMPLES
Infectious diseases	Canine adenovirus type 1, babesiosis, bacterial endocarditis, bartonellosis, blastomycosis, borreliosis, brucellosis, coccidioidomycosis, dirofilariasis, ehrlichiosis, hepatozoonosis, leishmaniasis, pyelonephritis, pyometra, trypanosomiasis, chronic bacterial infections
Neoplasia	Hemangiosarcoma, hepatocellular carcinoma, lymphocytic leukemia, transitional cell carcinoma, lymphoma, bronchogenic adenocarcinoma, mastocytoma
Inflammatory, noninfectious disorders	Systemic lupus erythematosus, polyarthritis, other immune-mediated diseases, pancreatitis, periodontal disease, inflammatory bowel disease
Miscellaneous factors	Excessive corticosteroids, familial disorders, diabetes mellitus

II. Reactive amyloidosis may occur when serum amyloid A, an acute-phase reactant protein, is present in large quantities over prolonged periods of time.
   A. Chronic inflammation is a predisposing cause.
   B. The shar-pei disease resembles human familial Mediterranean fever, in which defective down-regulation of mediators of inflammation exist.

Clinical Signs

I. Clinical signs may not be apparent if proteinuria is diagnosed on routine urine screening.

II. Signs are usually vague and include weight loss, anorexia, poor hair coat, or body condition.
   A. Clinical signs of uremia may be present (vomiting, anorexia, uremic halitosis).
   B. Peripheral edema or evidence of thromboembolism may occur in advanced cases.

III. Clinical signs of underlying causes may be detected (e.g., coughing with heartworm disease).

Diagnosis

I. Urinalysis
   A. An elevated UPC >0.5 in the absence of inflammation (pyuria, hematuria, bacteriuria) is suggestive of glomerular disease.
   B. Dogs with amyloidosis or membranous nephropathy tend to have the highest UPC values.

C. Isosthenuria may or may not be present.
D. Dogs with protein-losing nephropathy may have urine specific gravity >1.035, with azotemia.
E. Urine sediment examination may reveal the following abnormalities:
1. Casts are generally hyaline, but any type is possible.
2. Microscopic hematuria with dysmorphic RBCs is uncommon in dogs.

II. Serum biochemical profile and hematology
A. Azotemia is present in late stages.
B. Other findings associated with CRF may be present in late stages.
C. Hypoalbuminemia occurs in 61% of dogs with GN (Grant and Forrester, 2001).
D. Hypercholesterolemia is common (50%) (Grant and Forrester, 2001).

III. Infectious disease screening for underlying causes of GN

IV. Radiographic imaging
A. Abdominal imaging may show normal, small, or enlarged kidneys.
B. Thoracic radiographs are recommended in middle-aged to older animals.

V. Renal biopsy
A. For definitive diagnosis, unless proteinuria resolves after treatment of underlying condition
B. Biopsy method
1. Ultrasound-guided needle biopsy: provides small sample of tissue
2. Laparoscopic biopsy: larger tissue sample
3. Keyhole wedge biopsy: small incision over flank
4. Open laparotomy: most invasive
C. Biopsy handling
1. Presence of several glomeruli (preferably >5) is ascertained at the time of biopsy using a dissecting microscope.
2. Needle biopsy specimen (or portion of wedge biopsy) is fixed in formalin.
3. Second needle biopsy (or portion of wedge) is split and fixed for immunofluorescence (freezing, Michel's solution) and for electron microscopy (4% formalin plus 1% glutaraldehyde).
D. Biopsy processing
1. Multiple stains are used on thin sections of tissue.
2. Immunofluorescence or immunohistochemical staining for IgA, IgG, IgM, and complement are recommended on all biopsies.
3. Electron microscopy is reserved for difficult cases.
E. Biopsy results
1. Membranoproliferative GN is probably the most common type in the dog and is characterized by thickened capillary loops and mesangial hypercellularity (Vaden, 2005).
a. Type I (mesangiocapillary GN): infectious diseases possible cause
b. Type II: uncommon in dogs
c. Rapidly progressive form with tubular necrosis and interstitial inflammation: associated with *Borrelia burgdorferi* infection in dogs
2. Membranous nephropathy is the second most common GN in dogs, the most common type in cats, and affects male cats more than females.
a. Generally it is an idiopathic disease.
b. The basement membrane becomes thickened with immune complex deposits.
3. Proliferative GN is poorly defined in dogs.
a. Histologically, mesangial cell proliferation occurs.
b. Antibodies directed against the glomerular basement membrane have not been described in dogs or cats.
4. Many dogs are positive for IgA on immunofluorescence, but this may reflect the polymeric nature of IgA and nonspecific binding.
5. Hereditary nephritis includes a variety of inherited glomerular defects of basement membrane collagen type IV.
a. Light microscopic changes include membranoproliferative or sclerosing GN.
b. Electron microscopy is necessary for a definitive diagnosis.
6. Glomerulosclerosis is a possible end-stage lesion of any glomerular injury.
7. Amyloidosis is characterized by acellular material in the glomerulus.

Differential Diagnosis

I. Lower urinary tract disease: UTI, neoplasia, sterile cystitis
II. Tubular disease: pyelonephritis
III. Transient glomerular insult: fever, seizures, extremes of temperature
IV. Hemoglobinuria, myoglobinuria, Bence Jones proteinuria

Treatment

I. Start specific therapy for any underlying disease.
II. Decrease proteinuria.
A. Give enalapril or benazepril 0.25 to 1.0 mg/kg PO SID to BID unless creatinine >5 mg/dL.
B. Start a protein-restricted diet and avoid supplemental protein (e.g., egg whites).

III. Inhibit platelets.
A. Aspirin (0.5 to 2.0 mg/kg PO SID in dogs and QOD in cats) inhibits platelet aggregation.
B. Coumadin is difficult to titrate, requires careful monitoring, and is rarely used.

IV. Control hypertension.
A. Hypertension is more common and more difficult to control compared with hypertension associated with other types of renal disease.
B. See later discussion of hypertension treatment.

V. Consider immunosuppressive drugs.
A. No evidence of efficacy exists in dogs or cats; they should be used with caution and based on renal biopsy results.
B. Immunosuppressive therapy may be warranted with membranous GN.
C. Corticosteroids can cause proteinuria and are not recommended in dogs unless the underlying disease is steroid responsive (e.g., systemic lupus erythematosus).

D. Corticosteroids may be helpful in cats.
E. Drugs with no proven benefit include the following:
1. Dogs: azathioprine 2 mg/kg PO SID to QOD
2. Cyclophosphamide 50 mg/m^2 PO SID for 3 to 4 days, then off for 3 to 4 days
3. Cyclosporine, may worsen prognosis (Vaden et al., 1995)

VI. Treat amyloidosis.
A. Colchicine (0.01 to 0.03 mg/kg PO SID) is given during febrile episodes in affected shar-peis.
1. It may decrease amyloid deposition.
2. No evidence of effectiveness is seen once renal failure has occurred.
3. The primary side effect is GI upset.
B. Dimethyl sulfoxide (DMSO) 90 mg/kg PO, SC three times weekly has questionable benefit; anorexia, nausea, and an unpleasant odor are possible side effects.

Monitoring of Animal

I. Proteinuria is monitored monthly when starting or adjusting therapy, then every 3 months if the animal is stable.
II. Serum biochemical profiles are monitored every 3 to 6 months and more frequently if azotemia is present.
III. Systemic blood pressure is evaluated every 3 to 6 months in normotensive or controlled hypertensive animals (and more frequently during dose changes).

NEPHROLITHIASIS

Definition

I. Nephroliths are calculi that form in the kidneys.
II. These calculi are usually located in the renal pelvis or diverticula.

Causes

I. Calcium oxalate or mixed-oxalate calculi
A. Comprise 40% of canine nephroliths (Ross et al., 1999)
B. Comprise 75% to 98% of feline nephroliths (Ling et al., 1998; Kyles et al., 2005)
II. Struvite calculi
A. Comprise 33% of canine nephroliths
B. More common in female dogs (75% of nephroliths) than male dogs (20%) (Ross et al., 1999)
III. Urate calculi: 12% of canine nephroliths (Ross et al., 1999)
IV. Other mineral types: xanthene, silica, cystine, compound, or mixed calculi

Pathophysiology

I. Breed predispositions and concurrent diseases increase the risk of urolith formation (see Chapter 50).
II. Incidence of ureteroliths and (presumptively) nephroliths is increasing in cats, although the cause for this change is unknown (see Chapter 49).

Clinical Signs

I. None: nephroliths detected serendipitously during abdominal radiography or ultrasonography
II. Hematuria, unassociated with dysuria
III. Signs of lower UTI: pollakiuria, stranguria
IV. Abdominal or flank pain: infrequent
V. Signs associated with uremia

Diagnosis

I. Abdominal imaging
A. Radiography: majority of calculi are radiopaque; small calculi often missed
B. Ultrasonography: occasionally difficult to differentiate calculi from renal mineralization
C. Excretory urography (IV pyelography): sensitive method of detection
D. Computed tomography (CT): sensitive method of detection
II. Additional recommended diagnostic tests
A. Serum biochemical profile
B. Urine culture
C. Renal scintigraphy to evaluate function of individual kidneys if nephrectomy considered

Differential Diagnosis

I. Renal mineralization
II. Traumatic renal injury
III. Renal neoplasia
IV. Pyelonephritis

Treatment

I. Asymptomatic calculi, no renal dysfunction
A. Treatment is aimed at slowing progression or dissolving the calculi.
1. If struvite is considered a possibility (female dog with concurrent UTI), then stone dissolution diets (Hill's s/d diet, Royal Canin SO Diet) and concurrent antibiotics are started.
2. If calcium oxalate is considered a possibility (cats), then avoidance of acidifying diets, addition of potassium citrate, and feeding a canned diet are begun because medical dissolution is not possible.
3. If urate is considered a possibility (dalmatians), then dietary therapy with restricted protein, restricted purine, alkalinizing properties (Hill's u/d), and allopurinol 10 mg/kg/day PO may cause stone dissolution.
B. Monitor progression of calculi and renal function.
1. If condition is worsening, then consider more active management (lithotripsy, surgery).
2. Surgical intervention decreases renal function by 20% (Bollinger et al., 2005).
II. Calculi and significant associated renal impairment
A. Medical management may be a better alternative than surgery.
B. Decision on type of therapy depends on extent of disease, involvement of contralateral kidney, and stone type.
III. Calculi causing obstruction or recurrent UTI
A. Surgical removal of calculus via pyelotomy or nephrotomy

1. Staged surgery (2 to 4 weeks apart) preferable for bilateral disease
2. Nephrectomy for irreversible renal damage and minimal function

B. Extracorporeal shockwave lithotripsy
1. Less invasive than surgery
2. Faster results than medical dissolution
3. Limited availability

C. Percutaneous lithotripsy
1. Small incision over kidney provides access by ultrasound or laser lithotripter
2. Causes less renal functional impairment than surgery
3. Procedure has limited availability

Monitoring of Animal

I. Abdominal radiographs every 2 to 6 months to assess size and recurrence of calculi
II. Serum biochemical profile at least every 3 to 6 months
III. Urinalysis and urine culture every 3 months

CHRONIC RENAL FAILURE

Definition

I. CRF is defined as azotemia in the presence of inadequately concentrated urine (urine specific gravity <1.035 in cats, <1.030 in dogs).
II. Disease must be present for >3 months.
III. A staging system for chronic kidney disease is presented in Chapter 47.

Causes

I. Tubulointerstitial nephritis is the most common histopathologic lesion, but it may be the end result of a variety of insults.
II. Other causes include GN, hereditary nephritis, amyloidosis, renal dysplasia, PKD, tubulonephrosis, lymphoma, chronic pyelonephritis, nephroliths or ureteroliths (causing partial obstruction), vasculitis, infarction, and incomplete resolution of ARF.

Pathophysiology

I. Irreparable damage to the glomerulus, tubule, or interstitium leads to loss of the entire nephron (because each nephron acts as a unit).
II. Remaining nephrons become hypertrophic.
III. Although initially an adaptive response, glomerular hypertension damages the nephron, leading to further nephron loss.
IV. After a certain level of damage has been sustained (generally when creatinine >3.5 mg/dL), renal failure becomes progressive despite resolution of the initiating cause.

Clinical Signs

I. Historical signs
A. Polyuria, polydipsia
B. Anorexia, weight loss, lethargy
C. Vomiting
D. Halitosis
E. Altered consciousness, seizures
F. Bleeding problems

II. Physical examination findings
A. Dehydration
B. Frequently small, irregular, or asymmetrical kidneys
C. Rarely, large kidneys
D. Renal pain uncommon
E. Uremic halitosis, oral ulceration
F. Poor hair coat, poor body condition
G. Mild pallor

Diagnosis

I. Serum biochemistry panel
A. Magnitude of abnormalities greater as severity progresses
B. Elevated blood urea nitrogen (BUN), creatinine
C. Hyperphosphatemia
D. Hypokalemia: more common in cats
E. Metabolic acidosis: more common in cats
F. Mild hypercalcemia or hypocalcemia

II. CBC
A. Nonregenerative anemia in some animals from decreased erythropoietin
B. Normal platelet count, decreased platelet function

III. Urinalysis
A. Isosthenuria or inadequately concentrated urine in addition to dehydration or azotemia (urine specific gravity <1.035 in cats, 1.030 in dogs) is expected, but urine concentrating ability may rarely be retained.
B. Casts indicate ongoing renal damage.
C. WBCs or bacteria may be detected (if active pyelonephritis or secondary bladder infection present).

IV. Radiographic imaging
A. Radiography may show small and irregular kidneys, kidneys of normal size and shape, enlarged kidneys, nephroliths, or ureteroliths.
B. Abdominal ultrasonography frequently shows increased echogenicity from fibrosis and deranged architecture, as well as renal pelvic dilation from infection, obstruction, or aggressive diuresis.
C. Excretory urography may show poor contrast uptake or structural abnormalities (see Chapter 4).

V. Other diagnostic tests
A. Blood pressure measurement
1. Hypertension occurs in about 20% to 90% of cases (Cook and Cowgill, 1996; Syme et al., 2002).
2. Risk of complications of hypertension increases with higher blood pressure (Table 48-6).

B. Measurement of glomerular filtration rate (GFR)
1. Not necessary if azotemia present
2. Useful in detecting early kidney disease

C. Parathyroid hormone measurement: renal secondary hyperparathyroidism

Differential Diagnosis

I. Prerenal azotemia from dehydration, high-protein diet, or GI bleeding is characterized by high urine specific gravity.

TABLE 48-6

Risk of Adverse Effects of Hypertension Based on Peripheral Indirect Arterial Blood Pressure

SYSTOLIC (mm Hg)	DIASTOLIC (mm Hg)	RISK CATEGORY
>180	>120	High
160	100	Moderate
150	95	Low
<150	<95	Minimal

II. Azotemia with inadequately concentrated urine may arise from the following:
  A. Renal failure: ARF, CRF
  B. Dehydration combined with extrarenal impairment of urine concentration
    1. Drug therapy: diuretics, glucocorticoids
    2. Osmotic diuresis: diabetes mellitus
    3. Impaired medullary concentration gradient: hypoadrenocorticism, portosystemic shunting
    4. Central diabetes insipidus
    5. Nephrogenic diabetes insipidus: hypercalcemia, pyometra, pyelonephritis
III. Postrenal azotemia (urinary obstruction, rupture) is differentiated from intrinsic renal failure by history, physical examination, and imaging studies.

Treatment

I. Prevention of progression
  A. Dietary therapy
    1. Renal diets contain restricted quantities of protein with high biological value, restricted phosphorus, and supplemental omega-3 polyunsaturated fatty acids.
    2. Dietary therapy prolongs survival in dogs and cats and diminishes the number of uremic crises requiring hospitalization in dogs (Jacob et al., 2005; Ross et al., 2005).
    3. Renal diets are instituted at the time of diagnosis, even if no clinical signs are apparent.
  B. Control of proteinuria
    1. Angiotensin converting enzyme (ACE) inhibitors (enalapril or benazepril 0.25 to 0.5 mg/kg PO SID to BID) slow progression of renal failure in dogs with GN.
    2. ACE inhibitors do not prolong survival in most cats with CRF.
      a. Some benefit in cats with UPC >1 (Gunn-Moore, 2003)
      b. Considered in cats with UPC >0.4 (Syme et al., 2006)
  C. Control of secondary hyperparathyroidism
    1. Calcitriol (2.5 ng/kg PO SID) prolongs survival in dogs (Polzin et al., 2005).
      a. Contraindicated: uncontrolled hyperphosphatemia, hypercalcemia
      b. Adverse effects: hypercalcemia, soft-tissue mineralization
      c. Careful monitoring: calcium, phosphorus, parathormone levels
    2. Beneficial in dogs (may not benefit cats)
  D. Control of conditions associated with renal damage
    1. Hypertension (Jacob et al., 2003)
    2. Infections
    3. Dehydration, hypoperfusion
    4. Avoidance of nephrotoxic drugs or substances
II. Treatment of uremic signs
  A. Dehydrated animals that are unwilling or unable to tolerate oral fluids or those with hypotension are admitted to the hospital for IV fluid therapy.
    1. Balanced polyionic fluids are used for initial therapy (lactated Ringer's, 0.9% saline, Plasmalyte).
    2. Fluids with lower sodium content (0.45% saline + 2.5% dextrose) are appropriate after initial rehydration period.
    3. Maintenance fluid needs (66 mL/kg/day) plus dehydration deficit (body weight (kg) × % dehydration = deficit in L) are replaced over 4 to 48 hours.
      a. Longer replacement time of large deficits in animals with cardiovascular compromise
      b. More rapid replacement in hypotensive or oliguric animals
    4. After rehydration, maintenance fluid need plus 2.5% to 6% of body weight is given every 24 hours to promote diuresis.
    5. When the lowest creatinine level is reached, fluid dose is tapered gradually.
  B. Chronically dehydrated animals being maintained at home may benefit from regular SC fluid therapy.
    1. Dosing is empirical and adjusted based on hydration status and sense of well-being.
    2. Consider 100 to 150 mL SC SID two to three times weekly for cats.
    3. Cats tend to respond better than dogs.
  C. Appetite stimulants may be needed for anorexia.
    1. Cat: cyproheptadine 1 to 2 mg PO SID to BID
    2. Cat: oxazepam 2 mg PO BID
  D. Feeding tube placement allows administration of an appropriate quantity of the desired diet, easy administration of oral medications, and is strongly recommended in animals not voluntarily consuming adequate calories.
  E. One or more of the following may be given for nausea or vomiting:
    1. Inhibitors of gastric acid secretion
      a. Famotidine 0.5 mg/kg IV, SC, PO SID (not given IV in cats)
      b. Ranitidine 0.5 to 2.5 mg/kg SC, PO SID
      c. Cimetidine 5 to 10 mg/kg PO BID
      d. Omeprazole 0.7 mg/kg PO SID
    2. Antiemetics
      a. Metoclopramide 0.2 to 0.4 mg/kg SC QID or 0.01 to 0.02 mg/kg/hr IV as constant rate infusion (CRI)

b. Chlorpromazine 0.2 to 0.5 mg/kg IM, SC TID to QID
c. Ondansetron 0.1 mg/kg PO BID to TID, 0.1 to 0.3 mg/kg IV BID to TID
d. Dolasetron 0.5 mg/kg PO, SC, IV SID
3. Motility modifiers: cisapride 0.1 to 0.5 mg/kg PO BID to TID
4. Dogs: sucralfate 0.25 to 1 g PO TID if GI ulceration known or considered a possibility (hematemesis, melena, anemia)

F. Hyperphosphatemia requires treatment.
1. Phosphate-restricted diet
2. Phosphate binders to prevent absorption of phosphorus from ingested food
a. Aluminum hydroxide or aluminum carbonate 30 to 90 mg/kg/day PO divided BID to QID and administered with meals
b. Calcium acetate 60 to 90 mg/kg/day PO; hypercalcemia a possible side effect

G. Hypokalemia is more likely in cats than dogs.
1. Potassium gluconate 0.45 mEq/kg/day PO
2. Potassium citrate 40 to 75 mg/kg PO BID

H. Metabolic acidosis is more likely in cats than dogs.
1. Consider treatment if total CO_2 <16 mEq/L or blood pH <7.2.
2. Give potassium citrate 40 to 75 mg/kg PO BID (also addresses hypokalemia).
3. Give sodium bicarbonate 10 mg/kg PO BID.

I. Several therapies are available for anemia.
1. Transfusion: based on clinical need
2. Human recombinant erythropoietin (EPO)
a. Starting dose is 100 U/kg SC three times a week until packed cell volume (PCV) nears the target value, then gradually decrease to 50 to 100 U/kg SC every 4 to 7 days.
b. Target PCV is 25% to 30% in cats and 30% to 35% in dogs.
c. Monitor PCV weekly during the initial period.
d. Administer iron during initial therapy to ensure adequate response.
e. Antibody formation occurs in 25% of animals, necessitating discontinuation of therapy (Cowgill, 2003).
3. Darbepoetin: a newer erythropoiesis-stimulating protein
a. Starting dose of 0.45 μg/kg SC once weekly, tapered to every 2 to 3 weeks
b. Unknown risk of antibody formation in dogs and cats

J. Treatment of hypertension helps prevent end-organ damage.
1. Goal is to decrease systolic pressure to <160 mm Hg.
2. Medications may be combined to achieve the desired blood pressure.
3. Amlodipine 0.625 mg PO SID is a good first drug in cats.
a. Dose for dogs is 0.5 to 1.0 mg/kg PO SID or 0.2 to 0.4 mg/kg PO BID
b. If it does not control hypertension, then add an ACE inhibitor.
4. ACE inhibitors are good first choices if proteinuria is present.
a. Enalapril 0.25 to 0.5 mg/kg PO SID to BID
b. Benazepril 0.25 to 1.0 mg/kg PO SID to BID
c. BUN, creatinine, and potassium (checked 1 week after dose adjustments)
5. Beta-antagonists are helpful if tachycardia is present.
a. Atenolol 2 mg/kg PO SID to BID
b. Propranolol 5 to 80 mg PO BID to TID in dogs and 2.5 to 10 mg PO BID to TID in cats
6. Hydralazine 0.25 to 2.0 mg/kg PO BID is reserved for unmanageable hypertension.

Monitoring of Animal

I. Recheck examinations include physical examination, body weight, biochemistry panel, and CBC or PCV, and the frequency depends on severity of the disease.
A. Stage 2 (creatinine <2.1 mg/dL in dogs, <2.8 mg/dL in cats), relatively asymptomatic: recheck every 6 months
B. Stage 3 (creatinine 2.8 to 5.0 mg/dL), stable on therapy: recheck every 2 months
C. Stage 4 (creatinine >5 mg/dL): recheck monthly

II. Urinalysis and urine culture are performed at least twice a year.

III. Blood pressure measurement is performed at least every 6 months or 1 week after adjusting antihypertensive drugs.

IV. Changes in clinical signs warrant recheck examination.

V. Longevity is difficult to predict and can range from days to years.

VI. Cats tend to live longer than dogs.
A. Cats: survival of >3 years possible (in asymptomatic cats)
B. Dogs: survival of >2 years possible

ACUTE RENAL FAILURE

Definition

I. ARF is an abrupt decrease in renal function.

II. Acute kidney injury is generally not recognized until late in the course of disease when clinical signs are present.

Causes

I. Prerenal azotemia occurs when renal blood flow decreases, such as with dehydration or hypotension.

II. Ischemic damage can occur from progression of prerenal azotemia, hypotension, hypovolemia, circulatory collapse, excessive renal vasoconstriction, or renal vascular disease (e.g., thrombosis, DIC, stenosis).

III. Nephrotoxins may be endogenous (hemoglobin, myoglobin, calcium) or exogenous (see Nephrotoxicosis).

IV. Primary renal diseases include infectious, immune, neoplastic, or degenerative conditions that primarily affect the kidneys.

V. Systemic diseases that may cause ARF include pancreatitis, sepsis, hemolytic anemia, and heat prostration.

VI. Postrenal azotemia arises when obstruction or diversion of urine occurs, such as with urethral obstruction; ureteral obstruction; or uroabdomen from rupture of the ureter, bladder, or urethra.

Pathophysiology

I. Ischemic and toxic insults to the kidney lead to acute tubular injury, which varies in severity from sublethal cell damage to cellular necrosis.
II. Four phases of acute kidney injury exist.
  A. Initiation: when damage occurs; early intervention may prevent progression
  B. Extension: renal hemodynamic alterations, sublethal injury to eventual cell death; intervention possibly unsuccessful
  C. Maintenance phase: critical amount of irreversible damage
  D. Recovery: regeneration and repair of renal tissue, lasts weeks to months

Clinical Signs

I. Polyuria, polydipsia
II. Anorexia, nausea, vomiting, diarrhea
III. Listlessness or depression
IV. Possible dehydration, depression, hypothermia
V. Oral ulceration, uremic halitosis, tongue necrosis
VI. Tachypnea, tachycardia or bradycardia
VII. Enlarged, painful kidneys: suggestive of ARF
VIII. Uncommon: dyspnea, seizures, syncope, ataxia, muscle fasciculations, oliguria, anuria

Diagnosis

I. Serum biochemistry panel
  A. Azotemia, hyperphosphatemia, metabolic acidosis, elevated anion gap
  B. Variable electrolyte disorders: hyperkalemia, hypokalemia
  C. ± Hypoproteinemia, especially hypoalbuminemia
II. CBC: normal, hemoconcentration, blood loss anemia (GI ulceration)
III. Urinalysis
  A. Isosthenuria is expected.
  B. Glucosuria without hyperglycemia indicates proximal tubular damage.
  C. Proteinuria may occur from tubular or glomerular damage.
  D. Urine sediment examination may reveal casts, WBCs, RBCs, or possible crystalluria (ethylene glycol toxicosis).
  E. Urine culture is performed.
IV. Abdominal imaging
  A. Radiography typically shows normal or enlarged kidneys with normal contours.
    1. Renal asymmetry may be detected if unilateral obstructive ureterolithiasis is present.
    2. Check for mineral density; however, in 20% to 30% of cats with ureteral obstruction, no calcification is seen (Kyles et al., 2005).
  B. Ultrasonography evaluates renal size, shape, and architecture, and is invaluable in differentiating acute from chronic disease.
  C. IV or antegrade pyelography may be helpful in cases of hydronephrosis or possible ureteral obstruction.
V. Renal histopathology
  A. Histopathology provides more information about the cause if less invasive testing does not confirm a diagnosis.
  B. Because uremia induces a platelet function defect, assessment of a buccal mucosal bleeding time is recommended before biopsy.
VI. Specific tests for certain causes
  A. Serological testing for leptospirosis is performed in all dogs in endemic areas with ARF.
  B. Test for ethylene glycol is indicated (see Nephrotoxicosis).
  C. Other tests to consider include serological assays for infectious diseases (e.g., borreliosis, leishmaniasis) or evaluations for systemic diseases (e.g., pancreatitis, DIC).

Differential Diagnosis

I. ARF must be differentiated from CRF to provide an accurate prognosis.
  A. Long-standing polyuria and polydipsia, as well as poor body condition suggest chronicity.
  B. Ultrasonographic evidence of altered renal architecture may suggest chronicity.
  C. Enlargement of parathyroid glands (detected by ultrasonography) also indicates chronicity.
II. Prerenal or postrenal azotemia generally resolves rapidly with therapy.

Treatment

I. Fluid therapy is the mainstay of treatment.
  A. The calculated fluid deficit (body weight [kg] × % dehydration = fluid deficit in L) is administered IV over 4 to 6 hours.
  B. If cardiovascular compromise is present, then rehydration may be done over a longer period.
  C. Maintenance fluid rate is 66 mL/kg/day based on average urine production.
  D. Additional fluids (2.5% to 5% of body weight per day) may be administered to induce diuresis.
    1. If the kidneys cannot excrete the additional fluid load, then overhydration occurs.
    2. Oliguric or anuric animals are given 20 mL/kg/day for insensible needs (fluid lost via respiration and normal bowel movements), plus replacement of measured urine output, plus replacement of any other losses (e.g., vomiting, diarrhea).
II. Urine output is ideally monitored via a urinary catheter and closed collection system.
  A. Collecting naturally voided urine or estimating volume is less precise.
  B. If urine output is low (<0.5 mL/kg/hr), and the animal is hydrated with a systolic blood pressure >80 mm Hg, consider diuretics.

1. Mannitol 0.5 g/kg IV over 20 minutes (avoided if animal overhydrated)
2. Furosemide 1 to 2 mg/kg IV
   a. If no response occurs in 20 to 30 minutes, then double the dose.
   b. Follow with CRI of 0.25 to 1.0 mg/kg/hr IV or 1 to 2 mg/kg IV QID.
   c. Although furosemide increases urine volume, it does not improve renal function.

III. Uremic manifestations require specific or supportive treatment.
   A. Hyperkalemia is treated via translocation of potassium until urine flow can be reestablished or dialysis instituted.
      1. Regular insulin (0.25 U/kg IV) and dextrose (1 to 2 g/U insulin IV, then 1 to 2 g/U IV over next 4 to 6 hours) requires 30 minutes for onset of action.
      2. Sodium bicarbonate (1 to 2 mEq/kg IV over 10 to 20 minutes) is contraindicated if partial pressure of carbon dioxide (PCO_2) is elevated, and it may cause hypernatremia or paradoxical CNS acidosis.
      3. Calcium gluconate 10% (0.5 to 1.0 mL/kg IV over 10 minutes) is cardioprotective, but it does not decrease potassium concentrations and requires concurrent electrocardiographic monitoring.
   B. Acidosis is treated if blood pH is <7.1.
      1. One half of the calculated sodium bicarbonate dose (body weight [kg] × 0.3 × [desired bicarbonate – measured bicarbonate]) is administered over 20 to 30 minutes, and the rest is given over the next 2 to 4 hours.
      2. Hypernatremia is a possible complication, and bicarbonate is contraindicated if PCO_2 is elevated.
   C. For treatment of GI disorders, see CRF section.
   D. Hypocalcemia is treated cautiously and only if the animal is symptomatic.

IV. Early nutritional support may improve outcome.
   A. If vomiting prohibits enteral feeding, then total or partial parenteral nutrition may be used.
   B. Once vomiting is controlled, a feeding tube is placed if the animal remains inappetent.
   C. A protein-restricted diet (such as used for CRF) is appropriate in most situations.
   D. Oral phosphate binders can be added when enteral feeding is started.

V. Specific treatments exist for certain causes of ARF, including antibiotics for pyelonephritis or leptospirosis, or 4-MP for ethylene glycol toxicosis.

Monitoring of Animal

I. Frequency of monitoring depends on the severity of disease.

II. Check hydration status at least BID, namely skin turgor, mucus membrane tackiness, body weight, urine output, blood pressure, PCV, total solids, and central venous pressure.

III. Acid-base and electrolyte determinations are done multiple times daily if severe abnormalities exist.

IV. BUN and creatinine are measured SID to QOD.

V. Mortality is about 60%, and 60% of survivors have subsequent CRF (Vaden et al., 1997; Worwag and Langston, 2004; Cowgill and Francey, 2005).

DIALYSIS

Definition

I. Hemodialysis removes uremic toxins and other solutes from the blood by diffusion from the blood into dialysate, with treatments varying in length (generally several hours).

II. Continuous renal replacement therapy (CRRT) removes uremic toxins and other solutes from the blood by diffusion (hemodialysis), by convection (hemofiltration via ultrafiltration), or by both.

III. Peritoneal dialysis (PD) removes uremic toxins by diffusion across a semipermeable peritoneal membrane into dialysate that is instilled into the abdominal cavity and drained after variable dwell times.

Principles

I. Molecules in solution diffuse from an area of high concentration to an area of low concentration.
   A. Blood, with high concentrations of uremic solutes, is placed in apposition to dialysate, a solution similar to plasma without the proteins.
   B. A semipermeable membrane separates the blood and dialysate.
   C. In hemodialysis and CRRT, the semipermeable membrane is housed in the dialyzer, or artificial kidney.
      1. The dialyzer membrane has pores that allow small molecules to diffuse freely but restricts movement of proteins and cells.
      2. Some membranes allow diffusion of middle molecules (e.g., parathyroid hormone, vitamin B_{12}).
   D. In PD, the semipermeable membrane is the animal's own peritoneum.

II. Solute removal kinetics vary with the type of treatment.
   A. In hemodialysis and CRRT, continual flow of fresh dialysate maximizes the concentration gradient difference, thereby increasing efficiency of treatment.
   B. In PD, uremic solute diffusion is most rapid when dialysate is first infused, when the gradient between blood and dialysate is highest, and with frequent exchanges and short dwell times (45 to 60 minutes).

III. Excess fluid can be removed from the animal by applying hydrostatic or osmotic pressure to the system to cause water to move from the blood compartment to the dialysate compartment.
   A. The solutes dissolved in the water are also removed in a process called *convective clearance*.
   B. With hemodialysis and CRRT, the pressure is hydrostatic and created by the machine.
   C. With PD, adding dextrose to the dialysate creates an osmotic gradient.

Indications

I. ARF unresponsive to traditional medical management
   A. Oliguria, anuria
   B. Life-threatening volume overload (pulmonary edema)
   C. Hyperkalemia
   D. Lack of improvement of azotemia after 24 hours of diuresis
   E. Severe azotemia (BUN >100 mg/dL, creatinine >10 mg/dL)
II. Intoxications with substances that can be removed by dialysis
   A. In general, hemodialysis is the most efficient and rapid method to remove toxins, compared with CRRT or PD.
   B. Ethylene glycol is the most common indication.
   C. Other toxic drugs include methanol, salicylate, lithium, ethanol, phenobarbital, acetaminophen, theophylline, aminoglycosides, and tricyclic antidepressants.
III. CRF, as long as the client is fully committed to therapy
   A. Geographic availability of hemodialysis unit is necessary.
      1. Transport to and from unit is necessary three times a week.
      2. Expense is high.
      3. Before renal transplantation, two to four treatments are used to improve stability.
   B. Complications associated with PD have limited its application in CRF.
   C. CRRT is not appropriate for CRF.
IV. Choice of modality (hemodialysis, CRRT, or PD) frequently based on availability

Technique

I. Hemodialysis and CRRT
   A. Access to the bloodstream is via a double-lumen catheter in most cases.
      1. Blood is circulated from the animal through the dialyzer and returned in a continuous loop.
      2. Volume of blood removed varies with dialyzer size and tubing set (60 to 150 mL) and limits patient size to >2.5 kg.
   B. Dialysate is either produced by the dialysis machine (hemodialysis) or supplied in sterile bags (CRRT).
      1. Dialysate flow rate is much higher in hemodialysis than CRRT, allowing greater diffusive clearance.
      2. Dialysate composition (e.g., sodium, potassium, calcium, magnesium concentrations) is selected to fit individual needs.
   C. Schedule for dialysis varies based on patient factors and modality used.
      1. Hemodialysis for ARF is generally 3 to 5 hours per day for 4 to 7 days, then three times weekly.
      2. Hemodialysis for CRF is generally 4 to 5 hours, three times weekly.
      3. CRRT is 24 hours per day until renal function returns or the animal is hemodynamically stable; then intermittent hemodialysis is started, if available.
   D. Anticoagulation of blood is required, with heparin infusion used most frequently.
II. Peritoneal dialysis
   A. The PD catheter is sterilely placed in the abdominal cavity percutaneously or surgically.
      1. PD catheters have multiple fenestrations to avoid occlusion by omentum.
      2. Acute PD catheters can be placed with a trocar, with the tip directed caudally toward the bladder.
      3. Chronic PD catheters are placed surgically and frequently have one to two Dacron cuffs that are imbedded in the rectus muscle and subcutis to anchor the catheters and limit infection from the skin.
   B. Warm dialysate is infused into the abdomen.
      1. Commercially produced dialysate is available.
      2. Sterile 0.9% saline or lactated Ringer's solution can be adapted for use.
      3. Additional potassium is added as needed.
      4. Dextrose is added based on the animal's volume status.
         a. If no fluid removal is desired, then add 1.5% dextrose.
         b. If moderate fluid removal is desired, then add 2.5% dextrose.
         c. If maximal fluid removal is desired, then add 4.5% dextrose.
      5. Dwell times vary.
         a. With acute, severe uremia, frequent exchanges (hourly) are needed the first day to decrease the degree of azotemia.
         b. Less frequent exchanges with longer dwell times are used as the animal improves.
      6. Dialysate solution is then drained from the abdomen and discarded, followed by infusion of fresh dialysate to start the cycle again.
   C. Strict attention to aseptic technique is necessary.
      1. Connections are scrubbed with antiseptic solution before connection and disconnection.
      2. Sterile gloves must be worn.

Complications

I. Hemodialysis and CRRT
   A. Hypotension associated with the volume of blood removed is most likely in smaller or hypotensive animals, so systolic blood pressure should be >80 mm Hg before instituting therapy.
   B. Hemorrhagic complications may be associated with excessive anticoagulation.
   C. Partial catheter tip thrombosis occurs within several weeks in many cases.
II. Peritoneal dialysis
   A. Catheter occlusion by the omentum is common.
      1. Acute PD catheters may function poorly within 24 hours of placement.
      2. A fluted T catheter (Ash Advantage) occludes less frequently and is considered if dialysis catheter placement is a scheduled event rather than emergency procedure.
   B. Peritonitis is common.

1. Cloudy dialysate or abdominal pain may be a sign of peritonitis.
2. Intraperitoneal antibiotics may be sufficient therapy.
3. If fever or signs of systemic infection occur, then systemic antibiotics are also used (Chew et al., 2000; Ross and Labato, 2006).

C. Hypoalbuminemia from loss into the dialysate can complicate case management.

Monitoring of Animal

I. Hydration, attitude, body weight, electrolytes, and blood pressure are assessed multiple times each day initially.
II. BUN, creatinine, and PCV are also assessed initially.

RENAL TRANSPLANTATION

Definition

I. A kidney from a healthy donor is placed in the recipient to provide adequate renal function.
II. Immunosuppressive therapy is necessary to prevent the host (recipient) immune system from rejecting the transplanted tissue.

Recipient Selection

I. Cause of renal failure is generally unresolved CRF or ARF.
   A. Infectious causes (pyelonephritis) are contraindications.
   B. Risk of recurrence is high if calcium oxalate nephrolithiasis or ureterolithiasis is the initial cause of renal failure.
II. Absence of concurrent conditions, including hyperthyroidism, diabetes mellitus, and inflammatory bowel disease is required.
III. Normal cardiac function is a prerequisite.
IV. Tractable animal that permits intensive handling and monitoring is also necessary.
V. Owners must be committed to patient care, associated costs, and willing to provide a home for the donor cat.

Timing of Transplantation

I. The appropriate stage of disease for transplantation is undetermined.
II. Transplantation is usually recommended at the first sign of decompensation, as determined clinically (i.e., inability to maintain condition despite medical therapy).
III. Some cats decompensate very rapidly and in an unpredictable fashion, so transplantation is sometimes based on clinicopathologic parameters (e.g., creatinine >4.0 mg/dL).

Technique

I. The renal artery and vein of the transplanted kidney are usually anastomosed to the aorta and caudal vena cava.
   A. The native kidneys are left in place, because they may provide some function if the transplanted kidney does not function immediately.
   B. Extremely large kidneys (PKD) may be removed to improve abdominal comfort.
II. The ureter is implanted into the bladder.
III. The transplanted kidney usually starts to function within 7 days.
IV. Immunosuppression is necessary to prevent rejection.
   A. Cyclosporine and prednisone are the standard drugs used in cats.
   B. A combination of cyclosporine, prednisone, and azathioprine; a combination of cyclosporine, prednisone, and leflunomide; or pretransplantation whole-body irradiation, followed by autologous bone marrow transplantation are used in dogs.
V. When renal function has stabilized and immunosuppressive drug levels are regulated, the animal is discharged from the hospital (usually 1 to 2 weeks after surgery).

Monitoring of Animal

I. Intensive postoperative monitoring (e.g., blood pressure, temperature, fluid status, mentation) is required for the first 24 to 48 hours.
II. During the first 2 weeks, serum creatinine, urine output, and urine specific gravity are monitored SID and cyclosporine blood levels are monitored every few days.
III. Weekly rechecks are done for the first month.
IV. Monthly rechecks are done for 3 months and are followed by quarterly rechecks.

NEOPLASIA

See Table 48-7.

TRAUMATIC DISORDERS

Definition

I. Renal contusion or bruising results from compression, with disruption of intraparenchymal blood vessels.
II. Laceration is tearing of the renal parenchyma.
III. Avulsion of the renal pedicle may sever the renal artery, vein, or ureter.

Causes

I. Blunt trauma: automobile accident
II. Sharp, penetrating wounds: gunshot, stab wounds

Pathophysiology

I. Substantial hemorrhage may lead to significant cardiovascular compromise.
II. Urine leakage may lead to uremia.

Clinical Signs

I. Hematuria
II. Hemorrhage, hypovolemia
III. Abdominal or flank pain from capsular swelling or local accumulation of blood or urine
IV. Uremia

Diagnosis

I. History or evidence of trauma
II. Physical examination findings of enlarging abdominal mass, pain, or fluid accumulation

TABLE 48-7

Renal Neoplasia

TUMOR TYPE	SPECIES/INCIDENCE	CLINICAL FEATURES	TREATMENT/PROGNOSIS
Lymphosarcoma	Dogs and cats	Most common renal tumor of cats: 50% of cats FeLV positive 40% have metastasis to CNS	Median survival time with chemotherapy: 3-6 months in cats
Renal cell carcinoma	Dogs: 70% Cats: 68%	Most common renal tumor of dogs: middle-aged to older dogs (7-9 years), more common in males Local invasion common 30% have metastasis at diagnosis	Median survival time with nephrectomy: 8 months
Transitional cell carcinoma	Dogs: 15% Cats: 16%	Arise from renal pelvis May cause obstruction	Nephrectomy, piroxicam Prognosis poor
Mesenchymal tumors: sarcoma, fibroma, hemangiosarcoma	Dogs and cats: 5%-10%	Nonspecific findings	Nephrectomy Prognosis poor
Renal adenoma	Dogs and cats: 2%-5%	Nonspecific findings	Long-term survival possible
Nephroblastoma	Dogs and cats: 4%-5%	Dogs <1 yr of age: 60% Metastasis at time of diagnosis: 65%	Nephrectomy Prognosis poor
Renal cystadenocarcinoma	German shepherd dogs	Inherited as autosomal-dominant trait Accompanied by nodular dermatofibrosis and uterine leiomyoma	Nephrectomy Prognosis poor

Data from Henry CJ, Turnquist SE, Smith A et al: Primary renal tumors in cats: 19 cases (1992-1998). Teton NewMedia, Jackson, Wyo, 2002.

FeLV, Feline leukemia virus; *CNS,* central nervous system.

III. Imaging procedures
   A. Plain abdominal radiography may show decreased serosal detail from fluid or expansion of retroperitoneal space.
   B. Excretory urography generally indicates the site of rupture (contrast extravasation).
IV. Abdominal paracentesis to distinguish hemorrhage from urine leakage

Differential Diagnosis

I. Renal neoplasia with disruption of tubular or vascular components
II. Traumatic injury to other abdominal organs

Treatment

I. Contusions may need no specific therapy.
II. Therapy depends on type and severity of lesion and may involve IV fluid administration, blood transfusion, or surgical exploration to repair defects.

Monitoring of Animal

I. Serial evaluation of PCV is used to detect ongoing hemorrhage.
II. Serial evaluations of creatinine and/or BUN are used to assess renal function and possible urine leakage.
III. Late complications (2 to 6 weeks) include abscess formation (penetrating wounds) or urinoma (blunt trauma causing retroperitoneal urine leakage with subsequent encapsulation by fibrous tissue).

CHAPTER 49

Diseases of the Ureter

Lori L. Ludwig | Jennifer S. Bonczynski

CONGENITAL DISORDERS

Ectopic Ureter

Definition

I. It is an embryologic abnormality that results in one or both ureters terminating distal to the bladder trigone.
II. Ectopic ureters are either extramural or intramural.
  A. An extramural ectopic ureter bypasses the urinary bladder entirely and inserts in the bladder neck, urethra, vagina, or uterus.
  B. An intramural ectopic ureter enters the bladder externally at the normal location but does not terminate in the trigone.
    1. The ureter traverses beneath mucosa and opens in a distal location.
    2. The ureteral opening may appear as a trough or as multiple openings along the submucosal tunnel.
    3. Bilateral ectopic ureters may open in a single orifice.

Causes

I. Congenital condition (likely genetic in dogs)
II. Reported rarely in cats
III. Females affected more often than males

Pathophysiology

I. During embryologic development the metanephric duct, which becomes the ureter, originates at an abnormal location or migrates in an abnormal fashion and prevents the development of a normal ureteral opening in the bladder.
II. Urinary incontinence results from the distal position of the ureteral opening and possibly from the presence of the submucosal tunnel within the urethra.
III. Associated conditions include absent or abnormally shaped kidneys, hydronephrosis, hydroureter, urethral sphincter incompetence, ureterocele, bladder hypoplasia, urachal remnants, and infection.

Clinical Signs

I. Continuous or intermittent incontinence may be noted since birth or weaning.
II. Normal urine voiding may also be seen.
III. Less urine dribbling may occur in male dogs because of their longer urethra.
IV. Urine may soak or stain the perineum of females.

Diagnosis

I. Physical examination may be normal or may reveal perineal urine staining or perivulvar dermatitis.
II. Male cats may have a constricted preputial orifice and urine accumulation within the sheath.
III. Results of hematological tests and serum biochemistry profile are normal or reveal concurrent renal disease.
IV. Urinalysis commonly reveals evidence of bacterial urinary tract infection (UTI).
V. Contrast radiography may provide a definitive diagnosis.
  A. Excretory urography (see Chapter 4) allows identification of the distal ureteral opening and is most likely to provide a diagnosis when combined with pneumocystography and/or fluoroscopy.
    1. A dilated ureter is the most common finding.
    2. The diagnosis may be missed from lack of opacification of the distal ureter secondary to peristalsis, poor renal excretion, or superimposition of other structures.
  B. Retrograde urethrography or vaginourethrography may cause filling of the ectopic ureter with contrast medium, thereby allowing its identification.
VI. Ultrasonography may be as accurate as contrast radiography for making the diagnosis (Lamb, 1998).
VII. Helical computed tomography (CT) might be more useful than excretory urography or urethrography when combined with fluoroscopy (Samii et al., 2004).
VIII. Cystoscopy of the urinary tract allows direct visualization of the normal or ectopic ureteral orifice, and evaluation of concurrent abnormalities.
  A. Single or multiple ureteral openings are seen in the urethra or vagina.
  B. A submucosal tunnel may also be detected.
IX. Cystometrography and urethral pressure profiles help identify concurrent functional abnormalities and provide information on likely prognosis after surgical correction (Lane et al., 1995).

Differential Diagnosis

I. Congenital structural anomalies of the urinary tract: urethral hypoplasia, urethrovaginal fistula, ureterocele, patent urachus
II. UTI
III. Congenital urethral sphincter incompetence
IV. Neurogenic disorders of micturition (see Chapter 51)
V. Partial obstruction or overflow associated with calculi or neoplasia
VI. Disorders causing polyuria: endocrine, renal, hepatic

Treatment

I. Surgery is the treatment of choice, and the procedure performed depends on the type of ectopic ureter and function of the associated kidney.
   A. Extramural ectopic ureters are ligated where they attach to the urethra, vagina or uterus, and they are reimplanted into the bladder cranial to or within the trigone (neoureterocystostomy).
   B. Two techniques have been described for intramural ectopic ureters.
      1. A new ureteral opening (neoureterostomy) is created where the ureter traverses the trigone, and the distal submucosal ureteral segment is ligated to prevent urine flow distal to the new opening.
      2. The submucosal ureteral segment is completely resected from the urethra and bladder neck before creating a new ureterostomy cranial to the trigone.
         a. The defect that was created by resecting the submucosal tunnel from the bladder neck and urethra is sutured closed.
         b. This technique may result in less postoperative incontinence because the submucosal tunnel disrupts the internal urethral sphincter mechanism (McLoughlin and Chew, 2000).
   C. Nephroureterectomy is performed if the kidney of origin is nonfunctional or chronically infected, providing the other kidney is functioning normally.
II. Additional procedures may be performed during or after surgical correction to improve postoperative incontinence associated with sphincter incompetence.
   A. Colposuspension, which involves suturing the vaginal stump to the body wall, increases pressure on the urethra.
   B. Endoscopic submucosal urethral injections of collagen or other substances increase resistance to urine flow (Barth et al., 2005).
III. Medical management is used to control UTIs or incontinence associated with concurrent bladder and urethral sphincter incompetence.
   A. Antibiotics are used to control UTI before surgery and may also be needed postoperatively.
   B. Alpha-adrenergic agonists may be helpful for postoperative incontinence (dogs).
      1. Phenylpropanolamine 12.5 to 50 mg PO TID
      2. Ephedrine 2 to 4 mg/kg PO BID to TID

Monitoring of Animal

I. The most common complication after surgery is persistent urinary incontinence.
II. Urinalysis, urine culture, cystoscopy, IV pyelography, cystourethrography, abdominal ultrasonography, and/or CT are used to evaluate the animal for the following possible causes of postoperative incontinence:
   A. Presence of a submucosal ureteral remnant or recanalization of a ligated distal ureteral segment
   B. Primary sphincter incompetence
   C. UTI
   D. Other congenital abnormalities of the urogenital tract
III. Dysuria is commonly seen for a few days after surgery.
IV. Hydroureter and hydronephrosis may occur from temporary obstruction of the ureter by inflammation, edema, or blood clots; permanent obstruction may result from stricture.

Ureterocele

Definition and Cause

I. It is a cystic dilation of the submucosal segment of the ureter near the ureteral orifice.
II. Ureteroceles are classified by location of the cystic dilation.
   A. When the dilation occurs in the normal location in the bladder trigone, the ureterocele is classified as orthotopic.
   B. An ectopic ureterocele occurs in a location distal to the bladder trigone.
III. Grading system proposed to identify presence of concurrent renal or ureteral disease is as follows (Stiffler et al., 2002):
   A. Grade 1: no concurrent ureteral or renal disease
   B. Grade 2: ipsilateral ureteral or renal disease
   C. Grade 3: bilateral ureteral or renal disease
IV. The embryologic cause of ureteroceles is unknown.

Clinical Signs

I. Animals may be asymptomatic.
II. Animals usually develop signs at a young age.
   A. Hematuria and dysuria may be related to UTI.
   B. Signs may result from the ureterocele obstructing the urethra or ureter.
   C. Incontinence may be seen with ectopic ureteroceles.

Diagnosis

I. Contrast radiography and ultrasonography allow a definitive diagnosis.
   A. An IV pyelogram combined with pneumocystography shows a contrast-filled dilation of the ureter.
   B. Retrograde urethrocystography reveals a filling defect.
   C. Ultrasonography usually identifies the ureterocele as a round, fluid-filled cystic structure in the bladder or proximal urethra.
II. Hydroureter or hydronephrosis indicating obstruction or pyelonephritis may also be seen.
III. Cystoscopy allows direct visualization of the ureterocele.

Differential Diagnosis

I. Other causes of congenital or acquired urinary incontinence
II. Urinary obstruction caused by uroliths or a blood clot in the trigone

Treatment

I. Cystoscopic incision or cystotomy with open resection is used to treat orthotopic ureteroceles.
II. Ectopic ureteroceles are treated by resection of the ureterocele, neoureterocystostomy, and reconstruction of the bladder neck and urethra.
III. If severe hydronephrosis or chronic infection (abscessation) of the associated kidney is found, then ureteronephrectomy may be performed if the contralateral kidney is functioning normally.

Monitoring of Animal

I. UTI is treated with appropriate antimicrobials.
II. Incontinence may persist in animals with an ectopic ureterocele.
III. IV pyelography, ultrasonography, and/or cystoscopy are warranted if clinical signs persist after correction.
IV. Because this condition is rare, prognosis is undetermined.

VESICOURETERAL REFLUX

Definition

I. Vesicoureteral reflux is the retrograde flow of urine into the ureter and renal pelvis from the urinary bladder.
II. Retrograde flow is the result of incompetence of the vesicoureteral junction.

Causes and Pathophysiology

I. Primary vesicoureteral reflux arises from maldevelopment of the vesicoureteral junction.
   A. Reflux occurs in many normal immature dogs but usually resolves with maturity.
   B. Primary reflux is usually bilateral and more prevalent in females.
   C. Maldevelopment of the junction can be associated with ectopic ureters.
II. Secondary vesicoureteral reflux is an acquired disorder that may lead to compression or obstruction of the vesicoureteral junction.
III. Causes of secondary reflux include inflammation, obstruction distal to the trigone, iatrogenic damage to the trigone, neurogenic diseases of the urinary bladder, and manual compression of the urinary bladder.
IV. Vesicoureteral reflux may be associated with pyelonephritis.
   A. Reflux may cause postvoiding retention of urine in the ureters that predisposes to infection.
   B. Pyelonephritis can result if reflux occurs during a lower UTI, but renal damage and pyelonephritis do not seem to occur without UTI.

Clinical Signs

I. Signs related to pyelonephritis, renal insufficiency, or failure
II. Signs of persistent UTI

Diagnosis

I. Contrast radiography may identify the reflux.
   A. Compression cystourethrography and maximal distention retrograde cystourethrography may be helpful.
   B. Poor positioning, the degree of distention, depth of anesthesia, and maturity of the animal may produce inaccurate results.
II. Cystoscopy is helpful to assess presence of ureteral ectopia or structural abnormalities of the vesicoureteral junction and trigone.

Treatment

I. Vesicoureteral reflux usually resolves as the animal matures.
II. Control lower UTIs to prevent pyelonephritis.

Monitoring of Animal

I. Frequent urine cultures followed by appropriate antibiotics are used to control UTIs.
II. Periodic assessment of biochemistry profile and urine specific gravity are performed to monitor for onset of renal insufficiency.

URETERAL OBSTRUCTION

Definition and Causes

I. Intraluminal obstruction
   A. Ureteroliths originating from the kidney are most commonly composed of calcium oxalate in dogs and cats.
   B. Blood clots may develop that are associated with severe hematuria from serious trauma or renal biopsy.
II. Intramural obstruction
   A. Primary neoplasia: transitional cell carcinoma
   B. Metastatic neoplasia
III. Extramural
   A. Compression
      1. Neoplasia of surrounding structures: uterus, bladder, trigone, bony pelvis, lymph nodes, gastrointestinal tract
      2. Perineal hernia with bladder entrapment
      3. Prostatic enlargement from inflammation, infection, neoplasia, or hypertrophy
   B. Iatrogenic surgical ligation
      1. It occurs most often during ovariohysterectomy.
      2. Most common site of ligation is near the uterine body.

Pathophysiology

I. The effect on renal function or glomerular filtration rate (GFR) depends on the duration and severity of the obstruction.
   A. Significant loss of function occurs in 24 hours, but normal GFR can return if the duration is <7 days (Kerr, 1956; Vaughn and Gillenwater, 1971; Yarger and Griffith, 1974).
   B. Permanent loss of function results with obstructions of >4 weeks.
II. Postobstructive diuresis occurs from an inability of the kidney to concentrate urine (which results from increased

blood flow and medullary washout), loss of response to antidiuretic hormone, and attempts to remove nitrogenous waste and restore electrolyte concentrations.
III. Impaired hydrogen ion excretion and increased potassium excretion occurs despite systemic hypokalemia, which leads to acid-base and electrolyte derangements.
IV. Hydroureter and hydronephrosis often occur with chronic obstruction.
V. Although the incidence of ureteral calculi is increasing, the pathogenesis is poorly understood (see Chapters 48 and 50).

Clinical Signs

I. Clinical signs are nonspecific and may include inappetence, lethargy, vomiting, and weight loss.
II. Bilateral ureteral obstruction results in severe clinical signs from uremia and hyperkalemia.

Diagnosis and Differential Diagnosis

I. A rectal examination is performed to assess for masses, prostatic disease, or perineal hernia with bladder entrapment.
II. Abdominal radiography may show radiopaque stones in the ureter or kidney, abdominal masses, or bony abnormalities of the pelvis.
III. Abdominal ultrasonography may identify hydronephrosis and hydroureter proximal to the obstruction.
IV. A combination of survey radiography and abdominal ultrasonography is 90% diagnostic in cats with ureteroliths (Kyles et al., 2005a).
V. Additional imaging studies, such as excretory urography, antegrade pyelography, or CT may be necessary to definitively diagnose the obstruction (Adin et al., 2003).

Treatment

I. Treat dehydration, hyperkalemia, and acid-base abnormalities first.
II. IV fluid diuresis is started to improve renal function and promote movement of a calculus.
III. Dialysis helps stabilize cats with ureteral obstruction but may not improve survival (Kyles et al., 2005b).
IV. Surgical correction is warranted if the obstruction cannot be relieved with medical management.
   A. Remove the obstruction as soon as the animal is stable enough for general anesthesia, because preservation of kidney function is inversely related to the duration of obstruction.
   B. If the obstruction is secondary to iatrogenic ligation, then remove the suture and assess ureteral damage.
      1. Neoureterocystostomy may be performed if ligation occurred close to the bladder.
      2. Resection of the damaged area and ureteral anastomosis are performed if ligation occurred at the midddle to proximal ureter.
   C. Surgical treatment of ureteroliths involves the following:
      1. Calculi are located by careful palpation and visualization.
      2. The ureter is usually dilated proximal to the obstructing stone.
      3. Because the ureter is typically embedded in mucosa and does not tend to move easily with flushing, the ureter is incised over the calculus.
      4. Once the stone is removed, a cannula or catheter is placed into the ureterotomy site and flushed to ensure patency.
      5. Alternatively, a piece of suture can be passed normograde or retrograde through the ureter to ensure patency.
      6. Ureteral leakage and persistent ureteral obstruction are common postoperative complications.
   D. Shockwave lithotripsy has been described in dogs but is not tolerated in cats (Block et al., 1996).
   E. If renal damage is severe or if abscessation has occurred and contralateral kidney function is normal, then consider ureteronephrectomy.
   F. Nephroureterectomy is often the only treatment for ureteral neoplasia that results in complete obstruction.
   G. See treatment of Ureteral Trauma in the following section.

Monitoring of Animal

I. Serial abdominal radiographs and abdominal ultrasonography are performed to assess patency of the surgical repair and to monitor for recurrence of ureteroliths.
II. Consider changing the urine pH, depending on type of calculus (see Chapter 50).
III. Monitor urinalysis and urine culture for recurrent UTI, especially if uroliths are still present in the kidney.

NEOPLASIA

See Chapter 50.

TRAUMA

Definition and Causes

I. Iatrogenic injury may arise from any abdominal surgery, abdominocentesis, cystocentesis, or needle biopsy of abdominal organs.
II. Penetrating or blunt trauma can cause laceration or rupture of the ureter.

Clinical Signs

I. Clinical signs are often nonspecific and may include lethargy, hematuria, abdominal discomfort, and shock.
II. Clinical signs may worsen if azotemia, metabolic acidosis, and hyperkalemia occur.
III. With traumatic ureteral rupture, 70% of animals arrive at the clinic in shock or with multiple organ injuries (Weisse et al., 2002).
IV. Concurrent injury to the kidney, surrounding vessels, and other organs may result in a hemoabdomen and signs of acute anemia.

Diagnosis and Differential Diagnosis

I. Ureteral obstruction, renal failure, bladder rupture, and proximal urethral rupture have similar clinical signs.

II. Abdominal radiographs may show loss of abdominal detail or increased opacification of the retroperitoneal space, but are not specific for uroabdomen or uroretroperitoneum.
III. Abdominocentesis is performed if uroabdomen is suspected.
  A. A fluid: serum creatinine ratio >2 hr : 1 hr or a fluid: serum potassium ratio >1.4 hr : 1.0 hr indicates uroabdomen (Schmeidt and Tobias, 2001).
  B. If hemorrhagic fluid is obtained, compare the abdominal fluid packed cell volume (PCV) with peripheral blood PCV (a higher fluid PCV indicates hemoabdomen).
IV. Excretory urography may localize the lesion.
  A. A retrograde cystourethrogram is performed first to rule out lower urinary tract rupture.
  B. Excretory urography is contraindicated if the animal is hypotensive.
    1. The animal must be hemodynamically stable to avoid renal failure, bradycardia, or cardiac arrest after administration of contrast agents.
    2. Poor renal perfusion also results in a nondiagnostic study (see Chapter 4).
  C. Excretory urography may help identify leakage from the ureter, but it does not always identify the location or severity of the tear.

Treatment

I. Fluid resuscitation with IV crystalloid solutions is initiated immediately for hypovolemic shock.
II. Dehydration is corrected over the next 6 to 24 hours with IV crystalloid solutions.
  A. Fluid rate is adjusted to maintain urine output at 1 mL/kg/hr.
  B. Ongoing losses from a peritoneal drainage catheter must be compensated for in the fluid rate.
III. Treat hyperkalemia and other metabolic disorders.
  A. Many abnormalities are corrected with fluid therapy.
  B. Hyperkalemia-associated cardiac disturbances are treated immediately.
    1. Regular insulin 0.25 to 0.5 U/kg and dextrose 1 to 2 g/U of insulin may be given as IV boluses.
    2. A 2.5% dextrose solution is also started as a constant rate infusion to prevent hypoglycemia.
    3. Alternatively, calcium gluconate 50 to 100 mg/kg is administered IV over 2 to 3 minutes, with continuous electrocardiographic monitoring.
IV. Establish abdominal drainage with a temporary peritoneal catheter.
V. Place a urethral catheter to monitor urine output if the opposite ureter is intact.
VI. Bilateral temporary nephrostomy tubes may be placed if bilateral ureteral trauma is suspected (Nwadike et al., 2000).
VII. Definitive surgical repair is not performed until the animal is stable.
  A. Surgical correction of the injury depends on its severity and location.
  B. Neoureterocystostomy or ureteral resection and anastomosis are options for surgical correction of ureteral tears.
    1. These techniques are difficult to perform and magnification is necessary in small dogs and cats.
    2. Tension on the ureteral repair is detrimental; relieve tension by psoas muscle pexy or renal descensus.
    3. Possible complications include ureteral obstruction, avulsion, stricture, and leakage.
  C. Neoureterocystostomy is used for injuries in the middle to distal one third of the ureter.
  D. Ureteral anastomosis is used for injuries in the middle to proximal one third of the ureter.
  E. Ureteronephrectomy is necessary if severe damage to the kidney and ureter occurs or if tension on a ureteral repair cannot be alleviated; however, the opposite kidney and ureter must be intact and functioning normally.

Monitoring of the Animal

I. Monitor urine output, serum blood urea nitrogen (BUN), creatinine, and potassium at least every 24 hours for 3 days postoperatively.
II. A decrease in urine output and increased serum potassium or azotemia may indicate renal failure, ureteral obstruction, or uroabdomen.
III. Abdominal ultrasonography is useful to assess for hydronephrosis or hydroureter related to a stricture or obstruction after surgery.

CHAPTER 50

Diseases of the Urinary Bladder

Lawren L. Durocher | Dennis J. Chew

CONGENITAL DISORDERS

See Table 50-1.

INFECTIOUS DISORDERS

Bacterial Cystitis

Definition

I. Infection by bacteria causes secondary inflammation of the bladder mucosa.
II. Bacterial urinary tract infections (UTIs) are the most common infectious diseases of the bladder.
III. Recurrent UTIs may arise from reinfection or relapsing infections.
IV. Reinfection occurs from different bacteria, after appropriate antibiotic therapy has been instituted.
V. A relapse is a bladder infection from the same bacteria, with the same or slightly different antibiotic susceptibility patterns, that develops after appropriate antibiotic therapy has been instituted.
   A. The clinician should determine if the UTI is caused by a relapse or by reinfection.

TABLE 50-1

Congenital Abnormalities of the Bladder

CONDITION	DEFECT/CAUSE	CLINICAL SIGNS	DIAGNOSIS	TREATMENT
Persistent (patent) urachus	Urachus (conduit from bladder to the umbilicus) did not close	Urine leakage in the area of the umbilicus (may only see damp hair) Signs present from birth Urine spotting when laying down	Physical examination findings Contrast radiography: contrast cystourethrogram or inject contrast directly into opening	Surgical resection of patent urachus
Urachal diverticulum (vesicourachal diverticulum)	Small outpouching of tissue at the bladder apex from incomplete closure of the fetal urachus Secondary diverticula can occur secondary to severe urethral obstruction or feline sterile idiopathic cystitis	Signs of secondary UTI: diverticula provide an area for bacterial colonization in bladder May contribute to signs of idiopathic cystitis	Survey radiography or abdominal ultrasonography (uncommon) Contrast radiography Cystoscopy	Diverticulectomy if the animal has clinical signs No treatment if no clinical signs
Pelvic bladder	Bladder >10% within the pelvic canal rather than in the abdomen Most common bladder anatomical abnormality	± Urinary incontinence ± Incidental finding	Survey radiography May be palpable on rectal examination Cystoscopy may be suggestive	Treat with colposuspension if clinical signs are present
Urachal cyst	Secreting urachal epithelium persists in isolated segments of the urachus after birth	Incontinence UTI	Contrast radiography	Surgical removal of cyst
Bladder duplication	Very rare, occasionally reported in dogs	Incontinence UTI	Survey and contrast radiography	Surgery

UTI, Urinary tract infection.

B. A relapse is more often associated with treatment failure, whereas reinfection is usually associated with proper treatment in the presence of an underlying problem that predisposes the animal to a new UTI.

Causes

I. Bacterial UTIs are commonly associated with other primary abnormalities that increase the bladder's susceptibility to infection.
   A. Recessed vulva
      1. The vulva is partially hidden by overhanging skin and is not readily visible.
      2. This leads to a warm, moist environment for bacteria to grow and ascend to the bladder.
   B. Urinary cystoliths
   C. Bladder catheterization
   D. Urinary incontinence, with wicking of bacteria through the urethra from decreased midurethral pressure
   E. Diseases that decrease urine specific gravity
      1. Hyperadrenocorticism
      2. Chronic renal failure
      3. Diabetes mellitus
      4. Diabetes insipidus
   F. Anatomical abnormalities of the bladder and ureters
      1. Urachal diverticulum
      2. Ectopic ureter
      3. Patent urachus
      4. Urachal cyst
   G. Detrusor areflexia and hyporeflexia or other neurological abnormalities of the bladder

II. Bacteria commonly associated with UTI include the following:
   A. *Escherichia coli:* 40% to 50% of cases (Ling et al., 2001)
   B. *Staphylococcus* spp.
   C. *Proteus* spp.
   D. *Streptococcus* spp.
   E. *Enterobacter* spp.

III. Bacterial UTIs are not commonly seen in cats <10 years of age that can concentrate their urine well.

IV. In cats >10 years of age, the incidence of bacterial UTI increases to >50% for those with lower urinary tract signs (Lekcharoensuk et al., 2001).

Pathophysiology

I. Bacteria can be introduced via four mechanisms.
   A. Hematogenous route: secondary to a bloodborne bacteria
   B. Iatrogenic: secondary to urinary catheterization
   C. Local infections: secondary to a pyometra, an infected surgical sponge in the area of the bladder
   D. Ascending infections
      1. Most common route of infection
      2. Associated with ascending bacteria from the skin or the gastrointestinal (GI) tract

II. Almost all animals with a UTI have a suboptimal host defense system.

III. Normal host defense mechanisms consist of many parts.
   A. Normal voiding of urine (hydrokinetic washout)
   B. Increased urea in the urine
   C. Increased acidity of the urine
   D. Increased osmolality of the urine (especially in cats)

Clinical Signs

I. Clinical signs often include pollakiuria, stranguria, hematuria, and periuria (urinating in abnormal areas, such as outside the litter box).

II. Signs may be misconstrued as urinary incontinence.

III. Evidence of systemic disease (e.g., fever, leukocytosis) is usually indicative of an upper UTI.

IV. If the bacteria involved are *Escherichia coli*, then polyuria and polydipsia (PU/PD) may be noted.
   A. *E. coli* can interfere with the action of antidiuretic hormone (ADH), even when infection is not in the kidneys (because of distant effects of its endotoxin).
   B. Other bacterial infections are not associated with PU/PD, unless organisms are within the kidneys.

V. Up to 10% of dogs with no clinical signs have a positive urine culture when urine cultures are submitted as a routine data base (Ling, 1995).

Diagnosis

I. Urinalysis often reveals pyuria, hematuria, and bacteriuria.
   A. Bacteriuria in the absence of pyuria can indicate contamination, unless the animal is immunosuppressed.
      1. Many things in the urine sediment resemble bacteria, especially cocci.
      2. Clumps of white blood cells (WBC) are compelling evidence of the presence of bacteria.
   B. Sediment is examined as soon as possible, because cellular degeneration can occur rapidly and identification of cells may become more difficult with time.

II. A quantitative urine culture (reported in colony-forming units/mL [cfu/mL]) is indicated in possible cases of bacterial UTI.
   A. Urine is collected via cystocentesis.
   B. Catheterized urine samples are useful in cats and in male dogs, but the degree of contamination in female dogs is too high to justify its routine use.
   C. Voided urine is usually of no value unless nothing grows, because the presence of organisms may reflect contamination.
   D. Culture allows organism identification and testing for susceptibility to antimicrobials.
      1. Growth of >1000 cfu/mL (cystocentesis sample) of a single organism is diagnostic of UTI.
      2. Most UTIs have results >10,000 cfu/mL and many have >30,000 cfu/mL.
   E. Culture and susceptibility testing are imperative with recurrent UTIs, because organisms may become resistant to multiple antibiotics.

Differential Diagnosis

I. Urinary incontinence

II. Other causes of PU/PD: endocrine diseases, diabetes insipidus, psychogenic polydipsia

III. Other causes of cystitis: fungal, idiopathic (sterile)

TABLE 50-2

Common Antibiotics Used to Treat Bacterial Cystitis in Dogs

DRUG	DOSE (mg/kg)	ROUTE	FREQUENCY	MEAN URINE CONCENTRATION (µg/mL)
First-Choice Antibiotics				
Ampicillin	22	PO	TID	309
Amoxicillin	11	PO	TID	201.5
Trimethoprim-sulfonamide	13	PO	BID	26/79
Cephalexin	8	PO	TID	225
Second-Choice Antibiotics				
Chloramphenicol	33	PO	TID	124
Nitrofurantoin	4.4	PO	TID	100
Gentamicin	6	SC	SID	107
Amikacin	15	SC	SID	342
Enrofloxacin	5-10	PO	SID	40
Tetracycline	18	PO	TID	138

Adapted from Greene CE (ed): Infectious Diseases of the Dog and Cat. 3rd Ed. Elsevier Saunders, St. Louis, 2006; Ling GV: Lower Urinary Tract Diseases of Dogs and Cats. Mosby–Year Book, St. Louis, 1995.

IV. Neurological abnormalities of the bladder with loss of house-training habits
V. Behavioral elimination disorders

Treatment

I. Select an antimicrobial agent based on culture and sensitivity results (Table 50-2).
   A. First-choice antibiotics are used while awaiting culture results.
      1. If the infection is recurring, then use the antibiotic that was appropriate based on the last susceptibility results.
      2. Good initial antibiotics reach high enough concentrations in the bladder to be effective and have few side effects.
   B. Second-choice antibiotics are not considered initially because of their toxicity, low mean urine concentration, or high potency, and they are reserved for resistant infections.
   C. Nitrofurantoin is used more commonly to prevent rather than treat UTIs, and some dogs may develop myasthenia-like signs when on the drug.
   D. The side effects associated with the aminoglycosides (amikacin and gentamicin) preclude their use in all but the most resistant bacterial cystitis.
   E. Although enrofloxacin reaches good concentration in the urine, the medication is considered too broad spectrum and potent to be used as a first line of defense for bacterial cystitis.
      1. Enrofloxacin is used with caution in cats because of the possibility of acute blindness.
      2. Some infections with *Pseudomonas* spp. require 20 mg/kg/day PO to be effective.
II. Treat uncomplicated cases of bacterial cystitis for 10 to 14 days.
   A. Culture the urine 3 to 7 days after antibiotic therapy has been discontinued to document eradication of organisms.
   B. If the culture remains positive, then use appropriate antibiotics for a longer period of time.
III. In complicated or recurrent cystitis (or in dogs with cystoliths), give antibiotics for 3 to 4 weeks.
   A. Urine is recultured 5 to 7 days after beginning therapy to document in vivo susceptibility to the antibiotic therapy chosen.
   B. Urine is recultured 7 days after stopping therapy to document treatment efficacy.
   C. If the culture is positive while on therapy, then a different antibiotic is chosen.
   D. If the culture remains positive after completing therapy, then a different antibiotic is chosen or the same antibiotic is used for a longer period of time.
IV. In animals with frequent, new infections, consider long-term, low-dose prophylactic antibiotic therapy after the active UTI has been eradicated.
   A. Administer 33% to 50% of the recommended therapeutic dose of the antimicrobial SID.
   B. The antibiotic is given in the evening to increase the amount of time it comes in contact with urine.
V. Also treat any predisposing factors, such as diabetes mellitus, hyperadrenocorticism, hyperthyroidism, recessed vulva, ectopic ureter, or urinary incontinence.

Monitoring of Animal

I. In animals with predisposing factors, urine cultures are indicated every 3 to 4 months regardless of the presence of clinical signs.
II. Monitor animals with recurrent UTIs for the development of cystoliths and pyelonephritis via radiography, ultrasonography, and evaluation of urine sediment for casts (indicative of kidney damage).
III. Sequelae of bacterial UTIs include the following (Table 50-3):
   A. Emphysematous cystitis
   B. Cystoliths, especially struvite from urease producing bacteria
   C. Pyelonephritis
   D. Encrusting cystitis
   E. Polyploid cystitis

Fungal Cystitis

Definition

I. Fungal cystitis is a rare inflammation of the bladder secondary to a fungal infection.
II. A confirmed fungal infection is treated whether or not the animal is symptomatic; however, fungal agents in the urine may also represent contamination of the sample rather than true infection.

TABLE 50-3

Uncommon Forms of Cystitis

TYPE OF CYSTITIS	CAUSES	SIGNS	DIAGNOSIS	TREATMENT
Emphysematous	Usually associated with diabetes mellitus Infection of bladder wall with gas produced in the bladder wall	Recurrent UTI Painful urination	Survey radiography Abdominal ultrasonography	Appropriate antibiotic therapy Rarely, surgical stripping of bladder wall
Encrusting	*Corynebacterium urealyticum*	Recurrent UTI Painful urination	Urine culture Abdominal ultrasonography Contrast radiography Cystoscopy	Long-term antibiotics Bladder wall submucosal resection often needed
Polypoid	Inflammatory response to UTI Benign condition	Recurrent UTI	Contrast radiography Ultrasonography Cystoscopy	Treatment of underlying UTI Surgery to remove polyps (partial cystectomy or submucosal resection)
Parasitic	Most common cause is *Capillaria* spp.	Dysuria, pollakiuria, periuria May be asymptomatic	Urine sediment examination	Only if symptomatic: Fenbendazole 50 mg/kg PO SID for 5-10 days Levamisole 2.5 mg/kg SID PO for 5 days Ivermectin 0.2 mg/kg PO once in dogs (avoid in collie type of dogs)
Drug-induced	Sterile cystitis caused by cyclophosphamide or ifosfamide May be caused by metabolite (acrolein) that is a local irritant	Hematuria is primary sign (can be severe) Stranguria Pain on palpation of bladder	History of drug administration Exclusion of other causes of cystitis	Discontinue drug Institute diuresis Treat blood loss

UTI, Urinary tract infection.

Causes

I. Infection with *Candida* spp. is the most common cause.
II. Other systemic fungi and algae may disseminate to the bladder, including *Blastomyces* spp., *Cryptococcus* spp., *Aspergillus* spp., *Prototheca* spp., and *Trichosporum domesticum*.

Pathophysiology

I. Fungal cystitis occurs primarily in animals that are immunosuppressed or have other predisposing factors (e.g., bladder neoplasia, cystostomy tubes, prolonged use of antibiotics).
II. Animals with urinary tract disorders, neoplasia, or renal failure are at increased risk for fungal infections (Jin and Lin, 2005).

Clinical Signs

I. Animals may be asymptomatic.
II. Clinical signs may include stranguria, pollakiuria, and periuria.
III. Animals with disseminated fungal infections often have systemic signs.

Diagnosis

I. Fungal organisms are noted in the urine sediment.
II. To avoid treating simple contamination, only treat if two positive samples are obtained.
III. If a fungal infection is documented, then examine the animal for evidence of systemic fungal disease.
IV. Examine the animal thoroughly for predisposing factors.

Differential Diagnosis

I. Bacterial cystitis
II. Sterile cystitis
III. Contamination of the urine sample

Treatment

I. Treat any underlying condition.
II. If possible, discontinue any immunosuppressive therapy (e.g., corticosteroids).
III. Selection of an oral antifungal agent is based on the organism that is identified and susceptibility testing.
   A. Ketoconazole: 10 to 20 mg/kg PO SID or divided BID (dogs); 10 mg/kg PO BID (cats)

B. Itraconazole: dogs and cats 5 mg/kg PO SID, BID
C. Fluconazole: 3.5 to 7 mg/kg PO BID (dogs); 3.5 to 6 mg/kg PO BID (cats)
D. Amphotericin B: various IV doses

IV. Bladder infusion of clotrimazole has been reported for *Candida* spp. (Toll et al., 2003).
V. Altering urine pH as a means of treating fungal infection has not been effective.

Monitoring of Animal

I. Routine urine cultures and examination of urine sediment are performed every 2 to 4 weeks until the animal is negative for the fungal organism.
   A. Continue antifungal agents for an additional 7 to 14 days after negative results.
   B. If a second urine culture and sediment are negative for the organism, then the antifungal agents are discontinued.
II. Once the infection has been successfully cleared, examine the urine sediment and culture every 1 to 2 months until three negative examinations are obtained.
III. Animals with predisposing factors must be monitored closely for recurrences.

INFLAMMATORY DISORDERS

Feline Idiopathic Cystitis

Definition and Causes

I. Feline idiopathic cystitis is inflammation (nonobstructive) of the bladder in which no infectious pathogen is identified.
II. In cats, it is considered an idiopathic disease.
III. Idiopathic cystitis is a diagnosis of exclusion.
IV. The terms *feline urologic syndrome* and *feline lower urinary tract* disease are nonspecific and do not indicate a diagnosis.

Pathophysiology

I. It may be induced or maintained by activation of neurogenic inflammation.
   A. Increased sensory neural input from the bladder
   B. Increased catecholamine outflow from the brainstem
   C. Altered uroepithelial structure and function
   D. Altered dynamics of urinary glycosaminoglycan
   E. Increased bladder permeability
   F. Mast cell infiltration
   G. Local axon reflex discharges in the bladder
II. Other contributing factors include the following:
   A. Gender: males affected more commonly
   B. Urethral disease: spasms, stricture, inflammation
   C. Stress: believed to play an important role
   D. Dry foods: low urinary output

Clinical Signs

I. Dysuria, stranguria, pollakiuria, periuria
II. Hematuria
III. Licking at the prepuce
IV. Can progress to urinary obstruction in males

Diagnosis

I. Clinical signs are often suggestive in cats.
   A. Presence of hematuria in young to middle-aged cats is highly suggestive.
   B. Recurrent episodes occur in about 50% of cats (Westropp and Buffington, 2003; Kruger et al., 2003).
   C. Episodes may be related to stressful events in the cat's life.
   D. Regardless of treatment, most acute episodes resolve within days.
II. Bacterial culture of the urine is negative.
III. Urinalysis shows a preponderance of red blood cells (RBCs), few WBCs, occasional transitional epithelial cells, and no bacteria.
   A. Hematuria and proteinuria may wax and wane in chronic cases.
   B. Urine pH is usually <7.0.
   C. Crystals are often absent or few in number.
      1. Crystals are thought to have no pathophysiological importance with nonobstructive cystitis.
      2. Significance of crystals in sterile cystitis is difficult to interpret (see Urolithiasis).
         a. Struvite crystals may occur in sterile urine, but urine pH is usually alkaline.
         b. Calcium oxalate crystals and uroliths usually develop in acidic urine.
         c. Crystalluria does not correlate well with urolith formation.
IV. Radiography is indicated to rule out the presence of cystoliths.
   A. Some animals (33%) have focal or diffuse bladder wall thickening on survey or contrast radiography (Figure 50-1) (Scrivani et al., 1998).
   B. Usually the bladder appears normal on double-contrast radiography.

FIGURE 50-1 Double-contrast cystogram of a cat with chronic idiopathic cystitis. Note the diffusely thickened bladder wall *(arrows)* and filling defects within the central contrast pool. *Courtesy Paul Barthez.*

C. Rarely, contrast material diffuses through the layers of the bladder wall.

V. Examination of the bladder may reveal mucosal edema, glomerulations (submucosal petechiations), and increased vascularity.

Differential Diagnosis

I. Bacterial cystitis
II. Fungal cystitis
III. Renal hematuria
IV. Urethral obstruction
V. Urolithiasis
VI. Neoplasia: transitional cell carcinoma (rare in cats)
VII. Behavioral elimination abnormalities

Treatment

I. Episodes of idiopathic cystitis usually resolve within 4 to 7 days regardless of treatment.

II. Symptomatic treatment includes environmental enrichment, increasing water intake, and medical therapy.

A. A recent study showed an 80% decrease in recurrence of feline idiopathic cystitis when environmental enrichment was initiated (Buffington et al., 2006).

1. Provide stimulation (e.g., toys, windows for outside viewing, increasing time spent with the owner) to help affected cats.
2. Increase the number of litter boxes to equal the number of cats in the household plus one.
3. Remove dirty litter at least SID and clean the box at least monthly using water and mild detergents.
4. Use unscented litter.
5. Note that some cats show an aversion to or preference for certain types of litter (see Chapter 119).

B. Increasing water intake and decreasing urine specific gravity may reduce noxious irritants in the bladder.

1. Provide affected cats with plenty of fresh water.
2. Circulating water fountains, adding water to food, or providing the cat with ceramic water bowls may increase their proclivity to drink.
3. Feed canned food to decrease urine specific gravity.
4. Subcutaneous fluids may be helpful in some cats.

C. Medical therapy for acute episodes includes medications to decrease stress, provide pain relief, and combat inflammation of the bladder.

1. Acepromazine is given at 0.05 to 0.1 mg/kg SC every 4 to 6 hours or 0.25 to 1.0 mg/kg PO BID.
   a. Tranquilizing effects reduce stress associated with the episode and helps to relieve urethral spasms.
   b. The drug is given to the point where the cat is mildly sedated and the third eyelid is elevated.
2. Oral diazepam is avoided because of the possibility of acute hepatocellular necrosis.
3. Butorphanol (0.2 to 0.4 mg/kg SC every 4 to 6 hours or 1.0 to 2.5 mg PO SID-BID) or buprenorphine (0.005 to 0.01 mg/kg SC, PO TID to QID) is given for pain.
   a. Buprenorphine may be preferable, because it can be given less frequently.
   b. The injectable form of buprenorphine can be given orally and is well tolerated by cats.
4. Tricyclic antidepressants are not recommended for acute episodes, because their maximal effect may take weeks.
5. Antibiotics are not usually warranted, especially in young cats.
6. Glucocorticoids are contraindicated after any recent urinary obstruction because of the increased susceptibility to bacterial UTI and pyelonephritis (Barsanti et al., 1992).
7. For more information, see treatment of associated urethritis and urethral spasms in Chapter 52.

III. Medical therapy for chronic idiopathic cystitis may include medications to modify behavior or inflammation.

A. Tricyclic antidepressants are used for their antiinflammatory effects (Chew et al., 1998).

1. They are not used in recently obstructed cats because of their anticholinergic effects on the detrusor muscle of the bladder, which is adversely affected from overdistension.
2. Amitriptyline is given at 2.5 to 12.5 mg PO SID.
3. Clomipramine is given at 0.5 mg/kg PO SID and affects norepinephrine reuptake less than amitriptyline (Dell and Butrick, 2006).
4. Abrupt withdrawal can lead to exacerbation of clinical signs.

B. Buspirone (5 to 10 mg PO BID to TID) maybe useful in some cats.

C. Feline pheromone (Feliway) may be beneficial in some cases (Gunn-Moore and Cameron, 2004).

1. Use with caution around people with asthma.
2. Effects on cats with asthma are unknown.

D. Other therapies with no proven benefit include the following:

1. Pentosan polysulfate sodium (*Elmiron,* Cartrophen Vet) 50 mg PO BID on food for a minimum of 4 weeks
2. Glucosamine-chondroitin sulfate (*Cosequin* for cats) 1 capsule PO SID
3. Polysulfated glycosaminoglycans 1.1 to 4.8 mg/kg IM every 4 days for six doses

Monitoring of Animal

I. Once idiopathic cystitis is diagnosed in a cat, institute preventative measures.

A. This includes environmental enrichment, long-term medical management, and reducing stress.

B. Treating cats prophylactically with acepromazine, butorphanol, and/or buprenorphine before a known stressful event may prevent recurrent episodes (Buffington et al., 2006).

C. Note that the stress of a visit to the veterinarian's office may exacerbate the signs.

D. See www.vet.ohio-state.edu/indoorcat for further information regarding environmental enrichment.

II. Despite preventative measures, recurrences are common and the time between episodes is variable (weeks to years).

III. Male cats must be closely monitored for the development of urethral obstruction (see Chapter 52).

Urinary Cystolithiasis

Definition

I. Uroliths (calculi) are concretions of minerals and matrix proteins that form in the urinary tract, especially the bladder.

II. Uroliths often form when urine is oversaturated with minerals.
   A. Supersaturation occurs when the concentration of calculogenic minerals is increased.
   B. An increase in concentration of minerals can occur in animals without formation of uroliths.
   C. Urine pH and promoters or inhibitors of crystal formation may affect the solubility of calculogenic minerals.

Causes and Pathophysiology

I. Crystals or microscopic precipitates in urine are not always evidence of urolith formation.
   A. Uroliths may be present without crystals, and crystals may be present without forming uroliths.
   B. The type of crystals present may be different from the type of calculi found.

II. Struvite uroliths are the most common uroliths found in dogs.
   A. Struvites are formed from magnesium, ammonium, and phosphate ions.
   B. In both dogs and cats, struvite uroliths are more likely to form in alkaline and infected urine.
   C. In dogs, UTIs with urease-producing bacteria predispose to struvite formation.
      1. Calculi can form in the absence of infection, which is more common in cats (95% of cat struvite uroliths are sterile) (Houston et al., 2004b).
      2. Urease-producing organisms include *Staphylococcus* spp., *Proteus* spp., *Streptococcus* spp., *Klebsiella* spp., and *Ureaplasma* spp.
      3. Urease-producing bacteria alkalinize the urine and increase concentrations of ammonium and trivalent phosphate ions in the urine.
   D. Predisposed canine breeds include the miniature schnauzer, shih tzu, bichon frisé, Lhasa apso, and miniature poodle.
      1. American cocker spaniels are predisposed to sterile struvite urolithiasis.
      2. Predisposed feline breeds include the ragdoll, British shorthair, domestic shorthair, Oriental shorthair, Chartreux, and Himalayan.
      3. Devon Rex, Burmese, Abyssinian, Russian blue, Siamese, and Birman cats are at decreased risk.
   E. Other risk factors include diets high in protein, magnesium, and phosphorous, with increased urine excretion of magnesium and phosphorous.

III. Calcium oxalate uroliths are more likely to occur in acidic urine.
   A. Their formation is related to systemic acid-base effects rather than the physicochemical effects of pH in the urine.
   B. Hypercalcemia and calciuretic medications (e.g., saline, furosemide, prednisone) can increase formation of calcium oxalate uroliths.
   C. A familial defect causing primary hyperoxaluria has been reported.
   D. Pyridoxine deficiency and fat malabsorption theoretically may predispose to calcium oxalate stones, but no clinical cases have been observed.
   E. Male dogs are more commonly affected than female dogs.
   F. Predisposed breeds include the miniature schnauzer, shih tzu, bichon frisé, Lhasa apso, Yorkshire terrier, and miniature poodle.
   G. Calcium oxalate uroliths are the most common type seen in cats.
      1. Predisposed feline breeds include the Persian, Himalayan, ragdoll, British shorthair, exotic shorthair, Havana brown, and Scottish fold.
      2. Birman, Abyssinian, and Siamese cats are at decreased risk.

IV. Ammonium urate uroliths form when increased amounts of urates build up in the urine, usually from increased intake of purines (precursors of uric acid) in the diet.
   A. These uroliths are more likely to form in acidic urine.
   B. They also occur secondary to impaired ability to convert uric acid to allantoin, which is more soluble (especially in Dalmatians).
   C. They are associated with portosystemic shunts or hepatic microvascular dysplasia.
   D. Besides the Dalmatian, English bulldogs may be predisposed.

V. Calcium phosphate uroliths (hydroxyapatite) occur very infrequently in dogs and cats.
   A. Calcium phosphate is more commonly a component of other stones.
   B. Alkaline urine increases the precipitation of hydroxyapatite in urine.
   C. Hyperparathyroidism is the most common clinical disease associated with these calculi.
   D. Predisposed breeds include the miniature schnauzer, bichon frisé, shih tzu, and Yorkshire terrier.

VI. Cystine uroliths are uncommon in dogs and cats.
   A. The solubility of cystine crystals decreases in acidic urine, thereby increasing the likelihood of calculi formation.
   B. Predisposed breeds include the English mastiff, Newfoundland, English bulldog, dachshund, Tibetan spaniel, and basset hound.
   C. Siamese cats are also predisposed.

D. Male dogs and cats are more likely to develop these calculi.

VII. Xanthine uroliths are also uncommon in dogs and cats.
A. They usually occur secondary to allopurinol treatment, especially if the animal continues to eat a high-purine diet.
B. Breed predisposition includes any dog on allopurinol (especially Dalmatians), as well as the Cavalier King Charles spaniel and dachshund.

VIII. Silica uroliths are very rare in dogs and cats.
A. They occur in dogs and cats on diets high in corn gluten or soybean hulls.
B. The German shepherd dog and Old English sheepdog have an increased incidence.
C. Males are affected more frequently than females.

Pathophysiology

I. Urethral obstruction can occur if stones are small enough to move out of the bladder but too large to move through the urethra.
II. Calculi can cause irritation to the bladder mucosa, leading to inflammation and cystitis.
III. Calculi can also serve as substrate for bacteria, leading to persistent bacterial UTI.

Clinical Signs

I. Clinical signs are similar regardless of the type of urolith present.
II. Hematuria, stranguria, dysuria, and pollakiuria may be noted.
III. Bacterial infections associated with the uroliths may worsen the clinical signs.
IV. Some dogs and cats exhibit no clinical signs related to the uroliths.
V. Some uroliths may be passed in the urine.
VI. If the animal becomes obstructed from the stone moving into the urethra, then it has difficulty urinating.

Diagnosis

I. Uroliths are considered in animals that have predisposing factors (e.g., systemic disease, history of stone formation).
II. Physical examination may be unremarkable, but occasionally stones are palpable in the urinary bladder or the urethra.
III. Urinalysis may reveal hematuria, bacteriuria, and changes in pH typical for the type of stone present.
IV. Crystalluria may be present without stones, and stones may be present without crystalluria; therefore crystalluria is not very helpful in the diagnosis of calculi.
V. Urine culture is indicated to identify primary and secondary UTI.
VI. A complete blood count and biochemistry profile may be normal; however, hypercalcemia is observed in approximately 4% of dogs and 35% of cats with calcium oxalate uroliths (Bartges et al., 2004).
VII. Abdominal radiography may reveal stones that are radiopaque.
A. Radiopaque uroliths include struvite, calcium oxalate, and calcium phosphate.
B. Stones must be ≥3 mm in diameter to be seen on radiographs.
C. The entire urethra is radiographed to look for calculi that may cause obstruction.
D. Double-contrast radiography may be needed to demonstrate urate and cystine uroliths, which are radiolucent.
E. Ultrasonography is helpful in identifying calculi in the bladder and proximal urethra, regardless of their radiodensity; however, it cannot examine the distal portions of the urethra.

Differential Diagnosis

I. Any form of cystitis
II. Bladder neoplasia

Treatment

I. Surgical removal of calculi is often necessary, especially if the animal is obstructed or has had multiple episodes of urolithiasis.
A. If medical therapy is attempted and no improvement is seen after 4 to 6 weeks, then surgery is indicated.
B. Postoperative radiographs are taken to document that all calculi have been removed.
C. Submit all calculi for analysis (dry, not in formalin).

II. Voiding urohydropulsion may be used to retrieve stones that are smaller than the diameter of the urethra (Figure 50-2).
A. Approximate sizes are 5 mm in male dogs, 7 mm in female dogs, 1 mm in male cats, and 5 mm in female cats.
B. An alternative method is to insert a urinary catheter in the bladder and distend the bladder with saline, which dilates the urethra and helps the calculi pass.
C. Voiding urohydropulsion is less successful in male dogs and cats than in female dogs.

III. Indications for medical treatment include animals that are poor candidates for general anesthesia and the presence of dissolvable calculi (struvite, cystine, possibly xanthine).
A. Struvite uroliths may be treated as follows:
1. Infection-associated struvite stones are dissolved using appropriate antimicrobial therapy (based on culture and sensitivity testing) and dietary changes.
2. The average time for dissolution is 12 weeks in dogs and 11 weeks in cats (Osborne et al., 1999).
3. Diets formulated for struvite dissolution are protein and magnesium restricted and cause the urine pH to become acidic.
a. These diets are also supplemented with salt to induce diuresis.
b. Blood urea nitrogen (BUN) and urine specific gravity are monitored during dietary modification to ensure that the animal is receiving this diet exclusively.

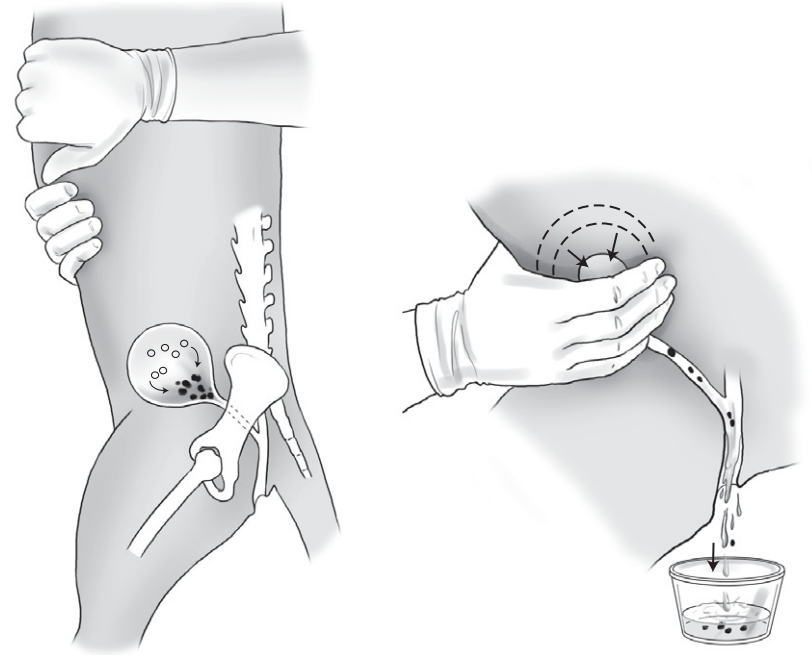

FIGURE 50-2 Technique for voiding urohydropulsion in a female dog. **A,** The animal is held so that the head points upward and the spine is relatively vertical to the floor. **B,** After the bladder has been filled to moderate distension, the urethral catheter is removed and the bladder is expressed to expel small stones *(black dots)*. The procedure is repeated several times until all stones have been expelled. *Arrows* indicate direction of bladder compression.

(1) Dogs should have low normal BUN owing to low protein in the diet.
(2) Cats should have normal BUN, because calculolytic diets in cats are not protein-restricted.
(3) Treated animals should have a urine specific gravity lower than before starting the diet, usually in the range of 1.006 to 1.017.

c. Feeding anything other than the prescribed diet (e.g., treats, other commercial pet foods, table scraps) dramatically decreases the success of dietary modification.

4. In sterile struvite urolithiasis, antimicrobial therapy is not needed; these uroliths may dissolve more quickly (4 to 6 weeks in dogs, 5 weeks in cats) (Osborne et al., 1999).

B. Calcium oxalate uroliths cannot be dissolved medically.

C. Treatment of ammonium urate uroliths varies.
1. Uroliths associated with portosystemic shunts are not amenable to medical dissolution.
a. Surgical removal is indicated and maybe done at the time of ligation of the shunt.
b. Uroliths may dissolve once the shunt is ligated if they are not removed at the time of ligation (because of surgical or anesthetic difficulties).
2. Urate calculi not associated with portosystemic shunts may often be dissolved medically.
3. Allopurinol may be tried in dogs at 10 to 15 mg/kg PO BID.
4. Allopurinol must be used cautiously in cats (9 mg/kg PO SID) because of limited data on its safety and efficacy.
5. Alkalinizing the urine through dietary changes may also be beneficial.
6. Diets low in purine, such as Hill's u/d, may be beneficial in the short term, but are not used long term.
7. Medical dissolution (successful in 50% of cases and usually takes 4 weeks) (Osborne et al., 1999).

D. Cystine uroliths may respond to the following:
1. 2-Mercatopropionol glycine (2-MPG) is given at 15 to 20 mg/kg PO BID in dogs
a. No feline dose identified.
b. Reported side effects include behavioral changes in dogs.
2. Dissolution takes approximately 4 to 12 weeks.
3. Feed a low-protein, alkalinizing diet.

E. For xanthine uroliths treatments of choice are discontinuation of allopurinol and feeding a low-purine diet.

IV. Calcium oxalate, calcium phosphate, and silica uroliths cannot be dissolved medically.

V. Other measures that may be beneficial regardless of type of urolith include the following:
A. Most dogs and cats are placed on a canned diet (higher moisture content) to decrease urine specific gravity, and attempts are made to increase water intake.
B. Treat any underlying disease, such as hyperadrenocorticism or hyperparathyroidism, appropriately.
C. Treat any associated bacterial UTI appropriately.

Monitoring of Animal

I. Monitoring for recurrence is essential.
II. Serial radiographs are performed for all radiopaque stones during dissolution, at least 3 to 4 months after dissolution and every 6 to 12 months thereafter.
III. Medical therapy is continued for at least 1 month after radiographic resolution.
IV. With struvite uroliths, preventing recurrence of infections is essential.
  A. Repeat urine cultures every 3 to 4 months.
  B. Treat any underlying cause of the infections (e.g., hyperadrenocorticism, recessed vulva).
  C. Low-dose antibiotic therapy may be used to prevent recurrent UTI.
  D. In those dogs with infection-induced struvite uroliths, changing the diet may not be needed, except to increase water intake.
  E. For those animals with sterile struvite uroliths, permanently changing to an acidifying diet can help to prevent recurrence.
    1. Avoid excessive acidification of the urine (<6.0 pH).
    2. Restrict dietary magnesium.
V. For calcium oxalate uroliths, no treatment has been shown to definitively prevent recurrence.
  A. Treating any underlying calcium abnormality may decrease recurrences.
  B. In dogs, a protein- and sodium-restricted diet may be helpful.
    1. Less acidifying diets may decrease calciuresis.
    2. Choose a diet that promotes a neutral pH (6.5 to 7.0).
    3. Alkalinizing diets may promote struvite formation in susceptible individuals.
  C. Adding potassium citrate to the diet may alkalinize the urine if diet alone does not prevent recurrence.
    1. Potassium citrate increases concentration of citrate in urine, facilitating interaction of urinary calcium with citrate.
    2. Calcium citrate is more soluble than calcium oxalate.
    3. Dose in dogs is 50 to 75 mg/kg PO BID.
    4. Efficacy is uncertain in dogs and cats.
  D. Cats are encouraged to increase their water intake by feeding a canned diet or adding water to the diet.
  E. Hydrochlorothiazide reduces urinary calcium excretion in normal dogs and may be tried in dogs with multiple recurrences at 2 mg/kg PO BID (Lulich et al., 2001).
  F. Serial radiographs are essential to document recurrence before clinical signs develop.
VI. If ammonium urate uroliths are associated with portosystemic shunts and the shunt is not treatable, then feeding a low-protein, alkalinizing diet may help prevent recurrences.
  A. Diets high in vegetable or dairy proteins have lower purine levels than those derived from other protein sources.
  B. Dry formulations of low-purine diets are less effective than canned diets.
  C. If calculi arise from other causes (e.g., feeding a low-protein diet), then feeding an alkalinizing diet prevents recurrence in 80% of dogs (Bartges, 1993).
  D. Cats may also benefit from a low-protein, alkalinizing diet.
  E. Allopurinol can be used in dogs without portosystemic shunts at 5 to 10 mg PO BID to help prevent recurrences.
VII. Maintaining neutral pH of urine can prevent calcium phosphate uroliths.
VIII. To prevent cystine uroliths, animals are fed a low-protein, alkalinizing diet.
  A. Potassium citrate (50 to 75 mg/kg PO BID) is given, with the dose adjusted to maintain a urine pH ≥7.5.
  B. In dogs, 2-MPG (15 to 20 mg/kg PO BID) can be given with alkalinizing therapy, if dietary modification is not possible.
    1. Regenerative anemia and myopathy have been reported with 2-MPG.
    2. Behavioral aggression has also been associated with 2-MPG.
IX. Discontinuing use of allopurinol and changing to a low-purine diet can prevent xanthine uroliths.
X. Avoiding diets high in plant proteins can prevent silica uroliths.

NEOPLASIA

Definition and Causes

I. Bladder tumors occur more often in dogs than in cats.
II. Bladder tumors account for <1% of all canine neoplasms (Mutsaers et al., 2003).
III. Bladder tumors are more common in older animals, and females may be predisposed (Mutsaers et al., 2003).
IV. Transitional cell carcinoma (TCC) is the most frequently identified tumor.
  A. The Scottish terrier, Shetland sheepdog, collie, Airedale terrier, and beagle are predisposed.
  B. The German shepherd dog is resistant to bladder neoplasia.
V. Other identified bladder tumors include the following:
  A. Rhabdomyosarcomas: most common in young, large-breed, male dogs
  B. Lymphoma
  C. Squamous cell carcinoma
  D. Adenomas
  E. Adenocarcinomas

Pathophysiology

I. Previous exposure to lawn herbicides, flea products, and cyclophosphamide has been associated with increased risk of developing TCC (Raghavan et al., 2004).
II. Approximately two thirds of bladder tumors involve the trigone region.

Clinical Signs

I. Clinical signs are similar regardless of tumor type and are related to secondary cystitis or urinary outflow tract obstruction.
II. The most common clinical signs are hematuria, pollakiuria, and stranguria.
III. The index of suspicion is highest in older dogs with stranguria.
IV. Uremia may occur if the tumor is obstructing the ureters or urethra.

Diagnosis

I. The bladder tumor may be palpable on rectal examination.
II. Fresh urine cytology on voided urine may reveal clumps of epithelial cells associated with RBCs and few WBCs.
  A. Cellular atypia and mitotic figures in the epithelial cells are evidence of neoplasia and are highly suggestive of TCC.
  B. Avoid taking cystocentesis samples because of the possibility of seeding tumor cells along the cystocentesis tract (Nyland et al., 2002).
III. Survey abdominal radiography may be normal, but contrast radiography or abdominal ultrasonography often reveals a mass in the bladder.
  A. Ultrasonography may detect the presence of a bladder mass, but double contrast-cystography is more sensitive for detecting small masses.
  B. Survey radiographs are examined closely for alterations in adjacent organs and regional lymph nodes.
  C. Thoracic radiographs are examined for signs of metastasis.
IV. Cystoscopy is more sensitive than imaging modalities in diagnosing and staging a mass and determining the extent of bladder involvement, and it can also be used to biopsy the tumor.
V. Traumatic catheterization (blind or ultrasound-guided) may be helpful to obtain cells from the tumor.
  A. It must be performed under heavy sedation or general anesthesia.
  B. The largest catheter that can be passed is used for the procedure.
  C. After obtaining urine, the catheter is rigorously moved back and forth while applying negative pressure.
VI. The bladder tumor antigen test (V-BTA Test; Polymedco, Cortlandt Manor, N.Y.) detects the presence of tumor antigens in urine.
  A. It has a high negative predictive value (98.6%), but its positive predictive value is poor (31%) (Billet et al., 2002; Henry et al., 2003).
  B. False-positives occur in the presence of proteinuria, pyuria, hematuria, and glucosuria.

Differential Diagnosis

I. Any cause of cystitis
II. Polypoid cystitis
III. Tumors of adjacent structures: vagina, prostate, urethra

Treatment

I. Surgical excision offers the best chance for a good outcome if the tumor is not in the area of the trigone.
  A. Urethrocystoscopy often shows multiple areas of seeding of malignant sites throughout the bladder (not just in the area of the obvious tumor mass).
  B. Complete excision is often impossible.
  C. Small apical tumors have the best chance for complete excision.
II. Some neoplasms, such as lymphoma, are sensitive to chemotherapy (see Chapter 69).
III. Piroxicam is recommended in all dogs for its antiinflammatory and antitumor properties.
  A. The dose in dogs is 0.3 mg/kg PO SID to QOD.
  B. Side effects include anorexia, vomiting, diarrhea, and GI ulceration.
  C. Secondary renal toxicity is possible but uncommon.
IV. Diverting urine from the bladder through a tube cystostomy may be considered in animals with tumors that are inoperable and obstructing the urethra.
  A. Urine scald and recurrent UTIs have been associated with tube cystostomy.
  B. Other surgical procedures that divert urine (e.g., urethral-colonic anastomosis) are not advised because of their side effects.
V. Radiation therapy has not been used successfully in TCC in dogs.
VI. Treat any secondary UTI with appropriate antibiotics.

Monitoring of Animal

I. Prognosis for long-term survival with bladder neoplasia is poor.
II. Monitoring the animal's quality of life is important.
  A. Special regard must be paid to the animal's ability to urinate.
  B. Many animals respond positively to piroxicam, including those with urinary outflow obstruction.
III. Frequent rechecks (at least monthly) are performed.
IV. Monitor urine cultures at least every 2 to 3 months.

TRAUMA

Definition and Causes

I. Injury to the bladder can be caused by surgery, blunt (e.g., automobile crash), or penetrating (e.g., knife, stick, gunshot wound) trauma to the abdomen.
II. Occasionally, overzealous palpation of the bladder, especially if the bladder is distended or diseased, may lead to bladder rupture.
III. Bladders can also be traumatized by cystocentesis, improper placement of urinary catheters, improper abdominocentesis techniques, or overdistention during cystoscopy or contrast radiography.
IV. Rupture may occur with prolonged urethral obstruction.

Pathophysiology

I. Small rents in the bladder wall usually heal spontaneously, without incident.

II. Transient leakage of sterile urine into the abdomen after cystocentesis or a small rent is usually self-limiting and resolves quickly.
III. Larger rents or tears in diseased bladders may not heal and the animal may develop clinical signs of bladder rupture.
IV. The fundus of the bladder is the most frequent site of rupture.

Clinical Signs

I. Hematuria is common.
II. Difficulty urinating may be noted; however, normal urination does not rule out bladder trauma.
III. A decrease in urine output and an increase in abdominal distention may be seen with a ruptured bladder.
IV. Occasionally, a urinary catheter still drains urine from a ruptured bladder, therefore urine output may remain stable and it may appear as though the animal is passing urine normally.
V. Sterile peritonitis may occur from exposure to urine; if the urine is infected, then the peritonitis is more severe.
VI. Anorexia, depression, fever, abdominal pain, and azotemia can occur secondary to bladder rupture.
VII. Systemic signs are secondary to absorption of waste products across the peritoneum into the circulation.

Diagnosis

I. A history of trauma and compatible clinical signs raises the index of suspicion.
II. Survey radiographs may show loss of serosal detail and/or displacement of the bladder.
III. Pelvic bone fractures are highly associated with bladder rupture.
IV. Ultrasonography may reveal free fluid in the abdomen.
V. Abdominocentesis reveals bloody fluid with creatinine concentrations higher than the serum creatinine concentration.
   A. Culture the fluid if bacterial peritonitis is suspected.
   B. Examine the abdominal fluid microscopically for the presence of blood and/or degenerative neutrophils.
VI. BUN and creatinine are usually increased early in the course, with BUN more elevated than creatinine because of differences in their diffusion characteristics.
VII. Decreases in serum sodium and chloride and increases in potassium may occur as the effects of urine in the abdomen equilibrate with extracellular fluid.
VIII. Positive contrast radiography is the diagnostic test of choice (see Chapter 4).

Differential Diagnosis

I. Urine leakage from other sites of trauma: urethra, ureters
II. Other causes of ascites and abdominal effusions
III. Urinary obstruction from uroliths, neoplasia
IV. Ruptured paraprostatic (males) or perinephric pseudocyst
V. Other causes of peritonitis

Treatment

I. Treatment depends on the extent, location, and cause of the trauma.
II. The animal is assessed for more life-threatening injuries first.
III. If the rupture is small, then a urinary catheter (preferably flexible) is inserted and continuous drainage using a closed system is performed for 3 to 10 days, so the bladder is allowed time to heal.
IV. If the bladder rupture is large, then surgical repair is attempted once the animal is stabilized.
V. Antibiotics can be used if a high possibility of infection exists.
VI. Short-term peritoneal dialysis or peritoneal drainage may be needed if the animal is in poor condition and urine flow cannot be established adequately with catheterization.

Monitoring of Animal

I. Urinations are monitored after removal of the urinary catheter to make sure no obstruction develops secondary to surgical repair (stricture).
II. The urine is often cultured after removal of the urinary catheter to rule out a nosocomial UTI.
III. Serum electrolyte abnormalities and azotemia usually resolve within days.
IV. If clinical signs recur or persist, then contrast radiography is repeated.

CHAPTER 51

Micturition Disorders

Joan R. Coates | Marie E. Kerl

GENERAL INFORMATION

Definition and Classifications

I. The lower urinary tract stores and allows periodic elimination of urine.
II. The process of micturition includes both storage and emptying of the urinary bladder.
III. *Urination* refers to the voiding process.
IV. The storage phase includes passive filling of the urinary bladder and mechanisms to maintain continence.
V. The emptying phase requires sphincter relaxation with coordinated voluntary bladder contraction.
VI. Urinary continence requires a normal, compliant bladder and an active, competent urethral sphincter.
VII. The micturition process is under control of the central nervous system (CNS), which integrates the autonomic and somatic nervous systems.
VIII. Micturition dysfunction includes retention of urine or incontinence.
IX. Neurogenic bladder describes bladder dysfunction caused by an underlying nervous system dysfunction.
X. Classification of micturition disorders is as follows:
   A. Neurogenic versus nonneurogenic
      1. Neurogenic disorders result in mechanical dysfunction of the urethra and urinary bladder secondary to underlying pathology in the nervous system.
         a. Upper motor neuron (UMN): suprasacral spinal cord lesion (lumbar [L] segment 7 to brainstem)
         b. Lower motor neuron (LMN): sacral spinal cord lesion, peripheral neuropathy, myopathy, neuromuscular junctionopathy, dysautonomia
      2. Nonneurogenic lesions may be anatomical or functional.
         a. *Anatomical* refers to a structural lesion in the lower urinary tract causing dysfunction.
         b. *Functional* refers to nonstructural lesions causing mechanical dysfunction of the urinary bladder and urethra, as well as to neurogenic disorders.
   B. Failure to empty versus failure to retain urine
      1. Urinary retention
         a. Incomplete or absent detrusor muscle contraction (detrusor hyporeflexia and areflexia)
         b. Urethral obstruction
      2. Urinary incontinence
         a. Inappropriate urination
         b. Bladder storage dysfunction
         c. Urethral dysfunction
      3. Anatomical and functional causes

Functional Neuroanatomy

I. The urinary bladder is divided into a neck (trigone) and body, and it serves as a low-pressure reservoir.
   A. Urinary bladder musculature, or the detrusor muscle, is composed of three interwoven layers of smooth muscle.
   B. Smooth muscle fibers form a syncytium via tight junctions that propagate excitatory transmission from a pacemaker cell throughout the detrusor muscle.
   C. Adrenergic and muscarinic cholinergic receptors lie within the detrusor smooth muscle.
II. The urethral musculature consists of two sphincters that are considered outlets for urine from the urinary bladder.
   A. The internal smooth muscle (internal urethral sphincter) is composed of outer and inner longitudinal and middle circular layers, and it begins at the bladder neck and extends distally.
   B. The external striated muscle (external urethral sphincter) is interwoven with the proximal urethral smooth muscle but is more prominent in the distal half of the urethra.
   C. The adrenergic and nicotinic cholinergic receptors are located on the internal smooth and external striated muscles, respectively.
III. Bladder receptors are as follows:
   A. β-Adrenergic receptors predominate in the body of the detrusor muscle.
      1. They mediate information conveyed by postganglionic sympathetic fibers of the hypogastric nerve.
      2. Stimulation causes detrusor muscle relaxation and allows bladder filling at constant pressures.
   B. Muscarinic cholinergic receptors are located within the body (at the base of the detrusor muscle).
      1. They mediate information conveyed by postganglionic parasympathetic fibers of the pelvic nerve.
      2. Stimulation causes detrusor muscle contraction and bladder emptying.
   C. Sensory receptors lie within muscle fascicles and connective tissue of the smooth muscle layers.
      1. They mediate sensory information arising from distention (stretch) and pain of the detrusor muscle.

2. The pelvic nerve innervates all regions of the bladder and relays information from the receptors.
3. The filling threshold triggers the micturition reflex.
4. Pain receptors within the submucosa are innervated by hypogastric nerve terminations located near the base of the bladder.

IV. Urethral receptors are as follows:
- A. α-Adrenergic receptors predominate at the base of the detrusor muscle and internal sphincter of the proximal urethra.
  1. They mediate information relayed by postganglionic sympathetic fibers of the hypogastric nerve.
  2. Stimulation causes contraction of smooth muscles of bladder neck and proximal urethra to counter urine flow and facilitate bladder filling.
- B. Nicotinic cholinergic receptors are located within the striated muscle fibers of the external urethral sphincter.
  1. These somatic receptors mediate information relayed by the pudendal nerve.
  2. Stimulation causes external sphincter muscle contraction to counter urine flow and to facilitate bladder filling.
- C. Sensory receptors mediate information about stretch, pain, and urine flow.

Neurophysiology

I. Storage phase of micturition (Figure 51-1)
- A. The pelvic nerve conveys information from stretch receptors in the detrusor muscle (generated during bladder filling) to a sacral and thoracolumbar intersegmental spinal reflex pathway.
  1. Activation of preganglionic sympathetic neurons mediates relaxation of the detrusor muscle and contraction of the proximal urethral sphincter.
  2. Activation of the pudendal motor neurons mediates contraction of the striated external urethral sphincter muscle.
- B. Reticulospinal fibers descend from the lateral cell group of the brainstem micturition center within the pons to activate pudendal motor neurons.

II. Emptying phase of micturition (Figure 51-2)
- A. Urinary bladder capacity exceeds threshold and stimulates mechanoreceptors to trigger the micturition reflex.
  1. Signals from stretch receptors are relayed via the pelvic nerve.
  2. Inhibition of preganglionic sympathetic neurons, and pudendal motor neurons result in relaxation of smooth and striated sphincter muscles, respectively.
  3. Fibers ascend cranially to the brainstem micturition center in the pons.
  4. Reticulospinal fibers descend from the medial cell group of the brainstem micturition center to activate preganglionic parasympathetic neurons of the pelvic nerve.
  5. The detrusor muscle contracts and the urethral sphincters relax, resulting in coordinated emptying of bladder.
     - a. Detrusor muscle contraction pulls the bladder neck open.
     - b. Sensory receptors within the urethra detect urine flow.
     - c. The pudendal nerve conveys the sensation of urine flow.
- B. Sensory information ascends the spinal cord to the cerebral cortex.
- C. Descending fibers from the cerebral cortex then activate the brainstem micturition center for voluntary control of urination and continued urine flow until bladder emptying is complete.

III. Reflexes
- A. The detrusor reflex is a pathway for urination via a brainstem and spinal cord reflex arc (see Figure 51-2).
- B. The micturition reflex is a pathway that involves the integration of bladder filling, storage, and emptying of the bladder with urethral sphincter contraction and relaxation (see Figure 51-2).

Diagnosis of Micturition Dysfunction

I. Historical findings
- A. Neutering or other urogenital surgeries
- B. Failure of housebreaking behavior
- C. Onset and progression of signs
- D. Urination attempts and awareness
- E. Frequency of urination
- F. Volume of urine
- G. Presence of urine leakage
- H. Behavioral changes

II. Physical examination findings
- A. Observe voiding patterns.
  1. Stream size is evaluated as normal or thin.
  2. Evidence of dysuria or stranguria is common with voiding disorders.
  3. Duration of voiding provides evidence of urine retention and dyssynergia.

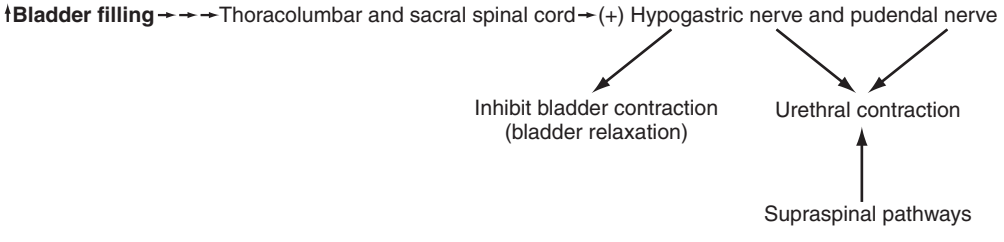

FIGURE 51-1 Neurophysiologic aspects of the storage phase of micturition.

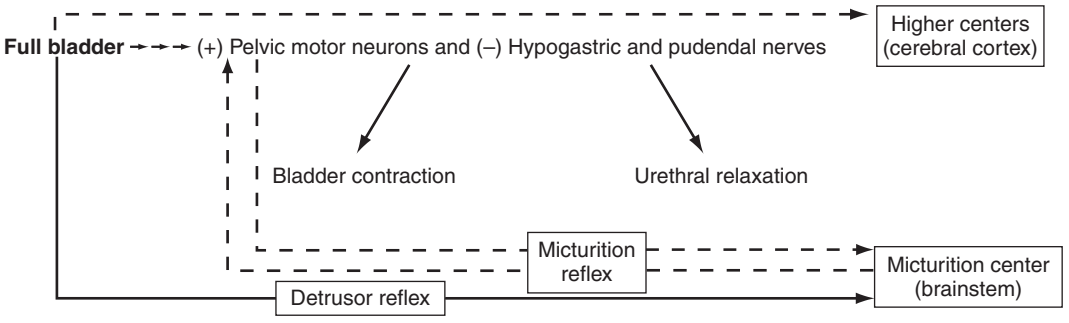

FIGURE 51-2 Neurophysiologic aspects of the emptying phase of micturition, showing the micturition *(dotted lines)* and detrusor *(solid line)* reflexes.

4. Urine color may reveal evidence of hematuria.

B. Examine external genitalia for masses, abnormal conformation, strictures, and urine scalding.
C. Palpate abdomen to reveal bladder size and presence of other masses.
D. Palpate urinary bladder before and after urination.
   1. Assess tone and flaccidity.
   2. Normal bladder is firm on palpation and difficult to manually express.
   3. Ease of manual bladder expression may reflect urethral tone.
E. Palpate urethral papilla and vaginal vault in female dogs for masses.
F. Palpate rectum and pelvic urethra for masses and to assess anal tone.
G. Use urethral bladder catheterization to assess for obstructive lesions.
H. Measure residual volume when emptying phase is in question.
   1. Residual volume is defined as the amount of urine remaining in the bladder after voiding is complete.
      a. Normal residual volume: 0.2 to 0.4 mL/kg
      b. Normal dog: <10 mL
      c. Normal cat: <2 mL
   2. Large residual volume indicates a urine retention disorder.

III. Presence of neurologic disease
   A. Anal and urethral tone is assessed during rectal palpation.
   B. Tail function, position, and tone are observed because they reflect coccygeal nerve function.
   C. The perineal reflex is contraction of the anal sphincter when the anal sphincter is pinched, with simultaneous assessment of sensation of the perineum.
   D. The bulbocavernosus reflex is contraction of the anal sphincter when the bulb of penis or clitoris is pinched.
   E. Low lumbar paraspinal hyperesthesia is commonly associated with pathology of the bones and nerve roots.

IV. Localization of neurologic disease
   A. UMN signs localize as suprasacral (L7 to brainstem).
      1. Reflexes are normal to increased.
      2. Postural reaction deficits are present.
   B. LMN signs localize as sacral (sacral [S]1 to 3), peripheral neuropathy, or dysautonomia.
      1. Reflexes are decreased to absent.
      2. Loss of muscle tone occurs.
      3. Postural reaction deficits may be present if the sciatic nerve is affected.

V. Clinicopathologic findings
   A. A complete blood count (CBC) and chemistry profile are done to assess the presence of inflammatory disease, renal insufficiency, and underlying metabolic causes of polyuria.
   B. Urinalysis is performed to evaluate for urinary tract infection (UTI), which is a common sequela to neurogenic bladders and urine retention.
   C. Urine culture also can be performed to screen for underlying UTI.
   D. Serology is used to detect infectious diseases.

VI. Plain radiography
   A. Survey abdominal and pelvic radiography (including entire urethra) assesses bony or soft tissue abnormalities of the lumbosacral spine and pelvis and detects radiodense urinary calculi.
   B. Thoracic radiography may detect metastatic disease.

VII. Contrast urography
   A. Contrast cystography and urethrography evaluate for anatomical obstructions.
   B. IV pyelogram evaluates renal architecture.

VIII. Advanced imaging
   A. Computed tomography gives anatomical detail on bony structures of the lumbosacral spine and pelvis.
   B. Magnetic resonance imaging provides detail on soft tissue structures associated with the spinal cord and pelvic region.
   C. Myelography is used to assess compressive spinal cord disease cranial to L7.
   D. Ultrasonography assesses integrity of the bladder wall and lower urinary tract anatomy.

IX. Cystoscopy and urethroscopy: identify masses, obtain biopsies, remove small calculi

X. Cerebrospinal fluid analysis: presence of spinal cord disease

XI. Electrodiagnostic testing

A. Electromyography (EMG) of perineum and urethra assesses innervation status.
B. Nerve conduction velocity of sciatic nerve evaluates axon and myelin pathology associated with peripheral neuropathy.
C. Somatosensory and spinal-evoked potential studies evaluate sensory pathways and nerve root function.

XII. Urodynamic testing
A. Cystometry measures bladder pressure during filling and emptying, and it detects the presence of a detrusor reflex.
B. Urethral pressure profilometry measures urethral length and assesses urethral tone.
1. A catheter is connected to a pressure transducer and fluid is infused at a constant rate as the catheter is withdrawn.
2. Maximum urethral pressure and functional urethral profile length are recorded.
C. Leak point pressure testing is a functional technique used to simulate urethral compliance associated with an external abdominal press.
D. Sphincter muscle EMG is used to assess pudendal nerve function.

DISORDERS OF URINE RETENTION

Definition

I. Urine retention is associated with incomplete or absent detrusor muscle contraction or urine outflow obstruction from either an anatomical or a functional cause.
II. Disorders associated with voiding usually involve abnormalities of the lower urinary tract and cause outflow obstruction of urine.
III. Secondary overflow incontinence may occur when urinary bladder pressure exceeds urethral resistance.

Clinical Signs

I. Incomplete or absent detrusor muscle contraction
A. The animal's attempt to void depends on the integrity of the pelvic nerve and spinal cord.
B. An animal with dyssynergia may attempt to void in small amounts or without success.
1. Dyssynergia is the simultaneous contraction of muscles with actions in opposite directions.
2. The disorder is usually associated with contraction of the detrusor muscle without relaxation of the sphincter muscle.
C. Urine scald may be evident with secondary overflow incontinence.
D. Physical examination findings with an UMN bladder (suprasacral lesion) are as follows:
1. No attempt is made to void.
2. The bladder is large and firm on palpation and difficult to express manually.
3. Sphincter tone is hypertonic or normal.
4. A large amount of residual urine is present.
5. The perineal reflex is present.
6. Evidence of secondary overflow incontinence may be noted.
E. Physical examination findings with a LMN bladder (sacral spinal cord or peripheral nerve lesion) are as follows:
1. No attempt to void is noted, and urine leakage is continuous.
2. The bladder is large and flaccid, with leakage on manual expression.
3. The bladder may be difficult to express manually because the internal urethral sphincter is still innervated by the hypogastric nerve.
4. Sphincter tone is normal to hypotonic.
5. A large amount of residual urine is present from secondary overdistension.
6. Presence of other LMN signs (loss of perineal reflex and sensation and/or tail tone and sensation) may be noted.
7. In dysautonomia the bladder is overdistended, flaccid, and easy to express manually.
8. Urine scald is present from overflow incontinence.
F. Physical examination findings with primary detrusor muscle dysfunction from overdistension are as follows:
1. Attempts are made to void but are unsuccessful.
2. The bladder is difficult to express manually.
3. Sphincter tone varies with the underlying disorder.
4. A large amount of residual volume is present.
5. The perineal reflex is normal.
G. A dyssynergic-like syndrome associated with LMN dysfunction occurs when incomplete detrusor muscle contraction is unable to override urethral sphincter tone.
1. Attempts are made to void, but the stream is thin and intermittent (small spurts).
2. The bladder is difficult to express manually.
3. Sphincter tone is normal.
4. Large or variable amounts of residual volume are present.
5. The perineal reflex is decreased.
H. The animal may have other neurologic signs.
1. UMN bladder dysfunction is common with thoracic (T)3 to L3 myelopathies.
2. LMN bladder dysfunction occurs with sacral myelopathies, neuromuscular disease, and dysautonomia.

II. Urethral obstruction
A. The animal may sense bladder fullness and seek an appropriate place to void.
B. The animal makes multiple attempts to void without success.
C. Physical examination findings with an anatomical and functional urethral obstruction are as follows:
1. A urination posture is assumed.
2. The urine stream is thin or interrupted as spurts.
3. The bladder is difficult to manually express.
4. Urethral catheterization is difficult or impossible.
5. The perineal reflex is intact.

D. Reflex dyssynergia (detrusor-sphincter dyssynergia) is associated with recovery from spinal cord injury and manifests as the following:
   1. Attempts to void are made, but the stream is thin and intermittent (small spurts).
   2. The bladder is large, firm, and difficult to express manually.
   3. Sphincter tone is hypertonic.
   4. A large or variable amount of residual volume is present.
   5. The perineal reflex is normal.

Differential Diagnosis

I. Incomplete or absent detrusor muscle contraction (detrusor hypoflexia or areflexia, bladder atony) (Table 51-1)
   A. Primary diseases of the urinary bladder may cause enough damage to disrupt detrusor muscle contraction and result in secondary bladder storage dysfunction.
      1. Infiltrative neoplasms cause primary damage to the detrusor muscle.
      2. Chronic cystitis may cause secondary muscle fibrosis.
      3. Chronic LMN disease may cause neurogenic atrophy of the detrusor muscle.
   B. Suprasacral lesions involving the spinal cord and brainstem micturition center disrupt coordination of micturition, cause loss of the detrusor reflex or deficient detrusor muscle contraction, and produce hypertonic to normal urethral sphincter tone.
      1. Loss of micturition function occurs with loss of voluntary motor and sensory nerve function.
      2. Loss of inhibitory pathways alters urethral sphincter relaxation mechanisms.
      3. UMN bladder dysfunction is common with T3 to L3 myelopathies (see Chapter 24).
      4. Secondary overflow incontinence occurs when bladder pressure exceeds urethral sphincter tone.
   C. Lesions of the sacral spinal cord and pelvic plexus, neuromuscular disease, and dysautonomia alter pelvic nerve function, abolish the detrusor reflex, and produce normal to hypotonic urethral sphincter tone (see Chapters 24 and 25).
      1. Absent detrusor muscle contraction causes secondary overdistension and bladder flaccidity (detrusor areflexia, bladder atony).
      2. External urethral sphincter tone is lost from pudendal nerve dysfunction.
      3. The internal sphincter muscle may still remain innervated by the hypogastric nerve and may make expression of the bladder difficult.
      4. Dysautonomia usually causes an overdistended bladder that is flaccid and easily expressed from loss of innervation to the detrusor and sphincter smooth muscles, respectively.
   D. Cauda equina syndrome and pelvic plexus injury affect the pelvic nerve, resulting in weakened detrusor muscle contraction (detrusor hyporeflexia and areflexia) and failure to override normal urethral sphincter tone (dyssynergic-like conditions).
   E. Nonneurogenic disorders cause bladder atony (hypotonia) as a result of overdistention of the detrusor muscle and disruption of tight junctions between the myofibers.
      1. Anatomical obstructive diseases preventing urine outflow
      2. Painful disorders of the pelvic region
      3. Opioids and epidural anesthesia: incomplete micturition, with urge to urinate
      4. Prolonged recumbency, reluctance to urinate in cage

TABLE 51-1

Disorders of Urine Retention Associated with Bladder Dysfunction

	FUNCTIONAL ABNORMALITIES	
ANATOMIC LESIONS	**NEUROGENIC DISORDERS (DETRUSOR HYPOREFLEXIA AND AREFLEXIA)**	**NONNEUROGENIC DISORDERS (OVERDISTENSION CAUSING DETRUSOR AREFLEXIA)**
Chronic cystitis Infiltrative neoplasms Neurogenic atrophy of detrusor muscle Overdistension secondary to obstructive disease	UMN (sphincter tone hypertonic or normal) T3-L3 myelopathies that are severe enough to cause loss of voluntary motor and sensory function Reflex dyssynergia Disorders that affect the brainstem micturition center LMN (sphincter tone normal or hypotonic/atonic) Sacral spinal cord lesion Pelvic plexus lesion Generalized severe peripheral neuropathy Myopathy Neuromuscular junction lesion Dysautonomia	Secondary to urethral obstruction Disorders associated with pain in pelvic region Drugs (opioids, epidural anesthesia) Prolonged recumbency

UMN, Upper motor neuron; *LMN,* lower motor neuron; *T,* thoracic; *L,* lumbar.

II. Urethral obstruction (Table 51-2)
  A. Anatomical obstructive diseases mechanically prevent urine outflow and limit ability of the urethra to dilate during urination.
    1. Intraluminal diseases include urolithiasis, blood clots, tissue blockage, neoplasia, and urethritis.
    2. Intramural diseases include neoplasia, inflammation, edema, and strictures.
    3. Extraluminal diseases include prostatic disease, strictures, urethral granuloma, and bladder neck and pelvic neoplasms.
  B. Functional obstructive diseases are neurogenic or nonneurogenic disorders that result in failure of urethral sphincter relaxation.
    1. Neurogenic disorders include those that affect the LMN or UMN pathways and prevent relaxation of the internal or external urethral sphincter.
    2. Urethral hypertonia (spasticity) results from UMN lesions that cause increased resistance.
      a. Urethral sphincter tone is uninhibited because of loss of descending inhibition.
      b. It is often associated with detrusor areflexia.
    3. Reflex dyssynergia (detrusor-sphincter dyssynergia) is associated with partial UMN spinal cord disease and loss of inhibition of pudendal nerves during the detrusor reflex, which prevents coordinated urinary bladder contraction and urethral sphincter relaxation.
      a. Initiation of voiding is normal, but involuntary contraction of urethral sphincter causes interruption of urine stream.
      b. It is more often observed in male dogs.
      c. Diagnosis is made by exclusion of other more common disorders.
    4. Nonneurogenic disorders are those for which an anatomical or underlying neurologic cause is not identified.
      a. Idiopathic detrusor-urethral dyssynergia
      b. Urethral irritation after relief of urethral obstruction

Diagnosis

I. The residual volume is usually large.
II. Urethral bladder catheterization determines the presence or absence of urethral obstruction.
III. Urinalysis and urine culture ascertain the presence of a UTI, which is a common sequela of urine retention disorders.
IV. Abdominal radiography, ultrasonography, and contrast cystourethrography delineate obstructive or mass lesions.
V. Cytoscopy is useful to visualize small obstructions in urethra.
VI. Urodynamic testing evaluates detrusor muscle function and urethral tone.
  A. Cystometry may demonstrate lack of a detrusor reflex on volume threshold stimulation.
  B. Urethral pressure profilometry can detect areas of higher than normal pressure, suggesting a stricture or spasm.

Treatment

I. Stimulate detrusor muscle contraction.
  A. Cholinergic agonists enhance detrusor muscle contraction.
    1. Bethanechol chloride is a direct-acting cholinergic.
      a. Dogs: 5 to 25 mg PO TID
      b. Cats: 1.25 to 5.0 mg PO TID
      c. Side effects: salivation, diarrhea, bronchoconstriction
    2. Cisapride is an indirect-acting cholinergic that enhances presynaptic release of acetylcholine.
      a. Dogs: 0.5 mg/kg PO TID or 2.5 to 10 mg PO TID (dose varies with body size)
      b. Cats: 1.25 to 5.0 mg PO TID
      c. Side effect: diarrhea
  B. β-Adrenergic blockade with propranolol enhances detrusor contractility.
    1. Dogs: 2.5 to 20 mg PO BID to TID (dose varies with body size)
    2. Cats: 2.5 to 5.0 mg PO BID to TID

TABLE 51-2

Disorders of Urine Retention Associated with Urethral Obstruction

	FUNCTIONAL ABNORMALITIES	
ANATOMIC LESIONS	**NEUROGENIC DISORDERS (URETHRAL HYPERTONIA)**	**NONNEUROGENIC DISORDERS (URETHRAL HYPERTONIA)**
Intraluminal disease Intramural disease Extraluminal disease	UMN (sphincter tone hypertonic or normal) T3-L3 myelopathies that are severe enough to cause loss of voluntary motor and sensory function Spasticity Reflex dyssynergia Disorders that affect the brainstem micturition center	Idiopathic detrusor-urethral dyssynergia Urethral irritation after relief of obstruction

UMN, Upper motor neuron; *T,* thoracic; *L,* lumbar.

3. Side effects: bradycardia, lethargy, hypotension, bronchoconstriction

II. Decrease urethral sphincter tone.
   A. α-Adrenergic antagonists decrease internal urethral smooth muscle sphincter tone.
      1. Phenoxybenzamine is a nonspecific α-antagonist.
         a. Dogs: 0.5 mg/kg PO BID or 2.5 to 15 mg PO TID
         b. Cats: 1.25 to 5.0 mg PO SID to BID
         c. Side effects: hypotension, tachycardia, gastrointestinal (GI) disturbance
      2. Prazosin is an α-1 antagonist.
         a. Dogs: 1 mg/15 kg PO BID to TID
         b. Cats: 0.25 to 0.5 mg PO SID to BID
         c. Side effects: hypotension, sedation, salivation
      3. Acepromazine is a nonspecific α-antagonist.
         a. Dogs: maximum dose 3 mg IV
         b. Cats: 0.1 mg/kg SC, IV SID to BID; 1 to 2 mg/kg PO SID to BID
         c. Side effects: hypotension, sedation
   B. Skeletal muscle relaxants decrease external urethral striated muscle tone.
      1. Diazepam is centrally acting.
         a. Dogs: 2 to 10 mg PO TID
         b. Cats: 0.2 to 0.5 mg/kg IV TID; 2 to 5 mg PO TID
         c. Side effects: sedation, excitation, acute hepatocellular necrosis (cats)
      2. Dantrolene is direct-acting.
         a. Dogs: 3 to 15 mg/kg PO TID
         b. Cats: 0.15 to 0.6 mg/kg PO TID
         c. Side effects: weakness, hepatotoxicity, vomiting, hypotension
      3. Methocarbamol is centrally acting.
         a. Dogs: 15 to 20 mg/kg PO TID
         b. Cats: initial dose 33 mg/kg PO TID, then 20 mg/kg PO TID
         c. Side effects: sedation, lethargy, salivation, vomiting, weakness

III. Prevent bladder overdistension.
   A. Urinary bladder catheterization
      1. Continuous, closed-system, indwelling catheter may be used.
      2. Intermittent catheterization has a lower risk of inducing UTI.
   B. Manual bladder expression
      1. Female dog has shorter urethra and less resistance than male dog
      2. Less likely to induce a UTI
   C. Treatment for secondary UTI
      1. Periodically perform a urinalysis and urine culture.
      2. Avoid use of prophylactic antibiotics in animals with indwelling catheters because they can predispose to resistant UTI.

Monitoring of Animal

I. Recheck examinations
   A. Monitor for bladder size and changes in residual volume.
   B. Perform urinalysis and urine culture to monitor for UTI.
   C. Follow up with owner to determine compliance.
   D. Consider periodic adjustment of medication dosing to increase efficacy.
   E. Remember that side effects are limited if drug administration is started at a low dose and gradually increased.

II. Expected outcome
   A. Micturition function improves with recovery of neurologic status in most cases.
   B. Intermittent catheterization or bladder expression may be required for life in animals that are paraplegic.
   C. A reflex bladder may develop in animals with severe UMN dysfunction.

III. Prognosis
   A. The prognosis for underlying neurogenic causes is dependent on recovery of neurologic functions (presence of sensation and voluntary motor movement).
   B. Chronic cases of urinary retention refractory to medical management have a guarded prognosis.
   C. The prognosis for return of function in chronic cases of bladder atony is poor.
   D. Detrusor atony is often reversible in animals with acute overdistention.
   E. The prognosis is good with resolution of anatomical or nonneurogenic functional obstructions.

DISORDERS OF URINE STORAGE (URINARY INCONTINENCE)

Definition

I. Urinary incontinence can result from urinary bladder storage problems or urethral dysfunction.
   A. Bladder storage dysfunction often arises from poor compliance and elasticity or increased bladder contraction (detrusor hyperreflexia).
   B. Urethral dysfunction arises from decreased urethral resistance.
   C. Structural anomalies may disrupt normal urinary bladder or urethral function.

II. Bladder storage disorders often are characterized by involuntary leakage of small amounts of urine.

III. The bladder is usually small to normal in size in animals with no underlying neurologic disease.

IV. Incontinence must be distinguished from inappropriate urination.

V. Neurologic examination is necessary when localizing the cause of incontinence.

VI. Lower urinary tract disease must be considered in incontinent animals that are neurologically normal and have normal residual volume.

VII. Secondary overflow incontinence may occur with urinary retention disorders when urinary bladder pressure exceeds urethral resistance.

Clinical Signs

I. Inappropriate urination
   A. Animals have normal voiding but the time and place are inappropriate.
   B. Physical examination reveals normal bladder size and residual volume.

II. Bladder storage dysfunction (Table 51-3)
   A. This dysfunction is characterized by involuntary voiding at low bladder volume and pressure.
      1. Urinary incontinence
      2. Urine leakage on standing, barking, jumping
   B. Pollakiuria may result from bladder irritation or underlying metabolic causes of polyuria-polydipsia.
   C. The pattern of incontinence is usually intermittent.
   D. Physical examination findings with neurogenic detrusor hyperreflexia are as follows:
      1. Normal or large amount of residual volume depending on the underlying neurologic cause
      2. Small amounts of urine leakage associated with involuntary voiding
   E. With primary urinary bladder disease (poor compliance), the animal may show urge incontinence, with involuntary voiding of small amounts of urine and pollakiuria.
      1. The bladder is not distended, but a thickened wall may be evident on palpation.
      2. A normal to small amount of residual volume is present.

III. Urethral dysfunction (Table 51-4)
   A. A pattern of incontinence may be continuous or intermittent, and severity of incontinence is dependent on the amount of urethral tone lost.
   B. The bladder size and voiding pattern may vary, depending on the presence of underlying neurologic disease.
   C. Physical examination findings with a congenital structural anomaly (ectopic ureter) are as follows:
      1. Normal voiding pattern
      2. Bladder not distended
      3. Normal residual volume
      4. Continuous pattern of incontinence
   D. Neurogenic urethral dysfunction is usually associated with an LMN bladder.
      1. No attempt is made to void.
      2. The bladder may be large and flaccid.
      3. Ease of manual expression is dependent on the amount of urethral tone maintained by the hypogastric nerve.
      4. A large residual volume is present.
      5. The pattern of incontinence is intermittent or continuous, depending on severity.
      6. Neurologic deficits are detected.
   E. Animals with urethral incompetence show the following:
      1. The voiding pattern is normal.
      2. The bladder is not distended and may be easy to express manually.

TABLE 51-3

Disorders of Urinary Incontinence Associated with Bladder Storage Dysfunction

	FUNCTIONAL ABNORMALITIES	
ANATOMIC LESIONS	**NEUROGENIC DISORDERS (DETRUSOR HYPERREFLEXIA)**	**NONNEUROGENIC DISORDERS (BLADDER WALL IRRITATION)**
Chronic cystitis Patent urachus	UMN (sphincter tone hypertonic or normal) Cerebellar disease Reflex bladder Detrusor instability secondary to other neurologic disease	Infiltrative diseases Chronic inflammation Urge incontinence Idiopathic detrusor hypercontractility

UMN, Upper motor neuron.

TABLE 51-4

Disorders of Urinary Incontinence Associated with Urethral Dysfunction

	FUNCTIONAL ABNORMALITIES	
ANATOMIC LESIONS	**NEUROGENIC DISORDERS (URETHRAL SPHINCTER HYPOTONIA AND ATONIA)**	**NONNEUROGENIC DISORDERS (DECREASE URETHRAL SPHINCTER RESISTANCE)**
Ectopic ureter Urethral hypoplasia Prostatic disease	LMN (sphincter tone hypo-/atonic) Sacral spinal cord disorders that altering external urethral sphincter tone Dysautonomia altering internal and external urethral sphincter tone	Polyuria/polydipsia UTI Hormone-responsive urethral incompetence

LMN, Lower motor neuron; UTI, urinary tract infection.

3. The residual volume is normal.
4. The pattern of incontinence is continuous or intermittent, depending on severity.
5. Urine leakage occurs when the animal is at rest or asleep.

Differential Diagnosis

I. Inappropriate urination is the act of voluntarily voiding urine at the wrong time and in the wrong place.
   A. The diagnosis is ascertained by history and observation of the animal.
   B. Differential considerations include senility, forebrain disease, and physical limitations that prevent reaching an acceptable place to urinate.
   C. Animals with forebrain disease may have seizures, behavioral changes, and contralateral response deficits (hemineglect).

II. Bladder storage dysfunction is deficient bladder compliance and elasticity during the filling phase or involuntary voiding at low bladder pressure (detrusor hyperreflexia).
   A. Anatomical causes include infiltrative diseases that alter elasticity of the detrusor muscle and functional storage capacity.
      1. Bladder wall inflammation (cystitis) causing secondary fibrosis
      2. Patent urachus
   B. Functional disorders may be neurogenic or nonneurogenic.
      1. Neurogenic causes include disorders of detrusor hyperreflexia.
         a. Generalized cerebellar disease can result in frequent voiding with normal residual volume.
         b. Reflex bladder occurs in chronic UMN disease (rare) and causes weak uncoordinated contractions with inadequate bladder emptying.
         c. Detrusor instability may occur in cats positive for feline leukemia virus.
      2. Nonneurogenic causes include infiltrative diseases or disease processes that irritate the bladder wall.
         a. Infiltrative diseases include neoplasia and chronic inflammation.
         b. Bladder wall irritation causes the urge incontinence often associated with UTI.
         c. *Idiopathic detrusor instability* is the term used for no identifiable cause for decreased detrusor compliance.

III. Urethral dysfunction results from weakened urethral smooth or striated muscle tone, which causes urine leakage during the storage phase of micturition.
   A. Anatomical lesions
      1. Congenital anomalies (e.g., ectopic ureter, urethral hypoplasia) may alter urethral closure mechanisms and tone.
      2. Prostatic disorders can disrupt urethral closure function in male dogs.
   B. Functional abnormalities
      1. Neurogenic disorders
         a. Sacral spinal cord disorders affect influence of the pudendal nerve on the striated external urethral sphincter muscle (causing decreased tone).
         b. Dysautonomia alters sympathetic nerve function and the influence of the hypogastric nerve on the smooth internal urethral sphincter muscle (causing decreased tone).
      2. Nonneurogenic disorders
         a. Polyuric disorders can intensify an underlying incontinence problem, because an increased urine volume places further stress on an incompetent urethra.
         b. UTIs and inflammation can cause transient urethral incompetence.
         c. Hormone-responsive urethral incompetence is the most common cause of incontinence in female dogs.
            (1) Urine leakage usually occurs when the dog is at rest or asleep.
            (2) The voluntary urination pattern is normal.
            (3) A correlation exists between body weight and incidence of incontinence (incontinence is worse in animals with increased body weight).
            (4) The intrapelvic bladder position may contribute to urethral incompetence.
            (5) The onset after spaying may be immediate or up to 10 years (mean of 3 years after surgery) (Arnold, 1992).

Diagnosis

I. The residual volume is small or normal in animals with no evidence of neurologic disease.
II. An abnormal neurologic examination determines the presence of UMN or LMN disease.
III. A vaginal examination evaluates for strictures causing urine pooling.
IV. Urinalysis and urine culture are performed to ascertain the presence of UTI.
V. Low urine specific gravity indicates poor concentrating ability and necessitates the need for further blood tests to determine the underlying cause.
VI. Imaging studies (abdominal radiography, ultrasonography, and contrast cystourethrography or urethrography) delineate abnormal anatomy, and indications include the following:
   A. Incontinence observed in animals <1 year of age or in male dogs
   B. Incontinence around time of ovariohysterectomy
   C. Continuous pattern of incontinence
   D. Recurrent UTI
VII. Cystoscopy is useful to visualize congenital anomalies and lesions of the bladder and urethra.
VIII. Urodynamic testing is used to detect detrusor hyperreflexia and decreased urethral tone.
   A. Cystometry may demonstrate a low volume threshold associated with detrusor hyperreflexia or decreased

compliance of the bladder associated with urge incontinence.
B. Urethral pressure profilometry may detect areas of lower than normal maximal urethral closure pressures and shortened functional profile length, which suggest decreased resistance and urethral sphincter muscle tone.
C. Leak point pressures can aid the diagnosis of underlying urethral incompetence.

Treatment

I. Decrease detrusor muscle contraction.
A. Direct-acting smooth muscle relaxants
1. Oxybutynin chloride has direct antimuscarinic and spasmolytic effects on smooth muscle.
a. Dogs: 1.25 to 5 mg PO BID to TID
b. Cats: 0.5 mg PO BID
c. Side effects: diarrhea, sedation
2. Propantheline bromide is an antimuscarinic agent with actions similar to atropine, but it does not cross into the CNS.
a. Dogs: 0.2 mg/kg PO TID to QID or 5 to 30 mg PO TID
b. Side effects: similar to atropine, prolonged GI motility
3. Aminopromazine fumarate acts directly to cause smooth muscle relaxation and is used for urge incontinence.
a. Dogs: 2 mg/kg PO BID
b. Cats: 2 mg/kg PO BID
c. Side effects: mild tranquilization or excitability
B. Treatment of underlying bladder inflammation
II. Increase urethral sphincter tone.
A. Direct nonspecific α-adrenergic agonist, such as phenylpropanolamine
1. Dogs: 12.5 to 50 mg PO TID or 1 mg/kg PO TID
2. Cats: 12.5 mg PO TID
3. Side effects: restlessness, irritability, hypertension, anorexia
B. Indirect α-adrenergic agonist
1. Imipramine is a tricyclic antidepressant agent that indirectly acts by increasing norepinephrine and has nonspecific adrenergic and anticholinergic effects.
a. Dogs: 5 to 15 mg PO BID
b. Cats: 2.5 to 5.0 mg PO BID
c. Side effects: sedation, tremors, seizures, excitability, anticholinergic effects, adverse hematologic changes, diarrhea
2. Diethylstilbestrol increases urethral sphincter smooth muscle sensitivity to norepinephrine.
a. Dogs: 0.1 to 1.0 mg PO for 3 to 5 days followed by once-weekly administration of the lowest effective dose
b. Side effects: bone marrow toxicity, blood dyscrasias
c. May be used with phenylpropanolamine
3. Testosterone cypionate has an unknown mechanism of action that increases sphincter sensitivity.
a. Male dogs: 2.2 mg/kg IM every 30 days
b. Cats: 5 to 10 mg IM (testosterone propionate)
c. May be used with phenylpropanolamine
d. Adverse effects: uncommon, behavioral changes, prostatic disease, perineal hernias
C. Surgical methods for urethral incompetence refractory to medical therapy
1. Submucosal urethral polymeric injections (Arnold et al., 1989)
2. Cystourethropexy, urethropexy and colposuspension procedures (Gregory et al., 1994; Rawlings, 2000; White, 2001)
a. Move the bladder neck to an intraabdominal position
b. Restore continence by increasing pressure transmission to the bladder neck and proximal urethra
3. Mesh and sling procedures (Bushby et al., 1980; Dean et al., 1989)

Monitoring of Animal

I. Recheck examinations
A. Animals with urinary incontinence are periodically monitored for UTI.
B. Animals unresponsive to medical management are reevaluated with urinalysis, urine culture, neurologic examination, and imaging procedures.
C. Underlying behavioral disorders often require trial therapy with various drugs.
II. Expected outcome
A. Most affected dogs can be managed with appropriate medical therapies.
B. Medical therapies may require periodic adjustment or adjunctive therapies.
III. Prognosis
A. Success rate is reduced in male dogs, juvenile dogs, and dogs with marked anatomical abnormalities (Lane, 2003).
B. The control of urinary incontinence varies with each animal.
C. Poor control is commonly attributed to UTIs, polyuric disorders, and behavioral disorders.
D. Success rates have been variable for the surgical procedures but may be enhanced with adjunctive medical therapies.
E. The prognosis is guarded in urinary incontinence attributed to underlying neurologic disease that is not recognized early in its disease course.

CHAPTER 52

Diseases of the Urethra

Nyssa J. Reine

CONGENITAL DISORDERS

Hypospadias

See Chapter 59.

Urethrorectal Fistula

Definition and Cause

I. Failure of complete separation of the fetal cloaca into an anterior urethrovesical segment and a posterior rectal segment by the urorectal septum occurs, resulting in a permanent communication between the urethra and the rectum.
II. The incidence is quite rare and the cause is unknown.

Clinical Signs

I. Signs typically develop shortly after weaning and are associated with abnormal micturition.
II. Passage of urine through the rectal orifice is most common in dogs, although urination may be observed from both the anus and urethra.
III. Cystitis, perianal dermatitis, hematuria, struvite urolithiasis, and diarrhea may also occur.

Diagnosis

I. The defect may be visualized via a speculum or proctoscopic examination of the rectum.
II. If the defect cannot be seen, then a urethral catheter may be used to explore the floor of the rectum.
III. The catheter can usually be passed into the urinary bladder.
IV. Positive-contrast urethrography (normograde or retrograde) can also be used to confirm the diagnosis.

Differential Diagnosis

I. Traumatic rectovaginal fistula
II. Older age and history of previous trauma: suggestive of acquired, traumatic disease

Treatment

I. Surgical correction is undertaken via abdominal laparotomy, perianal exploration, or ventral pubic symphysiotomy (Bjorling, 2003).
II. Concurrent UTIs are also treated (see Chapter 50).

Monitoring of Animal

I. The surgical site is monitored for infection.
II. Urinalysis and urine culture are performed after completion of treatment to ensure resolution of the infection.
III. Follow-up positive-contrast urethrography may be performed 4 to 6 weeks after surgery to confirm fistula closure.

INFLAMMATORY DISEASES

Urethritis

Definition and Causes

I. Inflammation of the urethra
II. Causes
  A. Idiopathic: granulomatous urethritis, proliferative urethritis, inflammatory polyp
  B. Bacterial: cystitis, vaginitis, prostatitis
  C. Traumatic: secondary to calculi or urethral catheterization
  D. Neoplastic

Pathophysiology

I. Breakdown of the urothelial lining secondary to traumatic disruption or neoplastic infiltration of the urethral mucosa may result in erosion and ulceration.
II. Granulomatous urethritis is frequently associated with marked epithelial hyperplasia, probably related to elaboration and release of growth factors by inflammatory cells.
III. Proliferative urethritis may be secondary to chronic bacterial infection or immune-mediated disease.

Clinical Signs

I. Stranguria, hematuria, pollakiuria
II. Vaginal or preputial discharge, possibly bloody
III. Possible partial or complete urinary obstruction

Diagnosis

I. Physical examination findings
  A. A rectal examination is essential and may reveal urethral thickening that is either tubular or masslike.
  B. A digital vaginal examination may reveal an irregularly shaped urethral papilla.

C. Catheterization may help localize the lesion by partial or complete resistance to passage of the catheter.
   1. Procedure must be done under sedation in female dogs.
   2. Attempts may be unsuccessful in cases with luminal compromise.

II. Laboratory results
   A. Urinalysis may reveal pyuria, hematuria, bacteriuria, and/or proteinuria.
      1. Urine specific gravity is variable.
      2. Culture and sensitivity are indicated.
   B. Biochemical profile may reveal azotemia, particularly if urinary is obstruction present.
   C. Increased serum alkaline phosphatase, creatinine kinase, lactate dehydrogenase, cholesterol, and globulin concentrations may also occur.
   D. Complete blood count (CBC) may be normal or reveal leukocytosis.

III. Imaging studies
   A. Survey radiographs may show no abnormalities, the presence of urinary calculi, or a large and distended urinary bladder.
   B. Contrast retrograde cystourethrography may reveal filling defects within the urethral lumen, irregularities of the mucosa, or urethral stricture.
   C. Ultrasonography may reveal diffuse bladder wall thickening with extension into the urethra or masses within the bladder.

IV. Urethral cytology
   A. Urethral scraping for cytology is a noninvasive test that may help establish a diagnosis.
   B. Under sedation a urinary catheter is passed to the most proximal aspect of the lesion (based on rectal palpation).
   C. Inject sterile saline into the catheter using a syringe, and apply negative pressure to the syringe while moving the catheter back and forth through the affected region.

V. Urethral biopsy
   A. Urethroscopy is used to localize the lesion and facilitate biopsy.
   B. Place female dogs in ventral, dorsal, or right lateral recumbency, and use a rigid cystoscope with a 30-degree angle of view and a cystoscopy sheath to enable biopsy through the biopsy channel.
   C. Place male dogs in right lateral or dorsal recumbency, and use a flexible cystoscope.
   D. Attach a fluid source (0.9% saline) to the cystoscope, in addition to a drainage line, if possible.
   E. Clip and aseptically prepare the perivulvar or preputial area.
   F. Apply a liberal amount of sterile lubricant to the cystoscope.
   G. For female dogs, insert the cystoscope in the vestibule; apply firm, gentle traction to the vulva.
      1. Visualize the vagina, urethra papilla, and cingulum.
      2. Orient the cystoscope so that the vagina is at the top of the screen.
      3. Guide the cystoscope into the urethra while the urethra is distended with fluid.
      4. Visualize the lesion and pass the biopsy instrument through the biopsy channel to obtain biopsies.
   H. For male dogs, an assistant is required to extrude the penis from the prepuce.
      1. Pass the scope through the urethra while the urethra is distended with fluid.
      2. Typically, flexible cystoscopy does not enable biopsy acquisition through the scope.
      3. Biopsies can be obtained by passing a biopsy instrument alongside the scope during visualization.
      4. Alternatively, measurement of the distance to the lesion via the cystoscope can guide a blind biopsy.

VI. Interpretation of biopsies
   A. Histopathology of granulomatous urethritis lesions reveals lymphocytes, plasma cells, and macrophages, with low numbers of neutrophils.
   B. Histopathology of proliferative urethritis is characterized by lymphoplasmacytic or suppurative inflammation but no granulomatous changes.
   C. Histopathology of a urethral polyp reveals fibrous connective tissue, with some inflammatory cells.

Differential Diagnosis

I. Urethral neoplasia
II. Urethral calculi
III. Urethral stricture
IV. Cystitis
V. Vaginitis

Treatment

I. Proliferative urethritis in dogs (Hostutler et al., 2004)
   A. Antiinflammatory treatment with piroxicam 0.3 mg/kg PO SID or immunosuppression with azathioprine 2 mg/kg PO QOD to SID and prednisone 2 mg/kg PO BID may be effective.
   B. Antibiotic therapy, either with the previously mentioned drugs or as a single therapy, may also be considered.

II. Granulomatous urethritis in dogs (Moroff et al., 1991)
   A. Prednisolone 1.1 mg/kg PO BID for 14 days, then tapered to 0.07 mg/kg PO BID
   B. Cyclophosphamide 2.2 mg/kg PO SID for 4 days per week
   C. Concurrent antibiotic treatment for up to 6 weeks

III. Neoplasia: see Neoplasia later in this chapter
IV. Urethral polyps: removal via neodymium:yttrium-aluminum-garnet laser (Elwick et al., 2002)
V. Tube cystopexy for long-term management of obstructed dogs

Monitoring of Animal

I. Monitor the animal's ability to urinate or the patency of any urinary tube or catheter.
II. For dogs on piroxicam, monitor a biochemical profile 1 week after initiation of therapy, then every 1 to 6 months.
III. For dogs taking azathioprine, a CBC and platelet count are done initially every 1 to 2 weeks, then every 1 to 2 months, with a decrease in white blood cell or platelet

count necessitating a decrease in dose or discontinuation of therapy.
IV. Perform a urinalysis and urine culture during therapy, then at 3 to 5 days and 1 month after discontinuation of antibiotics.
V. Follow-up urinalysis and urine culture is then performed every 3 to 6 months.

Urethral Prolapse

Definition and Causes

I. A red or purple mass protrudes from the tip of the penis.
II. The mass is only reported in male dogs and is most often seen in young, male English bulldogs.
III. The exact cause is unknown; however, prolonged sexual excitement, urolithiasis, urethral infections, and increased abdominal pressure (from coughing, stranguria, and tenesmus) have been implicated.

Clinical Signs

I. Excessive licking of the prepuce
II. Preputial bleeding
III. Straining to urinate

Diagnosis

I. Visually examine the extruded penis.
II. The prolapsed tissue is red to purple in color, swollen, involves 360 degrees of the urethral orifice, and extrudes 3 to 4 mm from the penis.

Differential Diagnosis

I. Squamous cell carcinoma or transitional cell carcinoma of the tip of the penis or urethra
   A. Usually asymmetrical and do not involve just the tip of penis
   B. Tend to occur in older animals
II. Transmissible venereal tumor
   A. Occurs in young dogs
   B. Cytology of mass reveals a round cell tumor

Treatment

I. Attempts can be made to reduce prolapsed tissue, followed by a purse-string suture; however, recurrence is likely.
II. Surgery is the treatment of choice.
   A. Tissue reduction technique (Bjorling, 2003)
      1. Insert a urinary catheter, then apply an encircling tourniquet caudal to the os penis to maintain the penis in an extruded position and to minimize hemorrhage.
      2. Incise through the prolapsed urethral mucosa at the point of reflection, continuing for 180 degrees.
      3. Suture the urethra circumferentially to the tunic of the penis with 4-0 or 5-0 nonabsorbable suture in an interrupted pattern.
      4. Continue the incision and suture the remaining 180 degrees of the urethra.
   B. Urethropexy technique (Kirsch et al., 2002)
      1. Manually extrude the penis.
      2. Introduce a groove director (Miltex Instrument Co, Lake Success, N.Y.) to the distal aspect of the os penis to reduce the prolapse.
      3. Pass a 2-0 or 3-0 absorbable suture through the full thickness of the penis, from the external surface (as far proximally on the penis as the needle curvature allows) to the intraluminal surface, directing the needle distally out the urethral orifice.
      4. In a reverse fashion, pass the needle from the urethral lumen to the external surface of the penis and exit 0.5 cm distal to the initial needle entry site.
      5. Tie the suture snuggly with four throws, starting with a surgeon's knot.
      6. A slight depression occurs in the surrounding tissue, such that the top of the knot is even with the surface of the mucosa.
      7. Repeat the procedure until two to four evenly spaced sutures are placed.
      8. Pass a urinary catheter to confirm urethral patency.
III. Systemic antibiotics are indicated when urinary infection is present.

Monitoring of Animal

I. Hemorrhage is the most common postoperative complication.
   A. Minor bleeding may be reported up to 2 weeks after surgery.
   B. Sedation and an Elizabethan collar may be necessary for 3 to 5 days after surgery to prevent self-inflicted trauma.
   C. Minimize excitement and limit access to other pets and bitches in heat.
II. After the urethropexy technique, sutures are not removed.
III. Consider castration to minimize recurrences.

URETHRAL UROLITHIASIS

Definition and Causes

I. Calculi located within the urethra typically cause complete or partial obstruction and traumatic urethritis.
II. See Chapter 50 for specific causes of calculi formation.

Pathophysiology

I. Generally small cystic calculi migrate to the neck of the bladder during voiding and pass into the urethra.
II. In male dogs, urethral calculi often lodge caudal to the os penis.
III. In female dogs, calculi may lodge at any location along the urethra.
IV. Urethral calculi cause urinary obstruction more commonly in male dogs than females.

Clinical Signs

I. Stranguria, hematuria, pollakiuria, with or without blood dripping from the prepuce or vulva
II. Complete urinary obstruction: abdominal distension and pain, straining with no urine passage, azotemia, hyperkalemia

III. Partial urinary obstruction: frequent attempts to void with passage of urine during urination, bladder moderately large in size
IV. Severity of signs: dependent on degree and duration of obstruction

Diagnosis

I. Compatible clinical signs and physical examination findings
II. Inability or difficulty in passing a urinary catheter
III. Survey radiography or positive-contrast retrograde urethrography
IV. Cystoscopic examination

Differential Diagnosis

I. Neoplasia
II. Urethral stricture
III. Urethritis
IV. Urethral trauma

Treatment

I. Attempt to relieve any complete urinary obstruction.
   A. Try passing a small-diameter urethral catheter alongside the calculus.
   B. Try to flush stones retrograde into the urinary bladder.
   C. Under sedation or anesthesia, pass the largest-bore, high-density polyethylene urinary catheter possible through the os penis to just distal to calculus.
   D. Flush the catheter with saline while compressing the tip of the penis with dry gauze.
   E. If this technique fails, then place a finger in the rectum, palpate the urethra, and occlude its lumen.
      1. Repeat the previous steps.
      2. When maximum pressure is exerted on the urethra by the saline, suddenly release the digital urethral occlusion, allowing the lodged calculi to move into the bladder.
   F. If unable to relieve the obstruction, then consider tube cystostomy or frequent cystocentesis until corrective surgery can be performed.
II. Remove calculi from the bladder via cystotomy.
III. Urethrotomy via an incision over the calculi may be performed to remove stones that cannot be retropulsed.
IV. Urethrostomy to establish a permanent opening may be indicated in cases of recurrent calculi (e.g., urate calculi in Dalmatians).
   A. Scrotal urethrostomy is the technique of choice.
   B. Castration is performed simultaneously, if necessary.
V. Holmium:yttrium-aluminum-garnet laser lithotripsy has been used to fragment urethral calculi, with few complications (Davidson et al., 2004).
VI. Treatment of UTI and dietary management of calculi are discussed in Chapter 50.

Monitoring of Animal

I. After cystostomy, small quantities of blood and blood clots may be passed for 2 to 3 days.
II. Animals with postrenal azotemia are kept on IV crystalloids until resolution of azotemia, which typically occurs in 24 to 48 hours.
III. After urethrotomy and urethrostomy, hemorrhage from the urethral stoma is the most common postsurgical complication.
   A. It generally occurs within 4 to 5 days and may last up to 2 weeks.
   B. An Elizabethan collar is applied to prevent self-inflicted trauma.
IV. Monitor for recurrence of pollakiuria, because this could indicate development of a urethral stricture.

NEOPLASIA

Definition

I. Primary neoplasia of the urethra in the dog is uncommon, but bladder and prostatic neoplasia may extend into the urethra.
II. Transitional cell carcinoma and squamous cell carcinoma are the most common tumors, but hemangiosarcoma and chondrosarcoma have also been reported.

Cause

I. The cause is unknown.
II. The reported incidence is higher in older, female dogs.

Pathophysiology

I. Urethral tumors are usually locally infiltrative and may metastasize to the sublumbar lymph nodes and lungs (Norris et al., 1992).
II. Urethral inflammation may arise secondary to erosion or ulceration of the mucosa by the invading neoplasm.

Clinical Signs

I. Stranguria, hematuria, pollakiuria
II. Vaginal discharge or dripping blood from prepuce
III. Partial or complete urinary obstruction

Diagnosis

I. Suggestive clinical signs
II. Physical examination findings
   A. Rectal palpation may reveal thickening or a mass effect in the urethra.
   B. An abnormal urethral papilla may be found on vaginal examination.
   C. It may not be possible to pass a urinary catheter beyond the lesion.
III. Laboratory results
   A. Urinalysis
      1. Microscopic hematuria is common.
      2. Rarely bacteriuria, pyuria, or neoplastic cells may be seen.
   B. Biochemical profile: ± azotemia and/or hyperkalemia with chronic obstruction
IV. Imaging studies

A. Survey radiography may reveal an enlarged bladder or sublumbar lymph nodes.
B. Ultrasonography may reveal a mass near the neck of the bladder, but the pelvic urethra is difficult to visualize with ultrasonography.
C. Positive-contrast cystography often reveals irregular filling defects within the urethra.

V. Urethral cytology
A. Often equivocal
B. ± Inflammation associated with secondary ulceration of neoplasm or urethritis

VI. Urethral biopsy
A. See previous discussion of Urethritis for techniques.
B. Cystoscopically obtained biopsies are often small and may be inadequate to confirm a diagnosis.
C. Biopsy may be difficult if tumor location is subepithelial.

Differential Diagnosis

I. Neoplasia of the bladder, prostate
II. Urethritis
III. Transmissible venereal tumor
IV. Urethral calculi
V. Nonpenetrating trauma

Treatment

I. If obstruction is present, then relieve the obstruction by inserting a urinary catheter attached to a collection system.
A. While hospitalized, the urinary collection system is changed SID to minimize ascending infection.
B. Treat any prerenal or postrenal azotemia.

II. Surgery may be attempted, using several approaches.
A. In dogs with tumors involving less than one third of the intrapelvic urethra, wide surgical excision via sagittal pubic osteotomy may be helpful (Davies and Read, 1990).
1. Postoperative complications include death, persistent uremia, and tumor recurrence.
2. Reported survival is 2 to 22 months.
B. Transurethral resection via rigid cystoscopy and electrocautery may successfully reduce tumor volume in dogs with urethral transitional cell carcinoma (Liptak et al., 2004).
1. Postoperative complications include hemorrhage and urethral perforation.
2. Transurethral resection syndrome (excessive absorption of lavage solution after perforation), bacteriuria, and seeding of the surrounding areas with tumor cells may also occur.
C. Urinary diversion may be done via ureterocolonic or trigonal-colonic anastomosis for long-term, palliative management of obstructions from urethral neoplasia (Smith et al., 1995).
1. Postsurgical complications include UTI, pyelonephritis, hypochloremic acidosis, low survival time (1.5 to 5 months) (Montgomery and Hanks, 1988; Smith et al., 1996).
2. Urinary bladder empties into the colon.
3. UTI is a frequent complication.
4. It does not reduce tumor burden.

III. Urinary diversion or urethral stenting are palliative procedures.
A. Permanent tube cystopexy through the body wall allows diversion of urine.
1. Owners must empty the tube several times a day.
2. UTI is a frequent complication.
B. Urethral stenting with expandable stents may be performed using interventional radiography (Weisse et al., 2006).

IV. Chemotherapy may be tried, but clinical studies of urethral tumors are lacking.

Monitoring of Animal

I. Monitor frequently for UTI via urinalysis and urine culture.
II. Animals with urinary diversion into the colon must be allowed to defecate four to five times per day.
A. Frequent evaluation of hydration status, electrolytes, and acid-base status are required.
B. Excretory urography or ultrasonography is performed at 3 and 6 months to evaluate the ureters and kidneys for signs of dilation, stricture, and infection.

TRAUMA

Definition and Causes

I. Urethral damage may result from blunt or penetrating injuries, or it may be secondary to perforation associated with catheterization.
II. Incidence is variable.
A. For dogs struck by cars, 2 per 600 had urethral injuries (Kolata and Johnson, 1975).
B. For dogs with pelvic trauma, urethral rupture ranged from 5% to 10% (Kleine and Thornton, 1971; Selcer, 1982).
C. Most dogs with urethral rupture have been males (Selcer, 1982).

Pathophysiology

I. Blunt trauma is more likely to cause contusions.
II. Lacerations are commonly associated with pubic or os penis fractures, penetrating wounds (knife, gunshot, animal bite), or catheterization.
III. Pubic or os penis fractures may cause urethral obstruction.

Clinical Signs

I. Partial or complete urethral obstruction
A. Pollakiuria is common with either no or little urine evacuation.
B. The bladder is inappropriately large for repeated attempts at urination.
C. With partial lacerations, hematuria may be the only clinical sign, and a urinary catheter may pass normally.

II. Urethral disruption leading to accumulation of urine within abdomen, pelvic canal, or subcutaneous tissues
III. Chronic subcutaneous leakage leading to formation of urethrocutaneous fistula

Diagnosis

I. Urethral trauma must be considered in animals with pelvic trauma or penetrating injuries.
II. Unexplained uremia after trauma is highly suggestive.
III. Plain radiography is rarely diagnostic.
IV. Positive-contrast urethrocystography usually identifies disruption of the urethra.
  A. Positive-contrast cystography (Essman, 2005)
    1. Before catheterization, fill the catheter with saline or 2% lidocaine to minimize air bubble artifact and prevent bladder spasm that can occur secondary to pain.
    2. Iodinated contrast media is used and sometimes diluted to a 20% solution before infusion (see Chapter 4).
  B. Retrograde urethrography (Burke and Feeney, 2003)
    1. An undiluted, water-soluble radiopaque contrast medium is used (see Chapter 4).
    2. The tip of a catheter is positioned just beyond the urethral papilla in female dogs and just caudal to the os penis in male dogs.
    3. Contrast is manually injected (forcibly), and a radiograph is obtained as the last portion of the contrast is injected.
    4. Distension of the urinary bladder may not be necessary.

Differential Diagnosis

I. Periurethral hematoma or abscess
II. Neoplasia
III. Trauma to other areas of the urinary tract

Treatment

I. Urethral contusion without rupture can often be managed medically.
  A. Urethral catheterization to relieve urinary obstruction
  B. Treatment of underlying cause (e.g., stabilization of pelvic fractures)
II. Incomplete laceration of the urethra may heal if urine is diverted by placement of a urethral catheter for 3 to 5 days (Cooley et al., 1999).
III. Complete urethral transection requires surgical intervention.
  A. Resection of damaged tissue is done, followed by anastomosis to prevent formation of strictures or a urethrocutaneous fistula.
  B. If primary suturing causes excessive tension, then closure of the urethra may be reinforced using a flap of muscle raised from the rectus abdominis or internal obturator.
  C. An indwelling urinary catheter is inserted for 3 to 5 days postoperatively.
IV. Intrapelvic urethral injuries may require pubic osteotomy to allow débridement and repair (Bjorling, 2003).
  A. Urethral repair is done with 4-0 or 5-0 monofilament absorbable suture in an interrupted pattern.
  B. Maintenance of a urethral catheter intraoperatively facilitates identification of the urethral lumen and may improve results of anastomosis (Layton et al., 1987).
V. Os penis injuries may require surgery (Kelly and Clark, 1995).
  A. Obstruction may result from callus and fibrous tissue formation.
  B. Avoidance of these sequelae may require stabilization with a finger bone plate.

Monitoring of Animal

I. Urine diversion is continued during the period of urethral healing.
  A. Indwelling catheters are connected to a closed collection system, which is changed once daily.
  B. Catheter patency and urine volume are monitored.
  C. Urine culture and sensitivity are performed after catheter removal.
II. To ensure healing, urethrography is repeated at the time of catheter removal, using caution to minimize breakdown of the healing area.
III. Activity is restricted in animals that have had a pubic osteotomy.
  A. Complete healing and osseous union may not occur for >4 months.
  B. Bony healing is monitored with serial radiography.
IV. Retrograde urethrography may be performed at 3 and 6 months to monitor for postoperative urethral stricture.

URETHRAL OBSTRUCTION

Definition and Causes

I. Urethral obstruction is a partial or complete inability to empty the urinary bladder because of impaired flow of urine through the urethra.
II. Structural causes include urethral neoplasia, calculi, mucus plugs, strictures, and urethritis.
III. Functional causes include urethral spasm, upper motor neuron spinal cord lesions, and feline idiopathic cystitis.
IV. It occurs more commonly in male dogs and cats than females.

Pathophysiology

I. With complete obstructions, contraction of the detrusor muscle is unable to overcome the obstruction, which leads to urine retention in the bladder.
II. With partial obstructions, small amounts of urine are passed.

Clinical Signs

I. Straining to urinate, with incomplete bladder emptying
II. Lethargy, anorexia, preputial licking, tenesmus, vocalization
III. Prolonged obstruction: bradycardia or tachycardia, acute renal failure, shock, acute death

Diagnosis

I. Large, firm, palpable, inexpressible bladder suggestive
II. Difficulty or inability to pass a catheter into the bladder

Differential Diagnosis

I. Pollakiuria associated with UTIs

II. Tenesmus from other causes
III. Micturition disorders (see Chapter 51)

Treatment

I. Maintain circulatory volume and correct acid-base and electrolyte abnormalities.
   A. A balanced crystalloid solution is administered IV to correct fluid deficits.
   B. Hyperkalemia is treated (see Acute Renal Failure in Chapter 48).
II. Relieve the urinary obstruction (see previous discussion of Urolithiasis).
   A. Perform hydropulsion for urethral calculi (see Chapter 50).
   B. For obstructions associated with feline idiopathic cystitis, insert a urinary catheter attached to a closed collection system for 24 to 72 hours.
   C. If a catheter cannot be passed, consider repeated cystocentesis until the animal can undergo anesthesia and surgery.
   D. Culture the urine retrieved from the obstructed bladder.
   E. Surgically correct any structural abnormalities after the animal is stabilized.
   F. For recurrences, consider a perineal urethrostomy in cats or a prescrotal urethrostomy in dogs.
III. After relief of the obstruction, institute diuresis.
   A. Continue IV or SC crystalloid solutions.
   B. Monitor urine output, because postobstructive diuresis is common.
   C. Meet or exceed urine output and needs for diuresis with appropriate amounts of the crystalloid solutions.
IV. Long-term management of urethral spasms may involve the following:
   A. Environmental enrichment for cats with idiopathic cystitis (see Chapter 50)
   B. Reduction of muscle spasms
      1. Phenoxybenzamine and prazosin
         a. Phenoxybenzamine 2.5 to 7.5 mg PO SID to BID
         b. Prazosin 0.25 mg PO SID to BID
         c. Little evidence of clinical efficacy
         d. Side effects: hypotension, weakness, nausea, vomiting
         e. Ideally initiated with urinary catheter in place because of their slow onset
      2. Diazepam and dantrolene
         a. Diazepam 0.1 to 0.25 mg/kg PO BID to TID
         b. Dantrolene 0.5 to 2.0 mg/kg PO TID
         c. Little evidence of clinical efficacy
         d. Side effects: hyperexcitability, acute hepatic failure in cats (diazepam), acute hepatopathy in dogs (dantrolene)
V. Institute preventative measures for other causes of urethral obstruction, such as urolithiasis and other forms of functional obstruction (see Chapter 51).

Monitoring of Animal

I. Monitor serum biochemistries SID until azotemia and hyperkalemia have resolved.
II. Monitor urine output until postobstructive diuresis has resolved.
III. Once the urinary catheter has been removed, closely monitor the animal's ability to urinate for at least 24 hours before discharge from the hospital.
IV. Animals receiving muscle relaxants are monitored for hypotension for 1 to 2 weeks after initiation of therapy.
V. Perform a biochemical profile within 1 to 2 weeks of initiating therapy in animals receiving diazepam or dantrolene.

CHAPTER 53

Diseases of the Prostate

Kerry J. Heuter

DEGENERATIVE DISORDERS

Benign Hyperplasia and Cystic Hyperplasia

Definition

I. Benign prostatic hyperplasia (BPH) is a nonmalignant enlargement of the prostate from excessive cellular growth of the glandular and stromal elements.
   A. BPH is the most common prostatic disorder in the dog.
   B. All dogs with normal testes develop histologic evidence of BPH with aging, but most dogs are asymptomatic (Berry et al., 1986).
II. Cystic hyperplasia of the prostate is the formation of multiple fluid-filled cavities throughout the parenchyma.
III. The feline prostate does not develop age-related hyperplasia.

Causes

I. Hyperplasia occurs in two phases.
II. Benign glandular hyperplasia is characterized by an increase in the amount and size of secretory epithelium.
   A. Condition is first seen at 1 to 2 years of age.
   B. Condition is progressive for ≥10 years, and peaks at 5 to 6 years of age (Berry et al., 1986).
III. Benign complex hyperplasia is characterized by glandular hyperplasia intermingled with areas of atrophic secretory epithelium.
   A. A relative increase in the stroma occurs in the atrophic areas that is composed of collagen and muscle.
   B. Frequently, alveoli are dilated and filled with eosinophilic material.
   C. Cysts can be present anywhere in the gland but are most often found in the periurethral area.
   D. Chronic inflammation and squamous metaplasia of the epithelium may also be present.
   E. BPH begins at 2 to 3 years of age and continues to increase with age, reaching a prevalence of 70% at 8 to 9 years (Berry et al., 1986).

Pathophysiology

I. Development of hyperplasia is associated with an altered androgen:estrogen ratio and requires the presence of the testes.
   A. Proposed effects of absolute or relative excess of androgens
      1. Proliferation of prostatic epithelial cells occurs.
      2. 5α-Dihydrotestosterone (DHT) within the gland probably serves as main hormonal mediator for hyperplasia.
   B. Proposed effects of absolute or relative excess of estrogens
      1. Atrophy of glandular epithelial cells
      2. Proliferation of prostatic basal cells
      3. Squamous metaplasia of epithelial ducts
      4. Enhancement of androgen receptors
   C. Increased estrogen effects: allow development of hyperplasia even as androgen production decreases with age
II. Development of cysts is usually associated with fibromuscular proliferation or squamous metaplasia.
   A. Hyperplastic or metaplastic tissue causes obstruction of excretory ducts.
   B. Despite obstruction of the ducts, secretion continues by prostatic acini, which allows fluid to accumulate, creating cysts.
III. In dogs, BPH is a diffuse process that expands away from the urethra, making dysuria an uncommon clinical sign.
IV. Secondary effects of an enlarged prostate may cause the following:
   A. Partial urinary obstruction: rare in dogs (see previous point regarding dogs)
   B. Hemorrhagic urethral discharge and hematuria from increased vascularity of the prostate
   C. Partial obstruction of descending colon, causing constipation or tenesmus
   D. Occasional perineal hernias
V. Predisposition to prostatitis may arise from decreased flow of prostatic secretions, cyst formation, and/or alteration of the composition of prostatic fluid.

Clinical Signs

I. Most dogs are asymptomatic.
II. Symptomatic dogs are alert, active, and afebrile, with one or more of the following:
   A. Tenesmus associated with defecation
   B. Hematuria and/or urethral discharge (hemorrhagic to clear or yellow) independent of urination
   C. Rarely, dysuria

Diagnosis

I. Signalment: intact, mature male dog
II. Physical examination findings
  A. Rectal palpation reveals a nonpainful, symmetrically enlarged prostate with variable consistency (normal to mildly irregular).
  B. Perineal hernia is occasionally found.
III. Laboratory findings: urine or prostatic fluid normal or mildly hemorrhagic
IV. Radiographic findings
  A. Survey abdominal radiographs may show prostatomegaly with dorsal displacement of the colon and cranial displacement of the bladder.
  B. Positive-contrast retrograde urethrography may reveal a narrowed urethra or urethroprostatic reflux.
  C. Ultrasonography shows normal to moderate enlargement that is symmetrical.
    1. Smooth margins and normal to slightly increased echogenicity
    2. Small, well-defined cysts with smooth margins
V. Definitive diagnosis
  A. Diagnosis is obtained by biopsy.
  B. Presumptive diagnosis is often made with previously mentioned diagnostic tests.
  C. Positive response to treatment helps confirm the diagnosis.

Differential Diagnosis

I. BPH accompanies most other prostatic diseases in older, intact dogs.
II. It can be difficult to distinguish from chronic prostatitis or neoplasia.
  A. With chronic prostatitis, inflammation or infection is found in the urine or prostatic samples.
  B. Prostatic neoplasia does not respond to therapy for BPH.
III. Scottish terriers have prostate glands four times larger than those of other dog breeds of similar weight and age (Kutzler and Yeager, 2005).

Treatment

I. Castration is the recommended treatment.
II. Prostatic size decreases by 50%, and clinical signs are alleviated within 3 weeks after castration (Sirinarumitr et al., 2001).
III. Medical therapies are not as effective as castration in reducing prostatic size, but they offer an alternative for owners who decline surgery.
  A. Finasteride is a 5α-reductase inhibitor that prevents conversion of testosterone to 5α-DHT and causes a dose-dependent regression in prostate size.
    1. At a dose of 1 mg/kg/day PO, prostatic size was reduced by 70% within 10 weeks (Shibata et al., 2001).
    2. At a dose of 0.1 to 0.5 mg/kg/day PO for 16 weeks, serum DHT decreased by 58% and prostatic volume and secretory function decreased by 43%, without adversely affecting semen quality (Sirinarumitr et al., 2001).
    3. Treatment is lifelong; if stopped, then the effects are reversed in <8 weeks (Kutzler and Yeager, 2005).
    4. Drug is potentially teratogenic to male fetuses if pregnant females are exposed to the drug during the first one third of gestation.
  B. Several antiandrogenic drugs (e.g., chlormadinone acetate, osaterone acetate, flutamide, megestrol acetate) are effective at reducing prostate size but can adversely affect gonadal function and are not recommended in breeding animals.
  C. Liposterolic extract of the saw palmetto plant berries or the American dwarf palm tree *(Serenoa repens)* has had little effect in dogs (Barsanti et al., 2000).
  D. Estrogens have historically been used to treat BPH; however, because of the risk of myelosuppression and prostatic abscess formation, they are no longer recommended.

Monitoring of Animal

I. If the dog is asymptomatic and castration is declined, watch for the development of typical clinical signs and perform a rectal examination at every physical examination.
II. If the dog is symptomatic, palpate the prostate gland 3 weeks after castration to be sure that the gland is involuting as expected.
III. Failure of involution after surgery may indicate a more serious prostatic disease, such as neoplasia or prostatitis.
IV. If medical therapy is chosen, monitor for changes in prostatic size and for the development of adverse effects secondary to drug therapy.

Prostatic Cysts

Definition and Causes

I. Prostatic and paraprostatic cysts are single or multiple, epithelial-lined, fluid-filled (serosanguineous) structures.
II. Prostatic cysts can vary tremendously in number, size, and location.
  A. Small cysts may be present in a hyperplastic gland (see previous discussion under Cystic Hyperplasia).
  B. Prostatic retention cysts most likely develop secondary to obstruction of parenchymal ducts, resulting in accumulation of prostatic secretions.
    1. They can be very large but are intimately associated with the prostate.
    2. They may also connect to the urethra (Olson et al., 1987; White, 2000).
  C. In the past, researchers believed that paraprostatic cysts resulted from accumulation of fluid within remnants of the Müllerian duct (uterus masculinus).
    1. More recently, researchers theorize that paraprostatic cysts have the same origin as retention cysts (Olson et al., 1987; White, 2000).
    2. These cysts can be very large but are located outside the prostatic parenchyma, attached to the prostate via a stalk, and do not connect with the urethra.

Pathophysiology

I. Large cysts may impinge on the colon, urethra, or other abdominal organs.
II. Infection may occur secondary to prostatitis and urethral or iatrogenic contamination.
III. Mineralization of paraprostatic cysts has been reported (Head and Francis, 2002).

Clinical Signs

I. Cysts may produce no clinical signs until their size is sufficient to affect other structures, such as the urethra (dysuria) or colon (tenesmus or constipation).
II. Abdominal or perineal distention can develop secondary to a mass effect.
III. Infected cysts may cause hematuria, pyuria, and dysuria.

Diagnosis

I. Signalment
  A. Intact, mature male dog
  B. Rarely, male cats (Newell et al., 1992)
II. Physical examination findings
  A. Paraprostatic cysts may be palpable in the caudal abdomen or perineal area.
  B. With intraprostatic cysts, rectal palpation may reveal mild or marked enlargement of the prostate, with or without asymmetry.
  C. Fluctuant areas may or may not be palpable.
  D. Calcified cysts feel firm.
III. Laboratory test results
  A. Submit urine, prostatic wash fluid, or ejaculate for analysis and culture.
  B. Results may show hemorrhage and/or infection if communication between the cyst and the urethra exists.
IV. Prostatic fluid analysis
  A. Samples are often obtained via ultrasonography or surgery.
  B. Fluid is usually yellow to turbid and brown in color.
  C. It may reveal low numbers of white blood cells, variable numbers of red blood cells and epithelial cells, and is usually sterile.
  D. If infected, then the cyst is classified as an abscess.
V. Radiographic findings
  A. Survey abdominal radiographs may show asymmetrical prostatomegaly, two bladderlike structures, and possibly mineralization within the cyst.
  B. Positive-contrast retrograde urethrography may reveal a narrowed urethra and/or increased urethroprostatic reflux, and contrast may enter the cyst if communication with the urethra exists.
  C. Ultrasonography shows a fluid-filled cyst inside or outside of the parenchyma.
VI. Definitive diagnosis: exploratory laparotomy, excision, biopsy

Differential Diagnosis

I. Prostatic cysts are often associated with other prostatic diseases (BPH, prostatitis, neoplasia) that may coexist or contribute to cyst formation.
II. Without surgery, prostatic abscesses may be impossible to differentiate from an infected prostatic cyst.

Treatment

I. Recommended treatment is surgical drainage, with excision or omentalization (White, 2000).
II. Castration is also recommended to help prevent further cyst formation and other prostatic diseases.

Monitoring of Animal

I. Treat other coexisting prostatic diseases as indicated.
II. If infection is present, follow the recommendations under Prostatic Abscessation in the following section.

INFLAMMATORY DISEASES

Prostatitis and Prostatic Abscessation

Definition

I. Prostatitis is inflammation of the prostatic parenchyma in response to infection; it may be acute or chronic in nature.
II. Acute or chronic prostatitis may lead to encapsulation of infected material and cavitation within the prostate, thus forming a prostatic abscess.

Causes

I. Route of infection is usually ascending through the urethra.
II. Hematogenous spread or spread of infection from the kidneys, bladder, testes, or epididymis is also possible.
III. Causative organisms are usually those that are common in urinary infection, such as *Escherichia coli* (most common), *Staphylococcus* spp., *Klebsiella* spp., *Pseudomonas* spp., *Proteus* spp., *Streptococcus* spp., *Enterococcus* spp., and *Mycoplasma* spp. (Krawiec and Helfin, 1992; Klausner et al., 1995).
  A. *Brucella canis* may infect the canine prostate but is more commonly associated with testicular infection.
  B. Infection by anaerobic bacteria and fungi *(Blastomyces dermatitidis*, *Cryptococcus neoformans*, *Coccidioides immitis)* is rare.
IV. Prostate is predisposed to infections via several mechanisms.
  A. Urethral diseases: urolithiasis, neoplasia, strictures, congenital abnormalities
  B. Prostatic diseases: BPH, cyst formation, neoplasia, squamous metaplasia
  C. Urinary tract infections (UTIs)
  D. Impaired host immunity: drugs (corticosteroids, chemotherapy), disease (diabetes mellitus, hyperadrenocorticism)

Pathophysiology

I. Acute prostatitis
  A. Mild prostatic enlargement occurs unless coexisting prostatic disease exists.
  B. Acute prostatitis may result in systemic illness (septicemia) via hematogenous spread of infection or a secondary peritonitis.

II. Chronic prostatitis
  A. Mild prostatic enlargement occurs unless coexisting prostatic disease exists.
  B. It may develop secondary to an acute infection or progress gradually over time.
  C. The prostate may serve as a nidus of infection for the urinary tract.
  D. Chronic prostatitis is the second most common prostatic disorder in intact male dogs and may be the most common one associated with clinical signs (Krawiec and Helfin, 1992).
III. Prostatic abscessation
  A. Abscesses may form secondary to chronic infection and subsequent accumulation of pockets of purulent material.
  B. They may also form from acute infection of preexisting cysts.
  C. Abscesses may become quite large and rupture, leading to peritonitis.

Clinical Signs

I. Acute prostatitis
  A. Urinary tract signs: hematuria, pyuria, dysuria, urethral discharge (hemorrhagic or purulent), and/or urinary incontinence
  B. Constipation, tenesmus
  C. Pain: reluctance to rise, stiff gait, arched back, tensed abdomen
  D. Systemic signs: fever, anorexia, depression, tachycardia, vomiting
II. Chronic prostatitis
  A. Recurrent or chronic UTIs, urethral discharge, and/or hematuria
  B. Constipation, tenesmus
  C. Infertility
III. Prostatic abscess
  A. Signs are similar to those for either acute or chronic prostatitis, because abscessation is associated with prostatitis.
  B. With rupture of the abscess and subsequent peritonitis, the following may occur:
    1. Acute abdominal pain, fever, vomiting, lethargy
    2. Septic shock with tachycardia, icterus, injected or pale mucus membranes, collapse

Diagnosis

I. Acute prostatitis
  A. Signalment: intact, mature male dog
  B. Physical examination findings
    1. Rectal palpation commonly reveals prostatomegaly from coexisting disease (BPH, cysts, neoplasia).
    2. Pain and/or urethral discharge may be elicited on palpation.
  C. Laboratory results
    1. Neutrophilic leukocytosis often exists, with or without a left shift.
    2. Azotemia, electrolyte disturbances, or hemoconcentration may be seen if a systemic illness is present.
    3. Hematuria, pyuria, and bacteriuria are common.
    4. Urine culture results may be positive if concomitant UTI exists.
  D. Prostatic fluid analysis
    1. Samples are difficult to obtain (because of pain) and difficult to interpret when a concomitant UTI is present.
    2. If samples are obtained, then cytology shows evidence of inflammation and infection.
  E. Radiographic findings
    1. Survey abdominal radiographs may show prostatomegaly and/or loss of detail in the area of the prostate suggestive of local peritonitis.
    2. Positive-contrast urethrography may reveal urethroprostatic reflux.
    3. Ultrasonography may show a focal to diffuse increase in echogenicity of the prostate gland.
  F. Definitive diagnosis
    1. Requires biopsy and culture of prostatic tissue (not usually performed).
    2. Positive response to treatment helps confirm the diagnosis.
II. Chronic prostatitis
  A. Signalment: intact, mature male dog; rarely, male cats (Roura et al., 2002)
  B. Physical examination findings
    1. Rectal palpation commonly reveals prostatomegaly from coexisting disease (hyperplasia, cysts, or neoplasia).
    2. Prostate may be small and irregular, especially with significant fibrosis and loss of tissue.
  C. Laboratory findings
    1. Hematuria, pyuria, and bacteriuria are common.
    2. Urine cultures may be positive if a concomitant UTI exists.
  D. Prostatic fluid analysis
    1. Fluid collected by ejaculation is usually purulent, septic, and may also be hemorrhagic.
    2. Quantitative culture of urine and prostatic fluid yields significant numbers of the same organisms.
      a. Dogs with experimental chronic bacterial prostatitis had >1000 organisms/mL (Barsanti et al., 1983).
      b. Establishing a definitive number of bacteria to differentiate infection from contamination is difficult.
    3. Samples collected by ejaculation are preferred over prostatic wash samples.
      a. Prostatic wash samples are difficult to interpret because of the large number of bacteria present in the urinary tract.
      b. If prostatic wash samples are used, then the UTI must be controlled first.
    4. Ultrasound-assisted aspiration may also be used to obtain samples if cysts are present.
  E. Radiographic findings
    1. Survey abdominal radiographs may show prostatomegaly and/or intraprostatic mineralization.

2. Positive-contrast urethrography may reveal urethroprostatic reflux.
3. Ultrasonography may show multifocal mineralization.

F. Definitive diagnosis: prostatic tissue culture and histopathology

III. Prostatic abscess
A. Signalment: intact, mature male dog
B. Physical examination findings
1. Rectal palpation commonly reveals dramatic prostatomegaly, with marked asymmetry.
2. Pain and/or urethral discharge are often elicited on palpation.
C. Laboratory results
1. Neutrophilic leukocytosis with a left shift often exists.
2. Azotemia, electrolyte disturbances, or hemoconcentration may be seen if systemic illness is present.
3. Elevated liver enzymes, hyperbilirubinemia, and hypoglycemia may be seen with sepsis.
4. Hematuria, pyuria, and bacteriuria are common.
5. Urine culture is positive if a concomitant UTI exists.
D. Prostatic fluid analysis
1. Samples are often obtained via ultrasonography or surgery.
2. When obtained, the fluid is usually purulent and septic.
E. Radiographic findings
1. Survey abdominal radiographs show prostatomegaly.
2. Loss of detail in the area of the prostate or diffuse loss of detail is seen with peritonitis.
3. Intraprostatic mineralization may be present.
4. Positive-contrast urethrography may reveal periurethral asymmetry, narrowing of the prostatic urethra, and contrast medium entering the abscess if communication with the urethra is present.
5. Ultrasonography shows an asymmetrical prostate that is hyperechoic, with fluid-filled cavitations.
F. Definitive diagnosis
1. Diagnosis is made with ultrasound-guided aspiration and/or surgical exploration.
2. At surgery, samples are obtained for histopathology and culture (aerobic and anaerobic).

Differential Diagnosis

I. For acute prostatitis, consider the following:
A. Major differential considerations are prostatic neoplasia, prostatic abscess, and pyelonephritis.
B. All can induce a painful abdomen, signs of inflammation on laboratory tests, and systemic illness.

II. For chronic prostatitis, considerations are prostatic neoplasia and other causes of chronic UTI.

III. Prostatic abscessation, neoplasia, and paraprostatic cysts all cause marked prostatic enlargement.

Treatment

I. Acute prostatitis
A. Antibiotics (based on culture results) are given for at least 4 weeks.
1. Initially, all antibiotics reach the prostate because the blood-prostate barrier is not intact.
2. IV antibiotics may be ideal initially, but an oral antibiotic with prostatic penetration is preferred to finish the therapy (see Chronic Prostatitis, following).
B. Castration is not helpful immediately and may be dangerous in a systemically ill animal.
C. After stabilization, castration helps resolve the current infection and assists in preventing future infections.

II. Chronic prostatitis
A. Antibiotic that penetrates the blood-prostate barrier must be chosen if therapy is to be successful.
1. Enrofloxacin (5 to 10 mg/kg PO SID), chloramphenicol (25 to 50 mg/kg PO TID), clindamycin (5 to 11 mg/kg PO BID), erythromycin (10 to 22 mg/kg PO TID), trimethoprim-sulfonamide (15 to 30 mg/kg PO BID), and doxycycline (4.4 to 11 mg/kg PO BID) all penetrate the prostate (Greene et al., 2006).
2. Ciprofloxacin and norfloxacin do not concentrate in the prostate (Dorfman et al., 1995).
B. Antibiotics are continued for at least 6 to 8 weeks.
C. Castration may be beneficial in the resolution of chronic bacterial prostatitis.
1. In one study, castrated dogs cleared the infection in 4.2 weeks, compared with 9.5 weeks for intact dogs (Cowan et al., 1991).
2. Castration may also help prevent future infections and relapses.

III. Prostatic abscess
A. Surgery is the treatment of choice.
1. Current recommendation is intracapsular prostatic omentalization (White, 2000).
a. Most animals can be discharged from the hospital within 24 hours.
b. Complications include recurrence and urinary incontinence.
2. Castration is also recommended to help with involution of the prostate and to lessen the likelihood of recurrence.
3. Other surgeries (e.g., ventral drainage, prostatic marsupialization, and prostatectomy) are no longer recommended because of increased recurrence and complication rates, as well as prolonged recovery times.
B. Antibiotics, based on culture results, are given for at least 6 to 8 weeks.
1. Initially all antibiotics reach the prostate because the blood-prostate barrier is not intact.
2. IV antibiotics may be ideal to start, but an oral antibiotic with prostatic penetration is preferred to finish the therapy (see previous discussion under Chronic Prostatitis).
C. Nonsurgical methods of treatment have variable efficacy.
1. Antibiotic therapy in conjunction with castration has not been effective at resolving most prostatic abscesses (White, 2000).

2. Percutaneous, ultrasound-guided drainage followed by alcoholization of the cavity was effective at resolving a prostatic abscess in one dog (Kutzler and Yeager, 2005).

Monitoring of Animal

I. Acute prostatitis
   A. Physical examination and cytology and culture of urine and/or prostatic fluid are performed 7 days after finishing antibiotics.
   B. If any evidence of persistent infection is seen, antibiotics are continued for another 6 to 8 weeks (and the condition is treated as chronic prostatitis).
II. Chronic prostatitis
   A. Physical examination and cytology and culture of urine and/or prostatic fluid are performed at the following times:
      1. After 3 to 4 weeks of antibiotic therapy
      2. Seven days after finishing antibiotic therapy
      3. Monthly for 2 to 3 months after finishing antibiotic therapy
   B. Relapses are common within a few months after discontinuing antibiotics.
   C. If the initial therapy fails, then longer courses of antibiotics (12 weeks) must be given.
III. Prostatic abscess
   A. Repeated examinations are as outlined for chronic prostatitis.
   B. In addition, ultrasonography is performed at the previously mentioned times until resolution of the abscess is confirmed.
   C. Reabscessation and recurrent UTIs are common.

NEOPLASIA

Definition

I. Primary prostatic neoplasia is a tumor arising from any of the cellular elements of the prostate gland.
   A. Prostatic neoplasia is the most common prostatic disease diagnosed in dogs castrated before development of clinical signs (Krawiec and Heflin, 1992).
   B. Adenocarcinoma is the most common tumor type.
   C. Transitional cell carcinoma and undifferentiated carcinomas also occur.
   D. Other primary tumors, such as leiomyosarcomas, are rare (Hayden, 1999).
II. Prostate may also be the site of metastasis of other tumors.

Causes

I. Effects of hormones and castration are still being investigated, but some conclusions are as follows:
   A. Castration does not protect against the development of prostatic carcinoma (Obradovich et al., 1987).
   B. Castration does not initiate development of prostatic carcinoma, but it does favor tumor progression (Teske et al., 2002).
II. High-grade prostatic intraepithelial neoplasia is considered to be a precursor of malignancy in dogs and humans (Cooley and Waters, 2001).
   A. Atypical lesion diagnosed on histopathology
   B. Prostatic carcinoma often accompanied by intraepithelial neoplasia

Pathophysiology

I. Local invasion of prostatic neoplasia may cause the following:
   A. Enlarged, irregular prostate gland
   B. Growth into the urethra causing dysuria or obstruction
   C. Growth into the trigone of bladder, with obstruction of ureters
   D. Outward extension that impinges on the colon and causes tenesmus and constipation
   E. Growth through blood vessels causing hematuria
   F. Obstruction of normal ducts causing cyst formation and predisposing to infection
II. Metastasis is commonly found in the regional lymph nodes and lungs.
III. Skeletal metastasis is common and frequently occurs in the lumbar vertebrae and pelvis.

Clinical Signs

I. No clinical signs may occur initially.
II. Most clinical signs are related to local effects.
   A. Hematuria, dysuria, incontinence, urethral discharge (hemorrhagic or purulent)
   B. Constipation, tenesmus
   C. Mimics other prostatic diseases
III. Signs may also be related to metastasis.
   A. Abnormal gait, myelopathic signs with skeletal metastases
   B. Dyspnea, hemoptysis, cough with pulmonary metastases
   C. Fever, anorexia, weight loss with systemic illness

Diagnosis

I. Signalment: mature, male dog (intact or castrated); rarely, male cats
II. Physical examination findings
   A. Rectal palpation usually reveals an enlarged and asymmetrical prostate, with increased firmness and obliteration of the median raphe.
   B. The prostate may be painful and/or fixed to the pelvic floor.
   C. Sublumbar lymph nodes may be palpably enlarged.
III. Laboratory results
   A. Neutrophilia, with or without a left shift, and/or a mild nonregenerative anemia may be present (Bell et al., 1991).
   B. Azotemia may occur from systemic illness and/or obstruction of urine flow.
   C. Many dogs have elevations of serum alkaline phosphatase, and only some of these have skeletal metastases (Bell et al., 1991).

D. Samples of urine, prostatic wash, or ejaculate may be hemorrhagic, show signs of inflammation, and occasionally reveal malignant cells.
E. No serum biochemical marker has been found in dogs.

IV. Radiographic findings
A. Survey abdominal radiographs may show asymmetrical prostatomegaly, intraprostatic calcification, sublumbar lymphadenopathy, and/or lytic or proliferative changes in the lumbar vertebrae, pelvis, or long bones.
B. Survey thoracic radiographs may reveal evidence of metastases.
1. Metastases appear as generalized, increased nodular-interstitial densities or single to multiple discrete nodules.
2. In one study, 38% of dogs with normal thoracic radiographs had pulmonary metastases at necropsy (Bell et al., 1991).
C. Positive-contrast retrograde urethrography may reveal a narrowed or irregular urethra and/or urethroprostatic reflux, with or without local invasion of the bladder.
D. Ultrasonography may show focal to multifocal increased echogenicity of the prostate and/or an irregular prostatic contour.
1. Focal or multifocal mineralization may also be present.
2. Other lesions may be seen from concurrent diseases (BPH, prostatitis, cyst formation).

V. Definitive diagnosis
A. Requires cytological or histopathologic examination.
B. Aspirates and/or biopsies may be obtained transabdominally, perirectally, or surgically.
C. Enlarged lymph nodes are also sampled.
D. In some cases, neoplasia and nonneoplastic disease coexist within the prostate, so neoplasia cannot be excluded if another process is found.

Differential Diagnosis

I. Prostatic neoplasia must be distinguished from BPH, prostatitis, and a prostatic abscess.
II. Because these diseases may coexist with neoplasia, a definitive diagnosis can be difficult.
III. Scottish terriers have prostate glands four times larger than those of other breeds of similar weight and age, which can be mistaken for prostatic masses (Kutzler and Yeager, 2005).

Treatment

I. Prostatectomy may be effective for local control or palliation of clinical signs.
A. Surgery is technically difficult and complications are common.
B. Laser-assisted transurethral partial resection of the prostate (TURP) may provide short-term palliation, with a median survival time of 103 days in one report (L'Eplattenier, 2006).

II. Balloon-expanding or self-expanding metallic stents may provide palliative relief of urethral obstruction from prostatic neoplasia (Weisse et al., 2006).
III. Prostatic neoplasia is considered poorly responsive to chemotherapy or radiation therapy.
IV. Intraoperative radiotherapy is the current treatment of choice for local control of prostatic adenocarcinoma.
A. Median survival of 10 dogs treated for prostatic carcinoma with radiation therapy to surgically exposed tumors was 114 days (Turrel, 1987).
B. Median survival for seven dogs with only local disease was 180 days, as compared with the median survival of 80 days in the three dogs with metastatic disease (Turrel, 1987).
C. External beam radiation therapy may be more readily available than intraoperative radiation therapy.
D. Palliative doses may have lower risk of long-term radiation side effects (urethritis, cystitis, colitis), but no reports of efficacy are available (Anderson et al., 2002).

V. Piroxicam, a cyclooxygenase inhibitor, administered at 0.3 mg/kg PO SID has been used successfully to reduce the size of several canine carcinomas (Knapp et al., 1994; Schmidt et al., 2001), and in vitro experiments suggest the drug is effective for prostatic adenocarcinomas (van der Boon, 2002).
VI. No current treatments are effective against extraprostatic metastases (Cooley and Waters, 2001).
VII. Castration has no beneficial effects on the tumor itself, but is recommended to help with concurrent diseases that contribute to the clinical signs.

Monitoring of Animal

I. Prognosis for dogs with prostatic adenocarcinoma is guarded.
II. Early cancers are seldom detected, and metastases are usually present at the time of diagnosis.
III. During treatment, the size of the prostate is monitored and urine is routinely evaluated for any secondary infections.
IV. The animal's quality of life is monitored and euthanasia must be considered at the appropriate time.

CHAPTER 54

Introduction

Ronald M. Bright

GENERAL INFORMATION

Definition

I. Reproductive problems encompass a wide variety of disorders.
II. They may result in limited or nonexistent reproductive capacity.
III. Sometimes the purposeful surgical removal of an affected organ renders the animal sterile.
  A. Reasons for surgery: inflammatory, infectious, behavioral, metabolic, hormonal, or neoplastic diseases
  B. Rationale for ovariohysterectomy: sterilization, treatment of pyometra or metritis, adjunctive therapy for mammary neoplasia, management of diabetes mellitus
  C. Rationale for castration: prostatitis, prostatic abscessation
  D. Prevention of (or treatment for) tumors that are influenced by reproductive hormones
    1. Dogs: perianal adenomas, tumors of the testes
    2. Dogs and cats: mammary neoplasia
IV. Some reproductive problems are congenital diseases.
  A. Testicular hypoplasia, cryptorchidism (see Chapter 56)
  B. Vaginal hymen membrane remnants or hypoplasia, double vagina, blind-ending vaginal pouch (see Chapter 58)
  C. Persistent penile frenulum, paraphimosis, phimosis, preputial abnormalities (see Chapter 59)
V. Various reproductive disorders may respond to medical management.
  A. Dystocia
  B. Pyometra
  C. Infertility
  D. Neoplasia
  E. Inflammatory conditions

Diagnosis

I. History, clinical signs
II. Physical examination
  A. Rectal palpation
  B. Vaginal examination
  C. Abdominal palpation
  D. Thorough mammary evaluation
III. Clinicopathologic data: complete blood count, biochemistry profile
IV. Cytology of vaginal smears, prostatic washes, fine-needle aspirates of tumors
V. Diagnostic imaging
  A. Radiography
    1. Staging neoplastic disease: abdominal, thoracic, osseous
    2. Contrast cystourethrogram
    3. Contrast vaginography
  B. Ultrasonography
  C. Computed tomography, magnetic resonance imaging
  D. Bone scans
VI. Endoscopy
VII. Hormonal assays

NEWER CLINICAL APPROACHES

I. Male genitalia (see Chapter 59)
  A. Inguinal retained testes are more common than abdominal testes.
  B. Preventing recurrence of paraphimosis may be achieved with a phallopexy.
II. Feline reproductive disorders (see Chapter 62)
  A. Intravaginal and transcervical insemination is successful, but surgical insemination appears to be superior with respect to rates of pregnancy.

B. Housing the tom and queen together only at the time of breeding may enhance the tom's ability to successfully impregnate the queen.
C. Inability of the tom to complete copulation may result in the need for artificial insemination.

III. Uterine disorders (see Chapter 57)
A. Progesterone receptor blockers not yet available in the United States may be safe and effective treatments for pyometra.
B. Research has shown that the efficacy of prostaglandin $F_2\alpha$ in treating pyometra is related to the status of the cervix (open versus closed).

IV. Mammary gland diseases (see Chapter 60)
A. Metoclopramide appears to have some influence on promoting lactin secretion, so it may be helpful for agalactia.
B. Agalactia and galactostasis are now considered separate entities, and therapeutic decisions must be based on the correct diagnosis.
C. Influence of the time of spaying in dogs with mammary neoplasia is further defined with respect to survival.
D. Mammary duct ectasia is described as a separate entity.

RECENT ADVANCES

I. Mammary neoplasia
A. Possible use of piroxicam and meloxicam as antineoplastic agents (Knottenbelt et al., 2006)
B. Review of mammary tumors in the female dog (Hellmen, 2005)
C. Incidence of mammary tumors and survival of female dogs in a large population in Sweden (Egenvall et al., 2005)
D. Genetic links for mammary cancer in beagles (Lloyd et al., 2005)
E. Role of steroid hormones and prolactin in canine mammary cancer (Queiroga et al., 2005)
F. Relationship between dysplastic and neoplastic mammary lesions and pseudopregnancy in the bitch (Veronesi et al., 2003)
G. Histological grading and prognosis for dogs with mammary carcinomas (Karayannopoulou et al., 2005)

II. Reproductive problems
A. Relationship of urinary incontinence to early spaying in bitches (Stocklin-Gautschi et al., 2001)
B. Comparison of laparoscopic ovariohysterectomy and standard ovariohysterectomy in dogs (Davidson et al., 2004)
C. Neodymium:yttrium-aluminum-garnet surgical laser versus bipolar electrocoagulation for laparoscopic ovariectomy in dogs (Van Nimwegen et al., 2005)
D. Cryopreservation of canine ovaries (Ishijimai et al., 2006)

CHAPTER 55

Diseases of the Ovary

Lisa M. Howe

CYSTIC OVARIAN DISEASE

Definition and Cause

I. Ovarian cysts are fluid-filled cavities within the ovaries of dogs and cats.
II. Exact cause of most cysts is unknown.

Pathophysiology

I. Follicular cysts represent failure of fluid to be absorbed from an incompletely developed follicle.
II. Cysts may be small (diameter <1 cm) or large (diameter >10 cm).
III. Functional cysts may produce estrogen and progesterone.

Clinical Signs

I. Most cats and dogs show no clinical signs or reproductive abnormalities.
II. Clinical signs of ovarian cysts are related to excess sex hormone secretion by the cyst or decreased function of the remaining ovarian tissue.
III. Persistent estrus is commonly observed.
  A. In the bitch, the duration of estrus is typically 5 to 9 days and is considered abnormal if it lasts longer than 3 weeks.
  B. Continuous secretion of estrogen by follicular cysts or by functional ovarian tumors may be the cause.
  C. Prolonged behavior consistent with estrus or a persistent hemorrhagic vaginal discharge may be noted.
  D. Prolonged proestrus behavior without sexual receptivity can also occur.
IV. Persistent anestrus may also be seen.
  A. Increased interestrous interval or persistent anestrus is a common clinical sign with follicular and luteinized cysts.
  B. With nonfunctional follicular cysts, persistent anestrus is probably the result of a decrease in the surrounding functional ovarian tissue from a mass effect as the cyst enlarges.
  C. Prolonged progesterone secretion from luteinized cysts results in persistent anestrus.
V. Persistent nonseasonal estrus can occur in older queens with cystic follicular hyperplasia.
VI. Occasionally, very large ovarian cysts result in a palpable abdominal mass.
VII. Dogs and cats with functional follicular cysts are at risk for cystic endometrial hyperplasia and pyometra complex because of estrogen-induced endometrial changes.

Diagnosis

I. Most ovarian cysts do not result in clinical signs, and diagnosis occurs incidentally at ovariohysterectomy (OHE).
II. Vaginal cytology is performed to confirm persistent estrus.
III. Plasma estrogen concentrations may confirm excess serum estradiol secretion.
  A. Normal levels in the bitch are <15 pg/mL for anestrus and 15 to 100 pg/mL for proestrus; however, normal concentrations may vary greatly in different laboratories (Susaneck and Cain, 1997).
  B. With follicular cysts, estrogen concentrations are often similar to those occurring during proestrus.
  C. Normal estrogen concentrations do not rule out functional ovarian cysts.
  D. In cats, follicular cysts also result in elevated (>20 pg/mL) estrogen concentrations.
IV. Abdominal radiography may be helpful in identifying very large cysts.
V. Abdominal ultrasonography helps identify cystic ovarian structures, but cannot definitively identify normal from abnormal cystic structures.
VI. Surgical exploration with histopathology provides a definitive diagnosis.

Differential Diagnosis

I. Ovarian neoplasia or neoplasia of kidneys or adrenals
II. Polycystic kidneys
III. Ovarian neoplasia
IV. Midabdominal masses of other organs
V. Overlapping periods of follicular activity in queens that result in persistent estrus

Treatment

I. Many follicular cysts resolve spontaneously in a few months without treatment.
II. OHE is the treatment of choice for nonbreeding animals and is curative.
III. Medical management has limited success.
  A. In breeding bitches, pharmacologic agents may be used to induce luteinization of cysts.

1. Gonadotropin-releasing hormone (GnRH) 50 to 100 μg IM SID for one to three treatments
2. Human chorionic gonadotropin (HCG) 22 IU/kg IM (may be repeated once 48 hours later) (Davidson and Feldman, 2004)

B. Positive response to medical management is termination of estrus behavior or a decrease of estrogen and an increase of progesterone serum concentrations.
C. Within 2 to 3 weeks the animal completely ceases sexual activity.

IV. Because follicular cysts may spontaneously undergo atresia, not all bitches require treatment.

Monitoring of Animal

I. Bitches treated with GnRH or HCG are at risk for pyometra.
II. They must be monitored closely for 60 to 90 days after treatment (luteal phase).
III. Monitoring of morphology with ultrasonography shows regression of hypoechoic structures.

OVARIAN REMNANT SYNDROME

Definition

I. Ovarian remnant syndrome is the presence of functional ovarian tissue in the abdomen after OHE in dogs and cats.
II. Signs of proestrus, estrus, and (rarely) false pregnancy may occur from persistent production of estrogen and progesterone.

Causes and Pathophysiology

I. Ovarian remnant syndrome occurs after routine OHE.
II. Incomplete removal of all ovarian tissue results from inappropriate surgical techniques.

Clinical Signs

I. Ovarian remnant syndrome causes signs of proestrus and estrus.
II. Syndrome may occur days to years after OHE.
III. Signs of false pregnancy with lactation rarely occur and are more commonly seen in the dog than in the cat.

Diagnosis

I. Vaginal cytology during proestrus or estrus is the easiest (and least expensive) method to diagnose ovarian remnant syndrome.
   A. Elevated serum estrogen concentrations result in cornification of vaginal epithelial cells.
   B. Exogenously administered estrogen, such as diethylstilbestrol, can also cause vaginal cytology changes consistent with ovarian remnant syndrome; therefore clinicians should question owners about exogenous sources of estrogen.
II. Hormonal assays may be helpful in making the diagnosis.
   A. Resting serum estradiol concentrations may be measured, but timing and interpretation are critical when using single samples.
      1. In the bitch the sample is collected during proestrus because estrogen levels peak toward the end of proestrus and then rapidly decline.
      2. Serum estradiol concentration >20 pg/mL is consistent with follicular activity (Wallace, 1992).
      3. In the queen the sample is collected during estrus behavior, although some queens will continue to exhibit signs of estrus for several days after the serum estradiol levels have decreased.
      4. Resting estradiol assays are unreliable because the assays are affected by serum lipids, the rise in estradiol may be transient, and the low concentrations of estradiols that occur in dogs and cats may be below the sensitivities of certain assays (Wallace, 1992).
   B. Serum progesterone assays are more useful (especially in bitches) than estradiol assays.
      1. In bitches, the sample is collected in early diestrus or 1 to 3 weeks after completion of estrus.
      2. Serum progesterone values >2 ng/mL are consistent with the presence of an ovarian remnant (Johnston et al., 2001).
      3. In cats the test is not useful as a diagnostic tool because the cat is an induced ovulator, and no detectable rise in serum progesterone may occur.
   C. Hormone challenge tests can be used.
      1. Challenge testing is the best way to use the serum progesterone assay to confirm the presence of ovarian tissue in the cat.
      2. Administration of a gonadotropin that mimics the luteinizing hormone surge causes the follicles to ovulate, luteinize, and secrete progesterone.
      3. HCG is given during behavioral and cytologic estrus at 44 IU/kg IM in dogs and 250 IU IM in cats.
      4. GnRH is an alternative to HCG.
         a. It is administered during behavioral and cytologic estrus.
         b. Dose in dogs is 2.2 μg/kg IM and the dose in cats is 25 μg IM.
      5. With HCG or GnRH stimulation tests, poststimulation progesterone concentration >2 ng/mL confirms the presence of functional ovarian tissue.
   D. In many instances, the diagnosis is made during exploratory laparotomy.

Differential Diagnosis

I. Owner confusion about reproductive status of animal (intact versus neutered)
II. Vaginitis, vaginal neoplasia
III. Causes of hematuria
IV. Uterine stump pyometra
V. Trauma
VI. Coagulopathy

Treatment

I. Surgical exploration with excision of the remnant tissue is the treatment of choice.
II. Delay surgery until the animal is in estrus (for easier identification of the remnant).

III. Submit all excised tissue for histologic evaluation.
IV. Clinical signs resolve within days of removal of the ovarian remnant.

Monitoring of Animal

I. The animal is carefully monitored for any recurrent signs of proestrus or estrus.
II. Absence of such signs confirms resolution of the problem.

NEOPLASIA

Definition

I. Tumors may occur in the ovaries of dogs and cats, but they are rare.
II. They include granulosa cell tumors, thecal cell tumors, adenocarcinomas, adenomas, teratomas, dysgerminomas, leiomyomas, fibromas, and metastatic carcinomas and sarcomas.

Causes and Pathophysiology

I. Most ovarian tumors are of unknown cause.
II. Experimental administration of diethylstilbestrol in young dogs has produced malignant adenocarcinomas of the ovaries.
III. Sex-cord stromal tumors are composed of granulosa or thecal cells and are the functional counterpart to Sertoli's cell tumors in males.
  A. Granulosa cell tumors
    1. They occur frequently in the bitch and are the most common ovarian tumor in the queen.
    2. English bulldogs are at increased risk for development.
    3. They are often large, unilateral tumors that may be palpable.
    4. They are malignant in the cat but are often benign in the dog, with metastasis occurring in only 10% to 25% of cases (Johnston et al., 2001).
  B. Thecomas and luteomas
    1. Rarely occur
    2. May be found in combination with granulosa cell tumors
IV. Three important epithelial tumor types exist.
  A. Papillary adenoma
    1. Benign tumor that often occurs bilaterally
    2. One of the most common ovarian tumors in the bitch
  B. Cystadenoma
    1. Less common benign tumor
    2. Consists of multiple cysts
  C. Adenocarcinoma
    1. Malignant tumor that may occur bilaterally
    2. Most common malignant tumor of the ovary of the bitch
    3. May metastasize through the ovarian bursa into the abdominal cavity, as well as to regional lymph nodes and distant sites
    4. Peritoneal effusion possible from abdominal cavity metastasis
V. Two germ cell–origin tumors are of importance.
  A. Teratomas
    1. Large, palpable unilateral tumors that may result in abdominal enlargement
    2. Often benign and well-differentiated, containing multiple tissue types (e.g., hair, bone, cartilage, epithelium, or nervous tissue)
  B. Dysgerminomas
    1. Rare, large, unilateral tumors of primordial germ cells of the ovary
    2. Metastasis unusual (10% to 20% of cases) (Johnston et al., 2001)
VI. Miscellaneous ovarian tumors include leiomyomas, fibromas, and metastatic tumors from other locations.

Clinical Signs

I. Possibly no signs with many benign ovarian tumors (unless very large)
II. Granulosa and thecal cell tumors
  A. They may produce abdominal enlargement and a palpable abdominal mass.
  B. Clinical signs of endocrine disease occur with tumor production of estrogen and progesterone.
  C. Irregular or persistent signs of estrus, vulvar enlargement, nipple enlargement, and alopecia may also occur.
  D. High levels of estrogen may result in bone marrow hypoplasia and bleeding diatheses.
  E. Cystic endometrial hyperplasia and pyometra complex are possible.
III. Ovarian adenocarcinoma
  A. Vaginal bleeding unrelated to estrous cycles may occur.
  B. Tumor rupture may result in seeding of the abdomen with tumor cells.
    1. Tumor cells may implant on the diaphragm, omentum, mesentery, lymph nodes, or other abdominal organs.
    2. Ascites and abdominal enlargement often result.
IV. Teratomas and dysgerminomas
  A. They are often asymptomatic unless they become very large.
  B. With large tumors, clinical signs may include abdominal enlargement, lethargy, depression, anorexia, intestinal obstruction, and bloody vaginal discharge.

Diagnosis

I. Midabdominal mass may be found with abdominal palpation.
II. Abdominal radiography may identify or confirm an abdominal mass.
III. Abdominal ultrasonography is useful in determining the origin of the mass.
IV. Fluid analysis of ascitic fluid may be performed.
V. Exploratory laparotomy with histopathology is often necessary for a definitive diagnosis.

Differential Diagnosis

I. Ovarian cysts
II. Renal tumors or cysts

III. Other tumors of abdominal organs
IV. Other causes of neoplastic effusions or ascites

Treatment

I. OHE is the treatment of choice.
II. Treatment may be curative for certain tumor types if metastasis has not occurred.

Monitoring of Animal

I. Monitoring for evidence of metastasis is indicated with malignant ovarian tumors.
II. Physical examination and thoracic and abdominal radiography (or abdominal ultrasonography) are performed every 3 months to monitor for recurrence or metastasis.

CHAPTER 56

Diseases of the Testes and Epididymides

Harry W. Boothe

CONGENITAL/DEVELOPMENTAL DISORDERS

Anorchism and Monorchism

Definition and Clinical Signs

I. Anorchism is the congenital absence of both testes.
II. Monorchism is the absence of one testicle and usually involves the left testis (Johnston and Archibald, 1984).

Diagnosis

I. Diagnosis is made by careful palpation of the scrotum and inguinal region, followed by exploratory celiotomy.
II. Search the abdomen thoroughly to establish the lack of one or both testes, epididymides, and ductus deferentes.

Differential Diagnosis

I. Cryptorchidism
II. Testicular hypoplasia

Treatment

No treatment is available.

Testicular Hypoplasia

Definition and Causes

I. Testicular hypoplasia results from abnormal development of the seminiferous tubular germinal epithelium (Soderberg, 2000).
II. It may be unilateral or bilateral.
III. Some dogs with testicular hypoplasia exhibit signs of feminization.

Clinical Signs

I. Hypoplastic testes are usually freely movable within the scrotum and may be difficult to palpate, particularly in the obese animal.
II. Hypoplastic testes are usually normal or soft in consistency.
III. When accompanied by excessive connective tissue, however, the hypoplastic testis is firmer than normal (Ladds, 1993).

Diagnosis

The diagnosis is based on the previously mentioned clinical signs and physical examination findings.

Differential Diagnosis

I. Anorchism, monorchism
II. Cryptorchidism

Treatment

Treatment is orchidectomy.

Cryptorchidism

Definition

Cryptorchidism is a failure of one or both testes to descend into the scrotum at the usual time.

Causes and Clinical Signs

I. Testicular descent usually occurs at birth, although it may occur normally at any time up to 6 months of age (Dunn et al., 1968).
II. Cryptorchidism may be unilateral or bilateral, and the position of the ectopic testis may be prescrotal, inguinal, or abdominal.
   A. Unilateral cryptorchidism is most common, with the right testis being more commonly affected in dogs (Dunn et al., 1968; Yates et al., 2003).
   B. Inguinal ectopic testes are more common than abdominal ectopic testes (Yates et al., 2003).
   C. Dogs have a reported prevalence of 0.8% to 10% (Reif and Brodey, 1969).
   D. Cats have a reported prevalence of 0.4% to 2% (Millis et al., 1992).
III. The ectopic testis has endocrine function, but not exocrine function.
   A. Secondary sexual characteristics develop, even in the bilateral cryptorchid.
   B. Unilateral cryptorchidism results in disturbed scrotal testicular function (Kawakami et al., 1988).

Diagnosis

I. Ectopic testes, particularly intraabdominal testes, are more susceptible to torsion and neoplasia than descended testes (Pearson and Kelley, 1975; Cox et al., 1978).
   A. Presumably, the ectopic position allows greater movement of the testis than is possible in the scrotum (Pearson and Kelly, 1975).

B. Cryptorchid dogs have a 13.6 times greater risk of testicular tumors than normal dogs (Hayes and Pendergrass, 1976).
C. Approximately 50% of Sertoli's cell tumors and 33% of seminomas occur in cryptorchid testes, compared with 10% and 12%, respectively, in breed-matched noncryptorchid control dogs (Cox et al., 1978).
D. Neoplasms of ectopic testes are also observed at a younger age than neoplasms of descended testes.

II. Diagnosis, particularly in a young pup or kitten, may be difficult.
A. Scrotal testes are difficult to palpate because of their small size, especially in the obese pup.
B. Testes may freely move between the scrotum and inguinal region.
C. Extraabdominal ectopic testes can often be palpated; however, only enlarged intraabdominal ectopic testes are palpable.

III. Commonly affected breeds are the boxer, Chihuahua, German shepherd dog, miniature schnauzer, Pomeranian, poodle, Shetland sheepdog, Siberian husky, Yorkshire terrier, and Persian cat (Yates et al., 2003).
IV. Small breeds have a 2.7 times greater risk of cryptorchidism than other breeds (Pendergrass and Hayes, 1975).
V. The higher risk of neoplasia in cryptorchid testes justifies bilateral orchidectomy (Burke and Reynolds, 1993).

Differential Diagnosis

I. Anorchism, monorchism
II. Testicular hypoplasia
III. Palpably small but descended testis

Treatment and Monitoring

I. Technique for removal of the cryptorchid testis varies with its location.
A. Remove the extraabdominal ectopic testis by the usual technique, except make the skin incision directly over the testis.
B. Approach abdominal testes in the dog from a paraprepatial skin and ventral median abdominal incision.
C. Make a caudal ventral midline incision in the cat (Millis et al., 1992).
D. Locate the ectopic testis by tracing the ductus deferens from its prostatic termination to the testis.

II. Prognosis after cryptorchid castration is generally good, although inadvertent prostatectomy has been identified as a complication (Schulz et al., 1996).

INFLAMMATORY DISORDERS

Orchitis and Epididymitis

Definition

I. Orchitis is inflammation or infection of the testis.
II. Infection of the testis is frequently accompanied by epididymitis.

Causes and Pathophysiology

I. Testicular infection occurs most commonly by reflux along the ductus deferens from the urinary tract or prostate, although infection via the hematogenous route or local extension (penetrating scrotal wounds) is also possible (Johnston and Archibald, 1984; Ladds, 1993).
II. Frequently found bacterial organisms include *Escherichia coli*, *Staphylococcus* spp., *Streptococcus* spp., and *Mycoplasma* spp. (Flanders et al., 2000).
III. Orchitis may occur with *Brucella canis* infections (George et al., 1979).
IV. Epididymitis can result from an ascending infection of the genital tract, canine distemper virus, or a hematogenous infection (particularly *B. canis*).
V. Canine distemper virus produces cytoplasmic and intranuclear inclusions in the epididymal epithelial cells (Ladds, 1993).

Clinical Signs

I. Clinical signs of acute orchitis and epididymitis include testicular pain, epididymal enlargement, and scrotal edema.
A. Acute orchitis is usually suppurative and may progress to abscess formation.
B. Systemic signs of infection, such as leukocytosis, pyrexia, anorexia, and listlessness, may be present.
C. Inflammation of the parietal vaginal tunic may result in fistula formation through the scrotal skin (Ladds, 1993).

II. Evidence of chronic orchitis includes a small, firm, irregular testis with an enlarged epididymis and palpable adhesions between scrotal contents and tunics (Ladds, 1993).
III. Because of accompanying inflammation and an autoimmune reaction, testicular infection rapidly results in reduced fertility or infertility (Feldman, 1989; Flanders et al., 2000).

Diagnosis

I. Diagnosis is made by physical examination, cytological and bacteriological examination of the semen, and possibly serological examination.
II. Identification of the causative organism often requires microbiological testing of semen, urine, fluid within the vaginal tunics, and possibly blood.
A. Diagnosis of canine brucellosis involves both serological and bacteriological testing (see Chapter 113).
B. Canine distemper-induced epididymitis is diagnosed by histological evaluation.

Differential Diagnosis

I. Testicular neoplasia
II. Testicular trauma and secondary immune-mediated orchitis
III. Urethritis, prostatitis
IV. Testicular torsion

Treatment

I. Treatment of orchitis depends on the extent of infection and the intended breeding use of the animal.

II. Surgically remove abscessed or chronically inflamed testes to prevent episodes of acute inflammation (Burke and Reynolds, 1993).
III. Use antimicrobial drugs, local hypothermia, and possibly antiinflammatory drugs to treat less severe orchitis and epididymitis (Feldman, 1989).
  A. Drain the cavity of the vaginal tunics and allow it to heal by second intention (Johnston and Archibald, 1984).
  B. Use antimicrobial agents to control infection based on culture and susceptibility testing.
IV. Eliminate any primary foci of infection elsewhere in the urogenital tract.
V. Locally treat sinus tracts in the parietal tunic and scrotum by excising, draining, and flushing them with appropriate antimicrobial agents.
VI. No uniformly successful treatment exists for canine brucellosis (see Chapter 113).

Monitoring of Animal

I. Testicular atrophy and fibrosis and epididymal stenosis are possible sequelae.
II. Repeated physical, ultrasonographic, and possibly semen examinations are indicated to determine outcome.
III. Prognosis for maintaining fertility after orchitis and epididymitis is guarded, because orchitis is usually quite resistant to medical treatment.

Testicular Torsion

Definition

I. Testicular torsion or torsion of the spermatic cord varies from a loose 360-degree torsion to several tight revolutions (Pearson and Kelly, 1975).
II. Torsion is more commonly seen with retained, neoplastic abdominal testes than with scrotal testes, presumably because of their greater mobility.
III. Torsion may also occur in scrotal testes.

Causes

I. A retained neoplastic testicle may be prone to torsion from its increased mass and weight.
II. For torsion of a scrotal testicle to occur, the scrotal ligament must be anatomically absent, abnormal, or have traumatically ruptured.

Clinical Signs

I. With retained testes, signs of acute abdominal pain, vomiting, abdominal distention, pyrexia, and lethargy are commonly observed (see Chapter 39).
II. Scrotal testicular enlargement occurs with torsion of the spermatic cord.
  A. Testicular enlargement may precede torsion, especially with neoplasia.
  B. Venous occlusion, edema, and inflammation cause testicular enlargement.

Diagnosis

I. Presumptive diagnosis is based on clinical signs and the presence of at least one ectopic testis.
II. Ultrasonography may reveal a uniform decreased echogenicity and absence of blood flow in the affected testis.
III. Definitive diagnosis is by exploratory surgery.

Treatment and Monitoring

I. Bilateral orchiectomy is used to treat the animal.
II. Animals with acute abdominal signs are stabilized with IV fluid therapy and supportive care before surgery.
III. See Chapter 39 for further treatment and monitoring advice for acute abdomen syndrome.

Spermatocele

Definition and Causes

I. Spermatoceles are localized areas of sperm in stasis within the epididymis.
II. Sperm granulomas result from a granulomatous inflammatory reaction to spermatoceles after leakage of sperm.
III. Possible causes include trauma, infection, and congenital anomalies (Johnston et al., 2001).

Clinical Signs and Diagnosis

I. Palpable nodule in testis
II. Decreased production of sperm
III. Varying degrees of infertility
IV. Definitive diagnosis: biopsy and histopathology

Differential Diagnosis

I. Epididymitis
II. Chronic or subclinical orchitis
III. Neoplasia

Treatment and Monitoring

I. No effective treatment has been described.
II. Castration is recommended, especially to prevent antisperm antibodies (immune-mediated orchitis) from developing.

NEOPLASIA

Definition

I. Testicular tumors are the second most frequently reported tumor in the male dog.
II. They include seminomas, interstitial cell tumors, and Sertoli's cell tumors, with each occurring in about equal frequency (Hayes and Pendergrass, 1976; Reif et al., 1979).
III. Tumors in scrotal testes are most often benign.
IV. Seminomas and Sertoli's cell tumors involving ectopic testes are more likely to be malignant.
V. Interstitial cell tumors are usually tumors of the scrotal testes.
VI. Sertoli's cell tumors are the most common testicular neoplasm in retained testes.

Clinical Signs

I. Testicular tumors occur commonly in older dogs, with age at diagnosis ranging from 9 to 11 years (Johnston et al., 2001).
II. Clinical signs may include increased testicular firmness or nodular enlargement, pain, or signs of feminization (Barrett and Theilen, 1977).
  A. Enlarged and firm testes are more likely with seminomas and Sertoli's cell tumors.
  B. Signs of feminization include a bilateral, symmetrical alopecia of the trunk and flanks, hyperpigmentation of the inguinal skin, gynecomastia, attraction of male dogs, and bone marrow depression in severe cases (see Chapter 87).
  C. Sertoli's cell tumors are most likely to produce signs of feminization.
III. Testicular tumors can occur individually or in combination within a testis.

Diagnosis

I. Signs of feminization in an intact male dog are suggestive of Sertoli's cell tumor.
II. Testosterone-producing tumors (e.g., interstitial cell tumor) can contribute to benign prostatic hyperplasia.
III. Definitive diagnosis of testicular neoplasia is by biopsy of the involved testis.
  A. Excisional wedge biopsy away from the epididymis is performed.
    1. Hemorrhage is controlled with digital pressure and closure of the tunica albuginea.
    2. Adhesions are reduced by offsetting incisions in the parietal vaginal tunic and the tunica albuginea (Feldman and Nelson, 1996).
  B. Percutaneous needle biopsy techniques are less informative (Burke, 1983).

Differential Diagnosis

I. Torsion of the spermatic cord
II. Testicular and spermatic cord trauma
III. Orchitis and epididymitis
IV. Spermatocele
V. Scrotal hernia or neoplasia

Treatment

I. Bilateral orchidectomy is the recommended treatment for testicular neoplasia.
II. In dogs, orchidectomy is performed by either open or closed methods.
  A. In the open method, the parietal vaginal tunic is incised over the spermatic cord at the point where ligatures are to be placed.
    1. Doubly ligate the spermatic cord using transfixation ligations.
    2. Ligate the parietal vaginal tunic and cremaster muscle distal to the spermatic cord ligation.
    3. Alternatively, incise the parietal vaginal tunic before exteriorizing the testis.
  B. In the closed method, the intact spermatic cord and vaginal tunics are doubly ligated using transfixation ligations.
III. Castration in cats is performed through longitudinal scrotal incisions.

Monitoring of Animal

I. Feminizing signs usually resolve within 21 days of removal of a Sertoli's cell tumor.
II. Chemotherapy (single agent or combination) or radiotherapy has been used for metastatic seminomas and Sertoli's cell tumors (McDonald et al., 1988; Dhaliwal et al., 1999).
III. Hyperestrogenism in dogs with Sertoli's cell tumor can be monitored by exfoliative cytology of the preputial mucosa (Johnston et al., 2001).

TESTICULAR TRAUMA

Definition and Causes

I. Testicular injury may occur via blunt or penetrating trauma.
II. Testicular trauma is uncommon in dogs and cats.

Clinical Signs

I. Clinical signs usually include local pain, testicular swelling, and possibly pelvic limb lameness.
II. Scrotal swelling and bruising are seen with more severe testicular lesions.
III. Massive scrotal hematoma formation from local hemorrhage and rupture of the tunica albuginea may occur with severe blunt trauma.
IV. Penetrating wounds frequently cause hemorrhage and may lead to local infection.
V. Any trauma to the testis, epididymis, or spermatic cord is potentially dangerous.
  A. Hemorrhage frequently accompanies trauma to these tissues.
  B. The expansile nature of the scrotum permits development of large hematomas (Burke and Reynolds, 1993).
VI. Damage to testicular tissue causes sperm leakage into the interstitial tissue and eventual spermatic granuloma formation owing to the antigenic properties of sperm.
  A. Immune-mediated orchitis may develop.
  B. Reduced spermatogenesis throughout both testes may result.
VII. Reduced fertility from trauma-induced testicular hyperthermia can also occur.
VIII. Traumatized testes are predisposed to infectious orchiepididymitis because of accompanying edema and congestion (Larsen, 1977).
IX. Self-inflicted scrotal trauma often aggravates the original injury.

Diagnosis

I. Carefully palpate the testis to evaluate the integrity of the tunica albuginea and epididymis.

II. Ultrasonography may help determine the extent of damage.
   A. Rupture of the tunica albuginea is often difficult to detect because of scrotal and testicular swelling.
   B. Local hypothermia, loss of sensation, and bluish scrotal discoloration are grave signs indicating irreversible damage from ischemia.

Treatment

I. Medical treatment is indicated for minor testicular trauma.
   A. Local hypothermia, antimicrobials, corticosteroids, analgesics, and possibly supportive bandaging are used.
   B. Aseptically aspirate any fluid accumulations.
II. Surgically explore the testis by longitudinally incising the cranial scrotum.
   A. Remove fluid and systematically search the scrotum and testes.
   B. Ligate bleeding vessels with fine synthetic absorbable sutures.
   C. Incise the parietal vaginal tunic to repair wounds of the tunica albuginea.
   D. Suture tears in the tunica albuginea with fine synthetic absorbable sutures after excising protruding testicular tissue, and thoroughly lavage with physiologic saline solution.
   E. Separately close the parietal vaginal tunic and scrotum with fine sutures.
III. Severe testicular trauma often requires unilateral or bilateral orchidectomy, with possible scrotal ablation.
   A. Delay orchidectomy until the extent of the injury can be assessed.
   B. Indications for orchidectomy after trauma include persistent pain, swelling, or local hyperthermia (Burke and Reynolds, 1993).
   C. With scrotal ablation, make curvilinear incisions near the scrotal base, leaving adequate skin for closure (Harvey, 1973).
   D. Control bleeding by cautery or ligation, and remove both testes.
   E. After transecting the scrotal septum, close the skin in the usual manner.

CHAPTER 57

Diseases of the Uterus

Lisa M. Howe

INFLAMMATORY DISORDERS

Cystic Endometrial Hyperplasia/ Pyometra Complex

Definition

I. Cystic endometrial hyperplasia (CEH) complex is a common condition of older, intact, female dogs.
II. CEH is the result of an abnormal and exaggerated response of the endometrium to chronic exposure to progesterone.
III. CEH predisposes to pyometra.

Causes and Pathophysiology

I. Progesterone promotes endometrial glandular secretion, suppresses myometrial activity, and inhibits leukocyte responses, which promote the accumulation of secretions and stimulates endometrial hyperplasia.
II. Pyometra is a hormonally mediated condition of diestrus.
  A. It is typically preceded by progesterone-induced CEH in dogs older than 6 years.
  B. Pyometra is caused by an ascending bacterial infection within the uterus.
  C. It is also observed in bitches <6 years of age, but that group is less likely to have CEH.
  D. Estrogen compounds administered for mismating may produce acute endometritis or pyometra in young dogs 1 to 10 weeks after treatment (Johnston et al., 2001)
  E. In cats, CEH and pyometra can arise secondary to influence of progesterone or estrogen.

Diagnosis

I. Suggestive historical features
  A. Middle-aged or older bitch in diestrus
  B. Young bitch recently treated with estrogens for mismating
  C. Previous treatment with megestrol acetate or other progestin
  D. Pseudopregnant queen
II. Compatible physical examination findings
  A. Purulent vulvar discharge
  B. Evidence of systemic illness
  C. Palpable uterine enlargement (avoid overzealous palpation to prevent rupture)
III. Hematologic abnormalities
  A. Neutrophilia (usually >25,000 cells/μL), with a left shift
  B. Degenerative left shift with toxic neutrophils
  C. Normal or decreased white blood cell counts
  D. Mild normocytic normochromic, nonregenerative anemia (hematocrit 25% to 35%)
IV. Biochemical profile results
  A. Hyperproteinemia with hyperglobulinemia, hypoalbuminemia
  B. Increased blood urea nitrogen
  C. Occasionally abnormal liver enzymes
V. Urinalysis
  A. Variable specific gravity, pyuria, hematuria, and/or proteinuria may be noted.
  B. Cystocentesis is not recommended, because rupture of a friable uterus may occur.
VI. Radiographic findings
  A. A fluid-dense tubular structure, larger than small intestinal loops, may be seen in the ventrocaudal abdomen.
  B. With an open-cervix pyometra, the uterus may not be visibly enlarged.
VII. Abdominal ultrasonography
  A. Allows determination of uterine size, wall thickness, and the presence of intraluminal fluid.
  B. Stump pyometras can be visualized dorsal to bladder.

Differential Diagnosis

I. Pregnancy
II. Mucometra or hydrometra
III. Metritis
IV. Vaginitis
V. Uterine neoplasia
VI. Other conditions causing systemic illness or septicemia and toxemia

Treatment

I. Ovariohysterectomy (OHE) is the preferred treatment for pyometra.
II. Medical management is tried only for open-cervix pyometra with few signs of systemic illness.
III. In the valuable breeding animal, medical management may be considered; however, the owner must be educated as to the dangers of delaying surgical treatment.
IV. Surgical treatment and perioperative care is important in managing these cases successfully.

A. Before, during, and after surgery, treat with adequate fluid therapy and broad-spectrum antimicrobials.
B. Other appropriate therapy is provided to stabilize the animal before surgery (e.g., treatment for shock, azotemia), but do not unduly delay surgery in the severely ill animal.

V. Prostaglandin $F_2\alpha$ ($PGF_2\alpha$) therapy is used in select cases.
A. $PGF_2\alpha$ therapy may be attempted if the owner wishes to salvage the dog for breeding purposes.
B. $PGF_2\alpha$ use is limited to animals <6 to 8 years of age that are not critically ill, have an open cervix, and do not have concurrent illnesses (Kustritz, 2004).
C. The use of $PGF_2\alpha$ may not result in improvement for 48 hours to 2 weeks.
D. If the cervix is closed or the uterus is friable, then $PGF_2\alpha$ use may result in uterine rupture or expulsion of uterine contents into the abdomen.
E. Only naturally occurring $PGF_2\alpha$ *(Lutalyse)* is used, because synthetic $PGF_2\alpha$ products are more potent and their use could result in shock and death (Kustritz, 2004).
1. In the dog, *Lutalyse* is given at 0.25 mg/kg SC SID for 5 to 7 days.
a. To help the bitch acclimate to the drug, a lower dose is given initially (0.1 mg/kg on day 1 and 0.2 mg/kg on day 2).
b. Give injections in the morning so that the bitch may be observed throughout the day.
2. In the queen a dose of 0.1 mg/kg SC SID is effective.
3. $PGF_2\alpha$ therapy is generally needed for <7 days.
4. Appropriate ancillary medical therapy is also given.

VI. Progesterone receptor blockers (mifepristone, aglepristone) are reported to be safe and effective treatments for pyometra (Kustritz, 2004); however, they are not currently available in the United States.

VII. Many animals with pyometra have a concurrent urinary tract infection that requires treatment.

Monitoring of Animal

I. Animals receiving $PGF_2\alpha$ must be closely monitored throughout the treatment period.
A. Perform abdominal ultrasonography before treatment and then every 2 to 3 days thereafter until uterine size approaches normal.
B. In addition, evaluate the animal for evidence of peritonitis.

II. Evidence that $PGF_2\alpha$ is producing the desired clinical effect includes resolution of clinical signs, decrease in uterine size, change of purulent discharge to serous discharge, and return of leukogram values to normal.

III. Side effects of $PGF_2\alpha$ commonly occur and include restlessness, pacing, vomiting, hypersalivation, panting, defecation, tachycardia, fever, and abdominal cramping.
A. Cats often show intense grooming and vocalization.
B. Side effects usually begin within 5 to 60 minutes of administration and last 20 to 30 minutes.

IV. Efficacy of $PGF_2\alpha$ therapy varies with the status of the cervix (Kustritz, 2004).
A. In selected animals with open-cervix pyometra, the efficacy is good; some treated animals may eventually whelp healthy litters.
B. Reported recurrence of pyometra in bitches is 10% to 77% within 27 months of therapy (Kustritz, 2004).
C. In closed-cervix pyometra, the efficacy of $PGF_2\alpha$ is diminished, with only 34% of dogs responding (Feldman, 2000).

V. After $PGF_2\alpha$ treatment, bitches are bred during the next estrus cycle.

Metritis

See Chapter 61.

Subinvolution of Placental Sites

See Chapter 61.

UTERINE PROLAPSE

Definition

I. Uterine prolapse is an extrusion of a portion of the uterus through the cervix into the vagina that usually develops when the cervix is dilated during or after parturition (or abortion).

II. The condition is rare but occurs more commonly in the queen than in the bitch.

Causes

I. Excessive straining during parturition

II. Forced fetal extraction or excessive traction on retained fetal membranes

III. Metritis

IV. Retained placenta

V. After normal parturition from idiopathic causes, particularly in the cat

Clinical Signs

I. Mucosal mass is found protruding from the vulva.
A. Everted tissue is doughnut shaped and often discolored from venous congestion, attached debris, or trauma.
B. Tissue may be ischemic or necrotic, and self-mutilation may occur.

II. If the prolapse does not extend through the vulva, then a mass is not visible; however, the following clinical signs may be noted:
A. Abdominal pain, restlessness
B. Vaginal discharge, licking
C. Straining, dysuria
D. Perineal bulging
E. Abnormal postures

III. Signs of hemorrhagic shock may occur if the ovarian or uterine vessels are ruptured.

Diagnosis

I. Partial uterine prolapse that does not protrude through the vulva is diagnosed using digital examination of the vagina or by vaginoscopy.

II. If the mucosal mass protrudes through the vulva, then it must be examined closely to determine if the mass is uterine or vaginal in origin.

Differential Diagnosis

I. Vaginal prolapse, hyperplasia, or edema
II. Vaginal tumor
III. Vaginal hyperplasia
IV. Uterine neoplasia
V. Uterine torsion

Treatment

I. Stabilize the animal before definitive treatment of the prolapse with therapy for shock, dehydration, and blood loss.
II. OHE is often necessary because manual reduction is not very successful.
III. Manual reduction may be attempted if the prolapsed uterus is not devitalized, and reduction may necessitate an episiotomy.
   A. Administer systemic antimicrobial agents to treat metritis if the uterus is replaced.
   B. If external manual reduction is unsuccessful and the animal's reproductive capacity is important, then internal reduction may be performed.
   C. General or epidural anesthesia is required before attempting uterine reduction.
      1. Prolapsed tissue is cleaned with an antiseptic solution and any necessary debridement performed.
         a. Lavage with warm saline or hypertonic dextrose solution, and gently massage to help decrease uterine edema.
         b. Lubricate the mass thoroughly with a water-soluble lubricant gel and manually replace it.
      2. After reduction, oxytocin (5 to 10 U SC) may help induce uterine involution.
IV. External amputation is performed only if the uterus cannot be reduced or if it has become devitalized or necrotic.
V. OHE is performed after any uterine amputation.

Monitoring of Animal

I. After manual reduction or surgery, monitor the animal closely for hemorrhage, shock, dehydration, dysuria or anuria (urethral obstruction), recurrence, or infection.
II. Within 24 hours, the animal's cervix should be closed enough to prevent recurrence.
III. Continue antimicrobials if the uterus is traumatized and OHE was not performed.

UTERINE TORSION

Definition

I. Uterine torsion is a twisting of all or part of the uterus perpendicular to its long axis.
II. Uterine torsion is rare in small animals but generally occurs near the end of gestation (although the condition is reported to occur without pregnancy) and may result in dystocia.

Causes

I. Torsions occur during pregnancy or near the end of gestation, because a heavy, gravid uterus is more susceptible to rotational forces than is a nongravid uterus.
II. Other pathologic conditions of the uterus that may predispose to uterine torsion include uterine tumors, pyometra, mucometra, and hydrometra.

Clinical Signs

I. Clinical signs include abdominal pain, abdominal distention, bloody or mucoid vulvar discharge, anorexia, depression, lethargy, vomiting, and shock.
II. History of prolonged unproductive labor is common, although normal delivery of some offspring may occur 24 to 48 hours earlier if torsion involves only one horn.
III. Abdominal palpation often reveals a caudal abdominal mass, and the abdomen may be distended with fluid if uterine rupture has occurred.
IV. Potentially fatal hemorrhagic shock can occur if the uterine artery ruptures.

Diagnosis

I. Abdominal radiographs are consistent with either a gravid or fluid-filled uterus.
II. If fetal death has occurred, then radiographic signs include intrauterine and fetal gas formation, decomposition, and collapse of the cranial bones.
III. Abdominal ultrasonography confirms pregnancy and determines fetal viability.
IV. Exploratory surgery permits a definitive diagnosis of uterine torsion.

Differential Diagnosis

I. Dystocia
II. Pyometra, mucometra, hydrometra
III. Uterine neoplasia
IV. Neoplasia of other caudal abdominal organs

Treatment

I. Before surgery, aggressive supportive therapy is initiated.
II. OHE is the treatment of choice because uterine tissue is often devitalized or necrotic.
III. The friable uterus is surgically isolated from the rest of the abdomen and minimally manipulated during removal.
IV. Avoid attempts to derotate the uterus before removal, if possible.

Monitoring of Animal

I. Postoperatively, monitor for hemorrhage, shock, and infection.
II. Continued use of antimicrobials is indicated for the following conditions:
   A. Uterus was devitalized, necrotic, or ruptured.
   B. Fetal death occurred.
   C. Systemic signs of infection are present.

NEOPLASIA

Definition and Causes

I. Benign uterine tumors include the leiomyoma (most common uterine tumor in the dog), fibroleiomyoma, fibroma, fibroadenoma, and endometrial polyps.
II. Malignant uterine tumors include the adenocarcinoma (most common uterine tumor in cats), undifferentiated carcinoma, endometrial carcinoma, lymphosarcoma, and metastatic transmissible venereal tumor.
III. The cause of most uterine tumors is unknown.

Clinical Signs

I. Uterine tumors are uncommon in female dogs and cats.
II. They usually occur in bitches >10 years of age.
III. Uterine tumors may not cause any clinical signs and may be discovered as an incidental finding during abdominal surgery or necropsy.
IV. Large uterine tumors may cause abdominal enlargement or distention; they may also cause compression of the urinary or gastrointestinal tracts, resulting in dysuria or tenesmus.
V. Carcinomas often result in mucoid, purulent, or hemorrhagic vaginal discharge; if located near the cervix, they may cause uterine obstruction, with secondary pyometra or mucometra.
VI. Infertility may result from a large intrauterine tumor.
VII. If an animal with a uterine tumor does become pregnant, then the tumor may cause dystocia during parturition.

Diagnosis

I. Suspicious findings include a palpable or radiographically detectable caudal abdominal mass in an intact queen or bitch.
II. Ultrasonography is valuable in localizing the mass to the uterus and in differentiating it from pregnancy or pyometra.
III. Exploratory laparotomy and histopathology are often needed for a definitive diagnosis.

Differential Diagnosis

I. Other causes of uterine enlargement
II. Other causes of vulvar discharge
III. Neoplasia of other caudal abdominal organs

Treatment

I. OHE is the treatment of choice for uterine neoplasia and is potentially curative unless metastasis has occurred.
II. Biopsy of the sublumbar lymph nodes assists in determining prognosis and is particularly important with adenocarcinomas.

Monitoring of Animal

I. After diagnosis of a malignancy, abdominal and thoracic radiographys are taken every 3 to 6 months to monitor for evidence of metastasis.
II. Leiomyosarcoma metastasizes late and most commonly metastasizes to the lung.
III. Uterine adenocarcinoma commonly spreads to the sublumbar and iliac lymph nodes.

CHAPTER 58

Diseases of the Vagina

Caroline Prymak | Ronald M. Bright

CONGENITAL DISORDERS

Definition and Cause

I. Several types of vaginal defects have been identified (Wykes and Soderberg, 1983).
   A. Hymen membrane remnants
   B. Segmental hypoplasia and aplasia
   C. Double vagina
   D. Blind-ending vaginal pouch (secondary vaginal pouch) (Mayenco-Aguirre et al., 2002)
   E. Hydrocolpos secondary to congenital vaginal obstruction (Viehoff and Sjollema, 2003)
II. The causes and heritability patterns are unknown.

Pathophysiology

I. Abnormal embryonic development is responsible for most congenital abnormalities.
II. Normal embryonic development of the vagina is as follows (McEntee, 1990):
   A. The vagina arises from fusion of the distal paired paramesonephric ducts (Müllerian ducts).
   B. The vestibule develops from part of the urogenital sinus.
   C. The hymen forms from fusion of the distal paired paramesonephric ducts with the urogenital sinus and normally disappears after birth, creating a patent vestibulovaginal junction.
III. Abnormal embryonic development may result in the following abnormalities (Wykes, 1986):
   A. Incomplete breakdown of the hymen membrane
      1. Annular remnants may cause circumferential narrowing at the vestibulovaginal junction.
      2. Vertical bands transect and often obstruct the vestibulovaginal lumen.
   B. Development of segmental hypoplasia or aplasia of the vagina or vestibulovaginal junction
   C. Incomplete fusion of all or part of the medial walls of the paramesonephric ducts, creating a double vagina or blind-ending vaginal pouch

Clinical Signs

I. Vestibulovaginal hymen remnants, double or blind-ending vagina, segmental vaginal hypoplasia, and aplasia may all have similar clinical signs.
II. The following signs can occur alone or in combination:
   A. Vaginitis from retention of vaginal fluids
   B. Pyometra from retention of uterine secretions
   C. Difficulty in breeding or inability to breed
   D. Dystocia
   E. Chronic urinary tract infections
   F. Urinary incontinence

Diagnosis

I. Compatible signalment, history, and clinical signs
II. Digital vaginal examination
   A. Vaginal bands or septa are usually palpated just cranial to the urethral tubercle at the vestibulovaginal junction, and a small opening may be palpated on either side of the partition.
   B. Segmental hypoplasia or annular hymen remnants may prevent digital penetration of the vagina.
III. Vaginoscopy
   A. Endoscopy is the preferred technique for examination of the cranial vagina, and insufflation with air is often necessary to prevent the mucosal folds from obscuring visualization of abnormalities.
   B. The caudal vagina is sometimes examined using simple instrumentation, such as a vaginal speculum or otoscope.
IV. Positive-contrast radiography
   A. Contrast radiography may be useful in identifying and differentiating vaginal hypoplasia, vaginal aplasia, persistent vaginal bands, double vagina, and a blind-ending vaginal pouch.
   B. It may also be useful in crudely assessing the ability of the vaginal tract to distend.
V. Vaginal cultures
   A. Congenital vaginal abnormalities may predispose to secondary infection.
   B. Guarded swabs taken from the cranial vagina are cultured for aerobic and anaerobic bacteria, as well as *Mycoplasma* spp. and *Ureaplasma* spp.

Differential Diagnosis

I. Closed pyometra: differentiated from pyometra secondary to segmental aplasia or hypoplasia using contrast radiography
II. Physiologic narrowing of the vestibulovaginal junction
   A. Anesthesia may relax a contracted vestibularis muscle.

B. Vestibulovaginal narrowing detected in anestrus may resolve with estrus.

III. Vaginitis from other causes
A. Immaturity of the vaginal tract secondary to estrogen deficiency
B. Primary infectious cystitis or metritis
C. Trauma
D. Neoplasia
E. Infectious diseases
F. Immunologic conditions

Treatment

I. Incidental findings in asymptomatic animals may not require treatment, especially if the following are true:
A. The bitch is not intended for breeding.
B. Future problems are not anticipated based on lack of clinical signs at the time of diagnosis.

II. Surgical treatment is recommended in certain cases.
A. Breeding and/or parturition will be affected.
B. Future problems such as pyometra are anticipated.
C. Clinical signs are present.

III. Type of surgical treatment depends on the specific lesion.
A. Annular hymen remnants and hypoplasia at the vestibulovaginal junction (Kyles et al., 1996)
1. Generally poor response to manual dilatation
2. T-shaped vaginoplasty to enlarge the luminal diameter
3. Partial vaginectomy and anastomosis
4. Complete vaginectomy
B. Small, thin vaginal bands
1. Surgical resection via episiotomy
2. Endoscopic resection
C. Large, thick vaginal septum or band
1. Episiotomy and band resection
2. Mucosal closure at the origin and insertion of the band to prevent scarring
D. Caudal and midvaginal segmental hypoplasia in breeding bitches
1. Segmental vaginal resection and anastomosis (Wykes and Olson, 1985)
2. Elective cesarean section at conclusion of pregnancy
E. Extensive hypoplasia or failure of the previous treatments
1. Ovariohysterectomy
2. Vaginectomy

Monitoring of Animal

I. Bitches may have multiple congenital anomalies, and a successful outcome requires treatment of all of them.
A. Annular-vertical hymen membrane remnants may occur in combination with vaginal hypoplasia.
B. Short vertical bands may give the impression of a concurrent annular band.

II. Repeatedly evaluate the diameter of the vaginal lumen after each surgical procedure.

INFLAMMATORY DISORDERS

Vaginal Edema

Definition

I. Marked edema of the vagina that mainly affects the ventral, distal surface (Johnston, 1989)
II. Synonyms: vaginal hyperplasia, vaginal prolapse, vaginal fold prolapse

Causes

I. The condition arises from the effects of estrogen on the vaginal wall.
II. Clinical signs occur during proestrus and estrus.
III. The condition is not considered to be hereditary.
IV. Certain breeds may be predisposed, including the boxer, English bulldog, mastiff, German shepherd dog, Saint Bernard, Labrador retriever, Chesapeake Bay retriever, Airedale terrier, and weimaraner.

Pathophysiology

I. Edematous tissue is most pronounced on the ventral wall of the caudal vagina, just cranial to the urethral tubercle.
II. Classification systems are based on the degree of vaginal swelling.
A. Type I: mild eversion of the vaginal wall
1. Vaginal mucosa is not visible at the vulva.
2. The perineum may bulge slightly.
B. Type II: protrusion of a fold of vaginal mucosa through the vulva
C. Type III: a doughnut-shaped prolapse of the entire circumference of the distal vagina and urethral orifice through the vulva

Clinical Signs

I. Usually affects young bitches
II. Protruding mass from the vulva
III. Difficulty in mating
IV. Perineal swelling
V. Excessive licking of the perineal region
VI. Dysuria, stranguria, pollakiuria

Diagnosis

I. History of previous episode of vaginal edema
II. Clinical signs as described previously
III. Compatible stage in the estrus cycle: proestrus, estrus
IV. Visible mass on vaginoscopy in the typical location
V. Palpation of a pedunculated or doughnut-shaped vaginal mass

Differential Diagnosis

I. Vaginal tumors
II. Uterine prolapse

Treatment and Monitoring

I. Supportive therapy
A. Keep the exposed mucosa clean and lubricated with saline-soaked gauze.

B. Prevent self-inflicted trauma by using an Elizabethan collar.
C. Place temporary retention sutures across the vulva to prevent vaginal prolapse and tissue trauma.
D. Ensure that urination is possible; place a temporary urinary catheter if urinary retention occurs.
E. Edematous tissue normally resolves spontaneously at the end of estrus.

II. Hormonal therapy
A. Induction of ovulation during the follicular phase of the estrus cycle can be tried.
B. Gonadotropin-releasing hormone at 2.2 μg/kg IM shortens the time of estradiol release if given before ovulation.

III. Surgical therapy
A. Surgery is performed in late estrus or diestrus to reduce surgical bleeding.
B. Ovariohysterectomy is both a primary therapy and prevents future recurrence.
C. Resection of edematous vaginal tissues may be indicated in certain cases (Pettit, 1998).
1. Resolution of the edematous tissue is prevented by secondary fibrosis.
2. Exposed tissue is devitalized or traumatized.
3. The physical effects of the edematous tissue cause abnormal urination despite conservative therapy.

Vaginitis

Definition

I. Vaginitis is inflammation of the vagina.
II. Secondary infection from overgrowth of resident organisms is common.

Causes and Pathophysiology

I. May occur at any age in intact or spayed females
II. Predisposing factors
A. Anatomical abnormalities of the vagina
1. Persistent hymen remnants
2. Vaginal hypoplasia or segmental aplasia
3. Double vagina or blind-ending vaginal pouch
B. Clitoral hypertrophy
1. Androgenic stimulation
2. Chronic inflammation
C. Vaginal trauma
1. Mating
2. Parturition
3. Iatrogenesis
4. Foreign bodies
D. Vaginal neoplasia
E. Vaginal wall immaturity (Johnson, 1991)
1. Juvenile vaginitis occurs in prepubertal puppies.
2. Cytological examination generally shows a nonseptic inflammatory response.
F. Urine pooling
1. Urinary tract abnormalities
2. Example: ectopic ureters entering the vagina
G. Urinary tract infections
1. Possible concurrent anatomic abnormalities
2. Especially chronic and recurrent infections

III. Primary bacterial infections
A. In most cases, bacterial cultures are qualitatively and quantitatively similar to normal vaginal flora and may reveal the following agents:
1. *Escherichia coli*
2. *Staphylococcus* spp.
3. *Streptococcus* spp.
4. *Proteus* spp.
5. *Pasteurella* spp.
6. *Corynebacterium* spp.
7. *Brucella canis*
B. Infection usually occurs secondary to other predisposing factors (Olson and Mather, 1986).

IV. *Mycoplasma* spp. and *Ureaplasma* spp.: both normal commensals and pathogens
V. Viral infections
A. Herpesvirus infection
B. Latent infections reactivated in times of stress

Clinical Signs

I. May occur at any age in intact or spayed females
II. Perineal irritation
A. Vulval licking
B. Rubbing the perineal area
III. Vulval discharge
IV. Discomfort during or after urination
V. Males interested in spayed, juvenile, or anestrus females
VI. Reluctance to mate

Diagnosis

I. Compatible clinical signs
II. Vaginoscopy
A. Vaginal wall inflammation
1. Ulceration
2. Hyperemia
3. Nodular lymphoid hyperplasia
B. Possible presence of congenital abnormalities, trauma, neoplasia, urine pooling

III. Laboratory evaluation
A. Vaginal cytology
1. Neutrophilia: healthy to degenerate cells
2. Bacteria: general increase in numbers or specific bacterial overgrowth
3. Macrophages and lymphocytes: suggestive of chronic inflammation
4. Intracytoplasmic inclusions: *Mycoplasma* spp., *Ureaplasma* spp., *Chlamydia* spp.
B. Urinalysis and culture
1. Rule out urinary tract infection as a predisposing factor.
2. Obtain urine by cystocentesis to prevent secondary contamination.

IV. Vaginal bacteriology
A. Results are often difficult to interpret because of contamination and overgrowth of normal flora.

B. Secondary infections commonly occur.
C. Special sampling techniques are indicated.
1. Guarded swab
2. Sample from the cranial vagina
3. Sample during anestrus
D. Special media are required for *Mycoplasma* spp. and *Ureaplasma* spp.
E. Perform titers or polymerase chain reaction assays for *Brucella canis* and herpesvirus infections.

V. Vaginal biopsy
A. Assess for inflammatory changes.
B. Rule out neoplasia.

VI. Diagnostic imaging
A. Survey abdominal radiography and ultrasonography are rarely diagnostic.
B. Positive-contrast vaginography is indicated to rule out neoplasia and anatomic abnormalities.
C. Excretory urography may rule out ectopic ureters.

Differential Diagnosis

I. Open-cervix pyometra
A. History of recent estrus
B. Systemic illness
C. Uterine abnormalities on abdominal radiography and ultrasonography
D. Systemic leukocytosis

II. Metritis
A. History of recent whelping
B. Uterine wall thickening on ultrasonography

III. Uterine stump granuloma
A. Abdominal radiography
B. Ultrasonography

Treatment

I. Correction of predisposing factors

II. Juvenile (prepubertal) vaginitis
A. The condition may resolve after the first estrus.
B. Estrogens allow maturation of the genital tract, with encouragement of the natural defense systems.
C. Ovariohysterectomy is postponed until after the first estrus and after the vaginitis has resolved.
D. Systemic antibiotics, douches, and vaginal suppositories are rarely beneficial.

III. Bacterial infections
A. Treat bacteria only if they are the primary cause.
B. Systemic antibiotics are chosen based on the results of culture and sensitivity testing.

IV. Viral infections
A. No therapy is currently recommended.
B. Avoid stress.
C. Isolate affected animal from pregnant bitches and neonatal puppies.

Monitoring of Animal

I. If signs persist, then reconsider the original diagnosis and repeat diagnostic tests (as outlined previously).

II. Avoid breeding animals with active vaginitis.

NEOPLASIA

Definition and Causes

I. Common benign tumors include the leiomyoma and fibroma (Ogilvie and Moore, 1996).

II. Malignant vaginal tumors include the leiomyoma sarcoma, fibroma sarcoma, squamous cell carcinoma, rhabdomyosarcoma, and transmissible venereal tumor (TVT).

III. Vaginal tumors are more common in intact bitches, suggesting a possible hormonal influence.

IV. Vaginal tumors usually occur in older animals, with a mean age of 11 years (range 5 to 16 years), except for TVT, which is more common in young, sexually active animals (Thacher and Bradley, 1983; Ogilvie and Moore, 1996).

V. No obvious breed predisposition exists.

Pathophysiology

I. Vaginal tumors may develop anywhere in the wall of the vagina.

II. Benign vaginal tumors are more common than malignant tumors (Thacher and Bradley, 1983).

III. Pedunculated vaginal tumors tend to be benign.

IV. Multiple vaginal tumors may develop in the wall of the vagina.

V. Malignant vaginal tumors can vary in their metastatic potential.

VI. TVT is often transmitted during coitus, and metastasis occurs in <5% of cases (usually in immunosuppressed animals).

Clinical Signs

I. Perineal swelling

II. Tumor prolapsed from the vulva

III. Vulvar bleeding

IV. Dysuria and pollakiuria

V. Fecal tenesmus and constipation

VI. Difficulty in mating

VII. Solitary or multiple soft, friable masses: characteristic of TVT

Diagnosis

I. Suspicious signalment, history, and clinical signs

II. Evidence of mass on vaginal and rectal examination

III. Identification of a mass with vaginoscopy

IV. Diagnostic imaging
A. Positive-contrast vaginography to further evaluate origin and size of mass
B. Magnetic resonance imaging (MRI) or computed tomography (CT) to assess degree of infiltration

V. Definitive diagnosis: biopsy via tissue sampling

VI. Tumor staging
A. The metastatic potential of a vaginal tumor depends on the tumor type and its biologic behavior.
B. For most malignant tumors, metastasis first occurs to the subiliac lymph nodes.
C. Distant metastatic spread may occur later in the disease process.

D. Imaging techniques are used to detect gross metastatic disease.
   1. Abdominal ultrasonography
   2. Abdominal and thoracic radiography
   3. MRI and CT

Differential Diagnosis

I. Vaginitis
II. Vaginal trauma
III. Tumors arising from the lower urinary tract, cervix, or uterus
IV. Perivaginal tumors
V. Vaginal edema
VI. Uterine prolapse

Treatment

I. Surgery
   A. Surgery is the treatment of choice for nonmetastatic vaginal tumors except TVT.
   B. Solitary benign tumors in the caudal vagina are removed by episiotomy and local resection.
   C. Multiple benign tumors, malignant tumors, and tumors extending into the cranial vagina are best removed by vaginectomy (Bilbrey et al., 1989).
   D. Nonpedunculated, vaginal tumors may require vaginectomy combined with an urethroplasty (Salomon et al., 2004).
   E. Ovariohysterectomy eliminates any hormonal influence and is necessary when a complete vaginectomy is performed.
II. Chemotherapy
   A. Chemotherapy is the treatment of choice for TVT.
      1. Vincristine is administered at 0.6 mg/m^2 IV weekly.
      2. The cure rate is reported to be nearly 100% (Boscos, 1988).
      3. The response time is usually within 2 to 6 weeks.
   B. The benefits of chemotherapy alone or combined with surgical resection of malignant tumors are not well documented.
III. Radiation therapy
   A. Radiation therapy is very effective in the treatment of solitary TVT.
   B. A single radiation dose of 10 Gy is reported to result in a 100% cure rate (Thrall, 1982).

Monitoring of Animal

I. For malignant tumors, follow-up examinations are performed at 1, 3, and 6 months posttreatment.
   A. Assess for local recurrence.
   B. Assess for distant metastasis.
II. After excision of benign tumors, monitor animal for 1 to 3 months to ensure excision was complete and effective.

CHAPTER 59

Diseases of the External Male Genitalia

Harry W. Boothe

CONGENITAL/DEVELOPMENTAL DISORDERS

Hypospadias

Definition

I. Hypospadias is a fusion failure of the urogenital folds, with incomplete formation of the penile urethra.
II. Glandular, penile, scrotal, and perineal hypospadias have been reported (Ader and Hobson, 1978).
III. Rather than at the tip of the penis, the urethral orifice is located on the ventral aspect of the penis or the perineal area.

Causes and Pathophysiology

I. Hypospadias is the most common developmental anomaly of the male external genitalia.
II. The condition is encountered most frequently in Boston terriers (Johnston and Archibald, 1984).
III. Hypospadias is usually associated with preputial fusion failure and underdevelopment of the penis.

Clinical Signs

I. Clinical signs may be absent if the prepuce is normal and the external urethral orifice is near the end of the penis.
II. Occasionally the skin and hair around the urethral orifice are urine soaked and irritated.

Diagnosis

I. Diagnosis of hypospadias is made by close inspection of the penis.
II. The external urethral orifice is found anywhere on the ventral aspect of the penis.

Treatment and Monitoring

I. Surgical correction is not usually attempted in the dog because the urethra cranial to the abnormal orifice is deficient (Johnston and Archibald, 1984).
II. Excision of preputial and penile remnants, bilateral orchidectomy, and maintenance of the urethral orifice in the perineal region may be indicated in severe cases (Hobson, 1998).

Persistent Penile Frenulum

Definition and Cause

I. Persistent penile frenulum is a persistent connection between the penis and prepuce after puberty.
II. Cause is unknown.

Pathophysiology

I. In the immature dog, the frenulum (a fine band of connective tissue) joins the penis and prepuce ventrally.
II. The frenulum normally ruptures by puberty under androgenic influences (Bharadwaj and Calhoun, 1961).

Clinical Signs

I. Persistence of the penile frenulum occurs in the cocker spaniel, miniature poodle, Pekingese, and in mixed-breed dogs (Begg, 1963; Hutchison, 1973).
II. Pain may be evident during sexual excitement or when the penis is extruded.
III. The animal may also continually lick the area.
IV. A ventral deviation of the glans is usually noted when extrusion is attempted.
V. Balanoposthitis may also be seen.

Diagnosis

I. Suggestive clinical signs
II. Close examination of penis

Treatment

Surgically sever the minimally vascular connective tissue.

Paraphimosis

Definition and Causes

I. Paraphimosis occurs when the penis protrudes from the preputial sheath and cannot be returned to its normal position.
II. Paraphimosis has both congenital and acquired causes.
   A. Congenital causes include a narrowed preputial orifice and an abnormally shortened prepuce.
   B. Acquired causes include trauma, infection, and priapism (Hobson, 1993).

III. Paraphimosis is usually seen after coitus, trauma, or masturbation, particularly in young male dogs (Johnston and Archibald, 1984).

Clinical Signs

I. Clinical signs depend on the duration of paraphimosis.
II. Exteriorized glans penis becomes congested and discolored because of the constricting ring of retracted prepuce.
III. Dog frequently licks at the exposed penis, exacerbating the inflammation.
IV. Severe penile damage can result from prolonged paraphimosis.
V. Necrosis of the exposed penis and urethral obstruction can occur quickly.

Diagnosis

I. Diagnosis of paraphimosis is made by close inspection of the penis and prepuce.
II. Inability to replace the penis into the preputial sheath is indicative of paraphimosis.

Differential Diagnosis

I. Penile trauma
II. Priapism

Treatment and Monitoring

I. Treatment is directed at replacement of the penis into the prepuce.
II. Lubricants, hyperosmolar solutions, and local heat or cold may be adequate to reduce the size of the penis and permit replacement.
III. With the animal sedated, push the penis caudally as the prepuce is drawn cranially.
IV. If replacement cannot be accomplished within a few hours, suture an indwelling urethral catheter in place.
V. Temporary or permanent surgical enlargement of the preputial orifice may be necessary.
VI. Creation of a permanent adhesion between the dorsal penile surface and the adjacent preputial mucosa has been described (Somerville and Anderson, 2001).
VII. Long-standing cases accompanied by necrosis require partial penile amputation.
VIII. Paraphimosis complicated by a deficient prepuce usually requires partial penile amputation to be effective.
IX. Monitor the animal for recurrence, particularly with congenital causes (Hobson, 1993).

Phimosis

Definition and Causes

I. Phimosis is the inability to protrude the penis beyond the preputial orifice.
II. Two general causes exist.
   A. Congenital
   B. Acquired: scarring after preputial trauma, neoplasia

Clinical Signs

I. Clinical signs depend on the cause (congenital or acquired) and size of the preputial orifice.
II. Congenital phimosis is usually accompanied by a distended prepuce and inability to urinate normally.
III. Urine is often passed only in drops or as a thin stream (Johnston and Archibald, 1984).
IV. Preputial retention of urine results in balanoposthitis, and the infected area may ulcerate (Proescholdt et al., 1977).
V. Acquired phimosis is accompanied by preputial inflammation and edema.
VI. Associated licking of the area is common.
VII. Neoplasia or a healing wound may also be present.
VIII. Retention of urine within the prepuce can occur in severe cases.

Diagnosis

Diagnosis is made by close inspection of the prepuce.

Treatment

I. Surgically enlarge the preputial orifice and correct the primary condition.
II. Create a triangular incision over the dorsal preputial surface near the preputial orifice.
III. Remove adequate tissue, while ensuring that the penis remains covered by the prepuce.
IV. Excise or treat neoplasms appropriately, avoiding stenosis of the preputial orifice.
V. Ligate or cauterize bleeding vessels and suture the preputial mucosa to the skin with simple interrupted, fine, nonabsorbable sutures.

Monitoring of Animal

I. Recheck young animals at regular intervals until growth is complete, because another surgery may be necessary to further enlarge the preputial orifice after the dog is fully grown.
II. If phimosis is caused by neoplasia, monitor for recurrence of the tumor.
III. Monitor the size of the preputial orifice, because postoperative fibrosis can be significant.
IV. Monitor for paraphimosis, which can occur if too much tissue is removed, particularly from the ventral prepuce.

Preputial Abnormalities

Definition and Causes

I. The prepuce may be hypoplastic or absent, or it may fail to fuse normally.
II. Failure of closure of the genital folds over the penis results in a deficient prepuce.
III. Failure of preputial fusion usually accompanies hypospadias and underdevelopment or absence of the penis (Croshaw and Brodey, 1960).
IV. Deficiency in the length of the prepuce is seen occasionally in the dog.

Clinical Signs

I. Clinical signs arise from exposure of the distal penis.
II. The dog frequently licks at the penis, causing inflammation.

III. The end of the penis is exposed, subjecting it to trauma and drying.
IV. Trauma results in hemorrhage.

Treatment

I. Failure of preputial fusion is usually treated by removal of the open prepuce, partial penile amputation, orchidectomy, and scrotal or perineal urethrostomy (Hobson, 1993).
II. A deficiency in the length of the prepuce is corrected by advancing the prepuce cranially along the abdominal wall or by partial penile amputation (Leighton, 1976).
III. Simple cranial advancement of the prepuce is often unsuccessful if much of the distal penis is exposed.
IV. Partial penile amputation and cranial advancement of the prepuce may be necessary to treat a severely deficient prepuce.

Monitoring of Animal

I. Monitor for adequate penile coverage by the prepuce after recovery from anesthesia.
II. Monitor for urethral stricture after partial penile amputation, especially if healing is complicated.

INFLAMMATORY DISORDERS

Balanoposthitis

Definition

I. Balanoposthitis is inflammation of the penile or preputial mucosa.
II. Infection of the penis and prepuce is fairly common, constituting approximately 20% of canine penile and preputial lesions (Ndiritu, 1979).

Causes

I. Penile injury
II. Phimosis
III. Preputial foreign body
IV. Neoplasia
V. Atopic dermatitis (Root Kustritz, 2001)

Clinical Signs

I. A copious yellow or blood-tinged preputial discharge suggests balanoposthitis or prostatic disease.
II. The affected dog frequently licks at the prepuce.

Diagnosis

I. Examination reveals an inflamed, thickened penile and preputial mucosa.
II. Enlarged lymphoid nodules are seen, particularly near the fornix of the preputial cavity.
III. Adhesions may develop between the prepuce and penis in severe cases.

Differential Diagnosis

I. Prostatic disease
II. Penile or preputial neoplasia

Treatment

I. Treatment is directed at eliminating the primary cause.
II. Anesthetize the animal to allow complete examination and treatment.
III. Thoroughly irrigate the penis and preputial cavity with warm saline solution.
IV. Superficially curette the lymphoid nodules with a gauze sponge.
V. Sever adhesions between the penis and prepuce.
VI. Instill dilute povidone-iodine or chlorhexidine solution into the preputial cavity.
VII. Instill an antimicrobial ointment into the preputial cavity for a few days after curettage.

Monitoring of Animal

I. Monitor the dog for recurrence of balanoposthitis.
II. Look for recurrence of a copious preputial discharge.

Priapism

Definition and Causes

I. Priapism is persistent erection that is not associated with sexual excitement.
II. Priapism is usually secondary to spinal cord injury, although it may accompany constipation or genitourinary infection (Johnston and Archibald, 1984).

Diagnosis

I. Priapism is distinguished from paraphimosis by the fact that the penis can be manually replaced into the prepuce with priapism.
II. This distinguishing feature is lost with additional penile congestion and swelling from drying and licking.

Differential Diagnosis

I. Paraphimosis
II. Penile strangulation

Treatment

I. Treatment is directed at eliminating the primary cause.
II. The exposed penis is kept clean and moist by applying a soothing ointment.
III. Use of an Elizabethan collar prevents licking.

NEOPLASIA

Definition and Causes

I. Tumors involving the penis of dogs include transmissible venereal tumor (TVT), papilloma, and squamous cell carcinoma (O'Keefe, 1995).
II. Prepuce and scrotum are affected by the same tumors as the skin (Barron, 1949; Weipers and Jarrett, 1954; O'Keefe, 1995).
   A. Mast cell tumors are frequently reported.
   B. TVTs, melanomas, and perianal gland tumors also occur (Ladds, 1993).

Clinical Signs

I. Licking and a serosanguineous preputial discharge are seen commonly with penile TVT (Brown et al., 1980).
II. Signs are often minimal, unless the tumor ulcerates or involves the preputial orifice.
III. Phimosis and balanoposthitis can result.

Diagnosis

I. Diagnosis is frequently made by cytologic evaluation of fine-needle aspirates or impression smears from the mass.
II. Biopsy (incisional or excisional) confirms the diagnosis.

Differential Diagnosis

I. Urethral prolapse
II. Balanoposthitis

Treatment

I. TVTs respond to many modes of treatment, including radiation therapy, chemotherapy, and surgery (Richardson, 1981).
   A. Simple surgical excision may be tried, but recurrence is common.
   B. Radiotherapy may be used alone or in combination with surgery.
      1. Total dose of 1000 to 2000 rad is commonly used (Theilen and Madewell, 1979).
      2. Most tumors recede entirely and do not recur with this therapy.
   C. Vincristine is the chemotherapeutic agent of choice.
      1. Dosage is 0.5 to 0.7 mg/m^2 IV once weekly.
      2. Most tumors begin to shrink within 2 weeks and require four to six treatments.
II. Other tumors involving the distal penis may require partial penile amputation, while more extensive or proximal tumors may necessitate ablation of the external genitalia.
   A. Surgically remove the tumor and close the prepuce in two layers.
   B. Take care to assure that the penis remains covered by the prepuce.
   C. In addition, consider a partial penile amputation if a large portion of the prepuce has been excised.
III. Wide excision of a scrotal neoplasm may necessitate orchidectomy and scrotal ablation.

Monitoring of Animal

I. Observe the external genitalia and regional lymph nodes for tumor recurrence.
II. Monitor for distant metastasis with malignant tumors via repeated physical examinations, abdominal and thoracic radiographs, and abdominal ultrasonography.

PENILE, PREPUTIAL, AND SCROTAL TRAUMA

Definition

I. Penile wounds include lacerations, crush injuries, fractures of the os penis, and urethral trauma.
II. Trauma to the prepuce can result from a laceration, an abrasion, or a foreign body.
III. Scrotal injuries include abrasions and lacerations.

Causes and Pathophysiology

I. Because of their exposed location, the penis, prepuce, and scrotum are relatively accessible to injury.
II. Penile and preputial wounds may occur during mating, fights, and fence jumping, as well as from automobile accidents and gunshot wounds (Hall and Swenberg, 1977; Ndiritu, 1979).
   A. Repeated hemorrhage is associated with penile erection, which in turn is caused by irritation from injury.
   B. Penile lacerations and gunshot wounds may involve the urethra.
   C. Severe penile trauma may produce a fracture of the os penis.
   D. Fractures usually are transverse and cause limited soft-tissue damage, although they may be comminuted (Johnston and Archibald, 1984).
   E. Malicious application of a rubber band around the penis or constriction of a ring of preputial hairs can cause strangulation of the penis.
III. Wounds that penetrate into the preputial cavity or are near the preputial orifice are most likely to require surgical management.
IV. Migration of a foreign body through the preputial mucosa at the fornix results in swelling and abscessation of the tissues surrounding the penis.

Clinical Signs

I. Hemorrhage, frequently intermittent but often profuse, is most commonly seen with penile wounds.
II. The dog usually exhibits pain and may frequently lick the prepuce.
III. Rupture of the penile urethra is usually accompanied by fluctuant subcutaneous swelling associated with urine extravasation.
   A. Dysuria and hematuria are commonly observed with fracture of the os penis.
   B. Crepitus is apparent, and urethral obstruction may be present.
IV. With penile strangulation, the penile mucosa becomes swollen with an encircling necrotic area, or the entire penis distal to the constriction may be necrotic (Johnston and Archibald, 1984).
V. Local preputial swelling, edema, and irritation are typical of superficial lacerations.
VI. Purulent, blood-tinged preputial discharge may accompany frequent licking of the prepuce when a preputial foreign body is present.
   A. The animal with a preputial foreign body is usually in pain, listless, mildly pyretic, and walks stiffly.
   B. A draining tract may be present ventral or lateral to the prepuce.
VII. The scrotum is frequently sensitive to palpation and may be bruised after soft tissue trauma.

Diagnosis

I. Closely inspect the extruded penis, prepuce, preputial cavity, and scrotum for injury.
II. Determine the amount of damage to the os penis using radiography.
III. Radiography, including contrast urethrography, may be indicated to determine the extent of urethral damage.

Differential Diagnosis

I. Paraphimosis
II. Urethral prolapse

Treatment

I. Clean minor wounds and treat them with a topical antimicrobial ointment.
II. Minor wounds are usually allowed to heal by second intention.
III. To avoid self-inflicted trauma, prevent licking of the wound through use of an Elizabethan collar.
IV. Remove any foreign body from the preputial cavity.
    A. Open draining tracts and explore for foreign bodies.
    B. After removal of the foreign body, flush the tract and preputial cavity with an antiseptic solution.
V. If significant hemorrhage occurs, debride and suture the wound.
    A. Control arterial bleeding by ligation; control cavernous bleeding by suturing the tunica albuginea with fine absorbable material.
    B. Close the penile mucosa with fine absorbable material.
    C. Suture full-thickness preputial wounds by closing the preputial mucosa and skin separately, after thorough cleansing and possible wound debridement.
VI. Treat wounds of the penile urethra by catheterization, provided that the urethra has not been transected.
    A. Suture a transected urethra with fine absorbable material and catheterize the urethra.
    B. Maintain a closed catheter system for 5 to 7 days for minor penile urethral tears.
    C. Maintain a closed catheter system for 10 days after urethral anastomosis.
VII. Minimally displaced simple fractures of the os penis do not require immobilization (Johnston and Archibald, 1984).
    A. Some fractures can be adequately immobilized with a urethral catheter.
    B. Position the end of the catheter beyond the fracture site and maintain a closed collection system for 7 days.
    C. If a catheter cannot be passed because of urethral damage, or if the fracture is unstable following urethral catheterization, open reduction and fixation with a finger plate may be performed (Stead, 1972).
    D. Fractures accompanied by severe penile trauma may necessitate partial penile amputation.
VIII. Severe penile wounds may require partial penile amputation and a scrotal urethrostomy.
IX. Use parenteral and local antimicrobials postoperatively.
X. Prevent penile erection by sedating the animal.
XI. Avoid antiseptics on the scrotum because they may be irritating.
XII. Perform orchidectomy and scrotal ablation for severely contaminated scrotal wounds.

Monitoring of Animal

I. Monitor urination carefully, particularly if urethral trauma has occurred.
II. Urethral stricture is possible, especially following transection and anastomosis.
III. Monitor for urethral obstruction associated with callus formation from healing of an os penis fracture, and perform a prescrotal urethrostomy as needed.
IV. Monitor healing of draining tracts.

CHAPTER 60

Diseases of the Mammary Glands

Robert N. White

CONDITIONS OF LACTATING MAMMARY GLANDS

Galactostasis (Congestion)

Definition and Causes

I. Galactostasis is either cessation of milk secretion or an abnormal collection of milk in the mammary glands.
II. The condition may be associated with sterile or septic mastitis.

Pathophysiology and Clinical Signs

I. Galactostasis is a condition of uncertain etiology and is seen just before or shortly after parturition, after weaning, or during pseudopregnancy.
II. The condition may also develop in a dam after abrupt weaning of the litter.
III. Engorgement of the glands with residual milk induces localized inflammation and discomfort of the mammae, leading to a further failure of milk let-down.
IV. The cranial glands may be more commonly affected in lactating queens (Colby and Stein, 1983).
V. The condition is not generally associated with signs of systemic illness, although in cases of septic mastitis, severe systemic disease can occur.

Diagnosis

I. Galactostasis is a likely sequela to mastitis.
II. The condition is more commonly seen in bitches on a high plane of nutrition.
III. Galactostasis is most likely to develop during the early period of lactation, when the nursing young are inexperienced at suckling.
IV. The teat anatomy of affected glands (commonly, inverted nipples) may play a role in the development and progression of the condition.
V. Cytological examination of the milk taken from affected glands may be unremarkable, although an elevated white blood cell (WBC) count (>3000/μL) can be found (Wheeler et al., 1984).
VI. Other cytological findings, such as nondegenerate neutrophils and macrophages, are considered nonspecific, although the presence of phagocytosed fat droplets can indicate the stasis of milk within an affected gland.

Differential Diagnosis

Galactostasis must be differentiated from agalactia because the treatment and outcome for these conditions are different.

Treatment

I. Treatment depends on the underlying cause of the galactostasis.
II. When the condition is seen in early lactation and is possibly associated with inexperienced neonate sucking behavior, do the following:
   A. Confirm the neonates' ability to suckle.
   B. Confirm the dam's acceptance of the offspring and her ability to nurse.
   C. Attempt to evert any inverted nipples.
   D. Fast the dam for 24 hours, followed by a more limited feeding regimen.
   E. Consider manual milking of affected glands.
III. When the condition is related to mastitis, consider the following measures:
   A. Treat the mastitis as described (see Mastitis).
   B. Apart from the notable exceptions discussed under Mastitis, the neonates may be encouraged to suckle.
IV. When the condition is associated with abrupt weaning or pseudopregnancy, institute the following:
   A. In these instances the suckling of offspring is unlikely to relieve congestion; therefore the goal is to reduce further production of milk.
   B. Do not encourage manual milking of glands, because this causes additional milk production and let-down.
   C. Lower the dam's plane of nutrition and institute a limited feeding regimen for several days.
   D. Remove any further stimulus for milk production (e.g., the local presence of the recently weaned offspring).
   E. Cool compresses are applied to the affected gland(s) to reduce local inflammation and provide some comfort to the dam.
   F. Diuretics and glucocorticoids are, in most cases, of no benefit.

Monitoring of Animal

I. Most cases respond to treatment within a few days.
II. The sooner the condition is recognized and treatment initiated, the quicker the response to therapy.

III. Cases that are not recognized and treated promptly have the greatest likelihood of developing complications, such as mastitis.

Mammary Duct Ectasia

Definition and Causes

I. Mammary duct ectasia is a common cause of nonneoplastic enlargement of the mammae in the bitch.
II. The condition is characterized by dilatation of the ducts, inspissation of secretions, and a marked periductal and interstitial chronic granulomatous inflammatory reaction.

Pathophysiology and Clinical Signs

I. Mammary duct ectasia comprised 48% of nonneoplastic mammary gland disease in the dog (Miller et al., 2001).
II. The underlying cause of the ectasia remains unclear.
III. Mature, sexually intact and spayed bitches over a wide age range are affected.
IV. Ectasia is nodular, cystic, or multiglandular, and affects the caudal glands most frequently.
V. It may develop independently of ovarian or exogenous progestogens and has an inconsistent association with pregnancy or lactation.
VI. It causes gross enlargement and engorgement of mamma or mammae.

Diagnosis and Differential Diagnosis

I. Diagnosis of mammary duct ectasia is made histologically after incisional or excisional biopsy of affected glandular tissue.
II. Mammary duct ectasia can be commonly mistaken for mammary neoplasia.

Treatment and Monitoring

I. Mastectomy of affected glands is considered the treatment of choice for mammary duct ectasia.
II. Mastectomy is usually curative, although all excised lesions must be submitted for histopathology to rule out neoplasia.
III. Unsubstantiated evidence indicates that in some individuals the condition might recur after excision of affected mammae.

Galactorrhea

Definition

I. Galactorrhea is an excessive or spontaneous flow of milk that persists irrespective of nursing.
II. This lactation is not associated with pregnancy or parturition and is considered inappropriate.

Causes and Pathophysiology

I. Inappropriate lactation is mostly dependent on increasing prolactin and decreasing progesterone serum concentrations.
II. It occurs most commonly in association with pseudopregnancy (England, 1998).
III. Ovariohysterectomy or ovariectomy during diestrus mimics luteal regression, and this sometimes induces galactorrhea.
IV. The withdrawal of exogenous progestogen administration can cause inappropriate lactation in both the dog and cat (Johnston and Hayden, 1980).

Clinical Signs

Galactorrhea is evidenced by inappropriate mammary development and lactation that are unrelated to pregnancy and parturition.

Diagnosis

I. Presence of pseudopregnancy 6 to 12 weeks after the end of estrus
II. History of removal of the ovaries during the luteal phase
III. History of recent cessation of exogenous progestogen treatment

Treatment

I. Spontaneous resolution
   A. Galactorrhea associated with pseudopregnancy often resolves spontaneously and requires no treatment.
   B. Eliminating the stimulus for continued lactation, such as suckling neonates, helps galactorrhea subside.
II. Conservative treatment
   A. Application of an Elizabethan collar prevents bitches from stimulating further milk production and let-down through licking of the teats.
   B. Sedative agents (not phenothiazines because they are dopamine agonists and produce a rise in serum prolactin concentrations) may calm an agitated bitch and minimize licking of the teats (Figure 60-1).
   C. Administration of diuretics (e.g., furosemide) may lead to some improvement.
   D. Decreasing food and water for 24 to 48 hours to lessen milk production is recommended.
III. Administration of steroid preparations
   A. Progestogen
      1. Induces suppression of pituitary release of prolactin (see Figure 60-1)
      2. Available agents
         a. Megestrol acetate *(Ovaban, Ovarid)* 2 mg/kg PO SID for 5 days
         b. Proligestone (*Delvosteron,* not available in United States) 20 to 30 mg/kg SC
         c. Delmadinone acetate (*Tardak,* not available in United States) 1.0 to 1.5 mg/kg SC
         d. Medroxyprogesterone acetate (MPA [*Depo-Provera*]) 5 to 11 mg/kg SC, IM (maximum three times per year)
      3. Adverse effects
         a. Mammary gland enlargement
         b. Coat and temperament changes
         c. Delayed return to estrus after administration
   B. Estrogens and androgens
      1. Mechanism of action the same as that of progesterone (see Figure 60-1)
      2. Available androgenic agents

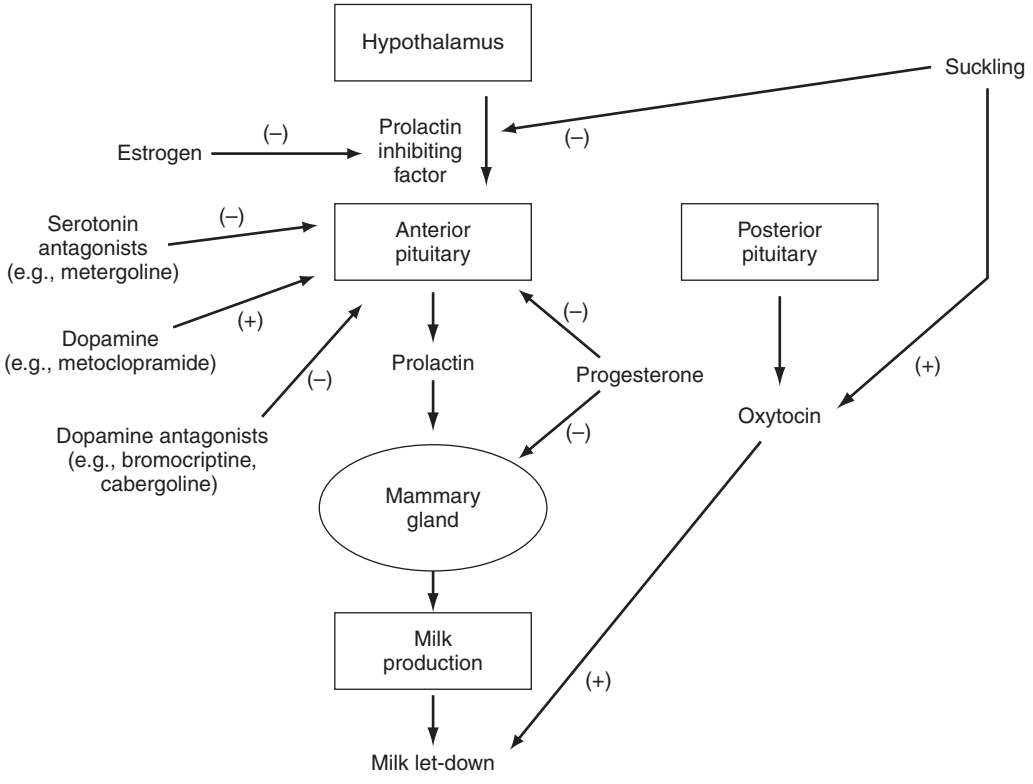

FIGURE 60-1 Pharmacophysiology of milk production and let-down.

a. Mibolerone *(Cheque Drops)* 16 µg/kg PO SID for 5 days
b. Methyltestosterone
(1) Plus estradiol (*Sesoral*, not available in the United States) at 0.7 mg/kg of methyltestosterone PO SID for 5 to 10 days
(2) Methyltestosterone *(Estratest)* 1 to 2 mg/kg PO for 5 to 7 days (maximum 25 mg/kg)

3. Adverse effects of estrogens: bone marrow suppression
4. Adverse effects of androgens: clitoral enlargement, aggression
5. Androgens not recommended in cats

IV. Administration of prolactin antagonists
A. Mechanism of action: dopamine antagonism that inhibits prolactin secretion (see Figure 60-1)
B. Available agents
1. Bromocriptine mesylate 20 µg/kg PO SID for up to 10 days
2. Cabergoline *(Galastop, Dostinex)* 5 µg/kg PO SID for 5 to 10 days
C. Adverse effects
1. Vomition common with bromocriptine
2. Reduction in plasma progesterone concentration leading to fetal resorption or abortion in pregnant animals
3. Reduction of the interval to the next fertile estrus

V. Ovariohysterectomy
A. Ovariectomy (or ovariohysterectomy) has no value for the treatment of clinical pseudopregnancy; removal of the ovaries causes a further reduction in plasma progesterone and potentiates the rise in prolactin.
B. Ovariohysterectomy prevents the occurrence of pseudopregnancy, but the procedure must be performed during deep anestrus (at least 3 months after the end of estrus).
C. In bitches that have repeated clinical pseudopregnancy, the best time to perform surgery is during the subsequent estrus.

Monitoring of Animal

I. Pseudopregnancy often recurs after subsequent heats; therefore unless affected bitches are to be used for breeding, spaying during anestrus is advised.
II. Treatment for bitches that have been spayed and appear to have "permanent" galactorrhea is reproductive steroids or bromocriptine.

Agalactia

Definition

I. Agalactia is defined as an absence or failure of the secretion of milk.
II. It occurs as a result of either failure of milk let-down or a failure in milk production.

Causes and Pathophysiology

I. It may occur when a congenital failure of mammary gland development occurs.
A. This is a very rare cause of agalactia in small animals.

B. The underlying cause is poorly understood, and the condition is not well documented.

II. Failure in milk let-down develops in association with psychological abnormalities or inappropriate hormonal interactions.
   A. Young, possibly primiparous or highly nervous dams may fail to settle and allow the litter to suckle.
   B. In the highly stressed animal, the release of oxytocin from the pituitary may be blocked by the production of excessive amounts of adrenaline.

III. Other debilitating conditions such as metritis, mastitis, and systemic infections can also lead to agalactia.

IV. Poor nutrition is an uncommon cause of decreased milk production.

Diagnosis

I. Diagnosis is based on clinical examination revealing an absence of milk in the teat canal.

II. The mammary glands often appear normal on physical examination.

Differential Diagnosis

Agalactia must be differentiated from galactostasis because the treatment and prognosis for these conditions are different.

Treatment

I. Congenital abnormalities in mammary gland development are unlikely to be treatable.

II. In very nervous dams, judiciously try sedatives such as acepromazine.
   A. The recommended dosage in dogs is 0.125 to 0.5 mg/kg PO BID to TID.
   B. Acepromazine can also increase milk production directly because the drug is a dopamine agonist (see Figure 60-1).

III. Metoclopramide, acting as a dopamine antagonist, can be used to promote prolactin secretion.
   A. The recommended dose in dogs is 0.2 to 0.5 mg/kg IM, SC, PO BID to TID.
   B. Metoclopramide may infrequently cause mental changes ranging from hyperactivity to depression.

IV. Suckling by the litter is encouraged, and in cases with persistent failure of milk letdown, the use of oxytocin is considered.
   A. The recommended dose of oxytocin in dogs is 2 to 20 IU SC, IM and in cats is 1 to 10 IU SC, IM.
   B. Treatment continues daily until milk production is established.
   C. The use of oxytocin to stimulate milk letdown is only effective in bitches with adequate milk production.

V. Severe debilitation from poor nutrition or systemic disease is managed according to the disease process present.

Monitoring of Animal

I. The prognosis for stimulating milk let-down in dams with true agalactia is poor.
   A. The offspring require hand rearing.
   B. Ideally, affected dams are not bred again.

II. Nervous dams can usually be persuaded to allow the litter to suckle, and adequate milk production can be achieved, with or without the use of oxytocin.
   A. The young may require supplemental feeding for a few days.
   B. Most affected dams do not suffer from agalactia after the birth of subsequent litters.

CONDITIONS OF NONLACTATING MAMMARY GLANDS

Mammary Fibroadenomatous Hyperplasia

Definition

I. Mammary fibroadenomatous hyperplasia is characterized by a marked increase in the size of one or multiple mammary glands (Hayden and Johnson, 1986).

II. It usually develops in young estrous-cycling cats and pregnant cats, but may also be seen in aged or neutered individuals of either sex after prolonged treatment with exogenous progestogens (Hayden et al., 1989).

III. It occurs rarely in dogs of either sex receiving exogenous progestogens.

IV. Other names for the same condition include *fibroadenomatosis, fibroadenoma, mammary fibroepithelial hyperplasia, benign mammary gland hyperplasia,* and *feline mammary hypertrophy*.

Causes

I. The exact mechanism is poorly understood.

II. High levels of serum progesterone exert a growth-stimulating effect on mammary gland epithelium (Hayden et al., 1981).

III. Significant quantities of growth hormone are produced directly by the feline mammary gland in response to increased levels of serum progesterone.
   A. Associated with the luteal phase of the estrous cycle in the young queen and with early stages of pregnancy
   B. Occurs after prolonged administration of progestogen compounds (e.g., megestrol acetate, methylprogesterone)

Pathophysiology

I. The increase in size of the mammary tissue is generally well circumscribed and within one or more of the gland complexes.

II. The condition is characterized by a proliferation of mammary duct epithelia and periglandular myoepithelial cells, marked edema, and increased amounts of connective tissue surrounding the glands (Nimmo and Plummer, 1981).

III. Two distinct histologic forms have been described and are considered to have similar biologic behavior and response to treatment.
   A. Diffuse fibroepithelial hyperplasia
      1. Characterized by proliferation of fibroglandular elements within the affected tissues
      2. Typical of lesions seen in young, postestral queens (Johnston and Hayden, 1980)

B. Intraductular papillary hyperplasia
   1. Characterized by proliferation of the ductular epithelium
   2. Typical of lesions induced by exogenous progestogen therapy (Hayden et al., 1989)

Clinical Signs

I. A few or all mammary glands are symmetrically enlarged.
II. Multiple lesions can occur in mammary glands, making it possible to have more swellings than there are glands.
III. Affected glands vary considerably in size (from 2 to 10 cm in diameter); in some instances the overlying skin may be tense and erythematous, with multiple cutaneous ulcerations.
IV. Milk secretion is uncommon.
V. Enlarged glands are usually nonpainful and soft on palpation.
VI. When gland enlargement is profound, glands may become inflamed and palpation may be resented.

Diagnosis and Differential Diagnosis

I. Diagnosis is based on signalment, age of the animal, sexual status, reproductive history (including treatment with progestogens), and clinical findings.
II. Differentiating the condition from mammary carcinoma and mastitis is important.
   A. These conditions can be readily distinguished by histologic examination of biopsy tissue.
   B. Aspiration cytology is often inconclusive; therefore obtaining a core biopsy specimen is desirable.
   C. Generally, excisional biopsy is not required.

Treatment and Monitoring

I. Treatment is usually aimed at the elimination of the source of progestin.
II. In animals not receiving exogenous progesterone, the condition can regress spontaneously.
III. Ovariectomy is considered the treatment of choice in young cycling females and usually leads to regression of the mammary tissue within 3 to 4 weeks, although in some cases regression may take up to 5 to 6 months.
IV. The administration of antiprogestins may be tried (Wehrend et al., 2001).
   A. Aglépristone (*Alizine,* not available in the United States) 10 mg/kg SC SID for 4 to 5 days can be used.
   B. Complete involution of the hyperplastic mammary glands may take 3 to 4 weeks.
   C. No side effects are reported.
   D. When treating intact female cats, pregnancy must be ruled out before treatment because of the abortive effects of antiprogestins (Gorlinger et al., 2002).
V. Stop the exogenous administration of progestogens.
   A. In such cases, regression of lesions may take up to 5 to 6 months.
   B. Testosterone and cabergoline may hasten the regression of hyperplastic tissues.
VI. Surgical excision is controversial.
   A. Excision is reserved for cases that fail to respond to conventional therapy.
   B. Excision may be indicated in severe cases when the glands show evidence of trauma or infection.

Mastitis

Definition

I. Inflammation of the mammary glands (mastitis) is a disease almost entirely limited to lactating glands and is restricted to the postpartum or pseudopregnant bitch or queen.
II. The condition is uncommon in small animals.

Causes and Pathophysiology

I. Most cases have an infectious component.
   A. Ascending bacterial infection via the streak canal (teat orifice) is most likely, although infection via the blood stream is a possibility.
      1. The streak canal is an anatomic barrier that normally prevents bacteria from entering the gland.
      2. Alterations during lactation allow ascending bacteria easier access.
      3. Chemical, cellular, and immune responses provide further defenses within the gland, but these mechanisms may be overwhelmed during the period of lactation.
   B. Causal organisms include coliforms (especially *Escherichia coli*), streptococci, and staphylococci (Johnston and Hayden, 1980).
II. It can be associated with prolonged galactostasis or keeping animals in poor sanitary conditions.
III. It rarely results from trauma (possibly from suckling pups or kittens).

Clinical Signs

I. Acute mastitis
   A. One or more glands are affected; the caudal glands are the most commonly involved.
   B. Affected mammae are painful, erythematous, and swollen.
   C. Anorexia, malaise, and pyrexia are often present.
   D. Dams may be brought to the clinic because of neonatal morbidity or mortality.
   E. Abnormal secretions may be expressed from the affected glands.
      1. The presence of discolored milk, or hemorrhagic or purulent secretions, is highly suggestive.
      2. Mastitis may occur in animals with apparently normal milk production and also in those with agalactia (especially of the affected mammae).
   F. In certain cases the glands may become gangrenous or abscessed.
      1. Affected glands are discolored, bruised, and cool to the touch.
      2. In more advanced cases, deep ulceration develops.
      3. Signs of systemic sepsis may be present.

II. Chronic mastitis
  A. Chronic bacterial mastitis may occur as an incidental finding in older, nonlactating queens (Colby and Stein, 1983).
  B. Inflammatory changes are usually minimal, although affected glands may appear thickened, with palpable nodules.
  C. Importantly, the gross changes observed are very similar to those of mammary neoplasia.
III. Associated conditions
  A. Consider a diagnosis of mastitis for any dam whose nursing neonates become sick or die unexpectedly.
    1. Dams with mastitis probably provide inadequate passive immunity, nutrition, and hydration to their offspring.
    2. Ingestion of infected milk is an unproven cause of neonatal septicemia.
    3. Neonates with bacterial diseases may cause an ascending mastitis in the dam during suckling (Wheeler et al., 1984).
  B. Many of the clinical signs associated with galactostasis are similar to those observed in animals with mastitis.

Diagnosis

I. Suggestive physical findings
II. Hematology
  A. In general, hemograms reveal a neutrophilic leukocytosis.
  B. In the peracute case the hemogram is often normal.
III. Cytological assessment and culture of milk samples from affected glands
  A. Degenerative neutrophils are the predominant cell type.
  B. Free and phagocytosed bacteria within degenerative neutrophils and macrophages may be present.
  C. Significant elevations in WBC counts (>3000/μL) are considered abnormal.
  D. Note that elevated WBC counts are occasionally observed in samples taken from apparently normal dams (perhaps indicating subclinical disease).
  E. Bacterial culture and sensitivity and evaluation of the pH of infected milk (see following section) aid in antimicrobial selection.

Treatment

I. Treatment is instituted as soon as possible after diagnosis.
II. Administer an antibiotic based on the results of culture and sensitivity testing.
III. If culture results are not available, then do not delay treatment using a broad-spectrum antibiotic.
IV. In acutely inflamed mammary glands, most antibiotics achieve therapeutic levels because a breakdown of the milk-plasma barrier occurs.
V. In the more chronic or relapsing cases, the presence of the milk-plasma barrier makes assessment of culture and sensitivity tests, as well as milk pH evaluations, critical for the effective management of the condition.
  A. If milk is more acidic than normal plasma pH, then antibiotics that are weak bases (e.g., potentiated sulfonamides, lincomycin) are indicated.
  B. If milk is more alkaline than normal plasma pH, then antibiotics that are weak acids (e.g., ampicillin, cephalexin) are used.
  C. Be careful when considering the use of agents that may have an adverse effect on the nursing neonates; for example, tetracyclines are not to be used because they potentially cause staining of the tooth enamel in nursing pups and kittens.
VI. Aminoglycosides are not recommended because of their poor penetration of the blood-mammary gland barrier.
VII. Keep the affected glands empty of abnormal secretions; methods by which this is achieved are controversial.
  A. Manual milking by the owner can be performed, but is often difficult and ineffective.
  B. The neonates may be allowed to continue nursing from the affected dam.
    1. Affected milk is likely to have a poor nutritional content.
    2. The nursing neonates ingest any medications that are administered to the dam that cross the milk-plasma barrier (see previous discussion).
    3. Do not allow neonates to suckle from severely infected glands or from those with abcessation or gangrene.
      a. If only one or two glands are involved, then bandages may be applied around the bitch to cover the affected glands, thereby preventing interference from the young.
      b. Neonates that cannot be nursed by the dam require hand rearing.
      c. Offer specific advice regarding hand-rearing techniques to the owners of such animals.
VIII. Gangrenous or abscessed mammae require more aggressive therapy.
  A. Anaerobic organisms may be involved, so choose antibiotics accordingly.
  B. Prevent offspring from suckling from affected glands.
  C. Milk secretions are stripped manually from affected glands at least twice daily.
  D. In severe cases surgical drainage may be required.
  E. The use of warm compresses may provide some relief for the dam.
  F. Chronic, persistently infected glands ultimately require mastectomy.
IX. Individuals with signs of systemic disease associated with the mastitis (septicemia) often require intensive management including IV fluid therapy and IV antibiotics.

Monitoring of Animal

I. Prognosis for animals suffering from peracute mastitis with concurrent systemic sepsis is guarded.
II. Prognosis for the majority of cases with acute or chronic mastitis is good, provided that therapy is instituted without delay.

NEOPLASIA

Definition

I. Mammary tumors are neoplasms of epithelial and/or myoepithelial cells of the mammae.
II. Mammary tumors are the second most common tumors in all dogs and the most common tumor in the bitch (Rutteman et al., 2001).
  A. Occur most commonly in older animals (mean age 10 years)
  B. Usually occur in animals that are intact or have been spayed after numerous estrous cycles
  C. All breeds affected
III. In the cat, mammary tumors occur less frequently but are still the third most common type of all tumors (Rutteman et al., 2001).
  A. Older cats are most often affected (mean age 10 to 12 years).
  B. Intact animals are usually affected.
  C. Siamese cats may be more at risk than other breeds (Hayes et al., 1981).

Causes

I. The production of estrogen and progesterone is linked to the development of mammary tumors in both dogs and cats.
II. The relative risk of developing a mammary tumor is related to the number of estrus cycles a bitch has experienced.
  A. Relative risk with ovariohysterectomy after first season is 0.05%.
  B. Relative risk after first estrus is 8%.
  C. Risk after second estrus is 26% (Schneider et al., 1969).
III. In the intact cat a sevenfold increase exists in the risk of developing mammary tumors compared with cats neutered at puberty (Dorn et al., 1968).
IV. Both estrogen and/or progesterone receptors are present in 40% to 70% of canine mammary tumors (Sartin et al., 1992).
  A. Administration of some progestogens increases the risk of benign tumor development in dogs (Schneider et al., 1969).
  B. In the bitch, more malignant, undifferentiated tumors tend to be receptor negative.
V. Low concentrations of progesterone receptors are reported in feline mammary tumors, and approximately 10% of tumors contain estrogen receptors (Hamilton et al., 1976).
VI. Use of progesterone-type drugs in the cat may increase the development of benign or malignant mammary masses.

Pathophysiology

I. Benign tumors
  A. Do not invade locally or metastasize
  B. Tendency for bitches to develop multiple benign tumors
  C. Tendency for new benign tumors to develop in the same or other glands after excision of an existing nodule
II. Malignant tumors
  A. They may behave relatively benignly or very aggressively.
  B. Rapid metastasis occurs with tumors showing local invasion.
    1. Local lymph nodes: superficial inguinal for caudal glands, axillary or cranial sternal for cranial glands
    2. Lungs
    3. Abdominal organs and bones
  C. Feline mammary carcinomas are especially aggressive and have often metastasized by time of presentation.

Clinical Signs

I. The caudal two pairs of mammary glands are most often affected in the dog.
II. Cranial glands are most commonly affected in the cat.
III. Tumors are often easily palpable as discrete nodules or masses within mammary glands.
  A. May be single or multiple
  B. May be attached to overlying skin or underlying muscle
  C. ± Skin ulceration
IV. Small benign masses may be an incidental finding.
V. Some aggressive inflammatory carcinomas are accompanied by diffuse mammary swelling, edema, and ulceration.
VI. Respiratory distress is rarely noted in dogs with pulmonary metastasis, but is common in cats from pleural carcinomatosis and extensive pulmonary involvement.
VII. Paraneoplastic syndromes are responsible for some systemic signs.
  A. Some dogs with advanced tumors may have hemorrhagic diatheses or disseminated intravascular coagulation.
  B. Subclinical hemostatic abnormalities are more likely (Stockhaus et al., 1999).

Diagnosis

I. Signalment and history often suggest neoplasia.
II. Hematological and biochemistry tests are generally normal.
III. Radiographic assessment of the lungs for metastasis is undertaken when malignant disease is either confirmed or thought likely.
  A. Abdominal films may show sublumbar lymph node enlargement.
  B. Skeletal survey films may indicate bony metastasis.
IV. Ultrasonography may be used to image the primary lesion but is most often used to screen local lymph nodes and the abdomen for evidence of metastasis.
V. Scintigraphy may be used to detect bony metastasis.
VI. Biopsy is required for a definitive diagnosis.
  A. Fine-needle aspiration is not always easy to interpret by cytologic examination but may give an indication of whether the lesion is neoplastic or nonneoplastic.
  B. Fine-needle aspiration is most useful for assessment of metastasis to the local lymph nodes.
  C. Mammary lesions may be wedge or core biopsied to provide a sufficient sample size for histopathologic investigation.

D. Small nodules are best biopsied via complete excision, as part of the treatment.
E. Incisional biopsy usually is not necessary for mammary tumors, because the type of surgical treatment for most cases does not depend on their histologic type.
F. Incisional biopsy helps, however, to distinguish neoplasms from nonneoplastic conditions that may not require surgery.

VII. The frequency of various canine mammary tumors is almost evenly distributed (Box 60-1).
A. In the bitch several different tumor types may occur in the same gland or affect different glands in the same animal.
B. In the bitch the most important feature of carcinomas that predicts their behavior and likely outcome is whether they appear well defined or if they are infiltrative and invasive.
C. In cats nearly all mammary tumors are malignant; over 80% are carcinomas, and the rest are mainly fibroadenomas.

VIII. Tumor-node-metastasis (TNM) staging systems are used for mammary carcinomas in both the dog and cat (Box 60-2).
A. Multiple tumors are evaluated independently.
B. The staging process includes the results of clinical and radiographic evaluations, and it may also include findings obtained at the time of surgery.

Differential Diagnosis

I. Mastitis
II. Mammary hyperplasia
III. Galactostasis
IV. Other benign and malignant tumors, such as lipomas or mast cell tumors
V. Mammary duct ectasia in the dog

Box 60-1

Frequency of Morphologic Types of Canine Mammary Tumors

Tumor Type	Relative Frequency (%)
Benign Mammary Tumors (total)	**51.0**
Benign mixed tumors/fibroadenomas/ complex adenomas	45.5
Simple adenomas	5.0
Benign mesenchymal tumors	0.5
Malignant Mammary Tumors (total)	**49.0**
Total carcinomas	44.9
Solid carcinomas	16.9
Tubular adenocarcinomas	15.4
Papillary adenocarcinomas	8.6
Anaplastic carcinomas	4.0
Sarcomas	3.1
Carcinoma/malignant mixed tumors	1.0

From Bostock DE: Canine and feline mammary neoplasms. Br Vet J 142:506, 1986; with permission.

Treatment

I. The treatment for most mammary tumors is surgical excision.
A. A number of surgical options exist.
1. Nodulectomy and lumpectomy are used as a biopsy procedure for small, unifocal lesions <0.5 cm in diameter.
2. Mammectomy, or removal of the affected gland, may be sufficient for fixed or mobile tumors centrally positioned within the gland.
3. Local mastectomy is removal of the affected gland along with any glands that drain lymph or blood from it.
4. Total or radical mastectomy is removal of the entire mammary chain.
5. In the dog, no study has shown that the type of surgery performed influences the outcome dramatically, and many surgeons favor simple mastectomy over radical mastectomy, ignoring lymphatic drainage patterns.

Box 60-2

TNM Staging of Canine and Feline Mammary Tumors*

T	Primary Tumor†
T0	No evidence of tumor
T1	Tumor <3 cm maximum diameter (<1 cm in cat)
T1a	Not fixed
T1b	Fixed to skin
T1c	Fixed to muscle
T2	Tumor 3-5 cm maximum diameter (1-3 cm in cat)
T2a	Not fixed
T2b	Fixed to skin
T2c	Fixed to muscle
T3	Tumor >5 cm maximum diameter (>3 cm in cat)
T3a	Not fixed
T3b	Fixed to skin
T3c	Fixed to muscle
T4	Tumor any size, inflammatory carcinoma
N	**Regional Lymph Nodes**
N0	No evidence of involvement
N1	Ipsilateral involvement
N1a	Not fixed
N1b	Fixed
N2	Bilateral involvement
N2a	Not fixed
N2b	Fixed
M	**Distant Metastasis**
M0	No evidence of metastasis
M1	Distant metastasis including distant lymph nodes

From Owen LN: TNM Classification of Tumours in Domestic Animals. World Health Organization, Geneva, 1980; with permission.
TNM, Tumor-node-metastasis.
*Tumor sizes for the cat are given in parentheses where appropriate.
†Evaluate multiple tumors independently.

6. Feline mammary tumors are usually very aggressive, so in most cases radical mastectomy is indicated.

B. Larger and multiple tumors require either local or radical mastectomy.
   1. Inguinal lymph nodes are removed as part of the most caudal gland.
   2. Axillary lymph nodes are only excised if they are enlarged or have been shown to contain neoplastic cells.
   3. Performing complete bilateral mastectomy during the same procedure is not recommended because closure may prove very difficult and postoperative dehiscence is a likely consequence.

C. Although researchers thought that concurrent ovariohysterectomy at the time of mammary tumor excision in the bitch had no effect on the development of new benign tumors, the progression of malignant tumors, the time to metastasis, or overall survival (Morris et al., 1998), more recent work suggests that bitches spayed <2 years before their mammary surgery survive longer (45%) compared with dogs that were either intact or spayed >2 years before their mastectomy surgery (Sorenmo et al., 2000).

D. In cats, ovariohysterectomy is considered part of the treatment, because ovarian and uterine disease occasionally coexists with mammary tumors in this species.

II. Radiotherapy has not been effective in the treatment of canine and feline mammary tumors (Rutteman et al., 2001).

III. Chemotherapy has been attempted for mammary carcinomas, but no protocol has been very effective in improving disease-free interval or survival beyond that obtained by surgery alone.

A. Doxorubicin has antitumor effects in vitro, but its effects in the clinical situation are variable (Ogilvie et al., 1989).

B. The advanced nature of most feline mammary tumors results in a poor response to chemotherapy; however, doxorubicin (25 mg/m^2 IV slowly), alone or in combination with cyclophosphamide (50 to 100 mg/m^2 PO on certain days after doxorubicin administration), may help to delay metastasis after surgery (Mauldin et al., 1988).

Monitoring of Animal

I. The prognosis for most benign canine mammary tumors that are surgically excised is good.

II. The prognosis for well-differentiated carcinomas is reasonable, with survival times >2 years for some histological types (Bostock, 1975).

III. The prognosis for invasive carcinomas is grave, because most metastasize rapidly despite surgical removal (Morris and Dobson, 2001).

A. Solid carcinomas: survival time of 36 weeks

B. Anaplastic carcinomas: survival time of 11 weeks

C. Sarcomas: survival time of approximately 6 months

IV. Recent studies suggest that in dogs, tumor stage, tumor size, and ovariohysterectomy status are significant prognostic factors associated with survival 2 years after malignant tumor resection (Chang et al., 2005).

A. Tumors ≥5 cm in diameter that were present for >6 months before resection had a higher risk of lymph node metastasis.

B. Dogs in which ovariohysterectomy had been performed had a better prognosis, especially in individuals with complex carcinomas.

V. In cats, the prognosis for mammary tumors is much more guarded, because most are highly malignant and local recurrence and metastasis are common.

VI. Recent studies suggest that cats spayed before 1 year of age have significantly decreased risk of mammary carcinomas (Overley et al., 2005).

A. Cats spayed before 6 months of age have a 91% reduction in risk, whereas those spayed before 1 year have an 86% reduction in risk.

B. Parity does not show any effect on mammary carcinoma development.

CHAPTER 61

Disorders of Canine Reproduction

Margaret V. Root Kustritz

DISORDERS OF INFERTILITY

Infertility in the Bitch

Definition

I. Infertility in the bitch is defined as lack of pregnancy after ovulation of normal ova into a patent, healthy reproductive tract and insemination with normal semen near the time of ovulation.
II. Normal estrous cycling is a prerequisite of normal fertility in the bitch.
  A. Primary anestrus is the lack of obvious estrous cycling by 24 months of age.
  B. Secondary anestrus is the lack of estrous cycling within 12 months of a previous estrous cycle.
  C. Normal interestrous interval (number of days between onset of proestrus and the subsequent proestrus) averages 5 to 8 months in dogs but may range from 4.5 months (German shepherd dogs, rottweilers) to 12 months (basenjis, wild dog crosses).

Causes and Clinical Signs

I. Primary or secondary anestrus may arise from malnutrition, stress, lack of exposure to cycling bitches, systemic disease, previous ovariohysterectomy, silent heat (normal ovarian activity without external signs), or chromosomal abnormalities (Johnston, 1991).
II. Improper breeding management (mistimed or inadequate number of breedings), the most common cause of apparent infertility in bitches that are cycling normally, is reported in 40% to 50% of infertility cases (Johnston et al., 1994).
  A. The average bitch ovulates about 12 days after first signs of vulvar swelling and exudation of serosanguineous vaginal discharge; however, ovulation may occur as early as 3 to 4 days or as late as 25 to 26 days after proestrus onset.
  B. Breeding by day of the cycle alone yields pregnancy rates as low as 78% (England, 1992).
  C. Secretion of estrogen from the mature preovulatory follicle stimulates division of vaginal epithelial cells.
    1. Cytological specimens contain an increasing percentage of cornified cells as dogs progress through proestrus.
    2. Estrus, or standing heat, is defined cytologically as complete cornification, with >50% of the cells appearing anuclear.
    3. Six days after ovulation, cornified cells are sloughed, and the onset of diestrus is signaled by an abrupt return to noncornified vaginal cytology (Holst and Phemister, 1974).
  D. Ovulation timing is best performed by measurement of serum progesterone.
    1. Serum progesterone concentration is 2 ng/mL 2 days before ovulation and 4 to 10 ng/mL on ovulation day (Box 61-1) (Johnston and Root, 1995).
    2. Luteinizing hormone (LH) can be measured using a commercially available semiquantitative assay (Status-LH; Synbiotics, San Diego, Calif.).
    3. Serum LH concentration >1 ng/mL occurs (on average) 2 days before ovulation.
III. Subclinical uterine infection is a reported cause of infertility in bitches.
  A. Infection may cause conception failure by creating a hostile environment for the ova and spermatozoa, or

Box 61-1

Use of Serum Progesterone Concentration to Determine Ovulation Day in the Bitch

Serum Progesterone Concentration (ng/mL)	Event, Recommendation
<1.0	Well before ovulation—recheck in several days
1.0-1.9	±3 days before ovulation—recommend recheck
2.0-2.9	2 days before ovulation
3.0-3.9	1 day before ovulation
4.0-10.0	Ovulation day NOTE: Optimal breeding day is 2 days after ovulation
>10.0 with cornified vaginal cytology	1-5 days after ovulation—breed immediately
>10.0 with noncornified vaginal cytology	Diestrus—too late to breed this season

by causing early embryonic death (see Pregnancy Loss later in this chapter).
   1. Because the canine uterus is inaccessible to most practitioners without performing laparotomy and hysterotomy, culture samples taken from the cranial vagina during estrus have traditionally been used to infer the presence of uterine infection (Bjurstrom and Linde-Forsberg, 1992; Bjurstrom, 1993).
   2. Requesting quantitative culture results, with the assumption that heavy growth of a single organism is indicative of reproductive tract infection, may enhance accuracy.
   3. Some breeders require negative vaginal cultures of breeding bitches before introduction to the male, but this is an illogical practice and is discouraged.

B. Canine brucellosis is a specific uterine infection associated with infertility (see Pregnancy Loss later in this chapter).

IV. Hypothyroidism has been associated with infertility in the bitch.
   A. It may cause primary anestrus, prolonged or irregular interestrous intervals, prolonged proestrus, decreased intensity or duration of estrous cycles, galactorrhea, and increased incidence of spontaneous abortion.
   B. Many dogs with reproductive dysfunction secondary to hypothyroidism exhibit no extrareproductive clinical signs (Reimers, 1983; Johnson et al., 1997).

V. Hypoluteoidism is a proposed cause of infertility and pregnancy loss in dogs.

Diagnosis

I. The recommended diagnostic tests depend on the presence or absence of normal estrous cycling in the bitch (Box 61-2).

II. Cases refractory to standard diagnostic tests may benefit from the following tests:
   A. Uterine biopsy via laparotomy and hysterotomy to look for cystic endometrial hyperplasia, an age-related change in the uterine lining that may interfere with implantation and placentation and predispose the bitch to uterine infection
   B. Direct uterine culture via laparotomy and hysterotomy (often performed at the time of uterine biopsy)
   C. Abdominal ultrasonography to assess the uterus
      1. The normal, nonpregnant canine uterus is not visible as a distinct entity on ultrasonography.
      2. If the uterus is visible, and especially if the uterine lining can be visualized as a fluffy gray layer, then cystic endometrial hyperplasia is present.

Treatment

I. Attempt to convert primary and secondary causes of anestrus.
   A. Ensure the bitch is on a proper plane of nutrition and is not stressed by the environment in which she is housed or by overwork.
   B. Perform a complete blood count, serum chemistry profile, and urinalysis to assess for treatable systemic diseases.
   C. Measure canine thyroid-stimulating hormone and free thyroxine in serum to assess for hypothyroidism.
   D. Perform vaginal cytological examination weekly and/or progesterone assays monthly to identify silent heat.
   E. Submit whole blood or tissue for a karyotype to determine if the bitch has a normal chromosome complement.
   F. Attempt estrus induction.
      1. Diethylstilbestrol 5 mg PO SID for 6 to 9 days or until proestrus is induced
      2. Cabergoline 5 μg/kg PO SID for 7 to 10 days or until proestrus is induced
      3. Efficacy of estrus induction protocols: variable in dogs

II. Minimize improper breeding practices by optimizing the time of breeding.
   A. Optimal breeding time is 2 days after ovulation.
   B. If dogs are to be bred by natural service, then they are mated every other day while the bitch allows the male to mount.
   C. If the number of breedings by natural service is limited in number, or if artificial insemination with fresh or

Box 61-2

Diagnostic Scheme for Infertility in Bitches

Is Normal Estrous Cycling Occurring?

No	Yes
1. Evaluate husbandry and nutrition.	**1.** Assess fertility of male dog.
2. House with cycling bitches.	**2.** Obtain serum chemistry profile, complete blood count, urinalysis to assess general health.
3. Obtain serum chemistry profile, complete blood count, urinalysis to assess general health.	**3.** Perform serologic testing for canine brucellosis (see Table 61-1).
4. Evaluate thyroid hormones: concurrent measurement of free thyroxine by dialysis and canine thyroid-stimulating hormone for assessment of hypothyroidism (Panciera, 1994; Peterson et al., 1997).	**4.** Optimize breeding management with measurement of serum progesterone.
5. Perform serial vaginal cytology to monitor for silent heat.	**5.** Perform quantitative anterior vaginal culture during proestrus. Treat with appropriate antibiotic therapy throughout proestrus and estrus if necessary.
6. Consider karyotyping.	
7. Perform serologic testing for canine brucellosis (see Table 61-1).	

Modified from Johnston SD, Olson PN, Root MV: Clinical approach to infertility in the bitch. Semin Vet Med Surg (Small Anim) 9:2, 1994.

chilled semen is intended, then vaginal insemination is performed 2 and 4 days after ovulation.
D. If frozen-thawed semen is to be used, then intrauterine insemination is undertaken 3 or 4 days after ovulation.

III. Institute appropriate antibiotic therapy for subclinical uterine infection.
A. Retrieve a culture specimen from the anterior vagina of the estrous bitch early in proestrus; moderate to heavy growth of a single organism is significant.
B. Treat with an appropriate antibiotic based on sensitivity testing until the bitch enters diestrus, as evidenced by lack of vulvar discharge and standing behavior, or abrupt onset of noncornified vaginal cytology.
C. Empiric antibiotic treatment without culture is not recommended.

IV. Canine brucellosis is not curable in dogs; no recommended treatment exists for infertility caused by *Brucella canis*.
A. Euthanize *Brucella*-positive bitches housed in a kennel situation.
B. Individually housed bitches may be treated by performing ovariohysterectomy and administering tetracycline 30 mg/kg PO BID for 28 days and streptomycin 20 mg/kg IM SID for 14 days.
1. Oral enrofloxacin may be used to treat canine brucellosis, but no specific dose regimen has been described.
2. Antibiotic therapy induces remission, but does not eradicate the organism.
C. Canine brucellosis is a zoonotic disease; therefore caution owners of *Brucella*-positive bitches of possible human transmission, especially if pediatric, geriatric, or immunosuppressed persons live in the household.

V. Start thyroid supplementation.
A. Supplement with L-thyroxine 0.01 to 0.02 mg/kg PO BID.
B. Recheck serum concentration of thyroxine 4 to 6 weeks after treatment is instituted.
C. Hypothyroidism may be hereditary in dogs, so advise owners that bitches with hypothyroidism are not good candidates for breeding.

VI. Bitches with apparently normal reproductive tracts, normal estrous cycling, no evidence of intrauterine infection, negative brucellosis serology, and normal thyroid hormone status may benefit from intrauterine insemination.
A. Intrauterine insemination is performed surgically or with endoscopy.
B. Surgical intrauterine insemination requires general anesthesia and laparotomy.
1. Exteriorize the uterine body and horns, and inject semen through the uterine wall with a 22-gauge needle or catheter and syringe.
2. Hold off the injection spot briefly, and close the abdomen routinely.
C. Endoscopic intrauterine insemination requires neither general anesthesia nor sedation.
1. Pass a long, narrow-diameter, rigid endoscope the length of the vagina to visualize the cervix.
2. Pass a polypropylene urinary catheter through the cervix and into the uterus, and inject the semen through the catheter.

Monitoring of Animal

I. Prognosis for return to fertility varies with the cause.
A. Proper breeding management, with collection of serial vaginal cytology specimens and measurement of serum progesterone concentrations, is corrective of apparent infertility in 40% to 50% of cases.
B. Diagnosis and treatment of subclinical uterine infection with appropriate antibiotic therapy is the next most common corrective therapy for infertility.
C. Brucellosis is an irreversible cause of infertility in bitches.
D. Hypothyroidism may be a reversible cause of infertility with proper supplementation with thyroxine; however, bitches with hypothyroidism are not good candidates for breeding.
E. Abnormal chromosome complement is an irreversible cause of infertility in bitches.

II. The owner may benefit from a discussion regarding potential heritability of the cause of the animal's infertility, as well as the wisdom of removing subfertile animals from the breeding program.

Infertility in the Male Dog

Definition

I. Infertility in the male dog is defined as complete inability to effect pregnancy in normal females bred multiple times near the time of ovulation (Ellington, 1994).

II. Subfertility is defined as the siring of litters infrequently or the siring of litters containing few pups for that particular breed.

Causes and Clinical Signs

I. Lack of normal breeding behavior and poor libido
A. Inability to copulate
1. Failure of normal copulation in dogs may have behavioral or physical causes.
2. Behavioral causes include introduction to a nonreceptive female, attempting to breed to a dominant female that will not allow the male to mount, and inexperience or apprehension (Root Kustritz, 2005).
3. Intact male dogs that have been disciplined throughout their lives whenever exhibiting mounting and thrusting behavior are unlikely to show normal breeding behavior at the desired time.
4. Physical causes for failure of normal copulation include prostate disease and any painful condition of the spine or hind limbs that prohibits the male from mounting, thrusting, and maintaining the copulatory lock.
B. Inability to ejaculate
1. Lack of ejaculation may have behavioral or physical causes.

2. Behavioral causes for an ejaculation include lack of sexual maturity, inexperience, and apprehension.
3. Conversely, some very experienced stud dogs will not ejaculate in the absence of an estrous teaser bitch.
4. Subordinate males may refuse to mount a bitch they perceive to be dominant.
5. Physical causes for lack of ejaculation include prostate disease, any painful condition of the spine or hind limbs, or retrograde ejaculation (ejaculation of semen into the urinary bladder instead of antegrade, through the penile urethra).

II. Poor semen quality (Table 61-1)

III. Prostate disease
   A. Benign prostatic hypertrophy, prostatitis, and prostatic neoplasia may be associated with pain during prostatic contraction.
   B. Prostatic contraction occurs whenever the male is excited and throughout ejaculation (Olson et al., 1987).

Diagnosis

I. Collect historical data.
   A. Determine whether normal copulation is occurring.
      1. Causes of abnormal copulation include pain in the spine or pelvic limbs and prostate disease.
      2. Behavioral incompatibilities between the bitch and male dog may also preclude normal copulation.
   B. Determine whether normal ejaculation is occurring.
      1. Causes of abnormal ejaculation include pain in the spine or pelvic limbs, prostate disease, and apprehension on the part of the male.
      2. Retrograde ejaculation of semen into the urinary bladder may appear as lack of ejaculation.
         a. Diagnosis requires collection of a urine sample by cystocentesis after semen collection.
         b. Compare the numbers of spermatozoa in the antegrade ejaculate and in the urine sediment.

II. Perform a complete physical examination.
   A. Evaluate the dog for any evidence of systemic disease and clinical signs of hypothyroidism, such as weight gain and bilaterally symmetrical alopecia (Box 61-3).
   B. Prostate disease is diagnosed by rectal palpation of the prostate, culture of seminal fluid, and imaging of the prostate, either by retrograde urethrography or ultrasonography (see Chapter 53).

III. Collect and evaluate semen.
   A. Note color and turbidity of sample.
      1. Normal semen is milky white.
      2. Red or brown discoloration indicates contamination with fresh or old blood, and yellow discoloration indicates contamination with urine.
      3. A clear sample is indicative of azoospermia.
   B. Evaluate percentage of progressive motility of spermatozoa.
      1. Examine an unstained, undiluted drop of semen under the ×10 objective of a light microscope.
      2. Make a subjective assessment of percentage of spermatozoa moving forward.
      3. The normal percentage of progressively motile spermatozoa is >70%.
   C. Calculate the total number of spermatozoa in the ejaculate. The hemacytometric method described is more accurate than computer-assisted systems (Kuster, 2005).
      1. Measure concentration of spermatozoa by dispensing semen with the capillary pipette into the diluent container provided with the white blood cell Unopette kit. Dispense the diluted semen into a hemacytometer chamber.
      2. The number of spermatozoa in one of the nine large squares of the hemacytometer grid visible under the ×10 objective of the light microscope is the concentration in millions (millions of spermatozoa per milliliter).
      3. The total number of spermatozoa is the more valuable number, because concentration varies with the amount of prostatic fluid collected in the ejaculate.
         a. The total number is calculated by multiplying concentration (millions of spermatozoa per milliliter) by volume collected (milliliters per ejaculate).
         b. The normal total number of spermatozoa is 300 million to 2 billion.

Box 61-3

Diagnostic Scheme for Infertility in Male Dogs

Are Normal Copulation and Ejaculation Occurring?

Yes	No
1. Measure serum thyroid hormones: concurrent measurement of free thyroxine by dialysis and canine thyroid-stimulating hormone for assessment of hypothyroidism (Panciera, 1994; Peterson et al., 1997).	**1.** Investigate the prostate by rectal palpation, quantitative culture of seminal fluid, and ultrasonography and radiographic imaging, with possible fine-needle aspirate or biopsy.
2. Perform serological testing for canine brucellosis (see Table 60-3).	**2.** Investigate sites of pain in the spine or hind limbs by complete physical examination and radiography.
3. Collect and evaluate semen (see Table 60-3).	**3.** Assess for behavioral problems described in text.
4. Investigate the prostate by rectal palpation, quantitative culture of seminal fluid, and ultrasonography and radiographic imaging, with possible fine-needle aspirate or biopsy.	**4.** Assess for retrograde ejaculation by collection of a urine sample by cystocentesis after breeding or semen collection.

Data from Meyers-Wallen (1991), Olson (1991), and Olson et al. (1992).

TABLE 61-1

Types of Semen Abnormalities Described in the Dog

DEFINITION	CAUSES	DIAGNOSIS
Azoospermia: ejaculation of seminal fluid containing no spermatozoa	Pretesticular causes include hypothyroidism, fever (as may be seen with illness), drug therapy Testicular causes include intersex states, bilateral cryptorchidism, direct testicular injury, indirect testicular injury following increased intrascrotal temperature as may occur with testicular neoplasia or inguinal hernia, orchitis Post-testicular causes include outflow obstruction of the epididymes	Physical examination findings: abnormally small, soft, or firm testes may have been damaged and may not regain function Measurement of alkaline phosphatase in seminal fluid: concentration of >5000 IU/L indicates complete ejaculation with no outflow obstruction (Frenette et al., 1986) Measurement of thyroid hormones: concurrent measurement of thyroxine by dialysis and canine thyroid-stimulating hormone for assessment of hypothyroidism (Panciera, 1994; Peterson et al., 1997) Serologic testing for canine brucellosis: The rapid slide agglutination test (Synbiotics, San Diego, Calif.) is a good screening test that is accurate as early as 8-12 weeks after infection Negative results with this test are accurate; positive tests must be rechecked with a nonagglutination method The preferred nonagglutination method in the United States is the agar gel immunodiffusion (AGID) test available at Cornell University Ultrasonography of the scrotum Culture of seminal fluid: quantitative culture is performed and finding of >10,000 bacteria/mL of a single organism is considered significant Perform serum chemistry profile, complete blood count, and urinalysis to assess for systemic diseases
Oligozoospermia: a total number of spermatozoa in the ejaculate <300 million Dogs with a low number of spermatozoa in the ejaculate are not necessarily infertile A total of 250 million normally shaped spermatozoa must be introduced into the bitch over the fertile period from 3 days before to 4 days after ovulation to reliably effect pregnancy (Mickelsen et al., 1993)	Prostate disease Orchitis	Prostate diagnostic tests (see Box 61-3) Culture of seminal fluid Serology for canine brucellosis Measurement of serum thyroid hormones Serum chemistry profile, complete blood count, and urinalysis to assess for systemic disease
Teratozoospermia: <80% normally shaped spermatozoa in the ejaculate	Orchitis Testicular neoplasia Contaminated semen collection equipment Prostate disease	Culture of seminal fluid Ultrasonography of the scrotum Re-collection with different equipment Prostate diagnostic tests
Asthenozoospermia: <70% progressively motile spermatozoa in the ejaculate	As for oligozoospermia	As for oligozoospermia

D. Evaluate the percentage of morphologically normal spermatozoa.
   1. Place a drop of undiluted semen on one end of a glass slide, smear it out as for a blood smear, and allow it to air dry.
   2. Examine the slide under oil immersion (×100 objective of the light microscope) and evaluate 100 spermatozoa.
   3. The normal percentage of morphologically normal spermatozoa is >80%.

IV. Perform serological testing for canine brucellosis (see Table 61-1).

V. Cases refractory to standard diagnosis and therapy may benefit from testicular fine-needle aspirate or biopsy.
   A. Testicular fine-needle aspiration requires that the dog be sedated.
      1. Using a 20-gauge needle on a 10-mL syringe, insert it on the testicular midline, and apply suction while the needle is directed in several directions (Dahlbom et al., 1997).
      2. Submit the sample for histological examination.
      3. Ongoing spermatogenesis, inflammation, and neoplasia may be identified.
      4. Because testicular architecture is not maintained, complete information about spermatogenesis is not obtained with this technique.
   B. Testicular biopsy is performed with the animal under general anesthesia.
      1. Exteriorize the testis through a prescrotal incision.
      2. Incise through the tunica albuginea with a scalpel blade, and shave off the tissue that bulges through the incision.
      3. Place the tissue in modified Bouin's or Zenker's fixatives rather than formalin.
      4. Evaluate for the presence of the hierarchy of spermatogenesis within the seminiferous tubule, as well as for inflammation and neoplasia.

Treatment

I. Behavioral causes of poor libido may be overcome.
   A. Administer gonadotropin-releasing hormone (GnRH) at 1 to 2 μg/kg IM 1 hour before attempted breeding or semen collection (Purswell, 1994).
   B. This method is not to be used routinely in valuable stud dogs, because frequent artificially enhanced serum testosterone concentrations may exert negative feedback on the pituitary, producing an eventual decline in serum testosterone concentration and reduced spermatogenesis.

II. Retrograde ejaculation is treated with sympathomimetic drugs (e.g., pseudoephedrine 4 to 5 mg/kg PO 1 and 3 hours before attempted breeding or semen collection) to effect antegrade ejaculation (Root et al., 1994).

III. Treatment of prostate disease varies with the specific abnormality present (see Chapter 53).

IV. Canine brucellosis is not curable in dogs, and no recommended treatment exists for infertility caused by *B. canis*.
   A. Euthanize *Brucella*-positive male dogs housed in a kennel situation.
   B. Individually housed dogs may be treated by performing castration and administering tetracycline 30 mg/kg PO BID for 28 days and streptomycin 20 mg/kg IM SID for 14 days.
   C. Antibiotic therapy induces remission but does not eradicate the organism.
   D. Canine brucellosis is a zoonotic disease, so caution owners of *Brucella*-positive dogs of possible human transmission, especially if pediatric, geriatric, or immunosuppressed persons live in the household.

V. Start thyroid supplementation.
   A. Supplement with thyroxine 0.01 to 0.02 mg/kg PO BID.
   B. Recheck serum concentration of thyroxine 4 to 6 weeks after treatment is instituted.
   C. Hypothyroidism may be hereditary in dogs, so advise owners that dogs with hypothyroidism are not good candidates for breeding.

Monitoring of Animal

I. Prognosis for return to fertility varies with the cause.
   A. Behavioral causes of lack of normal copulation or ejaculation may be overcome with administration of GnRH (as described previously) or circumvented by use of artificial insemination.
   B. The prognosis is better for dogs with poor semen quality than for dogs with azoospermia.
   C. The prognosis is better for dogs with normal testicular size and consistency than for dogs with testicular atrophy or fibrosis.

II. A definitive prognosis for future fertility may be made after testicular biopsy. If spermatogenic cells are absent from the seminiferous tubules, or if a significant percentage of the seminiferous tubules are atrophied or fibrotic, then infertility is irreversible in that animal.

III. Brucellosis is an irreversible cause of infertility.

IV. Hypothyroidism may be a reversible cause of infertility with proper supplementation with thyroxine; however, dogs with hypothyroidism are not good candidates for breeding.

DISORDERS OF PREGNANCY

Pregnancy Loss

Definition

I. Early embryonic death (death of the fetuses with subsequent resorption in the first half of gestation) is indistinguishable from lack of conception.

II. Abortion (fetal death with expulsion of the fetus and placental tissues) occurs in the second half of gestation.

III. Birth of stillborn pups or retention of nonviable pups in the uterus without onset of parturition can also be defined as pregnancy loss.

Causes

I. Bacterial causes
   A. *Brucella canis* may cause pregnancy loss
      1. Transmission usually occurs by ingestion of aborted tissues or urine excreted from infected males or females (Carmichael and Joubert, 1988).
      2. Transient lymphadenopathy and colonization of many tissues occurs, especially in the reproductive tract (Johnson and Walker, 1992).
      3. The classic presentation is abortion late in gestation.
      4. Birth of stillborn or weak pups and persistent discharge of purulent vaginal discharge may also be seen.
      5. Infertile bitches infected with canine brucellosis may be asymptomatic.
   B. Miscellaneous bacteria implicated in canine pregnancy loss include *Campylobacter* spp., *Salmonella* spp., *Escherichia coli*, and *Streptococcus* spp. (Johnston and Raksil, 1987).

II. Viral causes
   A. Canine herpesvirus
      1. Canine herpesvirus can be transmitted by aerosol, via licking, or venereally.
      2. Most infected adult animals are asymptomatic or have mild vesicular lesions of the genitalia.
      3. Animals at greatest risk are naive bitches exposed to the virus in the last 3 weeks of gestation.
      4. Necrotizing placentitis develops, with subsequent birth of stillborn, macerated, mummified, or weak pups of various sizes, often all within the same litter (Poste and King, 1971).
   B. Other viruses: parvovirus and canine distemper virus

III. *Mycoplasma* spp. and *Ureaplasma* spp.
   A. *Mycoplasma* spp. and *Ureaplasma* spp. are ubiquitous organisms that lack a rigid cell wall.
   B. They have been associated with infections of the reproductive tract and pregnancy loss and also are part of the normal vaginal flora (Doig et al., 1981).

IV. Protozoal causes *(Toxoplasma gondii)*
   A. Toxoplasmosis infection is uncommon in dogs and is a very uncommon cause of pregnancy loss.
   B. Pups have been experimentally infected with toxoplasmosis transplacentally.
   C. Dogs that lose pregnancies from toxoplasmosis may be clinically ill from systemic disease (Dubey et al., 1990).

V. Hypoluteoidism and hypolutemia
   A. Hypoluteoidism is a hypothesized cause of pregnancy loss in dogs.
   B. The corpora lutea are the sole sources of progesterone, which is required throughout pregnancy.
   C. If the corpora lutea fail prematurely, then progesterone concentrations decline and pregnancy loss occurs.

Clinical Signs

I. Most bitches have nonspecific clinical signs, including anorexia, lethargy, and fever.

II. Signs specific to the reproductive tract include exudation of purulent or bloody vaginal discharge from the vulva.

Diagnosis

I. Diagnostic testing both of the bitch and any pups is beneficial in determining the cause of pregnancy loss (Box 61-4) (Purswell, 1992).

II. *Mycoplasma* spp. and *Ureaplasma* spp. are difficult to grow in culture, and differentiating pathologic from nonpathologic isolates is also difficult.

III. Hypoluteoidism is diagnosed by measurement of serum progesterone concentrations during pregnancy.
   A. Weekly measurement of serum progesterone concentration is recommended in bitches with a history of possible hypoluteoidism, for the first 6 to 8 weeks after breeding.
   B. If serum progesterone falls to <10 ng/mL, then daily monitoring of serum progesterone concentration is recommended.
   C. Treatment is instituted with progesterone supplementation if serum progesterone concentration falls to <5 ng/mL.

Treatment

I. Canine brucellosis is not curable in dogs.
   A. Antibiotic therapy can be tried, but the infection usually persists and the dog may exhibit bacteremia when stressed months to years after therapy.
   B. Brucellosis is a zoonotic disease and may be reportable in the state or country where the disease is diagnosed.
   C. Neutering minimizes shedding of the organism in urine.
   D. Eradication of canine brucellosis in a kennel may require euthanasia of affected animals.

II. Treatment of the bitch for a bacterial cause of pregnancy loss often is not useful at the time she is aborting.
   A. Even if the cause can be identified, the pups are not viable; therefore pregnancy loss is allowed to continue, with monitoring to ensure its completion and normal uterine involution.
   B. Antibiotic therapy to prevent sepsis in the bitch is instituted as needed.
   C. *Mycoplasma* spp. and *Ureaplasma* spp. infections can be treated with tetracycline, which is contraindicated during pregnancy, and with enrofloxacin, which is not approved for use during pregnancy.

III. Treatment of the bitch with canine herpesvirus rarely is necessary.
   A. Treat viremic pups by increasing environmental temperature to decrease replication of the virus within the pups.
   B. An infected bitch should not lose more than one litter to canine herpesvirus, apparently because she retains enough memory cells to allow an adequate immune response if she is reexposed to the virus.

IV. Bitches with documented hypoluteoidism are treated with progesterone (in oil) 2 mg/kg IM every 3 days, or with

Box 61-4

Diagnostic Scheme for Pregnancy Loss in Dogs

Is the Bitch Pregnant and, If So, Are the Pups Viable?

Abdominal ultrasonography is the diagnostic method of choice for this assessment, but radiographs may be used after 45 days from breeding to give some idea of fetal viability.

Yes

1. Serological testing for canine brucellosis is performed (see Table 60–3).
2. Serum progesterone concentration is measured. Serum progesterone concentration of <10 ng/mL at midgestation, and <5 ng/mL anytime before the last 2 to 3 days of gestation, is suggestive of poor luteal function.
3. A sample of the vaginal discharge of the bitch is submitted for aerobic culture, and empirical treatment is instituted with amoxicillin-clavulanate at 14 mg/kg PO BID.
4. Continuing viability of the pregnancy is monitored weekly, preferably with abdominal ultrasonography.
5. If nonviable pups are passed, they are submitted for necropsy.

No

1. If the pups are not viable, expulsion of the pups is allowed to continue, and the bitch is monitored with abdominal ultrasonography and/or abdominal palpation to ensure complete loss of the pregnancy and normal involution of the uterus. Expulsion of uterine contents may be augmented with oxytocin or prostaglandin $F_2\alpha$.
2. A sample of the vaginal discharge of the bitch is submitted for aerobic culture.
3. Serologic testing for canine brucellosis is performed.
4. Any nonviable pups passed or stillborn pups are submitted for necropsy. Pups that died from canine herpesvirus have pathognomonic hemorrhagic lesions on the major abdominal organs. Contents of the stomach can be cultured to identify what organisms were in the pup's amniotic fluid.
5. Serologic testing for canine herpesvirus may be performed on the bitch, but the antigenicity of the virus is poor, so low titers do not indicate lack of exposure.

altrenogest *(Regumate)* 0.088 mg/kg PO SID (Purswell, 1991; Eilts, 1992).

A. Therapy must be withdrawn (to mimic the normal decline in progesterone) in the last 2 to 3 days of gestation.
B. Bitches receiving altrenogest may have poor milk production in early lactation.

Monitoring of Animal

I. All breeding bitches are tested for canine brucellosis twice yearly, even if they are not actively being bred.
II. The poor antigenicity of canine herpesvirus and the variability of titers because of environmental and host factors preclude regular serologic testing as a means of defining naive and exposed dogs (Ronsse et al., 2004).
III. In dogs with a history of pregnancy loss from bacterial infections, obtain quantitative culture of the cranial vagina early in proestrus, with administration of appropriate antibiotic therapy throughout proestrus and estrus while the cervix is open.
IV. Cleanliness of the environment must be assessed.
V. Bitches with a history of hypoluteoidism are monitored via weekly serum progesterone assays during subsequent pregnancies.
   A. Serum progesterone concentrations of <10 ng/mL at midgestation or <5 ng/mL anytime before the last 2 to 3 days of gestation are suggestive of poor luteal function.
   B. Empiric administration of progesterone to pregnant dogs is not desirable, because progestogens are teratogenic and nonviable pups need to be expelled.

Dystocia

Definition

Dystocia comes from the Greek words *dys*, meaning abnormal, and *tokos*, meaning birth, and is abnormal parturition.

Causes

I. Maternal causes
   A. Uterine inertia
      1. Primary uterine inertia is lack of initiation of second-stage labor by the bitch.
      2. Secondary uterine inertia is the lack of progression of second-stage labor as the uterine muscle fatigues.
   B. Obstruction of passage, as might be seen in a bitch with an artificially narrowed birth canal after pelvic fracture
   C. Abnormality of pregnancy, such as uterine torsion
II. Fetal causes
   A. Developmental abnormality, such as hydrocephalus
   B. Obstruction of passage from relative or absolute oversize of the pup
   C. Malpresentation
      1. Both cranial (head and extended forelimbs) and caudal (tail and extended hind limbs) presentation is normal in the dog.
      2. Examples of malpresentation include breech presentation (caudal presentation with the hind limbs flexed) and cranial presentation with only one or neither forelimb extended.
III. Breeds at increased risk for dystocia: Pekingese, Chihuahua, Scottish terrier, dachshund, Yorkshire terrier, miniature

poodle, Pomeranian, and English bulldog (Gaudet and Kitchell, 1985)

Clinical Signs

I. An obvious malpresentation is present.
II. The bitch has been in first-stage labor for >12 hours, in weak and intermittent second-stage labor for >4 hours, or in hard second-stage labor for >30 minutes before delivering any pups.
III. It has been >2 hours since the last pup was born.
IV. Abnormal vaginal discharge is present.
  A. Frank blood indicates hemorrhage.
  B. Black or green discharge indicates placental separation and is most valuable as an indicator before the first pup is born.
V. The pregnancy is a high-risk one (e.g., former pelvic fracture, predisposed breed, known single-pup litter).

Diagnosis

I. At the minimum, diagnosis of dystocia requires a good history, a physical examination including a digital vaginal examination, and a lateral abdominal radiograph.
II. Abnormalities that may be noted on physical examination are as follows:
  A. The bitch appears systemically ill.
  B. Abnormal vaginal discharge is present (see previous discussion).
  C. Digital vaginal examination findings are abnormal (no pup in the birth canal or vagina, very large pup palpable in birth canal or vagina, obvious malpresentation).
III. Abnormalities are found on radiography.
  A. Extremely large pup(s)
  B. Dead pups: gas within or around fetuses, collapse of axial skeleton and/or skull
  C. Large number of pups remaining in a fatigued bitch
IV. Obtain an abdominal ultrasound if viability of the pups is in question.
  A. Fetal heart rate of <150 beats per minute is indicative of fetal distress.
  B. Lack of visible movement or heart beats at term is indicative of fetal death.
V. Measure serum calcium.
  A. Serum calcium <7 mg/dL is diagnostic of hypocalcemia.
  B. Hypocalcemia causes dystocia by prohibiting normal muscle contraction.
VI. Evaluate labor with an external whelping monitor, which may suggest a decrease in fetal viability or show an abnormal pattern of uterine contractions (Whelp Watch; Vet Watch Corporation [888-200-8044]).

Treatment

I. Manipulation
  A. If a pup is palpable within the birth canal, then manipulation may allow it to pass.
  B. Use caution when manipulating pups, because limb dislocation and skin tearing may occur.
  C. Clamps, forceps, and other instruments have been described for relief of dystocia but must be used with extreme caution.
II. Pharmacological therapy
  A. Oxytocin causes uterine contractions and contributes to cervical dilatation.
    1. It also promotes placental separation.
    2. Oxytocin is not to be used unless the cervix is open (pup or significant vaginal discharge passed) and no present obstruction exists (as determined by abdominal radiography).
    3. The recommended dose is 2 to 5 IU SC, IM.
    4. If no response to oxytocin is seen after three doses (administered at 20- to 30-minute intervals), then institute some other form of therapy (Wallet Darvelid and Linde-Forsberg, 1994).
  B. Hypocalcemic bitches with no signs of eclampsia other than dystocia may benefit from parenteral calcium gluconate at 5 to 10 mL SC, IM.
  C. Oxytocin and calcium are often given together, because calcium may potentiate the effects of oxytocin.
  D. Some reports suggest that bitches in dystocia may respond to parenteral dextrose; however, hypoglycemia has not been reported as a cause of dystocia in the bitch.
III. Surgical therapy
  A. Surgical treatment of dystocia is via cesarean section.
  B. Use anesthetic agents with a short half-life and agents that can be reversed in the pups.
    1. Premedicate with atropine 0.04 mg/kg IM.
    2. Examples of suitable induction agents include thiopental 4 to 8 mg/kg IV (to effect) or oxymorphone 0.1 to 1.0 mg/kg IV (to effect).
    3. Intubate and maintain on inhalant anesthesia; isoflurane is the inhalant anesthesia of choice.
  C. No contraindications exist to ovariohysterectomy at the time of cesarean section.
  D. Ovariohysterectomy at the time of cesarean section is recommended if uterine rupture has occurred or if the owner has no further plans to breed the bitch.

Monitoring of Animal

I. The prevention of dystocia requires good client education.
II. Feed the bitch a well-balanced diet and provide consistent exercise throughout pregnancy.
III. Stress good breeding management to optimize litter size.
  A. Vaginal cytological examination and measurement of serum progesterone concentration allow determination of ovulation day.
  B. Optimal litter size is achieved by breeding 2 days after ovulation.
IV. Provide the bitch with a stress-free, sanitary whelping environment.

Pseudocyesis

Definition

I. Pseudocyesis is mammary development, lactation, and behavior typical of whelping, nursing, and mothering in nonpregnant bitches at the end of diestrus.
II. The term *false pregnancy* is a misnomer.

A. All bitches undergo a hormonal false pregnancy, with luteal production of progesterone for an approximately 2-month diestrus, regardless of breeding or pregnancy status.
B. The terms *pseudocyesis* or *false whelping* more accurately describe this phenomenon.

III. Pseudocyesis is a normal reproductive phenomenon in dogs and is not associated with reproductive tract disease.

Causes and Clinical Signs

I. All bitches produce luteal progesterone for approximately 2 months after ovulation, which causes mammary development.
II. The abrupt decline in serum progesterone at the end of diestrus stimulates release of prolactin from the anterior pituitary, with subsequent mothering behavior and lactation.
III. Onset of pseudocyesis can be triggered by withdrawal of exogenous progestogen therapy or by a decline in endogenous progesterone after ovariohysterectomy during diestrus.
IV. Physical changes of pseudocyesis include distention of the mammary glands and exudation of serous fluid or normal milk from the mammae.
V. Behavioral changes include nesting behavior, mothering of inanimate objects, and possible aggression.

Diagnosis

I. Diagnosis of pseudocyesis is based on a history of having been in estrus approximately 2 months before presentation, as well as the presence of the previously mentioned clinical signs.
II. If breeding occurred, or if the owner is unsure if the bitch was bred, then perform abdominal radiography to rule out pregnancy and imminent whelping.
III. Diagnose secondary mastitis if the mammary glands are enlarged, hot, and painful (see Chapter 60).

Treatment

I. Spontaneous remission occurs in most cases within 2 to 3 weeks of onset of clinical signs.
A. Do not milk out the mammary glands, because increased intramammary pressure inhibits prolactin release and continuing milk production.
B. Wrapping the mammary glands with an elastic bandage may hasten this pressure effect and protects the distended glands from trauma.

II. Megestrol acetate *(Ovaban)* at 2.5 mg/kg PO SID for 8 days is the only therapy approved for treatment of pseudocyesis in dogs.
A. Signs resolve with treatment but very often recur when the drug is withdrawn.
B. Side effects of progestogen therapy include increased appetite and changes in temperament.
C. Progestogens are not given to bitches with a history of mammary neoplasia, diabetes mellitus, or pyometra.
D. The author does not recommend the use of megestrol acetate for treatment of pseudocyesis in dogs.

III. Testosterone cypionate at a dose of 0.5 to 1.0 mg/kg IM may decrease milk production in dogs.
IV. Prolactin inhibitors decrease milk production in dogs.
A. Bromocriptine is administered at a dose of 30 μg/kg PO SID for 16 days, with the most common side effect being emesis.
B. Cabergoline is administered at a dose of 1.5 to 5.0 μg/kg PO SID for 2 to 8 days, with emesis as a rare side effect.

V. Ovariohysterectomy is not curative of a given episode of pseudocyesis but prevents subsequent episodes.
VI. Short-term tranquilization may be necessary in aggressive animals.
A. Diazepam is the drug of choice.
B. Phenothiazine tranquilizers (e.g., acepromazine) and butyro-phenone tranquilizers (e.g., haloperidol) are not recommended, because they may stimulate prolactin release and worsen clinical signs.

Monitoring of Animal

I. Pseudocyesis is not associated with uterine disease and may, in fact, be a historical indicator of normal ovarian function in the bitch.
II. Age at onset of pseudocyesis is variable, and a given bitch may not exhibit signs of pseudocyesis after every estrous cycle.
III. Increased incidence of pseudocyesis in a given bitch may be associated with predisposition to malignant mammary neoplasia, presumably because of inflammatory changes and release of free radicals within the distended mammary tissue (Verstegen and Onclin, 2003).

POSTPARTUM DISORDERS

Eclampsia

Definition

I. Eclampsia is hypocalcemia arising from inadequate stores of usable calcium in the extracellular compartment.
II. Eclampsia is also known as *postpartum hypocalcemia* and *puerperal tetany*.

Causes and Pathophysiology

I. Hypocalcemia occurs most commonly in small breed dogs nursing large litters, especially at peak lactation (2 to 3 weeks postpartum) (Kaufman, 1986).
II. Eclampsia can also occur during parturition and may precipitate dystocia.
III. The disorder develops because the bitch's body is incapable of drawing enough calcium from intracellular sources, such as bone, and cannot ingest enough oral calcium to meet the excessive demands of lactation.
IV. Supplementation with oral calcium during pregnancy may predispose bitches to eclampsia during peak lactation.
V. Excessive calcium intake during pregnancy causes down-regulation of the bitch's own calcium regulatory system and subsequent clinical hypocalcemia when calcium demand is high.

Clinical Signs

I. Eclampsia is characterized by progressive neurologic changes, with initial tremors followed by ataxia and disorientation, collapse with seizures, and, finally, coma and death (Drobatz and Casey, 2000).
II. Elevated body temperature (>40.5° C [105° F]) may be present.

Diagnosis

I. Putative diagnosis is made by signalment (small breed dog, nursing large litter), history (2 to 3 weeks postpartum), and clinical signs as described previously.
II. Confirmatory diagnosis requires demonstration of total serum calcium concentration <7 mg/dL.

Differential Diagnosis

I. Differential diagnoses for seizures in dogs include idiopathic epilepsy, meningoencephalitis, and toxicities (see Chapter 22).
II. Evaluate dogs for hypoglycemia that do not respond to empiric treatment with calcium.

Treatment

I. Mild tremors, ataxia, and disorientation in the lactating bitch
   A. Provide 10% calcium gluconate 0.2 to 0.4 mL/kg IM, SC.
   B. Dispense oral calcium carbonate or calcium gluconate (1 to 3 g/day) with concurrent vitamin D.
   C. Puppies may continue to nurse unless signs worsen or recur.
II. Severe tremors, ataxia or disorientation, or seizures in a bitch at peak lactation
   A. Administer 10% calcium gluconate 1 to 10 mL IV, to effect, while ausculting the heart.
   B. Stop administration of calcium if any cardiac abnormality is evident.
   C. If hyperthermia is present, then gradually cool the bitch.
   D. Provide a depot of 10% calcium gluconate 0.2 to 0.4 mg/kg IM, SC, and dispense oral calcium carbonate or calcium gluconate (1 to 3 g/day), with concurrent vitamin D, when the animal is discharged.
   E. Remove pups from the bitch for 24 hours, or permanently if signs recur during the same lactation.

Monitoring of Animal

I. If signs worsen or recur, then the puppies are removed from the bitch and either hand raised (<4 weeks of age) or weaned (>4 weeks of age).
II. Bitches with a history of eclampsia may benefit from oral calcium supplementation during lactation after subsequent whelpings.

Metritis

Definition

I. Metritis is a primary bacterial infection of the uterus that occurs postpartum.
II. Metritis is not synonymous with pyometra, which is primary cystic endometrial hyperplasia with secondary bacterial infection that occurs during or after diestrus.

Causes and Clinical Signs

I. Metritis is caused by an ascending infection with vaginal aerobic organisms after normal parturition, or after abortion, fetal infection, dystocia, and/or retention of placentas.
II. Clinical signs include fever, anorexia, depression, neglect of pups, and exudation of foul-smelling purulent discharge from the vulva.

Diagnosis

I. Cytological examination of the vulvar discharge: inflammation, contains numerous polymorphonuclear leukocytes (some of which may be degenerative) and bacteria
II. Aerobic culture and sensitivity of the vulvar discharge to guide antibiotic therapy
III. Complete blood count to demonstrate neutrophilia with a left shift (common)
IV. Abdominal radiographs or ultrasonography to diagnose retention of placentas and/or fetuses
V. Serological examination for canine brucellosis

Differential Diagnosis

I. Other causes of purulent vulvar discharge in the postpartum bitch include brucellosis and vaginitis.
II. Rule out other causes of uterine disease (see Chapter 57).

Treatment

I. Administer an appropriate antibiotic, based on culture and sensitivity testing, for 14 days.
II. While awaiting culture results, start on a broad-spectrum antibiotic, such as ampicillin at 20 mg/kg PO TID.
III. Evacuate the uterine contents by administration of oxytocin at 1 IU/kg IM or prostaglandin $F_2\alpha$ *(Lutalyse)* at a dose of 0.25 mg/kg SC.
IV. Perform ovariohysterectomy on bitches that become septic (as evidenced by worsening clinical signs, hypoglycemia, and positive blood cultures) and on bitches that are not intended for future breeding.
V. Bitches with mineralized retained fetal tissue may require hysterotomy or ovariohysterectomy for its removal.

Monitoring of Animal

I. Vaginal discharge resolves within 3 weeks postpartum or 2 weeks after institution of appropriate antibiotic therapy.
II. Properly treated, metritis should have no effect on future fertility of bitches left intact.

Subinvolution of Placental Sites

Definition

Subinvolution of placental sites (SIPS) is exudation of serosanguineous, noninflammatory vulvar discharge beyond the time normal postpartum lochia generally is present (>3 weeks postpartum).

Causes and Pathophysiology

I. Histological examination of placental sites in affected bitches reveals eosinophilic protrusions of nodular epithelium with necrosis and hemorrhage from failure of normal thrombosis and occlusion of endometrial blood vessels.
II. Underlying cause is unknown.

Clinical Signs

I. SIPS is most common in young bitches after whelping their first litter.
II. Clinical presentation is of an apparently healthy bitch with prolonged exudation of serosanguineous vulvar discharge.

Diagnosis and Differential Diagnosis

I. SIPS is diagnosed by ruling out other causes of persistent vulvar discharge, such as metritis and canine brucellosis.
II. Perform cytological examination of the vulvar discharge.
  A. Vulvar discharge characteristic of SIPS is noninflammatory.
  B. It contains noncornified vaginal epithelial cells, occasional healthy polymorphonuclear leukocytes, and mucoid proteinaceous debris.
III. Perform culture of the vulvar discharge.
  A. Because the vagina of the normal bitch is not sterile, ask the laboratory for a quantitative culture.
  B. Moderate to heavy growth of a single organism is significant and leads to a diagnosis of infection of the reproductive tract, not SIPS.
IV. Perform serological examination for canine brucellosis, which also produces persistent vaginal discharge.
V. Perform abdominal palpation, radiography, and/or ultrasonography.
  A. Assess uterine size and evaluate for retained fetuses or placentas.
  B. The presence of excessive intrauterine fluid or retained tissues from parturition suggest metritis is present, not SIPS.
VI. Perform a complete blood count to assess hematocrit, white blood cell count, and cell differential count.
  A. Chronic exudation of serosanguineous discharge may be excessive enough to cause a regenerative anemia.
  B. Neutrophilia with a left shift is suggestive of metritis, not SIPS.
VII. Definitive diagnosis of SIPS requires histopathology of uterine tissue and is rarely, if ever, performed in the bitch.

Treatment

I. If the bitch is not intended for future breeding, then ovariohysterectomy is performed.
II. If the bitch is to be left intact, then monitoring is recommended.

Monitoring of Animal

I. Evaluate cytological findings of the vulvar discharge weekly.
  A. If the vulvar discharge becomes cytologically purulent, then perform aerobic vaginal culture.
  B. Next, treat with an appropriate antibiotic (based on culture and sensitivity testing) for 14 days.
II. Monitor hematocrit weekly, because bitches rarely become anemic to an extent requiring transfusion of whole blood.
III. The serosanguineous vulvar discharge of SIPS may persist until onset of the subsequent proestrus.
IV. SIPS rarely recurs after subsequent whelpings.

CHAPTER 62

Disorders of Feline Reproduction

Milan B. Hess

NORMAL PATTERNS

Estrous activity

I. The breeding season extends from mid January to August in the Northern Hemisphere.
II. On average, queens cycle every 2 to 3 weeks during this period.
III. Queens may also cycle during nonseasonal months because of consistent household lighting (Herron, 1977; Stabenfeldt and Shille, 1977).
IV. Behavioral changes result from repeated waves of follicular growth and regression.
  A. The growth phase consists of proestrus and estrus (average 6 to 7 days).
    1. The condition is marked by increased vocalization and rubbing behavior, crouching and elevation of hindquarters, hind limb treading, and subsequent acceptance of a male.
    2. Plasma estradiol levels range from 25 to >80 pg/mL (Shille et al., 1979).
  B. The regression phase (average 8 to 9 days) is denoted by sexual nonreceptivity.
    1. The condition is also termed *interestrus*.
    2. Plasma estradiol concentrations are usually <15 pg/mL.

Pregnancy and Pseudopregnancy

I. The queen is considered an induced ovulator, requiring coitus or mechanical stimulation of the cervix and/or cranial vagina for luteinizing hormone (LH) release from the pituitary gland.
II. Spontaneous ovulation also occurs (Lawler et al., 1993).
  A. If pregnancy results after ovulation is induced, then progesterone production occurs for approximately 65 to 66 days.
  B. If pregnancy fails to occur after ovulation is induced, then a pseudopregnant state of approximately 40 to 50 days ensues.

Clinical Evaluation

I. In addition to a thorough physical examination, obtain information regarding reproductive behavior, past reproductive history, breed-related traits, and sibling and offspring fertility.
II. Consider the following parameters:
  A. Queen
    1. Vaginal cytology contributes little to the clinical workup.
    2. Hormonal profiles, appropriate serology, ultrasonography, and evaluation of the uterus at surgery are key.
  B. Tom
    1. Evaluate the scrotum for evidence of dermatitis and determine the presence of both testicles.
    2. Ascertain mobility of testes within the scrotal sac.
    3. Evaluate the testes for symmetry, texture, size, and shape.
    4. A semen sample is collected if necessary.

INFERTILITY IN THE QUEEN

Definition

I. Failure of the queen to cycle normally
II. Failure of the queen to breed or conceive after mating with a fertile tom

Causes and Pathophysiology

I. Persistent anestrus
  A. Inadequate photoperiod
    1. Queens housed indoors may not receive adequate intensity or duration of light, which may result in unpredictable ovarian cycles and anestrus.
    2. Approximately 12 to 14 hours of daylight are required for normal cyclicity.
  B. Progesterone-secreting ovarian cyst or neoplasm
    1. Persistently elevated progesterone may inhibit ovarian activity.
    2. This can result in anestrus (Johnston et al., 2001).
  C. Abnormality of sexual differentiation
    1. Queens with persistent anestrus that are phenotypically normal may have abnormal karyotypes, such as XO, XX/XY, or XY (Johnston et al., 2001).
    2. Persistent anestrus can be associated with pseudohermaphrodite disorders.
  D. Estral behavior after previous ovariohysterectomy (OHE)
    1. Queens that have undergone OHE occasionally are presented for estrus behavior.
    2. Confirmation of ovarian tissue is accomplished by treating with human chorionic gonadotropin (HCG)

or gonadotropin-releasing hormone (GnRH) during periods of estrus behavior, then measuring serum progesterone 7 to 10 days later.
3. Progesterone concentration >1.0 ng/mL indicates the presence of luteal tissue and confirms the presence of ovarian tissue.

II. Persistent estrus
A. A careful history is required to discriminate between persistent estrus and normal cyclic estrus behavior.
B. Persistently elevated plasma estradiol concentrations can result in prolonged estrus behavior (Feldman and Nelson, 1996).
C. Queens with estradiol-producing ovarian cysts or neoplasms can display persistent estrus.

III. Copulation failure
A. Sexual partner discrimination can result in the queen's refusal to mate with the tom (Schmidt, 1986).
B. Young or inexperienced queens may refuse to mate with the tom.
C. Vestibular and vaginal abnormalities may prevent normal intromission.

IV. Ovulation failure
A. Multiple copulations are necessary to induce a sufficient LH surge and ovulation in the queen.
B. Anovulatory cycles occur in the majority of queens that copulate with the tom only once (Schmidt, 1986).

V. Infectious causes
A. Infection of the reproductive tract is a common cause of infertility in the queen.
B. *Escherichia coli* is frequently isolated from the uterus in many queens with cystic endometrial hyperplasia (CEH).
C. Feline panleukopenia, feline infectious peritonitis (FIP), feline leukemia virus, and feline herpesvirus 1 are potential causes of infertility in the queen (Johnson, 1998).

VI. CEH-pyometra complex
A. As in the bitch, pyometra is a diestral disease and develops during progesterone domination (Dow, 1962; Kenney et al., 1987).
B. Pyometra can occur in the queen during the luteal phase, resulting from a copulation-induced ovulation or spontaneous ovulation.

VII. Anatomic abnormalities of the female reproductive tract
A. Nonpatent uterine tubes
B. Infantile tracts
C. Segmental hypoplasias and aplasias

Clinical Signs

I. Queens with persistent anestrus will fail to cycle during the normal breeding season when exposed to an adequate duration and intensity of light.
II. Queens with true persistent estrus will remain continuously in estrus for prolonged periods; normal estrus durations should not exceed 19 days (Shille et al., 1979).
III. Queens that fail to display estrus despite normal ovarian function have historical anestrus with no other clinical signs.
IV. Queens that are presented for ovulation failure may have a history of inadequate copulatory stimulus.
V. CEH-pyometra complex may be present.
A. Vaginal discharge
B. Lethargy
C. Weight loss
D. Unkempt hair coat
E. Abdominal distention
F. Polyuria/polydipsia

Diagnosis

I. Detailed medical and reproductive histories, as well as a complete physical examination, are imperative.
II. Routine screening tests such as blood chemistries, complete blood count, urinalyses, feline leukemia virus testing, and feline immunodeficiency virus testing are indicated in all cases of infertility.
III. Reproductive hormone analyses can be useful in determining the presence or absence of hormonally active ovarian cysts or neoplasms.
A. Normal fluctuations in hormone concentrations make interpretation of pathologic conditions difficult.
B. Hormone concentrations must be assessed repeatedly and interpreted in light of other clinical findings.
C. Measurements of estradiol may help identify follicular ovarian cysts and estrous cycles in queens suspected of having unobserved estrus cycles.
D. Pathologic increases in estradiol concentrations, however, may be less than the detectable levels of some assays.
E. Therefore measurement of plasma estradiol concentrations may have no diagnostic value (Johnson, 1998).
F. Serum progesterone concentrations can help distinguish between stages of the estrous cycle.
1. Progesterone concentrations are at basal levels until ovulation in the normal queen.
2. After ovulation, serum progesterone concentrations are >1.5 ng/mL for the duration of the luteal phase (Johnson, 1998).
3. Serum progesterone concentrations that remain elevated for longer than 40 to 45 days in the nonpregnant queen indicate a progesterone-producing ovarian cyst or neoplasm (Johnston et al., 2001).

IV. Karyotyping may reveal abnormalities in chromosomal number or chromosomal sex.
V. Exploratory laparotomy may be required to identify anatomic abnormalities within the reproductive tract.
VI. Biopsy and culture of the uterus and ovarian biopsy may be necessary to diagnose bacterial infections, CEH, ovarian cysts, and ovarian neoplasms.
VII. Ultrasonographic examination of the reproductive tract is a useful diagnostic tool.
A. Thickening of the nonpregnant uterine lining and fluid within the uterine lumen indicates pyometra, with or without CEH.
B. Large cystic or masslike structures associated with the ovaries in the queen with abnormal estrous cycles are consistent with ovarian cysts or neoplasms.

VIII. Culture and cytological examination of vaginal discharge is recommended.
  A. Used to determine appropriate antibiotic therapy
  B. *Escherichia coli*, hemolytic *Streptococcus* spp., and *Staphylococcus* spp. most frequently isolated (Kenney et al., 1987)

Treatment and Monitoring

I. Persistent anestrus
  A. Exposure to 12 to 14 hours of daily light will induce estrus in those queens with anestrus associated with insufficient photoperiod (Michel, 1993).
  B. Housing the queen with cycling females or a fertile male may induce estrus in a queen with historical anestrus.
  C. Surgical excision of progesterone-producing ovarian cyst or neoplasm may be required.
II. Persistent estrus
  A. Attempt luteinization of follicular cyst with 250 to 500 IU HCG IM or 25 μg GnRH IM (Johnston et al., 2001).
  B. Surgical excision of ovarian cyst or neoplasm is frequently curative.
III. Copulation and ovulation failure
  A. Allow the queen and tom to copulate multiple times daily during estrus and monitor for the "after reaction" by the queen, indicating intromission has occurred (Schmidt et al., 1983).
  B. Artificial insemination may be required in the case of the queen that persistently refuses the tom.
    1. Historically, surgical insemination is recommended but transcervical insemination is possible.
    2. Intravaginal insemination is also successful but requires significantly more sperm to obtain conception rates similar to surgical insemination conception rates (Zambelli and Cunto, 2005).
  C. Induce ovulation after natural service or artificial insemination.
    1. Administer 250 IU HCG IM or 25 μg GnRH IM.
    2. Give the HCG 15 to 30 hours before insemination (Tanaka et al., 2000).
IV. CEH-pyometra complex
  A. OHE is indicated if the queen is not part of a breeding program or is systemically ill.
  B. Medical management using prostaglandin $F_2\alpha$ can be attempted in young and otherwise healthy, hospitalized queens with an open-cervix pyometra.
    1. Administer 0.1 to 0.25 mg/kg SC SID to TID.
    2. Treatment continues 24 hours beyond resolution of the clinical signs.
    3. Supportive fluids and antibiotic therapy are indicated in queens displaying signs of systemic illness.

FETAL RESORPTION AND ABORTION

Definition

I. Fetal loss in utero
II. Premature parturition and delivery of immature fetuses

Causes and Pathophysiology

I. Viral diseases most frequently reported
  A. Feline leukemia virus
  B. Feline herpesvirus 1 (Smith, 1997)
  C. Feline immunodeficiency virus: abortion under experimental conditions (Ueland and Nesse, 1992; Sellon et al., 1994)
  D. FIP (Grahn, 1991)
II. Taurine deficiency (Sturman et al., 1986; Dieter et al., 1993)

Clinical Signs

I. Resorption may go unnoticed, especially if the pregnancy has gone undiagnosed.
II. Expelled fetuses and vaginal discharge may be seen with late-term abortions.
III. Queens may begin to cycle again if the litter is lost during the physiologic breeding season.

Diagnosis

I. Serological testing for viral disease
II. Ultrasonographic examination to detect fluid in the uterine lumen or thickening of the wall
III. Exploratory laparotomy
  A. To obtain biopsy and culture samples of the reproductive tract
  B. To identify gross abnormalities of the uterus and ovaries
IV. Abortion screening on any fetus to detect chromosomal, developmental, or infectious causes

DYSTOCIA

Definition

I. Difficult birth
II. Inability to expel kitten from birth canal

Causes and Pathophysiology

I. Uterine inertia and fetal malpresentation are the most frequently reported causes of dystocia in the queen (Ekstrand and Linde-Forseberg, 1994; Gunn-Moore and Thrusfield, 1995).
  A. Uterine inertia
    1. Primary uterine inertia is the failure to initiate labor at term.
    2. Secondary uterine inertia is the failure to progress once labor is initiated (uterine fatigue).
  B. Fetal malpresentation
    1. Both anterior and posterior presentations are normal in the queen.
    2. Common malpresentations include true breech, forward flexion of one hindlimb, flexion of head or neck, simultaneous presentation of two kittens, and transverse presentations (Ekstrand and Linde-Forsberg, 1994).
II. Dystocia is significantly more prevalent in purebred queens than mixed-breed queens.

III. Dolichocephalic and brachycephalic head types have higher rates of dystocia compared with mesocephalic head types (Gunn-Moore and Thrusfield, 1995).
IV. Less common causes of dystocia in the queen include narrowed birth canal, oversized fetuses, and fetal malformation.
V. Dystocia from uterine torsion occurs uncommonly in the queen.

Clinical Signs

I. Gestation length that is >71 days from the first breeding is abnormal.
II. Serum progesterone concentration <2 ng/mL in a near-term queen with no signs of labor is consistent with primary uterine inertia.
III. Failure to deliver a fetus after 20 to 30 minutes of straining, or failure to deliver a fetus within 15 minutes of entering the birth canal, is consistent with dystocia.
IV. The presence of uteroverdin (greenish-black vaginal discharge) before delivery of a fetus is abnormal and indicates separation of the placenta from the uterus and significant fetal compromise.
V. Copious hemorrhagic vaginal discharge or significant maternal distress indicates dystocia.
VI. Hypovolemic shock and abdominal pain indicate uterine torsion; there may be only hours between normal birth and uterine torsion (see Chapter 57).

Diagnosis

I. Clinical signs and history
II. Ultrasonography
  A. To determine fetal viability and heart rate
  B. Fetal stress: heart rate <190 to 200 beats per minute
III. Abdominal radiography of fetus (or fetuses)
  A. Fetal size
  B. Number of fetuses
  C. Position of fetuses
IV. Laparotomy necessary to diagnose uterine torsion
V. Digital vaginal examination to identify fetus in vagina

Treatment

I. Surgical intervention (cesarean section) is indicated for evidence of fetal stress, a uterine tear, uterine torsion, or primary uterine inertia.
  A. OHE is preferred if the queen is not intended for use in a breeding program.
  B. OHE is indicated for a uterine tear or uterine torsion resulting in significant uterine compromise or with the presence of decomposing fetuses.
II. Oxytocin therapy is used cautiously because it can cause placental separation and fetal compromise.
  A. Oxytocin is contraindicated in the presence of fetal malpresentation, obstruction of the birth canal, and fetal or maternal compromise.
  B. The dose is 1 to 3 IU oxytocin SC, IM repeated in 20 to 30 minutes if necessary.

INFERTILITY IN THE TOM

Definition

I. Failure to breed queens of known estrous activity
II. Failure to cause conception after mating to queens of known fertility

Causes and Clinical Signs

I. Noninfectious disorders
  A. Behavior
    1. A dominant or aggressive queen may discourage mating behavior in an inexperienced male.
    2. Previous negative breeding may inhibit normal behavior for future matings.
    3. This is exaggerated by uninterrupted housing in a restricted environment (Christiansen, 1984).
    4. Poor libido may have a genetic basis in Persian cats and is worse during immaturity and senescence.
  B. Physical abnormalities
    1. Persistent penile frenulum
    2. Hair rings at the base of the penis
    3. Retrograde ejaculation
    4. Hypoplastic or degenerate testicles
  C. Semen quality
    1. Causes of reduced sperm quality or quantity have not been extensively investigated.
    2. Known causes include the following:
      a. Age: immaturity and senescence
      b. Intersex conditions such as the tortoiseshell male XXY karyotype
      c. Testicular hypoplasia
  D. Cryptorchidism and abdominal testicle
    1. Normal reproductive behavior in toms possible
    2. Infertile from failure of spermatogenesis if bilateral
II. Infectious causes
  A. Chronic illness may affect libido and/or semen quality.
  B. Reproductive tract infections are not commonly associated with infertility.
  C. Orchitis has been observed in association with FIP virus (Stein, 1991; Johnston et al., 2001).

Diagnosis

I. Diagnosis is based on findings of a detailed reproductive history, general physical examination, and examination of the reproductive organs.
II. Evaluation of a semen sample may be necessary for diagnosis.
  A. Collection of semen may be accomplished manually by training to an artificial vagina (AV) or via electroejaculation (EE).
    1. The volume of semen ranges from 0.01 to 0.12 mL when collected by AV and from 0.001 to 0.738 mL when using EE (Johnston et al., 2001).
    2. Ejaculate concentration varies based on collection technique.
    3. Normal sperm motility is at least 60%, with at least 70% morphologically normal sperm.

   B. Postcoital vaginal smears are not optimal for evaluating semen.
III. Test for feline leukemia virus, feline immunodeficiency virus, and urinary tract disease, and measure serum thyroxine.
IV. Serum testosterone concentrations can be used to differentiate between a castrated and cryptorchid animal.
   A. Serum testosterone concentration is >1000 pg/mL in an intact tom.
   B. Because of the episodic release of testosterone, however, GnRH or HCG stimulation is recommended before sampling.
   C. Serum testosterone concentration should increase at least twofold by 1 to 2 hours after administration of 25 μg GnRH IM or 250 IU HCG IM in an intact tom.
   D. Castrated animals show no response to GnRH or HCG stimulation.
V. Karyotyping can be used to evaluate for potential chromosomal anomalies.

Treatment

I. Management changes can be instituted.
II. House the tom and queen together only for breeding.
III. Consider artificial insemination.
IV. Artificial insemination is becoming more common in cats, but the procedure is not routine in most veterinary practices.

CHAPTER 63

Introduction

A. Eric Schultze

HEMOLYMPHATIC SYSTEM COMPONENTS

I. Hematopoietic tissues (blood and bone marrow)
   A. In adult mammals, blood cells are produced in the bone marrow and released into the blood.
   B. In the fetus, blood cell production occurs in the yolk sac, liver, spleen, and eventually in bone marrow.
II. Hemostatic system
   A. Composed of vessels, platelets, coagulation factors and inhibitors, and fibrinolytic factors/proteins
   B. Necessary for vascular integrity, to cease hemorrhage, and to maintain blood fluidity
III. Lymphoid system
   A. Composed of lymph nodes, spleen, thymus, bone marrow, and lymphatic vessels
   B. Develops and maintains cellular and humoral immune responses to foreign antigens, microbial agents, and virally infected and transformed cells

DISORDERS OF RED BLOOD CELLS (ERYTHROCYTES)

I. Erythrocytes transport oxygen from lungs to tissues and carbon dioxide from tissues to the lungs.
II. Abnormalities of erythrocytes may be quantitative or qualitative.
   A. Anemia is a decrease in functional erythrocyte mass defined by decreased packed cell volume, hemoglobin concentration, and/or the total erythrocyte count.
   B. Classification of anemia as regenerative or nonregenerative is helpful in refining a diagnosis, determining prognosis, and monitoring response to treatment.
      1. Regenerative anemias are usually the result of blood loss or hemolysis.
      2. Nonregenerative anemias occur as a result of reduced or defective erythrocyte production and may have extramarrow or intramarrow causes, or both.
   C. Polycythemia is defined by a relative or absolute increase in the erythrocyte mass.
      1. Relative polycythemia: plasma volume decreased secondary to vomiting, diarrhea, or other causes of volume contraction
      2. Absolute polycythemia: true red blood cell mass increased from polycythemia vera or occurring secondary to physiologically appropriate or inappropriate stimuli
III. Tests used to evaluate the erythron are frequently performed serially and include the complete blood count, reticulocyte count, and bone marrow aspirate or core biopsy.

DISORDERS OF WHITE BLOOD CELLS (LEUKOCYTES)

I. Functions of white blood cells (WBCs) include the following:
   A. Neutrophils engulf or destroy microorganisms and transformed cells, modulate acute inflammatory reactions, and control granulopoiesis.
   B. Lymphocyte functions include humoral and cell-mediated immunity.
   C. Monocytes phagocytose and kill microorganisms, engulf and digest foreign materials and dead cells, secrete inflammatory mediators, participate in immune recognition and tissue remodeling, and produce cytokines and several colony-stimulating factors.
   D. Eosinophils destroy parasites, modulate hypersensitivity reactions, and promote inflammation.
   E. Basophils participate in immunoglobulin E–mediated inflammatory reactions, initiate plasma lipolysis, and participate in immune surveillance.
II. Disorders of leukocytes may be quantitative, qualitative, or both.
   A. Quantitative abnormalities are detected by smear evaluation and confirmed by actual counting of leukocytes in blood.

B. Accurate interpretation of leukocyte numbers is best made using an absolute count (% leukocyte type × total leukocyte count).
C. Some qualitative abnormalities may be observed with blood smear morphology and confirmed with leukocyte function tests.

III. The total WBC count and the relative and absolute differential WBC counts, coupled with the blood smear morphology, are collectively called the *leukogram*.
IV. Leukograms provide valuable information regarding pathologic and physiologic WBC responses to several stimuli, severity of disease, prognosis, and response to treatment.
V. Tests to assess the leukon are often performed serially and include complete blood counts and bone marrow aspirate or core biopsies.

MYELOPROLIFERATIVE DISORDERS

I. Myeloproliferative disorders (MPDs) occur from unregulated proliferation of one or more nonlymphoid hematopoietic cell lines.
A. Acute MPDs are characterized by large numbers of poorly differentiated blast cells of one or more nonlymphoid hematopoietic cell lines in the bone marrow, blood, or tissues.
B. Chronic MPDs are characterized by marked proliferation and some partial differentiation of the abnormal nonlymphoid hematopoietic cell line.

II. Myelodysplastic syndromes are a vague group of bone marrow disorders characterized by abnormal development of one or more nonlymphoid hematopoietic cell lines that result in various cytopenias; these disorders are often called *preleukemias.*
III. Diagnosis is based upon examination of serial complete blood counts, with or without serial bone marrow aspirates and/or core biopsies; special cytochemical stains of blood and/or bone marrow may be required to identify the cell of origin.

PLATELET DISORDERS AND VON WILLEBRAND DISEASE

I. Platelets
A. Anucleate fragments of megakaryocyte cytoplasm
B. Cause primary hemostasis

II. Abnormalities in platelets
A. Quantitative or qualitative
B. Congenital or acquired (more common)

III. Quantitative disorders of platelets
A. Thrombocytopenia may have many causes.
B. Thrombocytosis may arise from reactive thrombocytosis, neoplasia, and/or select splenic disorders.

IV. Qualitative disorders of platelets
A. Inherited platelet defects (uncommon): basset hound thrombopathia, Chédiak-Higashi syndrome, Glanzmann's thrombasthenia of Great Pyrenees
B. Acquired disorders of platelets (common): drug therapy, liver disease, uremia, infectious agents

V. von Willebrand disease
A. It is the most common inherited, extrinsic platelet disorder of the dog.
B. It occurs from decreased concentrations of all multimers of von Willebrand factor (vWF) (Type I), decreased concentrations of vWF high-molecular-weight multimers (Type II), or undetectable concentrations of vWF multimers of all sizes (Type III).
C. Clinical signs are intermittent mucosal bleeding and prolonged bleeding postsurgery.
D. Diagnosis is by evaluation of blood vWF antigen concentration, molecular techniques, and/or platelet aggregation studies.

DISORDERS OF COAGULATION AND FIBRINOLYSIS

I. Coagulation factors
A. Soluble proteins and cofactors
B. When activated, cause conversion of soluble fibrinogen to an insoluble fibrin clot

II. Abnormalities in coagulation/fibrinolytic factors
A. Quantitative or qualitative
B. Congenital or acquired (more common)

III. Characteristics of hemorrhages
A. Petechial and mucosal hemorrhages suggest platelet disorders.
B. Large hemorrhages into joints or body cavities suggest coagulation disorders.

DISORDERS OF LYMPH NODES, LYMPHATICS, AND SPLEEN

I. Lymph nodes and lymphatic vessels filter the lymph and provide an avenue for lymphocytes to respond in immune challenges.
II. The spleen removes effete erythrocytes and other damaged cells from circulation, produces lymphoid and plasma cells, functions in the immunologic defense system, and acts as a reservoir for certain cell types.
III. Congenital abnormalities include aplasia or hypoplasia of lymph nodes, lymphatic vessels, or spleen, with resultant decreased function (immune or phagocytic).
IV. Acquired abnormalities include inflammation, hyperplasia, or neoplasia of lymph nodes, lymphatics, or spleen.
V. Diagnosis is dependent upon a combination of history, physical examination, laboratory assessment, cytological examination, surgical biopsy, diagnostic imaging, and/or exploratory laparotomy.

TRANSFUSION MEDICINE

I. Indications for whole blood or component therapy include anemia, coagulopathy, selective cytopenias, and/or hypoproteinemia.

II. Whole blood or its components (packed erythrocytes, plasma, and platelets) may be administered depending upon the animal's need.
III. Cross-matching of blood is recommended for safe transfusions; typing of the donor and recipient animals is also helpful.
IV. Careful, periodic screening of the donor animals for infectious agents is essential for safety.

PRINCIPLES OF ONCOLOGY

I. Neoplasia is a growth of abnormal cells that proliferates independently of physiologic control.
II. Neoplastic conditions may be benign or malignant.
III. Neoplastic growths may have a genetic or acquired origin.
IV. Diagnosis of neoplasia is dependent upon a combination of history, physical examination findings, laboratory analysis, biopsy, diagnostic imaging, and endoscopy/bronchoscopy.
V. Treatments for neoplasia are numerous and depend upon the individual tumor cell type.
VI. Treatments include chemotherapy, surgery, radiation, biological response modifiers, photodynamic therapy, hyperthermia, or palliative therapy.

PARANEOPLASTIC SYNDROMES

I. Paraneoplastic syndromes (PNS) are defined as neoplasia-associated alterations in tissue structures and/or functions that occur at sites distant from a neoplasm.
II. Many PNS are systemic in nature, occur before actual detection of the tumor, and can induce more morbidity than the tumor.
III. Examples include humoral hypercalcemia of malignancy, hypoglycemia, hyperhistaminemia, cachexia, hypertrophic osteopathy, fever of unknown origin, inappropriate secretion of antidiuretic hormone, and hyperviscosity syndrome.

CHAPTER 64

Disorders of Red Blood Cells

Dina A. Andrews

CLASSIFICATION AND LABORATORY INTERPRETATION OF ERYTHROCYTE ABNORMALITIES

Definition and Causes

I. The red blood cell (RBC, erythrocyte) transports oxygen (O_2) and carbon dioxide (CO_2), buffers hydrogen ions, maintains vascular integrity, and participates in coagulation.
II. Clinical signs occur when RBC mass is decreased (anemia), increased (polycythemia), or when there are significant red cell morphologic abnormalities that impair normal RBC function.
III. An anemia may be regenerative or nonregenerative (Figure 64-1).
  A. A regenerative anemia occurs when RBC mass is reduced in the presence of a functional bone marrow able to produce and release RBCs.
  B. A nonregenerative anemia occurs when RBC mass is reduced because of a poorly or nonresponsive bone marrow or there is an inability to release RBCs peripherally.
  C. Anemia is a secondary process caused by decreased RBC production, increased destruction, or blood loss.
IV. Polycythemia is defined as increased red cell mass.
  A. Relative polycythemia occurs secondary to dehydration and is more common than absolute polycythemia.
  B. Absolute polycythemia may be a primary myeloproliferative disease or secondary to changes in erythropoietin concentrations.
V. Hereditary RBC anomalies recognized by changes in RBC shape or RBC indices may lead to a clinical manifestation of disease (Table 64-1).
  A. Increased nucleated RBCs in schnauzers
  B. Increased packed cell volume (PCV) in greyhounds
  C. Microcytosis in Japanese fighting dogs (Akita, Shiba inu)
  D. Microcytosis in dogs with portosystemic shunts

Clinical Signs

I. Clinical manifestations of anemia are dependent on duration and severity.
  A. General clinical signs include pallor, lethargy, tachypnea, and tachycardia.
  B. Hemolytic anemias can cause icterus, hemoglobinemia, and hemoglobinuria.
  C. Sources of blood loss include melena, epistaxis, petechiae, ecchymosis, hematuria, and hematemesis.
  D. Many anemias are subclinical and not identified unless a routine PCV or complete blood count (CBC) is performed.
II. Polycythemia is characterized by deep red to purple congested mucus membranes with mild cyanosis.

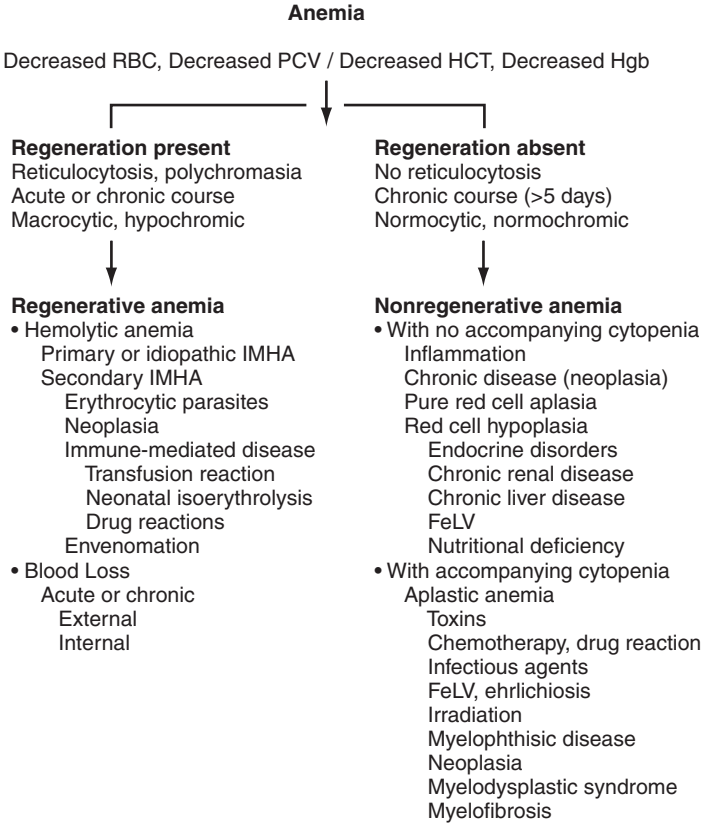

FIGURE 64-1 Anemia classifications and differential diagnoses. *RBC,* Red blood cell; *PCV,* packed cell volume; *HCT,* hematocrit; *Hgb,* hemoglobin; *IMHA,* immune-mediated hemolytic anemia; *FeLV,* feline leukemia virus.

TABLE 64-1

Hereditary Erythrocyte Defects

DEFECTS	AFFECTED BREEDS	CLINICAL CHARACTERISTICS	DIAGNOSTIC TESTS
Enzyme Defects			
PK deficiency	Dogs: Basenji, West Highland white terrier, beagle, American Eskimo, miniature poodle Cats: Abyssinian, Somali	Regenerative hemolytic anemia; icterus; osteosclerosis in dogs <5 years; myelofibrosis, liver cirrhosis Hemolytic anemia, splenomegaly	PCR-based DNA testing R-PK enzyme activity assay
PFK deficiency	English springer spaniel, American cocker spaniel, mixed breed dogs	Hyperventilation, excitement-induced (alkalemic) hemolytic crisis	PCR-based DNA testing PFK enzyme activity assay
Cb_5R deficiency	Dogs: isolated reports in the Chihuahua, borzoi, English setter, cock-a-poo mixed breeds Cats: DSH	Cyanosis, slight polycythemia, exercise intolerance	Cb_5R enzyme activity Methemoglobin spot test or measurement
Porphyria	Siamese cats, DSH cats	Photosensitivity, severe anemia, and renal disease in a Siamese cat Discoloration of the teeth and urine	Red fluorescence of teeth, urine, and body fluids when exposed to UV light
RBC Membrane Abnormalities			
Hereditary spherocytosis: spectrin deficiency	Golden retrievers originating from Netherlands	Severe hemolytic anemia, osmotic fragility of RBCs, spherocytes present	Osmotic fragility test Spectrin quantitation
Stomatocytosis	Alaskan malamute, miniature and standard schnauzers, Drentse Patrijshonds	Chondrodysplasia Clinically normal Hypertrophic gastritis	High numbers of stomatocytes on PBS Concurrent breed-specific clinical manifestations
Macrocytosis	Miniature and toy poodles	Clinically normal	Macrocytosis, normal PCV, hypersegmented PMNs
Nonspherocytic hemolytic anemia	Beagle	Clinically normal or chronic mild anemia	Unknown defect
Increased osmotic fragility	Cats: Abyssinian, Somali Dogs: English springer spaniel	Macrocytosis with moderate to severe anemia	Unknown defect Increased osmotic fragility of RBCs

Modified from Giger U: Hereditary blood diseases. p. 955. In Feldman BF, Zinkl JG, Jain NC (eds): Schalm's Veterinary Hematology. 5th Ed. Lippincott Williams & Wilkins, Philadelphia, 2000.

PK, Pyruvate kinase; *PCR,* polymerase chain reaction; *DNA,* deoxyribonucleic acid; *R-PK,* red blood cell isoform of pyruvate kinase; *PFK,* phosphofructokinase; *Cb_5R,* cytochromic b_5 reductase; *DSH,* domestic shorthair; *UV,* ultraviolet; *RBC,* red blood cell; *PBS,* peripheral blood smear; *PCV,* packed cell volume; *PMN,* neutrophil.

Diagnosis

I. Routine laboratory tests for characterizing red cell mass
   A. PCV and hematocrit (HCT) are used interchangeably.
      1. PCV is the percentage of whole blood composed of erythrocytes obtained using a microhematocrit tube and centrifuge.
      2. The HCT is a calculated value generated by automated machines after determining the mean erythrocyte size and RBC count.
      3. PCV and HCT must be interpreted relative to total plasma protein (TP).
         a. Dehydration (increased TP) falsely increases RBC mass.
         b. Overhydration (decreased TP) falsely underestimates RBC mass.
   B. Hemoglobin concentration (Hgb) is measured by a colorimetric method (cyanmethemoglobin) or by direct measurement of the optical density of oxyhemoglobin in a population of lysed RBCs.
      1. Hgb × 3 should approximate the PCV.
      2. Hgb can be falsely increased with hemolysis, lipemia, or Heinz bodies.
   C. Total RBC numbers can be obtained using a manual hemocytometer, although there may be a large margin of error; automated hematology analyzers count RBCs based on cell size or light scatter and are very accurate.

TABLE 64-2

Evaluating Absolute Reticulocyte Number

DEGREE OF REGENERATION	DOG	CAT (AGGREGATE FORM)
Normal or nonregenerative	<60,000/μL	<15,000/μL
Mild	60,000-150,000/μL	15,000-50,000/μL
Moderate	150,000-300,000/μL	50,000-100,000/μL
Marked	>300,000/μL	>100,000/μL

Modified from Tvedten H, Weiss D: Erythrocyte disorders. p. 31. In Willard MD, Tvedten H, Turnwald GH (eds): Small Animal Clinical Diagnosis by Laboratory Methods. 3rd Ed. WB Saunders, Philadelphia, 1999.

D. Total plasma protein is determined with a refractometer.

II. Reticulocyte enumeration
   A. A quantitative measure of reticulocytes (immature, anuclear RBCs) in circulation is the most important determinant in identifying a regenerative anemia (Table 64-2).
   B. Reticulocytes have retained intracytoplasmic organelles that precipitate when stained with new methylene blue (NMB) or brilliant cresyl blue (BCB), forming a reticulum recognized under light microscopy.
   C. A reticulocyte percentage (RP) >1% is indicative of regeneration although this does not correct for the degree of anemia and can be misleading (see corrected reticulocyte percent, below).
      1. Peripheral blood is mixed 1:1 with NMB or BCB, and reticulocytes are counted per 1000 RBCs; nucleated RBCs are not counted.
      2. In the dog, any RBC with a stainable reticulum is counted as a reticulocyte (mature to RBC in approximately 24 hours).
      3. Cats have two types of reticulocytes.
         a. Aggregate reticulocytes have large aggregates of RNA and are the best indicator of marrow activity.
         b. Punctate reticulocytes have a few dots of reticulum and can circulate for 10 to 12 days before full maturation. They assess the cumulative regenerative response and are commonly not enumerated.
   D. An absolute reticulocyte count (reticulocytes/μL) is most accurate and calculated by multiplying the RBC count (RBC/μL) by the RP present.
   E. A corrected reticulocyte percentage (CRP) corrects for the degree of anemia without requiring a RBC count.
      1. CRP = reticulocyte % × PCV ÷ normal PCV, where PCV in dog = 45%, and in cat = 37%.
      2. A CRP >1% supports regeneration.
   F. A reticulocyte production index (RPI) is used in the dog to compensate for younger reticulocytes (>24-hour maturation time) in circulation in response to a severe anemia.
      1. RPI = reticulocyte percentage × (HCT ÷ 45) × (1 ÷ maturation time).
         a. Maturation time varies depending on HCT.
         b. Maturation times are as follows: HCT 45% = 1 day, HCT 35% = 1.5 days, HCT 25% = 2.0 days, HCT 15% = 2.5 days.
      2. An RPI >1.0 = mild regeneration.
      3. An RPI >3 = marked regenerative response.

III. Peripheral blood smear evaluation
   A. The severity of the anemia (mild, moderate, severe) can be estimated by evaluating the decrease in RBC density in a peripheral smear.
   B. The degree of polychromasia reflects responsiveness of the bone marrow.
      1. Polychromatophils are large, blue-staining RBCs identified in the monolayer portion of a peripheral blood smear (Wright's, Diff-Quik stain).
      2. The degree of polychromasia correlates well with reticulocytosis.
      3. Normal dogs have approximately 1% polychromatophils and normal cats have approximately 0.5%.
   C. Identification of RBC morphologic abnormalities can elucidate the pathogenesis of the anemia (Table 64-3).

IV. RBC indices
   A. Mean cell volume (MCV) is the average size of the RBC expressed in femtoliters (fL).
      1. MCV can be directly determined by automated hematology analyzers or calculated by (HCT × 10) ÷ RBC ($\times 10^6$).
      2. A population of small RBCs = microcytic, normal RBCs = normocytic and large RBCs = macrocytic.
   B. Mean corpuscular hemoglobin concentration (MCHC) quantifies hemoglobin relative to the volume of packed erythrocytes.
      1. MCHC (g/dL) = (Hb concentration × 100) ÷ HCT
      2. RBCs with normal Hgb are normochromic and RBCs with decreased Hgb are hypochromic.
      3. Hyperchromic RBCs do not spontaneously occur.
      4. Increased MCHC is caused by in vivo or in vitro hemolysis, lipemia or Heinz body formation.
   C. The red cell distribution width (RDW) is obtained by an automated hematology analyzer.
      1. The RDW correlates with the size distribution of RBCs.
      2. Anemias with a large population of macrocytes or microcytes have an increased width.

V. Bone marrow examination: aspirate or core biopsy
   A. Indicated if there are no peripheral signs of RBC regeneration (reticulocytosis, polychromasia)
   B. Indicated if the degree of the reticulocyte response is not consistent with the degree of anemia

VI. Classification schemes for anemia
   A. Bone marrow responsiveness (Table 64-4)
      1. Regenerative anemia: anemia with a concurrent reticulocytosis/polychromasia
      2. Nonregenerative anemia: anemia without a concurrent reticulocytosis/polychromasia

TABLE 64-3

Red Blood Cell Morphological Changes of Clinical Significance

CHANGES	DESCRIPTION	CLINICAL SIGNIFICANCE
Shape Change		
Spherocytes	Small, dense, spherical-shaped cells with lack of central pallor	IMHA: extravascular hemolysis Fragmentation anemia Acanthocytosis (liver disease)
Ghost cells	Remnant membranes of RBCs	IMHA: intravascular hemolysis
Eccentrocytes	Eccentrically placed clear areas with displaced hemoglobin	Oxidative damage
Keratocytes	Two uniform hornlike projections	Oxidative damage
Dacryocytes	Tear shaped	Myelofibrosis
Schistocytes	Irregularly shaped, small fragments	DIC Iron deficiency anemia
Acanthocytes	2-10 irregularly shaped, blunt-ended projections	Liver disease Hemangiosarcoma
Target cells	Extra round outfolding of membrane in middle of cell	Usually with polychromasia Possibly liver disease
Agglutination	Three-dimensional clumping of RBCs	IMHA
Rouleaux	Coin stacking or linear chains of RBCs	Increased plasma proteins owing to inflammation
Size Change		
Anisocytosis	Variation in RBC size	Associated with polychromasia
Macrocytes	Large RBCs	Associated with polychromasia FeLV
Microcytes	Small RBCs	Iron-deficiency anemia Fragmentation anemia
Inclusions		
Basophilic stippling	Small, variably sized blue dots	Associated with polychromasia Lead poisoning
Howell-Jolly bodies	Single, small round remnants of nuclear material	Associated with polychromasia If no polychromasia, decreased splenic function
Heinz bodies	Refractile protuberances from membrane	Oxidative injury
Nucleated RBCs	RBCs with retained nucleus	Should be in low numbers with polychromasia present If no polychromasia, consider bone marrow injury, lead poisoning, myeloproliferative disease, hyperadrenocorticism
Color change		
Polychromatophils	Large blue RBCs	Associated with polychromasia
Hypochromic cells	Lack of hemoglobination	Iron deficiency

IMHA, Immune-mediated hemolytic anemia; *RBC,* red blood cell; *DIC,* disseminated intravascular coagulation; *FeLV,* feline leukemia virus.

B. Morphological classification based on RBC indices (population size, shape)
   1. Macrocytic, hypochromic: regenerative anemia
   2. Normocytic, normochromic: nonregenerative anemia
   3. Macrocytic normochromic: early regenerative response or defective erythropoiesis, especially with feline leukemia virus (FeLV)
   4. Microcytic hypochromic: iron deficiency
   5. Microcytic normochromic: iron deficiency, portosystemic shunts

C. Severity of anemia
   1. Can help identify the underlying clinical processes
   2. Dictates the aggressiveness of treatment (Table 64-5)

TABLE 64-4

Regenerative and Nonregenerative Response to Anemia

LABORATORY PARAMETERS	REGENERATIVE	NONREGENERATIVE
Reticulocytes		
Absolute count	>60,000/μL	<60,000/μL
Percentage	>1% dog, >0.5% cat	<1%
Corrected reticulocyte percentage	>1	<1
Reticulocyte production index	>1	<1
Peripheral blood smear	Polychromasia	Lack of polychromasia
	Anisocytosis	Lack of anisocytosis
	± nRBCs (low numbers)	No nRBCs detected unless bone marrow damage, lead poisoning or myeloproliferative disease present
	± Howell-Jolly bodies	Scattered to none present
	± Basophilic stippling	None present
	± Macrocytes	Normal-sized RBCs
	± Hypochromic cells	Normal pallor
	± Target cells	Normal shape
RBC indices	Macrocytic, hypochromic	Normocytic, normochromic
Bone marrow aspirate, biopsy	Erythroid hyperplasia	Normal to erythroid hypoplasia

nRBCs, Nucleated red blood cells; *RBCs,* red blood cells.

TABLE 64-5

Classifying the Severity of Anemia and Potential Causes

SEVERITY	DOG	CAT	POTENTIAL CAUSES	ACTION
Mild	PCV = 30% to 37%	PCV = 20% to 26%	Inflammatory disease, early iron deficiency, endocrinopathies, statistical chance of normal Consider age of animal, breed differences, sample error (clotting)	Repeated PCV Evaluate for underlying disease
Moderate	PCV = 20% to 29%	PCV = 14% to 19%	Hemolytic anemias, severe blood loss, chronic renal failure, chronic iron deficiency	Examine peripheral blood smear for parasites, RBC morphological abnormalities Assess clinical signs for need of transfusion; if PCV < 15%, whole blood transfusion is indicated Institute supportive care (fluids, plasma expanders) to restore circulating blood volume Evaluate for underlying diseases
Severe	PCV = 13% to 19%	PCV = 10% to 13%		
Very severe	PCV < 13%	PCV < 10%		

Data from Tvedten H, Weiss DJ: Classification and laboratory evaluation of anemia. p. 143. In Feldman BF, Zinkl JG, Jain NC (eds): Schalm's Veterinary Hematology. 5th Ed. Lippincott Williams & Wilkins, Philadelphia, 2000.

PCV, Packed cell volume; *RBC,* red blood cell.

REGENERATIVE ANEMIAS

Hereditary Causes of Hemolytic Anemia

See Table 64-1.

Immune-Mediated Hemolytic Anemia

Definition

I. Immune-mediated hemolytic anemia (IMHA) is a clinical condition where immunoglobulin (Ig) G and/or IgM antibodies bind to RBC surface antigens.
II. This reaction initiates RBC destruction via the complement system (intravascular destruction) and the mononuclear-phagocyte system (extravascular destruction).

Causes

I. Idiopathic or primary IMHA has no apparent underlying disorder and is more common in dogs than cats (Giger, 2005; Kohn et al., 2006).
II. Secondary IMHA is more common than primary IMHA and can be caused by the following:
  A. Erythrocytic parasites
  B. Neoplasia: hemangiosarcoma, lymphosarcoma (Gunn-Moore et al., 1999; Mellanby et al., 2004)
  C. Immune-mediated diseases: systemic lupus erythematosus, recent vaccination (Duval and Giger, 1996)
  D. Neonatal isoerythrolysis (Barker, 2000)
  E. Transfusions (Melzer, 2003; Castellanos et al., 2004)
  F. Drug reactions: penicillins, trimethoprim-sulfa, cephalosporins (Bloom et al., 1988), and carprofen (Mellor et al., 2005)
  G. Envenomation: bee sting (Noble et al., 1999)

Pathophysiology

I. Idiopathic or primary IMHA is caused by autoantibodies on RBCs, most frequently glycophorins in the RBC membrane (Barker, 1995).
II. Secondary IMHA occurs when a drug or antigen binding directly or indirectly to the RBC induces an antigenic state.
III. Removal of RBCs from circulation is by extravascular or intravascular hemolysis.
  A. The degree of hemolysis caused by the bound antibody depends on the quantity, specificity, complement-fixing ability, and binding to tissue macrophages.
  B. Resident macrophages in the spleen and/or liver represent the primary site of extravascular destruction and spherocyte formation.
  C. Macrophages phagocytose IgG, IgM, and complement-coated RBCs with partial (spherocyte formation) or full phagocytosis of RBCs.
  D. IgM and IgG (lesser extent) coated RBCs readily activate the complement system, with lysed RBCs forming ghost cells (Gehrs and Friedberg, 2002).
  E. Intravascular hemolysis is not as frequent as extravascular hemolysis because of regulatory RBC proteins that control complement activation.
IV. Moderate to severe tissue injury from hypoxia and thrombus formation is often present with IMHA (McManus and Craig, 2001).

Clinical Signs

I. Signalment
  A. Cocker spaniels are consistently overrepresented.
  B. English springer spaniels, poodles, Old English sheepdogs, bichon frise, collie breeds, and miniature pinschers are at increased risk (McManus and Craig, 2001; Miller et al., 2004).
  C. Age is variable, ranging from 2 to 12 years (mean 6.9 ± 2.9 years).
  D. Gender is highly variable; some reports favor females, whereas others show no difference.
II. Signs of anemia
  A. Pale mucous membranes
  B. Weakness, exercise intolerance
  C. Fever
III. Fulminant hemolysis
  A. Jaundice, severe pallor, hemoglobinuria
  B. Splenomegaly
  C. Disseminated intravascular coagulation (DIC), frank hemorrhage

Diagnosis

I. Complete blood count
  A. PCV, RBC, and Hgb are often severely decreased (PCV <20%, McManus and Craig, 2001).
  B. Hgb value may not be decreased to the same degree as PCV and RBC owing to intravascular hemolysis increasing the MCHC.
  C. Reticulocyte counts >60,000/μL are often seen after 3 days of anemia.
  D. IMHA can be nonregenerative if the immune response is directed at RBC precursors.
  E. Moderate to severe leukocytosis with a left shift and lymphopenia (inflammation and stress) are common.
II. Peripheral blood smear (Bain, 2005)
  A. Marked regenerative anemia: decreased RBC smear density, anisocytosis, polychromasia, macrocytes and hypochromic RBCs
  B. Evidence of intravascular and extravascular RBC destruction
    1. Spherocytes are partially phagocytosed RBCs.
    2. Ghost cells are empty RBC membranes.
  C. Agglutination (antibody-mediated three-dimensional clumping) versus rouleaux (nonspecific adherence of RBCs)
    1. Blood is mixed well with normal saline at a 1:5 ratio and placed on a glass slide.
    2. If the RBCs remain clumped, it is agglutination.
    3. If the cells disperse, rouleaux is present.
  D. Neutrophil toxicity common
III. Coagulation profiles
  A. Many dogs with IMHA are in a hypercoagulable state and at risk for developing DIC.

B. Cats do not appear at high risk for thromboembolic disease.

IV. Biochemistry profile and urinalysis: hemoglobinemia, hemoglobinuria, hyperbilirubinemia, bilirubinuria with severe hemolysis

V. Coombs test (direct antibody test)
   A. Detects IgG, IgM, and complement on RBC membranes with species-specific reagents.
   B. Antisera and RBC-associated immunoglobulin or complement result in macroscopic and/or microscopic agglutination in a positive Coombs test.
   C. In cats where spherocytes are difficult to identify because of lack of central pallor, the Coombs test can be helpful (Kohn et al., 2006).

VI. Bone marrow aspirate and core biopsy
   A. It is not commonly performed if there is peripheral evidence of a regenerative anemia.
   B. With a regenerative anemia, erythroid hyperplasia (decreased myeloid to erythroid [M:E] ratio) is present, although a concurrent leukocytosis may bring the M:E ratio into the normal range (erythroid and myeloid hyperplasia).
   C. In a nonregenerative hemolytic process, ineffective erythropoiesis (abrupt maturation arrest) supports immune-mediated destruction of immature RBCs (rubricyte, metarubricyte, prorubricyte).

Differential Diagnosis

I. Definitively eliminate all secondary causes of IMHA.

II. Examination of the peripheral blood smear is essential to identify parasites or RBC morphologic changes (schistocytes, acanthocytes, lack of spherocytes).

III. IMHA may be Coombs negative, as low numbers of antibodies may be washed off during the assay.

Treatment

I. Corticosteroids are the initial treatment of choice for IMHA (McCullough, 2003).
   A. Give prednisone or prednisolone 1 to 2 mg/kg PO BID for 2 weeks until the hematocrit increases or there is evidence of regeneration.
   B. When a response is identified, decrease dose by 25% every 2 to 4 weeks and taper over a 3-month period.

II. Use immunosuppressive drugs in combination with prednisone if there is a lack of response to prednisone therapy, severe hemolysis, or autoagglutination.
   A. Azathioprine *(Imuran)*
      1. A loading dose in dogs of 1.4 to 2.2 mg/kg PO SID is given for 4 to 7 days, followed by QOD tapering when remission is assured.
      2. One report documented increased survivability of dogs when ultra-low–dose aspirin (0.5 mg/kg PO SID) was administered with azathioprine (Weinkle et al., 2005).
      3. Azathioprine is not recommended in cats.
   B. Cyclophosphamide *(Cytoxan)*
      1. Many protocols are available for dogs and cats.
         a. Single IV or oral dose of 200 mg/m^2 initially
         b. Maintenance dose of 50 mg/m^2 PO or IV SID for 4 consecutive days of each week; discontinued when PCV increases significantly
         c. Alternative maintenance dose of 75 to 90 mg/m^2 PO SID
      2. Administration must be done cautiously because of increased risk of death and potential for side effects, such as myelosuppression, and hemorrhagic cystitis (Grundy and Barton, 2001; Mason et al., 2003; Burgess et al., 2000).
   C. Cyclosporine A
      1. Dose in dogs is 10 mg/kg PO SID or 6 mg/kg PO BID.
      2. Trough concentrations of 100 to 300 ng/mL should be maintained and serum concentrations measured every 2 to 4 weeks.
      3. Discontinue treatment when dog has been in remission for at least 2 weeks.
      4. Drugs using the cytochrome P450 pathway in the liver (e.g., diazepam, phenobarbital, erythromycin, piroxicam) may affect cyclosporine concentrations in the blood and cause vomiting, diarrhea, and anorexia.

III. Alternative treatments and supportive care include the following:
   A. Danazol *(Danocrine)* may be considered.
      1. Clinical response may take 3 weeks, so the drug is started with prednisone.
      2. Dosages in dogs range from 3 to 12 mg/kg PO BID and are gradually reduced after the animal is weaned off prednisone (Miller, 1997).
   B. Human gammaglobulin 0.5 to 1.5 g/kg IV as a 12-hour continuous infusion (CRI) may improve short-term survival (Scott-Moncrieff et al., 1997).
   C. Heparin can be administered if there is evidence of DIC or thromboembolism.
      1. Initial dose is 200 IU/kg IV followed by 75 to 125 U/kg SC TID to QID or a CRI of 15 to 20 IU/kg/hr IV.
      2. Prolongation of the activated partial thromboplastin time by 1.5 to 2.0 × normal or an increase in the activated clotting time by 15 to 20 seconds is recommended.
   D. Transfusions of whole blood, packed cells, or oxygen-containing whole blood substitutes can be initiated for severe anemia (see Chapter 71).

Monitoring of Animal

I. Measure PCV SID initially to determine response to treatment.
   A. If PCV is increasing with evidence of strong reticulocytosis, it can then be measured once or twice weekly.
   B. To assess the tapering of immunosuppressive drugs when remission is evident, measure PCV on a weekly basis.

II. Weekly monitoring of liver enzyme activity, renal function, white blood cell count and platelet count is warranted if cytotoxic drugs are used.

Erythrocytic Parasites

Definition

I. A hemolytic anemia is caused by epicellular or intracellular erythrocyte parasites.
II. RBC destruction is commonly extravascular from immune complexes attached directly to the parasite or from the exposure of novel RBC antigens that activate the immune system.

Causes

I. Hemotrophic *Mycoplasma* spp.
  A. *Mycoplasma felis* (formerly *Haemobartonella felis*) in cats
  B. *Mycoplasma canis* (formerly *Haemobartonella canis*) in dogs
II. *Babesia* spp.
  A. *Babesia canis vogeli* and *Babesia gibsoni* in dogs
  B. *Babesia felis* in cats (not reported in United States)
III. *Cytauxzoon felis*

Pathophysiology

I. Hemotrophic mycoplasmal agents are epicellular parasites of RBCs.
  A. *M. felis* is probably transmitted through a blood-sucking ectoparasite, with blood transfusions oral ingestion of infected blood, transmission to newborns by infected queens and cat bites as possible alternative modes of transmission (Woods et al., 2005).
    1. Parasitic incubation takes 7 to 30 days.
    2. Parasitemia is cyclical and can last for months.
    3. RBC destruction occurs from increased rigidity of infected RBCs, with sequestration in the spleen (Messick, 2004).
    4. Cats can recover by mounting an immune response, but a carrier state ensues.
  B. *M. canis* is transmitted by the brown dog tick, *Rhipicephalus sanguineus*, and via infected blood.
    1. The organism is nonpathogenic unless a splenectomy was done or other splenic dysfunction (neoplasia) is present.
    2. Organism is closely related to *M. felis* (Birkenheuer, 2002).
II. Babesiosis is a tick-borne disease caused by an intracellular protozoan parasite.
  A. *B. canis* is probably transmitted by the brown dog tick, *R. sanguineus.*
  B. The vector of *B. gibsoni* is unknown.
  C. Canine RBCs are infected by sporozoites in the saliva of a feeding tick.
  D. Asexual reproduction and binary fission of the organism causes RBC lysis.
  E. Incorporation of parasite antigens into the RBC surface induces opsonizing antibodies, with removal of RBCs by macrophages.
III. Cytauxzoonosis is a tick-borne protozoal disease of cats (Meinkoth and Kocan, 2005).
  A. The parasite is transmitted from bobcats to domestic cats (dead end hosts) via the tick, *Dermacentor variables*.
  B. The organism has a complex lifecycle with a tissue (schizogenous) phase followed by an intraerythrocytic phase that occurs late in infection.
  C. In the tissue phase, macrophages become engorged with schizonts obstructing vessels in major organs, resulting in severe clinical signs and rapid death.
  D. If the cat survives the tissue phase, merozoites from ruptured macrophages infect RBCs causing a severe hemolytic anemia.

Clinical Signs

I. Hemotrophic mycoplasmal agents
  A. *M. felis*
    1. Nonspecific signs of hemolytic anemia such as splenomegaly, fever, weakness and pallor are often present.
    2. Concurrent disease (FeLV), immunosuppression or splenectomy predispose to acute infection.
  B. *M. canis:* hemolytic disease in a compromised animal
II. Babesiosis
  A. *B. canis* is most common along the Gulf Coast and in the southern, central, and southwestern states.
  B. *B. gibsoni* is found worldwide and occurs most often in American Staffordshire and American pit bull terriers (Macintire et al., 2002).
  C. Dogs <1 year of age are most likely to show clinical illness.
III. Cytauxzoonosis
  A. Sudden onset of fever (39.8° to 40.1° C [103.8° to 104.2° F]), lethargy, jaundice, anorexia, dyspnea, and pallor are caused by rapid multiplication during the tissue phase.
  B. The incubation period is 5 to 20 days, with a rapid course of illness and death (approximately 5 days).
  C. Most cases are presented March to September (Birkenheuer et al., 2006; Greene, 2006).
  D. It occurs in central and southeastern states, and was recently documented in the Midatlantic states (North Carolina, South Carolina, Virginia) (Birkenheuer et al., 2006).
  E. History of tick exposure or living near a wooded area is common.

Diagnosis

I. Hemotrophic mycoplasmal agents
  A. *M. felis*
    1. Mild to severe regenerative anemia (with increased Howell-Jolly bodies, nRBCs) occurs.
    2. Autoagglutination is often present.
    3. An underlying disease (e.g., FeLV, feline immunodeficiency virus [FIV]) may cause a nonregenerative anemia.
    4. Organism is present <50% of time on RBCs owing to cyclic parasitemia and appears as small, blue-staining rods, coccoid, and ring forms.
    5. Blood smears should be made from an ear prick and in the absence of EDTA.

6. Polymerase chain reaction (PCR) tests are currently used to identify infection.

B. *M. canis*
1. Organism forms chains and Y-shaped branches of cocci across the surface of the RBC.
2. PCR tests can be used to identify the organism (Brinson and Messick, 2001).

II. Babesiosis
A. Examination of buffy coat or ear prick peripheral blood smear increases the chance of identifying low numbers of RBCs infected with 2 to 5 μm, paired, pyriform-shaped, light-blue organisms with an eccentric nucleus *(B. canis),* or 1 to 3 μm, round forms *(B. gibsoni).*
B. Indirect fluorescent antibody test and enzyme-linked immunosorbent assay (ELISA) are used for serologic screening of infection.
C. PCR tests are available for identification of the organism (Birkenheuer et al., 2005).

III. Cytauxzoonosis
A. Intraerythrocytic piroplasms, characterized by 1 to 5 μm, bluish-staining organisms with a "signet ring" or "safety pin" appearance, occur late in the disease process.
B. Cytological or histopathologic examination identifies the schizogenous tissue phase and allows for a definitive diagnosis early in the disease.
C. Normocytic, normochromic nonregenerative anemia (PCV 24 ± 5.5%) that is mild relative to the severity of icterus occurs, along with neutropenia and thrombocytopenia (Birkenheuer et al., 2006).
D. Increased serum bilirubin and bilirubinuria are common.
E. Infected cats are at increased risk for DIC.

Differential Diagnosis

I. Most RBC parasites are overdiagnosed because of stain artifacts, Howell-Jolly bodies, basophilic stippling, platelets overlying RBCs, and refractile elements on RBCs.
II. Investigate all infected animals for an underlying disease (e.g., FeLV, FIV, neoplasia).
III. If additional cytopenias are observed, test for ehrlichiosis.

Treatment

I. Hemotrophic mycoplasmal agents
A. Treat *M. felis* with doxycycline 5 mg/kg PO BID for 3 weeks or enrofloxacin 5 mg/kg PO SID (if doxycycline is not tolerated).
1. Both drugs have been used concurrently in refractory cases.
2. Blood transfusion is indicated for severe anemia.
3. Prednisone at 2 mg/kg PO BID is used to control hemolytic anemia.
4. Recovered cats remain carriers but seldom relapse with clinical disease once the HCT returns to normal.

B. Treat *M. canis* with doxycycline 5 mg/kg PO BID for 3 weeks.
1. Dogs become latent carriers.
2. Do not use treated dogs for blood transfusions.

II. Babesiosis
A. Give imidocarb dipropionate *(Imizol)* at 7.5 mg/kg IM once, but dogs may become carriers.
B. Give immunosuppressive doses of prednisone (1 to 2 mg/kg PO BID) for 2 to 3 weeks to control hemolytic anemia.
C. Supportive care may be required to correct dehydration, anemia, and acidosis.
D. *B. gibsoni* infection has been cleared using a combination of atovaquone 13.3 mg/kg PO TID with a fatty meal and azithromycin 10 mg/kg PO SID in one study (Birkenheuer et al., 2004).

III. Cytauxzoonosis
A. Mortality rate is extremely high, even with adequate therapy.
B. Supportive care (IV fluids) and heparin therapy are indicated for DIC.
C. Imidocarb dipropionate 5.0 mg/kg IM (two injections given 1 to 2 weeks apart) has had some success (Greene et al., 1999; Birkenheuer et al., 2006).

Monitoring of Animal

I. Use serial CBCs to monitor response to treatment.
II. Institute preventative ectoparasite control.

Acquired Erythrocyte Metabolic Defects

Definition

I. Indirect and direct oxidative damage to RBC membranes and the hemoglobin molecule form Heinz bodies and eccentrocytes, with secondary hemolytic anemia.
II. Lack of energy (adenosine triphosphate [ATP]) production leads to oxidative damage and the inability to reduce methemoglobin back to a nontoxic form.
III. Metabolic derangements in cats (e.g., diabetes, hyperthyroidism, and cancer) induce oxidative damage but usually are not associated with a clinically relevant anemia.

Causes

I. A variety of naturally occurring and manufactured hemolytic agents cause indirect and direct oxidative injury.
A. Certain foods: Allium family (onions and garlic)
B. Drugs and chemicals
1. Acetaminophen
2. Benzocaine-containing products
3. Propylene glycol: additive in wet cat foods
4. Methylene blue: historically used as a urinary analgesic
5. Naphthalene: moth balls
6. Propofol
7. Phenazopyridine: urinary analgesic
8. Vitamin K_3: dosages >1.25 mg/kg/day
9. DL-Methionine: for feline urologic syndrome
10. Skunk musk: contains thiols and other oxidizing agents

II. Zinc
A. Nuts and bolts

B. United States pennies minted since 1983
C. Zinc oxide dermatologic creams

III. Feline Heinz bodies
A. Normal cats may have increased numbers of Heinz bodies that are of little clinical significance.
B. Cats with metabolic derangements such as ketoacidotic diabetes mellitus, hyperthyroidism, and lymphoma have high numbers of Heinz bodies, with a minimal decrease in PCV.

IV. ATP depletion in RBCs
A. Hypophosphatemia from diabetes mellitus, hepatic lipidosis, enteral and parenteral hyperalimentation, and oral administration of phosphate binding antacids
B. Pseudohypophosphatemia from hemolysis and conjugated bilirubinemia
C. Pyruvate kinase (PK) and phosphofructokinase (PFK) deficiency (see Table 64-1)

Pathophysiology

I. Oxidative injury
A. Overwhelming oxidative insult results in the formation of one or multiple oxidative changes in the RBC.
1. Heinz body formation
a. An oxidative agent overwhelms the RBC reductive pathways, forming irreversibly denatured hemoglobin molecules (hemichromes) that aggregate to form Heinz bodies.
b. Sulfhydryl groups on the globin portion of hemoglobin can also oxidize and form Heinz bodies.
2. Eccentrocyte formation
a. Direct or indirect oxidation of RBC membrane proteins results in cross-linking.
b. The two membrane surfaces adhere to one another.
3. Methemoglobin formation
a. Severe oxidative insults overwhelm the RBCs' capability to reduce iron back to a usable state.
b. When methemoglobin predominates, transportation of oxygen is inhibited.
B. Extravascular hemolysis removes oxidatively damaged RBCs.
1. Heinz bodies cluster the intracellular portion of band 3, an integral RBC membrane protein, thereby altering the RBC surface; this is a signal for macrophages to remove the damaged RBC.
2. Damaged RBCs are less deformable and enhance removal by macrophages in the spleen.
3. Heinz bodies are "pitted" by the spleen, causing the formation of spherocytes, RBC fragments (schizocytes), or both.
C. Heinz body formation occurs in healthy cats because of higher numbers of sulfhydryl groups on the hemoglobin molecule, which potentiates oxidative injury.
1. Normal feline splenic architecture reduces the pitting function of the macrophage system (Blue and Weiss, 1981).
2. Cats with metabolic derangements have increased numbers of Heinz bodies likely caused by elevations of β-hydroxybutyrate.

II. Hypophosphatemia
A. It depletes concentrations of RBC ATP,2,3-bisphosphoglycerate, and reduced glutathione.
B. This decreases RBC deformability, increases osmotic fragility, and increases susceptibility to oxidative injury.

Clinical Signs

I. Oxidative injury is associated with the following:
A. Heinz body and eccentrocytic anemia
1. Severity of anemia is dependent on dose of offending agent and duration of oxidative injury.
2. Lethargy, pale mucous membranes, tachypnea and tachycardia are often seen.
B. Methemoglobinemia
1. Oxygen depletion can cause tachypnea, dyspnea, and tachycardia.
2. Mucous membranes, blood, and urine may appear brown.
C. Signs of underlying systemic illnesses in older cats

II. Hypophosphatemic cases often have a concurrent myopathy with cardiovascular dysfunction, weakness, ataxia, and seizures.

Diagnosis

I. Confirmation of oxidative injury
A. Heinz bodies stain as peripheral pale, refractile protuberances (Wright's stain) or as light greenish to dark blue small spherical structures (NMB stain) on the RBC.
B. Eccentrocytes have a clear region on one portion of the cell and a region of concentrated hemoglobin on the other.
C. Methemoglobinemia may be detected via two techniques.
1. Spot test involves the following:
a. One drop of animal and control blood is dropped on white filter paper and exposed to air.
b. The control spot turns red from oxygenation, whereas the methemoglobin blood remains brown, indicating methemoglobin concentration exceeds 10% of total hemoglobin (Giger, 2005; Harvey, 2000).
2. Commercial laboratories can quantify methemoglobin spectrophotometrically.

II. Documentation of hypophosphatemia
A. Serum phosphate <2.5 mg/dL can cause hemolysis in the dog and cat.
B. Clinical signs, hemolysis, or serum phosphate concentrations <1.5 mg/dL require treatment.
C. Serum phosphate concentrations often overestimate total body phosphate stores.

III. Presence of heavy metal in gastrointestinal tract on radiography

IV. Zinc toxicosis
A. Serum zinc concentrations >2.0 ppm
B. Liver biopsy zinc concentrations >70.0 ppm

Differential Diagnosis

I. Rule out other underlying causes of hemolytic anemia.
II. In an aged cat with systemic disease, the anemia may not be entirely from Heinz body production; other causes of the anemia (blood loss) must be considered.

Treatment

I. Oxidative injury (see also Chapter 127)
  A. Immediate removal of the oxidative agent
  B. Use of antioxidants
    1. Severe methemoglobinemia can be treated with one slow IV injection of methylene blue (0.2 mg/kg), although its use remains controversial, because it can aggravate oxidant-induced hemolysis (Harvey and Keitt, 1983; Giger, 2005).
    2. In cats with acetaminophen intoxication, give *N*-acetylcysteine *(Mucomyst)* at an initial dose of 140 mg/kg PO or IV, followed by seven treatments of 70 mg/kg PO TID (Giger, 2005).
    3. Dietary antioxidant supplementation is controversial, and only bioflavonoid administration (*Proanthozone* 10 mg/cat/day PO) has demonstrated any protective effect (Allison et al., 2000; Hill et al., 2001; Hill et al., 2005).
    4. Intravenous fluids, transfusions, and supportive care are required in severe cases.
II. Hypophosphatemia
  A. For severe hypophosphatemia, give sodium or potassium phosphate at 0.01 to 0.03 mmol/kg/hr IV (maximum 0.06 mmol/kg/hr), with concurrent monitoring of serum calcium and phosphorus concentrations QID to ensure calcium homeostasis is maintained (Giger, 2005).
  B. Treat mild hypophosphatemia with oral administration of skim milk or commercial diets enriched in phosphorus.

Monitoring of Animal

I. Oxidative injury
  A. A CBC and review of a peripheral blood smear are used to assess response to therapy and decreased oxidative injury.
  B. Animals with resolving methemoglobinemia have clinical resolution of hypoxia.
  C. Serum zinc concentrations can be monitored for resolution of toxicity.
  D. With early removal of inciting oxidative insult and supportive care for the hemolytic crisis, the prognosis is favorable for a full recovery.
II. Hypophosphatemia
  A. Hypocalcemia, acute renal failure, and dystrophic soft tissue calcification can occur with intravenous sodium or potassium phosphorus administration.
  B. Immediate correction with calcium gluconate and cessation of phosphate administration is recommended (Giger, 2005).
  C. If the animal survives the initial insult with appropriate treatment and adequate supportive care, and the underlying cause is corrected or managed, the prognosis can be favorable.

Microangiopathic Hemolytic Anemia

Definition

I. Mechanical damage to RBCs occurs from turbulent shear forces of blood in altered organs.
II. Fragmentation of RBCs develops from intravascular fibrin strands.

Causes

I. DIC
II. Vasculitis
III. Neoplasia: especially hemangiosarcoma
IV. Altered rheologic blood flow: heartworm disease, heart valve disease, IV catheters
V. Acanthocytosis: associated with liver disease

Pathophysiology

I. Direct erythrocyte trauma can be caused by fibrin strands produced as a consequence of DIC.
II. RBCs are fragmented, or fibrin strands cause direct intravascular hemolysis.
III. Organs altered by vasculitis, neoplasia, etc. have tortuous, narrowed vessels with high shear forces that fragment RBCs during their circulation.
IV. Acanthocytes frequently have blebs sheared off, leading to fragmentation.

Clinical Signs and Diagnosis

I. Clinical signs are variable and associated with a primary disease process.
II. Identification of the primary disease process (DIC, neoplasia, liver disease, etc.) is imperative.
III. Examination of peripheral blood smear identifies small, irregularly shaped RBC fragments (schistocytes or schizocytes).
IV. With acute DIC, thrombocytopenia is also present.

Differential Diagnosis

I. Chronic iron-deficient states
II. Zinc toxicity

Treatment

I. Identification and treatment of the underlying disease process are the primary goals.
II. Supportive care and treatment for DIC may be indicated.

Monitoring of Animal

I. Examination of a peripheral blood smear is the most sensitive method of detecting schistocytes.
II. Even a few schistocytes are significant.

Blood Loss Anemia

Definition

I. Loss of blood externally (e.g., gastrointestinal tract, urinary tract, trauma) or internally (e.g., hemoperitoneum, hemothorax) lead to anemia.
II. Blood loss can be acute or chronic.

Causes

I. Hemorrhage
  A. Vascular damage from trauma or changes in vascular architecture (neoplasia)
  B. DIC
  C. Thrombocytopenia (platelet count <30,000/μL)
  D. Congenital or acquired (rodenticide poisoning) coagulation factor deficiency
II. Iatrogenic causes
  A. Repeated phlebotomies
  B. Surgery
  C. Parasitism: hookworms, whipworms, fleas, ticks

Pathophysiology

I. Acute blood loss
  A. Acutely, total blood volume is decreased, but PCV and TP are constant, as proportional amounts of RBCs and protein are lost.
  B. Within 2 to 3 hours, blood volume is restored by movement of interstitial fluid, which dilutes RBC mass, decreases PCV, and causes hypoproteinemia.
  C. The anemia causes hypoxia that stimulates erythropoietin production by the kidney.
  D. Erythroid hyperplasia in the bone marrow takes 3 to 5 days to fully develop, although peripheral signs of regeneration (polychromasia) can be present within 48 hours.
  E. Regenerative responses can be robust unless there has been significant loss of iron.
  F. In the dog, the hemogram should return to normal within 1 to 2 weeks after an acute hemorrhagic episode.
II. Chronic blood loss
  A. Blood loss occurs over weeks to months.
  B. Early erythroid response is regenerative because of adequate body stores of iron.
  C. Over time, iron deficiency occurs with small and hypochromic RBCs produced.

Clinical Signs

I. Acute blood loss
  A. Tachypnea, tachycardia, hypovolemic shock, and death
  B. Visible signs of external hemorrhage
  C. Epistaxis, petechiation, and ecchymosis, suggesting a platelet problem
  D. Hemothorax, hemoperitoneum, and hemarthrosis, suggesting a coagulopathy
II. Chronic blood loss
  A. Clinical signs may be nonspecific, and animals may tolerate extremely low PCV values.
  B. Pale mucous membranes, exercise intolerance, fatigue, melena, and hematuria are possible.
  C. Pica is often present in iron-deficient states.
  D. Evidence of external parasitism (e.g., fleas, ticks) may be noted.

Diagnosis

I. Peripheral signs of regeneration are dependent on the time elapsed since the hemorrhage.
II. Early in the process, a normocytic, normochromic anemia may be mistaken for a nonregenerative anemia.
III. Hallmark findings are anemia and hypoproteinemia, with early evidence of bone marrow responsiveness (developing polychromasia, increasing reticulocytes) by 48 hours.
IV. Regenerative anemia (reticulocytosis, polychromasia) is seen after 3 to 5 days, with maximal response within 4 to 7 days.
V. Bone marrow responsiveness may be dampened by limited iron stores.
VI. Coagulation profile, von Willebrand factor assay, platelet count, and buccal mucosal bleeding time may determine the cause of bleeding.
VII. If blood loss is chronic, a microcytic, hypochromic anemia occurs owing to depleted iron stores.

Differential Diagnosis

I. Other causes of regenerative anemia
II. Investigation into cause of underlying blood loss

Treatment

I. Acute blood loss
  A. Administer IV fluids, hetastarch, hemoglobin solutions, or transfusions of whole blood to restore circulating blood volume (see Chapter 71).
  B. Iron supplementation is usually not necessary.
II. Chronic blood loss
  A. Treatment of the underlying disease is essential.
  B. Iron supplementation is indicated.
    1. Give ferrous sulfate 10 mg/kg PO SID in food for several weeks to months.
    2. If a gastrointestinal disorder prevents oral iron administration, give iron dextran complex (50 mg iron/mL) IM.
      a. Initially, inject a small dose is to test for hypersensitivity.
      b. Give a maximum dose of 2 mL IM SID.

Monitoring of Animal

I. A competent bone marrow requires 2 weeks to restore blood volume after acute blood loss.
II. With resolution of the primary problem and supplementation with iron, it takes months to repopulate RBC mass with normal erythrocytes in cases of chronic blood loss.

NONREGENERATIVE ANEMIAS

Definition

I. PCV is decreased with no evidence of marrow response (lack of polychromasia or reticulocytosis).
II. An anemia is nonregenerative only if it has been present >3 days, which allows enough time to allow the bone marrow to respond.

Causes

I. Nonregenerative anemia with no other accompanying cytopenia

A. Inflammation and/or chronic disease: most common causes
B. Pure red cell aplasia
   1. Immune-mediated
   2. Treatment with recombinant human erythropoietin (rhEPO)
C. Red cell hypoplasia
   1. Endocrine disorders: hypothyroidism, hypoadrenocorticism, hyperestrogenism
   2. Chronic renal insufficiency
   3. Chronic liver disease
   4. FeLV
   5. Nutritional deficiencies: iron from chronic blood loss or a milk diet in young kittens

II. Nonregenerative anemia with other accompanying cytopenias or aplastic anemia
A. Bone marrow toxicity from chemotherapy or drug reaction (Weiss, 2005a)
B. Infectious agents: FeLV, parvovirus, acute ehrlichiosis
C. Irradiation: therapeutic, environmental
D. Myelophthisic disease (Weiss, 2005b)
E. Neoplasia: primary hematopoietic, metastatic
F. Myelodysplastic syndrome (Hisasue et al., 2001)
G. Myelofibrosis (Weiss and Smith, 2002)

Pathophysiology

I. Nonregenerative anemia with no other cytopenias
A. Inflammation and/or chronic disease
   1. Pathogenesis is multifactorial and influenced by induction of inflammatory cytokines (tumor necrosis factor, interleukin [IL]-1α, IL-1β, interferon-γ).
      a. Reduced uptake of iron by gastrointestinal tract from decreased synthesis of transferrin (negative acute phase protein), and iron sequestration in bone marrow
      b. Increased erythrocyte destruction
      c. Decreased erythropoietin secretion
      d. Decreased marrow response to erythropoietin
   2. Onset can be short (hours to days).
B. Pure red cell aplasia
   1. Most often an immune-mediated destruction of an erythroid precursor or a committed erythroid stem cell (Stokol et al., 2000, Weiss, 2002)
   2. Identified in dogs treated with rhEPO for chronic renal failure (Randolph et al., 2004)
C. Red cell hypoplasia
   1. Endocrine disorders
      a. Thyroid hormones and cortisol stimulate and facilitate RBC production.
      b. An estrogen-induced substance produced by thymic stromal cells causes severe bone marrow suppression.
   2. Chronic renal insufficiency
      a. Inadequate and impaired hematopoietic response to erythropoietin
      b. Decreased RBC lifespan owing to uremic toxins and underlying inflammation
   3. Chronic liver disease
      a. Acanthocyte formation can potentiate a fragmentation anemia (schistocytes).
      b. Altered liver production of coagulation proteins can lead to hemorrhage.
   4. FeLV: erythroid stem cells and progenitors selectively killed
D. Nutritional deficiencies
   1. Iron loss occurs from hemorrhage or decreased intake.
   2. RBCs continue to divide in the bone marrow until a critical concentration of Hgb is reached, producing small RBCs that eventually lack a full complement of Hgb (microcytic, hypochromic anemia).

II. Nonregenerative anemia with other cytopenias
A. Bone marrow toxicity from chemotherapy, drug reaction or irradiation kills stem cells and/or causes necrosis of the bone marrow.
B. Infectious agents (FeLV, parvovirus, acute ehrlichiosis) preferentially attack multipotent stem cells (Shelton and Linenberger, 1995).
C. Replacement of the bone marrow by primary hematopoietic neoplastic cells (leukemia), metastatic cancer cells or fibrocytes (myelofibrosis) may also be a cause.
D. Infection with FeLV can cause aplastic anemia, a myeloproliferative disorder or myelodysplastic syndrome.

Clinical Signs

I. General signs of anemia such as pallor, weakness, or lethargy may be noted with severe anemia.
II. If anemia is mild and longstanding, there may be no clinical signs.
III. Clinical signs related to primary disease problems are usually present.

Diagnosis

I. Nonregenerative anemia with no accompanying cytopenias
A. Inflammatory diseases
   1. PCV is mildly to moderately decreased (PCV ≥25% in cats; PCV ≥20% in dogs).
   2. Other changes include decreased serum iron concentration, normal or decreased total iron-binding capacity, normal or increased serum ferritin, and normal or increased stainable iron stores in the bone marrow.
   3. Inflammatory leukogram is identified on the CBC.
B. Pure red cell aplasia (Weiss, 2002)
   1. The median age in dogs is 6.5 years and most cats are <2 years of age (Stokol and Blue, 1999).
   2. Marked nonregenerative anemia (PCV <15%), with normal leukocyte and platelet counts is a typical finding.
   3. Bone marrow aspirate reveals absence of erythroid precursors with pure red cell aplasia, although erythroid precursors with maturation arrest may be found with simple nonregenerative immune-mediated anemia.
   4. Cats are often FeLV- and FIV-negative (Stokol and Blue, 1999).

C. Red cell hypoplasia
   1. Anemias can be mild to severe.
   2. Evidence of renal disease and liver disease or dysfunction may be detected on a biochemistry profile.
   3. FeLV can cause a mild to severe, often macrocytic, (MCV >50 fL) anemia, with atypical erythrocytes (megaloblasts) in the blood and bone marrow.

D. Nutritional deficiencies
   1. Early in an iron-deficient state, PCV may be mildly decreased, MCV is often normal, and there is regeneration with low numbers of microcytes in the circulation.
   2. Over time, high numbers of small RBCs are seen with decreased MCV and hypochromic cells.
   3. With severe iron depletion, a microcytic, hypochromic anemia occurs and is accompanied by schistocyte formation and concurrent fragmentation anemia.

II. Nonregenerative anemia with other cytopenias (Weiss et al., 1999)
   A. Anemias are commonly severe (PCV <15%), with no evidence of regeneration.
   B. Leukopenia and/or thrombocytopenia are common.
   C. Dacryocytes (tear-shaped RBCs) are seen with myelofibrosis.
   D. Bone marrow aspirate and core biopsy reveal pancytopenic aplasia, either as a primary lesion or from a space-occupying lesion (fibroblasts, neoplasia).

Differential Diagnosis

I. A healthy bone marrow with inadequate time to respond to anemia
II. Evidence of underlying chronic disorder

Treatment and Monitoring

I. Nonregenerative anemia with no accompanying cytopenia
   A. Identification and resolution of the underlying disorder are paramount.
   B. Iron administration is not beneficial in anemias of chronic inflammatory disease.
   C. Pure red cell aplasia may respond to immunosuppressive therapy with prednisone or prednisone and cyclophosphamide, with recovery taking weeks to months (Stokol and Blue, 1999; Weiss, 2002).
   D. If a true iron-deficient state exists, give ferrous sulfate 10 mg/kg PO SID in food for several weeks to months.
   E. If a gastrointestinal disorder prevents oral iron administration, give iron dextran complex (50 mg iron/mL) IM.
      1. A small dose is initially injected to test for hypersensitivity.
      2. A maximum dose of 2 mL is given IM SID.
   F. With hyperestrogenism, some dogs recover in 30 days but others develop severe, chronic aplasia.

II. Nonregenerative anemias with other cytopenias
   A. Treat the underlying cause and give supportive care.
   B. Prognosis is usually poor.

POLYCYTHEMIA

Definition

I. Increased circulating numbers of RBCs from physiologic changes or neoplasia
II. Classification of polycythemia
   A. Relative
      1. True RBC mass is unchanged, although PCV, Hgb concentration, and RBC counts are increased.
      2. Decreased plasma volume or splenic contraction causes erythrocytosis.
   B. Absolute
      1. RBC mass: truly increased, with elevated PCV, Hgb concentration, RBC count
      2. Primary or polycythemia vera (PV): a myelodysplastic syndrome characterized by clonal proliferation of neoplastic erythroid cells and high numbers of normal-appearing RBCs in the circulation (see Chapter 66)
      3. Secondary: physiologically appropriate or inappropriate

Causes

I. Relative polycythemia is the most common type and is caused by dehydration or fluid shifts that decrease plasma volume.
II. Physiologically appropriate erythrocytosis (increased PCV, in conjunction with decreased partial pressure of oxygen in arterial blood (Po_2) occurs in response to hypoxic conditions, such as congenital or acquired right-to-left heart shunts, cardiac failure, chronic pulmonary disease, hyperthyroidism, and high altitude.
III. Physiologically inappropriate erythrocytosis (increased PCV, normal Po_2) may be caused by renal cysts, renal neoplasia, metastatic diseases of the kidney, and nonrenal tumors that produce an erythropoietin-like substance.
IV. Primary polycythemia is a well-differentiated myeloproliferative disorder.

Pathophysiology

I. With relative polycythemia, dehydration causes an increase in blood components from decreased plasma volume.
II. Pain or excitement causes epinephrine-induced splenic contraction.
III. Appropriate secondary erythrocytosis occurs from increased production of erythropoietin that is triggered by tissue hypoxia.
IV. Inappropriate secondary erythrocytosis occurs when production of erythropoietin or an erythropoietin-like substance is triggered in the absence of hypoxia.
V. PV is a neoplastic proliferation of erythroid precursors that is erythropoietin independent and results in increased numbers of RBCs.

Clinical Signs

I. Relative polycythemia
   A. History of vomiting, diarrhea, or both
   B. Tacky or dry mucous membranes

II. Splenic contraction
   A. Commonly a history of excitement, anxiety, or pain
   B. More common in breeds with higher normal PCVs: greyhound, Afghan hound, saluki, whippet
III. Absolute polycythemia
   A. Congestion and deep red color of mucous membranes may be detected.
   B. Cyanosis may be present.
   C. Lethargy, blindness, and seizures may develop from decreased vascular perfusion and venous return to the heart.

Diagnosis

I. Secondary and appropriate polycythemia
   A. Reconfirm that erythrocytosis is present.
   B. Decreased Po_2 (<92% or 60 mm Hg) is required to trigger erythrocytosis (Campbell, 1990; Thrall, 2004).
   C Perform diagnostic imaging for pulmonary and heart diseases.
   D. Serum erythropoietin is commonly increased.
II. Secondary and inappropriate polycythemia
   A. Increased concentrations of erythropoietin are documented with normal Po_2 (>97%).
   B. Perform diagnostic imaging of the kidneys and obtain renal cytology or biopsy.
   C. With primary PV, the PCV is commonly >70%, with a normal Po_2.
      1. Diagnosis requires eliminating all other causes of erythrocytosis.
      2. Bone marrow aspirate and core biopsy identify erythroid hyperplasia with a normal maturation sequence.
      3. Serum erythropoietin is commonly normal or decreased.

Differential Diagnosis

I. Ensure erythrocytosis is a repeatable finding.
II. Rule out dehydration, as it is the most common cause of an increased PCV.

Treatment

I. Relative polycythemia: treatment of underlying disease and correction of dehydration
II. Absolute polycythemia
   A. Treat the underlying disease process.
   B. Phlebotomy is usually not indicated because the animal is hypoxic.
III. Primary PV
   A. Treat with repeated phlebotomies to bring PCV into the high-normal range.
   B. Remove 20 mL/kg blood, which results in a PCV decrease of approximately 15%.
   C. Give saline or plasma expanders to maintain circulating blood volume.
   D. With Primary PV, iron supplementation is often necessary.
   E. Oral hydroxyurea is indicated if phlebotomy is needed more often than every 4 to 8 weeks (Campbell, 1990).
      1. Dose in dogs is 15 mg/kg PO SID until the PCV normalizes.
      2. Check PCV every 7 to 14 days until normal and then every 4 months.

Monitoring of Animal

I. Monitor for hemostatic abnormalities, such as thrombosis and hemorrhaging.
II. PCV is monitored every 2 weeks, depending on the cause of the erythrocytosis and resolution of the underlying problem.
III. Many animals respond to treatment and survival time can be >1 year in most cases.

CHAPTER 65

Disorders of White Blood Cells

Laura I. Boone

GENERAL CONSIDERATIONS

Leukogram Evaluation

I. The complete blood count (CBC) evaluates white blood cells (WBCs [leukocytes]), red blood cells (RBCs [erythrocytes]), and platelets.
II. The leukogram is composed of total, relative, and absolute differential leukocyte counts and morphology evaluation.
  A. Absolute differential leukocyte counts (total WBC × WBC type relative percent) are the preferred evaluation method and result in fewer interpretation errors.
  B. Canine and feline leukocytes are present in the following numeric order of prevalence in healthy animals: neutrophils, lymphocytes, monocytes, eosinophils, and basophils.
III. Published total leukocyte counts in health are 6000 to 17,000/μL in dogs and 5500 to 19,500/μL in cats (Mahaffey, 2003).
  A. These numbers are provided as guidelines; use the reference ranges provided by each laboratory to interpret the leukogram.
  B. Interpretation of the leukogram is based on the absolute leukocyte count (reported as numbers/μL) rather than the relative percentages.
  C. The absolute numbers of the various WBCs are altered by physiological, pathologic, or pharmacological processes.
  D. Increased numbers of leukocytes are denoted by the addition of the suffix "ilia" or "osis."
    1. *Neutrophilia* is defined as absolute neutrophil counts >12,000/μL in dogs and >12,500/μL in cats; it is the most common contributor to leukocytosis.
    2. *Monocytosis* is defined as absolute monocyte counts >1400/μL in dogs and >850/μL in cats.
    3. *Lymphocytosis* is defined as absolute lymphocyte counts >2900/μL in dogs and >7000/μL in cats.
    4. *Eosinophilia* is defined as absolute eosinophil counts >1300/μL in dogs and >750/μL in cats; it generally occurs with hypersensitivity reactions or parasitic infections.
    5. *Basophilia* is defined as absolute basophil counts >140/μL in dogs and >200/μL in cats.
    6. Basophilia is rare, is often accompanied by eosinophilia, and is associated with parasitic diseases (particularly dirofilariasis); hypersensitivity reactions; inflammation; neoplasia (basophilic leukemia, mast cell tumor/mastocytosis, lymphomatoid granulomatosis, essential thrombocythemia); and drug reactions (heparin, penicillin).
  E. Decreased numbers of leukocytes are denoted by the addition of the suffix "penia" or "cytopenia."
    1. *Neutropenia* is defined as absolute neutrophil counts of <2900/μL in dogs and <2500/μL in cats.
    2. *Lymphopenia* is defined as absolute lymphocyte counts <400/μL in dogs and <1500/μL in cats.
    3. Monocytopenia and basopenia occur infrequently and are of no clinical importance.
    4. Eosinopenia and basopenia are difficult to define, because the lower limit of normal in dogs and cats typically extend to 0/μL.
      a. Eosinopenia may occur with acute inflammation or infection.
      b. Eosinopenia also may follow endogenous corticosteroid release secondary to stress, trauma, or hyperadrenocorticism, and may be associated with exogenous corticosteroid or adrenocorticotropic hormone (ACTH) administration.
IV. Assessment of WBC morphology is extremely important.
  A. Altered WBC morphology and the presence of cytoplasmic inclusions are important indicators of physiological abnormalities or disease (Tables 65-1 and 65-2).
  B. Abnormal morphology does not always indicate abnormal or compromised cell function; normal morphology does not guarantee normal cell function.
  C. Characteristic and cyclical patterns of changes in WBC numbers over time are unique to certain disorders (e.g., canine cyclic hematopoiesis).

Peripheral Blood Neutrophil Pools

I. Neutrophils in peripheral blood randomly disperse into two interchangeable populations—the circulating and the marginated pools.
II. The circulating pool includes neutrophils located within the vasculature that are sampled with routine blood collection and quantified in the CBC.
III. The marginated pool is composed of neutrophils that are loosely attached to capillary and venule endothelial surfaces

TABLE 65-1

Morphological Alterations in Leukocytes

ALTERATION	CELL TYPE AFFECTED	KEY MORPHOLOGICAL FEATURE(S)	INTERPRETATION	CAUSES	REFERENCES
Hypersegmentation	Neutrophils	≥5 nuclear lobes	Increased vascular transit time	Increased endogenous (protracted stress, hyperadrenocorticism) or exogenous corticosteroid administration	Schultze (2000)
Hyposegmentation	Neutrophils	Round, bean- or horseshoe-shaped nuclei	Cellular immaturity or failure of the nucleus to segment (congenital or acquired)	Left shift: release of immature neutrophils or Pelger-Huët anomaly	Kociba (2000), Schultze (2000)
Toxic change	Neutrophils	Cytoplasmic abnormalities: Döhle bodies (basophilic, pale, angular, peripherally located inclusions), vacuolation, basophilia, toxic granulation, and/or giant neutrophils	Accelerated production of neutrophils and decreased neutrophil maturation time in the marrow Affected cells lack some functions (guarded prognosis) Can be a sensitive diagnostic aid for inflammation, systemic disease, or drug toxicity, as they may precede changes in neutrophil number and appearance of immature forms	Severe inflammation from localized or systemic infection, endotoxemia, sterile inflammation, or drug toxicity	Aroch et al. (2005)
EDTA artifact	Neutrophils	Cytoplasmic vacuolization, membrane irregularity, and pyknosis	Artifact (must be differentiated from toxic change)	Prolonged exposure to EDTA (delayed blood smear preparation)	Gossett and Carakostas (1984)
Reactive lymphocytes	Lymphocytes	Increased cell size, deeply basophilic cytoplasm, perinuclear clear zone, aggregated chromatin, and indistinct nucleoli	Antigenic stimulation	Many causes; occurs secondary to inflammation, infection, or recent immunization	Kociba (2000)
Large granular lymphocytes	Lymphocytes	Variable numbers of azurophilic to eosinophilic cytoplasmic granules Dogs: small granules clustered near the nucleus Cats: larger, evenly dispersed granules	Neoplasia or inflammation	Neoplasia or inflammation	Weider et al. (1991)

EDTA, Ethylenediamine tetraacetic acid.

TABLE 65-1

Morphological Alterations in Leukocytes—*cont'd*

ALTERATION	CELL TYPE AFFECTED	KEY MORPHOLOGICAL FEATURE(S)	INTERPRETATION	CAUSES	REFERENCES
Lymphocytes in Sézary syndrome	Lymphocytes	Large circulating neoplastic lymphocytes with intensely cleaved nuclei with prominent nucleoli	Neoplasia	Neoplasia	Foster et al. (1997)
Plasma cells	Lymphocytes	Characterized by basophilic cytoplasm, eccentrically placed nucleus with condensed chromatin, and prominent perinuclear Golgi zone	Rarely found in circulation	Antigenic stimulation from infection, inflammation, hypersensitivity reactions, systemic disease	Schultze (2000)
Degranulation or vacuolation of eosinophils (dogs)	Eosinophils	Complete or partial clearing of eosinophilic staining of granules	Artifact	Unknown, but not indicative of injury or abnormal function	Schultze (2000)

TABLE 65-2

Leukocyte Cytoplasmic Inclusions

INCLUSION	CELL(S) AFFECTED	KEY MORPHOLOGIC FEATURES	REFERENCES
Bacteria	Neutrophils, monocytes, eosinophils (rarely)	Dogs, cats: positively or negatively staining rods or cocci	Tvedten et al. (1990)
Hepatozoon spp. gametocytes	Neutrophils or monocytes	Dogs: oval, unstained to pale blue basophilic inclusions (5-10 μm)	Barton et al. (1985), Panciera et al. (2000)
Canine distemper virus	Leukocytes (particularly lymphocytes), red blood cells	Dogs: round to irregularly shaped, homogeneous, blue-gray to magenta, intracytoplasmic inclusions	McLaughlin et al. (1985)
Histoplasma capsulatum	Neutrophils, monocytes, eosinophils (rarely)	Dogs, cats: round to oval, uniform, basophilic yeast (2-4 μm) with dark central area and clear halo	Clinkenbeard et al. (1988a, 1988b)
Ehrlichia spp. morulae	*E. ewingii, E. equi,* or human granulocytotropic *Ehrlichia* spp.: neutrophils and eosinophils *E. canis:* monocytes, lymphocytes	Dogs: magenta to basophilic inclusion (2-6 μm) resembling a mulberry	Cowell et al. (1988), Rikihisa (2000)
Leishmania spp. amastigotes	Neutrophils	Dogs: 1-2 small, round to oval organisms with oval nucleus, basophilic ventral kinetoplast, and light blue cytoplasm	Schultze (2000)
Hemosiderin	Neutrophils and monocytes	Dogs: brown crystals (1-4 μm) that stain positively with Prussian blue stain; reported with immune-mediated hemolytic anemia	Gaunt and Baker (1986)

and, therefore, are not sampled during blood collection procedures.

Bone Marrow Neutrophil Production and Kinetics

I. Neutrophil production and maturation occurs in the bone marrow, with precursors progressing through stages, such as myeloblast, progranulocyte, myelocyte, metamyelocyte, band neutrophil, and mature segmented neutrophil.
II. Neutrophil precursors are divided into two pools based on their mitotic capabilities.
   A. The proliferation-mitotic pool is composed of myeloblasts, progranulocytes, and myelocytes.
   B. The storage-maturation pool (no cell division) is composed of metamyelocytes, band, and segmented neutrophils.
III. The marrow transit time (myeloblast to released segmented neutrophils) is 3.5 to 6 days.

ALTERATIONS IN WHITE BLOOD CELL NUMBERS AND MORPHOLOGY

Neutrophilia

See Box 65-1.

Neutropenia

Definition

I. Neutropenia is characterized by a neutrophil count below the lower limit of the reference range (<2900/μL in dogs and <2500/μL in cats) (Mahaffey, 2003).
II. It is common in dogs and cats and is often accompanied by leukopenia.
III. Neutropenia accompanied by anemia and thrombocytopenia indicates pancytopenia and is suggestive of bone marrow injury or effacement.

Causes and Pathophysiology

I. General mechanisms of neutropenia consist of decreased bone marrow production and tissue utilization exceeding marrow production and release (Box 65-2).
II. Neutropenia can be secondary to increased margination, sequestration, hemophagocytic syndrome, and immune-mediated damage to circulating neutrophils or granulocytic precursors in the bone marrow.
III. Neutropenia can be a negative prognostic indicator associated with increased mortality; the more severe the neutropenia, the greater the risk of infection (Aroch et al., 2005).
IV. Neutropenia resulting from tissue utilization in excess of marrow production can occur with severe, localized bacterial infections involving body cavities, the uterus, the respiratory or gastrointestinal (GI) tracts, or during generalized septicemia.
V. Neutropenia can be associated with neutrophil toxicity.
VI. Marrow suppression resulting in decreased leukocyte production may arise with the following:

Box 65-1

Causes of Neutrophilia*

Causes	Species Affected
Inflammation	
Infectious agents	
Bacteria: numerous species	Dog, cat
Fungi: numerous species	Dog, cat
Rickettsia: Rocky Mountain spotted fever	Dog
Viruses: canine distemper, feline rhinotracheitis, feline calicivirus	Dog, cat
Parasites: numerous species	Dog, cat
Protozoa: *Hepatozoon americanum*	Dog
Tissue necrosis	
Thrombosis/infarction	Dog, cat
Metabolic injury: uremia	Dog, cat
Physical injury: surgery, trauma, burns, frostbite	Dog, cat
Neoplasia	Dog, cat
Immune-mediated diseases	
Immune-mediated hemolytic anemia	Dog, cat
Polyserositis	Dog, cat
Polymyositis	Dog, cat
Rheumatoid arthritis	Dog, cat
Systemic necrotizing vasculitis	Dog (beagle)
Lupus erythematosus	Dog, cat
Physiologic leukocytosis: epinephrine release resulting from excitement, fear, exercise	Dog, cat
Corticosteroid-induced leukocytosis: increased endogenous or exogenous steroids, ACTH administration	Dog, cat
Neoplasia	
Leukemia: several types	Dog, cat
Paraneoplastic syndrome: benign and malignant tumors	Dog, cat
Genetic disorders: CD11b/CD18 leukocyte adhesion deficiency	Dog (Irish setter)
Drug administration: recombinant human or canine colony-stimulating factor	Dog, cat
Drug toxicity: early estrogen toxicosis	Dog
Miscellaneous	
Hemolysis	Dog, cat
Hemorrhage	Dog, cat
Toxemia/toxicity	
Blue-green algae toxicity	Dog
Botulism	Dog, cat
Endotoxemia	Dog, cat
Uremia	Dog, cat

ACTH, Adrenocorticotropic hormone.
*Absolute neutrophil counts >12,000/μL in dogs and >12,500/μL in cats (Mahaffey EA: Quality control, test validity, and reference values. p. 331. In Latimer KS, Mahaffey, Prasse KW (eds): Duncan and Prasse's Veterinary Laboratory Medicine: Clinical Pathology. 4th Ed. Iowa State University Press, Ames, 2003).

Box 65-2

Causes of Neutropenia*

Causes	Species Affected
Tissue utilization in excess of bone marrow release	
Infectious agents	
Acute endotoxemia, septicemia	Dog, cat
Bacteria: numerous species	Dog, cat
Rickettsia: *Ehrlichia canis*	Dog
Viruses: canine parvovirus, canine distemper virus, infectious canine hepatitis, FeLV, FIV	Dog, cat
Parasites: *Babesia canis*	Dog
Decreased bone marrow production	
Drug toxicity	
Estrogen toxicosis: iatrogenic, prolonged estrus, or Sertoli cell tumor–induced hyperestrogenism	Dog
Griseofulvin	Cat
Chloramphenicol	Cat
Idiosyncratic drug reactions	
Cephalosporins	Dog, cat
Noxzema skin creme	Dog, cat
Phenylbutazone	Dog
Trimethoprim-sulfadiazine	Dog
Phenobarbital	Dog
Thiacetarsamide	Dog
Methimazole	Cat
Myelodysplasia and myeloproliferative diseases	Dog, cat
Lymphoproliferative disease	Dog, cat
Myelophthisis	
Neoplasia: metastatic carcinoma	Dog
Granulomatous inflammation: disseminated *Histoplasma capsulatum*	Dog, cat
Myelofibrosis and osteopetrosis	Dog
Bone marrow necrosis	Dog, cat
Radiation	Dog, cat
Shifts from the circulating to marginated neutrophil pool	
Endotoxemia	Dog, cat
Anaphylaxis	Dog, cat
Congenital disorders	
Cyclic hematopoiesis	Dog (gray-coated collie)
Inherited vitamin B_{12} malabsorption	Dog (giant schnauzer)
Destruction/sequestration of neutrophils	
Immune-mediated neutropenia	Dog
Hemophagocytic syndrome	Dog

FeLV, Feline leukemia virus; *FIV,* feline immunodeficiency virus.
*Absolute neutrophil counts <2900/μL in dogs and <2500/μL in cats (Mahaffey EA: Quality control, test validity, and reference values. p. 331. In Latimer KS, Mahaffey, Prasse KW (eds): Duncan and Prasse's Veterinary Laboratory Medicine: Clinical Pathology. 4th Ed. Iowa State University Press, Ames, 2003)

A. Total body ionizing radiation
B. Myelosuppression with chemotherapeutic agents (see Chapter 72)
   1. Examples include cyclophosphamide, daunomycin, dimethyl myleran, doxorubicin, 6-thioguanine, azathioprine, cisplatin, carboplatin, chlorambucil, melphalan, methotrexate, mitoxantrone, and combination therapy with vincristine and L-asparaginase.
   2. The marrow neutrophil proliferation-mitotic pool is most sensitive to chemotherapeutics.
      a. Differentiated cells in the maturation-storage pool are unaffected, so release of mature neutrophils continues for 5 to 10 days.
      b. A neutropenic nadir often occurs during these 5 to 10 days as a result of decreased marrow production and the short (6-hour) lifespan of the circulating neutrophil.
   3. Chemotherapy-induced thrombocytopenia occurs in 1 to 2 weeks (circulating lifespan of platelets is 10 days).
   4. Anemia is uncommon.
C. Estrogen toxicosis in dogs
   1. Sources of estrogen exposure include the following:
      a. Diethylstilbestrol or estradiol cyclopentylpropionate therapy used for mismating, urinary incontinence, or infertility in females may be a cause.
      b. With exogenous estrogen therapy for perianal gland tumors in males, pancytopenia can occur with the neutropenia.
      c. Excessive endogenous estrogen with interstitial and Sertoli cell tumors (males) and granulosa cell tumors (females) can also be associated with pancytopenia.
   2. Sequential hematological abnormalities in canine estrogen toxicosis consist of the following:
      a. Immediate leukocytosis followed by rapid leukopenia
      b. Thrombocytosis followed by rapid thrombocytopenia
      c. Slow development of anemia and pancytopenia within 1 month
D. Prolonged (14 to 21 days) chloramphenicol therapy in cats: leukopenia and neutrophils with Döhle bodies
E. Idiosyncratic drug reactions with either neutropenia or pancytopenia
   1. Antibiotics: cephalosporins, trimethoprim-sulfadiazine
   2. Thiacetarsamide
   3. Griseofulvin
   4. Phenobarbital
   5. Phenylbutazone
   6. Albendazole
   7. Captopril
   8. Medicated skin cream *(Noxzema)*
   9. Methimazole
   10. Trimeprazine tartrate

F. Infectious causes of neutropenia or pancytopenia (see Chapters 112 and 115)
   1. Parvovirus infection of dogs and cats (feline panleukopenia)
   2. Feline leukemia virus (FeLV)
   3. Feline immunodeficiency virus (FIV)
   4. Canine ehrlichiosis

VII. Neutropenia or pancytopenia from significantly decreased hematopoiesis can result from the following:
   A. Reduction or complete effacement of the marrow space with bone marrow necrosis (rare) or myelophthisic disease
   B. Causes of myelophthisic disease in dogs and cats
      1. Myelofibrosis (see Chapter 66)
      2. Osteopetrosis: rare
      3. Myeloproliferative diseases or myelodysplasia (see Chapter 66)
      4. Multicentric lymphoma (lymphosarcoma [LSA]) (see Chapter 69)
      5. Disseminated granulomatous disease (e.g., systemic mycoses)
      6. Metastatic neoplasia

VIII. Neutrophils shift rapidly from the circulating to marginated pool, especially during episodes of anaphylaxis or endotoxemia in dogs (pseudoneutropenia).

IX. Hemophagocytic syndrome is a rare event.
   A. Hematology findings consist of cytopenias involving two or more of the hematologic cell lines and circulating fragments of erythrocytes.
   B. Bone marrow aspirate reveals increased numbers of macrophages containing phagocytized hematopoietic precursors, and predominantly erythroid precursors, with fewer neutrophils and platelets.

X. Uncommon causes of neutropenia include the following:
   A. Immune-mediated neutropenia can be idiopathic, drug-related, or associated with other immune-mediated diseases (e.g., rheumatoid arthritis, systemic lupus erythematosus).
      1. Presumptive diagnosis can be made with clinical response to immunosuppressive doses of corticosteroids and with termination of therapy in cases of drug-related neutropenia.
      2. Definitive diagnosis requires demonstration of antineutrophil antibodies, which is difficult owing to fragility of the neutrophils and potential release of intracellular enzymes.
   B. Canine cyclic hematopoiesis, a genetic disorder specific for gray-coated collies, is characterized by continuous, abnormal 2- to 4-day cycles of neutropenia.
      1. Affected dogs exhibit recurrent infections by 8 weeks of age.
      2. Death usually occurs by approximately 3 years of age from septicemia or systemic amyloidosis.
   C. Inherited vitamin B_{12} (cobalamin) malabsorption in giant schnauzers results in failure to express the necessary receptor for normal intestinal cobalamin absorption.
      1. Cobalamin deficiency induces maturation abnormalities in hematopoietic precursors.
      2. Characteristic findings consist of neutropenia, neutrophil hypersegmentation, nonregenerative anemia, nucleated red blood cells (nRBCs) with nuclear:cytoplasmic asynchrony, thrombocytosis, and rare giant platelets.

Diagnosis

I. Perform routine CBCs to identify and monitor neutropenia and concurrent hematological abnormalities.

II. Question clients regarding the administration of chemotherapeutics, estrogen, or other hematotoxic compounds.

III. Serological and other tests are used for diagnosis of canine and feline viral and ehrlichial diseases (see Chapters 112 and 115).

IV. Bone marrow evaluation is a useful procedure in cases of neutropenia when the aforementioned causes of neutropenia or pancytopenia have been eliminated, and may reveal the following:
   A. Myeloproliferative disease: blast cells in circulation and in bone marrow samples; cytochemical stains required for definitive diagnosis (see Chapter 66).
   B. Myelofibrosis: obliteration of marrow spaces by increased fibrous connective tissue
   C. Myelodysplasia: peripheral cytopenias to pancytopenia, abnormal cellular morphology and/or maturation, and hypercellular bone marrow with or without blast cells
   D. Identification of bone marrow abnormalities in inherited vitamin B_{12} deficiency: decreased cellularity, hypersegmented neutrophils, giant neutrophil precursors, and erythroid dysplasia

V. Measure serum cobalamin concentrations in giant schnauzers with suspected inherited cobalamin malabsorption.

Treatment

I. Consider discontinuing or delaying chemotherapy in animals with neutrophil counts of <1000/μL, and starting prophylactic broad-spectrum antibiotics, because they are predisposed to sepsis (Kociba, 2000).

II. Lithium carbonate (11 mg/kg PO BID for 6 weeks) may reverse marrow hypoplasia and pancytopenia secondary to estrogen toxicosis in dogs (Hall, 1992).

III. Lithium carbonate at 21 to 26 mg/kg/day PO may partially alleviate neutropenia of canine cyclic hematopoiesis, but can have toxic effects at this latter dose (Campbell, 1985).

IV. Recombinant human granulocyte colony-stimulating factor (G-CSF, 2.5 to 10 μg/kg/day SC for 3 to 5 days) can be used for short-term management of neutropenia in dogs and cats, but neutralizing antibodies develop in cats and dogs within 14 and 21 days, respectively; therefore, long-term use is not recommended (Ogilvie, 2000; Phillips et al., 2005).

V. Parenteral administration of 1 mg cobalamin once monthly has resulted in temporary remission; no improvement occurs with oral therapy (Fyfe, 2000).

VI. Bone marrow transplantation and lentivirus-mediated G-CSF therapy have been used experimentally to treat or lessen the severity of canine cyclic hematopoiesis (Lothrop et al., 1988; Yanay et al., 2003).

Monitoring of Animal

I. Prognosis for recovery from neutropenia is dependent on the cause and reversibility of bone marrow damage.
II. Neutrophil counts usually rebound when chemotherapeutic agents are discontinued.
III. Recovery following estrogen toxicosis is possible but variable.
   A. Recovery may occur within 3 months.
   B. Pancytopenia may be permanent in some cases.
IV. Neutropenia associated with idiosyncratic drug reactions may resolve within 1 to 2 weeks after therapy is discontinued.
V. Neutropenia induced by infectious diseases carries a fair (FeLV) to good (ehrlichiosis) prognosis.
VI. Neutropenia associated with bone marrow necrosis and myelophthisic disease has a guarded prognosis, but recovery is possible with successful treatment of certain underlying causes, such as lymphoma.

Lymphocytosis

See Box 65-3.

Lymphopenia

See Box 65-4.

Monocytosis

See Box 65-5.

Box 65-3

Causes of Lymphocytosis*

Causes	Species Affected
Physiological leukocytosis: epinephrine response	Dog, cat
Chronic antigenic stimulation	
Infectious agents	
Bacteria: brucellosis	Dog
Mycoses: various species	Dog, cat
Rickettsia: *Ehrlichia canis,* Rocky Mountain spotted fever	Dog
Viruses: feline leukemia virus	Cat
Vaccine-induced (acute response)	Dog, cat
Hypoadrenocorticism	Dog
Lymphoid neoplasia	
Acute or chronic lymphocytic leukemia	Dog, cat
Lymphoma	Cat
Thymoma	Cat

*Absolute lymphocyte counts >2900/μL in dogs and >7000/μL in cats (Mahaffey EA: Quality control, test validity, and reference values. p. 331. In Latimer KS, Mahaffey, Prasse KW (eds): Duncan and Prasse's Veterinary Laboratory Medicine: Clinical Pathology. 4th Ed. Iowa State University Press, Ames, 2003).

Eosinophilia

See Box 65-6.

Circulating Mast Cells

Definition

Mast cells are rarely seen in peripheral blood smears, but can occur with certain conditions.

Causes

I. Inflammatory conditions (dogs): allergic dermatitis, trauma, regenerative anemia, parvovirus infection, or non–mast cell neoplasia.

Box 65-4

Causes of Lymphopenia*

Causes	Species Affected
Corticosteroid-induced	
Increased endogenous corticosteroid levels	
Acute severe stress: inflammation, infection, trauma	Dog, cat
Hyperadrenocorticism	Dog
Exogenous corticosteroid or ACTH administration	Dog, cat
Septicemia or endotoxemia	Dog, cat
Acute viral infections	
FeLV, panleukopenia, FIV	Cat
Canine parvovirus, coronavirus, distemper, infectious hepatitis	Dog
Loss of lymph fluid	
Chylothorax (see Chapter 19)	Dog, cat
Chyloperitoneum	Dog, cat
Lymphangiectasia	Dog, cat
Gastrointestinal disease	
Protein-losing enteropathy	Dog
Ulcerative or granulomatous enteritis	Dog, cat
Neoplasia	
Gastrointestinal lymphoma	Dog, cat
Enteric tumors	Dog, cat
Lymph node effacement	
Granulomatous inflammation: numerous etiologies	Dog, cat
Multicentric lymphoma	Dog, cat
Hereditary disorders	
Severe combined immunodeficiency	Dog†
Treatment-induced	
Immunosuppressive drugs	Dog, cat
Chemotherapeutic drugs	Dog, cat
Radiation	Dog, cat

ACTH, Adrenocorticotropic hormone; *FeLV,* Feline leukemia virus; *FIV,* Feline immunodeficiency virus.
*Absolute lymphocyte counts <400/μL in dogs and <1500/μL in cats (Mahaffey EA: Quality control, test validity, and reference values. p. 331. In Latimer KS, Mahaffey, Prasse KW (eds): Duncan and Prasse's Veterinary Laboratory Medicine: Clinical Pathology. 4th Ed. Iowa State University Press, Ames, 2003).
†Basset hound, Parson (Jack) Russell terrier, Cardigan Welsh corgi.

Box 65-5

Causes of Monocytosis*

Causes	Species Affected
Acute or chronic inflammation	
Protozoal, fungal, or parasitic diseases: numerous species	Dog, cat
Bacterial diseases, particularly intracellular organisms such as *Mycobacterium* spp. or *Brucella* spp.	Dog, cat
Viral diseases: feline infectious peritonitis, FeLV	Cat
Foreign-body reaction	Dog, cat
Tissue necrosis	Dog, cat
Immune-mediated diseases: hemolytic anemia, arthritis	Dog
Pyogranulomatous inflammation	Dog, cat
Neoplasia-associated inflammation	Dog, cat
Hemolysis	Dog, cat
Corticosteroid-induced leukocytosis	Cat
Rebound from neutropenia (may be first indicator of recovery)	
Recovery from neutropenia with inflammation, infection, systemic disease	Dog, cat
Congenital cyclic hematopoiesis of gray-coated collies	Dog
Recovery from feline panleukopenia or canine parvovirus	Dog, cat
Neoplasia	
Monocytic leukemia	Dog, cat
Myelomonocytic leukemia	Dog, cat
Malignant histiocytosis	Dog

FeLV, Feline leukemia virus.
*Absolute monocyte counts >1400/μL in dogs and >850/μL in cats (Mahaffey EA: Quality control, test validity, and reference values. p. 331. In Latimer KS, Mahaffey, Prasse KW (eds): Duncan and Prasse's Veterinary Laboratory Medicine: Clinical Pathology. 4th Ed. Iowa State University Press, Ames, 2003).

II. Canine or feline metastatic mast cell neoplasia
III. Mast cell leukemia
  A. Myeloproliferative disease
  B. Atypical mast cells in circulation and in aspirate or biopsy samples from bone marrow, liver, and spleen

Diagnosis

I. Occasional mast cells are seen in peripheral blood smears.
II. Differentiation of mast cell leukemia from other conditions requires examination of cellular morphological characteristics, cytochemical staining, and histological examination of tissues.

Treatment

I. When mast cells are seen in peripheral blood smears, the underlying disease should be identified and treated.
II. See Chapter 70 for further discussion of treatment of mastocytosis.

Box 65-6

Causes of Eosinophilia*

Causes	Species Affected
Parasitic disease	
Heartworm disease	Dog, cat
Nematodes: numerous species	Dog, cat
Trematodes: various species	Dog, cat
Ectoparasites	Dog, cat
Protozoa: *Babesia canis, Hepatozoon americanum, H. canis, Pneumocystis carinii*	Dog, cat
Mycoses: *Cryptococcus neoformans, Aspergillus fumigatus, Pythium* spp., *Blastomyces dermatitidis*	Dog, cat
Immediate or delayed hypersensitivity reactions	
Oral granuloma	Dog
Gastrointestinal eosinophilic granuloma	Dog
Ulcerative gastroenteritis	Dog, cat
Pulmonary granuloma	Dog
Pulmonary infiltrates with eosinophilia	Dog
Asthma	Cat
Panosteitis	Dog
Pyometra	Dog
Atopy	Cat
Feline eosinophilic granuloma complex	Cat
Food hypersensitivity	Cat
Eosinophilic keratitis	Cat
Canine eosinophilic granuloma	Dog
Neoplasia	
Eosinophilic leukemia	Cat
Myeloid leukemia	Dog
Lymphoma	Cat
Lymphomatoid granulomatosis	Dog
Paraneoplastic conditions	
Carcinomas: select types	Dog, cat
Sarcomas: select types	Dog, cat
Mast cell neoplasia	Dog, cat
Endocrine conditions	
Hypoadrenocorticism	Dog
Hyperthyroidism	Cat
Estrus	Dog
Tetracycline administration	Dog
Idiopathic hypereosinophilic syndrome	Dog (rottweiler), cat

*Absolute eosinophil counts >1300/μL in dogs and >750/μL in cats (Mahaffey EA: Quality control, test validity, and reference values. p. 331. In Latimer KS, Mahaffey, Prasse KW (eds): Duncan and Prasse's Veterinary Laboratory Medicine: Clinical Pathology. 4th Ed. Iowa State University Press, Ames, 2003).

Inflammatory Leukocytosis

Definition

I. Neutrophil supply released from the bone marrow exceeds the migration of neutrophils into sites of inflammation.
II. The end result is an increase in circulating mature and immature neutrophils.

Causes and Pathophysiology

I. Tissue demand for neutrophils exceeds the reserve of mature neutrophils in the bone marrow.
   A. Release of immature cells (left shift) in the following order: band cells, then metamyelocytes, then myelocytes
   B. Regenerative left shift
      1. It occurs with acute inflammation.
      2. It is characterized by increased numbers of WBCs (leukocytosis) that are predominantly mature neutrophils, with increased immature neutrophil precursors.
   C. Degenerative left shift
      1. The WBC count is normal to decreased with excessive numbers of immature relative to mature neutrophils.
      2. It is often seen with septicemia or endotoxemia.
      3. Prognosis is poor, because tissue demand is greater than neutrophil production in the bone marrow.

II. Neutrophilic responses vary with inflammation.
   A. Peracute inflammation
      1. Transient neutropenia develops within 1 to 3 hours.
      2. It is often in response to endotoxemia or severe infections, particularly those involving the peritoneum, lungs, or thorax.
   B. Acute inflammation
      1. Bone marrow responds within 4 to 6 hours to increased tissue demands, causing an accelerated release of neutrophils (mature and immature).
      2. The resulting inflammatory leukogram is characterized by leukocytosis, neutrophilia, and a regenerative left shift (generally >450 immature neutrophilic precursors/μL in dogs or >500 to 1000/μL in cats) (Schultze, 2000; Cowell and Decker, 2000).
   C. Chronic, prolonged (days to weeks) inflammation
      1. Characterized by leukocytosis with mature neutrophilia
      2. Results from expanded marrow production that exceeds tissue demand

Corticosteroid-Induced Leukocytosis (Stress Leukogram)

Definition and Causes

I. It is characterized by leukocytosis with mature neutrophilia, lymphopenia, and eosinopenia.
II. Concurrent monocytosis is common in the dog and infrequent in the cat.
III. It accompanies increased endogenous corticosteroid concentrations (severe stress or hyperadrenocorticism) or exogenous glucocorticoid or ACTH administration.

Diagnosis

I. A CBC demonstrates the characteristic leukogram.
   A. WBC counts from 15,000 to 25,000/μL (Schultze, 2000)
   B. Neutrophilia in the absence of a left shift
   C. Lymphocyte count <1000/μL (Latimer and Prasse, 2003)

II. Stress leukogram can also occur concurrently with an inflammatory leukogram (see Inflammatory Leukocytosis).

Extreme Neutrophilic Leukocytosis (Leukemoid Response)

Definition

I. Pronounced leukocytosis from dramatic neutrophilia (up to 100,000/μL in dogs or 75,000/μL in cats), with a significant but orderly left shift (Kociba, 2000).
II. Occasionally accompanied by eosinophilia or lymphocytosis

Causes and Pathophysiology

I. It results from inflammation or nonhematopoietic neoplasia.
II. It mimics granulocytic leukemia in cellular magnitude and composition.
III. Several causes exist.
   A. Inflammation
      1. Localized infections: pyometra, peritonitis, pyothorax, pancreatitis
      2. Hepatazoonosis
      3. Hemolysis secondary to immune-mediated hemolytic anemia
         a. Dogs: *Babesia canis*
         b. Cats: *Mycoplasma haemofelis, Mycoplasma haemominutum*
   B. Paraneoplastic conditions
      1. Production of hematopoietic-stimulating cytokines
      2. See Chapter 73
   C. Other causes
      1. Early estrogen toxicity
      2. Recombinant canine or human granulocyte-colony stimulating factor therapy
      3. Leukocyte adhesion protein deficiency in Irish setters

Diagnosis and Differential Diagnosis

I. Differentiate from chronic myelogenous leukemia (CML).
II. Both conditions have neutrophilic leukocytosis with a left shift, nonregenerative anemia, and increased myeloid: erythroid ratio, with orderly granulocytic maturation in the bone marrow.
III. Suspect CML with a disorderly left shift, neutrophil dysplasia, thrombocytopenia, decreased marrow megakaryocytes, and granulopoietic precursors in extramedullary sites (liver, spleen, and lymph nodes).
IV. Neutrophil toxicity, indicative of inflammatory conditions, drug toxicity, or systemic disease, is not typically a feature of CML.

Physiologic Leukocytosis

Definition

I. Transient leukocytosis from epinephrine release with excitement, fear, or exercise that is characterized by mature neutrophilia and lymphocytosis

II. Common in puppies and kittens
III. Uncommon in adult dogs
IV. Rapid neutrophilia
    A. Neutrophil count up to 39,000/μL in cats (Latimer and Prasse, 2003) that generally diminishes within 20 minutes
    B. Neutrophilia often accompanied by lymphocytosis (absolute lymphocyte counts usually <20, 000/μL) in young cats (Cowell and Decker, 2000)

Causes and Pathophysiology

I. Neutrophilia
    A. It results from cellular shifts from the marginated to circulating pool.
    B. It is of greater magnitude in cats (larger marginated pool).
II. Lymphocytosis: decreased migration into lymphoid tissue or increased mobilization from the thoracic duct
III. Monocyte and eosinophil numbers: unchanged or slightly increased

CONGENITAL DISORDERS OF WBCS

Morphologic and Functional Disorders

See Table 65-3.

Lysosomal Storage Diseases

Definition and Causes

I. Autosomal recessive genetic disorders characterized by multiple organ failure (Table 65-4)
II. Intracellular accumulation of incompletely degraded substrates from deficiency of the lysosomal enzyme required for their metabolism

Diagnosis

I. Examination of peripheral blood smears may reveal vacuolation or abnormal granules within leukocytes.
II. Radiography helps characterize bony malformations in animals with clinically evident skeletal abnormalities.
III. Identification of deficient lysosomal enzyme activity in plasma, leukocytes, or cultured skin fibroblasts can be attempted.
IV. The structures of lysosomal enzymes are highly conserved; therefore, techniques developed for detection of enzymatic deficiencies in humans can be used in dogs and cats.
V. Polymerase chain reaction (PCR)-based genomic screening can be used to identify some cases.
    A. Examples include dogs with fucosidosis, mucopolysaccharidosis (MPS) I, and MPS VII, and cats with MPS VI.
    B. Novel genetic mutations can occur with these diseases that may not be detected by the established testing procedures; therefore, a negative result does not eliminate a storage disease (Skelly and Franklin, 2002).
VI. Excessive urinary glycosaminoglycan excretion in animals with MPS can be detected by a urine spot test.

Treatment and Monitoring

I. Storage diseases are generally untreatable and progressive.
II. Bone marrow transplantation has resulted in clinical improvement in dogs with MPS I and cats with MPS VI.

NEOPLASIA

Myeloproliferative Disorders

See Chapter 66.

Acute Lymphoblastic Leukemia

Definition

I. Acute lymphoblastic leukemia (ALL) is characterized by progressive lymphoblastic infiltration of lymphoid organs and bone marrow.
II. Unlike lymphoma, the bone marrow is the primary tumor site.

Clinical Signs

I. Affected animals present with nonspecific signs of anorexia, lethargy, weight loss, vomiting, diarrhea, lameness, altered mentation, and intermittent fever.
II. Physical examination findings consist of pallor, hepatosplenomegaly, lymphadenopathy, and petechia.

Diagnosis

I. Lymphocytosis with circulating lymphoblasts
II. Anemia, thrombocytopenia, variable WBC counts, or pancytopenia
III. Possible absence (aleukemia) or only small numbers (subleukemia) of circulating lymphoblasts
IV. Possible bone marrow aspiration and/or biopsy findings
    A. Homogeneous population of large immature lymphocytes
    B. Replacement of normal nucleated cell population with 40% to 50% lymphoblasts
V. Possible clinical chemistry abnormalities
    A. Increased alanine and aspartate transferases (ALT, AST) and alkaline phosphatase (ALP) activities indicative of potential liver involvement
    B. Increased blood urea nitrogen concentration indicative of azotemia (prerenal or renal) or GI hemorrhage
    C. Hypercalcemia uncommon

Differential Diagnosis

I. ALL is difficult to differentiate from multicentric lymphoma with bone marrow or blood involvement (stage V disease).
II. Unlike advanced lymphoma, ALL often occurs without lymphadenopathy, is poorly responsive to chemotherapy, and has a more rapid and progressive disease course.
III. Differentiation from acute myeloproliferative diseases (see Chapter 66) requires cytochemical and immunohistochemical staining of bone marrow preparations.
IV. Lymphocytosis with mature, well-differentiated lymphocytes distinguishes chronic lymphocytic leukemia (CLL) from ALL (see below).

TABLE 65-3

Morphological and Functional Disorders of Canine and Feline Leukocytes

DISORDER	INHERITANCE	CAUSE	SPECIES	APPEARANCE/CLINICAL SIGNS	DIAGNOSIS	TREATMENT	REFERENCES
Cyclic hematopoiesis	Autosomal recessive	Stem cell abnormality	Gray-coated collie, collie-mix dogs	Continuous abnormal hematological cycles Decreased neutrophil number and function: recurrent bacterial infections, defective platelet aggregation, systemic amyloidosis	Serial CBCs every 3-6 weeks: cyclic neutropenia and anemia Clinical signs: hair coat color dilution	Broad-spectrum antibiotics for sepsis Lithium carbonate 21-26 mg/kg/day PO (potential side effects) rhG-CSF 5 µg/kg SC BID (watch for neutralizing antibodies) Bone marrow transplantation is curative	Campbell (1985), Lothrop et al. (1988), Niemeyer and Lothrop (2000)
Inherited vitamin B_{12} (cobalamin) malabsorption	Autosomal recessive	Failure to express intestinal intrinsic factor cobalamin complex receptor (cubilin)	Inbred giant schnauzer	Nuclear chromatin maturation abnormalities, neutropenia, nonregenerative anemia	Decreased serum cobalamin concentration Classic hematological abnormalities	Parenteral administration of megadose cobalamin (1 mg IM) monthly No improvement with oral cobalamin	Fyfe (2000)
Birman cat neutrophil granulation anomaly	Autosomal recessive	Fine azurophilic granules similar to progranulocyte granules	Birman cat	Prominent neutrophil granulation	Serial CBCs Differentiate from MPS VI, MPS VII, and toxic change	None; neutrophils function normally	Hirsch and Cunningham (1984)
Canine leukocyte adhesion deficiency	Autosomal recessive	Deficient expression of CD18 (subunit of B_2 integrins)	Irish setter	Recurrent infections, marked neutrophilia, chronic anemia Bone marrow myeloid hyperplasia	Flow cytometry for neutrophil CD18 expression	Antibiotics alleviate signs but not infection Affected animals usually die	Andreason and Roth (2000)
Pelger-Huët anomaly	Uncertain inheritance Acquired secondary to sepsis, drugs, MPD, viral infections	Failure of the mature nucleus to form true filaments	Cats, dogs	Peanut-shaped nuclei in granulocytes, monocytes, or megakaryocytes	Serial CBCs	None; neutrophils function normally	
Chédiak-Higashi syndrome	Autosomal recessive	Failure of granule fusion	Persian cats	Yellow-green eyes Smoke-blue hair color Hypopigmentation of eyes, skin, hair	CBC: neutropenia, abnormal granules Prolonged bleeding times Abnormal platelet aggregation	Temporary improvement with rhG-CSF Bone marrow transplant	Meyers (2000)

CBC, Complete blood count; *rhG-CSF,* recombinant human granulocyte-colony stimulating factor; *IM,* intramuscularly; *MPS,* mucopolysaccharidosis; *MPD,* myeloproliferative disease.

TABLE 65-4

Lysosomal Storage Diseases of Dogs and Cats

DISEASE	ENZYME DEFICIENCY	BREEDS AFFECTED	WHITE BLOOD CELL ABNORMALITIES	CLINICAL SIGNS
Mannosidosis	α-D-Mannosidase	English springer spaniel DSH, Persian cat	Lymphocyte, neutrophil, eosinophil, monocyte cytoplasmic vacuolization	Neurological and skeletal abnormalities Retarded growth Facial dysmorphism (flattened features)
Fucosidosis	α-L-fucosidase	English springer spaniel	Lymphocyte vacuolization	Behavioral changes Ataxia Hearing and vision loss
MPS I	α-L-iduronidase	Plott hound DSH cats	Basophilic to metachromatic (pink-purple) neutrophil cytoplasmic granules Lymphocyte granulation or vacuolization	Skeletal abnormalities Facial dysmorphism Dwarfism Corneal opacities Neurologic abnormalities
MPS VI	Arylsulfatase B	Siamese and DSH cats Miniature pinscher	See MPS I	See MPS I
MPS VII	β-Glucuronidase	Dogs, cats	See MPS I	See MPS I
GM_1 gangliosidosis	β-D-Galactosidase	Siamese, DSH cats Beagle, English springer spaniel, Portuguese water dog, mixed breed dog	Lymphocyte vacuolization	Ataxia Visual deficits
GM_2 gangliosidosis	β-D-Hexosaminidase	Korat and DSH cats Japanese spaniel	Neutrophil granulation Lymphocyte and/or eosinophil vacuolization	Corneal clouding Muscle wasting Cerebral and/or cerebellar dysfunction

DSH, Domestic short hair; *MPS,* mucopolysaccharidosis.

V. Eliminate other causes of pancytopenia via bone marrow examination.

Treatment and Monitoring

I. Treat ALL using established protocol treatments for canine or feline lymphoma (Fan, 2003; Couto, 2001)
   A. Use of vincristine and L-asparaginase therapy together may result in neutropenia.
   B. Prognosis is poor, as treatment-induced remission is short and survival is generally less than a few months.
II. Initiate broad-spectrum antibiotic therapy in animals with fever or neutropenia (<1000/μL).
III. For animals with anemia and/or thrombocytopenia, consider fresh whole blood, packed RBCs, platelet-rich plasma, or platelet concentrate transfusions (see Chapter 71).

Chronic Lymphocytic Leukemia

Definition and Causes

I. Chronic lymphocytic leukemia (CLL) is characterized by lymphocytic leukocytosis, with a predominance of small lymphocytes.
II. There is no reported association between CLL and FeLV infection in cats.
III. Most cases of CLL in dogs are of T-cell origin.
IV. CLL is rare in cats.

Clinical Signs

I. Possibly asymptomatic
II. Nonspecific signs: lethargy, anorexia, weight loss, vomiting, diarrhea, polyuria/polydipsia, lameness
III. Physical examination: hepatosplenomegaly, peripheral lymphadenopathy, pallor

Diagnosis

I. CBC findings
   A. Persistent marked lymphocytosis
   B. Lymphocyte counts: >1,000,000/μL in dogs and up to 250,000/μL in cats (Workman and Vernau, 2003)
   C. Concurrent hematological findings: nonregenerative, normocytic, normochromic anemia, thrombocytopenia, neutropenia, or pancytopenia from myelophthisis
   D. Findings in cats: not well characterized
II. Bone marrow aspirate and/or biopsy samples: >30% small mature lymphocytes

III. Serum biochemistry results
  A. They can indicate multiple organ involvement.
  B. Serum and urine electrophoresis is indicated in dogs with hyperglobulinemia, as a monoclonal gammopathy occurs in up to 30% of dogs with hyperglobulinemia.
IV. Immunophenotyping procedures (Burnett et al., 2003)
  A. It uses PCR amplification of cellular DNA from peripheral blood.
  B. It identifies neoplastic populations of circulating small lymphocytes based on unique rearrangements of the T cell receptor γ (T-cell lymphoma) or immunoglobulin (B-cell lymphoma) sequences.
  C. It helps to differentiate CLL from other nonneoplastic causes of persistent lymphocytosis, which can be difficult.

Differential Diagnosis

I. Other causes of persistent lymphocytosis
  A. Transient leukocytosis (epinephrine response)
  B. Immune-mediated or other chronic, systemic diseases
  C. Chronic ehrlichiosis, Rocky Mountain spotted fever and babesiosis infections (dogs), and toxoplasmosis (cats)
II. Large granular lymphocyte (LGL) leukemia
  A. LGL leukemia in cats is uncommon, may accompany lymphoma, and involves the alimentary tract or mesenteric lymph nodes.
  B. In dogs, LGL leukemia presents as either ALL or CLL.
III. Acute lymphoblastic leukemia
IV. Multicentric lymphoma

Treatment and Monitoring

I. Treatment for CLL is not often required, especially in the absence of bone marrow involvement and hematological abnormalities (anemia or other cytopenias), or evidence for multiorgan involvement (lymphadenopathy, splenomegaly, enzyme abnormalities).
II. Chemotherapy is not recommended until the development of clinical signs, cytopenias, or marked lymphocytosis (generally defined as 60,000 to 100,000/μL).
III. A combination protocol of oral chlorambucil and prednisone is effective dogs and cats (Workman and Vernau, 2003).
  A. Treatment in dogs involves the following:
    1. Chlorambucil: 0.2 mg/kg or 6 mg/m^2 PO SID for 7 to 14 days, then 0.1 mg/kg or 3 mg/m^2 PO SID, then long-term maintenance at 2.0 mg/m^2 QOD
    2. Prednisone: 30 mg/m^2 PO SID for 7 days, followed by 20 mg/m^2 for 7 days and 10 mg/m^2 QOD
  B. Treatment in cats involves the following:
    1. Chlorambucil: 0.2 mg/kg or 2 mg/cat QOD
    2. Prednisone: 1 mg/kg SID
  C. Dosages are modified based on clinical response.
  D. Monitor CBCs weekly for the first month and monthly thereafter.
  E. Prognosis is variable and depends on the extent of disease and response to therapy.

Sézary Syndrome in Dogs

Definition and Cause

I. Lymphoproliferative disease in dogs (uncommon) and cats (rare)
II. Characterized by cutaneous lymphoma and a circulating population of large neoplastic T lymphocytes with intensely cleaved or indented nuclei and prominent nucleoli

Clinical Signs

I. Ulcerative dermatitis, pruritus, anorexia, alopecia, and peripheral lymphadenopathy
II. Hematologic abnormalities
  A. Lymphocytic leukocytosis with abnormal lymphocyte morphology
  B. Possible monocytosis, neutrophilia, and nonregenerative, normocytic, normochromic anemia

Diagnosis

Dermal-epidermal infiltration by neoplastic lymphocytes in skin biopsy samples combined with the presence of circulating neoplastic lymphocytes.

Treatment and Monitoring

I. Chemotherapeutic protocols for canine lymphoma can be tried.
II. Prognosis is poor.

CHAPTER 66

Myeloproliferative Disorders

Kristin L. Henson | Rose E. Raskin

MYELODYSPLASTIC DISORDERS

Definition and Classification

I. Primary myelodysplastic syndrome (MDS) consists of irreversible, acquired clonal (neoplastic) disorders of multipotential hematopoietic cells unrelated to concurrent diseases, nutritional deficiency, or drug-induced toxicosis.
II. Animals with MDS ("preleukemia") often suffer from chronic debilitation that may continue unchanged or evolve into acute myeloid leukemia (AML).
III. Myelodysplastic disorders are morphologically divided into subtypes (Table 66-1) relative to the percentage of myeloblasts in the bone marrow and the myeloid-to-erythroid (M:E) ratio.
   A. MDS-refractory cytopenia (MDS-RC) and MDS-excess blasts (MDS-EB) have an M:E ratio >1.0.
   B. The subtype MDS-erythroid predominance (MDS-Er) refers to feline cases with an M:E ratio ≤1.0 (Raskin, 1996; Jain et al., 1991), but has also been considered a variant of MDS-RC in dogs (Weiss, 2005).
IV. MDS-EB may be considered a form of oligoblastic leukemia that often behaves as an antecedent of AML and has a worse prognosis (McManus and Hess, 1998; Weiss, 2005).

Clinical Signs

I. Chronic infections with fever
II. Lethargy related to anemia
III. Anorexia
IV. Hemorrhage

Diagnosis

I. The peripheral blood indicates cytopenia of one or more cell lines, with ineffective hematopoiesis.
II. Abnormal morphology (dyshematopoiesis) must be observed in either the erythroid, granulocytic, or megakaryocytic cells.
   A. Dysplasia in the erythroid line may involve macrocytosis, megaloblastosis with asynchrony of maturation, nuclear fragmentation, unequal cell division, sideroblastosis, or siderocytosis.
   B. The granulocytic line may exhibit giant forms, nuclear hypersegmentation, hyposegmentation, or abnormal cytoplasmic granulation as evidence of dysmyelopoiesis.
   C. Dysplastic changes involving platelets include giantism, hypergranularity, or hypogranularity.
   D. Dwarf or micromegakaryocytes with asynchrony of maturity are common signs of dysthrombopoiesis.
III. Despite the altered development of these precursors (from increased apoptosis), the bone marrow is generally hypercellular, with blast forms accounting for <30% of nucleated cells.
IV. Myelofibrosis is often present in the marrow of cats with MDS (Blue, 1988).
V. Feline leukemia virus infection is common in cats with MDS (Hisasue et al., 2001)

Differential Diagnosis

I. The main differential diagnosis is secondary MDS, which includes cobalamin or folate deficiencies, drug-induced toxicosis, or concurrent immune-mediated or neoplastic diseases.
II. Other myeloid neoplasms, such as chronic granulocytic leukemia (CGL), chronic myelomonocytic leukemia (CMMoL), and chronic monocytic leukemia (CMoL), have <30% blast cells in the bone marrow and may have dyshematopoiesis.

Treatment and Monitoring

I. Because the condition may persist for long periods without significant clinical disease, the goal of treatment is often supportive, with antibiotics and blood transfusions.
II. A few cases have been treated, but with limited success.
   A. Dogs: human recombinant erythropoietin at 100 U/kg SC QOD for 10 days and prednisone at 2 mg/kg PO SID initially (Boone et al., 1998)
   B. Dogs: low doses of aclarubicin at 5 mg/m^2 IV SID for 5 days (Miyamoto et al., 1999)
   C. Cats
      1. Several treatment protocols were used for 16 cats (Hisasue et al., 2001).
      2. Whole blood transfusion was used to improve clinical signs in 15 cats.
      3. Prednisolone 1 to 4 mg/kg PO, IM SID was used in combination with other drugs for 13 cats.
      4. Low-dose cytarabine 0.7 to 1.4 mg/kg SC SID or cytarabine ocfosfate 2 to 4 mg/kg PO SID for 2 to 4 weeks was used along with prednisolone in nine cats.

TABLE 66-1

Myeloproliferative Disorders

TYPES AND SUBTYPES	MORPHOLOGICAL CHARACTERISTICS
Myelodysplastic disorders	Myeloblasts <30% of ANC; peripheral cytopenias and dyshematopoiesis common; may evolve into acute myeloproliferative disorder
MDS-Er (cats)	M:E ratio ≤1, myeloblasts <5% of ANC
MDS-RC (cats/dogs)	M:E ratio >1, myeloblasts <5% of ANC
MDS-EB (cats/dogs)	M:E ratio >1, myeloblasts ≥5% of ANC
Acute undifferentiated leukemia	Requires electron microscopy and/or immunophenotyping
Acute myeloid leukemia*	Blast cells ≥30% of ANC
Acute myeloblastic leukemia	
Without maturation	Type I myeloblasts ≥90% of ANC
With maturation	Types I-II myeloblasts ≥30% and ≤90% of ANC; also granulocytes ≥10% and monocytes ≤20% of NEC
Acute myelomonocytic leukemia	Myeloblasts and monoblasts ≥30% of ANC; also of differentiated granulocytes and monocytes ≥20% of NEC each
Acute monocytic leukemia	
Without maturation	Monoblasts and promonocytes ≥80% of NEC
With maturation	Promonocytes and monocytes ≥30% to ≤80% of NEC
Acute erythroleukemia	Erythroid cells >50% of ANC (M:E <1), myeloblasts and monoblasts ≥30% of NEC
With erythroid predominance	Erythroid cells >50% of ANC, rubriblasts, myeloblasts, and monoblasts ≥30% of ANC
Acute megakaryoblastic leukemia	Megakaryoblasts >30% of ANC
Chronic myeloproliferative diseases	Myeloblasts <30% of ANC; also mild to moderate hematodysplasia; may evolve into acute myeloproliferative disorder
Chronic granulocytic leukemia	Marked neutrophilia
Eosinophilic leukemia	Marked eosinophilia
Basophilic leukemia	Marked basophilia
Chronic myelomonocytic leukemia	Persistent monocytosis
Chronic monocytic leukemia	Persistent monocytosis
Polycythemia vera	Erythropoietin-independent erythrocytosis
Essential (primary) thrombocythemia	Thrombopoietin-independent thrombocytosis
Chronic idiopathic myelofibrosis	Anemia with leukoerythroblastosis, extramedullary hematopoiesis, splenomegaly, and marrow fibrosis
Related myeloproliferative disorders	Derived from hematopoietic stem cell
Malignant histiocytosis	Cytopenia and erythrophagia are common; pleomorphic histiocytes with multinucleated giant cells
Mast cell leukemia	Multiple cell lines affected; pleomorphic mast cells in size and nuclear features; erythrophagia possible

MDS, Myelodysplastic syndrome; *ANC,* all nucleated cells in bone marrow, excluding lymphocytes, plasma cells, macrophages, and mast cells; *M:E,* myeloid-to-erythroid; *NEC,* nonerythroid cells (ANC minus erythroid).
*Classification of canine and feline acute myeloid leukemia by blast cell type and percentage based upon modification of FAB system by the Animal Leukemia Study Group (Jain NC, Blue JT, Grindem CB et al: Proposed criteria for classification of acute myeloid leukemia in dogs and cats. Vet Clin Pathol 20:63, 1991).

5. Cyclosporin A at 2.5 to 5 mg/kg PO SID with prednisolone was used in one cat.
6. Daunorubicin 20 mg/m^2 IV SID for 3 days in 3 weeks, cytarabine at 100mg/m^2 SC SID for 4 days in 3 weeks, vincristine at 0.025 mg/kg IV weekly, and prednisolone were tried in three cats with advanced disease.

III. Animals with >5% marrow myeloblasts have shorter survival times and poorer responses to treatment (Couto and Kallet, 1984; Hisasue et al, 2001; Weiss and Smith, 2000).

ACUTE MYELOID LEUKEMIAS

Definition and Classification

I. AMLs are malignant, clonal proliferations of immature nonlymphoid hematopoietic cells resulting in the accumulation of blast cells in the bone marrow, peripheral blood, visceral organs, and lymph nodes.

II. *Aleukemic, subleukemic,* or *occult leukemias* are terms for acute leukemias in which blast cells are not observed, or are observed in low numbers in the peripheral blood, respectively.

III. AML is subclassified in animals according to the hematopoietic lineage of the blast cell population.
IV. In humans, AMLs have recently been reclassified under the World Health Organization (WHO) according to specific genetic abnormalities, therapy-related leukemias, presence of multilineage dysplasia, or leukemias with no evidence of genetic mutations, history of therapy, or dysplasia (Harris et al., 1999).
V. Under the WHO classification system, blast cell percentage for the diagnosis of acute leukemia decreased from 30% to 20% and use of the French-American-British (FAB) alpha-numeric system (AML: M1-M7) has been discarded (Harris et al., 1999; Vardiman et al., 2002).
VI. Classification of AML is based on the Animal Leukemia Study Group report, which standardized the diagnosis of AML for evaluation of clinical prognosis and treatment in dogs and cats (Jain et al., 1991).
   A. Cytomorphology by light microscopy, cytochemical staining, and immunophenotyping are used to identify the lineage of blast cells for subclassification of AML.
   B. The human WHO classification system has not yet been evaluated in animals; however, in recognition of this new system, the AML: M1-M7 numbering system is not used in this chapter.
   C. Subtypes of canine and feline AML described by the Animal Leukemia Study Group are as follows (see Table 66-1):
      1. Acute undifferentiated leukemia: lack morphological and cytochemical evidence of lineage for either lymphoid or myeloid cell types
      2. Acute myeloblastic leukemia without maturation
      3. Acute myeloblastic leukemia with maturation
      4. Acute promyelocytic leukemia (not identified in animals)
      5. Acute myelomonocytic leukemia
      6. Acute monocytic leukemia
         a. Acute monocytic leukemia without maturation
         b. Acute monocytic leukemia with maturation
      7. Acute erythroleukemia and/or acute erythroleukemia with erythroid predominance
      8. Acute megakaryoblastic leukemia

Diagnosis

I. Animals typically exhibit an acute onset and rapid progression of clinical signs related to peripheral blood abnormalities and organ or lymph node infiltration by leukemic cells.
II. Hematological findings include either leukopenia or leukocytosis with a disorderly left shift, nonregenerative anemia with or without macrocytosis and nucleated red blood cells (normoblastemia), and thrombocytopenia.
   A. Circulating blast cells may or may not be present.
   B. A significant monocytosis is usually present in acute monocytic leukemia.
   C. Morphological abnormalities in both marrow and circulating cells may include giant forms, granulocyte hypersegmentation, erythroid nuclear fragmentation and abnormal cell division, asynchronous maturation of erythroid cells, and hypogranular platelets.
III. Specific serum biochemical abnormalities suggest organ infiltration by neoplastic cells.
IV. Blast cells are sometimes seen in peripheral blood, lymph nodes, liver, spleen, occasionally kidneys, and cerebrospinal fluid.
V. Blast cells have round to indented nuclei, prominent single to multiple nucleoli, a high nuclear-to-cytoplasmic ratio, and basophilic cytoplasm.
VI. Definitive diagnosis requires identification of blast cell lineage and their percentages in bone marrow, blood, or both using morphological examination, cytochemical staining, and immunophenotyping.
   A. Cytochemical stains are species specific (Raskin and Valenciano, 2000).
   B. Submission of samples to a veterinary reference laboratory for cytochemical staining and interpretation by a board-certified clinical pathologist is recommended.
   C. Cytochemical staining is most useful for identification of myeloid, monocytic, and megakaryocytic neoplasms; good lymphocytic and erythroid cytochemical markers are lacking.
   D. Immunophenotyping (immunocytochemistry, immunohistochemistry, and flow cytometry) using antibodies that recognize specific enzymes or structural epitopes on the leukemic cells is also used to differentiate AML and acute lymphoid leukemia (ALL) and to subclassify AML.
   E. Other diagnostic tests used to identify or confirm blast cell lineage include ultrastructural analysis by electron microscopy and in vitro blast cell differentiation (Modiano et al., 1998).
   F. Use of a diagnostic algorithm derived from flow cytometry light scatter patterns (without use of monoclonal antibodies) to provide a preliminary classification of acute leukemia has also been evaluated and may provide more rapid evaluation of leukemias, although refinement of the algorithmic process is still needed (Fernandes et al, 2002).
   G. Genetic studies in animal leukemias have detected chromosomal abnormalities, although more information is needed regarding karyotypic, molecular DNA abnormalities, and their association with therapy and prognosis.

Differential Diagnosis

I. The primary and most significant differential diagnosis of AML is ALL.
II. In dogs and cats, lymphoid leukemia has a better response to chemotherapy and prognosis compared with AML; therefore, accurate differentiation is crucial.
III. Although morphological criteria can be used for differentiation, cytochemical staining, immunophenotyping, or both are recommended to distinguish between AML and ALL.

Treatment

I. AML has an extremely poor prognosis, with survival times ranging from days to <3 months in treated animals.
II. Supportive therapy is administered as needed.
III. Chemotherapy for AML, if attempted, is instituted as soon as possible after definitive diagnosis because of the rapid clinical course.
   A. Various combinations of cytotoxic agents, including doxorubicin, cyclophosphamide, vincristine, cytosine arabinoside, 6-thioguanine, busulfan, melphalan, and prednisone, have been used.
   B. Common side effects of these agents include leukopenia and thrombocytopenia resulting from myelosuppression, and gastrointestinal (GI) toxicity resulting in vomiting, anorexia, and diarrhea (see Chapter 72).

CHRONIC MYELOPROLIFERATIVE DISEASES

Chronic Granulocytic Leukemia

Definition and Classification

I. In animals, chronic granulocytic leukemia (CGL) and chronic myelogenous leukemia (CML) are synonymous and refer to a form of chronic myeloproliferative disease (MPD) characterized by a neoplastic proliferation within the granulocytic (neutrophilic) cell line.
II. CGL may terminate in a "blast crisis" with proliferation of immature blast cells and development of acute leukemia.
III. In humans, CML is characterized by a specific genetic translocation to form the BCR-ABL fusion gene or Philadelphia chromosome within pluripotential stem cells resulting in proliferations of neutrophils as well as other leukocytes, and to which targeted gene therapy is now available (Vardiman et al, 2002).
   A. A true clonal proliferation of neutrophils (chronic neutrophilic leukemia) is considered rare in people.
   B. Similar genetic abnormalities, as identified in human CML, have not been identified in animals.

Diagnosis

I. CGL is rare in animals; however, an increased risk has been reported in dogs exposed to high doses of radiation (Dungworth et al., 1969).
II. The hallmark of CGL is a marked and persistent leukocytosis consisting primarily of bands and segmented neutrophils, although a disorderly left shift may be present.
   A. White blood cell (WBC) counts may range to >100,000 cells/μL.
   B. Abnormal morphological features or dysplasia, such as giant bands, hypersegmentation, pyknosis, and nuclear fragmentation, are absent or uncommon.
III. Other laboratory findings are variable and include nonregenerative anemia ± normoblastemia, monocytosis, eosinophilia, basophilia, thrombocytopenia, and thrombocytosis.
IV. Bone marrow aspirates usually reveal a hypercellular marrow with a moderate to markedly increased M:E ratio; increased numbers of promyelocytes, neutrophilic myelocytes, and myeloblasts; but the latter cells are <30% of all nucleated cells.
   A. Bone marrow interpretation is often that of a leukemoid response.
   B. Bone marrow histopathologic examination is recommended to monitor the degree of fibrosis that may occur in later stages of CGL.
V. Although infiltration of liver, spleen, and other organs by leukemic cells is common, serum biochemical profiles are generally normal to mildly altered.
VI. Pseudohypoglycemia may occur from increased in vitro utilization of glucose by the excessive numbers of circulating granulocytes.
VII. Aspirates or biopsy of lymph nodes and visceral organs often reveal granulocytic infiltration and extramedullary hematopoiesis.
VIII. Rarely, a solid tumor of leukemic granulocytes (chloroma) is found.

Differential Diagnosis

I. The primary differential diagnosis for CGL is a leukemoid reaction (see Chapter 65) related to inflammation and manifested by marked neutrophilia with a left shift back to early precursors (progranulocyte or later).
II. Conditions associated with leukemoid reactions include pyogenic infections; immune-mediated hemolytic anemia; and neoplasms associated with necrosis, sepsis, production of hematopoietic growth factors (paraneoplastic neutrophilia), or metastasis to the bone marrow.
III. Exclusion of inflammatory diseases through appropriate clinical and diagnostic testing is used to rule out a leukemoid reaction and confirm suspected CGL.
IV. Laboratory criteria useful in the differentiation of CGL include the following (Fine and Tvedten, 1999):
   A. Persistent leukocytosis and left shift without evidence of neutrophil toxicity
   B. Macrocytic anemia accompanied by normoblastemia without a reticulocytosis
   C. Cytological evidence of granulocytopoiesis in lymph nodes and organs
   D. Histopathologic findings of granulocytic perivascular infiltration in liver, spleen, and other organs

Treatment

I. Treatment is somewhat controversial, because untreated animals may survive weeks to years, and the success of chemotherapy in prevention of a terminal blast crisis is uncertain.
II. Survival times of years can occur in treated animals, and reduction in numbers of circulating blasts via chemotherapy may decrease clinical signs and improve quality of life.
   A. Protocol 1: hydroxyurea 20 to 25 mg/kg PO BID until the WBC count decreases to 15,000 to 20,000 cells/μL,

then tapered to 10 to 12 mg/kg PO SID or to 50 mg/kg PO every 3 to 4 days (Young and MacEwen, 1996)

B. Protocol 2: hydroxyurea 50 mg/kg PO SID for 14 days until the WBC count is within normal reference range, then tapered to QOD and then to every 3 days (Leifer et al., 1983; Fine and Tvedten, 1999)
C. Side effects of hydroxyurea: myelosuppression (most serious), pruritus, erythema, alopecia, hyperglycemia
D. Protocol 3: busulfan 0.1 mg/kg/day PO until the leukocyte count is reduced to 15,000 to 20,000 cells/μL (Young and MacEwen, 1996)

III. No successful chemotherapeutic treatment for CGL in a blast crisis has been reported.

Eosinophilic Leukemia

Definition

I. Eosinophilic leukemia (EL) is a rare chronic MPD occurring primarily in cats and is characterized by peripheral eosinophilia, eosinophilic hyperplasia of the bone marrow, and eosinophilic infiltration in multiple organs.
II. EL is difficult to distinguish from the more common hypereosinophilic syndrome (HES), and some controversy exists whether EL is a distinct clinical entity or a variant of HES.
III. Support for the distinct, neoplastic nature of EL includes a more rapid disease progression, the presence of morphologically abnormal eosinophils, increased numbers of circulating and marrow eosinophilic precursors, and a more severe anemia (Huibregtse and Turner, 1994).
IV. In humans, demonstration of clonality is used to distinguish EL from the polyclonal proliferation of HES (McManus, 2005), but no such clonality studies have been performed in animals with eosinophilic proliferations.

Clinical Signs and Diagnosis

I. Older cats tend to be at greatest risk for EL, with a median age of 8 years at diagnosis.
II. EL has been reported in feline leukemia virus/feline immunodeficiency virus-infected and noninfected cats.
III. Affected animals may have vomiting, diarrhea, hepatosplenomegaly, and peripheral lymphadenopathy.
IV. Common laboratory findings include peripheral eosinophilia, hypogranular and immature eosinophils, moderate to severe anemia, and thrombocytopenia.
V. Bone marrow aspiration typically reveals eosinophilic hyperplasia with a significantly increased M:E ratio (>10:1), increased numbers of immature eosinophils, and dysmyelopoiesis.

Differential Diagnosis

I. Primary differential diagnoses for EL are HES and conditions associated with reactive eosinophilia, such as allergic bronchitis, pulmonary infiltrates with eosinophils, external and GI parasitism, heartworm disease, hypersensitivity reactions, eosinophilic enteritis, eosinophilic granuloma complex, and neoplasia (mast cell tumor, lymphoma, certain carcinomas).
II. Definitive diagnosis of EL requires a thorough clinical and diagnostic evaluation to rule out reactive eosinophilia and HES.

Treatment

I. Response to treatment in cats with EL is generally poor.
II. Average survival times of 6 months postdiagnosis have been reported with corticosteroid therapy (Goldman and Graham, 2000).
III. Give hydroxyurea initially at 40 mg/kg/day PO for 1 week, then QOD or every 3 days as needed to control the eosinophilia and prevent the development of neutropenia (Hamilton, 2002).
IV. Hydroxyurea is used in combination with prednisone 2 mg/kg PO BID initially, then reduced gradually.

Basophilic Leukemia

Definition and Classification

I. Basophilic leukemia (BL) is a chronic MPD rarely reported in dogs or cats.
II. BL is characterized by excessive marrow production of basophils, resulting in peripheral basophilia, increased circulating and marrow immature basophils, and increased numbers of marrow myeloid blast cells.

Clinical Signs and Diagnosis

I. Clinical signs of BL are nonspecific and include lethargy, inappetence, fever, lumbar pain, hepatosplenomegaly, and lymphadenopathy.
II. Clinicopathologic findings of basophilia, neutropenia, nonregenerative anemia, and thrombocytosis have been reported.
III. Bone marrow findings in one reported case of BL included 43% basophils and 29% marrow blast cells of all nucleated cells, with some blast cells exhibiting dark, basophilic-like granules (Mears et al., 1997).
IV. Cytochemical staining of marrow and blood smears with omega-exonuclease, a basophil-specific marker have been used to identify basophilic lineage of marrow blast cells and confirm the presence of immature and mature basophils (Mears et al., 1997).

Differential Diagnosis

I. BL must be differentiated from reactive basophilia associated with a hypersensitivity reaction, inflammation, or mast cell tumor/mastocytosis.
II. BL can occasionally be confused with mast cell leukemia because of the presence of dark cytoplasmic granules in both cell types.
   A. Basophils have a segmented nucleus and variable numbers of dark purple cytoplasmic granules.
   B. Mast cells are generally larger than basophils and possess a round nucleus with many small, metachromatic-

staining granules that appear pink to purple with Romanowsky-type stains.

Treatment

I. Give hydroxyurea at 20 to 25 mg/kg PO BID (Mears et al., 1997).
II. Side effects, such as severe myelosuppression, pruritus, alopecia, and diabetes mellitus, may require discontinuation of hydroxyurea in dogs with BL (Mears et al., 1997).

Chronic Myelomonocytic Leukemia/ Chronic Monocytic Leukemia

Definition and Classification

I. CMMoL and CMoL are clonal disorders with some similarity to CGL in that they present with increased granulocytic or monocytic counts, anemia, mild to moderate myelodysplasia, and <30% blast cells of all nucleated cells in the bone marrow.
II. CMMoL may occur as a form of oligoblastic or subacute leukemia, especially in cats, and may progress to acute leukemia (Raskin and Krehbiel, 1985; Hisasue et al., 2001).
III. In the human WHO classification system, CMMoL is placed in the category of myelodysplastic/myeloproliferative disease, as the disease displays both neoplastic and dysplastic features (Vardiman et al., 2002).
IV. In animals, CMMoL has been classified as a chronic myeloproliferative disorder (Jain et al., 1991) or a myelodysplastic disorder (Hisasue et al., 2000, Hisasue et al., 2001; Valli et al., 2002).

Clinical Signs and Diagnosis

I. Characteristic features of CMMoL and CMoL include an indolent clinical course with a persistent monocytosis unresponsive to antibiotic therapy.
II. Splenomegaly and hepatomegaly are common findings.
III. Bone marrow aspirates in CMoL reveal increased numbers of monoblasts and other monocytic precursors, particularly after splenectomy.
IV. The marrow contains >3% but <30% myeloblasts of all nucleated cells.
V. Peripheral blood findings include monocyte counts usually >10% (or >1,000/μL), low numbers of immature granulocytes (≤10%), some blast cells (<2%), and the presence of prominent granulocytic dysplasia.

Differential Diagnosis

I. Primary differential diagnoses for CMMoL and CMoL are inflammatory disorders, such as deep mycoses, immune-mediated diseases, and CGL.
II. Basophilia is common in CGL but not in CMMoL.
III. Demonstration of a persistent and unresponsive monocytosis, cytological and histological evidence of neoplastic cell infiltration in lymph nodes and other organs, and elimination of inflammatory causes for the leukocytosis are necessary to differentiate between CMMoL or CMoL and inflammatory disorders (Bearman et al., 1981).

Treatment

Treatment using combination chemotherapy and glucocorticoids has been attempted, but has not changed the course of disease.

Polycythemia Vera

See Chapter 64.

Essential (Primary) Thrombocythemia

Definition and Classification

I. Essential thrombocythemia (ET) is an uncommon MPD characterized by a proliferation of bone marrow megakaryocytes resulting in a significant and persistent thrombocytosis (>600,000/μL).
II. Evolution of ET to CGL has been reported in a dog (Degen et al., 1989).

Diagnosis

I. Clinical signs of ET are nonspecific and include lethargy, exercise intolerance, pallor, and hepatosplenomegaly.
II. Hemorrhage (GI or epistaxis) attributable to intrinsic platelet function defects may occur and contribute to anemia.
III. Thrombotic events (pulmonary embolism) related to the increased platelet mass, platelet hyperaggregation, or both, can arise.
IV. Splenectomy may unmask and exacerbate the disease (Degen et al., 1989).
V. Laboratory findings include a persistent thrombocytosis that may exceed 1,000,000 platelets/μL; large and hypergranular platelets (shift platelets), elevated mean platelet volume, minimally regenerative or nonregenerative anemia, neutrophilia, basophilia, and eosinophilia.
VI. Pseudohyperkalemia, most likely from release of intracellular potassium during clot formation, may be noted on the serum biochemical profile.
VII. Bone marrow aspiration reveals increased numbers of megakaryocytes, some of which may exhibit abnormal morphology, as well as erythroid hypoplasia, myeloid hyperplasia, sheets of large granular platelets, and increased numbers of free megakaryocyte nuclei.
VIII. Bone marrow histopathology often reveals increased paratrabecular reticulin fibrosis.
IX. Increased numbers of splenic megakaryocytes in the absence of extramedullary hematopoiesis are suggestive of splenic infiltration by leukemic cells (Dunn et al., 1999).

Differential Diagnosis

I. ET must be differentiated from conditions associated with reactive thrombocytosis, including iron deficiency, chronic blood loss anemia, chronic inflammation, solid tissue neoplasia, and other forms of MPD (see Chapter 67).
II. In humans, the Polycythemia Vera Study Group recommends the following criteria for diagnosis of ET (Murphy et al., 1986):
   A. Platelet count >600,000 cells/μL, with platelet counts usually >1,000,000 cells/μL

B. A normal initial hematocrit or packed-cell volume that does not increase with iron supplementation
C. Normal serum iron concentration and presence of stainable iron in the bone marrow
D. No evidence of collagen fibrosis in bone marrow
E. No identifiable cause for reactive thrombocytosis and no circulating blasts

Treatment

I. Asymptomatic animals may not require treatment.
II. In dogs, possible treatments include the following:
A. Radiolabeled phosphorus in combination with melphalan (Degen et al., 1989)
B. A combination protocol with cyclophosphamide, vincristine, cytosine arabinoside, and prednisone (Simpson et al., 1990)
C. Vincristine (0.7 mg/m^2 once IV) and hydroxyurea (500 mg/m^2 PO per day) (Favier et al., 2004).
1. The hydroxyurea dose was increased (2000 mg/m^2 PO per day) after 3 weeks in both dogs owing to insufficient response.
2. The dogs' conditions deteriorated, however, and pancytopenia was noted in the bone marrow at necropsy, most likely from the high-dose hydroxyurea therapy.
III. The following may be tried in cats:
A. Nandrolone decanoate 15 mg IM once (Evans et al., 1982)
B. Melphalan 0.5 mg PO SID for 4 days, then 0.5 mg PO QOD (Hammer et al., 1990)

Chronic Idiopathic Myelofibrosis

Definition and Classification

I. Many synonyms, such as agnogenic (idiopathic) myeloid metaplasia, osteomyelosclerosis, and chronic megakaryocytic-granulocytic myelosis, apply to this neoplastic transformation of a single hematopoietic stem cell.
II. The condition results in intramedullary and extramedullary hematopoiesis often accompanied by a nonclonal fibroblastic reaction of the bone marrow.
III. Myeloid metaplasia refers to those cases with neoplastic proliferation of predominately granulocytic and megakaryocytic precursors in organs, such as the spleen and liver, with or without marrow fibrosis.
IV. Primary myelofibrosis involves the replacement of normal hematopoietic tissue with increased fibroblasts depositing fine reticulin and thick collagen fibers (Breuer et al., 1999b).
V. Some cases of agnogenic myeloid metaplasia or idiopathic myelofibrosis were previously diagnosed as AML-M7 (Breuer et al., 1999a).

Clinical Signs and Diagnosis

I. Clinical signs include a gradual onset of lethargy, exercise intolerance, inappetence, pale mucous membranes, vomiting, diarrhea, fever, weight loss, and splenomegaly (Weiss and Smith, 2002).
II. Characteristic features include circulating immature granulocytes and erythroid cells (leukoerythroblastic reaction), splenomegaly, hepatomegaly, extramedullary hematopoiesis, and myelofibrosis.
III. Clinicopathologic abnormalities include nonregenerative anemia, poikilocytosis, dacryocytosis (teardrop-shaped erythrocytes), leukocytosis or leukopenia, thrombocytosis or thrombocytopenia (in addition to a leukoerythroblastic reaction), and pancytopenia as the disease progresses.
IV. Extramedullary hematopoiesis is often present in the spleen, liver, or both.
V. Intramedullary megakaryocytopoiesis involving variably sized or polymorphic precursors is commonly found associated with argyrophilic reticulin fibrosis.
VI. Diagnosis of myelofibrosis requires bone marrow histopathology to document replacement of normal marrow architecture by excessive amounts of collagen and reticulin fibers.
A. Evidence of marrow necrosis may be noted.
B. Aspiration for cytological examination is often unrewarding (dry tap).

Differential Diagnosis

I. The main differential diagnosis for primary myelofibrosis is secondary myelofibrosis associated with bone marrow damage and necrosis from conditions such as marrow neoplasia (lymphoproliferative, myeloproliferative, or metastatic), tumors outside the bone marrow, immune-mediated hemolytic anemia, congenital hemolytic anemia (see Chapter 64), drug-induced marrow damage, ehrlichiosis (see Chapter 115), and irradiation.
II. Other rule outs include CML, ET, and acute megakaryoblastic leukemia based on the neoplastic proliferation of granulocytic and megakaryocytic precursors.

Treatment and Monitoring

I. Immune-mediated destruction of erythroid precursors has been hypothesized to be a factor in the development of myelofibrosis in some dogs (Villiers and Dunn, 1999), so therapy is difficult.
II. Treatments that may be tried include the following (Villiers and Dunn, 1999):
A. Blood transfusions
B. Prednisolone 2 to 3 mg/kg PO SID for 3 to 4 weeks, then QOD with tapering of the dose as anemia resolves
C. Nandrolone decanoate 2 mg/kg IM weekly for 3 weeks, then once every 3 weeks
D. Azathioprine 2 mg/kg PO QOD if the anemia does not respond to initial treatments
III. In one study, four of seven dogs responded with resolution of anemia and survived for more than 2 years without continued treatment (Villiers and Dunn, 1999).

CHAPTER 67

Platelet Disorders and von Willebrand Disease

Jennifer S. Thomas

INHERITED DISORDERS

von Willebrand Disease

Definition

von Willebrand disease (vWD) is a bleeding disorder resulting from a deficiency of functional von Willebrand factor (vWF).

Cause and Pathophysiology

I. A deficiency of vWF causes decreased platelet adhesion to the blood vessel wall and impaired formation of the primary hemostatic plug.
   A. vWF circulates in plasma as variably sized multimers of a basic glycoprotein subunit.
   B. The higher molecular weight multimers are more functional in mediating adhesion of platelets to blood vessels.
II. vWF circulates complexed to coagulation factor VIII, thereby stabilizing factor VIII.
III. It is the most common hereditary hemostatic disorder in dogs; it is occasionally identified in cats.
IV. Classification of vWD is based upon the concentration or activity of circulating vWF.
   A. Type I
      1. Concentration or activity of all multimers is reduced but measurable.
      2. The severity of the bleeding disorder is variable.
      3. It is reported in a large number of dog breeds, including Doberman pinschers.
      4. Inheritance is complex, with multiple genetic defects likely; may be an autosomal dominant with incomplete penetrance or an autosomal recessive.
   B. Type II
      1. Concentration of vWF is decreased with a disproportionately greater reduction in high-molecular-weight multimers.
      2. It usually causes a moderate to severe bleeding disorder.
      3. It occurs in German shorthaired and wirehaired pointers, and is an autosomal recessive trait.
   C. Type III
      1. Plasma concentrations of all multimers are undetectable.
      2. It causes a severe bleeding disorder.
      3. It is inherited as an autosomal recessive trait in the Chesapeake bay retriever, Dutch Kooiker, Scottish terrier, and Shetland sheepdog, and is sporadically found in other breeds.
V. Although some reports suggest that hypothyroidism and vWD are related, recent studies demonstrate no clear association between them (Stockham and Scott, 2002).

Clinical Signs

I. Affected animals may have intermittent mucosal bleeding, but petechiae are uncommon (Box 67-1).
II. Some animals do not show clinical signs until they are hemostatically challenged (e.g., surgery, trauma, estrus), become thrombocytopenic, or receive drugs that impair hemostasis.

Diagnosis

I. Platelet concentration and aggregation are usually normal (Box 67-2).
II. Buccal mucosal bleeding time (BMBT) is prolonged with vWD, thrombocytopenia, or platelet dysfunction.
III. A platelet function analyzer (PFA 100) can be used as an in-house screening assay, with prolonged times occurring with vWD, thrombocytopenia, or platelet dysfunction (Callan and Giger, 2001).
IV. Decreased concentration of plasma vWF antigen measured by immunoassay indicates that an animal has vWD or carries the vWD trait.

Box 67-1

Clinical Findings Associated with Platelet Disorders and von Willebrand Disease

Findings	Definition
Petechiae	Pinpoint hemorrhages
Ecchymoses	Bruising
Mucosal hemorrhages	Epistaxis
	Gastrointestinal bleeding
	Gingival bleeding
	Hematuria
	Vaginal bleeding
Hyphema	Ocular anterior chamber hemorrhage
Bleeding tendencies	Excess hemorrhage following trauma, surgery, venipuncture

Box 67-2

Diagnostic Tests for Suggested Platelet Disorders

Tests for Thrombocytopenia

Assay	Comments
Complete blood count	Measures platelet concentration (automated or manual) Increased mean platelet volume suggests increased thrombopoiesis Microscopic examination of blood smears to detect organisms or neoplastic cells, assess for platelet clumping, estimate platelet concentration (each platelet/100× field ≈ 15,000-20,000/μL), or evaluate for enlarged platelets (suggests increased thrombopoiesis)
Bone marrow examination	Assesses megakaryocyte density, maturation, and morphology May detect organisms or neoplastic cells May detect antibodies bound to megakaryocytes using direct immunofluorescence
Serum serology	May detect exposure or response to infectious organisms
Polymerase chain reaction assay	May detect infectious organisms
Platelet flow cytometry	Detects platelet surface-associated immunoglobulins Measures reticulated platelets—increased percentage suggests increased thrombopoiesis

Tests of Platelet Function

Assay	Comments
Buccal mucosal bleeding time	In vivo assessment of primary hemostasis—prolonged with thrombocytopenia, platelet dysfunction, vWD, vascular disorders
Platelet function analyzer (PFA 100)	Assesses primary hemostasis—prolonged times to hemostatic plug formation with thrombocytopenia, platelet dysfunction, vWD
Platelet flow cytometry	Detects platelet activation, membrane glycoproteins, fibrinogen binding, aggregation, calcium fluxes
Platelet aggregation	Assesses ability of platelets to bind to one another
Platelet secretion	Assesses release of granule contents and/or production of thromboxane A2
Platelet adhesion	Detects ability of platelets to adhere to surface

vWD, von Willebrand disease.

A. Enzyme linked immunosorbent assay (ELISA) is commonly used and is rapid and sensitive.
B. vWF concentration <50% of normal pooled plasma is generally considered abnormal.
C. Antigen concentration does not reliably identify carrier animals and may not predict the severity of clinical bleeding.
D. Immunoelectrophoresis is used to differentiate type I from type II vWD.

V. Decreased vWF activity may be measured using agglutination or collagen binding assays, or both.
VI. Rarely, activated partial thromboplastin time (aPTT) is prolonged from a secondary deficiency of factor VIII.
VII. Prothrombin time (PT) should be normal.
VIII. Molecular tests to detect the genetic defect are available in some breeds (Bernese mountain dog, Doberman pinscher, German shorthaired and wirehaired pointers, Kerry blue terrier, Manchester terrier, papillon, Pembroke Welsh corgi, poodles, Shetland sheepdog, Scottish terrier) and can identify whether dogs are normal, carriers, or affected.

Differential Diagnosis

I. Primary platelet disorders: inherited or acquired platelet dysfunction, thrombocytopenia
II. Coagulation disorders: see Chapter 68

Treatment

I. Transfusion therapy is indicated (Table 67-1) during a bleeding episode or before surgery for animals with known bleeding tendencies.
II. Desmopressin acetate (DDAVP) causes release of vWF from endothelial cells.
A. Administration to dogs with vWD (1 μg/kg SC) improves hemostatic function while minimally increasing vWF concentrations (Callan and Giger, 2002).
B. Administration to healthy donor dogs (1 μg/kg SC) 30 to 120 minutes before blood collection increases vWF concentration in plasma or cryoprecipitate.
III. Thyroid supplementation of hypothyroid dogs with vWD may increase vWF concentration in some animals, whereas administration to euthyroid dogs with vWD has no significant effect on BMBT or vWF concentration/activity (Heseltine et al., 2005).
IV. Local bleeding may be controlled with topical hemostatic agents (e.g., methacrylate), cautery, or pressure bandages.

Monitoring of Animal

I. Avoid elective surgical procedures or administration of drugs that inhibit platelet function in known affected animals whenever possible.
II. Do not breed dogs with vWD.

Intrinsic Platelet Dysfunction

Definition and Cause

I. Inherited platelet disorders that are associated with abnormal platelet function are uncommon in the dog and cat (Table 67-2).

TABLE 67-1

Transfusion Therapy for Platelet Disorders and von Willebrand Disease

PRODUCT	DOSAGE	COMMENTS
Whole blood	10-20 mL/kg IV	Supplies erythrocytes, vWF, and platelets Used in animals with severe anemia Not effective as a source of platelets in thrombocytopenic animals Volume overload may occur, so limit administration to once every 24 hours as needed
Platelet-rich plasma	6-10 mL/kg IV	Supplies vWF and platelets Prepared by centrifugation of whole blood Lower volume delivered with higher platelet concentration compared with whole blood Risks of volume overload and production of antiplatelet antibodies increase with repeated transfusions Repeat every 8-12 hours as needed
Platelet concentrate	1 unit/10 kg IV	Supplies platelets Up to 10-fold higher concentration of platelets compared to platelet-rich plasma 1 unit is amount produced from 1 unit of whole blood Risk of production of antiplatelet antibodies occurs with repeated transfusions Repeat every 8-12 hours as needed Commercial cryopreserved product is available
Fresh or fresh frozen plasma	6-12 mL/kg IV	Supplies vWF Preferred over whole blood if there is no need to replace erythrocytes Risk of volume overload occurs with repeated transfusions Repeat every 8-12 hours as needed
Cryoprecipitate	1 unit/ 10 kg IV	Contains 5 to 10 times higher concentration of vWF than plasma 1 unit is amount produced from 200 mL of plasma Causes fewer side effects than plasma Repeat every 6-12 hours as needed

vWF, von Willebrand factor.

II. Most recognized disorders are associated with hemorrhagic tendencies.

Clinical Signs

I. Petechiation, ecchymoses, or both
II. Mucosal hemorrhages
III. Prolonged bleeding after trauma or surgery

Diagnosis

I. Platelet dysfunction should be suspected when clinical signs of a bleeding disorder are present and routine hemostatic tests (platelet concentration, vWF concentration, and coagulation tests) are normal or only mildly decreased (platelet or vWF concentration) or prolonged (PT or aPTT).
II. Prolonged BMBT or PFA 100 closure times are useful screening assays but are not specific for platelet dysfunction.
III. Specific tests to assess platelet function (adhesion, aggregation, secretion; see Box 67-2) require fresh samples (within 2 hours of collection) and are available at some specialty laboratories.
IV. DNA testing is available to detect affected or carrier basset hounds with inherited thrombopathia.

Differential Diagnosis

I. vWD or other platelet disorders: thrombocytopenia, acquired platelet dysfunction
II. Hypofibrinogenemia or other coagulation disorders: see Chapter 68

Treatment

I. No specific treatment is available.
II. Local bleeding may be controlled with topical hemostatic agents, cautery, or pressure bandages.
III. Transfusion therapy is indicated (see Table 67-1) for severe anemia or life-threatening hemorrhage.
IV. Avoid elective surgeries and drugs known to impair platelet function whenever possible.

Breed-Associated Thrombocytopenia

Definition

I. Healthy greyhounds may have mildly decreased platelet concentrations.
II. Clinically normal Cavalier King Charles spaniels frequently have platelet concentrations <100,000/μL and increased numbers of large platelets (Cowan et al., 2004).

TABLE 67-2

Inherited Disorders of Platelet Function

DISORDER	SPECIES	PLATELET ABNORMALITIES AND DIAGNOSIS	CLINICAL SIGNS
Chediak Higashi syndrome	Cat	Decreased dense granules, enlarged lysosomal granules, prolonged buccal mucosal bleeding time, abnormal platelet aggregation, impaired secretion of adenosine diphosphate, triphosphate, and serotonin	Persians with partial albinism, photophobia, risk for infection, neurological defects Bleeding tendencies vary from mild to severe and include easy bruising, mucosal hemorrhages, and excess hemorrhage after trauma or surgery
Cyclic hematopoiesis	Dog	Cyclic thrombocytopenia, decreased serotonin and calcium in dense granules, abnormal platelet aggregation and secretion	Collies with stem cell defect and cyclic neutropenia Diluted hair coat color, recurrent infections, bleeding tendencies
Glanzmann's thrombasthenia	Dog	Decreased or defective membrane glycoprotein IIbIIIa complex, impaired fibrinogen binding, impaired adhesion, abnormal platelet aggregation	Otterhounds, Great Pyrenees Bleeding tendencies vary from mild to severe and include spontaneous episodes of mucosal hemorrhage
Miscellaneous signal transduction disorders	Dog, cat	Associated with postreceptor defects in production or regulation of intracellular second messengers, abnormal platelet aggregation and/or secretion	Basset hounds, spitz, domestic shorthair cats Bleeding tendencies vary from mild to severe and include spontaneous episodes of mucosal hemorrhage.
Procoagulant deficiency	Dog	Abnormal membrane phosphatidylserine exposure, abnormal platelet activity in enzyme complexes in coagulation, normal platelet aggregation and secretion	German shepherd dogs with mild to moderate bleeding tendencies that include epistaxis, hyphema, hemorrhage postsurgery
Storage pool disorders	Dog	Decreased adenosine diphosphate in dense granules, normal number of dense granules, prolonged buccal mucosal bleeding time, impaired platelet aggregation to adenosine diphosphate	American cocker spaniels with moderate to severe bleeding following trauma or surgery

Clinical Signs and Treatment

I. Dogs are asymptomatic.
II. No treatment or monitoring is required.

ACQUIRED PLATELET DYSFUNCTION

Definition

I. Platelet hyporesponsiveness or hyperresponsiveness that results from an underlying disorder.
II. Underlying pathophysiology is often unknown but may be associated with alterations in platelet membranes, receptors, or signal transduction pathways.

Causes

I. Drugs
  A. Prostaglandin inhibitors: aspirin, carprofen, ibuprofen, indomethacin, ketoprofen, naproxen, phenylbutazone
  B. Regulators of cyclic adenosine monophosphate (cAMP) or cyclic guanosine monophosphate (cGMP): dipyridamole, prostaglandin I_2, prostaglandin E_1
  C. Calcium antagonists: diltiazem, verapamil
  D. Antibiotics/antimicrobials: carbenicillin, cephalosporins, penicillin, ticarcillin
  E. Others: acepromazine, aminophylline, antihistamines, chondroitin sulfate, dextran, halothane, heparin, protamine sulfate, propanolol, ticlopidine
II. Disorders associated with decreased reactivity
  A. Disseminated intravascular coagulation (DIC)
  B. Dysproteinemia
  C. Hepatic failure
  D. Infections: rickettsial, viral
  E. Immune-mediated thrombocytopenia
  F. Neoplasia
  G. Snake venoms
  H. Uremia
III. Disorders associated with increased reactivity
  A. Canine heartworm disease
  B. Feline cardiomyopathy
  C. Infections: rickettsial, viral
  D. Neoplasia
  E. Nephrotic syndrome

Clinical Signs

I. Spontaneous hemorrhage is uncommon unless the animal is hemostatically challenged (surgery, trauma), has a concurrent coagulation disorder or thrombocytopenia, or receives drugs that inhibit hemostasis.
II. Petechiae, ecchymoses, and mucosal hemorrhages may occur if platelets are hyporesponsive.
III. Signs associated with thrombosis may develop if platelets are hyperresponsive.

Diagnosis

I. Prolonged BMBT is a useful screening assay to detect hyporesponsive platelets.
II. No readily available in-house screening assays exist to detect hyperresponsive platelets.
III. Assays to evaluate specific platelet function (adhesion, aggregation, flow cytometry; see Box 67-2) are available in specialty laboratories but require fresh samples (<2 hours old).
IV. Serum biochemistry profiles are performed to evaluate organ function and plasma protein levels.
V. A hemostatic profile is used to detect DIC (see Chapter 68).
VI. Serology and/or polymerase chain reaction (PCR) assays may be run if infection is suspected.

Differential Diagnosis

I. vWD or other platelet disorders: thrombocytopenia or inherited platelet dysfunction
II. Coagulation disorders: see Chapter 68

Treatment and Monitoring

I. Discontinue administration of drugs suspected to cause platelet dysfunction.
II. Transfusion therapy (see Table 67-1) is recommended for severe anemia or life-threatening hemorrhage.
III. Institute specific therapy for any underlying disorder.
IV. Nonsteroidal antiinflammatory drugs (aspirin 0.5 mg/kg BID) may be used in dogs to inhibit platelet function if they are at risk for thrombotic disorders.
V. Platelet function usually returns to normal when the underlying disorder is resolved.

THROMBOCYTOPENIA

Immune-Mediated Thrombocytopenia

Definition

I. Decreased platelet numbers occur from an immune response directed against platelets, megakaryocytes, or both.
II. It is a common disorder in dogs and is found only sporadically in other species.

Causes

I. With primary immune-mediated trombocytopenia (IMT), the immune response is directed against autoantigens and is not associated with an underlying disease.
   A. Possible genetic predisposition: American cocker spaniel, poodle, Old English sheepdog (Lewis and Meyers, 1996)
   B. Predilection for middle-aged, female dogs
II. With secondary IMT, the immune response is associated with an underlying disorder.
   A. Systemic immune-mediated disorders: systemic lupus erythematosus, immune-mediated hemolytic anemia (IMHA)
   B. Neoplasia: lymphoma, myeloproliferative disorders, various solid tumors
   C. Drugs: sulfonamides in dogs, methimazole or propylthiouracil in cats
   D. Infections: certain bacteria, ehrlichiosis, canine distemper virus, feline immunodeficiency virus (FIV), feline leukemia virus (FeLV), leishmaniasis, babesiosis, histoplasmosis, heartworm disease
   E. Vaccination with modified live viruses

Pathophysiology

I. Immune response causes decreased platelet lifespan because of complement-mediated intravascular platelet lysis or (more commonly) platelet removal by the mononuclear phagocytic system.
II. A secondary platelet dysfunction may also exacerbate hemorrhagic tendencies.
III. In primary IMT, the immune response is most commonly directed against membrane glycoprotein (GP) IIbIIIa.
IV. Secondary IMT can result from the following mechanisms:
   A. Cross-reactive antibodies that recognize both foreign antigens and platelet antigens
   B. Exposure of previously hidden self-antigens in platelet membranes
   C. Formation of a neoantigen from reaction between the platelet and foreign antigens
   D. Antibody reaction against foreign antigen adsorbed to platelet membrane
   E. Formation of immune complexes that subsequently bind to platelet membrane

Clinical Signs

I. Dogs with primary IMT are often asymptomatic unless there is significant associated anemia.
II. The risk for hemorrhage (see Box 67-1) depends on platelet concentrations (Box 67-3) and the presence or absence of acquired platelet dysfunction.
III. Animals with secondary IMT usually have signs associated with the underlying disease process.

Diagnosis

I. The diagnosis of primary IMT is often based upon exclusion of other causes of thrombocytopenia and the response to immunosuppressive drug therapy.
II. Complete blood count (CBC) may reveal the following (see Box 67-2):
   A. Thrombocytopenia is often severe.
   B. Anemia may be present from hemorrhage or concurrent IMHA.

Box 67-3

Risk for Hemorrhage with Thrombocytopenia

Platelet Concentration*	Risk for Spontaneous Clinical Bleeding
<50,000/μL	Microscopic hemorrhage
<20,000/μL	Mild risk
<10,000/μL	Moderate risk
<5,000/μL	Severe risk

From Abrams-Ogg ACG: Triggers for prophylactic use of platelet transfusions and optimal platelet dosing in thrombocytopenic dogs and cats. Vet Clin North Am Small Anim Pract 33:1401, 2003.
*Spontaneous clinical bleeding may occur at higher platelet concentrations in animals with concurrent platelet dysfunction, von Willebrand disease, or coagulation disorders.

C. Leukocyte values may be normal or may indicate an inflammatory or stress leukogram.

III. Mean platelet volume (MPV) may be increased, decreased, or normal.
   A. Decreased MPV occurs frequently in dogs with IMT but may be an artifact of nonplatelet debris in samples with severe thrombocytopenia.
   B. Increased MPV is suggestive of increased thrombopoiesis.
   C. Blood collected in ethylenediaminetetraacetic acid (EDTA) may have platelet swelling and an artifactual increase in MPV.

IV. Assays to detect platelet surface-associated immunoglobulin (PSAIg) may be run.
   A. Currently available assays cannot differentiate primary and secondary IMT.
   B. Flow cytometric assays have high sensitivity; however, nonspecific binding of antibodies to the platelet surface may occur.
   C. Significant increases in PSAIg occur in vitro 24 to 72 hours after sample collection (Wilkerson et al., 2001).

V. PT and APTT are normal with uncomplicated primary IMT.

VI. Activated clotting time may be prolonged with severe thrombocytopenia (<10,000/μL).

VII. Microscopic examination of the bone marrow reveals normal to an increased number of megakaryocytes if the immune response is directed against platelets, and a decreased number of megakaryocytes if the response is directed against megakaryocytes.
   A. Direct immunofluorescence is used to detect antibodies bound to megakaryocytes.
   B. Thrombocytopenia does not preclude collection of a bone marrow sample.

VIII. Serological or PCR assays are used to identify infectious agents in secondary IMT.

Differential Diagnosis

I. Nonimmune causes of increased platelet destruction, consumption, or sequestration

II. Bone marrow suppression of platelet production

Treatment

I. Institute immunosuppressive therapy with prednisone (1 to 3 mg/kg PO BID) for at least 2 weeks (Lewis and Meyers, 1996).
   A. Generally expect a response within 24 to 96 hours.
   B. Gradually taper dose over weeks to months to the minimal effective dose.
   C. Consider also using H_2 blockers (famotidine 0.5 mg/kg SID) to help prevent gastrointestinal ulceration (Couto, 2003).

II. Consider adding these other therapies to prednisone if response is unsatisfactory:
   A. Vincristine 0.02 mg/kg IV as a single dose (Rozanski et al., 2002)
   B. Danazol 5 mg/kg PO BID (Lewis and Meyers, 1996)
   C. Azathioprine 2 mg/kg PO SID initially (Lewis and Meyers, 1996; Mackin, 1995)
      1. Eventually taper to a maintenance dose of 0.5 to 1.0 mg/kg QOD
      2. More effective in maintaining than inducing remission
   D. Cyclophosphamide 50 mg/m^2 PO SID for 4 days each week until positive response (Lewis and Meyers, 1996; Mackin, 1995)

III. Splenectomy, cyclosporine, colchicine, chemotherapeutic protocols for lymphoma, or human IV immunoglobulin may be considered in refractory cases (Couto, 2003; Lewis and Meyers, 1996; Mackin, 1995).

IV. Keep the animal quiet to minimize potential trauma, and avoid elective surgeries.

V. Transfusion therapy (see Table 67-1) may be used to replace erythrocytes if there is significant anemia; however, administration of platelet concentrates is of questionable value owing to rapid removal of transfused platelets and is usually reserved for life-threatening hemorrhaging.

VI. Avoid drugs known to inhibit platelet function whenever possible.

VII. Treat underlying causes of secondary IMT.
   A. Stop administration of drugs suspected to cause thrombocytopenia.
   B. Administer appropriate antimicrobial drugs in cases of suspected infection.
   C. Initiate appropriate chemotherapy, radiotherapy, or surgery for neoplasia.

Monitoring of Animal

I. Most cases of primary IMT have increased platelet concentrations (>50,000/μL) within 1 week of initiating prednisone therapy.

II. Measure platelets every 1 to 2 days until they exceed 50,000/μL, then weekly until the concentration normalizes.

III. Approximately 40% of dogs with primary IMT have a recurrence of thrombocytopenia and some require lifelong therapy (Lewis and Meyers, 1996).

IV. Secondary IMT usually resolves following successful treatment of the underlying disorder.

Infectious Thrombocytopenia

Definition and Causes

I. Decreased circulating platelet concentrations result from infection.
II. Causes are numerous (Table 67-3).

Pathophysiology

I. Various underlying mechanisms (individually or in combination)
II. Impaired megakaryocytopoiesis from direct infection of megakaryocytes, immune responses against megakaryocytes, or inflammatory responses in bone marrow
III. Altered platelet distribution, with sequestration in spleen or other tissues
IV. Increased platelet consumption from platelet activation, vasculitis, or secondary consumptive coagulopathy
V. Direct damage to platelets causing increased destruction and removal by mononuclear phagocytic system
VI. Secondary IMT, with increased platelet destruction

Clinical Signs

I. Hemorrhages (see Box 67-1) occur with severe thrombocytopenia (see Box 67-3), or if mild to moderate thrombocytopenia is associated with acquired platelet dysfunction or vasculitis.

TABLE 67-3

Infectious Agents Associated with Thrombocytopenia in Dogs and Cats

AGENTS	CLINICAL DISEASE	SPECIES AFFECTED
Viruses	Distemper	Dog
	Feline leukemia virus	Cat
	Feline immunodeficiency virus	Cat
	Feline infectious peritonitis	Cat
	Herpesvirus	Dog
	Infectious hepatitis	Dog
	Parvovirus	Cat, dog
Bacteria	Bacteremia/endotoxemia	Cat, dog
	Bartonellosis	Dog
	Borreliosis	Dog
	Leptospirosis	Dog
	Salmonellosis	Cat, dog
Rickettsia	Ehrlichiosis	Cat, dog
	Rocky Mountain spotted fever	Dog
Protozoa	Babesiosis	Dog
	Cytauxzoonosis	Cat
	Leishmaniasis	Dog
	Toxoplasmosis	Cat
Fungi	Disseminated candidiasis	Dog
	Histoplasmosis	Cat, dog
Miscellaneous	Heartworm disease	Cat, dog
	Hemotropic *Mycoplasma* spp.	Dog

II. Usually clinical signs are associated with the underlying infectious agent.

Diagnosis

I. CBC findings are variable.
  A. Thrombocytopenia ranges from mild to severe.
  B. Concurrent leukocytosis, leukopenia, and anemia may occur, depending on the organism.
  C. Microscopic examination of a blood smear may identify infectious agents.
II. Hemostatic profile may be abnormal if a secondary coagulopathy (see Chapter 68) is present.
III. A bone marrow sample may reveal an infectious agent, and megakaryocyte production may be decreased, increased or adequate depending on the organism's effect on hematopoietic cells and/or bone marrow microenvironment.
IV. Serologic and/or PCR assays are useful to identify the infectious agent.
V. Cytology of abnormal organs (lymph nodes, liver, spleen) may also reveal organisms.

Differential Diagnosis

I. Other causes of increased platelet destruction, consumption, and sequestration
II. Primary bone marrow disorder

Treatment

I. Begin antimicrobials specific for the inciting organism.
II. Supportive care includes fluid therapy, antiinflammatory drugs, or both.
III. Transfusion therapy (see Table 67-1) is indicated for significant anemia or life-threatening hemorrhage.

Monitoring of Animal

I. Prognosis depends on the underlying etiologic agent.
II. Thrombocytopenia often resolves with resolution of the underlying infection.

Drug- or Toxin-Induced Thrombocytopenia

Definition and Causes

I. Decreased circulating platelet concentration occurs secondary to administration of some drugs or toxins.
II. See Box 67-4 for a list of causes.
III. Thrombocytopenia may be predictable and dose dependent, or it may be idiosyncratic.

Pathophysiology

I. Impaired bone marrow production from direct destruction of megakaryocytes, immune responses targeting megakaryocytes, and altered microenvironment
II. Direct activation of platelets with increased consumption
III. Direct damage to platelets leading to increased destruction and decreased lifespan
IV. Secondary IMT causing increased platelet destruction by the mononuclear phagocytic system

Box 67-4

Drugs Associated with Thrombocytopenia in Dogs and Cats

Antibiotics/Antimicrobials

Cephalosporins, chloramphenicol, dapsone, sulfonamides

Antiinflammatory Drugs

Carprofen, phenylbutazone

Chemotherapeutic Drugs

Azathioprine, cisplatin, cyclophosphamide, cytosine arabinoside, doxorubicin, 5-fluorouracil, hydroxyurea, lomustine, melphalan, mitoxantrone

Miscellaneous

Albendazole, estrogen, griseofulvin, levamisole, methimazole, phenobarbital, propylthiouracil, protamine sulfate, thiacetarsamide

Clinical Signs

I. Hemorrhages (see Box 67-1) occur with severe thrombocytopenia (see Box 67-3) or with mild to moderate thrombocytopenia associated with platelet dysfunction.
II. Signs of anemia (weakness, lethargy) or leukopenia (infection) may occur with myelosuppressive drugs.

Diagnosis

I. Thrombocytopenia ranges from mild to severe.
II. Concurrent anemia, leukopenia, or both are possible with myelosuppressive drugs.
III. A bone marrow sample may reveal a decrease in the number of megakaryocytes with myelosuppressive drugs and an adequate number to an increase in the number of megakaryocytes with drugs that cause increased extramedullary platelet destruction or consumption.
IV. Diagnosis is often based on thrombocytopenia occurring after drug administration and normalization of platelet concentration with cessation of that drug.

Differential Diagnosis

I. Other causes of increased platelet destruction, consumption, and sequestration
II. Primary bone marrow disorder

Treatment

I. Discontinue administration of suspected drug or toxin.
II. Immunosuppressive prednisone therapy is indicated if thrombocytopenia is ongoing and secondary IMT is suspected (see Diagnosis under Immune-Mediated Thrombocytopenia).
III. Transfusion therapy (see Table 67-1) is indicated for significant anemia or life-threatening hemorrhage.

Monitoring of Animal

I. Measure platelets every 1 to 2 days until platelet counts exceed 50,000/μL, then weekly until they are normal.
II. Prognosis is good if platelets increase after drug is stopped.
III. Prognosis is poor if thrombocytopenia continues after drug is stopped.

OTHER THROMBOCYTOPENIC DISORDERS

See Table 67-4.

PLATELET PRODUCTION DISORDERS

Definition

I. Decreased circulating platelets result from impaired bone marrow production.
II. Decreased production may arise from primary bone marrow disorders or from exogenous factors affecting the bone marrow.

Causes

I. Drugs: cefazedone, chemotherapeutic drugs, chloramphenicol, estrogen, griseofulvin, methimazole, phenylbutazone, sulfonamides, thiacetarsamide
II. Infections: chronic ehrlichiosis, canine distemper, parvovirus, FeLV, FIV
III. Immune reactions targeting megakaryocytes, with megakaryocyte destruction or impaired thrombopoiesis
IV. Myelophthisis from neoplasia or myelofibrosis
V. Bone marrow necrosis
VI. Irradiation

Pathophysiology

I. Megakaryocytic hypoplasia from destruction of hematopoietic precursor cells or altered microenvironment in the bone marrow
   A. Occasionally selective megakaryocytic hypoplasia
   B. Generalized bone marrow disease associated with erythroid or myeloid hypoplasia
II. Occasional dysmegakaryocytopoiesis
   A. Associated with megakaryocyte maturation and morphologic abnormalities
   B. Most commonly associated with myelodysplastic disorders or acute leukemia
III. Myelophthisis
   A. Replacement of normal hematopoietic cells by a population of abnormal cells, such as neoplastic cells or fibrous connective tissue
   B. Neoplastic cells usually of hematopoietic origin (myeloproliferative or lymphoproliferative disorders) but occasionally metastatic from other sites

Clinical Signs

I. Hemorrhage occurs with severe thrombocytopenia (see Box 67-3) or with mild to moderate thrombocytopenia associated with acquired platelet dysfunction.
II. Clinical signs of anemia, leukopenia, or both may occur with hypoplasia of other cell lines.

TABLE 67-4

Other Thrombocytopenic Disorders

DISORDER	CAUSES/PATHOPHYSIOLOGY	DIAGNOSIS	TREATMENT/PROGNOSIS
Localized or disseminated neoplasia	Impaired bone marrow production Distribution disorder DIC Secondary IMT Platelet destruction by neoplastic cells Tumor-associated hemorrhage	Mild to severe thrombocytopenia Cytology and/or biopsy of abnormal tissue to identify neoplastic cells Abnormal hemostatic profile with DIC (see Chapter 68)	Transfusion for severe anemia or life-threatening hemorrhage Treatment and prognosis specific for underlying neoplasm
Increased platelet consumption	DIC Vasculitis Hemolytic uremic syndrome Envenomation Vitamin K antagonism	Mild to severe thrombocytopenia Clinical signs associated with underlying disorder Abnormal hemostatic profile with DIC or vitamin K antagonism (see Chapter 68)	Transfusion for severe anemia or life-threatening hemorrhage Treatment and prognosis specific for underlying cause DIC or vitamin K antagonism: see Chapter 68
Distribution disorder	Organomegaly, especially splenomegaly	Mild to moderate thrombocytopenia Diagnostic imaging and/or palpation to identify organomegaly Rule out other causes of thrombocytopenia	No specific treatment for thrombocytopenia
Platelet loss	Severe hemorrhage Vitamin K antagonists	Anemia and decreased total protein concentration Mild to moderate thrombocytopenia with blood loss, occasionally severe with vitamin K antagonists Severe thrombocytopenia with hemorrhage usually suggests hemorrhage from thrombocytopenia, not thrombocytopenia from hemorrhage. Prolonged PT and APTT with vitamin K antagonism	Control hemorrhage No specific treatment for thrombocytopenia Transfusion for severe anemia or life-threatening hemorrhage Vitamin K antagonism: see Chapter 68

DIC, Disseminated intravascular coagulation; *IMT,* immune-mediated thrombocytopenia; *PT,* prothrombin time; *APTT,* activated partial thromboplastin time.

Diagnosis

I. CBC findings are variable.
   A. Thrombocytopenia varies from mild to severe.
   B. Evidence of platelet regeneration is lacking (MPV normal, no increase in large platelets) with megakaryocytic hypoplasia.
   C. Abnormal cells may be identified with leukemia or myelodysplasia.
   D. Concurrent nonregenerative anemia and leukopenia may be detected.

II. Microscopic examination of a bone marrow sample is critical for diagnosis and prognosis.
   A. Megakaryocytic hypoplasia is characterized by decreased number of megakaryocytes.
   B. Dysmegakaryocytopoiesis is characterized by maturation and morphological abnormalities (mega-megakaryocytes, dwarf megakaryocytes, nuclear hypolobulation).
   C. Neoplastic cells or infectious agents may be identified.
   D. Direct immunofluorescence detects antibodies bound to megakaryocytes in secondary IMT.

Differential Diagnosis

I. Causes of platelet destruction
II. Causes of platelet consumption and sequestration

Treatment

I. Treat the underlying cause.
   A. Chemotherapy for neoplasia
   B. Immunosuppressive therapy (see Immune-Mediated Thrombocytopenia) for suspected immune-mediated destruction
   C. Drug discontinued if suspected drug reaction
   D. Antimicrobial drugs for suspected infections

II. Recombinant human interleukin (IL) 11 increases megakaryocyte production in normal dogs and shortens recovery following irradiation (Nash et al., 1995).

A. Controlled studies are lacking on the efficacy and safety of IL11 administration in dogs or cats with spontaneous thrombocytopenia.
B. There is a risk of production of neutralizing antibodies with extended use.

III. Administer transfusion therapy (see Table 67-1) for severe anemia or life-threatening hemorrhage.

Monitoring of Animal

I. The prognosis is guarded and depends on the underlying cause.
   A. Animals with IMT and megakaryocytic hypoplasia often have a poorer prognosis and a delayed response to treatment when compared with animals with adequate to increased megakaryocyte production (Stockham and Scott, 2002).
   B. Dogs with lymphoma and bone marrow involvement have a poorer prognosis than those with no bone marrow involvement.
   C. Animals with acute myeloid leukemia have a poor prognosis.

II. Measure platelets weekly until platelet concentration normalizes.

III. Perform a bone marrow examination weekly to monitor progress if the platelet concentration does not steadily increase.

Spurious Thrombocytopenia

Definition

I. Platelet clumping artifactually lowers measured platelet concentrations.

II. It occurs from the following:
   A. Activation of platelets during venipuncture or in vitro sample handling
   B. EDTA-dependent antibody binding causing platelet agglutination
   C. Cold agglutinins causing platelet agglutination

III. Samples with large numbers of large platelets may have falsely decreased platelet counts, because large platelets are excluded by some automated hematology analyzers.

Diagnosis

I. Blood smears are microscopically evaluated for platelet clumps.

II. When clumps are present, the measured platelet concentration is considered a minimal value.

Treatment and Monitoring

I. Collection of a new sample is required to obtain an accurate platelet concentration when clumps are present.

II. Clumping can be minimized by atraumatic venipuncture, use of citrate as an anticoagulant, or addition of platelet inhibitors to the sample (Norman et al., 2001).

III. Manual platelet counts may be effective in samples with increased numbers of large platelets.

THROMBOCYTOSIS

Definition

I. Increased circulating platelet concentrations

II. Associated with a variety of disorders

Causes and Pathophysiology

I. Myeloproliferative disorders arise from clonal expansion of hematopoietic precursor cells.
   A. Thrombocytosis occurs with acute megakaryocytic leukemia or essential thrombocythemia.
   B. Platelet function may be normal, hyporesponsive, or hyperresponsive.

II. Reactive thrombocytosis occurs from increased platelet production secondary to an underlying disorder associated with increased production of leukocytes, erythrocytes, or both.
   A. It may be associated with increased production of cytokines (IL1, IL4, IL6) that stimulate megakaryocyte production or maturation in the bone marrow.
   B. Platelet function is normal and hemostatic complications are uncommon.
   C. Reported causes include iron deficiency, blood loss anemia, chronic inflammation or infection, hemolytic anemia, hyperadrenocorticism, neoplasia, trauma, drugs (vincristine) or following splenectomy.

III. Redistribution thrombocytosis develops from release of platelets from the spleen or other storage sites.
   A. Transient increases are associated with exercise, fear, stress, or acute hemorrhage.
   B. Redistribution increases circulating platelet concentration but does not alter total body platelet numbers.

Clinical Signs

I. Animals with myeloproliferative thrombocytosis are at risk for hemorrhage or thrombosis.

II. Clinical signs may be associated with the underlying disorder in reactive thrombocytosis.

Diagnosis

I. Redistribution thrombocytosis causes a transient increase in platelet concentration.

II. Reactive thrombocytosis may result in the following:
   A. CBC often reveals anemia, leukocytosis, or both, as well as normal platelet morphology.
   B. Megakaryocytic hyperplasia is expected on microscopic examination of bone marrow.
   C. Identification of an underlying inflammatory or neoplastic disorder supports the diagnosis.

III. Myeloproliferative thrombocytosis is characterized by the following:
   A. CBC may reveal abnormal platelet morphology and circulating megakaryoblasts, as well as marked thrombocytosis.
   B. Diagnosis of essential thrombocythemia is based on ruling out causes of reactive thrombocytosis in an animal with a persistent thrombocytosis (see Chapter 66).

C. Microscopic examination of a bone marrow sample is helpful.
   1. Increased number of megakaryoblasts (blasts >30% of nucleated cell population) and abnormal megakaryocytopoiesis in animals with acute megakaryocytic leukemia
   2. Increased number of megakaryocytes with or without abnormal megakaryocytopoiesis in animals with essential thrombocythemia

Treatment and Monitoring

I. No specific antiplatelet therapy is required in animals with reactive or redistribution thrombocytosis, as the thrombocytosis normalizes with resolution of underlying disorder.
II. See Chapter 66 for treatment of essential thrombocythemia.

CHAPTER 68

Disorders of Coagulation and Fibrinolysis

Michael A. Scott | Matthew W. Beal

LABORATORY ASSESSMENT

I. Coagulation and fibrinolysis are intimately related, opposing processes that are often assessed together with tests of platelet function and von Willebrand disease (Chapter 67).
II. Appropriate sample collection and processing are critical for reliable results.
   A. Free-flowing blood must be collected by "clean" venipuncture.
   B. Samples should contain 1 part 3.2% or 3.8% sodium citrate anticoagulant to 9 parts blood.
   C. Blood may be collected from catheters after flushing with saline and discarding at least six times a catheter's dead space.
   D. It is best to remove plasma after centrifugation within 1 hour of collection (storage at room temperature) and to run tests within 4 hours.
   E. Plasma may be frozen and mailed on ice to arrive within 24 hours for testing.
   F. The activated coagulation time (ACT) is a cage-side test that requires specific ACT tubes.
III. Routine coagulation and fibrinolytic tests are used to recognize and characterize hemostatic disorders (Table 68-1).
   A. Prolongation of prothrombin time (PT) or activated partial thromboplastin time (aPTT) generally occurs with single-factor deficiencies ≤30% of normal and with moderate deficiencies of multiple factors.
   B. The ACT is less sensitive than the aPTT and requires single intrinsic factor deficiencies <5% to 10% of normal for prolongations.
   C. Fibrin degradation products (FDPs and D-dimers) are usually assessed for evidence of thrombosis and subsequent fibrinolysis.
   D. FDPs also increase with hyperfibrinogenolysis.
   E. Antithrombin III (ATIII) is an endogenous anticoagulant used to detect prothrombotic states that either arise from ATIII deficiency (from loss or decreased hepatic production) or cause ATIII consumption during the clotting process.
      1. ATIII inhibits all the enzymatic factors of the intrinsic and common pathway (XIIa, XIa, Xa, IXa, IIa), and its activity is greatly potentiated by heparins.

TABLE 68-1

Interpretation of Routine Tests of Coagulation and Fibrinolysis

TEST	RESULT	POTENTIAL CAUSES
ACT	Prolonged	Intrinsic and/or common pathway deficiencies, coagulation inhibitors
aPTT	Prolonged	Intrinsic and/or common pathway deficiencies, coagulation inhibitors
ATIII	Decreased	Protein-losing nephropathy/enteropathy, consumptive coagulation, decreased hepatic production, postheparin administration
D-dimers	Elevated	Fibrinolysis secondary to localized or disseminated coagulation, decreased D-dimer clearance, inflammation, trauma, surgery
FDPs	Elevated	Increased fibrin(ogen)olysis (possibly secondary to localized or disseminated coagulation), decreased FDP clearance, inflammation, trauma, surgery
PT	Prolonged	Extrinsic and/or common pathway deficiencies, coagulation inhibitors
TT*	Prolonged	Afibrinogenemia or hypofibrinogenemia from decreased hepatic production or increased consumption, dysfibrinogenemia

ACT, Activated coagulation time; *aPTT,* activated partial thromboplastin time; *ATIII,* antithrombin III; *FDPs,* fibrin(ogen) degradation products; *PT,* prothrombin time; *TT,* thrombin time.

*TT (Clauss method) is routinely used as a functional assay of fibrinogen and converted to a fibrinogen concentration (mg/dL), which is inversely related to the TT.

2. It is measured by functional assays for anti-IIa or anti-Xa activity.
3. Results are reported as the percentage of activity relative to either normal human or species-specific plasma.

IV. Additional tests are also available.
   A. For assessment of coagulation, tests include fibrinogen antigen (immunoassay), specific factor activities (II, VII, VIII, IX, X, XI, XII, prekallikrein, high-molecular-weight kininogen [HMWK]), and the Russell Viper Venom Test (RVVT) to assess the common pathway.
   B. Additional anticoagulation assays include an anti-Xa (activated Factor X) assay for animals receiving unfractionated or low-molecular-weight heparin (LMWH), and tests for protein C and lupus anticoagulants.
   C. Inhibitors of coagulation factors are assessed by functional coagulation assays and mixing studies using test plasma mixed with normal or factor-deficient plasmas.

V. Thromboelastography (TEG) is available at some institutions to analyze the entire process of clot formation and dissolution (Wiinberg et al., 2005).

INHERITED/CONGENITAL INTRINSIC PATHWAY DEFICIENCIES

Prekallikrein and Factor XII Deficiencies

Definition and Causes

I. The contact factors, Factor XII (Hageman factor), HMWK, and prekallikrein are produced by the liver; together they initiate coagulation via contact with activating surfaces (e.g., subendothelium).
II. Two of them, HMWK and prekallikrein, circulate together with Factor XI.
III. Assembly of contact factors on negatively charged endothelial cells or other activating surfaces results in the generation of Factor XIIa and subsequent cascade of the intrinsic and common pathways via Factor XIa.
IV. Decreased functional amounts of these factors in plasma are considered deficiencies.
   A. Deficiencies may occur as inherited or congenital defects.
   B. Deficiencies may also occur with hepatic failure, consumptive coagulation, or anti-factor antibodies (inhibitors).
   C. Factor XII deficiency is relatively common in cats and is an autosomal recessive trait.
      1. It may occur alone or with hemophilia A or B (Kier et al., 1980).
      2. It has been reported in a few purebred dogs, alone and combined with either von Willebrand disease (vWD) or prekallikrein deficiency.
   D. Prekallikrein deficiency has been reported in a few purebred dogs, and it may be inherited.
   E. HMWK deficiency has not been reported in dogs or cats.

Pathophysiology and Clinical Signs

I. Single contact factor deficiencies may promote hemorrhage; however, they do not *cause* hemorrhage, because the intrinsic pathway can be activated by the extrinsic and common pathways.
II. Deficiencies of these proteins may predispose to thromboembolic disease in people, but there is currently no evidence for a prothrombotic tendency in affected dogs and cats.
III. Clinical signs are not expected with single contact factor deficiencies, so recognition is incidental and occurs in animals undergoing hemostatic testing for other reasons.
IV. If hemorrhage or thrombotic disease is present, efforts are directed toward identifying other causes, although a deficiency of these factors may be contributory.

Diagnosis and Differential Diagnosis

I. Congenital contact factor deficiencies are considered when aPTT and/or ACT are prolonged, and PT and thrombin time (TT) values are normal.
II. Specific factor analyses are used to confirm a contact factor deficiency.
III. Other conditions to be considered include hemophilia A or B, Factor XI deficiency, liver disease, and intrinsic pathway factor inhibitors such as heparin, antibodies to coagulation factors (referred to as *inhibitors*), or antiphospholipid/protein antibodies.

Treatment and Monitoring

I. Treatment and monitoring are directed toward the primary problems.
II. Once other causes of aPTT prolongation have been excluded, elective surgical or other invasive procedures may proceed.
III. Fresh frozen plasma may be given before surgery for animals with prekallikrein or mixed deficiencies, or when these deficiencies may be contributing to hemorrhage.

Factor XI Deficiency (Hemophilia C)

Definition and Causes

I. Factor XI is produced in the liver and circulates with prekallikrein and HMWK.
II. Thrombin or Factor XIIa activates Factor XI to Factor XIa, which then activates Factor IX.
III. Factor XI deficiency is a decrease in functional Factor XI caused by either a dysfunctional protein or a decreased concentration of normal Factor XI.
IV. Factor XI deficiency is rare, but has been reported in Kerry blue terriers (Knowler et al., 1994), other purebred dogs, and a domestic shorthair cat.
V. It may be an autosomal trait, but heritability has been unproven in some cases.

Pathophysiology and Clinical Signs

I. Factor XI deficiency impairs the intrinsic coagulation pathway cascade.

II. Spontaneous hemorrhage is not expected, but epistaxis, menorrhagia, hematuria, bruising, hematomas, and prolonged hemorrhage after surgical or nonsurgical trauma may occur with severe deficiencies.
III. Posttraumatic hemorrhage may be delayed several days.
IV. With acute severe blood loss, clinical signs of anemia and hypovolemia may occur.

Diagnosis and Differential Diagnosis

I. Congenital or inherited Factor XI deficiency is considered along with other intrinsic pathway factor deficiencies (XII, prekallikrein, IX, and VIII) when there are unexplained prolongations of aPTT and/or ACT, and PT and TT values are normal.
II. Confirmation of a single Factor XI deficiency requires specific factor analyses.
III. Other laboratory and clinical findings help exclude secondary causes of prolonged aPTT and ACT, such as hepatic disease, vitamin K antagonism or deficiency, consumptive coagulation, Factor VIII deficiency associated with vWD, and the rare presence of coagulation factor inhibitors.

Treatment and Monitoring

I. Initial therapy is directed at expansion of circulatory volume, correction of anemia, and administration of Factor XI (Box 68-1).
II. Concurrent management of underlying or associated conditions may also be necessary.
III. With severe acute hemorrhage, initial monitoring focuses on restoration of euvolemia, a return to physiological homeostasis, and cessation of hemorrhage (Table 68-2).
IV. Avoidance of trauma, including surgical procedures, is recommended.
V. When surgical procedures are required, transfusion of plasma products is indicated.
VI. Familial genetic testing and breeding recommendations may be indicated.

Box 68-1

Initial Therapy for Acute Hemorrhage-Induced Anemia or Hypovolemia

Problem	Recommended Therapy
Hypovolemia	Expand circulatory volume with IV crystalloid or colloid fluids, and blood or blood components to normalize signs of hypovolemia (see Table 68-2). Fresh whole blood or appropriate blood components are often necessary.
Anemia	Administer 6 to 15 mL/kg packed RBCs IV. Administer 20 to 30 mL/kg fresh whole blood IV to replace RBCs and coagulation factors. Fresh whole blood and blood products may be delivered rapidly (over 5 minutes to 1 hour). Dilution of packed RBCs with 0.9% NaCl (1:1) speeds infusion by increasing the temperature of the product and decreasing viscosity. Therapeutic goals are a posttransfusion hematocrit of 20% to 25%, and resolution of signs of hypovolemia.
Coagulopathy*	Administer fresh plasma or fresh frozen plasma at 6 to 15 mL/kg IV over 30 minutes to 2 hours. Repeat as necessary until bleeding ceases. Reassessment of PT and aPTT may help guide plasma administration in certain disease processes. Fresh whole blood may be administered as outlined for anemia. Administer cryoprecipitate at 1 to 5 mL/kg IV over 1 hour for Factor VIII deficiency, fibrinogen deficiency, or von Willebrand disease. Cryosupernatant may be utilized at 10 to 15 mL/kg IV for deficiencies of Factors II, VII, IX, X, or XI when Factor VIII, fibrinogen, and von Willebrand factor are not needed. Normalize body temperature; coagulopathy is potentiated by hypothermia. Therapeutic goal is cessation of hemorrhage. Normalization of coagulation times is desirable, but may not be necessary to achieve adequate hemostasis.

RBC, Red blood cell; *aPTT,* activated partial thromboplastin time; *PT,* prothrombin time.
*Plasma, cryoprecipitate, or cryosupernatant may also be used in coagulopathic dogs that do not have hemorrhage-induced anemia or hypovolemia (e.g., before surgery).

Factor VIII and IX Deficiencies (Hemophilia A and B)

Definition and Causes

I. Factor IX is a vitamin K-dependent enzyme produced in the liver and activated by Factor XIa (intrinsic pathway) or tissue factor (TF) complexed with Factor VIIa (extrinsic pathway).
   A. Factor IXa activates Factor X at the start of the common pathway.
   B. Hemophilia B is an inherited deficiency of functional Factor IX.
      1. It has been reported in a variety of purebred and mixed breed dogs, sometimes with vWD.
      2. Affected cats include the British shorthair and Siamese-cross; some have had concurrent Factor XII deficiency.
II. Factor VIII is a nonenzymatic protein produced in the liver.
   A. It is activated to Factor VIIIa by thrombin to become a cofactor for activation of Factor X.
   B. Hemophilia A is a decrease in functional Factor VIII.
      1. It is a relatively common inherited coagulation factor deficiency in dogs.
      2. It most commonly occurs in purebred dogs, particularly in German shepherd dogs, but also in mixed-breed dogs and in cats.

TABLE 68-2

Monitoring of Animals with Acute Coagulopathy-Induced Anemia and Hypovolemia

CONCERN	PARAMETER TO MONITOR	MONITORING FREQUENCY	GOAL
Physiological homeostasis	Temperature Pulse rate Respiration rate Mucous membrane color Capillary refill time Pulse character Arterial blood pressure Arterial O_2 saturation Urine output	Every 5-15 min until normalized, then every 1-2 hr	Normalization of parameters
Blood loss	Hematocrit	Every 1 hr until Hct >20%, then every 6 hr	Hct = 20% to 25%
	Active bleeding	Every 15-30 min	Cessation of hemorrhage
	PT, aPTT, or ACT	Test coagulation times 15-30 min after transfusion	Normalization of coagulation desirable

Hct, Hematocrit; *PT,* prothrombin time*a*; a*PTT,* activated partial thromboplastin time; *ACT,* activated coagulation time.

III. Hemophilia A and B are sex-linked (X-chromosome), recessively inherited disorders.
   A. Males are either affected or clear of the defect.
   B. Females may be clear of the defect, carriers (heterozygous), or affected (homozygous).
   C. Offspring of carriers bred to unaffected males have a 50% chance of inheriting a defective X-chromosome, so 50% of males will be affected and 50% of females will be carriers.
   D. All female offspring of an affected male and a clear female are asymptomatic carriers.
   E. Female offspring from an affected male and a carrier female can be affected.

Pathophysiology

I. Mutations in the genes coding for Factor VIII or IX typically result in proportional decreases in activity and detectable antigen of these factors.
II. Several mutations have been defined for Factor IX in dogs and cats.

Clinical Signs

I. Because Factors VIII and IX are critical to normal hemostasis, severe deficiencies (<1% to 2% of normal activity) may lead to death at birth or to life-threatening spontaneous hemorrhage.
II. Milder deficiencies (3% to 30% activity) may go unnoticed in young dogs and only result in severe bleeding after surgical or nonsurgical trauma.
III. Clinical signs are related to hemorrhage and the secondary effects of acute blood loss.
   A. Hemarthrosis with lameness
   B. Spontaneous or trauma-induced hematomas
   C. Oral bleeding from tooth eruption or trauma
   D. Bleeding episodes following surgery (e.g., tail docking, dewclaw removal)
   E. Hemorrhagic effusions
   F. Hemomediastinum
   G. Hemorrhage into the central nervous system
   H. Bloody diarrhea
IV. Spontaneous hemorrhage is typically more severe in animals of greater size.
V. With acute, severe blood loss, clinical signs of anemia and hypovolemia may be present.

Diagnosis and Differential Diagnosis

I. Hemophilia A and B are considered along with other intrinsic pathway factor deficiencies (XII, prekallikrein, XI), especially in young animals, when there are unexplained prolongations of aPTT and/or ACT, and PT and TT values are normal.
II. Confirmation requires specific factor analyses.
III. Other laboratory and clinical findings help exclude secondary causes of prolonged aPTT and ACT, including hepatic disease, vitamin K antagonism or deficiency, consumptive coagulation, Factor VIII deficiency associated with vWD, factor inhibitors, or heparinization of the sample or animal.

Treatment

I. Initial therapy is directed at expansion of circulatory volume, correction of anemia, and administration of deficient coagulation factors (see Box 68-1).
II. Cryoprecipitate is preferable to plasma as a source of fibrinogen because it reduces the potential for volume overload and possibly transfusion reactions (Stokol et al., 1998).

III. Life-threatening bleeding is treated symptomatically and invasive procedures are avoided, if possible.
IV. Continued hemorrhage and prolongation of aPTT after appropriate plasma transfusion are evidence that a coagulation factor inhibitor may be contributing to the hemorrhage, especially in multiply transfused hemophiliacs.
V. Appropriate management may vary from strict rest in mild cases to euthanasia in large dogs with severe, recurrent bleeding episodes.
VI. Gene therapy for definitive treatment of Factor VIII deficiency shows promise in dogs (Jiang et al., 2006).

Monitoring of Animal

I. Affected animals are monitored as discussed under Factor XI Deficiency.
II. Carrier states cannot be reliably detected by coagulation studies, so pedigree analysis and genetic testing (in breeds with characterized mutations of Factor IX) may be required.
III. Familial genetic testing and breeding recommendations are indicated.
   A. Female carriers can be spayed without risk of bleeding from hemophilia.
   B. Males with hemophilia should not be used for breeding.

INHERITED/CONGENITAL EXTRINSIC PATHWAY DEFICIENCIES

Factor VII Deficiency

Definition and Causes

I. Factor VII is a vitamin K–dependent protein produced in the liver.
II. When activated by TF from extravascular tissues or activated monocytes, it forms Factor VIIa/TF complexes that activate the common (Factor X) and intrinsic (Factor IX) pathways.
III. Inheritance of Factor VII deficiency appears to be autosomal dominant with incomplete penetrance (Spurling et al., 1974; Spurling, 1986).
IV. Deficiency occurs in beagles and other purebred and mixed-breed dogs.

Pathophysiology and Clinical Signs

I. Mutations in the gene coding for Factor VII result in deficiencies of functional Factor VII and, typically, proportional decreases in Factor VII antigen and Factor VII activity.
II. Only low levels of Factor VII are necessary to prevent bleeding, so Factor VII–deficient dogs are often detected incidentally despite activities <10% of normal.
III. Deficient dogs may have bruising or prolonged bleeding after accidental, physiological, or surgical trauma, such as castration and parturition.

Diagnosis and Differential Diagnosis

I. Factor VII deficiency is considered when there are unexplained prolongations of PT, and aPTT, ACT, and TT are normal.
II. PT may be affected before other coagulation times in several coagulation disorders, because Factor VII has the shortest half-life of the coagulation factors.
III. Specific factor activity analysis is necessary to confirm Factor VII deficiency.
IV. Other laboratory and clinical findings help exclude secondary causes of prolonged PT, including hepatic disease, vitamin K antagonism or deficiency, consumptive coagulation, and coagulation factor inhibitors.
V. Genetic testing may identify affected beagles, including carriers not detected by PT testing.

Treatment and Monitoring

I. Because severe bleeding is rare, specific treatment often is not necessary.
II. With severe hemorrhage, initial therapy is directed at expansion of circulatory volume, correction of anemia, and administration of Factor VII (see Box 68-1).
III. Recombinant human Factor VII is immunogenic in dogs, so it is not recommended.
IV. Dogs with known factor VII deficiency are monitored for signs of bleeding during pregnancy, during and after parturition, and after invasive procedures.
V. Familial genetic testing and breeding recommendations may be indicated.

INHERITED/CONGENITAL COMMON PATHWAY DEFICIENCIES

Factor X Deficiency

Definition and Causes

I. Factor X is a vitamin K–dependent protein produced in the liver and activated by either Factor IXa (intrinsic pathway) or Factor VIIa/TF (extrinsic pathway) at the start of the common pathway.
II. It is critical to thrombin generation by either pathway.
III. Congenital or hereditary functional deficiency of Factor X has been reported in domestic shorthair cats, American cocker spaniels, and Jack Russell terriers.
IV. Inheritance of the deficiency appeared to be autosomal dominant with variable penetrance in cocker spaniels (Dodds, 1973).

Pathophysiology and Clinical Signs

I. Mutations in the gene coding for Factor X result in deficiencies of functional Factor X and hemorrhagic tendencies in homozygotes and heterozygotes.
II. Homozygous individuals typically die very young from severe hemorrhage, whereas heterozygous individuals have a mild to marked bleeding propensity.

Diagnosis and Differential Diagnosis

I. Factor X deficiency, although rare, is considered when there are unexplained prolongations of PT, aPTT, and ACT without prolonged normal TT values.
II. The RVVT time is also prolonged.
III. Specific factor analysis is necessary to confirm Factor X deficiency.
IV. Other laboratory and clinical findings help exclude secondary deficiencies, including hepatic disease, vitamin K antagonism or deficiency, and consumptive coagulation.
V. Factor X deficiency must also be differentiated from other common pathway factor deficiencies, vitamin K–dependent multifactor coagulopathy (see under Inherited/Congenital Multiple Pathway Deficiency, following), and coagulation inhibitors.

Treatment and Monitoring

I. Initial therapy is directed at expansion of circulatory volume, correction of anemia, and administration of Factor X (see Box 68-1).
II. Monitor as for Factor XI deficiency.

Factor II (Prothrombin) Deficiency

Definition and Causes

I. Factor II (prothrombin) is a vitamin K–dependent protein produced in the liver.
   A. When activated to thrombin by Factor Xa and Va, it converts fibrinogen to fibrin, which polymerizes into a clot.
   B. Thrombin also activates other coagulation factors and platelets.
II. Factor II deficiency is a quantitative or qualitative deficiency of prothrombin.
   A. It is very rare, but has been reported as a suspected autosomal hereditary disorder in an English cocker spaniel (Hill et al., 1982).
   B. It has also been reported in boxers as part of a defect in turnover of all the vitamin K–dependent factors.

Pathophysiology and Clinical Signs

I. Genetic defects responsible for Factor II deficiency in dogs have not been identified.
II. Spontaneous or traumatic mucocutaneous and cavitary hemorrhage may occur.

Diagnosis and Differential Diagnosis

I. Factor II deficiency is considered when there are unexplained prolongations of PT, aPTT, and ACT, without prolonged TT values.
II. Differential diagnoses include Factor X deficiency and its differential diagnoses.
III. Specific factor analysis is necessary to confirm Factor II deficiency.

Treatment and Monitoring

I. Treatment is the same as that for Factor XI deficiency.
II. Monitoring mirrors that of Factor XI deficiency.

Afibrinogenemia and Hypofibrinogenemia

Definition and Causes

I. Fibrinogen (Factor I) is a positive acute-phase protein produced by hepatocytes.
   A. It is the major bridging protein in platelet aggregation.
   B. It is consumed as the substrate for thrombin in the generation of a stable fibrin clot.
II. Congenital or hereditary functional fibrinogen deficiency (Factor I deficiency) is very rare and includes afibrinogenemia (absent), hypofibrinogenemia (decreased), and dysfibrinogenemia (dysfunctional protein).
   A. Afibrinogenemia reported in a bichon frise was probably congenital and possibly hereditary (Wilkerson et al., 2005).
   B. Hypofibrinogenemia and dysfibrinogenemia have been reported rarely in purebred dogs, sometimes with an apparent autosomal heritability.

Pathophysiology and Clinical Signs

I. Severe decreases in functional fibrinogen impair clot formation and result in hemorrhage.
II. Affected dogs may have mild to severe mucocutaneous or cavitary hemorrhage including epistaxis and hemarthrosis.
III. Life-threatening hemorrhage may occur after accidental or surgical trauma.

Diagnosis and Differential Diagnosis

I. Fibrinogen deficiency is considered with unexplained prolongations of all tests with fibrin clot endpoints.
   A. These include PT, aPTT, ACT, and TT.
   B. Buccal mucosal bleeding time may also be prolonged.
II. Hereditary fibrinogen deficiencies must be differentiated from fibrinogen deficiency or reduced fibrin formation from other causes.
   A. These include liver failure, consumptive coagulation, coagulation inhibitors, and hyperfibrinogenolysis from certain venoms or drugs.
   B. Clinical history, serum biochemistry, urinalysis, ATIII, FDP, and D-dimer tests may be helpful in identifying these conditions.
      1. ATIII concentration may be decreased in liver failure and consumptive coagulation.
      2. FDP and D-dimer concentrations may be increased in liver failure, consumptive coagulation, and hyperfibrinolysis.
III. In contrast to routine assessment of fibrinogen activity by the TT test, fibrinogen antigen may be assessed by immunoassay to help differentiate dysfibrinogenemia (fibrinogen antigen detected) from decreased or absent fibrinogen (little or no fibrinogen antigen detected).

Treatment and Monitoring

I. Initial therapy is directed at expansion of circulatory volume, correction of anemia, and administration of fibrinogen (see Box 68-1).
II. Cryoprecipitate is preferable to plasma as a source of fibrinogen because it reduces the potential for volume

overload and, possibly, for transfusion reactions (Stokol and Parry, 1998).
III. With severe, acute bleeding, initial monitoring focuses on restoration of euvolemia, a return to physiological homeostasis, and cessation of hemorrhage (see Table 68-2).
IV. Familial testing and breeding recommendations may be indicated.

INHERITED/CONGENITAL MULTIPLE PATHWAY DEFICIENCY

Vitamin K–Dependent Multifactor Coagulopathy

Definition and Causes

I. Vitamin K–dependent multifactor coagulopathy is a rare congenital disorder reported in Devon Rex cats and possibly a Labrador retriever (Mason et al., 2002).
II. It is caused by abnormal vitamin K–dependent gamma-glutamyl carboxylase (Soute et al., 1992).
III. Factors II, VII, IX, and X are produced in hepatocytes and require reduced vitamin K as a cofactor for posttranslational enzymatic carboxylation.
   A. Carboxylation is required for the activated factors to bind calcium and adhere to phospholipid surfaces.
   B. Defective carboxylation results in decreased plasma concentrations of carboxylated Factors II, VII, IX, and X, thus mimicking vitamin K deficiency or antagonism.

Pathophysiology and Clinical Signs

I. The responsible genetic defect has not been reported, but autosomal recessive heritability is suspected.
II. Clinical signs in affected cats vary from none to a severe bleeding diathesis manifested primarily as body cavity hemorrhage and unexplained hematomas.
III. Excessive bleeding may occur after surgical or nonsurgical trauma.

Diagnosis and Differential Diagnosis

I. The condition is considered in Devon Rex cats and other animals when there are unexplained prolongations of PT, aPTT, and ACT.
II. These prolongations occur because the factors participate in the intrinsic (IX), extrinsic (VII), and common (II, X) pathways.
III. Specific factor analyses reveal decreased activity of Factors II, VII, IX, and X.
IV. Similar and much more common conditions that must be excluded include vitamin K antagonism or deficiency (see Vitamin K Antagonism).
V. Hepatic disease and consumptive coagulopathy must also be excluded.

Treatment and Monitoring

I. Initial therapy and monitoring are the same as for Factor XI deficiency.
II. The abnormal carboxylase has decreased binding affinity for reduced vitamin K, but vitamin K supplementation results in improved carboxylation and correction of coagulation times.
   A. Give vitamin K_1 (phytonadione) at 5 mg PO SID initially.
   B. Decrease dose after signs are controlled to the minimum dose that keeps PT and aPTT within reference limits and minimizes the chance of Heinz body anemia.
III. Lifelong therapy with vitamin K_1 may be necessary.
IV. Prolongation of PT and aPTT after cessation of vitamin K supplementation supports the diagnosis.

ACQUIRED COAGULOPATHIES

Vitamin K Antagonism

Definition and Causes

I. Vitamin K antagonism is usually caused by ingestion and absorption of hydroxycoumarins and indanediones that block hepatic carboxylation of vitamin K-dependent coagulation factors (Factors II, VII, IX, and X) and vitamin K–dependent anticoagulants (protein C and protein S).
II. Sulfaquinoxaline has a similar effect.
III. Vitamin K antagonism may occur as a result of intentional therapy with warfarin for thromboprophylaxis, but it more often occurs from ingestion of vitamin K–antagonist rodenticides (see Chapter 124) or human medications.
IV. Most intoxications involve long-acting hydroxycoumarins (brodifacoum and bromodiolone) and indanediones (diphacinone).
V. It is common in dogs and less common in cats.

Pathophysiology

I. The reduced form of vitamin K is a necessary cofactor for the enzyme that carboxylates vitamin K–dependent factors in hepatocytes.
II. Carboxylation allows the factors to bind free calcium and phospholipid so they can participate in coagulation after activation.
III. Reduced vitamin K is oxidized to vitamin K epoxide during carboxylation, requiring reduction by vitamin K epoxide reductase before again functioning as a carboxylase cofactor.
IV. Vitamin K antagonists inhibit the reduction of vitamin K epoxide, thus leading to a decrease in the reduced form of vitamin K and decreased production of functional Factors II, VII, IX, and X.
V. These poorly carboxylated and poorly functional factors are still produced and transported to blood, where they are known as *proteins induced by vitamin K antagonism* (PIVKA).
VI. Hemorrhagic tendencies are most often delayed until 3 to 7 days after ingestion when circulating concentrations of functional Factors II, VII, IX, and X are depleted.
VII. These factors have half-lives of about 6 to 40 hours.

Clinical Signs

I. Clinical signs are delayed and usually occur 3 to 7 days after exposure.

II. Hemorrhage may be obvious or occult.
III. Hemorrhage occurs at any location, but is most common into potential spaces (especially the pleural space) and the lungs.
IV. Signs of hypovolemic shock (pale mucous membranes, prolonged capillary refill time, tachycardia, weak pulses) and respiratory compromise (dyspnea, increased respiratory rate and effort) are common and often accompanied by lethargy and weakness.

Diagnosis

I. The diagnosis is suspected with a history of exposure and accompanying prolonged coagulation times or evidence of hemorrhage.
II. In animals with overt bleeding, prolonged PT and aPTT or ACT are expected because vitamin K–dependent factors participate in the intrinsic (Factor IX), extrinsic (Factor VII), and common (Factors X and II) pathways.
III. PT is expected to be prolonged before aPTT because Factor VII has the shortest half-life of the vitamin K–dependent factors; however, this is not always the case.
IV. A modified PT assay (Thrombotest; Axis-Shield PoC AS, Oslo, Norway) reported to be sensitive to PIVKA is often called a *PIVKA assay,* but it is not specific for PIVKA.
    A. It is not widely available.
    B. It may detect a mild or early anticoagulant-induced coagulopathy, and may help differentiate vitamin K-antagonism from other coagulopathies (Mount et al., 2003).
V. Analysis of whole blood or postmortem liver samples for vitamin K antagonists may yield a definitive diagnosis.
VI. Factor analysis is typically unnecessary, but deficiencies of vitamin K-dependent factors would be detected.

Differential Diagnosis

I. Other conditions that can have similar presentations and hemostatic findings include liver failure (see Hepatic-Associated Coagulopathy), consumptive coagulation in the coagulopathy phase, common pathway factor deficiencies, vitamin K dependent multifactor coagulopathy, and vitamin K deficiency.
II. Response to vitamin K_1 therapy is supportive of vitamin K antagonism, vitamin K–dependent multifactor coagulopathy, or vitamin K deficiency.

Treatment

I. If ingestion occurred within the last 5 hours and earlier ingestion was not possible, induce emesis, then give activated charcoal with sorbitol (2 to 5 g/kg PO or via orogastric tube), and start vitamin K_1 (phytonadione) at 1.25 to 2.5 mg/kg PO BID.
II. Similarly, if ingestion occurred 5 to 12 hours before and earlier ingestion was not possible, give activated charcoal with sorbitol and start vitamin K_1 as previously described.
III. If ingestion occurred within the last 12 hours and earlier ingestion was possible, measure the PT.
    A. If the PT is normal and there is no bleeding, treat based on the time intervals described previously (I and II).
    B. If the PT is prolonged, do not induce emesis or orogastrically intubate the animal, but give activated charcoal with sorbitol at 2 to 5 g/kg PO and initiate vitamin K_1 therapy.
IV. If clinical hemorrhage is present, PT, aPTT, and ACT should be prolonged.
    A. The animal may need treatment for hypovolemia, anemia, and the coagulopathy (see Box 68-1).
    B. Vitamin K_1 is given at 2.5 to 5 mg/kg SC with a small-gauge needle and continued orally at the same dose, when feasible.
V. Poorly tolerated pleural or pericardial hemorrhage may require thoracocentesis or pericardiocentesis, but these procedures should follow therapy for the coagulopathy whenever possible.

Monitoring of Animal

I. Most common anticoagulant rodenticides are long-acting and necessitate treatment for 2 to 6 weeks.
    A. Ingestion of warfarin may require treatment for only 1 week.
    B. Repeated measurement of PT is unnecessary once an animal is receiving an appropriate dose of vitamin K_1, unless there are concerns about its absorption.
II. PT is measured approximately 36 hours after withdrawing vitamin K therapy to assess for residual toxicity, and therapy is reinstituted for 1 to 2 weeks if PT is prolonged.

Vitamin K Deficiency (Hypovitaminosis K)

Definition and Causes

I. Vitamin K is a fat soluble vitamin that is obtained from the diet and from production by intestinal bacteria.
II. It is absorbed with lipid through the actions of lipase and bile acids.
III. Hypovitaminosis K may develop with prolonged obstructive cholestasis, prolonged anorexia, vitamin K–deficient diets, decreased production by intestinal bacteria (e.g., after antibiotics), intestinal malabsorptive disease, or exocrine pancreatic insufficiency.
IV. Cats with hepatic lipidosis, severe inflammatory bowel disease, and cholangiohepatitis may develop laboratory evidence of impaired coagulation (usually without apparent bleeding tendencies) correctible by vitamin K administration (Center et al., 2000).

Pathophysiology and Clinical Signs

I. Hypovitaminosis K results in impaired carboxylation of vitamin K–dependent coagulation factors (II, VII, IX, and X), despite normal activity of vitamin K–reducing enzymes.
II. The effects are similar to vitamin K–antagonism, but are typically milder and often discovered only by prolonged PT, aPTT, or modified PT (Thrombotest) test results.
III. Clinical signs are related to the underlying disease and the coagulopathy.

Diagnosis and Differential Diagnosis

I. Hypovitaminosis K is considered when there is clinical hemorrhage or prolonged PT, modified PT (Thrombotest), aPTT, and ACT values in association with predisposing conditions.
II. Vitamin K antagonism and its differential diagnoses must also be considered (see Vitamin K Antagonism).
III. Appropriate diagnostic testing is done to define the underlying disease.
IV. Correction of the coagulopathy with vitamin K_1 therapy is supportive of the diagnosis.

Treatment and Monitoring

I. The underlying disease is treated.
II. Vitamin K_1 (phytonadione) is administered at 1 to 5 mg/kg SC as needed, or orally if the animal is eating and does not have a malabsorptive or maldigestive disorder.
III. Plasma may be required for severe hemorrhaging or if invasive diagnostic or therapeutic measures, such as a liver biopsy or surgery, are planned.

Hepatic-Associated Coagulopathy

Definition and Causes

I. Liver disease may result in dysregulation of hemostasis.
  A. There may be quantitative or qualitative defects in the production of procoagulants, anticoagulants, profibrinolytics, and antifibrinolytics.
  B. Thrombocytopenia or thrombopathia may occur.
  C. Clearance of coagulation and fibrinolytic factors may be decreased.
II. The net result of dysregulation is often clinically silent despite abnormalities in hemostatic laboratory tests.
III. Causative liver diseases include severe acute hepatitis, hepatic necrosis, primary or metastatic hepatic neoplasia, cirrhosis, and portosystemic shunts.

Pathophysiology and Clinical Signs

I. Markedly decreased functional hepatic mass results in multiple coagulation factor deficiencies and sometimes production of dysfunctional factors owing to abnormal cellular processes, such as carboxylation of vitamin K–dependent factors.
II. If consumptive coagulation is initiated, thrombosis may occur and contribute to a subsequent coagulopathy.
III. Clinical signs reflect the hepatic disease and the coagulopathy.
IV. Bleeding may be mild to severe and either mucocutaneous or cavitary in location.

Diagnosis and Differential Diagnosis

I. Attributing a coagulopathy to hepatic disease requires a diagnosis of hepatic failure or insufficiency, and exclusion of other causes of the coagulopathy.
II. Hemostatic test abnormalities vary, and may include prolonged PT and/or aPTT values, decreased ATIII and fibrinogen concentrations (prolonged TT), and increased FDP concentrations.
  A. Thrombocytopenia may also be present.
  B. These findings may mimic consumptive coagulation.

Treatment and Monitoring

I. Initial therapy is directed at expansion of circulatory volume, correction of anemia, and administration of deficient coagulation factors (see Box 68-1).
II. If hemorrhage is secondary to decreased functional hepatic mass, vitamin K_1 does not correct the bleeding.
III. Concurrent management of the underlying hepatic condition is necessary, if possible.
IV. With severe, acute hemorrhage, initial monitoring focuses on restoration of euvolemia, a return to physiological homeostasis, and cessation of bleeding (see Table 68-2).
V. When invasive procedures are required, transfusions of plasma products may be indicated, although prolonged PT or aPTT do not appear to be good predictors of hemorrhagic complications associated with biopsy procedures in dogs and cats (Bigge et al., 2001).

Other Acquired Coagulopathic Disorders and Factors

See Table 68-3.

CONSUMPTIVE COAGULATION AND COAGULOPATHY

Definition and Causes

I. Consumptive coagulation is a localized or disseminated increase in coagulation that results in decreased concentrations of circulating hemostatic factors.
  A. Disseminated intravascular coagulation (DIC) is always secondary to an underlying condition causing excessive or unbalanced intravascular activation of coagulation.
    1. Severe trauma, burns, tissue necrosis
    2. Disseminated neoplasia
    3. Shock, heat stroke
    4. Endotoxemia, sepsis
    5. Pancreatitis
    6. Endothelial cell injury, vasculitis
    7. Hepatic disease
    8. Some envenomations
  B. Localized consumptive coagulation may occur with activation of coagulation in a single organ or tissue.
II. Consumptive coagulopathy and clinical hemorrhage follow consumptive coagulation because of the destruction and removal of procoagulant factors and from of increased FDP concentrations.

Pathophysiology

I. Mechanisms that may contribute to excessive coagulation include excessive thrombin generation, decreased anticoagulation, impaired fibrinolysis, and inflammation.
II. Excessive coagulation leads to the following changes, which may be mild to severe.
  A. Destruction of nonenzymatic cofactors (V and VIII) by activated protein C

TABLE 68-3

Other Acquired Coagulopathic Disorders and Factors

DISORDER	CAUSES	PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT
Dilutional coagulopathy	Massive transfusion of plasma-poor packed RBCs, crystalloids, or colloids after hemorrhage	Dilution of coagulation factor concentrations Exacerbated by concurrent decrease in platelet concentration and function	Hemorrhage Signs of underlying disease	Suggested by increased hemorrhage after massive plasma-poor fluid volume replacement	Supportive Fresh frozen plasma, as needed Treat underlying disease
Hypothermia	Exposure to cold	Depression of coagulation, increased fibrinolysis, and decreased platelet concentration and function	Hemorrhage and signs related to underlying disease	Routine coagulation assays are done at 37° C and do not identify this disorder	Warming measures Fresh frozen plasma as needed Treat underlying disease
Anticoagulant Factors					
Heparin	Exogenous heparin therapy Contamination during collection Mast cell neoplasia	Increased anticoagulant activity of ATIII	Rare hemorrhage, such as hematoma formation (Mischke RH et al., 2001)	Prolonged aPTT and ACT PT and ATIII may be decreased Poor response to plasma transfusion	Protamine sulfate if hemorrhage is life-threatening
Fibrin degradation products	Fibrinolysis from consumptive coagulation, some envenomations, or administration of fibrinolytic agents	Competitive inhibition of thrombin's interaction with fibrinogen, the polymerization of fibrin, and the aggregation of platelets	Hemorrhage and signs related to underlying disease	Markedly increased fibrin degradation products and D-dimer concentration PT, aPTT, and TT may be prolonged Poor response to plasma	Monitor for bleeding when administering fibrinolytics Treat supportively
Coagulation factor inhibitors	Systemic autoimmune diseases, posttransfusion in hemophiliacs, plasma cell neoplasia	Rare allo- or autoantibodies bind to coagulation factors and decrease their activity	Hemorrhage and signs related to underlying disease	Coagulation studies Factor analysis Poor response to plasma transfusion	Supportive Fresh frozen plasma as needed Treat underlying disease
Lupus anticoagulants	Rare antibodies to phospholipids and proteins Not always associated with lupus erythematosus	Antibodies act as in vitro but not in vivo inhibitors of coagulation by binding to phospholipids Mechanism of in vivo thrombosis is unclear	Associated with thrombosis and signs related to underlying disease	Assay for lupus anticoagulants Poor response to plasma transfusion	Supportive Fresh frozen plasma as needed Treat underlying disease

RBCs, Red blood cells; *ATIII,* antithrombin III; *aPTT,* activated prothrombin time; *ACT,* activated clotting time; *PT,* prothrombin time; *TT,* thrombin time.

B. Clearance of activated coagulation enzymes by antiproteases and ATIII
C. Consumption of fibrinogen in the formation of fibrin
D. Consumption of platelets via thrombin activation
E. Impaired platelet function and fibrin formation caused by increased FDPs from fibrinolysis
F. Erythrocyte fragmentation from intravascular trauma (microangiopathic fragmentation)

Clinical Signs

I. Clinical signs vary from absent to severe, depending on the stage and underlying condition.
II. Signs usually reflect depletion of coagulation factors, and include circulatory collapse and widespread cavitary and surface bleeding.
III. Signs of thrombosis may occur in prothrombotic stages and vary with the affected organs.

Diagnosis and Differential Diagnosis

I. Definitive diagnosis is difficult to obtain and requires multiple tests.
II. Diagnosis is usually based on the presence of multiple hemostatic abnormalities in conjunction with a disorder known to be associated with consumptive coagulation.
III. Expected laboratory abnormalities include thrombocytopenia, prolonged PT and aPTT, increased D-dimer or FDP concentrations, decreased ATIII concentration and activity, or trends toward these abnormalities over serial measurements.
IV. Increased production of fibrinogen, a positive acute-phase protein, often masks its consumption.
V. It must be differentiated from liver failure, vitamin K antagonism, thrombotic thrombocytopenic purpura, afibrinogenemia, and mixed hemostatic disorders.

Treatment and Monitoring

I. The therapeutic approach varies with the underlying disorder, the severity of the hemostatic abnormalities, and the current equilibrium of prothrombotic and antithrombotic processes.
II. Treat the underlying condition and institute supportive therapies.
III. In the bleeding animal, treatment of coagulation abnormalities, hypovolemia, and anemia is indicated (see Box 68-1).
   A. Fresh frozen plasma helps to replace coagulation factors and inhibitors.
   B. Platelet concentrates may be helpful with severe thrombocytopenia (see Chapter 67).
IV. Use of heparin remains controversial, but low-dose heparin (75 U/kg SC TID) may be useful in animals with predominantly thrombotic tendencies.
V. Laboratory abnormalities in the absence of clinical signs may not necessitate treatment unless invasive diagnostic or therapeutic interventions are required.
VI. Prognosis varies from good to poor and depends on the success of treatment for the underlying disease process and on prevention of life-threatening hemorrhage.

THROMBOSIS

Definition and Causes

I. Inherited prothrombotic conditions have not been described in dogs and cats, but many acquired disorders and conditions may contribute to thrombosis.
II. Most notable of the acquired conditions is ATIII deficiency, which may occur from ATIII loss (protein-losing nephropathy/enteropathy or blood loss), consumption (consumptive coagulation or heparin therapy), or decreased production by the liver.
III. Additional acquired disorders that are associated with thrombosis include the following:
   A. Endocarditis, vasculitis
   B. Intravascular catheterization, injections of chemical irritant solutions such as hyperosmolar medications (e.g., dextrose, hypertonic saline), total parenteral nutrition
   C. Congestive heart failure, valvular insufficiency, vascular defects, feline cardiomyopathy
   D. Malignant neoplasia: some carcinomas, possibly hemangiosarcoma
   E. Surgery, trauma
   F. Immune-mediated hemolytic anemia
   G. Sepsis, parvoviral infection
   H. Hypothyroidism, hyperadrenocorticism
   I. Antiphospholipid/protein antibodies, including lupus anticoagulants (See Table 68-3)

Pathophysiology

I. Mechanisms responsible vary with the disorder and are often multifactorial or incompletely known.
II. They include vascular damage, altered blood flow, upregulated mediators of coagulation, decreased concentrations of endogenous anticoagulants, decreased fibrinolysis, platelet hyperaggregability, or a combination of these.

Clinical Signs

I. Clinical signs of thrombosis depend on the site of thrombus formation.
II. Arterial thrombus formation most commonly occurs in the terminal aorta, leading to pain, decreased pulse pressure and quality, cool extremities, decreased sensory and motor function, hyporeflexia, firm gastrocnemius muscles, and cyanotic nailbeds that may fail to bleed when cut.
III. Pulmonary arterial thrombus formation or thromboembolism most often manifests as hypoxemia that is not easily attributed to other common causes.
   A. It may be clinically silent or associated with severe dyspnea.
   B. Evidence of right-sided heart failure may be present.
IV. Signs of venous thrombosis vary with the site.
   A. Cranial vena cava: edema of the head and possibly the forelimbs
   B. Portal vein: portal hypertension, vomiting, diarrhea, peritoneal transudate

Diagnosis

I. Appropriate diagnostic tests depend on the suspected underlying disorders.
II. Common laboratory test results include decreased ATIII activity, thrombocytopenia, and increased concentrations of FDPs and D-dimers; however, increased fibrinogen production may mask its consumption (Nelson and Andreasen, 2003).
III. Other tests specific to the site of thrombus formation may be necessary for a diagnosis.
  A. Pulmonary thromboembolism (PTE)
    1. Arterial blood gas analysis frequently documents hypoxemia and hypocapnia, although findings are not specific for PTE.
    2. Thoracic radiography is useful to exclude other causes of respiratory distress, but findings are nonspecific and include truncation or pruning of lobar pulmonary arteries, oligemia, low volumes of pleural effusion, and variable pulmonary infiltrates.
    3. Selective pulmonary arterial angiography or helical computed tomographic (CT) angiography are currently the most sensitive and specific diagnostic methods for PTE in dogs and cats.
  B. Aortic thromboembolism or systemic arterial thromboembolism
    1. Diagnosis is most often based on physical examination findings, but additional findings may be supportive or confirmatory.
    2. Ultrasonic Doppler may be used to confirm absence of blood flow through an affected artery, using the contralateral limb for comparison if a single limb is affected.
    3. Color flow Doppler is useful to visualize the length and location of thrombi, with more mature thrombi appearing more hyperechoic.
    4. In limbs with decreased blood flow, blood lactate concentrations may be increased and blood glucose concentrations may be decreased compared with values for glucose and lactate in the systemic circulation.
    5. Selective angiography or helical CT angiography can be used to detect the presence or absence of blood flow in systemic arteries.
    6. Thrombosis of specific organs may result in specific laboratory abnormalities, such as azotemia with bilateral renal thrombosis.
  C. Cranial vena cava and portal vein thrombosis
    1. Ultrasonography may be used to visualize flow or the presence of a filling defect in the cranial vena cava or portal vein.
    2. Selective angiography or helical CT angiography may provide a definitive diagnosis of thrombosis of the cranial vena cava or portal vein.
    3. Animals with portal vein thrombosis and secondary portal hypertension are commonly critically ill, with ascites (transudate) and signs of gastrointestinal compromise (vomiting, diarrhea).

Differential Diagnosis

I. PTE
  A. Other causes of respiratory distress: pneumonia, congestive heart failure
  B. Pleural cavity diseases: pneumothorax, pleural effusion
II. Aortic or systemic arterial thromboembolism
  A. Any generalized compromise of perfusion or mechanical/extravascular vessel compression of the vessel
  B. Neurological and musculoskeletal conditions of the extremities
III. Cranial vena cava thrombosis
  A. Intravascular or extravascular mediastinal neoplasia
  B. Decreased oncotic pressure, retention of sodium and water
IV. Portal vein thrombosis
  A. Extravascular or intravascular neoplastic obstruction of the portal vein
  B. Various protein-losing enteropathies, gastrointestinal lymphoma, lymphangiectasia

Treatment

I. Institute treatment for the underlying disease process.
II. Heparin potentiates the activity of ATIII and is the most common thromboprophylactic agent used for non–life-threatening arterial and venous thrombosis/thromboembolism.
  A. Do not administer heparin to animals that already have evidence of spontaneous hemorrhage or are scheduled to undergo invasive diagnostic or therapeutic procedures.
  B. Heparin may result in hemorrhage, so monitor animals receiving heparin for clinical and laboratory evidence of bleeding.
  C. Many dosing regimens have been reported, but the following are recommended:
    1. Cats require lower heparin dosages than dogs.
    2. Use continuous rate infusion (50 to 200 U/kg IV bolus followed by 10 to 50 U/kg/hr IV) for sustained anticoagulation in animals with known thrombosis or at very high risk of thrombosis.
    3. To prevent thrombosis and enlargement of current thrombi, give heparin at 100 to 200 U/kg SC QID or 200 to 300 U/kg SC TID.
  D. Unfractionated heparin and LMWH have decreased anticoagulant effects during ATIII deficiency, but may still provide desirable effects with little toxicity.
  E. LMWH may allow less frequent dosing and a more predictable effect than unfractionated heparin once dosing and monitoring protocols become established.
    1. In dogs, give dalteparin at 150 U/kg SC BID.
    2. In cats, give dalteparin at 100 to 150 U/kg SC BID, but note there is a significant interindividual variation in anti-Xa Factor activity in cats receiving LMWH.
III. Coumadin has a delayed onset of action and is difficult to titrate to effect, so it is rarely used in dogs and cats.

IV. Platelet inhibitors may be useful to control thrombosis, particularly arterial thrombosis.
   A. Aspirin may be used at 0.5 mg/kg PO BID in dogs and 6 to 10 mg/kg PO every 2 to 3 days in cats.
   B. Clopidogrel, a platelet ADP receptor inhibitor that inhibits platelet aggregation, is well tolerated in cats at 18.75 mg PO SID, but its efficacy is unknown.
V. Fibrinolytic (thrombolytic) agents, such as streptokinase and tissue plasminogen activator, are reserved for acute life-threatening thrombosis/thromboembolic disease, because they are very expensive and require intensive monitoring.
VI. With ATIII deficiency, ATIII may be partially replaced via fresh frozen plasma transfusions at 10 to 15 mL/kg IV BID (Rozanski et al., 2001).

Monitoring of Animal

I. Goals of therapy vary with the situation.
   A. For animals that are at risk of thrombosis or thromboembolism, the goal is to prevent thrombus formation and thromboemboli.
   B. For animals with non–life-threatening thrombosis, the goal is to prevent enlargement of thrombi while allowing the normal fibrinolytic pathways to gradually break down the thrombi.
   C. The primary goal for animals with life-threatening thrombosis/thromboembolism is to restore blood flow via thrombolysis with thrombolytic agents.
II. Monitor animals receiving heparin with aPTT testing.
   A. The target aPTT is 1.5 to 2.5 times healthy control or baseline values.
   B. Assess aPTT 6 to 8 hours after initiating therapy and SID thereafter.
III. Animals receiving antiplatelet drugs or LMWH are often not monitored.
IV. Long-term prognosis is related to the underlying disease process, and short-term prognosis is related to the location and duration of thrombosis.
   A. With aortic and systemic arterial thromboembolism, the prognosis is fair to good for restoration of blood flow to affected organs.
   B. The prognosis is poor if PTE is extensive enough to cause severe dyspnea.
   C. With cranial vena cava thrombosis, prognosis is good for restoration of blood flow and resolution of clinical signs, with successful thrombolytic therapy.
   D. Prognosis is poor for portal vein thrombosis because of prolonged venous congestion of the splanchnic circulation, secondary bacterial translocation, and sepsis.
   E. Prognosis is good for partial thrombosis if only partial thrombosis is present and thrombolysis is successful.

CHAPTER 69

Diseases of Lymph Nodes and Lymphatics

Jennifer S. Thomas

CONGENITAL DISORDERS

Primary Lymphedema

Definition and Causes

I. Accumulation of interstitial fluid secondary to developmental abnormalities of the lymphatic system
II. Cause often idiopathic but congenital forms suspected in some dog breeds

Pathophysiology

I. Morphological and functional abnormalities
  A. Aplasia or hypoplasia of the lymphatic vessels or valvular incompetence
  B. Lymph node fibrosis or decreased lymph node size and number
II. Superficial lymphatics more commonly affected than deep or muscular lymphatics

Clinical Signs

I. Pitting edema is usually present at birth or within the first few months of life.
  A. Transient or permanent
  B. Pelvic limbs most commonly affected, often bilateral
  C. Generalized form less common and may involve limbs, trunk, head, and tail
II. Severity of edema varies from mild to severe.
  A. Pitting edema
    1. Edema is painless, not cool or warm to touch, and not affected by rest or massage.
    2. Animal is usually not lame unless there is severe enlargement of a limb.
    3. Activity and growth are normal.
    4. Affected area is at risk for trauma, infection, secondary inflammation, pain, ulceration, or drainage.
  B. Induration and fibrosis with long-standing edema
III. Regional lymph nodes may be normal, small, or absent.

Diagnosis

I. Often young animal with no history of trauma, surgery, neoplasia, or infection
II. Tests for underlying cause of edema (either lymphatic or venous in origin)
  A. Results of complete blood count (CBC), biochemical profile, and urinalysis are usually normal unless edema is complicated by secondary infection or inflammation.
  B. Diagnostic imaging (radiography, ultrasonography) of abdominal and thoracic cavities may be performed to rule out secondary causes of edema.
III. Fine-needle aspirate (FNA) of edematous swelling for cytological examination
  A. Poorly cellular transudate if uncomplicated
  B. Increased numbers of neutrophils, macrophages, or both if secondary inflammation or infection present
IV. Radiographic lymphangiography often diagnostic (Fossum et al., 1992)
  A. May demonstrate lymph node aplasia
  B. May show lymphatics that end blindly or do not empty into lymph node
V. Surgical biopsy and histological examination of tissue to rule out secondary causes of edema

Differential Diagnosis

I. Secondary lymphedema
II. Other causes of edema
  A. Vascular disorders: obstruction, arteriovenous fistula, vasculitis, thrombosis
  B. Hypoproteinemia
  C. Impaired venous return from congestive heart failure or portal hypertension

Treatment

I. Mild cases require no treatment.
II. Conservative management is tried initially.
  A. Pressure bandages or splints to limit fluid accumulation and encourage lymphatic flow
  B. Topical skin care as needed
  C. Long-term diuretic therapy contraindicated
III. Surgical management can be undertaken if conservative management is ineffective.
  A. Enhance lymphatic drainage: lymphangioplasty, bridging procedures, lymphatic to vein (lymphaticovenous) shunts, superficial to deep lymphatic anastomosis
  B. Excision of affected tissue

Monitoring of Animal

I. Prognosis is guarded for resolution of edema, although some cases spontaneously regress.

II. Severe generalized forms are usually lethal within the first few weeks of life.
III. The condition is not usually life-threatening if animals survive the neonatal period.

ACQUIRED DISORDERS

Lymph Node Atrophy

Definition and Causes

I. Lymph node atrophy is the loss of lymphoreticular cells in lymph nodes.
II. Acquired forms are more common than hereditary forms.
  A. Viral infections: feline immunodeficiency virus (FIV), feline leukemia virus (FeLV), parvovirus, canine distemper virus
  B. Advanced age and/or senility
  C. Severe malnutrition or cachexia
  D. Immunosuppressive or cytotoxic drugs: corticosteroids, chemotherapeutic agents
  E. Environmental toxins or radiation
III. Immunocompromise, with increased susceptibility to infections, is a common sequela.

Clinical Signs

I. Often associated with secondary chronic or recurrent infections
II. Systemic signs: weight loss, poor development, fever, lethargy, anorexia

Diagnosis

I. History of recurrent or unresponsive infections
II. Microbial culture to identify infectious agents
III. CBC and biochemical profile
  A. Possible lymphopenia
  B. Possible hypoglobulinemia
IV. FeLV and FIV testing in cats
V. Surgical biopsy and histological examination of lymphoid tissue to confirm atrophy

Treatment and Monitoring

I. Identify and treat underlying cause of acquired immunocompromise.
II. Administer appropriate antimicrobial therapy for secondary infections.
III. Provide supportive care and proper nutrition to support regeneration of lymphoid tissue.
IV. The efficacy of immunostimulants has not been proven in dogs and cats.
V. Prognosis depends on the degree of immunocompromise and the underlying cause.

Secondary Lymphedema

Definition and Causes

I. Secondary lymphedema is accumulation of interstitial fluid from acquired abnormalities of lymphatic system.
II. It is caused by destruction or occlusion of lymphatic vessels, lymph nodes, or both.
  A. Surgical excision or trauma
  B. Lymphangitis/lymphadenitis
  C. Compression or invasion by space-occupying mass (e.g., neoplasm)
  D. Radiation

Pathophysiology

I. The severity of lymphedema is determined by collateral circulation, interlymphatic and lymphaticovenous anastomoses, perilymphatic drainage of fluid, and venous fluid uptake.
II. Affected animals are at risk for infections, abrasions, and fibrosis.

Clinical Signs

I. Pitting edema of tissue, with extent depending on location and severity of lymphatic damage
  A. Edema is often localized to the periphery of the limb.
  B. Intrapelvic or sublumbar lesions cause edema of external genitalia and hind limbs.
  C. Mediastinal lesions cause edema of forelimbs, ventral thorax, neck, and head.
II. Clinical signs related to underlying disorder: weight loss, fever, anorexia

Diagnosis

I. Note history of previous surgery, trauma, infection, or neoplasia.
II. Search for underlying inflammatory, infectious, or neoplastic processes.
  A. CBC, biochemical profile, and urinalysis
  B. Radiography and/or ultrasonography of affected region for masses or destructive lesions
  C. Regional lymph node palpation, including rectal examination if pelvic limbs affected
  D. FNA of edematous tissue, enlarged lymph nodes, or masses for cytological evaluation
    1. Microscopically evaluate for inflammatory cells, organisms, or neoplastic cells.
    2. Fluid is a poorly cellular transudate unless complicated by infection or inflammation.
  E. Surgical biopsy of any affected tissue for histologic examination and microbial culture
III. Consider lymphangiography.
  A. Lymphatics are often enlarged and tortuous.
  B. Lymph nodes with inflammatory or neoplastic foci are often enlarged with filling defects.

Differential Diagnosis

I. Primary lymphedema
II. Nonlymphatic causes of edema, as listed under Primary Lymphedema

Treatment

I. Identify and treat underlying disorder.
  A. Long-term, antimicrobial therapy if secondary to infection

B. Surgical excision, chemotherapy, and radiation therapy if associated with neoplasia

II. Postsurgical or posttraumatic lymphedema may respond to short-term, antiinflammatory drugs (e.g., prednisone), diuretics, bandaging, or physical therapy.

III. If the underlying disorder cannot be resolved, treatment options include conservative medical and surgical management, as discussed under Primary Lymphedema.

Monitoring of Animal

I. Prognosis depends on the underlying disorder.

II. No treatment is required if lymphedema is mild, self-limiting, or localized.

Lymphangitis

Definition and Causes

I. Inflammation of lymphatic vessels

II. Usually secondary to drainage of inflammatory agents and by-products from an underlying inflammatory disorder (often involving skin, mucous membranes, or subcutaneous tissues)
   A. Infection: bacteria, fungi
   B. Neoplasia
   C. Trauma, chronic irritation or foreign body
   D. Immune-mediated disorder

III. May result in secondary lymphedema

Clinical Signs

I. Systemic clinical signs associated with underlying disorder: fever, depression, anorexia

II. Affected area swollen, warm, painful
   A. Lameness if involving a limb
   B. May ulcerate through overlying skin

III. Possible enlargement of regional lymph nodes from hyperplasia or lymphadenitis

Diagnosis

I. Clinical signs and history inconsistent with primary lymphedema

II. Cytological and histological examination: neoplastic cells, inflammatory cells, or infectious agents

III. Microbial culture for identification of infectious agent

IV. Contrast radiographs and surgical exploration for foreign body, abscesses, or fistulous tracts

Differential Diagnosis

I. Primary or secondary lymphedema

II. Nonlymphatic causes of edema

Treatment

I. Treat the underlying cause.
   A. Local and systemic antimicrobial therapy for infection
   B. Surgical exploration for foreign bodies, fistulous tracts, or abscesses
   C. Immunosuppressive therapy if immune-mediated disease detected
   D. Surgical excision, chemotherapy, and radiation therapy if neoplasia diagnosed

II. Apply warm, moist compresses or soaks to promote drainage.

Monitoring of Animal

I. Prognosis depends on the underlying disorder and is generally good for infections if appropriate antimicrobial therapy is instituted.

II. Fibroplasia and irreversible thickening of tissue may occur if chronic lymphedema develops.

Nonneoplastic Lymph Node Enlargement

Definition

I. Lymphadenopathy commonly refers to lymph node enlargement for any reason (hyperplasia, inflammation, primary or secondary neoplasia).

II. Lymphadenitis refers to an influx of inflammatory cells (neutrophils, eosinophils, or macrophages) into lymph nodes, often secondary to the drainage of by-products or infectious agents from a distant site of inflammation.

III. *Hyperplasia* (also called *reactive hyperplasia*) refers to increased numbers of lymphocytes, plasma cells, or macrophages in lymph nodes in response to antigenic stimulation.

Causes

I. Suppurative lymphadenitis
   A. Localized or systemic infections: bacteria, fungi
   B. Rapidly enlarging neoplasm
   C. Infarction
   D. Immune-mediated disorder

II. Pyogranulomatous or granulomatous lymphadenitis
   A. Fungal infection: histoplasmosis, blastomycosis, cryptococcosis, coccidioidomycosis
   B. Chronic or complex bacterial infection
   C. Chronic immune-mediated disorder
   D. Foreign body reaction
   E. Protozoal infection: toxoplasmosis, leishmaniasis
   F. Algal infection: protothecosis

III. Eosinophilic lymphadenitis
   A. Parasitism
   B. Allergic disorders
   C. Eosinophilic granuloma complex
   D. Some types of neoplasia: mast cell tumor, lymphoma
   E. Other infections: pythiosis

IV. Hyperplasia
   A. Systemic or localized infection
      1. Rickettsial infection: ehrlichiosis
      2. Viral infection: FIV, FeLV
      3. Bacterial infection
      4. Fungal infection
   B. Immune-mediated disorders or postvaccination
   C. Any source of chronic antigenic stimulation: neoplastic or inflammatory disorders

V. Idiopathic syndromes in cats (Couto et al., 2000)
   A. Generalized lymphadenopathy in young cats (1 to 4 years)

1. Some features of lymphoma were present on histological examination.
2. Lymphadenopathy spontaneously regressed in 5 to 120 days.
3. Cats were negative for FeLV antigen.

B. Distinctive peripheral lymph node hyperplasia in young cats (5 months to 2 years)
1. Generalized lymphadenopathy regressed in some cats.
2. Some cats were asymptomatic; others had fever, lethargy, anorexia.
3. Many cats were FeLV positive.
4. Histological findings resembled experimental FeLV infection in cats.

C. Plexiform vascularization of lymph nodes of unknown cause
1. Solitary cervical or inguinal lymphadenopathy in adult cats (most asymptomatic)
2. Histological findings: tissue replaced by plexiform proliferation of vascular channels
3. Surgical excision: curative, although lymphedema a possible sequela

Clinical Signs

I. Lymph node enlargement
A. Hyperplasia: usually nonpainful, firm, not warm, no adhesion to surrounding tissue
B. Lymphadenitis: often painful, soft, warm, ± adhesion to surrounding tissue
C. May cause obstruction or compression of adjacent tissues
1. Mandibular or retropharyngeal lymph nodes: dysphagia
2. Mediastinal or cervical lymph nodes: precaval syndrome or dyspnea
3. Thoracic lymph nodes: respiratory difficulties or pleural effusion
4. Sublumbar lymph nodes: tenesmus

II. Clinical signs associated with underlying diseases

Diagnosis

I. Look for an underlying disorder.
A. CBC: inflammatory leukogram (neutrophilia, left shift, monocytosis)
B. Biochemical profile: hyperglobulinemia, hypercalcemia rarely with granulomatous disease
C. Bone marrow examination: organisms with some systemic infections

II. Perform diagnostic imaging (radiography, ultrasonography) to identify involvement of thoracic and abdominal lymph nodes, liver, or spleen.

III. Lymph node cytology of FNA is often diagnostic.
A. Hyperplasia
1. Heterogeneous cell population with small lymphocytes predominating
2. ± Relative increase in medium and large lymphocytes, plasma cells, and macrophages
3. Few neutrophils, eosinophils, or mast cells

B. Lymphadenitis
1. Increased neutrophils (>5% of nucleated cells), eosinophils (>3% of nucleated cells), or macrophages (>2% of nucleated cells) (Duncan, 1999)
2. Often concurrent hyperplasia
3. May identify etiologic agent

IV. Lymph node biopsy with histologic examination is recommended if results of FNA are equivocal.
A. Core biopsy: sample size often too small for adequate assessment of architecture
B. Wedge biopsy: used if unable to remove entire node
C. Excisional biopsy: best sample to assess architecture
D. Special stains to identify organisms: fungi, bacteria, parasites, protozoa

V. Identify underlying infections.
A. Serological testing for certain infectious agents
B. Microbial culture of tissue sample

Differential Diagnosis

I. Lymphoma
II. Metastatic neoplasia

Treatment

I. Treat underlying disorder.
II. Surgical excision or drainage may be helpful for abscessed or fistulated lymph nodes.

Monitoring of Animal

I. Prognosis depends on the underlying disorder.
II. Resolution is expected with removal of antigenic or inflammatory stimuli.
III. Repeat surgical biopsy or FNA of lymph nodes if lymphadenopathy persists, because it may be difficult to differentiate severe hyperplasia from lymphoma, especially in cats.

NEOPLASTIC DISORDERS

Lymphangioma

Definition and Cause

I. Rare benign proliferation of lymphatic vessels
II. Cause unknown

Clinical Signs

I. Reported sites: subcutaneous tissue (most common), mediastinum, retroperitoneal space, mesentery, urinary bladder, liver, kidney, tongue, spleen, oral cavity, and nasopharynx
II. Poorly circumscribed, fluctuant masses with fluid-filled spaces lined by endothelial cells
III. Often incidental finding but may compress surrounding structures and alter function
IV. Possible leakage of lymphatic fluid onto skin through draining tracts

Diagnosis

I. Definitive diagnosis requires surgical excision and histological examination of tissue.

II. Cytological examination often reveals a poorly cellular transudate with variable protein concentration.

Differential Diagnosis

I. Lymphangiosarcoma or other neoplasm
II. Space-occupying, nonneoplastic masses: abscess or cysts
III. Lymphatic disorders: lymphedema, lymphangitis

Treatment and Monitoring

I. Surgical excision is the treatment of choice if complete removal is possible.
II. Recurrence is common because of difficulty in identifying tumor boundaries.

Lymphangiosarcoma

Definition and Cause

I. Rare malignant proliferation of endothelial cells lining lymphatic vessels
II. Cause unknown but medium- to large-breed dogs at greater risk

Clinical Signs

I. Primary site often subcutaneous tissue on extremities or ventral abdomen
II. Depends on site of primary tumor or metastases
   A. Pitting edema of affected region
   B. Chylous effusions (pleural, peritoneal, or subcutaneous spaces) in some cases
III. Poorly circumscribed, soft, fluctuant mass on palpation

Diagnosis

I. Cytological examination of FNA shows pleomorphic mesenchymal cells suggestive of sarcoma.
II. Surgical biopsy and histological examination of tissue are required for definitive diagnosis.
III. Look for evidence of metastasis.
   A. Examination of draining lymph nodes
   B. Diagnostic imaging (radiography, ultrasonography) of thoracic and abdominal cavities

Differential Diagnosis

I. Other soft-tissue sarcomas: hemangiosarcoma, fibrosarcoma, hemangiopericytoma
II. Lymphangioma

Treatment

I. Surgical excision if possible
II. Efficacy of radiation therapy and chemotherapy not determined in cats and dogs

Monitoring of Animal

I. Complete surgical excision of the neoplasm is difficult and the local recurrence rate is high.
II. The neoplasm tends to exhibit rapid local invasion, with frequent distant metastasis.

Lymphoma

Definition

I. Proliferation of malignant lymphoid cells originating outside of bone marrow and primarily affecting lymph nodes or visceral organs (e.g., liver, spleen, kidney)
II. Most common hematopoietic tumor in dogs and cats
III. Also known as *malignant lymphoma* or *lymphosarcoma*

Causes

I. Associated directly with FeLV or indirectly with FIV infection in cats (Louwerens et al., 2005)
II. No clear association with viral infection in dogs (Vail and Thamm, 2005)
III. Possible association with exposure to tobacco smoke in cats (Louwerens et al., 2005)
IV. Possible association with herbicides, magnetic fields, or environmental pollutants in dogs (Vail and Thamm, 2005)
V. Possible genetic predisposition (Louwerens et al., 2005; Modiano et al., 2005)

Classification

I. Anatomic site
   A. Distribution in dogs (Vail and Thamm, 2005)
      1. Most common: multicentric (80% to 85% of all cases)
      2. Less common: alimentary (7%), cutaneous (6%), mediastinal (3%), and other extranodal sites (<1%)
   B. Distribution in cats
      1. Distribution changing as prevalence of FeLV infection decreases; currently <15% of cats with lymphoma are FeLV positive (Louwerens et al., 2005)
      2. Distribution and FeLV association (Vail and Thamm, 2005)
         a. Multicentric: 10% to 25% of cases (approximately one third FeLV positive)
         b. Mediastinal/thymic: 10% to 20% of cases (majority FeLV positive)
         c. Alimentary: 50% to 70% of cases (few FeLV positive)
         d. Nasal: 10% of cases (few FeLV positive)
         e. Renal: 5% to 10% of cases (few to moderate FeLV positive)
         f. Other: 5% to 25% of cases (variable FeLV status)
      3. Feline Hodgkin's-like lymphoma (Walton and Hendrick, 2001)
         a. Majority of cats present with unilateral mandibular or cervical lymphadenomegaly.
         b. Preliminary study suggests it may be less aggressive than non-Hodgkin's lymphoma.
II. World Health Organization (WHO) clinical stage (Box 69-1)
III. Histological and cytological appearance (e.g., Kiel, National Cancer Institute Working Formulation)
   A. Lymphomas are graded based on architecture (diffuse, follicular), mitotic index, and cellular morphology (size, nuclear shape, chromatin density, nucleolar features).

Box 69-1

World Health Organization Clinical Stages for Lymphoma

Stage*	Clinical Findings
I	Involvement of single lymph node or lymphoid tissue in single organ (except bone marrow)
II	Involvement of multiple, regional lymph nodes
III	Generalized lymph node involvement
IV	Liver and/or spleen involvement, with or without lymph node involvement
V	Bone marrow or blood involvement and/or other organ systems

*Each stage is subdivided into (a) no systemic signs of disease and (b) systemic signs of disease.

B. They are divided into low, intermediate, and high grades.
   1. In dogs, approximately 75% of lymphomas are considered high grade (Fournel-Fleury et al.,1997).
   2. In cats, 54% of lymphomas are considered high grade, 35% medium grade, and 11% low grade (Valli et al., 2000).

IV. Immunophenotype
   A. Dogs (Modiano et al., 2005)
      1. Majority B cell: range 55% to 82%, average 67%
      2. Fewer T cell: range 18% to 42%, average 27%
      3. Occasional (4%) null cell or biphenotypic
   B. Cats (Valli and Thamm, 2005)
      1. Majority are B-cell tumors.
      2. Prevalence of T-cell lymphomas varies according to anatomical location (common in alimentary and mediastinal/thymic sites) and FeLV status (majority of lymphomas in FeLV-positive cats are T cell).

Clinical Signs

I. Signalment is as follows:
   A. Dogs (Modiano et al., 2005)
      1. Usually middle-aged to older: >90% are >5 years old, range <1 to >15 years old
      2. Numerous breeds affected
   B. Cats (Louwerens et al., 2005)
      1. Median age 11 years: range <1 to >20 years old
      2. Occurs in young cats if associated with FeLV infection
      3. Occurs in middle-aged to older cats if FeLV negative
      4. Numerous breeds affected
      5. High incidence of mediastinal lymphoma in Siamese-type breeds

II. Clinical signs depend on site(s) affected.
   A. Clinically ill (WHO substage b) (MacDonald et al., 2005; Rassnick et al., 2002; Vail and Thamm, 2005)
      1. Dogs: 10% to 44%
      2. Cats: >75%
   B. Multicentric
      1. Lymphadenopathy (WHO stage II or III) ± hepatosplenomegaly (WHO stage IV)
      2. Nonspecific findings: lethargy, inappetence, weight loss
      3. Polyuria/polydipsia if hypercalcemic
   C. Bone marrow involvement (WHO stage V)
      1. Cytopenia in blood if significant involvement
      2. Nonregenerative anemia, hemorrhagic diathesis from thrombocytopenia, or sepsis from neutropenia
   D. Alimentary
      1. Gastrointestinal involvement, with or without intra-abdominal lymphadenopathy
      2. Vomiting, diarrhea, or both (± melena)
      3. Inappetence, weight loss, depression
   E. Mediastinal
      1. Includes mediastinal lymph nodes, sternal lymph nodes, or thymus
      2. Dyspnea or coughing; muffled heart sounds from pleural effusion
      3. Pitting edema of thoracic limbs, face, and neck if invasion or compression of vena cava
      4. Polyuria/polydipsia if hypercalcemic
   F. Cutaneous
      1. Single to multiple lesions anywhere on skin or in oral cavity with possible pruritus
      2. Vary from erythematous scales, plaques, nodules, or serpiginous branching tracts
   G. Miscellaneous extranodal: variable presentation
      1. Spinal cord: limb paresis, ataxia
      2. Intracranial: ataxia, circling, blindness, seizures
      3. Renal: polyuria/polydipsia, weight loss, large irregular kidneys
      4. Nasal: sneezing, nasal discharge, exophthalmos, facial deformity
      5. Ocular: uveitis, hyphema, hypopyon, epiphora, blepharospasm, third eyelid infiltration

Diagnosis

I. Physical examination
   A. Palpate all accessible lymph nodes (including rectal and abdominal palpation).
   B. Palpate the liver, spleen, kidneys, mesentery, and intestines for enlargement or thickening.
   C. Auscultate the thorax in dogs and cats and perform thoracic compression in cats.
   D. Check the mucous membranes for anemia and petechiae.
   E. Perform an ocular (including funduscopic) examination.

II. CBC
   A. Anemia
      1. Nonregenerative anemia of chronic disease (most common) or if bone marrow infiltration by neoplastic cells
      2. Regenerative if blood loss or hemolysis
   B. Thrombocytopenia if bone marrow infiltration by neoplastic cells, immune-mediated destruction, splenic sequestration, or disseminated intravascular coagulation

C. Neutropenia from bone marrow infiltration or neutrophilia from inflammation
D. Lymphopenia or lymphocytosis: circulating atypical lymphocytes suggestive of bone marrow involvement (WHO stage V)

III. Bone marrow aspirate or core biopsy
A. Important for clinical staging: presence of neoplastic lymphocytes
B. Useful if lymphoma suspected but not identified elsewhere

IV. Biochemistry abnormalities
A. Hypercalcemia (Baskin et al., 2000; Vail and Thamm 2005)
1. Identified in 10% to 20% of all dogs with lymphoma.
2. Identified in approximately 40% of dogs with mediastinal involvement.
B. Azotemia (increased blood urea nitrogen or creatinine concentrations): renal infiltration, hypercalcemic nephropathy or dehydration
C. Increased liver enzyme activity and bilirubin concentration: hepatic infiltration
D. Hypoproteinemia secondary to alimentary lymphoma and protein-losing enteropathy
E. Monoclonal gammopathy occasionally with B-cell lymphoma

V. FeLV and FIV testing in cats

VI. Diagnostic imaging important for diagnosis and clinical staging
A. Options: radiography, ultrasonography, computed tomography, spinal myelography
B. Thoracic abnormalities: pulmonary infiltrates, thoracic or mediastinal lymphadenopathy, pleural effusion
C. Abdominal abnormalities: enlargement of sublumbar or mesenteric lymph nodes, organomegaly (e.g., liver, spleen, kidney), intestinal infiltration, abdominal effusion

VII. Cytological examination of FNA
A. Lymph nodes
1. There is usually a predominance of a homogeneous population of immature lymphocytes (Duncan, 1999).
a. Presence of >50% immature cells (medium and large lymphocytes) is suggestive of lymphoma.
b. Increased number of mitotic figures, tingible-body macrophages, cytoplasmic fragments, or cellular pleomorphism may also be found.
c. Lymphomas with mixed cellularity are easily missed.
2. Small-cell lymphomas are difficult to diagnose using cytology.
a. Absence of medium and large lymphocytes and plasma cells is suggestive.
b. Often surgical biopsy and histological examination is required for diagnosis.
3. Severe reactive hyperplasia may be confused with neoplasia (particularly in cats).
4. Cytological examination is diagnostic in a majority of lymphomas.
B. Fluid cytology: pleural, peritoneal, cerebrospinal fluid
C. Other organs if affected: liver, spleen, kidney, nasal mass, eye, dermal mass
D. Immunocytochemistry to phenotype cells: prognostic significance in dogs

VIII. Histological examination of tissue required if cytological findings equivocal
A. Excisional biopsy preferred: allows thorough evaluation of architecture and invasiveness
B. Various histochemical and immunohistochemical stains to characterize cells
1. Immunophenotyping: B cell, T cell, null (non-B, non-T cell), biphenotypic (coexpression of B- and T-cell markers)
2. Assessment of tumor proliferation rates, multidrug resistance expression, and apoptosis (Lee et al., 1996; Kiupel et al., 1999; Rassnick et al., 1999; Vail and Thamm, 2005)

IX. Additional diagnostic assays
A. Flow cytometry to phenotype cells (Wilkerson et al., 2005)
B. Detection of clonal rearrangement of immunoglobulin and T-cell receptor genes (Burnett et al., 2003)

Differential Diagnosis

I. Generalized lymphadenopathy
A. Hyperplasia, lymphadenitis, or both
B. Other hematopoietic (e.g., leukemia, histiocytic sarcoma) or metastatic neoplasms

II. Alimentary
A. Lymphoplasmacytic enteritis or other inflammatory bowel disorders
B. Nonlymphoid intestinal neoplasms

III. Cutaneous
A. Dermatitis: infectious or immune-mediated disorders
B. Other cutaneous neoplasms

IV. Mediastinal
A. Other neoplasms: thymoma, chemodectoma, ectopic thyroid tumor
B. Granulomatous/pyogranulomatous inflammatory disorders (e.g., systemic fungi)

Treatment and Monitoring

I. Options
A. Systemic chemotherapy is recommended in most cases.
B. Local surgery or radiation therapy may be used for solitary or extranodal lymphoma.
1. Systemic lymphoma is likely to develop months to years later at which time systemic chemotherapy is required.
2. Radiation therapy is most effective for nasal lymphoma.

II. Systemic chemotherapy in dogs
A. Combination chemotherapy usually results in longer disease-free intervals and survival periods than with single-agent protocols.

TABLE 69-1

Examples of Chemotherapeutic Induction Protocols for Dogs with Lymphoma

REFERENCE	DRUG PROTOCOL*	REMISSION RATE (CR/PR)	MEDIAN DURATION OF FIRST CR	MEDIAN SURVIVAL PERIOD
Khanna et al., 1998	PRED 40 mg/m^2 PO SID DOX 30 mg/m^2 IV: wk 3, 6, 9 VCR 0.65 mg/m^2/wk IV: wk 2, 4, 5, 8, 10, 11, 12 CTX 50 mg/m^2 PO (days 4-7): wk 2, 5, 8, 11, 12 L-ASP 20,000 IU/m^2 SC: wk 1	79%/8%	309 days	519 days
Boyce et al., 2000	PRED 20 mg/m^2 PO SID for 1 wk then QOD for 7 wk DOX 30 mg/m^2 IV: wk 6, 9, 12 VCR 0.5 mg/m^2 IV: wk 1, 2, 3, 4, 5, 7, 8, 10, 11, 12 CTX 50 mg/m^2 PO QOD for 8 wk L-ASP 10,000 IU/m^2 SC: wk 1, 2	80%/12%	36 wk CR, 4 wk PR	40 wk CR, 12 wk PR
Jeffreys at al., 2005	PRED 20 mg/m^2 PO BID; repeat for 6 wk VCR 0.7 mg/m^2 IV day 1; repeat for 6 wk CTX 50 mg/m^2 PO days 4, 5, 6, 7; repeat for 6 wk L-ASP 10,000 IU/m^2 SC day 2; wk 1, 2	79%/2%	25 weeks	NR
MacDonald et al., 2005	PRED 2 mg/kg PO SID for 1 wk, then 1.5 mg/kg PO SID for 1 wk, then 1.0 mg/kg PO SID for 1 wk, then 0.5 mg/kg PO QOD for 1 wk L-ASP 400 U/kg SC: wk 1 VCR 0.5-0.7 mg/m^2 IV: wk 1, 3, 6, 8, 11, 13, 16, 18 CTX 250 mg/m^2 IV: wk 2, 7, 12, 17 DOX 30 mg/m^2 IV: wk 4, 9, 14, 19	83%/6%	206 days	310 days
Carter et al., 1987	DOX 30 mg/m^2/wk IV every 3 wk for total of 5-8 treatments	76%/NR	206 days	270 days

CR, Complete remission; *PR,* partial remission; *PRED,* prednisone; *DOX,* doxorubicin; *VCR,* vincristine; *CTX,* cyclophosphamide; *L-ASP,* L-asparaginase; *NR,* not reported.

*Unless stated otherwise, drug given on day 1 of indicated week.

1. A number of protocols are available, with no clear optimal protocol (Table 69-1).
2. Complex protocols tend to provide the longest remission and survival times but are more expensive, require greater owner commitment, and have more toxic side effects.
3. Most complex protocols are modified protocols that include cyclophosphamide (C), doxorubicin (hydroxydaunorubicin [H]), vincristine (Oncovin [O]), and prednisone (P), (i.e., CHOP protocols).
4. L-asparaginase is frequently added but its effect on outcome is debated (Jeffreys et al., 2005; MacDonald et al., 2005).
5. Treatment generally starts with an induction phase (drugs administered weekly) followed by maintenance phases (drugs given less frequently, longer drug-free intervals).
6. Remission rates, duration of remission, and long-term survival rates depend on the presence or absence of factors known to affect prognosis (see Box 69-2).

B. Single-drug protocols are not ideal.
   1. Doxorubicin is the most effective single chemotherapeutic agent (see Table 69-1).
   2. Prednisone (2 mg/kg/day PO) alone often extends life 1 to 2 months; however, remission and survival times are shorter if additional chemotherapy is subsequently initiated.

III. Systemic chemotherapy in cats
   A. It generally induces lower remission rates, remission durations, and survival times than in dogs, but a significant percentage (30% to 40%) of cats that go into complete remission live longer lives (Vail and Thamm, 2005).
   B. Combination protocols are more effective than single-agent chemotherapy (Table 69-2).
   C. Doxorubicin is not effective as a single chemotherapeutic drug (see Table 69-2) but, when following a combination protocol, may prolong remission and survival rates (Kristal et al., 2001; Vail and Thamm, 2005).

IV. Monitoring during chemotherapy
   A. Frequency and severity of side effects depend on the protocol used.

Box 69-2

Factors Reported to Affect Prognosis in Dogs and Cats with Lymphoma

Factor	Effect
WHO clinical stage	Poorer prognosis for stage V with significant bone marrow involvement in dogs
WHO substage	Substage b associated with poorer prognosis in dogs and cats
Immunophenotype	T-cell origin: shorter remission and survival times in dogs; not shown to be predictive of outcome in cats
Histologic grade	Study results variable: not predictive of outcome in some studies, significant prognostic differences between subtypes in other studies Animals with low-grade tumors may live longer
Proliferation activity markers	Study results variable AgNORs assessment in tissue predictive of survival time in dogs in some but not all studies PCNA and AgNORs not predictive of outcome in cats
P-glycoprotein expression	Expression negative predictor of overall survival in dogs
FeLV positive	Shorter remission and survival times in cats
History of chronic inflammatory disorders	Shorter remission times in dogs
Hypercalcemia	Shorter survival times in dogs, possibly from T-cell association
Initial response to chemotherapy	Positive prognostic indicator in dogs and cats

WHO, World Health Organization; *AgNORs,* argyrophilic nucleolar organizer regions; *PCNA,* proliferation cell nuclear antigen; *FeLV, feline* leukemia virus.

1. Quality of life is considered acceptable in most animals.
2. Side effects include the following:
   a. Gastrointestinal disorders: vomiting, diarrhea, anorexia
   b. Leukopenia, thrombocytopenia, or both
   c. Cardiotoxicity: associated with doxorubicin
   d. Renal toxicity: associated with doxorubicin in cats
   e. Miscellaneous: hemorrhagic cystitis (associated with cyclophosphamide), fever, neurologic signs (e.g., psychosis, pelvic weakness), allergic reactions, alopecia

B. Perform a CBC before administering chemotherapeutic drugs, and alter protocol if significant thrombocytopenia or neutropenia is detected.
   1. For drugs that alter hematopoiesis, discontinue use for 5 to 7 days.
   2. After blood cell counts increase, give drugs at a decreased dose or frequency.

C. Monitor for organ damage associated with specific chemotherapeutic drugs.

D. Recheck monthly to detect recurrence.

E. Cytological examination of FNA is more effective than physical examination alone to determine remission status (Williams et al., 2005).

V. Rescue chemotherapy

A. Initiate once lymphoma recurs after remission or if initial chemotherapeutic protocol fails.
   1. Often more drug-resistant lymphoma
   2. Remission rates of 25% to 50%, with median remission periods of 1.5 to 2 months (Vail and Thamm, 2005)

B. First administer the chemotherapeutic protocol that caused the initial remission.

C. If there is no response, then initiate rescue protocols that use drugs not included in the initial induction protocol.
   1. Dogs: actinomycin D; mitoxantrone; doxorubicin with dacarbazine; combined mechlorethamine, vincristine, procarbazine, and prednisone (MOPP); cisplatin with cytosine arabinoside; lomustine (CCNU); dexamethasone, melphalan, actinomycin D, and cytosine arabinoside (D-MAC) (Kitchell and Dhaliwal, 2000; Rassnick et al., 2002; Vail and Thamm, 2005)
   2. Cats: mitoxantrone, doxorubicin, MOPP (Vail and Thamm, 2005)

VI. Extranodal lymphoma

A. Central nervous system involvement
   1. Add cytosine arabinoside (penetrates blood-brain barrier) to standard protocols.
   2. Consider radiation therapy.

B. Cutaneous forms
   1. Surgical excision or radiation therapy if solitary
   2. Systemic chemotherapy if multifocal
      a. Generally poorer response to chemotherapy than multicentric lymphoma
      b. Appropriate chemotherapeutic drugs (singly or in combination): vitamin A analogs (e.g., cis-retinoic acid), L-asparaginase, dacarbazine, CCNU, CHOP protocols (Vail and Thamm, 2005; Williams et al., 2006)

VII. Adjunctive or experimental therapies

A. Total-body or half-body radiotherapy (Williams et al., 2004)

B. Dietary modification: n-3 fatty acid supplementation (Ogilvie et al., 2000)

C. Experimental techniques: immunomodulation (e.g., tumor specific antibodies), stimulation of apoptosis, and limitation of development of multidrug resistance

VIII. Prognosis dependent on a number of factors (Box 69-2)

TABLE 69-2

Examples of Chemotherapeutic Induction Protocols for Cats with Lymphoma

REFERENCE	DRUG PROTOCOL*	REMISSION RATE (CR/PR)	MEDIAN REMISSION DURATION (CR/PR)	MEDIAN SURVIVAL PERIOD (CR/PR)
Mooney et al., 1989	PRED 2 mg/kg PO SID VCR 0.025 mg/ kg IV: wk 1, 3, 5, 7 CTX 10 mg/kg IV: wk 2, 6 L-ASP 400 IU/kg IP: wk 1 MTX 0.8 mg/kg IV: wk 4, 8	62%/20%	NR/NR	7 mo/2.5 mo

CHAPTER 70

Disorders of the Spleen

William L. Spangler

SPLENOMEGALY

Definition

I. Splenomegaly describes any enlargement of the spleen.
II. With uniform or symmetrical splenomegaly, the basic shape of the enlarged spleen is retained.
III. In nodular or mixed splenomegaly, one or more distinct nodules occurs within normal or congested splenic parenchyma, or in a background of generally expanded reticular tissue.

Causes and Pathophysiology

I. Uniform and/or symmetrical splenomegaly
  A. Congestive splenomegaly occurs when the flow of blood through the red pulp and vessels is impeded.
    1. Anesthetic agents or tranquilizers cause increased pooling of blood in the red pulp via relaxation of smooth muscle.
    2. Splenic torsion can occur alone or in association with gastric dilation-volvulus.
    3. Splenic arterial thrombosis from torsion of the splenic pedicle occurs spontaneously and results in focal areas of infarction or larger areas of ischemia in the spleen.
    4. Congestion may arise secondary to portal hypertension from right-sided congestive heart failure, obstruction of the caudal vena cava or portal vein, and increased intrahepatic vascular resistance (cirrhosis, hepatitis, lipidosis).
  B. Hyperplastic (reactive) splenomegaly results from the following:
    1. Immunological stimulation: increased volume and accumulation of lymphocytes, plasma cells, and macrophages
    2. Associated with certain diseases
      a. Systemic immune-mediated diseases: systemic lupus erythematosus
      b. Bacterial infections: canine brucellosis, bacterial endocarditis, mycobacterial infections, Lyme borreliosis
      c. Hemolytic anemias: immune-mediated, Heinz body, hemobartonellosis, pyruvate kinase deficiency
      d. Rickettsial infections: canine ehrlichiosis, Rocky Mountain spotted fever
      e. Protozoal infections: babesiosis, leishmaniasis, trypanosomiasis, cytauxzoonosis, toxoplasmosis
      f. Other infections: histoplasmosis, feline infectious peritonitis
      g. Myeloid metaplasia or hypersplenism
  C. Extramedullary hematopoiesis, although common in aging dogs, is seldom responsible for splenomegaly.
II. Nodular and/or mixed splenomegaly: nonneoplastic causes
  A. Nodular hyperplasia and hematoma formation
    1. Self-limiting nodular hyperplasia and hematoma formation are the most common causes in dogs.
      a. They account for 53% of canine splenectomies (Table 70-1).
      b. Similar lesions occur in cats but are less prevalent (see Table 70-1).
    2. Nodular hyperplasia (single or multiple nodules) consists of lymphoid cells, hematopoietic cells, and plasma cells.
    3. Disruption of the microvascular circulation in the marginal zone of lymphoid follicles results in hematoma formation.
    4. Nodular hyperplasia is usually self-limiting, but progressive enlargement of nodules results from sporadic bleeding episodes.
    5. Rupture of a large hematoma may account for significant blood loss.
    6. The mean age for dogs with hyperplastic nodule-related splenectomy is 11 years (Spangler and Kass, 1997).
  B. Splenic abscess
    1. Rare in dogs; not reported in cats
    2. Common isolate: *Staphylococcus* spp. (Spangler and Kass, 1997)
III. Nodular and/or mixed splenomegaly: neoplastic causes
  A. Benign neoplasms of dogs and cats (see Table 70-1)
    1. Lipoma and myelolipoma
    2. Hemangioma, leiomyoma, or both
    3. Plasmacytosis
  B. Malignant neoplasms of dogs: 31% of splenomegaly cases (see Table 70-1)
    1. Hemangiosarcoma (HSA)
      a. It is the most common splenic malignancy in dogs (18%) (Spangler and Kass, 1997).
      b. Mean age is 11 years.

TABLE 70-1

Relative Prevalence of Splenic Diseases in Dogs and Cats

SPLENIC DISORDER	PREVALENCE IN DOGS*	PREVALENCE IN CATS†
Nodular hyperplasia, hematoma	53%	9%
Hemangiosarcoma	18%	6%
Splenic sarcomas (fibrosarcoma, osteosarcoma, myxosarcoma, leiomyosarcoma, liposarcoma, undifferentiated sarcoma)	8%	4%
Splenic torsion, arterial thrombosis	5%	—
Splenic infarction alone	—	2%
Lymphosarcoma	4%	18%
Mastocytosis	<1%	30%
Myeloid, lymphoid, and/or reticuloendothelial hyperplasia	3%	1%
Myeloproliferative disease	<1%	13%
Miscellaneous benign neoplasms (e.g., fibroma, leiomyoma, lipoma)	3%	2%
Metastatic neoplasms	1%	4%
Malignant histiocytosis	1%	—
Plasma cell myeloma	<1%	2%
Splenic abscess	<1%	—
Nonspecific splenitis	—	4%
Mycobacterial splenitis	<1%	—
Amyloidosis	<1%	<1%
Accessory spleen‡	—	3%

*Combined and edited data from 1,429 splenectomies (Spangler WL, Culbertson MR: The prevalence, type and importance of canine splenic diseases [a diagnostic survey]. J Am Vet Med Assoc 200:829, 1992; Spangler WL, Kass PH: Pathologic factors affecting postsplenectomy survival in dogs. J Vet Intern Med 11:166, 1997).

†Combined and edited data from 217 splenectomies (Spangler WL, Culbertson MR: The prevalence and type of splenic diseases in cats: 455 cases [1985-1991]. J Am Vet Med Assoc 201:773, 1992).

‡Not associated with splenomegaly; an incidental surgical finding of dark, red islands of splenic tissue in the parenchyma of the pancreas or adjacent omentum.

   c. Neoplastic proliferation often activates coagulation and fibrinolysis sequence, resulting in systemic disseminated intravascular coagulation (DIC), and liquid blood-filled spaces within the spleen.
   d. Sometimes, vascular spaces filled with clotted blood cannot be distinguished (grossly) from a hematoma of nodular hyperplasia.
2. Lymphosarcoma (LSA): 4.9% of splenomegaly cases (Spangler and Kass, 1997)
3. Primary mesenchymal (nonangiomatous/nonlymphomatous) tumors of the dog
   a. Fibrosarcoma
   b. Undifferentiated sarcoma
   c. Leiomyosarcoma
   d. Osteosarcoma
   e. Myxosarcoma
   f. Histiocytic sarcoma
   g. Liposarcoma
   h. Malignant fibrous histiocytoma.
4. Fibrohistiocytic nodules (malignant fibrous histiocytoma): transitional nodular splenomegaly ranging from benign to malignant in behavior
5. Mast cell tumor, mastocytosis
   a. Most dogs with systemic mastocytosis and splenic involvement also have primary cutaneous mast cell tumors, of which 77% are grade III (O'Keefe et al., 1987).
   b. There is no breed or gender predilection; the mean age is 9.5 years.
6. Myeloproliferative diseases (see Chapter 66): splenomegaly and proliferation of neoplastic myeloid cells common

C. Malignant neoplasms of cats: 75% of splenomegaly cases (Spangler and Culbertson, 1992a)
1. Mastocytosis
   a. The most common cause of splenomegaly (30%), also reflects systemic mast cell disease
   b. Uniformly symmetric enlargement of the spleen with characteristic speckled, orange color
2. LSA (see Chapter 69)
   a. LSA is a major cause, accounting for 18% of splenic enlargement in cats and 5% in dogs (Spangler and Culbertson, 1992a, b).
   b. Splenomegaly is part of a multiorgan systemic disease.
3. Myeloproliferative disorders (see Chapter 66): splenomegaly common component
4. Hemangiosarcoma
   a. Minor cause of splenomegaly (8%)
   b. Usually life-threatening

D. Myeloid metaplasia, hypersplenism, histiocytosis of dogs
1. These are histologically distinctive causes of splenomegaly.

2. Changes range from reactive splenitis associated with immunological damage of red blood cells (RBCs) (hypersplenism) to neoplastic proliferation of histiocytic components (hemophagocytic histiocytic sarcoma).

Clinical Signs

I. Signalment
   A. Clinical signs are not generally helpful in differentiating splenic hematoma or hyperplastic nodules from neoplasms.
   B. Dogs in both groups have a mean age of 9 to 10 years, are medium- to large-breed dogs (e.g., German Shepherds, Labrador and golden retrievers), and are evenly distributed relative to gender.
   C. Dogs with myeloid metaplasia, splenic torsion, or splenic abscess are younger (6 to 7 years), and show no breed or gender predilection.

II. Nonspecific signs attributable to splenomegaly
   A. Abdominal distention, ± discomfort
   B. Malaise, lethargy, depression
   C. Decreased appetite, weight loss
   D. Polyuria, polydipsia
   E. Cardiac arrhythmias in approximately 30% of cases of nodular splenomegaly (Keyes et al., 1993)

III. Signs associated with splenic torsion and HSA
   A. Collapse, shock, ± vomiting, abdominal pain, pale mucous membranes, ± tense painful abdomen
   B. Splenic torsions: rapid onset and progression, massively enlarged spleen
   C. HSA: episodic weakness and collapse, sometimes with apparent recovery, hemoabdomen

IV. Clinical signs associated with systemic mastocytosis
   A. Affected cats often have gastrointestinal signs (e.g., vomiting, diarrhea, and bleeding) caused by histamine release.
   B. Although this type of mastocytoma is rare in dogs, signs are similar.

V. Signs associated with myeloid metaplasia, hypersplenism, malignant histiocytosis, and LSA
   A. Fever, lethargy, and anorexia
   B. Lymphadenopathy and hepatomegaly

VI. Signs suggestive of histiocytosis in Bernese mountain dogs
   A. Respiratory signs: cough, dyspnea, and abnormal lung sounds
   B. Weakness, pallor from anemia, thrombocytopenia

Diagnosis

I. History
   A. No specific historical attributes
   B. Nonspecific historical signs: lethargy, abdominal discomfort, decrease in stamina, malaise

II. Physical examination
   A. Splenomegaly is detected by palpation of a mass in the cranial abdomen.
   B. Free blood may be detected in the abdomen.
   C. Pallor from anemia or shock may be noted.

III. Hematology and serum biochemistry results
   A. Biochemistry profiles and complete blood counts are essential.
   B. Anemia, thrombocytopenia, leukopenia, reticulocytosis, and any combination of cytopenias are nonspecific findings in animals with splenic disease.
   C. Erythrocyte morphological abnormalities that reflect blood flow through an abnormal spleen include acanthocytes, nucleated or fragmented RBCs, normocytic target cells, increased numbers of Howell-Jolly bodies, schistocytes, and keratocytes.
   D. Spherocytes, Heinz bodies, and erythroparasites, as well as positive direct Coombs' test, antinuclear antibody, and rheumatoid factor assays are associated with hemolysis and splenic hyperplasia resulting from systemic disease.
   E. Circulating neoplastic leukocytes suggest secondary or primary splenic involvement in such diseases as LSA, acute leukemia, chronic leukemia, and systemic mastocytosis (see Chapters 66 and 69).
   F. Hypercalcemia suggests LSA or multiple myeloma.
   G. Hyperglobulinemia is associated with chronic inflammatory disease or lymphoid (myeloma) neoplasia (see Chapter 77).
   H. Hypoproteinemia and hypoalbuminemia may be noted in dogs with malignant histiocytosis.

IV. Bone marrow evaluation
   A. Examination of marrow aspirates is indicated in refractory anemia with splenomegaly.
   B. Potential findings include the following:
      1. Hemolymphatic neoplasms
      2. Excess macrophages and RBC phagocytosis in marrow that is inactive or depleted
         a. Myeloid metaplasia
         b. Hemophagocytic syndrome or hemophagocytic histiocytic sarcoma
         c. Immune-mediated hemolytic anemia
      3. Erythroid hyperplasia with hemolytic anemias
      4. Granulocytic hyperplasia possible with inflammatory disorders

V. Radiography and ultrasonography
   A. The size and location of the spleen are assessed by plain radiography unless abdominal effusion obscures detail.
   B. Congestive enlargement is expected in anesthetized or sedated animals.
   C. Patterns suggestive of splenic torsion include the following:
      1. Identification of the spleen in an abnormal location
      2. Displacement of other organs
      3. C-shaped spleen folded over on itself
      4. Gas bubbles in the spleen from gas-forming bacteria multiplying in ischemic areas
   D. Three views of the thorax are indicated to look for possible metastases and pleural effusion.
   E. Ultrasonography of the abdomen is essential.
      1. Ultrasonography is more sensitive in the diagnosis of LSA and HSA than plain radiography because it identifies masses and patterns compatible with neoplasia.

2. HSA produces a nonhomogeneous echogenic pattern with hypoechoic blood-filled spaces and hyperechoic solid tissue.
3. Ultrasonography provides a method for guiding fine-needle aspirates of the spleen.
4. An abdominal ultrasound in any aging dog should include detailed evaluation of the spleen.

VI. Cytology of fine-needle aspirates
- A. Cytology is most useful when a diagnosis or additional information is sought before abdominal surgery, when the spleen is diffusely affected, or in animals in which the spleen is only marginally enlarged.
- B. It is contraindicated if HSA is suspected, if coagulation abnormalities exist, or if the spleen cannot be immobilized.

VII. Exploratory laparotomy
- A. Indicated when less invasive procedures are nondiagnostic.
- B. First correct severe anemia or any existing coagulopathy.
- C. It allows assessment and biopsy of other organs for evidence of involvement.
- D. It permits intraoperative cytological evaluation of splenic tissue or splenectomy.

Treatment

I. Medical therapy of the underlying disease
- A. Chemotherapy for hemolymphatic neoplasms
- B. Appropriate antimicrobial therapy for infectious diseases
- C. Immunosuppressive therapy for immune-mediated diseases

II. Indications for splenectomy
- A. Splenomegaly
  1. Abdominal exploration and splenectomy are often the primary diagnostic and treatment methods when splenomegaly is discovered.
  2. Splenectomy is the treatment of choice for splenomegaly in many dogs and cats, especially if the underlying cause is refractory to medical therapy.
- B. Splenic torsion
- C. Splenic masses
  1. Gross appearance does not reliably distinguish hematoma or a hyperplastic nodule from HSA.
  2. Cytological evaluation of tissue imprints, histologic evaluation of splenic tissue, or both are needed to reliably distinguish benign versus malignant disease.
  3. Perform total splenectomy, unless an intraoperative diagnosis of benign disease is assured.
  4. Submit the entire spleen for pathologic evaluation.
- D. Mastocytoma
  1. Splenectomy significantly extends life expectancy in cats with mastocytosis.
  2. Splenectomy is beneficial in removing a large portion of the tumor cell burden.
- E. Splenic rupture regardless of the underlying disease
- F. Immune-mediated hemolytic anemia or thrombocytopenia that is recurrent or refractory to drug therapy
- G. Adjunctive procedure to chemotherapy for LSA
  1. Alleviation of signs of massive splenomegaly (if present) before chemotherapy
  2. Progressive splenomegaly despite chemotherapy

III. Preoperative care
- A. Stabilize animals in shock with IV fluids (for correction of acid-base balance), corticosteroids, antibiotics, whole-blood transfusions or packed RBCs, and treatment for DIC.
- B. With mastocytosis, minimize the effects of mast cell degranulation with preoperative antihistamines and histamine$_2$ receptor antagonists.

IV. Consequences of splenomegaly
- A. No higher incidence of infectious disease occurs in splenectomized dogs, except when they are exposed to erythroparasites.
- B. Splenectomized animals are more susceptible to infection when immunosuppressed and are more easily immunosuppressed.

Monitoring of Animal

I. Effective medical therapy of the underlying disorder results in reduction of splenic size, and resolution of clinical signs and laboratory abnormalities.

II. Following splenectomy, animals must be monitored carefully for several days.
- A. Monitor for recurrent abdominal hemorrhage or effusion, and coagulation abnormalities.
- B. Monitor electrocardiogram for ventricular arrhythmias.

III. Prognosis for specific splenic disorders is as follows:
- A. Splenic torsion
  1. The prognosis depends heavily on elapsed time between torsion and splenectomy.
  2. Expected mortality in the postsplenectomy interval is up to 50% (Stevenson et al., 1981).
- B. Hyperplastic nodule/hematoma (Spangler and Kass, 1997)
  1. The prognosis is good.
  2. Eighty-five percent of animals survive splenectomy, 65% are alive at the end of the first year, and 70% of those dying in the first year do so from unrelated causes.
- C. HSA (Spangler and Kass, 1997)
  1. The prognosis for splenic HSA is guarded.
  2. Expect 90% mortality in the 7 months after splenectomy.
  3. Early detection and splenectomy provide the longest survival times.
  4. Survival time in dogs is significantly improved (12 to 35 months) when a single nodule (rather than multiple nodules) of HSA is present.
- D. LSA (Spangler and Kass, 1997)
  1. Splenomegaly arising solely from nodular enlargements of neoplastic lymphoid tissue
     a. The prognosis is favorable.
     b. Expect 28% to 30% mortality within 6 months and mean survival of 8.4 months postsplenectomy.

2. Uniformly enlarged spleen from lymphocyte infiltration with regional nodular formations
   a. The prognosis is poor.
   b. Expect up to 90% mortality in the 6 months after splenectomy and mean survival of 2.8 months.

E. Nonangiomatous/nonlymphomatous sarcomas (Spangler et al., 1994)
1. With the exception of splenic mesenchymoma (median survival 12 months), dogs with all other types of sarcomas have a median survival time of 4 months, with 80% to 100% mortality in 12 months.
2. Prognosis for this class of splenic neoplasms is most closely correlated with the mitotic index (Spangler et al., 1994).

F. Myeloid metaplasia, hypersplenism, histiocytosis (Spangler and Kass, 1999)
1. Postoperative 12-month survival in dogs is 30%.
2. About 50% have multiorgan involvement at time of splenectomy or develop it shortly thereafter.
3. Hemophagocytic histiocytic sarcoma, as a distinct neoplastic entity within the broad category of splenic myeloid metaplasia, is a major cause of mortality for this category of splenic disease (Moore et al., in press).

G. Benign neoplasms (lipoma, myelolipoma, hemangioma): good prognosis

H. Fibrohistiocytic nodules, malignant fibrous histiocytoma
1. The prognosis is dependent on histological grading of the nodule (Spangler and Kass, 1998).
2. Grade I and II nodules have a 12-month survival of 87% (good prognosis).
3. Grade III nodules have a 12-month survival of 45% (guarded prognosis).

I. Mastocytosis (O'Keefe et al., 1987)
1. The prognosis is guarded because 88% of dogs die as a direct result of the neoplasm.
2. Mean survival time is 3 months.

CHAPTER 71

Transfusion Medicine

K. Jane Wardrop

GENERAL CONSIDERATIONS

Definition

I. Transfusion medicine is a multidisciplinary science concerned with the proper use of blood or blood products in the treatment or prevention of disease.

II. Optimal transfusion therapy requires knowledge of blood types and crossmatching procedures, blood sources and donor selection, blood collection and administration techniques, component therapy, transfusion reactions, and red blood cell (RBC) substitutes.

Canine and Feline Blood Types

I. Erythrocytes possess characteristic cell-surface glycolipid or glycoprotein antigens.
   A. A blood group system is a group of antigens produced by allelic genes located at a single locus and inherited independently of any other genes. Blood group systems are species specific.
   B. Animals commonly make antibodies against foreign blood group antigens. Naturally occurring alloantibodies may be a result of exposure to common environmental antigens that are similar or identical to foreign blood group antigens.
   C. The importance of any particular blood group system depends on both the frequency with which alloantibodies of the system occur and the characteristics of the alloantibody, such as titer, class, temperature-dependent activity, and ability to activate complement or agglutinate RBCs.

II. Canine blood groups have the following characteristics:
   A. Current nomenclature uses the prefix dog erythrocyte antigen (DEA) to describe canine blood types.
      1. Antibodies or typing sera for some of the originally identified canine blood groups are no longer available, and commercial typing sera currently test for six blood types in dogs (DEA 1.1, 1.2, 3, 4, 5, and 7).
      2. Several of these blood types can occur together on the erythrocyte and may vary in frequency with breed, geographic location, and antisera used (Table 71-1) (Bull, 1976; Giger et al., 1995; Hale, 1995).
   B. DEA 1 is a four-allele system.
      1. Dogs can be DEA 1 negative, DEA 1.1 positive or DEA 1.2 positive.
      2. DEA 1.3 also has been described in Australia (Symons and Bell, 1991).
      3. Naturally occurring antibody to DEA 1 is not present.
         a. Transfusion of DEA 1-positive blood into a DEA 1-negative recipient will result in anti-DEA 1 alloantibody synthesis and shortened lifespan of the transfused erythrocytes.
         b. Subsequent transfusions mismatched at that allele will result in an acute hemolytic transfusion reaction.
   C. DEA 3 and 5 are present in low incidence, and naturally occurring antibody to these antigens can occur (Swisher et al., 1962; Hale, 1995).
   D. DEA 4 is a high-incidence antigen with no naturally occurring antibody. A hemolytic transfusion reaction has been described in a DEA 4-negative dog given repeated transfusions of DEA 4-positive blood (Melzer et al., 2003).
   E. DEA 7 is a soluble nonerythroid antigen that is adsorbed onto the RBC surface (Bull et al., 1975), and dogs that are negative for DEA 7 may have naturally occurring anti-DEA 7 alloantibodies (Bull, 1990; Hale, 1995).

TABLE 71-1

Canine Blood Type Frequencies

DEA	FREQUENCY (%)
1.1	33 to 45
1.2	7 to 20
3	6 to 10
4	87 to 98
5	12 to 23
7	8 to 45

From Bull RW: Canine immunohematology. In Animal Models of Thrombosis and Hemorrhagic Diseases. Washington, DC, US Dept. of Health, Education, and Welfare Publication No. 76-982, 1976; Giger U, Gelens CJ, Callan MB et al: An acute hemolytic transfusion reaction caused by dog erythrocyte antigen 1.1 incompatibility in a previously sensitized dog. J Am Vet Med Assoc 206:1358, 1995.

DEA, Dog erythrocyte antigen.

F. Canine blood donors should be DEA 1.1 and 1.2 negative if their blood is to be used with type-unmatched recipients. Dogs that are 1.1 positive can be used with DEA 1.1-positive recipients.
G. Dogs that are negative for DEA 1.1, 1.2, 3, 5, and 7 and are positive for DEA 4 are considered to be universal donors.
H. Other RBC antigens may be present. The newly described Dal RBC antigen is capable of producing a hemolytic transfusion reaction in sensitized dogs (Blais et al., 2005).

III. The major blood group system recognized in cats is the AB system; cats can have blood types A, B, or AB.
A. Types A and B are allelic at the same gene locus, and the A allele (A) is dominant over the B allele (a).
B. The rare blood type AB is thought to be the result of a third allele; however, the exact mode of inheritance is unclear (Griot-Wenk et al., 1996).
C. The frequencies of feline blood types vary geographically and within breeds.
1. Type A is most common, with more than 95% of domestic shorthair (DSH) and domestic longhair (DLH) cats being typed as blood type A (Giger et al., 1989).
2. Type B is seen in a variety of cat breeds (Table 71-2) and is seen with higher frequency in DSH and DLH cats on the west coast of the United States (Giger et al., 1991).
D. Cats with type B erythrocytes have strong, naturally occurring anti-A hemagglutinins and hemolysins, consisting primarily of immunoglobulin (Ig) M and a lesser amount of IgG (Bucheler and Giger, 1993). Transfusion of type A blood into a type B recipient will result in an acute hemolytic transfusion reaction following the first transfusion.
E. Cats with type A erythrocytes have a low titer of naturally occurring anti-B alloantibodies, consisting of IgM hemagglutinins and IgG and IgM hemolysins (Wilkerson et al., 1991).
1. A transfusion of type B RBCs into a type A cat may induce only a minor transfusion reaction in the presence of alloantibodies.
2. However, rapid destruction of the donor RBCs will render the transfusion ineffective.
F. Type AB cats have neither anti-A nor anti-B alloantibodies.
G. Feline blood type A donors are essential, and ideally blood type B cats are also available.
H. Neonatal isoerythrolysis (hemolytic disease of the newborn) may be seen in kittens with type A blood born to type B queens (Bucheler and Giger, 1993).
I. An additional blood group antigen, the Mik RBC antigen, recently has been described . Cats that lack this antigen can form naturally occurring alloantibodies and may experience a hemolytic transfusion reaction if transfused with the Mik antigen (Weinstein et al., 2005).

TECHNICAL PREPARATIONS

Blood Typing and Crossmatching

I. Blood typing refers to identifying RBC blood group antigens by reacting RBCs with antibodies or other reagents in an agglutination or hemolytic assay.
II. Crossmatching refers to detecting the presence of anti-erythrocyte antibodies occurring between the donor and the recipient.
III. The rationale for blood typing and crossmatching is as follows:
A. Avoid an immediate hemolytic transfusion reaction.
B. Provide maximum survival of transfused cells by avoiding a delayed hemolytic transfusion reaction.
C. Prevent sensitization of the recipient to future incompatible transfusions.
D. Avoid sensitization of breeding females and subsequent hemolytic disease of neonates.
IV. Blood typing is performed in both dogs and cats.
A. Dogs
1. Canine donors are ideally DEA 1.1 and 1.2 negative.
2. If donors are typed as DEA 1.1 positive, blood is transfused only into recipients typed DEA 1.1 positive.
3. Antisera for typing is available from Midwest Animal Blood Services (517-851-8244; Stockbridge, Mich.), but the techniques involved require laboratory skills and experience.
4. Blood typing is also performed by some commercial veterinary laboratories or veterinary blood banks (send 2 to 7 mL of ethylenediamine tetraacetic acid [EDTA] or acid-citrate-dextrose [ACD] anticoagulated blood via overnight mail).
5. Cards for the typing of DEA 1.1 are available from DMS Laboratories, Inc., 2 Darts Mill Road, Flemington, NJ 08822, (800-567-4367).

6. Gel testing for DEA 1.1 (Giger et al., 2005) is available from Diamed North America, Inc. (305-558-0161; Miami, Fla.).

B. Cats
1. Blood type A and B donors are needed, but the majority of feline recipients are blood type A.
2. Blood typing can be performed by some commercial veterinary laboratories or veterinary blood banks (send 2 to 3 mL of EDTA or ACD anticoagulated blood via overnight mail).
3. Cards for the typing of A and B are available from DMS Laboratories, Inc. .
4. Gel testing for A and B typing (Stieger et al., 2005) is available from Diamed North America, Inc.

V. Crossmatching is very important.
A. Crossmatching in dogs is advised, even at first transfusion, to detect the presence of antibodies to blood groups.
B. Crossmatching is imperative in dogs that have been transfused previously.
C. Crossmatching in dogs does not indicate that the donor and recipient are the same blood type, and thus does not prevent sensitization.
D. Crossmatching does not guarantee that a transfusion reaction from white blood cell, protein, or platelet incompatibility will not occur.
E. Crossmatching is crucial in cats because of the high prevalence of naturally occurring alloantibodies.
F. Crossmatching is divided into two parts (Box 71-1).
1. In the major crossmatch, the recipient's plasma is mixed with the donor's RBCs.
2. In the minor crossmatch, the donor's plasma is mixed with the recipient's RBCs.
G. A major crossmatch kit that uses gel tubes to detect a positive/incompatible response is commercially available (Midwest Animal Blood Services, Inc.).
H. The major crossmatch is the most important for a safe transfusion.
1. The minor crossmatch is of less clinical significance because donor antibodies administered intravenously are rapidly diluted within the recipient.
2. Nonetheless, blood resulting in an incompatible minor crossmatch is best avoided for transfusion.

Box 71-1

Crossmatching Procedure

1. Obtain an anticoagulated (EDTA) and nonanticoagulated specimen of blood from animal and donor.
2. Centrifuge at 1000 × *g* (2500 to 3500 rpm) for 10 minutes and separate serum from RBCs.
3. Wash RBCs by adding 2 to 4 drops of EDTA blood to three quarters of a tube (12 × 75-mm size) of saline or phosphate-buffered saline, mixing and centrifuging for 1 minute at 1000 × *g*. Decant the saline and repeat three times.
4. After last wash, decant supernatant and resuspend cells with saline to give a 2% to 4% suspension (0.1 mL of RBCs in 2.4 mL saline gives a 4% suspension).
5. Make the following mixtures by adding the indicated amount of the well-mixed RBC suspension and serum to 12 × 75-mm tubes and mixing gently:
   a. *Major crossmatch:* 2 drops patient sera, 1 drop donor 2% to 4% RBC suspension
   b. *Minor crossmatch:* 2 drops donor sera, 1 drop patient 2% to 4% RBC suspension
   c. *Include controls:* 2 drops patient sera, 1 drop patient 2% to 4% RBC suspension and 2 drops donor sera, 1 drop donor 2% to 4% RBC suspension
6. Incubate tubes 15 to 30 minutes at 37° C.
7. Centrifuge for 15 seconds (1000 × *g*).
8. Examine tubes for hemolysis and agglutination.
   a. Rotate gently to observe cells coming off the red cell "button" in the bottom of the tube.
   b. In a compatible reaction, there is no hemolysis and the cells should float off freely, with no macroscopic or microscopic clumping/hemagglutination (compare to the control tubes).
9. Rouleaux formation can be falsely interpreted as agglutination. If rouleaux is suspected, a saline replacement technique can be used (replace serum with saline, mix, recentrifuge, and re-evaluate).

Blood Sources

I. Commercial sources
A. Several commercial veterinary blood banks exist in the United States.
B. These blood banks can supply canine and/or feline whole blood, plasma, and packed RBCs.

II. Blood donors
A. Inpatient donors are those that are kept on the premises, usually for emergency situations.
B. Outpatient donors, also known as *volunteer donors,* are generally client-owned animals brought in for emergency or regularly scheduled blood donations.
C. Selection and maintenance of canine donors is as follows:
1. Use large dogs (>30 kg), 1 to 7 years old, with a packed cell volume (PCV) >40% and in good physical condition.
2. Use DEA 1.1- and 1.2-negative donors if possible.
   a. DEA 1.1 negative status is a must unless recipients are type matched.
   b. Avoid donors with a history of previous transfusions or pregnancy, as they may have developed antierythrocyte antibodies.
3. Dogs should have normal von Willebrand factor (vWf) concentrations (if their plasma is to be used to provide this factor) and be negative for *Babesia canis*, *Babesia gibsoni, Leishmania donovani, Ehrlichia canis*, and *Brucella canis*.
4. Screening for other infectious organisms may be necessary, depending on the geographic region (Wardrop, 2005).

5. Keep canine donors current on routine immunizations (distemper, adenovirus, parvovirus, coronavirus, rabies, leptospirosis, parainfluenza).
6. Donor dogs should test negative for *Dirofilaria immitis,* and dogs in endemic areas should be on preventative therapy.
7. Fecal flotation, hemograms, and chemistry profiles should also be performed to ensure the health of the donor.
8. Iron supplementation is advisable with frequent donation.

D. Selection and maintenance of feline donors is as follows:
1. Use feline donors in good physical condition, >3.5 kg, 1 to 7 years old, and having a PCV >35%.
2. Blood type A donors are essential, and ideally blood type B cats are also available for use.
3. Cats must be negative for feline leukemia virus (FeLV), feline immunodeficiency virus, and *Mycoplasma* spp.
4. Screening for *Bartonella* spp. should also be considered (Wardrop, 2005).
5. Keep feline donors current on routine immunizations (feline parvovirus, viral rhinotracheitis, calicivirus, rabies, FeLV).
6. Annual fecal flotation, hemograms, and chemistry profiles are performed.
7. Consider iron supplementation with frequent donation.

Blood Collection and Storage

I. Canine blood collection
A. Jugular venipuncture is performed with the dog sitting, or in lateral or sternal recumbency.
B. Blood is collected by gravity or with the aid of a vacuum system into anticoagulant, such as ACD, citrate-phosphate-dextrose (CPD) or derivatives.
C. For whole blood, a single ACD, CPD or citrate-phosphate-dextrose-adenine (CPDA-1) plastic bag is used.
D. For components, a CPD or CPDA-1 bag is used with sterilely attached satellite bags or an additive solution (e.g., *Adsol, Optisol*) system.
E. If sedation is required, butorphanol (0.1 mg/kg IV) may be administered 15 minutes before collection (Hohenhaus, 2000).

II. Feline blood collection
A. Blood collection in cats generally requires sedation, and a combination of ketamine (1 to 2 mg/kg), diazepam (0.1 mg/kg) and atropine (0.01 mg/kg) can be administered IV (Griot-Wenk and Giger, 1995).
B. Inhalant anesthesia with sevoflurane has also been described (Troyer et al., 2005).
C. With the cat in sternal, lateral, or dorsal recumbency, blood is collected from the jugular vein into a syringe containing ACD, CPD, or CPDA-1 solutions (1 mL/9 mL blood), or heparin (5 units/mL blood).
D. Feline blood cannot be stored in a syringe.
1. If blood is to be stored, blood obtained via syringe can be sterilely transferred to a small collection bag.
2. Systems consisting of a syringe attached directly to a blood bag are available from commercial veterinary blood banks.

III. Frequency and volume of donation for canine and feline donors
A. Amount drawn from dogs
1. A total of 15 mL/kg or 450 mL can be safely taken from a 30-kg dog, with ideal frequency no more than every 6 weeks.
2. Reduce the frequency of donation if the PCV or total protein fails to return to baseline values.
B. Amounts drawn from cats
1. A total of 10 to 15 mL/kg or 60 mL total can be taken every 6 weeks in cats.
2. Reduce the frequency of donation if the PCV or total protein fails to return to baseline values.

THERAPEUTIC CONSIDERATIONS

Component Therapy

I. Whole blood is often centrifuged and processed into blood components, such as packed RBCs, plasma, platelets, and cryoprecipitate, by using multiple, sterilely connected plastic bags.

II. Advantages to blood component therapy include better conservation of blood resources, longer storage of components, more specific therapy, and fewer complications from circulatory overload because of the minimal volume administered.

III. Component types and indications are as follows:
A. RBCs
1. Fresh whole blood provides coagulation factors, other proteins (albumin and globulins), RBCs, and platelets.
a. It is used where multiple components are needed.
b. Stored whole blood does not provide viable platelets or sufficient labile coagulation factors.
2. Packed RBCs are the best product for most RBC needs and can be supplemented with plasma or platelets if needed.
3. The shelf life or expiration date of RBCs may vary with the anticoagulant-preservative used.
4. Whole blood can generally be stored for 3 to 4 weeks at 1° to 6° C, whereas packed RBCs in additive can be stored for 5 weeks (Wardrop, 1995).
B. Plasma
1. Fresh frozen plasma (FFP) is plasma that has been frozen within 6 hours of collection and stored at −18° C or colder.
a. It contains labile (V and VIII) and stable (II, VII, IX, and X) coagulation proteins.
b. It is used to treat hemophilia A, hemophilia B, von Willebrand disease, warfarin toxicity, or other factor deficiencies.

c. It can be stored for 1 year from the collection date (Brooks, 2000).

2. Cryoprecipitate-poor plasma is plasma with cryoprecipitate removed.
   a. This plasma contains the more stable clotting factors and can be used in cases of warfarin toxicity or hemophilia B.
   b. Cryoprecipitate-poor plasma and frozen plasma can be stored for up to 5 years.
3. Frozen plasma is plasma that has been frozen >6 hours after blood collection (e.g., removed from expired whole blood units), or FFP that has been stored >1 year.
4. Either FFP, cryoprecipitate-poor plasma, or frozen plasma may be used in cases of hypoproteinemia; however, synthetic colloids such as hetastarch are probably more effective in severe hypoproteinemias resulting from renal or intestinal protein loss.

C. Platelets
1. Platelet-rich plasma or platelet concentrates may be used to stop or prevent hemorrhage in animals with thrombocytopenia or platelet function disorders.
2. Fresh whole blood may be substituted as a source of platelets when components are unavailable.
3. Platelet products must be stored at room temperature (no refrigeration) and their storage time is short—3 to 5 days with continuous agitation.

D. Cryoprecipitate
1. Prepared from FFP as a concentrated form of factor VIII:C, vWf, and fibrinogen
2. Preferred component for treatment or prevention of hemorrhage resulting from hemophilia A or von Willebrand disease
3. Stored at −18° C or colder for up to 1 year from collection date

Administration

I. General guidelines
A. Use blood or component administration sets with filters (150 to 170 μm) to administer all blood or blood products.
B. Only normal saline (0.9%) may be mixed with blood components.
C. Monitor temperature, pulse and heart rate, and respiratory rate and sounds before, during, and after transfusion.
D. Volume overload can occur if too much of a blood product is given or if the product is given too quickly, especially if the animal has cardiac or renal disease.
E. Complete the transfusion within 4 hours.
F. Use the intravenous route; the osseous intramedullary route may be used if necessary.

II. Rate and volume
A. The desirable rate of infusion varies with the patient's blood volume, hemodynamic condition, and cardiac, renal and hepatic status of the animal.
1. Give slowly (<5 mL/kg/hr IV) for the first 15 minutes, then increase rate.
2. Give more rapidly in hypovolemic animals.
3. Give more slowly in animals with cardiac, hepatic, or renal failure (approximately 1 mL/kg/hr IV).

B. Volume of whole blood or packed RBC to administer is calculated as follows:
1. Determine the PCV of the animal.
2. Volume (mL) of donor blood in anticoagulant to administer is calculated as follows:

$$\text{Animal weight (kg)} \times \text{blood volume} \times \frac{\text{(desired PCV} - \text{present PCV)}}{\text{PCV of donor blood in anticoagulant}}$$

NOTE: The blood volume in the dog is approximately 90 mL/kg; the volume in the cat is approximately 70 mL/kg.

3. Transfusion of 20 mL/kg of whole blood or 10 to 15 mL/kg of packed RBC raises the PCV of the recipient by 10%.

C. FFP, frozen plasma or cryoprecipitate-poor plasma are given as follows:
1. To thaw, place in a waterproof plastic bag and thaw at 37° C.
2. Thawing at room temperature or in a refrigerator is avoided because cryoprecipitate will form.
3. Administer immediately on thawing, or store between 1° and 6° C.
4. Administer FFP within 24 hours of thawing if used as a source of labile coagulation factors.
5. Give at the rate of 5 to 10 mL/kg/hr IV.
6. Use 10 to 20 mL/kg of plasma to treat coagulation deficiencies or hypoalbuminemia (NOTE: Synthetic colloids may be preferred for increasing oncotic pressure in hypoalbuminemic cases).

D. Administer platelet-rich plasma or platelet concentrate as follows:
1. Give at 5 to 10 mL/kg/hr IV.
2. Dosage is 1 unit (from 450 mL of blood)/10 kg to increase the platelet count by 20,000 to 40,000/μL.
3. Frozen canine platelets are available commercially.
   a. One unit of frozen platelets/10 kg increases the platelet count by approximately 20,000 platelets/μL.
   b. The product expires 6 months from the time of collection.

E. Cryoprecipitate requires special handling.
1. Thaw in a waterproof plastic bag at 37° C; do not thaw in a refrigerator or at room temperature.
2. A bag of cryoprecipitate prepared from 200 mL of plasma contains approximately 100 to 150 units of vWf and factor VIII:C.
3. The product is administered at a dosage of 10 to 20 U/kg IV.

Transfusion Reactions

I. Immediate, immune-mediated reactions
A. Hemolytic transfusion reaction
1. Caused by antibodies in recipient plasma that destroy donor RBCs

2. Can occur as early as 5 minutes after initiating transfusion
3. Clinical signs: fever, tachycardia or bradycardia, hypotension, dyspnea, cyanosis, emesis, defecation, collapse, opisthotonus, cardiac arrest, hemoglobinemia, or hemoglobinuria (Giger and Akol, 1990; Giger et al., 1995)
4. Treatment
   a. Stop the transfusion and treat for shock, with maintenance of cardiac, respiratory, and renal function.
   b. Avoid this reaction through appropriate typing and crossmatching before transfusion.

B. Nonhemolytic febrile reaction
1. Characterized by temperature rise of 1° C (2° F) occurring within 1 to 2 hours of transfusion without hemolysis or another explanation.
2. The reaction arises from recipient antibodies directed against donor leukocyte antigens.
3. Rule out early hemolytic or septic reaction.
4. Stop transfusion; use antipyretics if necessary.

C. Urticarial reaction
1. Recipient antibodies directed against donor plasma proteins
2. A relatively common but mild complication of transfusions
3. Treatment: stop or slow transfusion, diphenhydramine 2 mg/kg IM

II. Immediate, nonimmune-mediated reactions

A. Sepsis
1. Usually not a problem if care has been taken to properly prepare donor phlebotomy site, a closed system is used, and the blood product is appropriately stored
2. Reactions generally from endotoxins
3. Signs of endotoxic shock: fever, hypotension, disseminated intravascular coagulation, renal failure
4. Treatment: for shock, antibiotics
5. Culturing of blood bag indicated

B. Circulatory overload
1. Seen more commonly with compromised cardiac, pulmonary or renal function, especially in cats and miniature or toy breeds of dogs
2. Signs: coughing, cyanosis, and dyspnea (pulmonary edema)
3. Treatment: stop transfusion, institute diuretics and cardiorespiratory support

C. Citrate toxicity
1. Hypocalcemia from rapid infusion of citrated products (whole blood, plasma)
2. Signs: vomiting, tremors, tetany
3. Treatment: stop transfusion, resume at slower rate, and administer calcium gluconate if reaction severe

D. Hemolysis
1. From improper blood handling (e.g., freezing or overheating of blood or mixing with nonisotonic solutions)
2. Causes hemoglobinemia/hemoglobinuria and must be differentiated from an immune-mediated hemolytic transfusion reaction

III. Delayed reactions

A. Immune-mediated: delayed hemolytic transfusion reaction
1. Within 3 days (anamnestic response) or several weeks (primary response) after transfusion
2. Not detected by crossmatching
   a. An unexplained decline in PCV and positive direct antiglobulin test
   b. Possibly asymptomatic or presence of fever and icterus
   c. Treatment: not generally required

B. Nonimmune-mediated
1. Reactions arise from infectious diseases.
2. All donors must be carefully selected and screened to avoid transmittance of disease.

Red Blood Cell Substitute

I. A hemoglobin-based oxygen-carrying solution (Oxyglobin, Biopure Corp., Cambridge, Mass.) has been approved by the Food and Drug Administration (FDA) for use in dogs with anemia (Rentko and Sharpe, 2000).

II. Oxyglobin is purified bovine hemoglobin in a modified lactated Ringer's solution.
   A. It is isosmotic, with a pH of 7.8, and half-life of 18 to 43 hours, depending on dosage.
   B. The product comes in 125 mL bags and can be stored for 3 years at room temperature.

III. The recommended dosage in dogs is 10 to 30 mL/kg IV at a maximal rate of 10 mL/kg/hr.

IV. A standard IV infusion set can be used, and crossmatching is not required.

V. Overdose or rapid administration can cause circulatory overload.
   A. Monitor using hemoglobin, not PCV.
   B. It is contraindicated in dogs with advanced cardiac disease or with acute renal failure, because of the potential for circulatory overload.

VI. Side effects include skin and mucous membrane discoloration, vomiting and diarrhea, alterations in serum chemistries from discoloration of serum, and transient hemoglobinuria.

CHAPTER 72

Principles of Oncology

Philip J. Bergman

GENERAL CONSIDERATIONS

Definition

I. Many resources attempt to define *tumor* (neoplasm); the simplest definition is that a tumor is an abnormal group of cells.
II. Older definitions commonly stated that tumors arose from uncontrolled cell division, but it is now known that they occur from increased cell division and/or decreased cell death.
III. Neoplasms can be categorized into benign and malignant forms.
  A. Benign neoplasms
    1. Benign tumors do not typically invade adjacent normal tissues, though exceptions exist.
    2. They do not have the capability to spread (metastasize).
    3. For most benign tumors, the tumor name ends in "oma," without "carc" or "sarc" as a prefix.
    4. Some exceptions exist (e.g., lymphoma, glioblastoma).
  B. Malignant neoplasms
    1. Cells may invade adjacent tissues.
    2. The ability to invade adjacent tissues provides potential for secondary tumors to form at distant sites (metastasize).
    3. Metastasis may occur through the bloodstream and/or through the lymphatics.
    4. The term *cancer* refers to a malignant tumor.
IV. Tumors are further classified according to their tissue of origin.
  A. Epithelial
    1. Adenomas are benign tumors of epithelial origin.
    2. Carcinomas are malignant tumors of epithelial origin.
    3. Adenocarcinomas are malignant tumors of epithelial glandular origin.
  B. Mesenchymal
    1. They are composed of connective tissue, such as bone, muscle, or vessels (blood, lymphatics).
    2. Leiomyomas are benign tumors of smooth muscle origin.
    3. Chondromas are benign tumors of cartilage origin.
    4. Sarcomas are malignant tumors of mesenchymal origin.
    5. Osteosarcomas are malignant tumors of bony origin.
    6. Leiomyosarcomas are malignant tumors of smooth muscle origin.
  C. Discrete cell tumors
    1. These tumors have a variety of origins and malignant potentials, but cytologically they look like separate cells that do not cluster together.
    2. They were previously called *round cell tumors.*
    3. They include lymphoma, mast cell tumor, transmissible venereal tumor (TVT), plasma cell tumor, and histiocytoma.

Differential Diagnosis

I. The list is extremely lengthy and includes autoimmune disorders, trauma, and infectious diseases.
II. Differential diagnosis for a given tumor is dependent on size, invasiveness, anatomical location, presence or absence of paraneoplastic syndromes (see Chapter 73), and the presence or absence of metastasis.
III. Tumors may generate secondary conditions that may mask the primary disorder (e.g., clotting abnormalities, renal failure, autoimmune hemolytic anemia).

Staging

I. The stage of the tumor is determined by a systematic evaluation of the extent of disease.
II. Staging is imperative for most tumors.
  A. This process allows for the most precise delineation of the prognosis.
  B. Correct staging also helps determine the most appropriate treatment.
III. The tumor-node-metastasis (TNM) scheme from the World Health Organization is the most commonly used staging system.
  A. T0 denotes no evidence of primary tumor, and T1 through T4 indicate increasing size of the primary tumor.
  B. N0 denotes no evidence of lymph node metastasis, and N1 through N3 indicate increasing size, firmness, or decreasing movability of the lymph node.
  C. M0 denotes no evidence of distant metastatic disease and M1 indicates distant metastasis.
  D. The designation *X* generally means it is impossible to assess the extent of disease in a particular area, which is not the same as finding no lesion in the area.

E. Some systems further define whether the outcomes were determined through pathologic or clinical means (e.g., pT2, cN0, cM0).

IV. Staging systems vary depending on the tumor but follow a general pattern of more extensive disease correlating with increased stage and decreased prognosis.

V. Subclassifications within a stage (e.g., a, b, c) are used to signify differences within that stage (e.g., IIa = no clinical signs, IIb = with clinical signs).

VI. *Stage 0* generally denotes intraepithelial (newer term for in situ) disease.
   A. This was previously called *tumor in situ* (Tis).
   B. This term is only appropriate for carcinomas as it refers to no invasion through the basement membrane, and nonepithelial tumors (sarcomas) do not have this characteristic.

VII. Additional descriptors used in conjunction with the TNM system include the following:
   A. R classification = presence of residual tumor after treatment
   B. G classification = inclusion of histological grading
   C. C factor = certainty of diagnosis
   D. L = lymphatic invasion
   E. V = vascular invasion

GENERAL THERAPEUTIC CONSIDERATIONS

I. It is imperative to determine a histopathologic diagnosis and stage (extent of disease) to be able to appropriately select a treatment course.

II. An understanding of the biological behavior of the tumor is also critical.
   A. The biological behavior of a tumor is related to two primary features.
      1. Local invasiveness
      2. Metastatic propensity
   B. Tumors are generally treated with one or more of three modalities, namely surgery, radiation, or chemotherapy (immunotherapy may become a fourth routine modality in the future).
      1. Locally invasive tumors are treated with local modalities (e.g., surgery, radiation).
      2. Tumors with a high propensity for metastasis are treated with systemic therapies (e.g., chemotherapy).
      3. Tumors that are locally invasive and have a high metastatic propensity are treated with surgery, radiation or both, in addition to chemotherapy.
   C. The goal of treatment (palliative versus curative intent) must be decided.
      1. Curative intent is ideal but may not be realistic in some cases (e.g., metastatic hemangiosarcoma).
      2. The most aggressive modalities with proven benefit are used first when there is curative intent.
      3. The initial use of less aggressive options, followed by more aggressive therapies, generally leads to treatment failure.
      4. The primary goal of palliation is an improved quality of life.

III. The animal must be evaluated for any concurrent medical problems that may impact the prognosis or treatment options.

IV. Tumors are evaluated before starting treatment and then serially at each recheck (in addition to a full physical examination).
   A. Single tumors are measured in three dimensions (with calipers when possible), and the results recorded.
   B. When multiple tumors are present, a minimum of two to three are measured in three dimensions; the remaining tumors are mapped and the single largest dimension is recorded.

V. Terms for response to treatment include the following:
   A. Complete remission (CR): complete disappearance of all clinically detectable tumor
   B. Partial response (PR): >50% decrease in tumor volume; no new tumors
   C. Stable disease (SD): <50% decrease or <10% increase in tumor volume
   D. Progressive disease (PD): >10% increase in tumor volume or appearance of new tumors
   E. Variations
      1. Percentages used for PR, SD, PD can vary across studies, but the above percentages are good starting guidelines.
      2. Volume (triaxial measurements) may not always be used.
         a. Single largest measurement systems or response evaluation criteria in solid tumors (RECIST) exist.
         b. Area-based systems (two largest measurements used) are commonly used when a third measurement is not possible.
      3. Lymphoma: CR, out of remission (OR)

VI. Combinations of modalities are commonly utilized for a wide variety of cancers, because therapies have differing mechanisms of action that increase efficacy without increasing toxicity.

SPECIFIC THERAPIES

Surgery

Definition

I. Surgery is the ideal treatment for localized tumors.

II. When indicated, surgery is the treatment modality that is most likely to provide a cure.

Applications and Goals

I. Cure
   A. A cure is possible with localized tumors with low metastatic propensity in an animal without distant disease on staging.
   B. Benign tumors and well-localized nonmetastatic malignancies are often cured with appropriate surgical

extirpation (e.g., benign and low-grade canine mammary gland tumors).

II. Debulking or cytoreductive surgery is commonly used to reduce a tumor to microscopic disease so it is more susceptible to other treatment modalities (e.g., soft-tissue sarcomas debulked followed by radiation therapy).

III. Animals with highly metastatic but slow-growing tumors may benefit from local control surgery (e.g., anal sac apocrine adenocarcinoma).

IV. Metastasectomy is rarely used.
   A. It may be useful in dogs with metastatic osteosarcoma, under stringent criteria.
   B. The procedure may be useful where lymph node metastasis does not automatically signal widespread metastasis (e.g., mast cell tumor with metastasis only to a lymph node).
   C. It may be useful when the metastatic lesion is significantly reducing quality of life, or is the cause of a paraneoplastic syndrome (e.g., hypertrophic osteopathy).

Principles

I. Knowing the tumor type via cytological examination and/or incisional biopsy is imperative.

II. The aggressiveness of surgery is extremely variable and dependent on the tumor type and its expected degree of invasiveness locally.

III. A minimum preoperative work-up includes complete staging, with a complete blood count (CBC), biochemistry profile, urinalysis, and three radiographic views of the thorax.

IV. The best chance for cure is obtained at the first surgery.
   A. Wide excision typically includes 2- to 3-cm lateral margins and one fascial plane deep.
      1. The definition of wide excision varies among tumor types, which reinforces the need to know the tumor type before surgery.
      2. Wide excision of a mammary tumor is typically 1 to 2 cm around it, and one fascial plane deep.
      3. Wide excision of a feline vaccine-associated sarcoma is typically 3 to 5 cm margins in all planes.
      4. Wide excision for a sebaceous adenoma is typically 0.5 to 1.0 cm.
   B. Previous needle aspiration or biopsy tracts are included in the resection to remove tumor cells that may have seeded these areas.
   C. Early vascular ligation may be important to reduce the chance of tumor embolization, especially from malignancies in retained testicles, the spleen, and the lungs.
   D. Avoid incising the tumor during removal.
   E. Handle tumors gently to reduce the risk of cells exfoliating into the operative field.
   F. Tumors commonly have a pseudocapsule that is composed of compressed tumor cells, so shelling out a tumor may lead to recurrence from incomplete margins.
   G. Hemostatic surgical clips (hemoclips) are useful to delineate the extent of surgery, especially if radiation therapy is planned in the future.
   H. Lasers may provide an easier and less bloody removal of a tumor, but coagulative necrosis induced at the edge of the resection can complicate histopathologic evaluation of margins, so their routine use is not recommended.

V. After the tumor has been removed, use clean instruments for closure to reduce the chances of tumor seeding of the surgical site, and when more than one mass is being removed, use different surgical packs.

VI. Every mass removed is submitted for histopathologic evaluation.
   A. Submit the entire mass, if possible.
   B. Partial submissions do not allow delineation of margins, which may require additional local therapy in the future (whether it is truly needed or not).
   C. Inking of surgical margins with yellow or black ink is commonly used to help delineate completeness of resection (www.bradleyproducts.com).
   D. Sutures, hemoclips, or both may also be used to mark edges and aid in orientation of the tissues (dorsal, lateral, ventral, medial).

VII. Fixation is important.
   A. A 10:1 ratio of formalin to tissue is needed to properly fix the tumor.
   B. Tumors >3 to 4 cm may be partially incised to allow increased penetration of the fixative.
   C. If the volume of formalin and tissue is so large as to prevent transport to the laboratory, the tissues can be fixed for 24 hours, removed from the formalin, and wrapped in formalin-soaked paper towels for submission.

Cryotherapy

Definition

I. The induction of a controlled rapid freeze and slow thaw of tissues via liquid nitrogen or nitrous oxide

II. Cell death mechanisms
   A. Direct cell death is from ice crystal formation and secondary damage of cell membranes.
   B. Indirect cell death arises from vascular damage to blood vessels.

Applications and Goals

I. Indications are primarily for small, benign tumors (recurrence rates increase with lesions >0.5 cm).

II. It is not often used because of the need for histopathologic evaluation of the extirpated tissue.

III. It is used for susceptible tumors (e.g., discreet cell tumors, melanomas) in areas where excision is difficult or disfiguring (e.g., periocular, oral, on the digits).

IV. Advantages are as follows:
   A. Short procedure
   B. Easy to perform
   C. Anesthesia not always necessary
   D. Possible multiple treatments over time

V. Disadvantages include the following:
   A. Expense of equipment

B. Need for postoperative cleaning or debridement of necrotic tissue
C. No ability for histopathologic determination of status of margins

Radiation Therapy

Definition

I. Radiation therapy (RT) uses high energy, penetrating waves or particles (x-rays, gamma rays, proton or neutron rays) to destroy cancer cells or sterilize them.
II. Radiation therapy is sometimes called *radiotherapy, x-ray therapy, cobalt therapy, electron beam therapy,* or *irradiation.*
III. The goal of RT is to kill or at least damage cancer cells.
  A. RT itself is painless.
  B. Radiation only acts on the area of the body exposed to it.
IV. High-energy radiation kills cells by damaging DNA.
  A. This damage blocks the ability of tumor cells to divide and inhibits tumor growth.
  B. Cancer cells generally grow and divide quickly, which makes them particularly vulnerable to radiation.
  C. Radiation also damages normal cells, but they are usually growing more slowly and are better able to repair radiation damage.

Types

I. Teletherapy
  A. Delivery of a beam of RT from outside the body
  B. Megavoltage radiation: ≥1 million electron volts (MeV)
    1. Cobalt-60 source machine or linear accelerator is the most common.
    2. Cobalt-60 machines are relatively inexpensive but require source changes intermittently because cobalt-60 has a 5-year half-life.
    3. Linear accelerators are relatively expensive but do not require source changes.
    4. Megavoltage radiation has good penetration of tissues.
    5. More even and predictable deposition in tissues allows for increased use of computer-based treatment planning.
    6. Some linear accelerators produce photons and electrons of varying energies, which allows greater treatment flexibility.
    7. The energy from cobalt-60 and linear accelerator-derived photons does not build to a therapeutic level until it has passed through 1 cm of tissue, so it is partially skin sparing.
    8. The use of tissue-equivalent material can increase energy deposition at the skin surface.
  C. Orthovoltage radiation
    1. Relatively low energy source of x-rays
      a. It is typically operated at 250 kV.
      b. Maximum dose is deposited at the skin surface.
      c. Acute skin effects are severe.
      d. Dose falls to 90% at approximately 2 cm depth.
      e. It is difficult to treat deep-seated tumors with this source.
    2. Differential absorption of dose in bone versus soft tissue
    3. Not commonly used in animals owing to its various limitations and rare indications
    4. Primarily for superficial tumors that do not involve adjacent bone
      a. Skin tumors
      b. Nasal cavity tumors after cytoreductive surgery
    5. Advantages
      a. Relatively inexpensive
      b. Equipment relatively easy to repair and maintain
      c. Less shielding and space required
II. Brachytherapy
  A. It is the implantation or application of a radioactive source to tissue.
  B. *Brachy* signifies the radiation source is close to the tumor.
  C. It is not routinely used in small animals.
  D. Iridium-192 is the most commonly used source.
  E. Use of iridium-192 requires quarantine of the animal.
III. Plesiotherapy
  A. It is the topical application of a radiation source.
  B. *Plesios* is Greek for *close* or *near*.
  C. Strontium-90 is the most common source.
    1. Beta-radiation is often applied via an ophthalmic applicator.
    2. Source is attached to a handle protected with Plexiglas.
    3. Dose falls off rapidly in tissues.
      a. Delivered to the surface: 100%
      b. Depth of 1 mm: 50%
      c. Depth of 2 mm: approximately 25%
    4. Potential indications include the following:
      a. Nasal planum squamous cell carcinoma in cats
      b. Squamous cell carcinoma in situ in cats
      c. Cutaneous mast cell tumors of cats
IV. Systemic therapy
  A. It is the systemic administration of a radioactive source.
  B. Iodine-131 is commonly used for feline hyperthyroidism.
  C. It routinely requires quarantine of the animal.

Applications

I. Useful in diseases that are not systemic or metastatic
II. ± Useful for palliation in the face of metastases
III. Most effective when used with other modalities
  A. Sequential combinations
    1. Postoperative RT may be used to eradicate residual tumor when complete surgical excision is not possible.
    2. When a tumor is not resectable, preoperative RT may be used to shrink it and make it more operable.
    3. RT followed by surgery and chemotherapy may be used for vaccine-associated sarcoma in cats and for other tumors.

B. Concurrent combinations
   1. Intraoperative RT delivers radiation to an open surgical tumor bed.
   2. Some chemotherapeutics can sensitize tumors cells to radiation therapy (chemoradiotherapy).

IV. The primary treatment modality for radiation-sensitive tumors and small superficial tumors
   A. Facial squamous cell carcinoma in cats
   B. Nasal lymphoma in cats
   C. Oral acanthomatous epulis, dental tumors
   D. Plasma cell tumors

V. Palliative intent RT
   A. It may not shrink the tumor or extend survival, but it may improve quality of life.
   B. Fractions (dose per treatment) are infrequent and typically larger than with curative intent (full course) RT.
      1. Minimizes numbers of treatments and visits
      2. Minimizes stress of animal and time commitment of owner
   C. Indications include relief of pain associated with bone tumors (osteosarcoma), rapid shrinkage of tumors (some lymphomas), and relief of dyspnea, pain, and dysphagia from oral tumors.

Chemotherapy

Definition

I. Chemotherapy is a systemic treatment and is the primary treatment for systemic malignancies (e.g., lymphomas, leukemias) and metastatic tumors.

II. It is most effective against small tumors and least effective against large tumors, unless they are extremely sensitive (e.g., lymphoma, TVT).
   A. Most effective against rapidly dividing cells
   B. Most effective against cells near a vascular supply
   C. Less effective against quiescent and hypoxic cells (e.g., large tumors)

III. Chemotherapy can be used in conjunction with other treatment modalities.

IV. The safety range for chemotherapeutic agents is narrow (i.e., therapeutic and toxic doses are similar).
   A. Dose response curves for most cytotoxic chemotherapy agents are sigmoidal and not linear.
      1. A 5% to 10% decrease in dose often translates into a ≥10% to 20% decrease in efficacy.
      2. A 5% increase in dose often leads to significant toxicity.
   B. It is imperative that doses be accurately calculated.
      1. Rounding down the dose to decrease toxicity leads to decreased efficacy and is not advisable.
      2. Many chemotherapeutic agents are dosed are based on body surface area (BSA), as shown in Tables 72-1 and 72-2.
      3. Because of the potential for mistakes, use BSA charts that provide doses in either kilograms or pounds of body weight (not both).

TABLE 72-1

Canine Body Surface Area Conversion Chart

BODY WEIGHT (kg)	SURFACE AREA (m^2)	BODY WEIGHT (kg)	SURFACE AREA (m^2)
0.5	0.064	25.0	0.864
1.0	0.101	26.0	0.886
2.0	0.160	27.0	0.909
3.0	0.210	28.0	0.931
4.0	0.255	29.0	0.953
5.0	0.295	30.0	0.975
6.0	0.333	31.0	0.997
7.0	0.370	32.0	1.018
8.0	0.404	33.0	1.029
9.0	0.437	34.0	1.060
10.0	0.469	35.0	1.081
11.0	0.500	36.0	1.101
12.0	0.529	37.0	1.121
13.0	0.553	38.0	1.142
14.0	0.581	39.0	1.162
15.0	0.608	40.0	1.181
16.0	0.641	41.0	1.201
17.0	0.668	42.0	1.220
18.0	0.694	43.0	1.240
19.0	0.719	44.0	1.259
20.0	0.744	45.0	1.278
21.0	0.769	46.0	1.297
22.0	0.785	47.0	1.302
23.0	0.817	48.0	1.334
24.0	0.840	49.0	1.352

V. Historically, emphasis was placed on a drug's effect within the cell cycle to delineate chemotherapy protocols; however, the use of standardized protocols and accurate dosages are likely more important in the clinical setting.

Types

I. There are six major categories of chemotherapeutic agents (Table 72-3).

II. Most cause bone marrow, alopecia, or gastrointestinal (BAG) side effects.
   A. Many agents cause bone marrow suppression; however, when used at normal doses, corticosteroids, vincristine, L-asparaginase, and bleomycin do not.
   B. Alopecia occurs primarily in breeds that continuously grow hair.
      1. Hair begins to regrow weeks to months after termination of chemotherapy and typically has a slightly different color.
      2. Shaved sites do not regrow while on chemotherapy.
      3. Cats typically do not experience chemotherapy-associated alopecia, but lose their whiskers instead.

Biological Response Modifiers (Immunotherapy)

Definition

I. These are natural or synthetic compounds that alter the host's response to a tumor.
II. Relatively few biological response modifiers (BRM) are available for clinical use in animals.
III. The availability of animal-specific BRMs is eagerly anticipated and likely in the next 5 to 10 years.

Types

I. Nonspecific immunomodulators
  A. Cytokines and hematopoietic growth factors are glycoproteins that stimulate differentiation, growth, and effector functions of hematopoietic or bone marrow-derived cells.
    1. Interferons
      a. Produced in response to viral infections and various mitogens
      b. Cytostatic, cytotoxic, and immunomodulatory properties
      c. No experience with cancers of small animals to date
      d. May be useful for feline leukemia virus infections in cats
    2. Interleukins
      a. Pleiotropic cytokines that activate lymphocytes and natural killer cells
      b. Initially promising results in vitro against cancer but toxicities have prevented widespread use
    3. Granulocyte and granulocyte-monocyte colony-stimulating factors
      a. Stimulate proliferation and maturation of neutrophils and monocytes (macrophages in circulation) in the bone marrow
      b. Used for chemotherapy-associated neutropenia
  B. Bacterial agents
    1. Bacillus Calmette-Guérin (BCG)
      a. Attenuated mycobacterium with activity against some human and equine tumors
      b. No uses to date in small animals
    2. Liposome encapsulated muramyl tripeptide-phosphatidylethanolamine (L-MTP-PE)
      a. Mycobacterial cell-wall fragment with macrophage activation properties
      b. Useful in canine osteosarcoma and hemangiosarcoma, but not mammary carcinoma
      c. Not commercially available at present but expected soon (*Junovan;* IDM Pharma, Irvine, Calif.)
  C. Miscellaneous agents
    1. Imiquimod (*Aldara)*
      a. Topical cream that activates toll-like receptor 7
      b. Potent immunomodulator with antiviral and anticancer properties
      c. May be useful for feline Bowen's disease, although no published studies to date
    2. Isotretinoin (*Accutane)*
      a. Oral vitamin A derivative with differentiation properties
      b. Used in mycosis fungoides and other epitheliotropic T-cell lymphomas
    3. Piroxicam (*Feldene)*
      a. Potent nonsteroidal antiinflammatory drug (NSAID) with anticancer and antimetastatic properties
      b. Used with mitoxantrone in dogs for urinary bladder transitional carcinoma
      c. Possibly useful in dogs with osteosarcoma
      d. May be useful in squamous cell carcinoma and other tumors that overexpress cyclooxygenase-2
    4. Cimetidine
      a. Histamine-2 receptor antagonist
      b. May be of use in recalcitrant canine papillomatosis
      c. True efficacy unproven
II. Specific immunomodulators
  A. Tumor cells frequently produce unique, abnormal, and embryonic proteins that can be targeted by the immune system.

Text continued on p. 724.

TABLE 72-3

Chemotherapeutic Agents and Their Applications in Dogs and Cats

DRUG NAME *(BRAND NAME)*	DRUG CLASS	PRIMARY INDICATIONS	DOSAGE	TOXICITIES AND PRECAUTIONS	GENERICS AVAILABLE	RELATIVE COST
Actinomycin-D *(Cosmegen)*	Antitumor antibiotic	Alternative for canine lymphoma	0.5-0.9 mg/m^2 IV slowly every 3 weeks	Myelosuppression, vomiting, diarrhea, and extravasation reaction	No	++
L-Asparaginase *(Elspar)*	Enzyme	Lymphoma	10,000 IU/m^2 or 400 IU/kg IM, SC	Anaphylaxis (treat for shock and never give again) Rarely pancreatitis, and coagulopathy can decrease clearance	No	++
Carboplatin *(Paraplatin)*	Platinum	Canine osteosarcoma, carcinomatosis, sarcomatosis malignant effusions Mild efficacy in canine melanoma Safe in cats	*Large dogs:* 300 mg/m^2 IV every 3 weeks *Small dogs:* 250 mg/m^2 or 10 mg/kg IV every 3 weeks *Cats:* 180 mg/m^2 IV every 4 weeks	Myelosuppression, mild vomiting or diarrhea, and mild nephrotoxicity Do not use in animals with renal compromise	Yes	+++
Chlorambucil *(Leukeran)*	Alkylating agent	Chronic lymphocytic leukemia and feline small-cell gastrointestinal lymphoma Used as substitute when cyclophosphamide not tolerated	Dosage varies greatly between protocols Continuous: 4-6 mg/m^2 PO SID Intermittent: 15 mg/m^2 PO SID for 4 days every 3 weeks	Myelosuppression Perform serial CBCs and platelet counts every 4-6 weeks Reduce dose or discontinue if neutropenia or thrombocytopenia occur	Yes	+
Cisplatin *(Platinol)*	Platinum	Canine osteosarcoma, malignant effusions, and some carcinomas Contraindicated in cats	*Dogs only:* 50-70 mg/m^2 IV every 3 weeks Saline diuresis required Prevent vomiting with butorphanol, dexamethasone, ondansetron, or dolasetron	Contraindicated in cats Severe nephrotoxin Myelosuppression, vomiting, and diarrhea	Yes	+++
Cyclophosphamide *(Cytoxan)*	Alkylating agent	Lymphoma, lymphoid leukemias, some carcinomas and sarcomas	200-250 mg/m^2 IV every 3 weeks or 200 mg/m^2 PO divided over 3-5 days every 3 weeks	Myelosuppression, mild vomiting, diarrhea, and sterile hemorrhagic cystitis Reduce chance of cystitis with injectable furosemide or corticosteroids	Yes	++
Cytosine Arabinoside *(Cytosar)*	Antimetabolite	Rarely used Renal and central nervous system lymphoma	200-300 mg/m^2 SC BID for 2 days or 100 mg/m^2/day constant rate infusion IV over 3-4 days	Myelosuppression, mild vomiting, diarrhea, and anorexia	Yes	++

+, Low relative expense; ++, moderate relative expense; +++, high relative expense; *CBC*, complete blood cell count.

TABLE 72-3

Chemotherapeutic Agents and Their Applications in Dogs and Cats—*cont'd*

DRUG NAME *(BRAND NAME)*	DRUG CLASS	PRIMARY INDICATIONS	DOSAGE	TOXICITIES AND PRECAUTIONS	GENERICS AVAILABLE	RELATIVE COST
Dacarbazine *(DTIC)*	Alkylating agent	Rarely used Rescue protocols for lymphoma Possible mild efficacy in melanoma	*Dogs:* 200 mg/m^2 IV slowly SID for 5 days every 3 weeks	Myelosuppression, vomiting, diarrhea, and extravasation reaction Should not be used in cats	No	++
Doxorubicin *(Adriamycin)*	Antitumor antibiotic	Lymphoma, lymphoid leukemias, canine osteosarcoma, and various solid tumors	*Medium to large dogs:* 30 mg/m^2 IV over 20 minutes every 3 weeks *Small dogs, cats:* 1 mg/kg to 25 mg/m^2 IV every 3 weeks	Myelosuppression, vomiting, diarrhea, serious extravasation reaction Cumulative doses >180 mg/m^2 increase risk of dilated cardiomyopathy in dogs Colitis and cardiotoxicity in dogs Possible nephrotoxin or hepatotoxin in cats Allergic reactions possible if given too quickly	Yes	+
Gemcitabine *(Gemzar)*	Antimetabolite	Poor efficacy to date May have a role as radiosensitizer	Not well delineated Bolus dosing not recommended owing to mechanism of action	Relatively few when given by bolus May cause myelosuppression, vomiting, and diarrhea when given at lower doses over longer periods Local tissue reactions when used with radiation	No	+++
Hydroxyurea *(Hydrea)*	Antimetabolite	Polycythemia vera, chronic myelogenous leukemia Used rarely for other diseases	*Dogs:* 80 mg/kg PO every 3 days *Cats:* 25 mg/kg PO three times per week	Myelosuppression and anemia Monitor serial CBCs and platelet counts and reduce dosage if neutropenia, thrombocytopenia and anemia occur	Yes	+
Ifosfamide *(Ifex)*	Alkylating agent	Canine lymphoma rescue protocols Some efficacy in feline vaccine-associated sarcomas or other solid tumors	*Dogs:* 350 mg/m^2 IV every 2-3 weeks *Cats:* 900 mg/m^2 IV every 3 weeks	Myelosuppression Urotoxicity prevented with diuresis and mesna administration	No	++
Lomustine *(CCNU; CeeNu)*	Nitrosourea	Lymphoma rescue protocols Mast cell tumors and central nervous system tumors	*Medium to large dogs:* 70-80 mg/m^2 PO every 4-6 weeks *Small dogs, cats:* 50-60 mg/m^2 PO every 4-6 weeks	Myelosuppression, vomiting, and diarrhea Thrombocytopenia with cumulative doses Hepatotoxicity in dogs Pulmonary toxicity in cats	No	+
Melphalan *(Alkeran)*	Alkylating agent	Multiple myeloma	*Dogs:* 0.1 mg/kg PO SID for 10 days, then 0.05 mg/kg PO SID for maintenance	Myelosuppression Monitor serial CBCs and platelet counts every 4-6 weeks Reduce dosage or discontinue if neutropenia or thrombocytopenia occur	Yes	+

Continued

TABLE 72-3

Chemotherapeutic Agents and Their Applications in Dogs and Cats—*cont'd*

DRUG NAME *(BRAND NAME)*	DRUG CLASS	PRIMARY INDICATIONS	DOSAGE	TOXICITIES AND PRECAUTIONS	GENERICS AVAILABLE	RELATIVE COST
Methotrexate *(Trexall, Rheumatrex)*	Antimetabolite	Very few indications May or may not be useful in multiagent lymphoma protocols	*Dogs:* 0.6-0.8 mg/kg IV every 3 weeks or as protocol dictates *Cats:* 0.8 mg/kg IV every 4 weeks or as protocol dictates	Myelosuppression, vomiting, and diarrhea	Yes	++
Mitotane *(Lysodren)*	Unclassified	Adrenocortical tumors	Induction: 25 mg/kg PO BID Maintenance (once ACTH stimulation test results have normalized): 50 mg/kg PO per week divided into two or three doses	Iatrogenic hypoadrenocorticism: adjust dose and give corticosteroids as needed Vomiting, diarrhea, and neurological signs	Yes	+
Mitoxantrone *(Novantrone)*	Antitumor antibiotic	Canine transitional cell carcinoma, anal sac apocrine adenocarcinoma, carcinomatosis/ sarcomatosis, malignant effusions Mild activity in rescue protocols for lymphoma Some efficacy for various other solid tumors	*Dogs:* 5.5-6.0 mg/m^2 IV every 3 weeks *Cats:* 5.0-6.5 mg/m^2 IV every 3 weeks	Myelosuppression, vomiting, diarrhea Possible mild cardiotoxin in dog Mild to moderate irritant with extravasation	No	+++
Mechlorethamine *(Mustargen)*	Alkylating agent	Rescue protocols for lymphoma and other lymphoid leukemias	*Dogs, cats:* 3.0 mg/m^2 IV on weeks 1 and 2 or 3 of the 4-week MOPP protocol	Myelosuppression, vomiting, diarrhea Serious extravasation reaction	Yes	++
Piroxicam *(Feldene)*	Nonsteroidal antiinflam-matory drug	Canine transitional cell carcinoma and osteosarcoma May have activity against squamous cell carcinoma and other tumors Good palliative agent	*Dogs:* 0.3 mg/kg PO SID *Cats:* 0.3 mg/kg PO SID-QOD	May cause nausea, vomiting, diarrhea, or melena Use gastrointestinal protectants concurrently Can also cause nephrotoxicity or hepatotoxicity	Yes	+
Prednisone	Corticosteroid	Lymphoma, mast cell tumor, other lymphoid leukemias, central nervous system tumors Palliative agent	Dosage extremely variable across protocols Follow specific protocol guidelines General dose: 1 mg/kg PO SID for 30 days, then QOD	Iatrogenic hyperadrenocorticism, gastrointestinal upset Do not give if diagnosis of lymphoma has not been confirmed Do not give alone if multiagent chemotherapy protocol for lymphoma is being considered	Yes	+

ACTH, Adrenocorticotropic hormone; *MOPP,* mustargen, oncovin, procarbazine, and prednisone.

TABLE 72-3

Chemotherapeutic Agents and Their Applications in Dogs and Cats—*cont'd*

DRUG NAME *(BRAND NAME)*	DRUG CLASS	PRIMARY INDICATIONS	DOSAGE	TOXICITIES AND PRECAUTIONS	GENERICS AVAILABLE	RELATIVE COST
Procarbazine *(Matulane)*	Alkylating agent	Lymphoma rescue as part of MOPP protocol Other lymphoid leukemias	*Dogs:* 50 mg/m^2 PO SID for 14 days every 4 weeks on MOPP protocol Use compounded formulations to increase dosing precision	Myelosuppression, vomiting, and diarrhea	Yes	+++
Vinblastine *(Velban)*	Mitotic inhibitor	Mast cell tumor, rescue protocol for lymphoma, or as substitute when vincristine not tolerated well	*Dogs, cats:* 2.0-3.0 mg/m^2 IV every 1 to 3 weeks	Myelosuppression, mild vomiting, diarrhea Extravasation reaction	Yes	+
Vincristine *(Oncovin)*	Mitotic inhibitor	Lymphoma, transmissible venereal tumor	*Dogs with lymphoma:* 0.5-0.75 mg/m^2 IV, as per protocol *Cats with lymphoma:* 0.025 mg/kg IV, as per protocol *Dogs with TVT:* 0.5 mg/m^2 IV weekly until resolution (typically ≤6 weeks)	Extravasation reaction Rarely ileus, peripheral neuropathy Rarely vomiting on administration to cats	Yes	+
Vinorelbine *(Navelbine)*	Mitotic inhibitor	Rescue protocols for lymphoma and lung tumor New agent, so more indications may be identified over time	*Dogs:* 15-18 mg/m^2 IV every 1-2 weeks	Myelosuppression and extravasation	No	++

B. Targeting approaches are numerous.
   1. Monoclonal antibodies (MAb)
      a. These are single antibodies that recognize tumor-specific antigens.
      b. Their use has not been reported in companion animals.
      c. MAb 231 (Synbiotics, Inc., Lyon, France) recognizes canine lymphoma cells and may be useful for this disease in the future.
   2. Vaccines and dendritic cell approaches are also used.
      a. Genetically engineered sources of antigens are used to generate an antitumor immune response.
      b. A xenogenic DNA vaccine was approved in 2007 for the treatment of canine malignant melanoma.
      c. Studies are ongoing for the use of DNA vaccines and dendritic cell approaches in canine lymphoma and other tumors.

Photodynamic Therapy

Definition

I. Photodynamic therapy (PDT) is a local anticancer treatment that uses a photosensitizer that interacts with a light source.
   A. The photosensitizer is generally administered systemically but is thought to preferentially accumulate in the tumor.
   B. Most photosensitizers are inert and only become activated upon interaction with a specific wavelength of light.
   C. When activated, the drug interacts with molecular oxygen to create oxygen radicals.
   D. Oxygen radicals then cause local tumor cell death, local vasculature cell death, and possibly death of nearby normal cells.
II. Materials needed include a photosensitizer (most are porphyrin derivatives) and a light source.
   A. Lasers are preferred but not absolutely necessary for PDT.
   B. The light source is applied a variety of ways.
   C. Fiberoptics are most consistently used because of their compatibility with lasers.

Applications

I. PDT has been used for a wide variety of tumors in small animals, including soft-tissue sarcomas, transitional cell carcinomas, mast cell tumors, and nasal squamous cell carcinomas in cats.
II. Advantages include the following:
   A. May only require a single treatment
   B. Typically well tolerated
   C. Easy to administer multiple treatments over time
III. Disadvantages are as follows:
   A. Expense of equipment and photosensitizers
   B. Can be toxic and large clinical studies not available to date
   C. Only useful for superficial tumors because of poor penetration of most light wavelengths (≤5 to 10 mm)
   D. Hypersensitivity reactions possible

Hyperthermia

Definition

I. Heating of tissues to ≥42° C to cause cell death
II. Most efficacious when used in conjunction with other modalities

Applications

I. Whole body by radiant heat
   A. Limited to institutional research settings
   B. Can be efficacious but also causes significant side effects
II. Regional hyperthermia
   A. Feasible in practice owing to less equipment needs
   B. Radiofrequency, ultrasonic, or microwave techniques
   C. Limited benefit or no benefit over surgery

Palliation

Definition

I. The goal of palliation is increased quality of life independent of changes in the course of the disease.
II. It is traditionally used in animals with poor to grave prognoses, and cancer-associated pain.
III. It often includes administration of analgesics or palliative RT.

Types of Analgesics

I. General aspects
   A. Analgesia is most effective if instituted before onset of pain.
   B. Give postoperative analgesics prophylactically instead of waiting for signs of pain.
II. NSAIDs
   A. Mild to moderate efficacy as analgesics
   B. Can be toxic to the gastrointestinal tract, kidneys, and liver
   C. Must not be used concurrently with corticosteroids (increased toxicity)
   D. Give with food whenever possible (unless not recommended)
III. Corticosteroids
   A. Mild to moderate efficacy as an analgesic
   B. May stimulate appetite
   C. May provide mild to moderate antiemetic activity during chemotherapy
   D. Must not be used concurrently with NSAIDs
IV. Nonnarcotic analgesics
   A. Tramadol
      1. It is useful for moderate to severe pain.
      2. Side effects include constipation, weakness, dizziness, sedation, and nausea; reduce dose if sedation is significant.

3. It should not be used with selective serotonin reuptake inhibitors (e.g., fluoxetine) or monoamine oxidase inhibitors (e.g., selegiline).
4. Dose is 2 to 4 mg/kg BID to QID in dogs.
5. Dose is 12.5 mg PO BID in cats.

B. Amantadine
1. It is an N-methyl-D-aspartate receptor antagonist.
2. It is useful for mild to moderate chronic pain when administered with NSAIDs or corticosteroids.
3. Reduce dosage if significant agitation or gastrointestinal toxicity occur.
4. Dose is 3 to 4 mg/kg PO BID in dogs.
5. Dose is 3 mg/kg PO SID in cats.

V. Narcotics
A. Greater efficacy with injectables
B. Butorphanol
1. It is a partial opiate agonist/antagonist.
2. It should not be used concurrently with opiate agonists owing to its partial antagonist properties.
3. It is generally well tolerated but may cause sedation without significant analgesia.
4. Dose is 0.2 to 0.6 mg/kg IV, IM, SC, PO every 1 to 4 hours in dogs.
5. Dose is 0.005 to 0.01 mg/kg IV, IM, SC, PO every 4 to 12 hours in cats

C. Buprenorphine
1. It is a partial opiate agonist.
2. It generally provides more analgesia than butorphanol.
3. Dose is 0.005 to 0.02 mg/kg IM, IV, SC, PO BID to QID in dogs.
4. Dose is 0.005 to 0.01 mg/kg IM, IV, SC, PO BID to QID in cats.

D. Oral sustained-release morphine
1. It is an opiate agonist.
2. Oral bioavailability in dogs is erratic, so it is not routinely recommended.
3. Dose is 1.5 to 3 mg/kg PO BID in dogs.

E. Fentanyl transdermal patches
1. Fentanyl is an opiate agonist.
2. Each patch delivers approximately 72 hours of steady-state blood levels of fentanyl.
3. It takes about 12 hours to reach steady state, so apply the patch before anticipated onset of pain, or use concurrently with other analgesics in the first 12 hours.

VI. Palliative RT: See Radiation Therapy earlier in this chapter.

CHAPTER 73

Paraneoplastic Diseases

Armando R. Irizarry-Rovira

CANCER-ASSOCIATED HYPERCALCEMIA

Definition

I. Hypercalcemia is defined as a value greater than the upper limit of the reference interval (generally ≥12.0 mg/dL) (Bergman, 2002).
II. It is the most common cause of persistent hypercalcemia in animals (Capen, 2002).

Causes

I. It is described most often in the dog and less frequently in the cat (Morrison, 2002).
II. In dogs, the tumors most often responsible include lymphoma, anal sac apocrine gland adenocarcinoma, and myeloma (Capen, 2002; Morrison, 2002).
III. In cats, the tumors most often responsible include lymphoma, squamous cell carcinoma, and some hematological malignancies (Capen, 2002; Morrison, 2002).
IV. Lymphoma is the leading cause in both dogs and cats (Capen, 2002).

Pathophysiology

I. Endocrine-mediated hypercalcemia (humoral) arises when tumor-derived products reach the bloodstream and have a systemic effect (uncontrolled hypercalcemia).
   A. Parathyroid hormone (PTH) is produced by a functional parathyroid tumor.
   B. Products of tumors mimic the effects of PTH or other hormones.
      1. PTH-like product called *parathyroid hormone-related protein* (PTHrP): most common mechanism
      2. Possible inappropriately increased circulating concentrations of $1,25(OH)_2$–vitamin D
      3. Transforming growth factor (TGF), tumor necrosis factor (TNF), and interleukin (IL)-1 possibly act with PTHrP (Sellers et al., 2002)
II. Paracrine-mediated hypercalcemia is associated with bone marrow neoplasms, such as myeloma.
   A. Tumors of the bone marrow may secrete products that act locally to cause resorption of calcium from bone and result in hypercalcemia (Teske, 2004; Capen, 2002).
   B. Implicated products include PTHrP, TGF, TNF, IL-1, and IL-6.
III. Mechanisms of hypercalcemia secondary to tumor metastases to bone are unknown, but a variety of cytokines, tumor products, and inflammatory mediators are implicated.
IV. Hypercalcemia has deleterious effects on multiple organs.
   A. Kidneys
      1. Decreased urine concentrating ability
      2. Interference with the effects of antidiuretic hormone (ADH)
      3. Secondary to renal tubular injury, mineralization, and ischemia
   B. Muscles of the skeleton and gastrointestinal (GI) tract: interference with muscle contractility
   C. Cardiovascular system
      1. Vasoconstriction
      2. Interference with contractility, rhythm and excitability of the myocardium
   D. Nervous system
      1. Interference with normal brain function
      2. Polydipsia from stimulation of the central nervous system (CNS) thirst center
   E. Metastatic mineralization in various organs

Clinical Signs

I. Clinical signs related to the primary neoplastic process
II. Clinical signs associated with hypercalcemia
   A. Most severe: calcium >16 mg/dL
   B. Polyuria, polydipsia
   C. Renal failure
   D. Vomiting, constipation, and anorexia
   E. Muscle weakness and twitching
   F. Bone pain, lameness
   G. Seizures, coma, stupor and/or depression, changes in behavior
   H. Cardiac arrhythmias and abnormalities in the electrocardiogram (e.g., shortened Q-T interval, prolongation of P-R interval, arrhythmias)

Diagnosis

I. Persistently increased ionized calcium or total calcium concentrations
   A. Because most calcium in blood is bound to albumin/proteins, correction formulas may be used in dogs to obtain an estimated total calcium concentration

to compensate for the effects of hyperproteinemia (Stockham and Scott, 2002a).
1. Adjusted total calcium concentration (estimated) = measured total calcium concentration − measured albumin concentration + 3.5
2. Adjusted, estimated total calcium concentration = measured total calcium concentration − (measured total protein concentration × 0.4) + 3.3

B. In a hyperproteinemic and hypercalcemic animal, a corrected total calcium concentration or an ionized calcium concentration that is normal supports the conclusion that hypercalcemia is secondary to changes in protein concentrations.
C. The acid-base status must also be considered, as acidemia increases the concentration of ionized calcium in the blood.
D. Inorganic phosphorus concentration is normal to decreased unless complicated by renal failure and inappropriately increased concentration of $1,25(OH)_2$–vitamin D.

II. Increased serum PTHrP concentration
A. Assays are available in commercial and university diagnostic laboratories
B. PTHrP concentration in normal dogs is low (<0.2 pmol/L) (Foley et al., 2000).

III. Serum PTH concentration: decreased to normal, unless hypercalcemia is secondary to parathyroid adenoma
IV. Azotemia and renal failure possible with extensive renal injury
V. Diagnostic tests for underlying neoplasia
A. Diagnostic imaging
B. Laboratory testing: complete blood count (CBC), serum biochemical profile, protein electrophoresis
C. Fine-needle aspirates, biopsy, and histopathology

Differential Diagnosis

I. Primary hyperparathyroidism
II. Intoxication from ingestion of vitamin D_3 or vitamin D_3 analogues, rodenticides, or nutritional supplements
III. Granulomatous inflammation (Stockham and Scott, 2002a): blastomycosis, cryptococcosis, histoplasmosis
IV. Adrenocortical insufficiency
V. Thiazide diuretics
VI. Iatrogenic hypercalcemia: administration of calcium-containing intravenous products.
VII. Urine acidifying diets in cats (McClain et al., 1999)
VIII. Primary renal failure

Treatment

I. The primary goal is treatment or elimination of the associated neoplasm; however, hypercalcemia must be controlled promptly to avoid detrimental effects on other organs.
II. Fluid therapy is used to induce diuresis and correct electrolyte abnormalities (Bergman, 2002).
A. NaCl 0.9% supplemented with potassium chloride if animal is hypokalemic
B. Dose: 50 to 70 mL/kg/day IV for mild (12 to 14 mg/dL) to moderate (14 to 16 mg/dL) hypercalcemia
C. ≥80 mL/kg/day IV for severe hypercalcemia (>16 mg/dL calcium concentration)

III. Correct acid-base disturbances.
IV. Diuretics such as furosemide at 1 to 2 mg/kg IV SID to BID, may be useful in well-hydrated animals (Bergman, 2002).
V. Prednisone 1 to 2 mg/kg PO SID to BID may be given after a diagnosis is reached in cases of moderate hypercalcemia (14 to 16 mg/dL [Bergman, 2002]) or when other therapies fail (Kirby et al., 2000).
VI. Other treatments for hypercalcemia (bisphosphonates, calcitonin, mithramycin) may be helpful but require further investigation.
VII. See Chapter 48 for treatment of renal failure.

Monitoring of Animal

I. Monitor serum calcium, acid-base status, and kidney function SID.
II. Repeat electrocardiographic evaluations if cardiac failure or arrhythmias were diagnosed initially.
III. Monitor for secondary infections owing to immunosuppression from chemotherapy or glucocorticoid therapy.

CANCER-ASSOCIATED HYPOGLYCEMIA

Definition

I. Decreased serum/plasma glucose concentration occurs in association with neoplastic disease.
II. Blood glucose concentration is <60 to 70 mg/dL (Ogilvie, 2000; Bergman, 2002).

Causes and Pathophysiology

I. Pancreatic beta-cell tumors (insulinoma) may produce hypoglycemia by inappropriate secretion of insulin.
II. Tumors other than pancreatic beta cell tumors may also result in hypoglycemia.
A. Examples include leiomyosarcoma, renal adenocarcinoma, hepatocellular neoplasms, hemangiosarcoma, salivary gland adenocarcinoma, melanoma, mammary carcinoma, primary pulmonary adenocarcinoma, and lymphoid leukemia (Morrison, 2002; Braund, 2003; Battaglia et al. 2005).
B. Tumors may produce an insulin-like substance, such as insulin-like growth factor (IGF) II.
C. Excessive consumption of glucose by the tumor occurs rarely.
D. Hepatic dysfunction or failure from destruction by the neoplasm may result in hypoglycemia.
E. Combinations of the preceding causes also occur.

Clinical Signs

I. Clinical signs are secondary to low glucose concentrations or to counterregulatory mechanisms mediated by the sympathetic system and adrenal gland (Braund, 2003).
II. Neurological signs are most common and typically occur if glucose is <45 to 50 mg/dL.
III. Neurological signs may arise from polyneuropathy (Dyer, 2004).

IV. Clinical signs worsen with precipitous drops in the concentration of glucose.
  A. Seizures
  B. Confusion, ataxia
  C. Weakness, lethargy, fatigue, collapse
  D. Muscle twitching
V. Clinical signs may also be related to the primary tumor.

Diagnosis

I. Decreased serum/plasma glucose concentration
  A. Persistently low fasting glucose concentration
  B. May need to fast for 24 to 48 hours to have reproducible results
II. ± Increased blood insulin concentration
  A. It is measured concurrently with glucose concentrations.
  B. Increased insulin concurrent with fasting hypoglycemia (<60 mg/dL) is strong evidence of an insulinoma.
III. Increased insulin to glucose ratio (I:G ratio) (Stockham and Scott, 2002)
  A. I:G ratio (μU insulin/mg glucose) = insulin concentration (μU/mL) ×100 ÷ glucose (mg/dL).
  B. Normal values must be determined by each laboratory.
  C. Increased I:G ratio with hypoglycemia suggests insulin is contributing to the hypoglycemia.
  D. Increased I:G ratio with hyperglycemia or normoglycemia suggests insulin resistance.
  E. Amended I:G ratio is not considered valid in dogs and cats (Stockham and Scott, 2002; Braund, 2003).
IV. To detect the causative neoplastic disease: diagnostic imaging, laboratory testing, biopsy, and histopathology

Differential Diagnosis

I. Iatrogenic hypoglycemia: insulin overdose
II. Malnutrition
III. Gastrointestinal disease
IV. Liver insufficiency
V. Adrenocortical insufficiency
VI. Sepsis

Treatment

I. Treat or eliminate the associated neoplasm.
II. Institute frequent feeding (3 to 6 meals daily) of a high complex carbohydrate, protein, and fat diet.
III. Prednisone 0.5 to 1 mg/kg PO BID may be used to increase glucose concentrations in dogs.
IV. Diazoxide 5 to 13 mg/kg PO BID may be useful in dogs with inoperable or metastatic insulinoma, but it is expensive (Nelson, 2000).
V. Intravenous infusion of a 5% dextrose solution immediately increases glucose concentrations, but infusion of more concentrated solutions may result in rebound hyperinsulinemia and profound hyperglycemia.

Monitoring of Animal

I. Regularly monitor the animal for clinical signs of hypoglycemia.
II. Monitor blood glucose concentration initially every 2 weeks, and then every 4 to 6 weeks once glucose concentrations are normal.
III. Prognosis is guarded to poor in dogs with insulinoma because of the high risk for recurrence and metastasis.

CANCER-ASSOCIATED HYPERGLYCEMIA

Definition

I. Increased serum/plasma glucose concentration occurs in association with neoplastic disease.
II. Blood glucose concentration is greater than the upper limit of normal (generally >110 to 130 mg/dL).

Causes and Pathophysiology

I. Tumors that may be associated with hyperglycemia include growth hormone-secreting pituitary tumors, adrenocortical tumors, glucagonomas, and vascular hamartomas (Padgett et al., 1997; Stockham and Scott, 2002b; Capen, 2002; Zerbe and Washabau, 2000; Feldman, 2000).
II. Hyperglycemia is caused by the production of hormones that stimulate release and synthesis of glucose, or by resistance to insulin.

Clinical Signs

I. Clinical signs are usually secondary to the primary tumor or hormone produced by the tumor.
II. Animals with growth hormone-producing acidophil adenomas may have acromegalic features.
III. Animals with functional adrenocortical tumors may have clinical signs of hyperadrenocorticism.
IV. Animals with glucagonomas may have cutaneous changes (superficial necrolytic dermatitis).

Diagnosis

I. Increased serum/plasma glucose concentrations are suspicious.
  A. Persistently increased fasting glucose concentrations (>130 mg/dL)
  B. Hyperglycemia refractory to insulin therapy
II. Diagnostic imaging, laboratory testing, biopsy, and histopathologic analysis assist in the detection of the underlying neoplastic disease.
III. Hormone determinations (glucagon, cortisol, growth hormone) may reveal a direct hormonal cause for the hyperglycemia.

Differential Diagnosis

I. Diabetes mellitus secondary to pancreatic islet injury or destruction
II. Insulin resistance unassociated with neoplastic disease
III. Iatrogenic hyperglycemia: glucocorticoids, megestrol acetate, dextrose, glucagon, ketamine, xylazine, streptozocin
IV. Stress or excitement: transient hyperglycemia

Treatment and Monitoring

I. The primary goal is treatment and/or elimination of the associated neoplasm.

II. Monitor blood glucose concentrations SID after elimination of the primary neoplasm, then every 2 weeks after concentrations stabilize.

MAST CELL-ASSOCIATED SYNDROMES

Definition

I. Mast cell-associated syndromes arise from increased concentrations of histamine and other products of mast cell tumors (Fox et al., 1990; Morrison, 2002; Kraegel and Madewell, 2000; Misdrop, 2004; Teske, 2004).
II. Syndromes most often described include gastroduodenal ulceration, localized cutaneous reactions, and systemic reactions.
III. These syndromes occur most often in dogs.

Causes and Pathophysiology

I. Dogs with mast cell tumors (MCT) typically have increased circulating concentrations of histamine (Fox et al., 1990).
II. Massive release of histamine from mast cell tumors may occur during surgical removal, trauma, or chemotherapy.
III. Gastroduodenal ulceration may occur.
   A. Histamine (H) interacts with H_2 receptors in the parietal cells of the stomach and stimulates secretion of gastric acid.
   B. Increased acidity in the stomach may result in ulceration of the stomach, duodenum, and esophagus.
   C. Histamine may also damage vascular endothelium, possibly causing ischemic necrosis of the GI mucosa.
IV. Release of histamine and other substances from mast cell granules may result in local recruitment of inflammatory cells and other cutaneous changes.
V. Marked release of histamine may also result in hypotensive shock that typically occurs with manipulation and treatment of large neoplasms, multiple tumors, and advanced stages of mast cell cancer.

Clinical Signs

I. Systemic signs
   A. Anorexia, inappetence
   B. Emesis
   C. Abdominal pain
   D. Hematochezia, melena
   E. Shock
II. Localized skin changes
   A. Poor wound healing
   B. Erythema, hemorrhage
   C. Pruritus
   D. Swelling
   E. Ulceration

Diagnosis

I. Clinical signs and physical examination findings may be suggestive.
II. Cutaneous MCT is often diagnosed by cytological examination of fine-needle aspirates.
III. Histological evaluation is necessary for proper grading of the tumor.
IV. Noncutaneous MCT often requires histopathology and other diagnostic tests.
V. Assays for plasma histamine are not usually necessary or widely available.

Differential Diagnosis

I. Other causes of GI bleeding, abdominal pain, anorexia
II. Other cutaneous tumors: histiocytoma, plasmacytoma, etc.
III. Other causes of circulatory shock and hypotension

Treatment

I. The primary goal is treatment and/or elimination of the tumor.
II. Pretreatment with H_1 and H_2 receptor blockers may be necessary to minimize the negative effects of massive histamine release during surgical removal.
   A. H_1 receptor blockers: diphenhydramine 1 mg/kg IM
   B. H_2 receptor blockers
      1. Ranitidine 0.5 to 2 mg/kg PO, SC, IV BID to TID
      2. Cimetidine 4 to 6 mg/kg PO, SC, IV TID to QID
      3. Dogs: famotidine 0.1 to 1 mg/kg PO, IV SID to BID
      4. Cats: nizatidine 2 to 5 mg/kg SID PO or 1 to 3 mg/kg SC, IM, IV TID
III. Proton pump inhibitors such as omeprazole or lansoprazole may be given to dogs at 1 to 2 mg/kg PO SID (maximum 20 mg/day) for cases of severe gastric ulceration (Hall, 2000).
IV. Sucralfate 0.5 to 1 g PO BID to QID may also be used in dogs for gastric ulcers, but must be administered 30 to 60 minutes after H_2 blockers to minimize interference with their absorption.
V. Prednisone 1 to 2 mg/kg PO SID to BID is used to minimize edema and inflammation at the site of the tumor, and possibly to inhibit tumor growth and granule formation (Bergman, 2002; Rogers, 1996).
VI. Palliative radiation therapy may be useful if complete removal of the tumor is not possible.

Monitoring of Animal

I. Monitor regularly for impaired wound healing after removal of MCTs.
II. Monitor for continued histamine-related problems, such as gastroduodenal ulceration, delayed wound healing, etc.

ZOLLINGER-ELLISON SYNDROME

Definition and Causes

I. Zollinger-Ellison syndrome is gastroduodenal ulceration associated with increased gastrin blood concentrations.
II. Excessive secretion of gastrin occurs from gastrin-secreting pancreatic tumors (gastrinomas).
III. Gastrin increases the secretion of acid in the stomach.

Clinical Signs

I. Anorexia, weight loss
II. Vomiting

III. Abdominal pain
IV. Depression, lethargy
V. Hematochezia, hematemesis, melena

Diagnosis

I. Suspicious clinical signs and physical findings
II. Determination of basal blood gastrin concentrations
  A. Increased in dogs and cats with gastrin-secreting tumors (normal = 3.65 ng/L in dogs, <18 pg/mL in cats [Garcia-Sancho et al., 2005; Goldstein et al., 1998]).
  B. Not entirely specific for gastrinoma, as basal gastrin may be increased with renal failure, chronic gastritis, liver disease, small intestinal resection, and during therapy with H_2 receptor blockers
  C. Stimulation tests possibly necessary for confirmation of the diagnosis
    1. These tests require additional investigation in dogs and cats.
    2. Secretin and calcium stimulation tests induce increases in gastrin with gastrinomas but not in normal animals.
  D. Assays for gastrin not widely available
III. Other tests to diagnose the neoplasm: diagnostic imaging, serum biochemical analyses, biopsy, histopathology

Differential Diagnosis

I. Other nonneoplastic causes of GI bleeding, abdominal pain, anorexia
II. Other neoplastic causes of gastroduodenal ulceration, such as mast cell tumors

Treatment and Monitoring

I. The primary goal is treatment and/or elimination of the tumor.
II. Correct any electrolyte, acid-base, and fluid disorders.
III. Start H_2 receptor blockers.
  A. Ranitidine 0. to 2 mg/kg PO, SC, IV BID to TID
  B. Cimetidine 4 to 6 mg/kg PO, SC, IV TID to QID
  C. Dogs: famotidine 0.1 to 1 mg/kg PO, IV SID to BID
  D. Cats: nizatidine 2 to 5 mg/kg SID PO or 1 to 3 mg/kg SC, IM, IV TID
IV. Sucralfate 0.5 to 1g PO BID to QID may be used in dogs to promote healing of gastric ulcers, but must be administered 30 to 60 minutes after H_2 blockers to minimize interference with their absorption.
V. Proton pump inhibitors such as omeprazole or lansoprazole may be given in dogs at 1 to 2 mg/kg PO SID for severe gastric ulceration (Hall, 2000).
VI. Prognosis in dogs and cats is grave owing to a high incidence of metastasis.

CANCER-ASSOCIATED CACHEXIA

Definition

I. It is general physical wasting and malnutrition associated with cancer (Ogilvie, 2000).
II. Cachexia may be defined as >20% weight loss; however, weight loss of 10% should be thoroughly investigated (Greco, 2000).

Causes and Pathophysiology

I. Cancer-associated cachexia is a derangement of lipid, protein, and carbohydrate metabolism in animals with cancer (Morrison, 2002; Ogilvie, 2000).
II. The chemical mediators have not been entirely defined; however, changes in cytokines and hormones such as interferon, TNF, interleukin-1, IL-6, insulin, and growth hormone may be involved.
III. There is a net loss of energy in the body.
IV. Tumor cells have a high rate of glucose consumption.
  A. Consumption occurs at the expense of the animal.
  B. Less glucose is available for healthy cells.
  C. Increased lactic acid concentrations occur from glycolysis in tumor cells.
  D. Lactic acid is converted to glucose by the animal's nonneoplastic tissues at a net loss of energy.
  E. Some animals may have concurrent insulin resistance that results in less glucose entering nonneoplastic cells.
V. Circulating concentrations of amino acids used for gluconeogenesis are also decreased.
  A. Protein catabolism is greater than protein synthesis.
  B. Indicators of severe protein catabolism include the following:
    1. Muscle wasting
    2. Decreased albumin concentrations
    3. Impaired healing of wounds
    4. Secondary infections from compromised immune function
VI. Derangements in fat metabolism also occur.
  A. Body fat is decreased owing to lipolysis, as the body tries to oxidize lipids for energy.
  B. Cancer cells do not utilize lipids as well as noncancerous cells.

Clinical Signs

I. Anorexia
II. Decreased body weight
III. Muscle wasting
IV. Weakness, fatigue

Diagnosis

I. Suspicious clinical signs, especially in the absence of malnutrition, malabsorption, cardiac disease
II. Tests to diagnose neoplasia: diagnostic imaging, laboratory testing (CBC, serum biochemical analyses), biopsy, histopathology, etc.

Differential Diagnosis

I. Malnutrition
II. Anorexia of nonneoplastic cause: dental disease, CNS disease, intoxication (e.g., aspirin, ethylene glycol, rodenticides)
III. Gastrointestinal malabsorption
IV. Severe parasitism
V. Chronic diarrhea, vomiting, or both
VI. Heart disease
VII. Diabetes mellitus, hyperthyroidism
VIII. Protein-losing nephropathy

Treatment

I. The primary goal is treatment or elimination of the tumor.
II. The secondary goal is to increase intake of nutrients.
III. Institute measures to increase appetite.
  A. Warm, aromatic foods
  B. Diazepam 0.05 to 0.15 mg/kg IV SID to QOD in cats (Bergman, 2002)
  C. Cyproheptadine 1 to 2 mg PO SID to BID in cats (Bergman, 2002)
IV. Nutritional supplementation includes the following (Ogilvie, 2000):
  A. Diets with highly bioavailable protein, modest amounts of simple carbohydrates, and n-3 fatty acids (Hill's n/d; Hill's Pet Nutrition, Inc., Topeka, Kan.)
  B. Increased fiber content
V. Increase frequency of feeding or consider enteral feeding.
VI. Provide parenteral nutrition if necessary.
VII. Avoid lactate and glucose-containing fluids during fluid therapy.

Monitoring of Animal

I. Monitor body weight on a weekly basis.
II. Repeat CBC every 2 weeks and serum biochemical profiles monthly to monitor general health and evaluate for opportunistic infections and anemia.
III. Document food intake at home and while hospitalized.
IV. Prognosis is poor.

CANCER-ASSOCIATED FEVER

Definition and Causes

I. Fever is an increase in body temperature above the expected normal temperature for that species.
II. Endogenous or exogenous pyrogens act on the thermoregulatory center in the anterior hypothalamus to elevate the body temperature (Miller, 2000).
III. Excessive heat production or inadequate heat loss occur to meet the new temperature "set-point."
IV. Fever develops from the presence of cancer in the body.
V. Fever of unknown origin (FUO) is a term typically used for fever that persists for a period ≥2 to 3 weeks and for which a cause has not been identified.
  A. With transient, self-limiting causes, fever usually resolves within 2 weeks.
  B. There are numerous causes of FUO, including cancer.
VI. Fever must be differentiated from other causes of hyperthermia, such as excessively high ambient temperatures (i.e., heat stroke), vigorous exercise on a hot day, excessive exercise, and injury to the thermoregulatory center.

Pathophysiology

I. Neoplasms produce cytokines and other chemical mediators that act on the thermoregulatory center to result in fever.
II. Specific immune-mediated reactions to the tumor or generalized inflammatory reactions to tumor necrosis may also elicit release of cytokines and chemical mediators.

Clinical Signs

I. Increased body temperature
II. Clinical signs associated with the neoplastic process
III. Weight loss or cachexia
IV. Anorexia and dehydration
V. Lethargy

Diagnosis

I. Rule out other causes of fever.
II. Diagnostic imaging, laboratory testing, biopsy, fluid analyses (e.g., joints, cerebrospinal fluid, abdominal fluid, urine), and histopathologic analysis help to diagnose neoplastic disease and to rule out other causes of fever.

Differential Diagnosis

I. Immune-mediated diseases (e.g., immune-mediated polyarthritis), noninfectious inflammatory diseases
II. Infections: bacterial, fungal, viral, parasitic
III. Tissue injury: trauma, infarction, ischemia
IV. Drugs: tetracycline (cats), levamisole (cats), bleomycin, colchicine, halothane, succinylcholine

Treatment

I. Primary treatment is directed at eliminating or controlling the neoplastic process.
II. If the fever exceeds 41° C (106° F), cool the animal.
  A. Bathe with cool water.
  B. Excessively cold water may interfere with release of heat because of vasoconstriction of the cutaneous vasculature.
  C. Consider cool water enemas or cool water gastric lavage.
III. Nonsteroidal antiinflammatory drugs may be given as antipyretics if fever persists.
  A. Dogs: aspirin 5 to 10 mg/kg PO SID to BID
  B. Cats: aspirin 3 to 6 mg/kg PO every 2 to 3 days

Monitoring of Animal

I. Measure and document the body temperature SID to QID (Bergman, 2002).
II. Monitor response to antitumor therapy and for recurrence and metastasis of the tumor.

HYPERGLOBULINEMIA

Definition

I. Increased concentration of immunoglobulins in the blood from excessive production by neoplastic cells
II. Generally arises from a monoclonal (sometime biclonal) synthesis of immunoglobulin (Ig) M, IgG, or IgA

Causes

I. Multiple myeloma
II. Extramedullary plasmacytoma
III. Lymphoma
IV. Lymphocytic leukemia

Pathophysiology

I. Neoplastic lymphocytes produce excessive amounts of immunoglobulins, such as IgA, IgG, IgM, or light chains.
II. Markedly increased protein concentrations result in increased resistance to the flow of blood or hyperviscosity.
III. Increased serum viscosity may result in hyperviscosity syndrome (HVS).
  A. In dogs HVS has been associated most often with elevations of IgM because of its larger size compared with IgG and IgA.
  B. Slow blood flow and distention of small blood vessels (e.g., retinal vessels) occur.
  C. Delivery of oxygen and nutrients to tissues is inadequate.
    1. Hypoxic injury to tissues results.
    2. Organs most commonly affected are the central nervous system, eyes, and kidneys (Morrison, 2002).
    3. Cardiac disease may occur secondary to hypoxic injury and excessive cardiac workload.
    4. Renal disease may be complicated by amyloidosis and light chain proteinuria (Bence-Jones proteinuria).
IV. Immunoglobulins produced by the neoplastic cells may interfere with coagulation and result in increased bleeding.
  A. Inhibition of platelet function
  B. Interference with clotting factors

Clinical Signs

I. Some clinical signs are directly related to the physical presence of the neoplasm.
II. Neurological abnormalities develop secondary to hyperviscosity
  A. Lethargy and weakness
  B. Seizures
  C. Dementia, depression
  D. Ataxia
  E. Anorexia and weight loss: common in cats with multiple myeloma
III. Abnormal bleeding also occurs with hyperviscosity.
  A. Epistaxis
  B. Mucosal hemorrhages
  C. Petechiae, ecchymoses
  D. Excessive bleeding at sites of venipuncture or injections
IV. Ocular abnormalities include hyphema, retinal hemorrhage, retinal detachment, and tortuosity and distention of retinal vessels.
V. Polyuria/polydipsia may develop from impaired renal function secondary to glomerular amyloidosis, decreased renal perfusion, or Bence-Jones proteinuria.

Diagnosis

I. Confirm and characterize the hyperglobulinemia.
  A. Increased total protein and globulin levels on serum biochemistry profile
  B. Serum protein electrophoreses
    1. Electrophoresis: monoclonal spike, sometimes biclonal spikes
    2. Immunoelectrophoresis: exact immunoglobulin identified
II. Search for an underlying cause.
  A. CBC, blood smear evaluation, and fine-needle aspirates of lesions, bone marrow, and lymph nodes
    1. Marked leukocytosis and neoplastic lymphocytes with leukemia
    2. Neoplastic plasma cells in lymph nodes, bone marrow, or masses
    3. Cytopenias from bone marrow infiltration
    4. Inflammatory leukograms with opportunistic infections
  B. Serum biochemistry analyses
    1. Evidence of renal insufficiency (azotemia with inappropriately concentrated urine) may be detected.
    2. Hypercalcemia may occur with some neoplasms.
  C. Urinalysis
    1. Bence Jones test: detects light chains in the urine
    2. Immunoelectrophoresis: identifies immunoglobulin light chains
  D. Other tests to consider
    1. Diagnostic imaging
    2. Fluid analyses
    3. Histopathology
    4. Coagulation assays
    5. Ophthalmologic examination

Differential Diagnosis

I. Infection with *Ehrlichia* spp. may cause monoclonal protein spikes on electrophoresis assays (See Chapter 115).
II. Other causes of hyperviscosity include primary or secondary polycythemia (see Chapter 64).

Treatment

I. Direct treatment at the elimination or control of the primary neoplasm.
II. Phlebotomy and administration of isotonic fluids may be necessary in severe cases.
III. Plasmapheresis is helpful for severe cases but is a complicated procedure.
IV. Antimicrobials may be needed to prevent or treat secondary infections from immunosuppression.

Monitoring of Animal

I. Monitor for response to chemotherapy.
II. Osteolytic lesions of multiple myeloma may take months to partially resolve.
III. Decreased serum immunoglobulin and urinary light chain concentration may occur within 3 to 8 weeks, if chemotherapy is successful.
IV. Evaluate CBCs and coagulation parameters every 2 to 4 weeks to monitor for improvement.
V. The prognosis for dogs with multiple myeloma uncomplicated by hypercalcemia, Bence-Jones proteinuria, and marked bone lysis is generally good.
VI. The prognosis for cats with multiple myeloma is typically poor because of a limited response to chemotherapy.

OTHER PARANEOPLASTIC SYNDROMES

See Table 73-1.

TABLE 73-1

Other Paraneoplastic Syndromes

CLASS OF DISORDER	SPECIFIC DISORDER	CAUSES	CLINICAL SIGNS
Cutaneous paraneoplastic diseases (Adapted from Turek, 2003; Angarano and Brewer, 1993)	Superficial necrolytic dermatitis	Glucagonoma (dogs) Pancreatic carcinoma (cat) Rule out hepatopathy	Well-demarcated erythematous erosions and alopecia involving haired skin and pressure points, mucocutaneous junctions, perineum, feet, muzzle Hyperkeratosis of the footpad
	Nodular dermatofibrosis	Cystadenoma or carcinoma of the kidney Females develop leiomyomas of the uterus	Multiple masses and papules in the dermis and subcutaneous tissues Extremities preferentially affected Predilection for German shepherd dogs
	Paraneoplastic pemphigus	Thymic lymphoma Splenic sarcoma	Erosions in the oral and nasal mucosa, mucocutaneous junctions, and haired skin In haired skin lesions may begin as vesicobullous lesions
	Feminization in male dogs	Sertoli cell tumor	Gynecomastia, bilateral symmetrical alopecia, pendulous prepuce, linear preputial dermatosis Possible enlarged testicles Possible cryptorchid testicle
	Feline thymoma-associated exfoliative dermatitis	Thymoma	Erythema and scaling progressing to alopecia Ulcers and crusts may occur Sebaceous debris in ear canals, nail bed, and between digits Nonpruritic
	Feline paraneoplastic alopecia	Pancreatic and biliary carcinoma	Progressive, bilaterally symmetrical alopecia Nonpruritic Footpads may be erythematous, dry, fissured, and crusted Concurrent clinical signs of illness (inappetence, vomiting, weight loss)
	Necrosis of skin	Lymphoma, possibly others	Necrotic skin on the extremities May be symmetrical
Hematological, coagulation	Anemia	Multiple tumors	Weakness, pallor, decreased hematocrit Anemia may arise secondary to blood loss, bone marrow infiltration by neoplastic cells, chemotherapy, iron or vitamin deficiency, and hemolysis
	Thrombocytopenia or coagulopathies	Multiple tumors	Petechiae, hemorrhages decreased platelet counts, increased coagulation times
	Polycythemia	Renal neoplasms, hepatic neoplasms, nasal fibrosarcoma	Increased hematocrit, lethargy, depression, anorexia, polyuria, polydipsia, vomiting, weakness

Continued

TABLE 73-1

Other Paraneoplastic Syndromes—*cont'd*

CLASS OF DISORDER	SPECIFIC DISORDER	CAUSES	CLINICAL SIGNS
		Rule out polycythemia vera, and dehydration	
	Leukocytosis (nonleukemic)	Multiple tumors	Increased white blood cell counts
Neurological (Adapted from Dyer, 2004; Braund, 1990)	Myasthenia gravis	Thymoma, other mediastinal tumors	Muscle weakness, exercise intolerance, difficulty holding up the head, and closing mouth or eyelids Dysphagia, regurgitation Megaesophagus
	Polyneuropathies	Multiple tumors	No clinical signs or weakness, paresis, ataxia
Urinary, endocrine	Nephrogenic diabetes insipidus (Cohen and Post, 1999)	Intestinal leiomyosarcoma	Increased water consumption Inability to concentrate urine despite adequate antidiuretic hormone concentrations Polyuria, polydipsia
	Inappropriate secretion of ADH (Bergman, 2002; Ogilvie, 2000)	Lymphoma, carcinoma, meningeal sarcoma Rule out other nonneoplastic causes (e.g., vincristine, barbiturates)	No clinical signs Hyponatremia, anorexia, increased body weight (water retention), vomiting, weakness, seizures, coma
Musculoskeletal	Hypertrophic osteopathy (see Chapter 81)	Primary or secondary pulmonary tumors are the most frequent cause in dogs Other neoplastic and nonneoplastic conditions of the thorax and abdomen	Thickened, painful, possibly deformed extremities Extremities may be warm to the touch

CHAPTER 74

Introduction

Ellen Miller

IMMUNE SYSTEM

I. The immune system is a complicated array of cellular and biochemical components designed to discriminate self from nonself.
II. Both the antigen-specific and antigen-nonspecific components of the immune system protect the individual from infectious agents, neoplastic cell growth, and noninfectious invaders.
III. The immune system has the ability to respond to a wide variety of antigens (diversity) that it is genetically preprogrammed before exposure to those antigens.
IV. The immune system can respond more rapidly when a particular antigen is recognized the second time (memory).
V. The immune system has the ability to distinguish self from nonself (discrimination).

NONSPECIFIC MECHANISMS

I. Nonspecific immunological mechanisms include physical barriers, granulocytes, monocytes, complement and other inflammatory cells, and mediators.
II. Physical barriers are the first line of defense against invaders and include the skin, respiratory mucociliary apparatus, and normal gastrointestinal flora.
III. Once the physical barriers have been penetrated, inflammatory cells move into the area and chemical mediators are released (see Chapter 65).
   A. The neutrophil contains azurophilic granules (e.g., defensins, myeloperoxidase, lysozyme, elastase, collagenase, cathepsin, lipases, ribonuclease, other proteinases) and specific granules (e.g., lysozyme, nicotinamide adenosine dinucleotide phosphate [NADPH] oxidase, collagenase, gelatinase, lactoferrin, histaminase, receptors for complement, fibrinogen, fibronectin).
      1. When circulating neutrophils detect chemoattractants, such as complement components, fragments of collagen, leukotriene (LT)B_4, prostaglandin (PG)D_2, platelet-activating factor (PAF), and interleukin (IL)-8, they marginate and emigrate into the site of inflammation.
      2. Once in the area of inflammation, neutrophils engulf bacteria, cellular debris, and foreign particulate matter, forming a phagosome that fuses with granules to create a phagolysosome.
      3. Degranulation of the granules into the phagolysosome results in release of proteins designed to kill bacteria or dissolve foreign material.
   B. Monocytes circulate in peripheral blood or reside (tissue macrophages) in almost every tissue of the body.
      1. They contain lysosomes that store the same enzymes as neutrophil lysosomes but are fewer in number.
      2. In general, phagocytosis is slower and engulfed material is broken down more slowly than with neutrophils.
      3. Macrophages produce the complement components: IL-1, IL-6, IL-12, IL-18, and tumor necrosis factor (TNF).
   C. Eosinophils are produced in the bone marrow under the influence of granulocyte-monocyte colony stimulating factor, IL-3, and IL-5.
      1. Granule contents are comparable to those of neutrophils; however, percentages of the different enzymes vary.
      2. Eosinophils engulf particles, form phagolysosomes, and undergo lysosomal degranulation, but bacterial killing power is less efficient than that of neutrophils.
      3. Eosinophils function to down-regulate the immediate hypersensitivity response and control parasitic infections.
   D. Basophils are produced in the bone marrow from myeloid progenitor cells.
      1. Basophils have receptors for immunoglobulin (Ig)E on their surface and participate in IgE-mediated reactions similar to mast cells.

2. Their granules contain histamine, heparin, serotonin, and other vasoactive substances.
3. When basophils degranulate, the end result is increased vascular permeability and an influx of serum proteins and effector cells.
4. When release of mediators occurs, systemic or local anaphylaxis occurs, depending on the magnitude of release and organ involved.

E. Mast cells are produced in the bone marrow and migrate to tissues where they develop under the influence of various cytokines.
1. Metachromatic granules contain preformed mediators (histamine, heparin, TNF, superoxide dismutase, peroxidase, and acid hydrolases) and precursors to synthesized mediators (prostaglandins and leukotrienes).
2. When an appropriate antigen binds to mast cell IgE, degranulation of mast cells occurs.
3. Two major groups of mast cells exist: those associated with the connective tissue and those that live at the mucosal surfaces.

F. Platelets are produced from megakaryocytes in the bone marrow.
1. They have a 10-day lifespan in the circulation.
2. Activation during the clotting cascade results in aggregation and release of granule contents that include arachidonate metabolites, growth factors, bioactive amines, PAF, and hydrolases.

G. Endothelial cells also play a role in the inflammatory response.
1. Although not really inflammatory cells, they are activated by IL-1, TNF, and interferon (IFN)-α and become more adhesive for monocytes and neutrophils.
2. They can also serve as antigen-presenting cells.

IV. The complement system is a multicomponent, biochemical system that produces specific proteins that destroy foreign invaders.
A. Complement bridges the nonspecific and specific arms of the immune system.
B. Complement system can be activated in several ways.
1. The classical pathway of activation is triggered when antibodies bind to an antigen.
2. The alternative pathway of activation does not require antibody and provides an immediate host defense mechanism in the absence of prior sensitization.

C. The end result of complement activation is a membrane attack complex that causes osmotic lysis and killing of the invader.

V. Cytokines are regulatory proteins produced by cells of the immune system.
A. ILs are cytokines that regulate the interaction between lymphocytes and other leukocytes.
B. IFNs are synthesized in response to viral infections and inhibit viral replication.
C. TNFs are derived from macrophages and T lymphocytes.
D. Growth factors or colony-stimulating factors stimulate the growth of new cells.
E. Chemokines are small proteins that act as chemoattractants or leukocyte activators in the inflammatory response.

VI. Arachidonic acid derivatives are substances produced by cyclooxygenation (PGs) or lipooxygenation (LTs) of arachidonic acid in phagocytic cells, mast cells, and platelets.
A. PGE_2, PGF_2, prostacyclin, and thromboxanes are proinflammatory molecules.
B. LTB_4, LTC_4, LTD_4, and LTE_4 are synthesized in mucosal mast cells.
C. LTB_4 is a potent chemoattractant, whereas the other three (collectively termed *slow-reacting substance of anaphylaxis*) induce smooth muscle contraction, bronchoconstriction, mucus secretion, and the wheal-and-flare response.

SPECIFIC MECHANISMS

I. Specific immunological mechanisms include B and T lymphocytes and their products.

II. T lymphocytes (T cells) are responsible for the cell-mediated portion of the immune system.
A. Helper T cells release cytokines that activate B and cytotoxic T lymphocytes.
B. Cytotoxic T cells directly lyse target cells (e.g., tumor cells, cells infected with virus).
C. Antigen bound to major histocompatibility proteins on the surface of macrophages (antigen-presenting cells) is recognized by the T-cell receptor.
D. Binding of antigen to the T-cell receptor leads to T-cell activation.
1. Helper T cells secrete IL-2, IL-4, IL-5, IL-10, IL-12, IL-13, and IL-18; IFN-α; and TNF.
2. These cytokines amplify the immune response by activating macrophages and B and T lymphocytes.

III. B lymphocytes (B cells) are responsible for the humoral portion of the immune response.
A. Activated B cells (plasma cells) produce immunoglobulin that is specific for a particular antigen.
B. The B-cell antigen receptor is immunoglobulin that is attached to the B-cell surface.
C. The immunoglobulins found in the dog and cat are IgA, IgE, IgG, and IgM.
1. IgA is secreted by plasma cells near mucosal surfaces and is responsible for limiting antigen access to the body.
2. IgE is also secreted by plasma cells located beneath body surfaces, is responsible for the immune response against parasites, and is also involved in allergic reactions.
3. IgG is made and secreted by plasma cells in the lymph nodes, spleen, and bone marrow and is the primary immunoglobulin involved in the systemic immune response.

4. IgM is also produced by plasma cells in the bone marrow, spleen, and lymph nodes and is the first antibody produced in response to antigenic stimulation.

D. B cells, usually with the help of T cells, are activated and divide in response to antigen.
1. A portion of these cells becomes plasma cells, actively secreting immunoglobulin.
2. The other portion becomes memory cells, waiting for a second exposure to the same antigen to be activated.

CLASSIC HYPERSENSITIVITY REACTIONS

I. These immunological reactions are designed to ward off microbial invaders and neutralize toxins; however, when directed at host tissues, they can cause significant damage.

II. Most immune-mediated diseases are classified into one or more of four different reaction types.

A. A type I reaction is the classic anaphylactic reaction.
1. This reaction is mediated by mast cells, eosinophils, basophils, and IgE, and can be a localized or systemic reaction, depending on the route and rate of administration of antigen.
2. Binding of antigen to surface IgE on mast cells results in production and release of vasoactive chemicals such as histamine, serotonin, proteases, LTs, and PGs.
3. Examples include urticaria and systemic anaphylactic shock caused by a penicillin allergy.

B. A type II reaction is a cytotoxic reaction.
1. When the antibodies bind antigen on the cell surface, complement is activated, resulting in generation of the membrane attack complex.
2. The cell bearing the antigen is then destroyed.
3. Examples include immune-mediated hemolytic anemia, immune-mediated thrombocytopenia, and pemphigus vulgaris.

C. A type III reaction is immune complex disease.
1. Type III reactions are mediated by IgG, IgM, complement, neutrophils, platelets, and arachidonic acid metabolites.
2. Antigen–antibody complexes are filtered out in organs with high blood flow and attract neutrophils and platelets.
3. Activation of neutrophils, platelets, and complement causes release of chemicals (e.g., proteases, free radicals, nitric oxide) that damage the affected organ.
4. Immune complexes may contain autoantibodies (antibodies against self-antigens) and may also cause damage even if antibodies are not directed against self-antigens (e.g., heartworm disease causing immune-mediated glomerulonephritis).
5. Examples include systemic lupus erythematosus and vasculitis.

D. A type IV reaction is a delayed-type hypersensitivity reaction.
1. This reaction is mediated by macrophages, lymphocytes, and their cytokines.
2. When antigen enters the body, some is taken up by specialized macrophages that migrate to the local lymph node.
3. Sensitized T cells interact with antigen and secrete IFN, IL-2, IL-8, and serotonin.
4. More T cells and macrophages are attracted to the area, and a granulomatous reaction develops.
5. Contact hypersensitivity (e.g., plastic dish dermatitis) is an example.

CHAPTER 75

Immunodeficiency Disorders

Ellen Miller

CONGENITAL/DEVELOPMENTAL DISORDERS

Primary Ciliary Dyskinesia

Definition and Causes

I. Primary ciliary dyskinesia is characterized by defective ciliary action within the respiratory tract.
II. The cilia of the respiratory epithelial cells have an abnormal microtubule arrangement.

Pathophysiology

I. The microtubular arrangement within the cilia is abnormal and results in random or dyscoordinated movement.
II. This defect results in reduced clearance of organisms that normally gain entry into the respiratory tract.
III. Therefore the escalator action of the mucociliary apparatus is disrupted.
IV. The disorder is inherited as an autosomal recessive trait.

Clinical Signs

I. Severe and recurrent respiratory tract infections such as rhinosinusitis, bronchitis, bronchiectasis, and bronchopneumonia
II. Reported in border collies, English setters, Doberman pinschers, and golden retrievers
III. Accompanied by situs inversus and immotile sperm
IV. Results in recurrent respiratory infections leading to chronic bronchitis and bronchiectasis

Diagnosis and Differential Diagnosis

I. A definitive diagnosis is made by examining respiratory cilia with electron microscopy and identifying the ultrastructural abnormalities in the cilia.
II. Ciliary dyskinesia is suggested in young animals with chronic respiratory disease, with or without situs inversus.
III. Mucociliary scintigraphy detects impaired clearance.
IV. Electron microscopy of tracheal and nasal epithelial biopsies reveals absence of the central pair of microtubules within the cilia.

Treatment and Monitoring

I. Treatment is supportive and symptomatic.
II. Appropriate antibiotic therapy based on culture and sensitivity of respiratory samples is imperative.
III. Supportive care includes oxygen therapy, airway humidification, and respiratory physiotherapy.
IV. Prognosis is guarded.

Cyclic Hematopoiesis

Definition and Cause

I. Cyclic hematopoiesis is caused by an autosomal recessive trait resulting in regular, cyclic fluctuations in leukocyte, platelet, and red blood cell numbers.
II. A cyclic decrease occurs in the production of hematopoietic cells in affected animals.
III. Because clinical signs are usually associated with low leukocyte numbers, this syndrome has also been called *cyclic neutropenia*.

Pathophysiology

I. The defect may arise from abnormal purine metabolism in the stem cells (Jezyk, 1988).
II. Myeloperoxidase deficiency in the neutrophils results in defective bactericidal activity as well.
III. The defect is inherent within the bone marrow environment and may be related to a cyclic decrease in erythropoietin and colony stimulating factor secretion.
IV. Condition is inherited as an autosomal recessive trait.
V. Reactive amyloidosis may develop from recurrent infections.

Clinical Signs

I. The disorder primarily affects gray-coated collies, which rarely live past 3 years of age.
II. In addition to life-threatening bacterial infections, affected animals are weak, have stunted growth, and have poor wound healing.
III. Hemorrhage secondary to thrombocytopenia is frequent.
IV. Neonatal death is common.

Diagnosis and Differential Diagnosis

I. Finding the classic cyclic pattern of neutrophil numbers in a gray-coated collie
II. Ruling out other diseases that can result in neutropenia

Treatment and Monitoring

I. Granulocyte colony-stimulating factor 5 μg/kg SC BID
II. Bone marrow transplantation
III. Lithium carbonate 21 to 26 mg/kg/day PO
IV. Supportive care: appropriate antibiotic therapy, correction of dehydration, oxygen therapy
V. Prognosis: guarded

Chédiak-Higashi Syndrome

Definition and Causes

I. It is characterized by abnormally large azurophilic granules in a number of cell types, including leukocytes.
II. Cells of numerous tissues, including leukocytes, contain abnormal giant azurophilic granules.

Pathophysiology

I. Decreased neutrophil chemotaxis and killing
II. Reduced neutrophil chemotactic activity and intracellular killing of bacteria
III. Defective defense against tumors and viruses by natural killer cells
IV. Transmitted in an autosomal recessive pattern

Clinical Signs

I. Affected cats have a smoke-blue hair coat and yellow-green eyes.
II. Dilution of coat color (abnormal melanin granules), photophobia (abnormal retinal pigment granules), and hemorrhagic tendencies (abnormal platelet function) are most commonly noted.
III. Although cats may have increased bleeding tendencies, the immunosuppression is mild.
IV. Syndrome affects Persian cats.

Diagnosis and Differential Diagnosis

I. Diagnosis is based on the characteristic appearance of neutrophil granules on a blood smear (eosinophilic granules up to 2 μm in diameter in about 50% of the neutrophils).
II. Must be differentiated from other phagocytic defects or infectious diseases that cause granules in neutrophils, such as the rickettsial diseases.

Treatment and Monitoring

I. Symptomatic treatment: appropriate antibiotics based on culture and sensitivity results
II. Supportive care
III. Prognosis: fair to good

Pelger-Huét Anomaly

Definition and Causes

I. This apparently benign condition is associated with incomplete neutrophil segmentation.
II. It is a benign, congenital leukocyte developmental disorder.

Pathophysiology

I. Incomplete segmentation of neutrophils and eosinophils gives the appearance of a left shift; however, neutrophil function is normal.
II. It is transmitted in an autosomal dominant mode.

Clinical Signs

I. Clinical signs are absent, with the exception of small litter size.
II. Hemograms appear to have a chronic left shift, but toxic forms are not encountered.
III. It affects foxhounds, domestic shorthaired cats, and various other breeds of dogs (Knoll, 1997).

Diagnosis and Differential Diagnosis

I. Diagnosis is made by finding the classic blood smear changes (left shift) in an animal without clinical signs of disease.
II. Differential diagnoses include sepsis, bacteremia, and other infectious diseases resulting in a left shift.

Treatment and Monitoring

I. None is required.
II. See Chapter 65.
III. Prognosis is good.

Complement Component 3 Deficiency

Definition and Causes

I. Compliment component 3 (C3)—the third component of complement—is of crucial importance in the classic and alternative pathway of complement activation.
II. Affected animals fail to make C3.
III. C3 deficiency is inherited as an autosomal recessive trait.

Pathophysiology

I. Lack of C3 prevents bacterial opsonization, chemoattraction of neutrophils, and development of membrane attack complex.
II. Deficiency of C3 results in severe bacterial infections.

Clinical Signs and Diagnosis

I. Homozygous animals suffer from recurrent infections, especially gram-negative septicemias.
II. Animals experience recurrent bacterial infections of the skin, respiratory system, and urinary tracts.
III. Heterozygotes are clinically unaffected and have C3 concentrations approximately 50% of normal.
IV. Measurement of serum complement concentrations helps identify both homozygotes and heterozygotes.
V. The condition occurs in Brittany spaniels.

Treatment and Monitoring

I. Treatment is symptomatic and primarily aimed at control of bacterial infections with appropriate antibiotics and provision of IV fluid.
II. No specific treatment is available.
III. Monitoring of body temperature, appetite, and white blood cell count helps detect early infections.
IV. Prognosis is guarded for homozygotes.

Canine Granulocytopathy Syndrome (Leukocyte Adhesion Molecule Deficiency)

Definition and Causes

I. It is an inherited autosomal recessive trait resulting in defective neutrophil function.
II. Affected dogs fail to express adhesion molecules CD11b and CD18 so that neutrophils cannot egress from the bloodstream into tissues to fight infection.

Pathophysiology

I. Deficiency develops in the leukocyte adhesion molecule, an integrin that allows neutrophils to adhere to vascular endothelium and eventually migrate into areas of inflammation or infection.
II. Neutrophils have impaired aggregation, chemotaxis, and phagocytosis.

Clinical Signs

I. Clinical signs arise before 12 weeks of age.
II. Recurrent pyogenic infections develop, such as pyoderma, omphalophlebitis, and pneumonia.
III. Delayed wound healing may occur.
IV. Condition occurs in Irish setters.

Diagnosis and Differential Diagnosis

I. Neutrophil counts are very high (sometimes >200,000/μL).
II. Measurement of CD11 to CD18 adhesion protein concentrations in the neutrophil membrane is the only definitive diagnostic tool.
III. Diagnosis is usually made by finding compatible clinical signs in an Irish setter.

Treatment and Monitoring

I. Treatment is symptomatic and involves the use of appropriate antibiotics based on culture and sensitivity testing.
II. No specific treatment is available.
III. Prognosis is poor.

Severe Combined Immunodeficiency

Definition and Causes

I. Severe combined immunodeficiency arises from defects in both the T-cell and B-cell components of the immune system.
II. A mutation in the common chain of the receptor molecules for cytokines interleukin (IL)-2, IL-4, IL-7, IL-15, and IL-17 results in impaired cellular and humoral immunity.

Pathophysiology

I. A mutation in the gene coding for the IL-2 receptor results in severe defects in T-cell function.
II. Antibody production is restricted to immunoglobulin (Ig) M because the class shift in antibody production does not occur.
III. Decreased lymphocyte blastogenic responses are identified in affected animals.
IV. It is inherited as a sex-linked (X chromosome) trait.

Clinical Signs

I. Affected animals fail to thrive and show increased susceptibility to viral and bacterial diseases, such as pneumonia, enteritis, and septicemia.
II. Severe, recurrent infections such as *Pneumocystis* pneumonia, otitis, and stomatitis are common.
III. Affected puppies exhibit a failure to thrive.
IV. It is reported in basset hounds and Cardigan Welsh corgis (Somberg et al., 1994).

Diagnosis

I. Suspicious findings include thymic and lymphoid dysplasia, as well as hypoglobulinemia with normal IgM concentrations.
II. Mild lymphopenia and lack of lymphoid tissue are noted in affected animals.
III. Affected dogs have no IgG or IgA.

Treatment and Monitoring

I. Treatment is supportive and symptomatic, with antibiotics and IV fluid therapy being most important.
II. Bone marrow transplantation has been done experimentally.
III. Prognosis is grave; most affected dogs die by 16 weeks of age.

Selective Immunoglobulin A Deficiency

Definition and Causes

I. The disorder is characterized by reduced amounts of IgA in the serum and in secretions on mucosal surfaces, resulting in deficient mucosal immunity.
II. Failure to produce adequate amounts of IgA at the mucosal surface occurs because of a mutation of the gene encoding the immunoglobulin alpha chain.
III. Mode of inheritance is unknown.

Clinical Signs

I. Affected animals have normal IgG and IgM concentrations but have increased incidence of chronic respiratory and skin infections.
II. High incidence of atopy occurs in affected Chinese sharpeis.
III. Recurrent small intestinal diarrhea occurs in German shepherd dogs.
IV. Condition is known to occur in the beagle, Chinese sharpei, and German shepherd dog.

Diagnosis

I. Diagnosis is made by measuring immunoglobulin concentrations in serum or intestinal secretions using radial immunodiffusion.
II. Serum IgA concentrations are normal to decreased compared with normal dogs, whereas IgM and IgG concentrations are normal.
III. Depending on the breed, local IgA concentration at the mucosal surface may also be decreased.

Treatment and Monitoring

I. Treatment is symptomatic and aimed at controlling infections with appropriate antibiotic therapy.
II. No specific treatment is available.
III. Prognosis is generally good.

Growth Hormone Deficiency

Definition and Causes

I. Growth hormone (GH) deficiency is an immunodeficiency syndrome documented in dwarf weimaraners (Roth et al., 1980).
II. Congenital GH deficiency results in thymic dysgenesis and lymphocyte depletion.

Pathophysiology

I. Lack of GH results in failure of thymic development and impairment of cell-mediated immunity.
II. Lack of thymosin, normally produced by the thymic epithelium, causes failure of T-cell differentiation.
III. GH deficiency in the Weimaraner is associated with a small thymus and depletion of lymphocytes in the thymic-dependent portions of lymphoid organs.

Clinical Signs

I. Pups look normal at birth, but fail to thrive; they develop severe, recurrent respiratory and skin infections.
II. Condition is characterized by stunted growth, unthriftiness, and persistent infections.
III. Affected animals die within weeks to months after birth.

Diagnosis

I. Diagnosis is made by finding low-serum GH concentrations and thymic depletion.
II. Classic clinical signs of wasting in a young Weimaraner are supportive of the diagnosis.

Treatment and Monitoring

I. Pups respond to thymosin fraction 5 therapy (1 mg/kg SC SID for 7 days) with improved growth and lymphocyte function (GH appears to increase thymosin fraction 5 production).
II. Experimentally, administration of thymosin fraction 5 or bovine GH resolves clinical signs.
III. Without treatment the prognosis is grave.

ACQUIRED IMMUNODEFICIENCIES

Definition

I. In small animals, acquired disorders are more common than congenital disorders.
II. Acquired disorders may involve nonspecific or specific components of the immune system.

Causes and Pathophysiology

I. Disorders of nonspecific immunity
  A. Diabetes mellitus (DM) is associated with defects in phagocytosis, bacterial killing, and reduced levels of complement.
  B. Hyperadrenocorticism suppresses the immune system in several ways.
    1. Hyperadrenocorticism is associated with decreased complement levels.
    2. Decreased skin thickness and delayed wound healing may also occur.
    3. Neutrophils in animals with hyperadrenocorticism exhibit impaired phagocytosis.
    4. Decreased production of leukotrienes and prostaglandins (critical to the inflammatory response) also occurs.
  C. Hypothyroidism is associated with decreased neutrophil function, decreased sebum production, and keratinization alterations that reduce the barrier function of the skin.
II. Disorders of specific immunity
  A. Hyperadrenocorticism results in decreased lymphocyte function from hypercortisolemia; reduced antibody concentrations have also been documented in some animals.
  B. Systemic infections suppress the immune system in a variety of ways.
    1. Canine distemper virus causes direct cell (lymphocyte) lysis.
    2. Feline leukemia virus infections result in certain cellular dysfunctions.
    3. Viral products may be immunosuppressive (e.g., p15e from feline leukemia virus).
    4. Immune complex formation (blocking of normal immune responses) occurs with feline infectious peritonitis.
    5. Immunosuppression caused by bacterial infections is poorly understood.
  C. Failure of passive transfer results in reduced immunity in neonates.
    1. Most (90% to 95%) of the immunity transferred from the mother to the offspring is via the colostrum in dogs and cats.
    2. Failure of passive transfer seems to have little clinical effect in puppies and kittens as long as cleanliness is maintained.
  D. Neoplasia may be associated with immunosuppression.
    1. Immunosuppression is primarily associated with lymphoreticular malignancies in small animals.

2. With multiple myeloma, the incidence of fatal infections is very high.
3. Primary defect with other tumors is in cell-mediated immunity.
4. Altered immunity may be both a cause and an effect of neoplasia.
5. Tumor-associated immune complexes may "block" immune cells from performing their normal functions.
6. Tumor cells may secrete soluble suppressive factors that have yet to be identified.

Diagnosis

I. The diagnosis of secondary immunodeficiencies is approached by selecting tests that identify an underlying disease such as DM or hyperadrenocorticism.
   A. Hyperglycemia and glucosuria are noted with DM (see Chapter 44).
   B. An exaggerated response to adrenocorticotropic hormone or inappropriate suppression after dexamethasone administration is seen with hyperadrenocorticism (see Chapter 45).
   C. Low serum thyroxine concentration with high endogenous thyroid-stimulating hormone concentration is diagnostic for hypothyroidism (see Chapter 42).

II. Feline leukemia virus and feline immunodeficiency virus testing is warranted in all cats with increased incidence of infections.

III. Physical examination, radiography, and ultrasonography are all important in identifying cancer.

Treatment and Monitoring

I. Treatment is specific for the underlying disease.

II. Adequate control of the underlying disease often results in resolution of the immunodeficiency.

CHAPTER 76

Immune-Mediated Diseases

Ellen Miller

GENERAL INFORMATION

I. Immune-mediated diseases are associated with all of the classic hypersensitivity reactions.
II. Allergic diseases of the skin (e.g., atopy, food allergy), respiratory tract (e.g., asthma in cats, bronchitis in dogs), and gastrointestinal (GI) tract (e.g., anaphylactic shock) are all immune-mediated diseases caused by a type I reactions.
III. Type II reactions are responsible for immune-mediated hemolytic anemia (IMHA) (see Chapter 64), immune-mediated thrombocytopenia (ITP) (see Chapter 67), and some of the autoimmune skin diseases (see Chapter 91).
IV. A type III reaction is responsible for systemic lupus erythematosus (SLE) and vasculitis.
V. Type IV reaction causes contact dermatitis.

ANAPHYLAXIS

Definition

I. Anaphylaxis is a severe, life-threatening, systemic manifestation of a type I hypersensitivity reaction.
   A. It occurs immediately after exposure to antigen in a sensitized animal.
   B. Mast cell- and basophil-bound immunoglobulin (Ig) E binds antigen, causing release of chemical mediators such as histamine, leukotrienes, and prostaglandins.
   C. With massive mediator release, anaphylactic shock occurs.
II. Anaphylactoid reactions are clinically similar to anaphylaxis; however, complement components (not IgE) mediate them.
III. Anaphylaxis is rare in dogs and cats.

Causes

I. Many antigens can cause anaphylactic reactions.
   A. Venoms from insects: bees, wasps, hornets, ants
   B. Drugs: antibiotics, L-asparaginase, vitamin K, IV radiopaque dyes, nonsteroidal antiinflammatory drugs, local anesthetics
   C. Vaccines: leptospiral bacterin
   D. Blood and plasma products
II. Usually the antigen is introduced parenterally.

Pathophysiology

I. After initial exposure to antigen, susceptible individuals produce IgE antibody.
II. IgE binds to receptors on mast cells and basophils.
III. Cross-linking of IgE by antigen binding results in cellular activation, degranulation, and release of chemical mediators.
   A. Primary granules contain preformed mediators such as histamine, heparin, eosinophil chemotactic factor, and proteases.
   B. Secondary mediators intensify and prolong the anaphylactic reaction.
      1. Secondary mediators are not preformed.
      2. These mediators are products of arachidonic acid metabolism and are of the prostaglandin and leukotriene families.
IV. Vasodilatation, increased vascular permeability, bronchoconstriction, platelet aggregation, pulmonary vasoconstriction, increased airway mucus, and cardiac depression occur.
V. Cardiovascular shock ensues, with the severity dependent on the antigen type, antigen amount, and route of exposure.

Clinical Signs

I. Signs of systemic anaphylaxis vary with the species.
II. The liver is the shock organ in the dog.
   A. Vomiting, diarrhea, and urination occur and progress to respiratory distress, collapse, and death if not treated.
   B. Postmortem findings include hepatic and GI venous engorgement and portal hypertension.
III. The respiratory and GI tracts are the shock organs in the cat.
   A. Anaphylactic reactions start with facial pruritus followed by dyspnea, salivation, vomiting, and diarrhea.
   B. Pathologic findings include bronchoconstriction, emphysema, pulmonary hemorrhage, and edema of the larynx.

Diagnosis

I. Diagnosis is based largely on history and physical examination.
II. Specific diagnostics are not available for systemic anaphylaxis.
III. Retesting the animal with the antigen is unwise.

Treatment

I. Treatment of systemic anaphylaxis depends on the organ system affected.
II. If the animal is dyspneic, establish an airway and administer oxygen.
  A. Insert an endotracheal tube or perform a tracheostomy.
  B. Administer bronchodilators.
III. Treat any hypotension aggressively.
  A. Place at least one large-bore IV catheter and administer isotonic crystalloid solutions at 50 to 150 mL/kg IV over several hours.
  B. If hypotension persists, administer epinephrine diluted to 0.1 mg/mL (1:10,000) at a dose of 0.05 to 0.1 mL/kg IV (maximum of 2.0 mL/dose).
  C. Consider giving dobutamine as a constant-rate infusion (2 to 5 μg/kg/minute IV) to maintain vascular pressure.
IV. Counteract chemical mediators with dexamethasone 1 to 2 mg/kg IV or prednisolone sodium succinate 10 to 25 mg/kg IV.
V. Administer atropine at 0.02 to 0.04 mg/kg IV, IM, if the animal is bradycardic.

Monitoring of Animal

I. Animals with systemic anaphylaxis should be monitored in the hospital for at least 24 hours.
II. Monitors systemic blood pressure, heart rate, hematocrit, blood glucose, and activated clotting times.
III. The animal can be discharged when it is stable (hemodynamically and clinically) and has been weaned off all fluid therapy.

URTICARIA AND ANGIONEUROTIC EDEMA

Definition

I. Urticaria (hives) is an acute, localized type I hypersensitivity reaction associated with pruritus.
II. Angioedema is similar to urticaria but involves the deeper subcutaneous tissues around the head and extremities, without producing pain or pruritus.

Causes

I. These disorders are caused by a type I hypersensitivity reaction.
II. Food or inhaled allergens, as well as parenterally administered antigens, can cause urticaria.
III. Nonimmunological causes include agents (e.g., cold, heat, pressure) that induce histamine release or activate complement.

Pathophysiology

I. Mechanisms are similar to those described previously under Anaphylaxis.
II. Wheal formation is caused by extravasation of fluid from vasodilation of capillaries.

Clinical Signs

I. Localized or generalized subdermal wheals
II. Swelling and edema of tissues of the head or extremities
III. Variable pruritus or self-mutilation
IV. Possible inspiratory stridor from laryngeal edema

Diagnosis

I. Diagnosis is usually based on history and physical examination findings.
II. Localized anaphylactic reactions are usually confirmed by intradermal skin testing or enzyme-linked immunosorbent assays for canine IgE.

Treatment

I. Treatment of localized anaphylaxis is less critical than systemic anaphylaxis.
II. Causative agent is removed, if possible.
III. Many cases resolve spontaneously without treatment.
IV. Antihistamines are administered, such as diphenhydramine 1 to 2 mg/kg IV, IM.
V. Prednisone (1 to 2 mg/kg PO SID to BID) beginning 12 to 24 hours after the reaction (with a rapid tapering dose) reduces delayed effects.

Monitoring of Animal

I. For animals with localized reactions, contact owners by phone SID for a few days to ensure that clinical signs have abated.
II. Avoid exposure to antigen in the future.

DRUG ALLERGY

Definition

I. Drug allergy is an immune-mediated hypersensitivity reaction caused by production of antidrug antibodies.
II. Sensitized T lymphocytes may also be produced and directed against a drug or its metabolites.

Causes

I. Large proteins contained in serum, vaccines, and biological extracts may be antigenic and cause allergic reactions.
II. Most drugs are not large enough in size to be allergenic but can act as haptens that covalently bind to larger host proteins, thereby causing a reaction.
III. The following drugs have been associated with allergic reactions:
  A. Sulfonamides
  B. Penicillins
  C. Cephalosporins
  D. Propylthiouracil
  E. Levamisole
  F. Gold salts
  G. L-asparaginase
  H. Doxorubicin
  I. Tetracyclines
  J. Methimazole
  K. Vaccines

IV. Some drugs of similar structure may cause cross-sensitivity, such as penicillin and cephalosporin.
V. Drug dose, duration of treatment, route of administration, and drug formulation affect the allergic reaction.
VI. Genetic factors may influence individual susceptibility, as in Doberman pinschers, in which sulfonamide reactions are common.

Pathophysiology

I. All four types of hypersensitivity reactions are implicated in drug reactions.
   A. In a type I reaction, the drug carrier binds to an IgE molecule, causing degranulation of mast cells and basophils.
   B. In a type II reaction, the antidrug antibody is IgG or IgM, which activates complement and causes cell lysis.
   C. In a type III reaction, the circulating drug carrier–antibody complexes are trapped in vascular endothelium, resulting in a neutrophilic inflammatory response.
   D. Tissue-fixed, drug-carrier complexes attract T lymphocytes, which release lymphokines and cause an inflammatory response.
II. Certain drug allergies may be manifestations of multiple hypersensitivity reactions.

Clinical Signs

I. Drug reactions occur only after an initial sensitization period of 5 or more days.
II. These reactions are seen in a small percentage of the population.
III. Reactions often mimic other immune-mediated diseases, such as IMHA, ITP, polyarthritis, and vasculitis.
IV. Clinical signs subside within days of discontinuing the drug.
V. Clinical signs recur with readministration of the drug.
VI. Specific clinical signs include the following:
   A. Fever
   B. Cutaneous manifestations (see Chapters 85 and 91)
      1. Urticaria
      2. Pruritus
      3. Erythema multiforme
      4. Allergic contact dermatitis
      5. Toxic epidermal necrolysis
   C. Polyarthritis
   D. Polymyositis
   E. Ataxia
   F. Glomerulonephritis
   G. Hematological manifestations: hemolytic anemia, thrombocytopenia, leukopenia, lymphadenopathy

Diagnosis

I. The diagnosis is usually made by taking a detailed history and finding the classic clinical signs (discussed previously).
II. Laboratory tests may reveal nonspecific, but suggestive, results.
   A. Rarely, a Coombs' test, antinuclear antibody (ANA) test, or rheumatoid factor test may be positive.
   B. Suppurative, nonseptic inflammation is found on cytology of joint fluid in cases of polyarthritis.
   C. Proteinuria and a urine protein:creatinine ratio >1.0 are noted with glomerulonephropathy.
   D. Immunoglobulin (immune complex) deposits may be identified with histopathology and immunohistochemistry or by immunofluorescence staining of affected tissues.
III. Drug challenge studies are not usually recommended.

Differential Diagnosis

I. Autoimmune disorders, such as SLE, IMHA, ITP, and immune-mediated polyarthritis, can have similar signs.
II. Infectious diseases, such as bacterial endocarditis, bacteremia, septic arthritis, fungal infections, and rickettsial diseases, are other considerations.

Treatment and Monitoring

I. Key treatment is drug withdrawal.
II. Administer antihistamines, epinephrine, IV fluids, and corticosteroids if the reaction is severe (see Anaphylaxis).
III. Blood transfusions or purified hemoglobin *(Oxyglobin)* therapy are occasionally necessary for IMHA and ITP (see Chapter 71).
IV. Prognosis is generally good for complete recovery.
V. Avoidance of the inciting drug and any cross-reacting drugs is imperative.

SYSTEMIC LUPUS ERYTHEMATOSUS

Definition

I. SLE is a multisystemic autoimmune disorder that may affect the joints, skin, kidneys, platelets, or erythrocytes.
II. Those most affected are young to middle-aged animals.
   A. No male or female predisposition exists.
   B. Many breeds can be affected, although German shepherd dogs are overrepresented.

Causes and Pathophysiology

I. Type III hypersensitivity reaction is responsible for the tissue damage.
   A. Autoantibodies in SLE are directed against intranuclear, intracytoplasmic, and cell surface antigens.
   B. Autoantibodies and self-antigens form immune complexes.
      1. Pathogenic immune complexes are formed in slight antigen excess and are medium-sized, soluble, and not readily phagocytosed.
      2. These immune complexes get trapped in the blood vessels of tissues with high circulatory volume, such as synovium and kidneys.
      3. When trapped, immune complexes attract neutrophils and platelets and fix complement.
II. Neutrophil lysosomal enzymes and complement products damage affected tissues.

Clinical Signs

I. The history is usually a chronic, progressive one of weight loss, anorexia, lameness, and dermatitis.

II. Physical examination findings are dependent on the systems affected.
  A. Skin lesions are variable and occur in one third of affected dogs (see Chapter 91).
    1. These include maculopapular, purpuric, vesiculobullous, or seborrheic eruptions.
    2. Patchy alopecia is also seen.
  B. Distal polyarthritis causing joint effusion, pain, and lameness is found in about two thirds of dogs with SLE (Grindem and Johnson, 1983).
  C. Other findings include muscle wasting, emaciation, and pale mucous membranes, with or without petechiation.

Diagnosis

I. Routine laboratory data may support a diagnosis of SLE.
  A. Complete blood count may show a nonregenerative anemia of chronic disease, a regenerative IMHA, an inflammatory leukogram, and possibly thrombocytopenia.
  B. A serum chemistry panel usually shows hyperglobulinemia and less commonly reveals an azotemia.
  C. Urinalysis indicates proteinuria approximately 50% of the time (Grindem and Johnson, 1983).
II. Specific tests for SLE include the ANA test and the lupus erythematosus (LE) clot test (Grindem and Johnson, 1983).
  A. ANA is the most sensitive and reliable test and is positive in 60% to 100% of dogs with SLE.
  B. LE clot test is positive in 60% to 80% of dogs with SLE.
  C. Coombs' test can be positive with IMHA, which occurs in about one third of affected dogs.
III. Biopsies of affected tissues may show classic histological lesions, including glomerular lesions, vasculitis, thrombosis, and dermatitis with pustule formation.
  A. Direct immunofluorescence techniques and immunohistochemistry techniques can localize the presence of immune complexes in specific tissues.
  B. Classically, skin biopsies show immunoglobulin deposition at the dermal–epidermal junction.
IV. Diagnosis of SLE in dogs must include at least one class I criterion and two or more class II criteria; drug-induced and infectious diseases must also be ruled out (Grindem and Johnson, 1983).
  A. Class I criteria include a positive ANA test or LE clot test.
  B. Class II criteria include clinical findings of polyarthritis, protein-losing nephropathy, hemolytic anemia, alopecia and dermatitis, or thrombocytopenia.

Differential Diagnosis

I. Because SLE is an immune-complex disease, other disorders that result in immune complex production can cause similar signs.
  A. Systemic bacterial infections, such as bacteremia, bacterial endocarditis, sepsis, and septic arthritis, can all mimic SLE.
  B. Systemic fungal infections are often chronic and can induce immune complex formation, resulting in polyarthritis, glomerulonephritis, and anemia.
  C. Neoplastic antigens may also form immune complexes and result in similar findings.
  D. Drug and vaccine reactions may mimic SLE.
II. Infectious and neoplastic diseases must be adequately ruled out because immunosuppression can be lethal to afflicted animals.

TABLE 76-1

Protocol for Reduction of Immunosuppressive Drugs in Animals with Systemic Lupus Erythematosus*

DAY	PREDNISONE/PREDNISOLONE DOSE	AZATHIOPRINE DOSE
1 to 7	2 mg/kg PO BID	1 mg/kg PO SID
8 to 28	2 mg/kg PO SID	1 mg/kg PO QOD
29 to 50	1 mg/kg PO SID	Same
51 to 72	0.5 mg/kg PO SID	Same
73 to 94	0.25 mg/kg PO SID	Same
95 to 116	0.25 mg/kg PO QOD	Same (given QOD with prednisone)
>117	0.25 mg/kg PO QOD	Discontinue

*Recheck the animal at every decrease in dose and continue if no signs recur.

Treatment

I. Prednisone or prednisolone 1 to 2 mg/kg PO BID is the mainstay of therapy.
II. A cytotoxic drug, such as azathioprine at 2 mg/kg PO SID for 7 days then QOD, can be used in combination with immunosuppressive doses of prednisone.

Monitoring of Animal

I. Examine the animal every 3 to 4 weeks (more frequently if not responding well to therapy or experiencing severe side effects from the drugs).
II. Decrease the dose of prednisone gradually once the animal is in remission (Table 76-1).
  A. Monitor for improvement in red blood cell count, platelet count, hyperglobulinemia, and proteinuria.
  B. Relapses may occur that require increased doses of prednisone and the addition of other immunosuppressive drugs.
III. Long-term prognosis is guarded because the disease is often refractory to treatment and can be progressively more difficult to control.

CHAPTER 77

Immunoproliferative Disorders

Bradley R. Schmidt

REACTIVE CONDITIONS

General Considerations

Definition

I. Appropriate or inappropriate benign expansion of cells of the immune system
II. Result from exposure to an exogenous or endogenous antigen

Causes

I. Infectious diseases: bacterial, viral, fungal, rickettsial, parasitic, protozoal
II. Allergic disease
III. Autoimmune disease
IV. Reactive histiocytosis
V. Nonimmunoproliferative or nonlymphoid neoplasms

Pathophysiology

I. Reactive conditions result from polyclonal immune cell proliferation.
II. Reactive conditions generally resolve when the inciting cause is identified and removed.

Clinical Signs

I. Clinical signs are usually nonspecific and result from the primary disease process.
II. Signs may include the following:
   A. Lethargy, anorexia, fever
   B. Lymphadenomegaly, splenomegaly
   C. Uveitis
   D. Central nervous system signs
   E. Cutaneous lesions: inflammatory lesions, petechial hemorrhages, plaques, edema

Diagnosis

I. Complete blood count (CBC), serum biochemistry, and urinalysis results are variable and dependent on the underlying cause.
   A. Red blood cell indices may reveal the following:
      1. Anemia of chronic disease: normocytic, normochromic, nonregenerative
      2. Regenerative anemia associated with hemolysis, possible agglutination or spherocytes with immune-mediated hemolysis
      3. Blood loss anemia
      4. May be normal
   B. White blood cells and platelets may be normal, increased, or decreased.
   C. Hyperglobulinemia (when present) is generally polyclonal but may be monoclonal in certain disease processes (e.g., ehrlichiosis, leishmaniasis, feline infectious peritonitis).
   D. Urinalysis may reveal proteinuria secondary to glomerular disease.
II. Needle biopsy or histopathology of lymph nodes or other organs often reveals a benign proliferation of lymphocytes, plasma cells, and other inflammatory cells.
III. Occasionally, specific pathologic processes (e.g., blood parasites, fungal organisms, neoplastic processes) may be identified in aspirates or on histopathology.
IV. Additional diagnostic tests such as flow cytometery and immunohistochemistry are helpful to distinguish between benign and malignant proliferative diseases.

Differential Diagnosis

I. All causes listed previously
II. Neoplastic processes: lymphoma or multiple myeloma

Canine Reactive Histiocytic Diseases

Definition

I. Conditions include cutaneous histiocytosis (CH) and systemic histiocytosis (SH), which are charaterized by benign, reactive, nonneoplastic proliferation of histiocytes.
II. CH is a benign, nodular proliferation of histiocytes within the skin and subcutis, with no systemic involvement.
III. SH is a benign proliferation of histiocytes in multiple organs, such as skin, lymphoid organs, bone marrow, spleen, nasal cavity, eyelids, sclera, lungs, and liver.

Causes

I. They arise from reactive histiocytic proliferation of interstitial histiocytic cells.
II. SH may be inherited in Bernese mountain dogs.

III. Clinical behavior and response to immunosuppressive agents support a dysregulated immune interaction between dendritic cells and T cells.
IV. An immune response to antigens may initiate the process (Moore and Affolter et al., 2005).

Pathophysiology

I. CH results in multiple cutaneous and subcutaneous lesions that may ulcerate and become infected.
   A. The Bernese mountain dog, beagle, collie, golden retriever, and German shepherd dog may be overrepresented.
   B. CH often occurs in younger dogs.
II. In addition to cutaneous lesions, SH may cause organ dysfunction from cellular infiltration and may progress to a hemophagocytic syndrome resulting in blood cytopenias.
   A. SH primarily affects Bernese mountain dogs but can occur in other breeds.
   B. Generally, SH affects young to middle-aged (2 to 8 years) male dogs, but females may also be affected.

Clinical Signs

I. With CH, multiple cutaneous and subcutaneous nodules occur predominantly on the head, neck, perineum, scrotum, and extremities.
   A. Ulcerations of the skin and secondary sepsis may develop.
   B. Regional lymph nodes may be involved.
   C. Lesions are not epidermotropic, which helps distinguish CH from cutaneous histiocytomas.
II. Multiple cutaneous plaques or nodules similar to CH also occur with SH, but other organ systems are generally involved, such as lymph nodes, eyes, and nasal mucosa.
III. Clinical signs for CH and SH may spontaneously wax and wane; however, the disorders are usually progressive unless therapy is instituted.

Diagnosis

I. Histopathology reveals a reactive process consisting of diffuse infiltration of histiocytic cells and a mixed population of neutrophils and lymphocytes.
   A. Minimal or no atypia is seen in CH.
   B. Mild atypia may be seen in SH.
II. Immunohistochemical stains are useful in confirming histiocytic origin and distinguishing these conditions from histiocytoma, histiocytic sarcoma (HS), and malignant histiocytosis (MH) (Moore and Alfolter, 2005).
III. Because CH and SH are clinically similar, additional diagnostics tests (abdominal ultrasonography, thoracic radiography, lymph node aspiration and biopsy, bone marrow aspiration) are needed to identify systemic involvement.
IV. Results of routine laboratory tests are variable, depending on the organs involved.
   A. CBCs and biochemistry profiles are usually normal with CH.
   B. Anemia, leukopenia, or thrombocytopenia may be seen secondary to hemophagocytic syndrome associated with SH.
V. Underlying infectious processes, such as fungal infections, must also be investigated.

Differential Diagnosis

I. Neoplasia
   A. Histiocytic tumors: cutaneous histiocytoma, HS, MH
   B. Other discrete round-cell tumors: lymphosarcoma, mast cell tumors
II. Fungal or atypical infections: ruled out with special stains
III. Idiopathic sterile nodular panniculitis
IV. Nodular granulomatous episcleritis and other causes of uveitis (see Chapters 98 and 99)

Treatment

I. Spontaneous remissions have been reported in a few animals with CH, but relapses are common and immunosuppressive therapy is generally required.
   A. Prednisone 1 to 2 mg/kg PO BID may be effective in some dogs.
      1. Continue at this dosage until remission, then taper.
      2. Long-term maintenance therapy with low-dose prednisone may be required.
   B. Other animals require additional therapy with azathioprine 2 mg/kg PO SID or cyclosporine 5 mg/kg PO SID to BID, with doses tapered as lesions resolve.
   C. Leflunomide may be considered at 2 to 4 mg/kg PO SID, with desired trough plasma levels of 20 μg/mL (Cannon et al., 2000).
   D. Combination of tetracycline and niacinamide (250 to 500 mg of each PO TID) may be useful as maintenance therapy once remission is obtained (Rosychuck, 2002).
II. SH is often poorly responsive to immunosuppressive therapy; however, corticosteroids, azathioprine, cyclosporine, and leflunomide may be tried.

Monitoring of Animal

I. Prognosis is guarded to fair for dogs with CH.
II. Although the clinical course of SH frequently waxes and wanes, the prognosis is poor for most dogs because of the overall progressive course and the chronic debilitating nature of the disease.
III. Monitor CBCs and biochemistry profiles for abnormalities secondary to the disease and/or immunosuppressive therapy.
IV. Monitoring blood levels of cyclosporine or leflunomide is recommended.

NEOPLASIA

Histiocytoma and Langerhans Cell Histiocytosis

Definition and Cause

I. Cutaneous histiocytoma is a benign proliferation of Langerhans cells.
II. Langerhans cell histiocytosis (LCH) is a rare condition that histologically resembles histiocytoma but has a more aggressive behavior.

III. In cats, feline progressive histiocytosis is rare and resembles LCH.
IV. The cause of these conditions is unknown.

Pathophysiology

I. Histiocytoma generally affects younger dogs but may occur in older dogs.
   A. It is usually a solitary cutaneous lesion, but multiple lesions are possible.
   B. Histiocytomas generally undergo spontaneous regression; however, metastasis to lymph nodes and lungs occurs rarely.
II. Cutaneous lesions in LCH may be confluent, and the condition usually progresses rapidly with metastasis.
III. Cats with progressive histiocytosis are middle-aged or older, and the disease is often progressive, with metastasis to internal organs.

Clinical Signs

I. Dogs usually have a solitary cutaneous nodule.
   A. Nodules are pink and hairless.
   B. Nodules are round, smooth, and possibly ulcerated.
   C. Multiple lesions are possible.
II. Cats have solitary to multiple cutaneous nodules that may be ulcerated.
III. Lymphadenomegaly and systemic clinical signs are only associated with the rare metastatic forms of this disease complex.

Diagnosis

I. Histologically, large histiocytes are accompanied by lymphocytes, neutrophils, and other inflammatory cells.
II. Epidermotropism and epidermal invasion are not features of CH and may aid in the diagnosis.
III. Immunohistochemical stains are useful in distinguishing histiocytoma from lymphoma, CH, and SH (Moore and Affolter, 2005).

Differential Diagnosis

I. Other round-cell tumors: lymphoma, mast cell tumors, plasmacytoma
II. Other histiocytic diseases
III. Xanthomas in cats

Treatment

I. In young dogs, histiocytomas generally regress spontaneously.
   A. Immunosuppressive agents may interfere with regression and are avoided.
   B. Surgical removal may be considered in cases in which lesions become traumatized or fail to regress.
   C. Many lesions, particularly nonregressing or nonresectable lesions in older dogs, respond to cryotherapy.
II. Treatment for metastatic lesions has not been reported.
III. No successful treatment has been reported for feline progressive histiocytosis.

Monitoring of Animal

I. Prognosis is good for most dogs with histiocytoma.
II. Prognosis is guarded to poor for dogs with metastatic histiocytoma or LCH.
III. Prognosis is poor for cats with progressive histiocytosis.

Malignant Histiocytosis and Histiocytic Sarcoma

Definition and Cause

I. MH is a systemic proliferation of malignant histiocytes, with rapid infiltration of multiple organs.
II. HS is a histiocytic neoplasm originating from a single site; when metastasis occurs, the disease is termed *disseminated HS*.
III. MH and disseminated HS are similar and may be difficult to differentiate.
IV. Both conditions usually affect Bernese mountain dogs, but can occur in other breeds, such as the rottweiler, flat-coated retriever, and golden retriever.
V. Male dogs are more commonly affected.
VI. Cause of this condition is unknown; however, it may have a polygenic mode of inheritance in the Bernese mountain dog.
VII. These conditions have been reported rarely in cats.

Pathophysiology

I. Proliferation of malignant histiocytes occurs in the periarticular tissues, spleen, liver, skin, lymph nodes, lung, and bone marrow of affected dogs.
II. Other organs may be affected, such as bones and the nervous system.
III. Infiltration with malignant histiocytes causes organomegaly and possible dysfunction.

Clinical Signs

I. Anorexia, depression, lethargy, fever, and cachexia are commonly seen.
II. Lymphadenomegaly and hepatosplenomegaly may be recognized on physical examination.
III. Other signs related to multiorgan infiltration may also occur.

Diagnosis

I. Histologically, a diffuse infiltration of malignant histiocytic cells occurs in multiple organs with phagocytosis of erythrocytes and leukocytes.
II. Immunohistochemistry stains may help to differentiate these disorders from SH, CH, and other tumors, such as lymphoma, mast cell tumors, and sarcomas.
III. CBC and serum biochemistry results are variable and often include anemia, thrombocytopenia, hypoalbuminemia, and elevated liver enzymes.
IV. Bone marrow aspiration may reveal histiocytic infiltration and erythrophagocytosis.
V. Radiography and ultrasonography may reveal lymphadenopathy, pulmonary masses, splenomegaly, and hepatomegaly.
VI. Hyperferritinemia occurs in malignant histiocytosis.

Differential Diagnosis

I. Large-cell lymphoma and other histiocytic diseases are the major differential considerations.
II. Differential diagnoses for pulmonary lesions include a primary lung tumor and granulomatous pulmonary disease.

Treatment

I. Surgery alone or combined with radiation therapy may be curative for localized HS.
II. In dogs with MH and disseminated HS, doxorubicin-based chemotherapy (liposomal doxorubicin) or CCNU (lomustine) may induce short-term responses.

Monitoring of Animal

I. Prognosis is guarded to favorable for dogs with localized HS.
II. Prognosis is generally poor in both dogs and cats with MH or disseminated HS.

Multiple Myeloma and Waldenström's Macroglobulinemia

Definition and Causes

I. *Multiple myeloma* and *Waldenström's macroglobulinemia* are defined as systemic neoplastic proliferation B cells in bone marrow or other organs, with high levels of a myeloma (M) protein in the bloodstream.
II. In dogs with multiple myeloma, the M protein is usually immunoglobulin (Ig) G or IgA, and cells typically range from poorly to well-differentiated plasma cells.
III. In cats with multiple myeloma, the M protein is typically IgG.
IV. Primary macroglobulinemia (Waldenström's macroglobulinemia) is a neoplastic proliferation of immune cells with excessive production of IgM.
    A. Cells do not have the typical plasmacytoid features and are more similar to the cells of small, lymphocytic lymphoma of the intermediate type.
    B. Skeletal lesions are rare.

Pathophysiology

I. Increased production of immunoglobulins may lead to the following:
    A. Bleeding diatheses secondary to decreased platelet aggregation and adhesiveness, and possible prolongation of thrombin and partial thromboplastin times
    B. Hyperviscosity syndrome secondary to increased production of IgM, IgA, or IgG
    C. Renal failure secondary to immunoglobulin light chains (Bence Jones proteinuria)
    D. Amyloidosis
    E. Cryoglobulinemia
II. Bone marrow infiltration may cause anemia, leukopenia, and thrombocytopenia.
III. Plasma cell dysfunction leads to immunodeficiency and increased susceptibility to infection.
IV. Hypercalcemia may arise from increased osteoclast activating factor secreted by the neoplastic plasma cells.
V. Bone infiltration can cause pathologic fractures, neurological signs, and bone pain.
    A. Most common bones involved are the vertebrae, long bones, ribs, and pelvis.
    B. Osteolysis is uncommon in primary macroglobulinemia and is less common in cats.

Clinical Signs

I. Vague clinical signs (anorexia and lethargy) may be seen.
II. Hepatosplenomegaly is a common finding in dogs and cats.
III. Renomegaly and lymphadenopathy are also reported in the cat (Patel et al., 2005).
IV. Skeletal pain may be a presenting sign.
V. Neurological signs may arise secondary to vertebral masses, primary neoplastic infiltration, or hyperviscosity syndrome; signs may include vision loss.
VI. Polyuria and polydipsia may occur secondary to renal dysfunction, hyperviscosity syndrome, or hypercalcemia.
VII. Bleeding tendencies, such as petechiation and ecchymoses may be noted.
VIII. Cardiac murmurs and arrhythmias occur from increased cardiac workload and myocardial hypoxia.
IX. Pyothorax, ascites, and peritonitis have been found in some affected cats (Patel et al., 2005).

Diagnosis

I. CBC
    A. It may be normal.
    B. Mild normochromic, normocytic anemia is usually present.
    C. Leukopenia secondary to bone marrow infiltration may be detected.
    D. Thrombocytopenia is variable (mild to marked).
II. Serum biochemistry profile
    A. Marked elevation in serum globulins (>9 g/dL) is typical.
        1. Total serum protein may be normal if there is a concurrent decrease in serum albumin or protein loss through the kidneys.
        2. Serum viscosity is generally >7 relative to water.
    B. Hypercalcemia is seen in 5% to 20% of affected dogs and cats (Hammer and Couto, 1994; Patel et al., 2005).
    C. Azotemia secondary to renal failure may be present.
    D. Increased liver enzymes are seen with hepatic infiltration.
III. Urinalysis
    A. Heat precipitation and electrophoresis of urine are performed to identify light chains (Bence Jones proteins).
    B. Standard urine dipsticks are not capable of this determination.
IV. Serum protein electrophoresis (to characterize hyperglobulinemia)
    A. Monoclonal gammopathy is a common finding.
    B. Biclonal gammopathy may occur in both dogs and cats (Peterson and Meininger, 1997; Patel et al., 2005).

C. In rare cases, excessive globulins are not produced (MacEwen et al., 1984; Marks et al., 1995).

V. Bone marrow evaluation: critical in diagnosis of multiple myeloma
   A. Plasma cell population greatly exceeds 20% of nucleated cells in both dogs and cats with multiple myeloma.
   B. Because the malignant plasma cells may be morphologically normal, a bone marrow core biopsy is helpful to identify clusters of plasma cells (consistent with malignancy) versus diffuse plasma cell infiltrates (suggestive of a reactive process, such as a rickettsial disease).
   C. Plasma cell atypia is supportive in cases with plasma cell counts less <20%.
   D. Decreased numbers of erythroid and myeloid cells may be present.

VI. Survey of skeletal radiographs
   A. Up to two thirds of dogs have osteolytic skeletal lesions in the vertebrae, long bones, ribs, or pelvis (Hammer and Couto, 1994).
   B. Bone scintigraphy may not be a sensitive test in these lesions.
   C. Bony lesions are not as common in dogs with primary macroglobulinemia or in cats.

VII. Cats: most feline leukemia negative

Differential Diagnosis

I. Diagnosis of multiple myeloma requires at least two of the following:
   A. Bone marrow infiltration with plasma cells
   B. Osteolytic bone lesions
   C. Monoclonal gammopathy
   D. Bence Jones proteinuria
   E. Visceral organ infiltration and plasma cell atypia in cats

II. If the previous criteria are not met, consider the following:
   A. Extramedullary plasmacytoma
   B. Other causes of monoclonal gammopathy: ehrlichiosis, leishmaniasis, feline infectious peritonitis, amyloidosis, B-cell lymphoma
   C. For osteolytic lesions: primary bone tumors, osteomyelitis
   D. For hyperglobulinemia: other causes of chronic antigenic stimulation (usually polyclonal)

Treatment

I. Goals of therapy are to ameliorate clinical signs, to reduce serum globulin levels and Bence Jones proteinuria by 50%, and to stabilize osteolytic lesions.

II. Melphalan and prednisone are recommended for dogs and cats with multiple myeloma.
   A. Melphalan is started at 0.1 mg/kg PO SID for 10 days, followed by 0.05 mg/kg PO SID continuously.
   B. Prednisone is given at 0.5 mg/kg PO SID for 10 days, followed by 0.5 mg/kg PO QOD.

III. Doxorubicin, cyclophosphamide, and vincristine in combination or as single agents have been used; however, they are not consistently more effective than melphalan and prednisone (Kisseberth et al., 1995).

IV. Ancillary therapy may be considered.
   A. Palliative radiation therapy may help alleviate bone pain and spinal cord compression.
   B. Antibiotics are recommended until remission is obtained.
   C. Plasmapheresis may be considered to remove excess immunoglobulins.
   D. Therapy for hypercalcemia is instituted when indicated (see Chapter 73).
      1. Saline diuresis and furosemide are the mainstays of therapy.
      2. Mithramycin and bisphosphonates may be considered for refractory cases.

V. Chemotherapy protocols for lymphoma or chlorambucil 0.2 mg/kg PO SID may be used in dogs with primary macroglobulinemia.

Monitoring of Animal

I. A positive response is usually seen in 1 to 2 months.
   A. Monitoring of serum protein levels, repeating serum protein electrophoresis, and bone marrow aspirate are recommended to assess response to therapy.
   B. Melphalan can cause neutropenia and thrombocytopenia, so monitor a CBC and platelet count every 30 to 60 days.

II. Prognosis is variable.
   A. Median survival is 540 days in dogs (Matus et al., 1986).
      1. Poor prognostic variables include a lack of response to therapy, hypercalcemia, Bence Jones proteinuria, pancytopenia, and renal failure.
      2. Dogs with primary macroglobulinemia successfully treated with chlorambucil had a median survival of 11 months (MacEwen and Hurvitz, 1977).
   B. Prognosis for cats is worse (Fox et al., 1999).
      1. Median survival time is 87 (1 to 1395) days.
      2. Average survival when treated with melphalan and prednisone is 183 days (if animal survived 2 weeks after the diagnosis).

Extramedullary Plasmacytoma

Definition and Cause

I. Extramedullary plasmacytoma is any neoplastic proliferation of plasma cells that does not fulfill the diagnostic criteria for multiple myeloma.

II. It is a common tumor in dogs, but is rare in cats.

III. Cocker spaniels may be overrepresented.

IV. Three forms are described in dogs.
   A. Skin and oral mucosal tumors
   B. Gastrointestinal (GI) masses
   C. Solitary osseous plasmacytoma (SOP)

V. In the cat the most common site is the skin, while the oral cavity, abdominal cavity, eye, and brain may also be affected.

VI. The cause is unknown.

Pathophysiology

I. Skin and oral mucous membranes are the most common sites in the dog.
   A. Not usually associated with excessive immunoglobulin production
   B. Systemic disease runcommon
   C. Usually benign
II. The GI tract is another potential site.
   A. Solitary or multifocal masses in the rectum, intestine, stomach or esophagus
   B. May secrete immunoglobulins
   C. Usually metastatic within the abdomen
III. SOP may progress to multiple myeloma.
IV. In the cat, extramedullary soft-tissue plasmacytomas and SOP can be associated with paraprotein secretion; metastasis is a frequent occurrence.

Clinical Signs

I. Oral and cutaneous forms are often solitary, pink, hairless, and ulcerated masses in the mouth or on the skin of the head and ears.
II. GI tumors may cause vomiting, melena, and hematochezia.
III. Osseous tumors may cause bone pain and/or fractures.

Diagnosis

I. Biopsy of the lesion demonstrates malignant proliferation of plasma cells.
II. Evaluate affected animals for multiple myeloma.
III. Diagnosis of extramedullary plasmacytoma is made when criteria for multiple myeloma are not met.

Differential Diagnosis

I. Multiple myeloma
II. Differential diagnoses for GI plasmacytoma: lymphoma, osteosarcoma, fibrosarcoma, other tumors, inflammatory diseases
III. Cutaneous plasmacytoma: lymphoma, histiocytoma, mast cell tumor, other cutaneous masses (see Chapter 89)

Treatment and Monitoring

I. Considerations in animals with canine oral and cutaneous plasmacytoma are as follows:
   A. Excisional surgery is the treatment of choice and is curative in most cases.
   B. Radiation therapy or cryotherapy may be effective for nonresectable tumors.
II. Considerations in animals with canine GI plasmacytoma or SOP are as follows:
   A. For GI plasmacytoma, long-term survival may be achieved in some cases with a combination of surgery and chemotherapy (melphalan and prednisone; see Multiple Myeloma).
   B. Local control of SOP may be possible with surgery and/or radiation therapy; however, most lesions progress to multiple myeloma within 6 months.
   C. Ancillary therapy includes antibiotics and plasmapheresis if severe hyperglobulinemia is present.
III. Treatment for feline extramedullary plasmacytomas is not well defined, but treatments similar to those used in the dog can be tried; prognosis is guarded because of the high incidence of metastasis.

CHAPTER 78

Diseases of the Thymus

Bradley R. Schmidt

BENIGN DISEASES

Thymic Hypoplasia

Definition

I. Decreased size of the thymus from aplasia or hypoplasia
II. Arises secondary to reduced numbers of lymphocytes and/or the epithelial framework

Causes

I. Genetic disorders
  A. Thymic atrophy of Mexican hairless dogs leading to reduced T-cell function in adults
  B. Thymic aplasia in cats resulting in hairlessness in Birman kittens
  C. Autosomal recessive, severe, combined immunodeficiency of Jack Russell terriers
  D. Severe, combined immunodeficiency in a colony of basset hounds
  E. Growth hormone deficiency resulting in thymic hypoplasia in Weimaraners
  F. Acrodermatitis with immunodeficiency in bull terriers
II. Acquired disorders
  A. Infectious diseases: canine distemper virus, canine parvovirus, feline panleukopenia virus, and feline retroviral infections
  B. Environmental conditions: malnutrition in puppies and kittens, toxin exposure, radiation therapy, chemotherapy, corticosteroid administration

Pathophysiology

I. Thymic aplasia is failure of differentiation of all thymic elements.
II. Thymic hypoplasia involves lack of development or loss of thymocytes.

Clinical Signs

I. Immunodeficiency develops and results in recurrent viral, fungal or bacterial infections of the skin or the respiratory and gastrointestinal tracts of young animals.
II. Signs attributable to the primary cause, such as vomiting and diarrhea, occur with canine parvovirus or feline panleukopenia virus.
III. "Fading" syndrome of puppies and kittens (neonatal death) may be the only presenting sign.
IV. Stunted growth is seen in some animals.

Diagnosis and Differential Diagnosis

I. Laboratory testing for viral causes is recommended, especially in fading puppies and kittens.
II. The congenital form is considered in affected Mexican hairless dogs and Birman cats.
III. History of malnutrition or environmental exposure to toxins, radiation therapy, chemotherapy, or corticosteroids may be noted with acquired forms.
IV. Primary differential consideration is nonthymic-related immunosuppression.

Treatment

I. Treat the specific cause, if possible.
II. Antibiotic, antifungal, and antiviral therapy may be warranted.
III. Immunomodulating drugs, cytokine therapy, and bone marrow transplantation have been attempted; however, the results have not been consistently effective.
IV. Severe immunosuppression is usually fatal because of overwhelming sepsis or organ dysfunction.
V. Future treatments may include gene replacement therapy.

Thymic (Mediastinal) Cysts

Definition

I. There are benign fluid-filled and cystic structures in the cranial mediastinum (see Chapter 20).
II. Thymic cysts are uncommon in dogs and cats.

Cause and Pathophysiology

I. Cystic structures arise from pleural, lymphatic, bronchogenic, or thymic structures.
II. Fluid is generally clear and of low cellularity.
III. Condition is likely congenital.

Clinical Signs

I. Thymic cysts are usually an incidental finding with no clinical signs.
II. Clinical signs relating to a space-occupying mass may be present, such as regurgitation or coughing.

Diagnosis

I. Radiographically, a soft-tissue density in the cranial mediastinum is seen.
II. Ultrasonography identifies a fluid-filled or cystic structure.
III. Fine-needle aspiration of the cyst reveals a clear, acellular fluid.

Differential Diagnosis

I. Thymoma
II. Other cranial mediastinal tumors

Treatment and Monitoring

I. No therapy is required if the animal is asymptomatic.
II. Ultrasound-guided aspiration of the mass is often curative and may be attempted in symptomatic animals.

Thymic Hemorrhage

Definition and Causes

I. It is spontaneous hemorrhage occurring in the involuting thymus in young dogs.
II. Thymic hemorrhage is uncommon in the dog and rare in the cat.
III. Causes are not well defined.

Clinical Signs

I. Clinical signs arise from acute blood loss within the mediastinum and include pallor, tachycardia, and weakness.
II. Hemothorax may also occur and may induce tachypnea or dyspnea (see Chapter 19).

Diagnosis

I. Thoracic radiography and ultrasonography of the cranial mediastinum reveal a mass or diffuse thickening secondary to hemorrhage and hematoma formation.
II. Coagulation profile is normal.
III. Definitive diagnosis requires exploratory surgery.

Differential Diagnosis

I. Mediastinal tumors (rare in young dogs)
II. Other causes of anterior thoracic bleeding: trauma, clotting abnormalities

Treatment

I. Supportive care with IV fluids, evacuation of any free blood in the chest, and respiratory support
II. Whole blood transfusion if indicated (see Chapter 71)

Monitoring of Animal

I. Prognosis is guarded because fatal hemorrhage may occur.
II. Animals that do recover have a good prognosis.

NEOPLASTIC DISEASES

Thymoma

Definition and Cause

I. Thymoma is a neoplastic proliferation of the epithelial component of the thymus, with varying degrees of benign lymphocytic infiltration.
II. It is generally seen in older animals and is more common in dogs than cats.
III. The underlying cause is unknown, but German shepherd dogs appear to be predisposed.

Pathophysiology

I. Thymoma may be malignant or benign.
II. Malignancy is based primarily on clinical behavior rather than histologic findings.
   A. Benign thymoma is more common, usually encapsulated, and surgically removable.
   B. Malignant thymoma is less common and is generally locally invasive.
   C. Hemorrhage, pleural effusion, and metastasis may be present with malignant thymomas.
III. Thymoma may be categorized as lymphocytic-predominant or epithelial-predominant.
IV. Cystic thymoma has been recognized in cats.

Clinical Signs

I. Clinical signs are related to the presence of a space-occupying mass and pleural effusion and may include regurgitation, cough, dyspnea, and muffled cardiac and respiratory sounds.
   A. Precaval syndrome (edema of the head, neck, and possibly forelimbs) may be noted in some animals.
   B. In cats, the cranial thorax may be noncompressible.
II. Peripheral nerve entrapment may result in laryngeal paralysis or Horner's syndrome.
III. Paraneoplastic syndromes are often associated with thymoma in the dog but occur less commonly in the cat.
   A. Myasthenia gravis resulting in megaesophagus and weakness
   B. Hypercalcemia resulting in weakness, anorexia, polyuria, and polydipsia
   C. Polymyositis
   D. Exfoliative dermatitis in cats (see Chapter 73 and 93)

Diagnosis

I. Radiography and ultrasonography reveal a cranial mediastinal mass that may be cystic.
II. Computed tomography is helpful in staging the tumor but cannot differentiate thymoma from other mediastinal masses.
III. Needle biopsy reveals mature lymphocytes and variable numbers of mast cells, eosinophils, macrophages, and neutrophils.
   A. Some thymomas contain large lymphocytes, making it difficult to distinguish from lymphoma.
   B. Epithelial cells are not always noted, especially in lymphocytic-predominant thymoma.
IV. Histopathology may be needed to distinguish thymoma from lymphoma.
V. Immunohistochemical stains, polymerase chain reaction (PCR) assays, and flow cytometry are also helpful in distinguishing thymoma from lymphoma.

Differential Diagnosis

I. Mediastinal lymphoma
   A. The condition is characterized by immature or large lymphocytes, in contrast to mature lymphocytes of lymphocytic-predominant thymomas
   B. Multicentric involvement is a possibility.
II. Thymic cysts
III. Other anterior thoracic or anterior mediastinal masses: hematoma, squamous cell carcinoma, ectopic thyroid tumors

Treatment

I. Surgery is the treatment of choice for noninvasive tumors.
II. Radiation therapy may be tried for invasive tumors, incompletely resected tumors, or as palliation.
III. Chemotherapy may be considered for palliative purposes.
   A. Prednisone alone or in combination with cyclophosphamide and vincristine may offer partial remissions by reducing the benign lymphoid component of the tumor.
   B. Platinum-containing agents or doxorubicin may decrease the epithelial component of the tumor.

Monitoring of Animal

I. Growth of the tumor may be slow in some animals, allowing prolonged survival with no therapy.
II. Prognosis is good with surgical removal of benign thymomas in animals that have no paraneoplastic syndromes.
   A. Dogs have a median survival of 16 to 19 months (Atwater et al., 1994).
   B. Cats have a median survival of 21 months (Gores et al., 1994).
III. Prognosis is guarded to poor for animals with invasive thymoma; however, radiation therapy may be beneficial (response rate in cats and dogs of 74%) even though complete remissions are rare (Smith et al., 2001).
   A. Median survival time in dogs after radiation therapy is 248 days.
   B. Median survival time in cats after radiation therapy is 720 days.
IV. Prognosis is guarded for animals with paraneoplastic signs, especially megaesophagus.
V. Dogs with lymphocytic-predominant lymphomas may have a longer survival.
VI. Metastasis has been reported in cats with cystic thymoma (Patnaik et al., 2003).

Thymic Lymphoma

Definition

I. Thymic lymphoma is neoplastic proliferation of lymphocytes within the thymus.
II. Many thymic lymphomas are actually lymphomas of the anterior mediastinal lymph nodes.
III. It may occur alone or be part of multicentric lymphoma.

Cause and Pathophysiology

I. The cause in dogs is unknown.
II. Thymic lymphoma may cause hypercalcemia, especially in dogs.
III. The tumor is frequently associated with the feline leukemia virus (FeLV) in young cats.

Clinical Signs

I. Clinical signs are related to the presence of a space-occupying mass and pleural effusion (see Thymoma).
   A. Precaval syndrome (edema of the head, neck, and possibly forelimbs) may be noted in some animals.
   B. Cranial thorax may not be compressible, and palpable tumor may extend beyond the thoracic inlet, especially in cats.
II. Clinical signs associated with hypercalcemia are polyuria, polydipsia, weakness, and anorexia.

Diagnosis

I. Radiography or ultrasonography usually reveals a cranial mediastinal mass ± pleural effusion.
II. Computed tomography is helpful in staging the tumor but cannot differentiate between lymphoma and other mediastinal masses.
III. Needle biopsy or fluid analysis shows large lymphoblasts; however, a definitive diagnosis may require histopathology, immunohistochemistry, flow cytometry, and PCR assays of biopsy specimens.
IV. Phenotyping often demonstrates a T-cell origin.

Differential Diagnosis

I. Thyoma: characterized by mature lymphocytes and PCR, flow cytometry, and immunohistochemistry negative for lymphoma
II. Thymic cysts
III. Other causes of anterior thoracic and mediastinal masses: hematoma, squamous cell carcinoma, and ectopic thyroid tumors

Treatment

I. Combination chemotherapy is used as described for lymphoma (see Chapter 69).
II. Radiation therapy may offer rapid local remissions.
III. Therapy for hypercalcemia is recommended (see Chapter 73); however, hypercalcemia generally resolves if remission is obtained.

Monitoring of Animal

I. Cats
   A. Prognosis is variable depending on stage of the tumor.
   B. Thymic and mediastinal lymphoma has poor survival times (2 to 3 months); however, survival is longer in FeLV-negative cats (17.5 months) (Mooney et al., 1989; Withrow and MacEwen, 2001).
II. Dogs
   A. Presence of a large cranial mediastinal mass and hypercalcemia warrants a poor prognosis (Rosenberg et al., 1991).

B. Longer survival times are possible if hypercalcemia is absent.

CHAPTER 79

Introduction

Nicholas J. Trout

BASIC CONSIDERATIONS

I. Dysfunction of the musculoskeletal system can produce pain, distortion, deviation, and disruption to bones, cartilage, muscles, ligaments, and tendons.
II. Most commonly, changes are noticed as a variation in movement or gait (lameness).
III. Severity of lameness can be categorized but may not correlate with the severity of underlying cause.
   A. Subtle: ligament sprain, strain, tendonitis, tenosynovitis
   B. Weight-bearing lameness: hip dysplasia with secondary degenerative joint disease, angular limb deformities, panosteitis
   C. Toe-touching lameness: hypertrophic osteodystrophy, acute cranial cruciate ligament rupture
   D. Nonweight bearing: long bone fracture, elbow luxation, footpad foreign body
IV. Appreciation of the dysfunction necessitates a familiarity with normal anatomy and a reproducible, systematic approach to the examination of the entire musculoskeletal system.
V. Lameness from neurological dysfunction can be differentiated from a musculoskeletal cause by a complete neurological examination.

CLINICAL APPROACH

I. Speed of onset of dysfunction frequently affects the musculoskeletal examination, which includes the following:
   A. Detailed history (anamnesis)
   B. Observation of how the animal sits, stands, and moves through different gaits
   C. Physical palpation and manipulation for abnormalities
   D. Ancillary diagnostic tests
II. Musculoskeletal disorders requiring emergency surgery are uncommon.
   A. Traumatic spinal fracture or luxation may require immediate stabilization.
   B. Septic arthritis may require immediate drainage and lavage.
   C. Open fractures with extensive soft tissue trauma and contamination may require debridement, protection, and stabilization; however, immediate, definitive surgical fixation is unusual.
   D. Life-threatening problems must be addressed first.
   E. History of concurrent disease(s) may affect the choice of diagnostic tests or treatment.
   F. Complete blood count, biochemical profile, urinalysis, and thoracic radiographs are obtained for all trauma victims as part of a minimum data base.
   G. Plain radiographs are used to identify soft tissue and osseous abnormalities using at least two standard views (mediolateral, craniocaudal), as well as oblique or tangential views when necessary.
   H. In cases of possible spinal injury, the entire spinal column is radiographed (initially without sedation or anesthesia).
III. Musculoskeletal disorders requiring urgent or nonelective surgery are more common and include most open and articular fractures and traumatic joint luxations.
   A. The animal must be stable (as defined by a minimum data base) before considering therapeutic options.
   B. Chemical restraint may be needed to obtain diagnostic radiographs of the affected and the contralateral, unaffected limb (for comparison).
IV. The majority of musculoskeletal disorders requiring evaluation are nonurgent or elective problems, such as biceps tenosynovitis, elbow dysplasia, immune-mediated polyarthropathy, and panosteitis.
   A. History taking is tailored to the individual problem and includes the following:
      1. Signalment: age, weight, breed, gender
      2. Owner assessment of problem

3. Duration of problem, speed of onset, association with trauma or exercise, relationship of signs to time of day

B. Determine the course of the problem and the influence of rest and medication.

C. Consider prior musculoskeletal history with information regarding the dam, sire, siblings, diet, and any exercise regimen.

D. More subtle degrees of lameness necessitate a more careful evaluation of the animal.
   1. Observation of how the animal sits, rises, stands, and moves through different gaits
   2. Serial palpation before and after exercise
   3. Use of sedation or anesthesia to complete palpation of a painful area in a fractious animal
   4. Use of additional diagnostic tools to define specific problems

DIAGNOSTIC TOOLS

I. Certain radiographic studies have become increasingly common in the investigation of certain musculoskeletal disorders.
   A. PennHIP films to evaluate hip dysplasia in young dogs
   B. Dorsal acetabular rim views of the pelvis to assess candidates for triple pelvic osteotomy
   C. Hyperextended and hyperflexed views of an unstable joint to define instability
   D. Preoperative stifle radiographs to define the angle of the tibial plateau for tibial plateau leveling osteotomy and the position of the straight patella ligament in stifle extension for tibial tuberosity advancement procedures

II. Arthrocentesis can be used to obtain synovial fluid for cytological evaluation to better define septic, degenerative, immune-mediated, or traumatic arthritides.

III. Ultrasonography provides useful information regarding lesions of tendons and muscular attachments to bone.

IV. Computed tomography helps delineate obscure skeletal abnormalities.

V. Magnetic resonance imaging is better at defining soft tissue abnormalities.

VI. Nuclear scintigraphy can be used to localize osseous lesions that are difficult to define with plain radiography.

VII. Arthroscopy has become the technique of choice to define and treat a variety of joint related disorders.

CHAPTER 80

Diseases of Joints and Ligaments

Michael P. Kowaleski

CONGENITAL/DEVELOPMENTAL DISORDERS

Avascular Necrosis of the Femoral Head (Legg-Calvé-Perthes Disease)

Definition and Causes

I. It is defined as noninflammatory, aseptic necrosis of the femoral head that occurs predominantly in adolescent, small breed dogs.
II. Interruption of blood flow to the femoral head occurs for an unknown reason.
III. Possible causes include hereditary factors, increased intra-articular pressure, infarction of the femoral head, hormonal factors, and anatomic conformation.
IV. A recessive mode of inheritance has been proposed in the Manchester terrier (Vasseur et al., 1989).

Pathophysiology

I. Initial change is osteonecrosis of the proximal femoral epiphysis, with viable articular cartilage.
II. Continued weight bearing results in microfractures of the necrotic trabeculae, subchondral bone collapse, subchondral cleft formation, and ischemic damage to the physis.
III. Normal metaphyseal bone responds and revascularization of the femoral head occurs; however, the femoral epiphysis is mechanically weakened and susceptible to collapse and fragmentation under normal physiologic loads.
IV. Resulting deformity of the femoral head leads to joint incongruity and osteoarthritis of the hip joint.

Clinical Signs

I. Initial sign is progressive pelvic limb lameness unassociated with trauma in a young, small-breed dog.
   A. Lameness slowly worsens over 6 to 8 weeks and may progress to a nonweight bearing.
   B. Acute-onset lameness is presumably related to a previously undiagnosed mild lameness that acutely progresses from sudden collapse of the epiphysis.
II. Average age at onset is 5 to 8 months (range of 3 to 13 months) (Gambardella, 1993).
III. Bilateral in 12% to 17% of cases (Gambardella, 1993).

Diagnosis

I. Physical examination reveals discomfort with flexion, extension, rotation, and abduction of the hip joint.
II. Radiography is essential to establish a diagnosis.
   A. Incongruency and widening of the coxofemoral joint space progressing to subluxation
   B. Flattening of the femoral head
   C. Foci of decreased density of the femoral head and neck (moth-eaten appearance)
   D. Irregular indentation of the subchondral bone of the femoral head, periarticular osteophyte formation
III. Histopathologic examination of the resected femoral head and neck is confirmatory.

Differential Diagnosis

I. Medial patellar luxation
II. Proximal femoral physeal fracture
III. Traumatic hip luxation
IV. Canine hip dysplasia

Treatment

I. Femoral head and neck excision is the treatment of choice.
II. Total hip replacement can be considered, depending on the size of the dog.
III. In bilateral cases the worst hip (clinically) is operated on first, followed by the second hip (generally in 4 to 6 weeks).

Monitoring of Animal

I. Postoperatively, low-impact activities are initiated that encourage use of the limb (e.g., leash walking, swimming).
II. Passive range-of-motion exercises may be needed if weight bearing does not begin within 10 to 14 days.
III. Radiographs are repeated if lameness develops in the opposite pelvic limb.

Patellar Luxation

Definition and Causes

I. Patellar luxation is intermittent or permanent displacement of the patella from the femoral trochlear sulcus.
II. It is associated with a malalignment of the quadriceps muscles, patella, and patellar tendon, as well as femoral and/or tibial deformities.

Pathophysiology

I. Medial malalignment of the quadriceps mechanism in growing dogs with medial patellar luxation can cause sufficient pressure on the medial distal femoral growth plate to retard growth, whereas reduced pressure laterally allows accelerated growth.
II. Deformities associated with medial luxation include distal femoral varus, external femoral torsion, and medial displacement of the tibial tuberosity.
III. Patellar luxation causes reduced pressure on the trochlear sulcus of the femur, allowing excessive growth of the articular cartilage and underlying bone, leading to a shallow or absent trochlear groove.
IV. Lateral luxation is associated with coxa valga (excessive angle of inclination of the femoral neck) and excessive anteversion angle (external rotation of the proximal femur with respect to the distal femur).

Clinical Signs

I. Medial luxation is a developmental disorder in small-breed dogs, may occur secondary to trauma in any breed, and is increasing in frequency in large-breed dogs.
II. Lateral luxation is seen most commonly in large-breed dogs.
III. Most animals have intermittent weight-bearing lameness and occasionally hold the limb in a flexed position for several steps.

Diagnosis

I. Grade I
   A. Patella may be luxated manually with the joint in extension, but reduction occurs when digital pressure is released.
   B. It is usually an incidental finding but may be associated with occasional lameness.
II. Grade II
   A. Patella can be luxated manually with the joint in extension, especially with rotation of the foot in the direction of luxation.
   B. Reduction occurs with flexion and rotation of the foot opposite to the direction of luxation.
   C. Patella luxates spontaneously and intermittently, and the gait ranges from "skipping" to non–weight-bearing.
III. Grade III
   A. Patella is permanently luxated; manual reduction is possible, but reluxation occurs when pressure is released or the stifle is flexed.
   B. Lameness ranges from weight-bearing to non–weight-bearing.
IV. Grade IV
   A. Patella is permanently luxated and cannot be manually reduced.
   B. Limb is non–weight-bearing if unilateral or the animal moves in a crouched posture if bilateral.

Differential Diagnosis

I. Avascular necrosis of the femoral head
II. Coxofemoral luxation
III. Cranial cruciate ligament rupture
IV. Distal femoral physeal fracture

Treatment

I. Grade I patellar luxations do not require surgical treatment unless lameness is frequent or progressive.
II. Grade II luxations commonly require surgery if episodes of lameness are frequent or severe.
   A. A combination of surgical procedures is performed to address each abnormality present.
   B. Deepening of the femoral trochlear sulcus is accomplished using trochlear wedge recession, trochlear block recession, trochleoplasty, or trochlear chondroplasty (Slocum and Slocum, 1993; Johnson et al., 2001).
   C. Tibial tuberosity transposition is done to align the quadriceps mechanism.
   D. Joint capsule imbrication is performed on the side opposite the luxation.
   E. Retinacular and joint capsule–releasing incision is made on the side of the luxation.
III. Grade III luxations require a combination of the previously discussed procedures and possibly femoral and/or tibial corrective osteotomy to address angular or torsional deformities.
IV. Grade IV luxations often also require corrective osteotomy of the femur and/or tibia.
   A. Prognosis for return of pet to a functional level is fair to good.
   B. Stifle joint arthrodesis may be required with poor return to function.

Monitoring of Animal

I. Postoperatively, low-impact activities are initiated that encourage use of the limb (e.g., leash walking, swimming).
II. Passive range-of-motion exercises may be needed if weight bearing does not begin within 10 to 14 days.
III. Physical examinations are repeated at 2 and 6 weeks to assess limb function and ensure the patella is stable.
IV. Radiographs are obtained to assess bony healing at 6 to 8 weeks.

Shoulder and Elbow Luxation

Definition and Causes

I. Congenital shoulder and elbow luxation are likely hereditary in origin.
II. Luxation of the shoulder or elbow can occur secondary to trauma.
III. Congenital medial shoulder luxation occurs most frequently in small and miniature breed dogs (e.g., Shetland sheepdog, toy poodle).
IV. Congenital elbow luxation has been reported in the Boston terrier, Yorkshire terrier, English bulldog, miniature poodle, Pomeranian, and pug.

Pathophysiology

I. The cause of congenital luxations is not known.
II. Congenital or developmental joint laxity may lead to luxation and hypoplastic joint surfaces.

Clinical Signs

I. Medial shoulder luxation: congenital or traumatic
   A. Affected limb is carried in flexion with foot rotated outward.
   B. Greater tubercle is palpable medial to the normal position.
II. Lateral shoulder luxation
   A. It is generally traumatic; large breeds are affected most.
   B. Affected leg is carried in flexion with foot rotated internally.
   C. Greater tubercle is palpable lateral to the normal position.
III. Elbow luxation
   A. Congenital elbow luxation results in lateral rotation of the proximal ulna, as well as subluxation or luxation of the humeroulnar joint.
   B. Most traumatic elbow luxations are lateral because of the large medial epicondylar ridge.
   C. Limb is abducted, externally rotated, and held in slight flexion.
IV. Congenital forms: possibly bilateral

Diagnosis

I. Malarticulation and displacement of normal bony landmarks are classic findings.
II. Diagnosis is confirmed radiographically.
III. Additional radiographic findings are flattening of the joint surfaces and angular or torsional deformities of the humerus, ulna, or radius.

Differential Diagnosis

I. Fractures of elbow or shoulder
II. Physeal trauma: fracture or growth deformity

Treatment

I. Congenital shoulder and elbow luxations
   A. Closed reduction and coaptation are generally unsuccessful.
   B. Surgical reduction and stabilization may result in acceptable joint function.
   C. Closed reduction and percutaneous fixation have been described in dogs (Dassler and Vasseur, 2003).
   D. Arthrodesis may be required if joint function is unacceptable.
II. Traumatic medial shoulder luxation
   A. Conservative management
      1. Closed reduction and cage rest for 2 to 3 weeks
      2. Reduction and placement of the limb in a Velpeau sling for 2 to 3 weeks to distract the humeral head laterally
   B. Surgical management: medial transfer of biceps brachii tendon and joint capsule imbrication
   C. Salvage procedures: excision arthroplasty of the humeral head, resection of the glenoid, shoulder arthrodesis
III. Traumatic lateral shoulder luxation
   A. Conservative management
      1. Closed reduction and cage rest for 2 to 3 weeks
      2. Closed reduction and placement of the limb in a spica splint or sling for 2 to 3 weeks
   B. Surgical management
      1. Lateral transfer of biceps brachii tendon and joint capsule imbrication
      2. Prosthetic glenohumeral ligament reconstruction using nonabsorbable suture material and bone anchors or tunnels in the scapular and humeral neck
   C. Salvage procedures: excision arthroplasty of humeral head, resection of glenoid, shoulder arthrodesis
IV. Traumatic elbow luxation
   A. Conservative management
      1. Closed reduction under general anesthesia
      2. Application of spica splint for 10 to 14 days
   B. Surgical management
      1. Open reduction is indicated if instability is present after closed reduction or for chronic or irreducible elbow luxations.
      2. Torn collateral ligaments may be primarily repaired, and a screw, washer, and heavy-gauge suture may be used to create a prosthetic collateral ligament.
      3. Spica splint is applied for 10 to 14 days.

Monitoring of Animal

I. Passive range-of-motion exercises are initiated, followed by low-impact activity once the coaptation has been removed.
II. Radiographs are repeated in 4 to 6 weeks to assess status of joint reduction and stability of implants.

Canine Elbow Dysplasia

Definition and Causes

I. Canine elbow dysplasia is a group of developmental diseases that researchers believe is caused by incongruity between the humerus, radius, and ulna.
II. Manifestations include fragmented medial coronoid process (FMCP) of the ulna, ununited anconeal process (UAP) of the ulna, and osteochondritis dissecans (OCD) of the medial portion of the humeral condyle.
III. In the past, decreased radius of curvature of the ulnar trochlear notch was the suggested cause.
IV. Recently, elbow incongruity from asynchronous growth between the radius and ulna has been implicated as the cause (Schultz and Krotscheck, 2003).

Pathophysiology

I. Lagging radial growth and a relatively long ulna may stress the medial coronoid process and humeral condyle, resulting in FMCP and, potentially, OCD of the humeral condyle.
II. A relatively long radius may increase the load on the anconeal process, preventing normal fusion of this center of ossification.
III. Dogs with unilateral UAP have a slightly longer radius on the affected side (Sjöström et al., 1995).

Clinical Signs

I. FMCP and OCD
  A. Thoracic limb lameness, initially evident at 5 to 8 months of age, is seen in retrievers, Bernese mountain dogs, and rottweilers.
  B. Dogs may not be presented until 1 to 2 years of age, after development of osteoarthritis.
  C. Lameness is worse after exercise, and joint effusion and periarticular fibrosis may be palpable.
    1. Lameness is usually unilateral, even if both joints are affected.
    2. Stiff or stilted gait may be observed if bilateral lameness is present (shortened stride).
  D. Pain is evident with supination or pronation of the pes, simultaneous flexion and extension of the joint, and palpation of the medial coronoid process.

II. UAP
  A. The anconeal process normally fuses with the proximal ulna by 20 to 24 weeks of age, so diagnosis of UAP before this may be premature.
  B. Large-breed dogs, especially the German shepherd dog, basset hound, and St. Bernard are affected.
  C. Signs of thoracic limb lameness, elbow abduction, and external rotation of the foot become apparent at 5 to 8 months of age.
  D. Crepitus, joint effusion, and periarticular thickening of the elbow may be noted.

Diagnosis

I. FMCP
  A. Presumptive diagnosis is based on typical history and clinical signs.
  B. Radiographs of both elbows are taken, because the disease is commonly bilateral.
    1. Radiographic findings are nonspecific; presence of osteoarthritis is suggestive of FMCP.
    2. Osteophytosis and superimposition of the radial head on the coronoid process make identification of the FMCP difficult.
    3. Obtain lateral and craniocaudal views; a flexed lateral view exposes the anconeal process to assess for osteophytosis.
    4. The craniolateral-caudomedial −15-degree oblique view (with 30 degrees of flexion) may help visualize the medial coronoid.
    5. Blunting of the coronoid, visible fragments, and osteophytes of coronoid process, anconeal process, or radial head may be visible.
    6. The earliest radiographic changes are osteophytes on the anconeal process.
    7. Later signs include subchondral bone sclerosis, articular and periarticular osteophytosis, joint space narrowing, joint effusion, and periarticular soft-tissue thickening; these signs indicate secondary degenerative joint disease (DJD).
  C. Definitive diagnosis can be made with arthroscopy, computed tomography, magnetic resonance imaging, or arthrotomy.

II. OCD
  A. An oval to triangular subchondral bone defect is evident in the medial portion of the humeral condyle in the craniocaudal radiographic projection.
  B. Earliest radiographic changes are similar to those of FMCP.

III. UAP
  A. Clinical signs, age, and breed allow for a tentative diagnosis.
  B. Flexed, lateral radiograph reveals an irregular radiolucent line between the anconeal process and the olecranon.
  C. Radiographs of the contralateral elbow may be useful for comparison.
  D. Bilateral UAP occurs in 11% to 47% of cases (Schultz and Krotscheck, 2003).

Differential Diagnosis

I. These conditions produce similar signs and can be differentiated radiographically.
II. Combinations of OCD, FMCP, and UAP may occur.
III. Humeroulnar subluxation resulting from premature physeal closure can be differentiated radiographically.
IV. Other diseases of the thoracic limb in young dogs are OCD of the shoulder and panosteitis.

Treatment

I. FMCP and OCD
  A. Medical management
    1. Asymptomatic dogs or those with severe DJD may be treated medically.
    2. Weight control, exercise moderation, nonsteroidal antiinflammatory drugs (NSAIDs), chondroprotective agents, and nutritional management are the cornerstones of treatment.
    3. Rest (2 to 3 weeks) and NSAIDs (Table 80-1) are used during episodes of lameness, followed by return to moderate regular exercise.
  B. Surgical management

TABLE 80-1

Nonsteroidal Antiinflammatory Drugs Approved for the Treatment of Osteoarthritis in Dogs

DRUG (BRAND NAME)	DOSE AND FREQUENCY
Carprofen *(Rimadyl)*	2.2 mg/kg PO BID
Deracoxib *(Deramaxx)*	1 to 2 mg/kg PO SID
Etodolac *(EtoGesic)*	10 to 15 mg/kg PO SID
Firocoxib *(Previcox)*	5 mg/kg PO SID
Meloxicam *(Metacam)*	0.1 mg/kg PO SID
Tepoxalin *(Zubrin)*	10 mg/kg PO SID

1. Indications include persistent lameness and mild DJD.
2. Some dogs with moderate or severe DJD may also benefit from loose fragment removal.
3. The joint is explored either arthroscopically or via arthrotomy; loose fragments of the FMCP or OCD lesion are removed, followed by debridement of the subchondral bone bed.
4. Surgical treatment does not halt the progression of osteoarthritis; therefore continued medical therapy is indicated.

II. UAP
   A. Removal of the anconeal process is an acceptable method of treatment but may lead to elbow instability and osteoarthritis.
   B. Surgical reconstruction and procedures that enhance fusion of the anconeal process may be preferred.
      1. Dynamic proximal ulnar osteotomy may allow fusion of the anconeal process in young (6 to 12 month) dogs.
      2. Dynamic proximal ulnar osteotomy and lag screw fixation may be required in older (>1 year) dogs and in dogs with loose attachment of the anconeal process to the olecranon (Schultz and Krotscheck, 2003).

Monitoring of Animal

I. FMCP and OCD
   A. Exercise is restricted for 4 to 6 weeks, followed by gradual return to normal activity.
   B. Prognosis for full function is guarded because of progressive DJD regardless of treatment.
   C. Most dogs are functional pets and have intermittent lameness.
   D. Osteoarthritis requires lifelong medical management.

II. UAP
   A. A soft, padded bandage is applied for 3 to 5 days from the digits to the middiaphysis proximal to the incision to minimize postoperative swelling.
   B. The dog is confined to leash walks for 6 weeks, then gradually returned to normal activity over the next 6 weeks.
   C. Radiographs are repeated in 4 to 6 weeks to assess fusion of the anconeal process and healing of the ulnar osteotomy (if performed).

Canine Hip Dysplasia

Definition and Causes

I. Canine hip dysplasia is an abnormal development of the hip joint with varying degrees of joint laxity that permits subluxation of the femoral head early in life.

II. Researchers agree that hip dysplasia is genetically mediated; however, the exact mechanism is unknown.

III. Environmental factors, such as increased energy and calcium intake, also play an important role (Todhunter and Lust, 2003).

Pathophysiology

I. If muscle development and rate of growth lag behind the development of skeletal structures, then the limit of the supporting structures is exceeded and joint laxity occurs.

II. Severity depends on the degree of overloading of the joint during its development.

III. Changes in cartilage, supporting soft tissue, and muscles cause alterations in bony architecture.

IV. Coxofemoral joint laxity leads to subluxation of the femoral head, which causes cartilage damage, release of degradative enzymes, and loss of cartilage matrix.

V. The end result is osteoarthritis (DJD).

Clinical Signs

I. Pelvic limb lameness is worse after exercise and varies from mild and intermittent to non–weight-bearing.

II. Decreased flexion and extension of the hip during a walk or trot and a "bunny-hopping gait" while running are common findings.

III. Pelvic limb muscle atrophy, joint laxity, and pain during range-of-motion examination of the coxofemoral joint are typical findings.
   A. Ortolani sign is a palpable click elicited as the subluxated hip reduces with abduction.
   B. Ortolani sign is often positive in young dogs with mild to moderate degenerative changes and is consistent with hip laxity and dysplasia.
   C. As the degeneration progresses, the acetabulum fills with new bone and the Ortolani sign becomes negative.
   D. A negative Ortolani sign can be a normal finding or indicative of advanced DJD.

Diagnosis

I. Radiographic changes range from mild subluxation of the femoral head to severe DJD.
   A. In young dogs (<10 months), subluxation is often the main abnormality.
   B. In dogs >10 months, evidence of DJD is typically present.
      1. Flattening of the femoral head
      2. Shallow acetabulum
      3. Osteophytosis of the femoral neck, femoral attachment of the joint capsule and acetabular margins
      4. Narrowing of the joint space
      5. Subchondral sclerosis of the femoral head and acetabulum

II. Stress radiographic techniques (e.g., PennHIP method) are useful to demonstrate laxity of the hip joint, which is a predictor of future DJD (Smith et al., 1990).

Differential Diagnosis

I. Cranial cruciate ligament rupture

II. Traumatic luxation

III. Degenerative myelopathy (older dogs)

IV. Femoral head, neck, or proximal femoral physeal fracture (younger dogs)

V. Infectious or inflammatory arthritis

Treatment

I. Medical management involves the following:
   A. Weight loss is important because it decreases loading of joints and muscles; the goal is a thin and athletic frame (body condition score of 2.5 to 3.5).
   B. Daily low-impact activity aids in weight loss and helps improve muscle mass, joint range of motion, and exercise tolerance.
   C. NSAIDs are administered as needed (see Table 80-1) (Bergh and Budsberg, 2005).
      1. Never administer NSAIDs with other NSAIDs (including aspirin) or corticosteroids.
      2. When switching from one NSAID (particularly aspirin) to another, wait a few days (according to the manufacturer's recommendations).
   D. Chondroprotective agents may mitigate inflammation and enhance reparative processes.
      1. Glucosamine hydrochloride 22 mg/kg PO SID, *with*
      2. Chondroitin sulfate 8.8 mg/kg PO SID
   E. Diets containing high levels of omega-3 fatty acids and eicosapentaenoic acid may help improve clinical signs associated with DJD.

II. Once the animal is refractory to medical management or is disabled by the condition, surgical therapy is indicated.
   A. An exception is the triple pelvic osteotomy (TPO), in which delay may preclude the animal from being a good candidate.
   B. Surgical management is divided into treatments that aim to diminish the progression of DJD and salvage procedures that remove the original hip joint.

III. Juvenile pubis symphysiodesis is electrocautery of the pubic symphysis to induce its premature closure (Dueland et al., 2001).
   A. The resulting asymmetrical closure of the pelvic symphysis (pubic is closed, ischial is not) and continued growth of the sacrum and ilium result in acetabular ventroversion, which enhances femoral head capture.
   B. Procedure is experimentally effective but must be performed at an early age (12 to 16 weeks).
   C. It is difficult to identify which dogs will benefit at such an early age.

IV. TPO increases the acetabular coverage of the femoral head.
   A. The ideal candidate is young (5 to 12 months), has minimal or no radiographic evidence of DJD, and has adequate femoral head capture.
   B. Femoral head capture is subjective assessment of dorsal acetabular rim wear, and is assessed by performing the Ortolani maneuver and determining the angle at which the femoral head reduces into the acetabulum (angle of reduction), as well as the angle at which it subluxates (angle of subluxation).
   C. The quality of femoral head capture may also help determine if the dorsal acetabular rim is excessively worn or able to maintain the hip in reduction postoperatively.
   D. Arthroscopic examination of the hip joint allows a more thorough evaluation of the joint before surgery.
   E. TPO entails osteotomy of the pelvis at the pubis, ischium, and ilium; external rotation (ventroversion) of the free acetabular segment; and stabilization of the ilial osteotomy with plate fixation, to provide more dorsal coverage to the femoral head and preventing continued subluxation.

V. Femoral head ostectomy (FHO) is a salvage procedure in which the femoral head and neck are removed and a scar tissue "joint" subsequently forms.
   A. Animals treated with this procedure have a limited range of motion, a mildly abnormal gait, and persistent muscle atrophy.
   B. Although range of motion is diminished, most animals <20 kg function well; results in animals ≥20 kg are less reliable.

VI. Total hip arthroplasty (THA) provides the animal with a prosthetic femoral component and acetabular cup.
   A. Currently, component systems are either cemented in place or are cementless in design.
   B. THA results in normal or near normal gait, muscle mass, and range of motion.
   C. THA is a sophisticated procedure that demands strict asepsis and precise surgical technique if a successful result is to be obtained.

Monitoring of Animal

I. Animals treated medically are monitored to assess efficacy of therapy and limb function.
   A. Initially, reevaluation is performed at monthly intervals.
   B. If the response to treatment is favorable, then the dog is reevaluated every 3 to 4 months and at times of disease flare-up.

II. Surgically treated animals undergo exercise restriction and are monitored for common complications as follows:
   A. Juvenile pubis symphysiodesis: progression of DJD
   B. TPO
      1. Exercise is restricted for 4 to 6 weeks.
      2. Radiography is conducted at 4 to 6 weeks postoperatively to assess bony healing.
      3. If clinically indicated, surgery may be performed on the contralateral side once bony healing is adequate on the initial side (typically 4 to 6 weeks).
      4. Long-term function is good despite progression of DJD (Rasmussen et al., 1998).
   C. FHO
      1. Initiate low-impact activities (e.g., leash walking, swimming) after 2 weeks.
      2. Passive range-of-motion exercises may be needed if weight bearing does not begin within 10 to 14 days.
      3. Gradual return to normal activities is encouraged during weeks 2 to 8.
   D. THA
      1. Walk the animal outside on a leash (for eliminations only) for the first 4 weeks.
      2. Duration of leash walks is increased progressively during weeks 5 to 8.
      3. Short episodes of off-leash activity are allowed during weeks 9 to 12.

4. Radiographs are taken at week 12 to assess implants, then yearly.
5. Most (92% to 95%) animals have good or excellent function postoperatively (Olmstead, 1987).

Osteochondrosis and Osteochondritis Desiccans

Definition and Causes

I. Osteochondrosis (OC) is failure of endochondral ossification and refers to the disease in general.
II. OCD is a combination of dissecting lesions of articular cartilage, communication of synovial fluid into subchondral bone, and synovitis (Schultz and Krotscheck, 2003).
III. Factors that have been implicated include nutrition (e.g., excessive nutrition, dietary calcium, protein), genetics, exercise, environmental factors, and trauma (e.g., excessive mechanical loading).

Pathophysiology

I. A defect in endochondral ossification results in a focal area of abnormal subchondral bone formation.
II. The overlying cartilage fails to ossify, resulting in focal retention of cartilage.
III. The thickened region of cartilage becomes necrotic and weak, and breaks down under normal loading conditions or secondary to trauma.
   A. Early in the disease process, OC affects only the epiphyseal cartilage and the animal is asymptomatic.
   B. Once a fissure occurs in the thickened cartilage, it extends through the necrotic cartilage to the subchondral bone, allowing access of the synovial fluid to the subchondral bone.
   C. This latter stage seems to correspond to the onset of clinical signs, at which time the disease is termed *OCD.*
IV. OCD results in two distinct joint abnormalities.
   A. Joint incongruity secondary to malformation of cartilage and subchondral bone
   B. Joint mouse formation
V. Cartilage flaps that remain attached may ossify, with the resulting bone remaining viable as long as the flap is attached.
VI. Detached cartilage flaps may survive in the joint fluid, grow in size, and mineralize or ossify if they attach to the joint capsule.

Clinical Signs

I. Common sites are the caudomedial humeral head (shoulder), distal humerus (elbow), trochlear ridge of the talus (hock), and femoral condyle (stifle).
II. Shoulder lesions often occur in large breed dogs, 4 to 8 months of age.
   A. Males are affected more commonly than females.
   B. Many dogs are clinically affected in only one limb, but lesions are bilateral in 43% to 65% of cases (Bloomberg and Lewis, 1998).
   C. Thoracic limb lameness may be noted before or after exercise.
   D. Pain is elicited with shoulder extension; crepitus, deltoid and spinatus muscle atrophy may be found.
III. Hock lesions typically occur in young (5 to 8 months) large-breed dogs, especially the rottweiler, Labrador retriever, and bullmastiff.
   A. OCD of the medial trochlear ridge is most common, whereas the lateral trochlear ridge OCD often occurs in rottweilers.
   B. Pelvic limb lameness is characterized by a shortened stride and hyperextension of the tarsocrural joint.
   C. Thickening of the tarsus occurs, especially if the medial trochlear ridge of the talus is involved.
IV. Stifle lesions occur in large-breed dogs that are 5 to 7 months of age.
   A. Lameness varies from mild to severe.
   B. Joint effusion, muscle atrophy, and crepitus may be evident.

Diagnosis

I. Normal cartilage is not visible radiographically unless significant dystrophic calcification has occurred.
II. Radiographically, an OCD lesion is a flattened or saucer-like "divot" in the subchondral bone.
III. Shoulder radiographs reveal a flattening of the humeral head in a properly positioned lateral view.
IV. An arthrogram of the shoulder may be needed if the lesion is not evident or if cartilage has migrated into the biceps tendon sheath.
V. Radiographic identification of hock lesions may be difficult because of the location of the lesion on the trochlear ridge.
   A. An extended dorsoplantar projection may reveal the defect in the trochlear ridge.
   B. A dorsolateral-plantar-medial 45-degree oblique projection in full extension outlines the medial trochlear ridge of the talus.
   C. A skyline view of the talus may identify a lesion on the center of the trochlear ridge of the talus.
VI. Slight flattening and sclerosis of the subchondral bone of the femoral condyle is evident in a caudocranial view of the stifle.
VII. Do not confuse the extensor fossa of the femur for an OCD lesion.

Differential Diagnosis

I. Panosteitis
II. Traumatic joint injury
III. Septic or inflammatory arthritis
IV. Other causes of thoracic limb lameness: elbow dysplasia
V. Other causes of pelvic limb lameness: cranial cruciate ligament rupture, hip dysplasia

Treatment

I. As the relative size of the osteochondral defect increases, the resulting joint incongruity also increases; therefore a small defect in a large joint (shoulder) has less of an affect than in a small (hock) or complex (elbow or stifle) joint.

A. Surgical treatment can result in normal or near-normal function in large joints with relatively small lesions (shoulder).
B. Function is improved, but clinical signs are not always alleviated in complex or small joints (elbow, hock, stifle).

II. Goals of surgery are to surgically debride the osteochondral defect, with minimal damage to the joint.
A. Arthrotomy or arthroscopy can be used.
B. Debride the lesion to the level of subchondral bleeding bone, using a curette, hand bur, or motorized shaver.
C. Debride the edge of the lesion peripherally until normal cartilage is reached, ensuring the edges are perpendicular to the subchondral bed.
D. Microfracture can be used to create vascular access channels from the lesion to the underlying subchondral bone.

III. Long-term medical management with weight control, exercise moderation, NSAIDs, chondroprotective agents, and nutritional changes are also helpful (see Osteoarthritis).

IV. Rest (2 to 3 weeks) and NSAIDs are used for recurrent episodes of lameness, followed by return to moderate regular exercise.

Monitoring of Animal

I. In the case of hock or stifle OCD, a soft, padded bandage is applied for 3 to 5 days from the digits to the middiaphysis proximal to the incision to minimize postoperative swelling.

II. The dog is confined to leash walks for 6 weeks, then gradually returned to normal activity over the next 6 weeks.

III. Degree of DJD in the joint before surgery has an inverse effect on long-term function.

IV. Dogs with OCD of the hock may fare well without surgery, because of the relatively large size of typical hock lesions and the tendency for significant preoperative DJD.

DEGENERATIVE DISORDERS

Osteoarthritis

Definition and Causes

I. Osteoarthritis (i.e., DJD) is a syndrome of pathologic changes in diarthrodial or synovial joints accompanied by signs of pain and disability.

II. It develops secondary to trauma, or from application of normal forces on abnormal joints, such as with hip dysplasia or cranial cruciate ligament disease.

III. Other less common causes include sepsis, prolonged joint immobilization, inflammatory joint disease, or developmental diseases (e.g., OCD).

Pathophysiology

I. All joint tissues are involved, including articular cartilage, joint capsule, subchondral bone, ligaments, and muscle.

II. Initially, degradative enzymes are released from chondrocytes, synoviocytes, and inflammatory cells.

III. The earliest form of articular cartilage damage is fibrillation or roughening of the cartilage surface.

IV. Once the superficial layer of cartilage loses its integrity, the deeper layers are exposed to progressively higher loads, leading to fissure formation.

V. Cartilage destruction leads to altered biomechanical function of the joint, which perpetuates the degradative process and worsens functional impairment and discomfort (Todhunter and Johnston, 2003).

Clinical Signs

I. Signs include slowly progressive, episodic or persistent lameness, pain, and disability.
A. Stiffness is often noted after periods of rest.
B. Stiffness and lameness partially or fully resolve with activity in most cases.
C. Lameness is exacerbated by strenuous activity, particularly if the activity is followed by a period of rest.

II. Discomfort is noted during range-of-motion examination of the joints.

III. Periarticular fibrosis, bony crepitus, joint effusion, and muscle atrophy are common findings.

Diagnosis

I. History and clinical findings allow a presumptive diagnosis.

II. Radiography reveals joint effusion, periarticular osteophytosis, muscle atrophy, and subchondral bone sclerosis.
A. Joint space narrowing may occur from cartilage thinning; however, most radiographs are not obtained under weight-bearing conditions, so this finding must be interpreted with caution.
B. Joint subluxation and luxation may also be seen.

III. Synovial fluid analysis is consistent with DJD (Table 80-2).

Differential Diagnosis

I. Trauma

II. Developmental joint disease

III. Inflammatory joint disease

TABLE 80-2

Interpretation of Synovial Fluid Analysis

CONDITION	TOTAL CELL COUNT ($\times 10^3$/L)	MONONUCLEAR CELLS (%)	NEUTROPHILS (%)
Normal	0.0-3.0	90-100	0-10
Nonsuppurative Inflammation			
Degenerative osteoarthritis	0.0-3.5	90-100	0-10
Suppurative Inflammation			
Nonerosive arthritis	4.4-370	5-85	15-95
Erosive arthritis	3.0-38	20-80	20-80
Bacterial arthritis	110-267	1-10	90-99

Treatment

I. Prevention of osteoarthritis is preferable, but the condition is usually well established before diagnosis.
II. Medical management of osteoarthritis involves five basic treatments.
  A. Weight loss decreases loading of joints and muscles, and the goal is a thin and athletic frame.
  B. Daily low-impact activity aids in weight loss and helps improve muscle mass, joint range of motion, and exercise tolerance.
  C. NSAIDs are administered as needed (see Table 80-1) (Bergh and Budsberg, 2005).
  D. Chondroprotective agents may mitigate inflammation and enhance reparative processes.
    1. Glucosamine hydrochloride 22 mg/kg PO SID, *with*
    2. Chondroitin sulfate 8.8 mg/kg PO SID
  E. Diets containing high levels of omega-3 fatty acids and eicosapentaenoic acid may help improve the clinical signs.
III. Surgical management is indicated in selected cases.
  A. If joint instability exists (e.g., cranial cruciate ligament rupture), then surgical stabilization mitigates clinical signs.
  B. Joint replacement is very effective in alleviating clinical signs but is routinely performed only in the hip (THA).
  C. Total elbow and knee arthroplasties may be performed.
  D. Excision arthroplasty may be performed in selected joints.
    1. FHO
    2. Resection of the glenoid excision arthroplasty of the humeral head: data on outcome lacking
  E. Arthrodesis may be performed in selected joints to salvage limb function.
    1. Partial or total carpal and or tarsal arthrodeses are well tolerated and result in acceptable limb function.
    2. Shoulder, stifle, and elbow arthrodesis result in significant mechanical lameness but may diminish clinical discomfort.

Monitoring of Animal

I. NSAIDs are administered only as needed at the lowest effective dose.
II. Reexamine the animal every 1 to 4 months to assess the efficacy of therapy and to monitor for any complications of treatment (Bergh and Budsberg, 2005).
  A. Perform a complete blood count and biochemical profile before initiating therapy.
  B. Laboratory tests are repeated every few months while the animal is on NSAIDs to monitor for hematological, hepatic, and renal abnormalities.
III. Perform follow-up radiographs 8 to 12 weeks after surgery in animals treated with surgical procedures.

Cranial Cruciate Ligament Rupture

Definition and Causes

I. Disruption of the cranial cruciate ligament (CCL) results in stifle instability and secondary DJD.
II. An acute mechanical overload from trauma can cause disruption of a normal CCL.
III. More commonly, a progressive deterioration of the ligament coupled with a normally high level of mechanical stress results in rupture.

Pathophysiology

I. The CCL ligament limits cranial tibial subluxation, internal rotation of the tibia, and stifle hyperextension.
II. Rupture results in stifle joint instability, which causes DJD and meniscal damage.
III. Meniscal injury occurs in approximately 20% to 80% of cases (Vasseur, 2003).
  A. The lateral meniscus is seldom damaged because of its mobility.
  B. The medial meniscus is commonly damaged because the structure is relatively immobile.
    1. Medial meniscal injury results from either crushing or tearing.
    2. Meniscal injury leads to further instability and synovitis.

Clinical Signs

I. Lameness can vary from mild and intermittent (partial tear) to non–weight-bearing (complete rupture and/or meniscal tear).
II. Non–weight-bearing lameness is often noted at the time of ligament rupture, followed by partial weight bearing within 48 to 72 hours.
III. Pain is elicited with palpation, manipulation, and full extension of the stifle joint.
IV. Stifle effusion, periarticular fibrosis (medial buttress formation), positive cranial drawer test, positive tibial compression test, bony crepitus, and muscle atrophy may be noted.
V. A meniscal click may be evident with flexion of the stifle, if the meniscus is torn.
VI. Bilateral CCL rupture may result in difficulty, inability, or unwillingness to rise and can be confused with neurological disease or myopathy.

Diagnosis

I. Stifle joint palpation is the most reliable noninvasive test.
II. Positive cranial drawer and/or tibial compression tests are diagnostic.
  A. To perform the cranial drawer test, position the animal in lateral recumbency.
    1. Place the thumb of the proximal hand behind the lateral fabella and the index finger on the patella.
    2. Place the thumb of the distal hand behind the fibular head, and place the index finger on the tibial tuberosity.
    3. Check the tibia for cranial movement with respect to the femur throughout a range of motion (from 30 degrees short of full extension to 90 degrees of flexion).
    4. In the adult, no cranial drawer is present.

5. In the juvenile, 3 to 4 mm of cranial drawer may be present; it ends with an abrupt stop and is symmetrical in both stifles.
6. Cranial drawer in flexion is consistent with a partial CCL rupture.

B. To perform the tibial compression test, position the animal in lateral recumbency.
1. Grasps the metatarsus with the distal hand.
2. Extend the index finger of the proximal hand down the straight patellar tendon, with the fingertip on the tibial tuberosity.
3. Monitor for cranial tibial translation as the hock is flexed.

III. Radiographic findings are consistent with DJD.
A. Effacement of the infrapatellar fat pad, with soft tissue opacity in the lateral view, is consistent with stifle joint effusion.
B. Periarticular or peritrochlear osteophytosis may be detected.
C. Osteophytosis of the base or apex of the patella, distal aspect of the fabella, and cranial intercondyloid area of the tibia may be noted.
D. Cranial tibial subluxation may be seen.
E. Medial buttress formation may be seen on the caudocranial view.

IV. Stifle arthrotomy or arthroscopy may be used to confirm the diagnosis.

Differential Diagnosis

I. Patellar luxation
II. Stifle OCD
III. Avulsion of the long digital extensor tendon
IV. Caudal cruciate ligament rupture
V. Hip dysplasia

Treatment

I. Very small dogs (<5 kg) and most cats may only require medical management (see Osteoarthritis).
II. Larger dogs, obese cats, and active small dogs benefit from stifle stabilization.
III. Extracapsular techniques use elements outside the joint to provide stability.
A. Lateral suture (lateral retinacular imbrication)
B. Fibular head transposition
IV. Intracapsular techniques use an intraarticular graft (patellar tendon or biceps fascia) to stabilize the joint.
A. Under-and-over fascial technique
B. Over-the-top procedure
V. Osteotomy procedures alter joint biomechanics to lessen or eliminate the cranial tibial thrust force, thereby eliminating the need for the cranial cruciate ligament.
A. Tibial plateau–leveling osteotomy
B. Tibial-closing wedge osteotomy
C. Tibial tuberosity advancement
VI. In young dogs, avulsion of the femoral origin or (more commonly) the tibial insertion of the CCL may occur; if the avulsed fragment is large enough, then it may be reduced and stabilized with internal fixation.
VII. If medial meniscal injury is present, the damaged portion (partial meniscectomy) or the entire meniscus (medial meniscectomy) is removed.

Monitoring of Animal

I. Institute medical management and monitoring for osteoarthritis in all animals.
II. A bandage may be placed after an arthrotomy to minimize postoperative swelling and edema.
III. Evaluate limb function and stifle stability 6 to 8 weeks postoperatively.
IV. Radiographically evaluate bony healing 6 to 8 weeks after osteotomy procedures.
V. Begin low-impact activity (e.g., leash walking) at weeks 2 to 4 and continue until lameness resolves (typically by weeks 6 to 8).
VI. The risk for contralateral CCL rupture in cases without a known traumatic event is high (Vasseur, 2003).
VII. Most procedures result in 90% of affected animals returning to good (occasional lameness) or excellent (no discernable lameness) function (Vasseur, 2003).
VIII. Deterioration of limb function after stifle stabilization may be the result of latent meniscal injury, which requires arthroscopic or open meniscectomy (partial or complete).

INFECTIOUS ARTHRITIS

Bacterial Arthritis

Definition and Causes

I. Bacterial joint infection results in arthritis.
II. Hematogenous spread of bacteria may occur from the respiratory, urinary, and digestive tracts; umbilicus; and endocardium, primarily in young or immunocompromised animals.
III. Exogenous sources are the most common and include trauma, surgical procedures, and intraarticular injections.
IV. Common organisms include staphylococci, streptococci, and coliforms.

Pathophysiology

I. Bacterial contamination of the synovium results in edema, hyperemia, and infiltration of neutrophils.
II. Inflammation of the synovium leads to capillary rupture and local areas of necrosis.
III. Lysosomal enzyme and enzyme by-products released by the synovial cells and neutrophils cause degradation of the cartilage matrix and collagen.

Clinical Signs

I. Joint effusion, periarticular swelling, and discomfort are found in one or more joints.
A. Hematogenous spread typically involves multiple joints.
B. Exogenous infections usually involve one joint.
II. Severe, weight-bearing or non–weight-bearing lameness occurs.

III. Pyrexia may be present.
   A. Systemic signs are often present in hematogenous cases.
   B. Systemic signs are uncommon in exogenous cases.

Diagnosis

I. Tentative diagnosis is based on clinical findings, particularly a history of recent joint surgery.
II. Definitive diagnosis is based on results of joint fluid analysis (see Table 80-2).
   A. Reduced viscosity
   B. Increased white blood cell (WBC) count
   C. Predominance of neutrophils
III. Joint fluid culture is commonly negative; however, inoculation of blood culture medium facilitates growth of the causative organism (Montgomery et al., 1989).

Differential Diagnosis

I. Trauma
   A. Ligamentous injury
   B. Intraarticular fracture
   C. Periarticular or physeal fracture
   D. Periarticular or intraarticular neoplasia
II. Other infectious arthritides
   A. Calicivirus infection of cats (Dawson et al., 1994)
   B. Mycoplasmosis
   C. Coronavirus
   D. Fungal infections: rare, usually associated with adjacent fungal osteomyelitis or immunocompromise

Treatment

I. Systemic antimicrobial therapy is initiated immediately after samples are obtained for fluid analysis and culture.
II. A broad-spectrum, bactericidal agent is started pending the results of culture, followed by long-term (6 to 8 weeks) oral administration.
   A. Cefazolin 20 to 25 mg/kg IV, IM TID to QID
   B. Cephalexin 11 to 33 mg/kg PO TID
   C. Enrofloxacin 5 to 20 mg/kg PO SID or 2.5 to 10 mg/kg PO BID (mature dogs)
   D. Tetracycline 15 to 20 mg/kg PO TID for 4 weeks or doxycycline 5 to 10 mg/kg PO BID for 4 weeks for *Borrelia* spp., rickettsiae, *Mycoplasma* spp., bacterial L-forms
III. Joint lavage is essential to decompress the joint and remove cellular and enzymatic agents that exacerbate cartilage damage.
   A. Fine-needle aspiration or ingress-egress drainage is rarely sufficient.
   B. Arthrotomy or arthroscopy, surgical debridement, and copious (5 L) lavage is recommended in the following cases (Bubenik and Smith, 2003):
      1. Postoperative infection
      2. Septic joints left untreated for >72 hours
      3. Septic joints that have not responded to antibiotics alone for 72 hours
      4. Penetrating wounds
IV. Severe infections may necessitate management of the joint as an open wound, with daily sterile bandage changes until the wound is fully granulated.

Monitoring of Animal

I. Parenteral (ideally) or oral antibiotic therapy, based on the results of culture and sensitivity, is continued for a minimum of 4 weeks or at least 2 weeks beyond resolution of clinical signs.
II. Residual lameness may be treated as outlined previously for Osteoarthritis.

Borreliosis (Lyme Disease)

See Chapter 113.

Ehrlichiosis

See Chapter 115.

Rocky Mountain Spotted Fever

See Chapter 115.

IMMUNE-MEDIATED ARTHRITIS

Nonerosive Arthritides

Definition and Causes

I. These inflammatory diseases are characterized by periarticular inflammation, without radiographic or histological evidence of joint destruction in their early stages.
II. The most common nonerosive immune-mediated arthropathies are idiopathic polyarthritis, systemic lupus erythematosus (SLE), polyarthritis of chronic disease, and drug-induced polyarthritis (Davidson, 2003).

Pathophysiology

I. Immune complex deposition in the synovial membrane results in synovitis.
II. Mononuclear cell infiltration occurs in the synovium.
III. Neutrophils migrate from synovial capillaries into the synovium.
IV. The inflammatory process results in weakening of the intraarticular and periarticular ligamentous structures and leads to joint instability.
V. In these cases, osteoarthritis may arise from chronic joint instability rather than the initial inflammatory process.

Clinical Signs

I. Lameness affects one or more limbs.
   A. The distal limb joints (carpus, tarsus, interphalangeal joints) are most often affected.
   B. Monoarticular disease is most commonly seen in the elbow.
II. Pain, joint effusion, periarticular fibrosis, periarticular soft tissue swelling, and palpable joint hyperthermia may occur.
III. Clinical signs may be intermittent or persistent and shift from limb to limb.
IV. SLE is often accompanied by abnormalities in other organs (see Chapters 76, 91, and 104).

Diagnosis

I. Radiographic findings are limited to joint effusion and periarticular fibrosis in the early stages.
II. Radiographic findings in late stages are similar to those of erosive polyarthritis (periarticular osteophytosis, joint space collapse).
III. Synovial fluid analysis is consistent with suppurative inflammation (see Table 80-2).
IV. Lupus erythematosus cell assays may be positive.
V. Serological testing for antinuclear antibody (ANA) may be positive.
VI. Serological testing for rheumatoid factor and infectious agents is negative.

Differential Diagnosis

I. Erosive arthritides
II. Infectious arthritides
III. Osteoarthritis

Treatment and Monitoring

I. Prednisone (1 to 2 mg/kg PO BID for 10 to 14 days) is used as the initial treatment.
II. In mild cases chronic administration of NSAIDs may control clinical signs (see Table 80-2).
III. If synovial fluid WBC counts drop to <4000 cells/μL, then the prednisone dose is slowly tapered over several weeks to 1 mg/kg PO QOD.
IV. If remission continues on reduced doses for 1 to 3 months, then elimination of prednisone can be considered.
V. In refractory canine cases, a cytotoxic drug may be added to the prednisone.
   A. Cyclophosphamide 1.5 to 2.5 mg/kg PO SID for 4 consecutive days each week (discontinued 1 month after remission, after 4 months of therapy, or if hemorrhagic cystitis develops)
   B. Azathioprine 2 mg/kg PO SID for 14 to 21 days, then 1 to 2 mg/kg PO QOD for 1 month beyond remission
   C. Methotrexate 2.5 mg/m^2 PO SID
VI. Arthrodesis may be considered for irreversibly damaged joints.

Erosive Arthritides

Definition and Causes

I. These arthritides are characterized by periarticular inflammation, with destruction of articular cartilage and bone.
II. They include rheumatoid arthritis (RA), erosive polyarthritis of greyhounds (EPG), and feline chronic progressive polyarthritis.

Pathophysiology

I. Specific causes have not been identified.
II. In RA, host immunoglobulin (Ig) G becomes antigenic and IgM (rheumatoid factor) is formed in response.
III. Immune complex deposition in the synovium causes synovitis.
IV. Destruction of the articular cartilage and bone results from the ensuing inflammatory process.

Clinical Signs

I. RA usually affects adult, small-breed dogs.
II. EPG affects greyhounds 3 to 30 months of age.
III. Feline chronic progressive polyarthritis affects cats 1 to 5 years of age.
IV. Lameness may occur in one or more limbs.
V. The most commonly affected joints are the distal limb joints, such as the carpus, tarsus, and interphalangeal joints.
VI. Pain, joint effusion, periarticular fibrosis, periarticular soft tissue swelling, and palpable joint hyperthermia may be noted.
VII. Clinical signs may be intermittent or persistent and shift from limb to limb.

Diagnosis

I. Radiographic findings include joint space collapse, periarticular fibrosis, periarticular soft tissue swelling, subchondral bone cysts, and periarticular osteophytosis.
II. In chronic cases, joint subluxation or luxation may be present.
III. Synovial fluid analysis is consistent with suppurative inflammation (see Table 80-2).
IV. Rheumatoid factor assays are positive in 25% to 75% of cases (Davidson, 2003).
V. ANA analysis must be negative for a diagnosis of RA.
VI. Animals with a positive ANA analysis probably have SLE.

Differential Diagnosis

I. Nonerosive arthritides
II. Infectious arthritides
III. Osteoarthritis

Treatment

I. Prednisone (1 to 2 mg/kg PO BID for 10 to 14 days) is used as the initial treatment.
II. In mild cases chronic administration of NSAIDs may control clinical signs (see Table 80-2).
III. In refractory cases a cytotoxic drug may be added to the prednisone (see Nonerosive Arthritis).
IV. In dogs, weekly injections of sodium aurothioglucose (1 mg/kg IM) have been successful for RA.
V. Arthrodesis may be considered in irreversibly damaged joints.

Monitoring of Animal

I. Complete resolution is rare, but remission may be achieved with 3 to 6 months of therapy.
II. CBC and platelet counts are monitored every 1 to 3 weeks in animals on cytotoxic therapy, depending on the dosage.
III. If synovial fluid WBC counts drop to <4000 cells/μL and clinical remission occurs, then dosages are slowly tapered over several weeks.
IV. Reexamination is recommended at 1- to 6-month intervals to assess for recurrence.
V. Treatment of EPG has been unrewarding, and the prognosis is poor.

VI. Cats are monitored at yearly intervals for infection with feline leukemia virus if treated with cytotoxic agents.

NEOPLASIA

Synovial Sarcoma

Definition and Causes

I. Synovial sarcoma is a malignant neoplasm that arises from primitive, undifferentiated, mesenchymal tissue adjacent to synovial membranes (Fox et al., 2002).
II. The etiology is unknown.
III. Presence and growth of the intraarticular tumor results in an inflammatory arthropathy and joint destruction.

Clinical Signs

I. Progressive lameness in a single limb is a classic sign.
II. Large-breed dogs are most commonly affected.
III. Joint effusion, periarticular soft tissue swelling, edema of the limb, and discomfort with manipulation of the limb are common.

Diagnosis

I. Radiographic findings may include intraarticular soft tissue opacity, subchondral and epiphyseal bone lysis, periarticular osteophytosis, soft tissue calcification, and an irregular periosteal reaction.
II. Definitive diagnosis requires arthroscopic or open biopsy, as well as histological examination.
III. Reliability of differentiating synovial sarcoma from other soft tissue sarcomas or round-cell neoplasia via histopathologic examination or immunohistochemistry is questionable (Fox et al., 2002).

Treatment

I. Limb amputation: local excision not possible
II. Chemotherapy: efficacy not well established

Monitoring of Animal

I. Monitor for local recurrence and distant metastasis.
II. The metastatic rate for synovial sarcoma is 40% to 50% (Vail et al., 1994).

TRAUMATIC DISORDERS

Caudal Cruciate Ligament Rupture

Definition and Causes

I. Trauma is the typical cause of this rare condition.
II. Force applied to the tibia in the caudal direction may cause isolated rupture because it prevents caudal subluxation of the tibia.
III. More commonly, this structure is damaged in association with collateral ligament rupture or stifle luxation.

Clinical Signs

I. Acute-onset lameness is seen after known or possible trauma (Johnson and Olmstead, 1987).
II. Stifle pain and joint effusion may be seen.
III. Caudal drawer sign, tibial sag, and an avulsion fragment (radiographically) may be evident in some cases.
   A. Caudal drawer sign must be carefully differentiated from a cranial drawer sign.
   B. Caudal drawer sign is present if the tibia moves from a neutral position to a position of caudal subluxation.

Diagnosis

I. Caudal drawer sign
II. Confirmed surgically by arthrotomy or arthroscopy

Differential Diagnosis

I. Cranial cruciate ligament rupture
II. Stifle collateral ligament rupture
III. Stifle luxation
IV. Meniscal injury
V. Patellar luxation

Treatment

I. Clinical signs may resolve with conservative treatment with cage rest and NSAIDs for 8 weeks.
II. In large dogs or cases of persistent lameness, extracapsular stabilization is recommended.
   A. Extracapsular suture stabilization
   B. Popliteal tenodesis

Monitoring of Animal

I. After surgery, restrict exercise for 6 to 8 weeks, then gradually return the animal to normal activity during weeks 8 to 16.
II. Prognosis for isolated rupture of the caudal cruciate ligament is good.

Stifle Luxation (Deranged Stifle)

Definition and Causes

I. Stifle subluxation is a complete or partial rupture of the stifle collateral ligaments or a combination of rupture of the stifle collateral ligaments and the cruciate ligaments (stifle luxation).
II. Severe trauma to the stifle joint is the cause.

Pathophysiology

I. Ligament injuries (sprains) can be mild (first degree), more severe with stretching and rupture of ligament fibers (second degree), or result in tearing or avulsion of the ligament (third degree).
II. Only third-degree and some second-degree injuries require surgical therapy.
III. Isolated rupture of the collateral ligaments is rare in small animals (Vasseur, 2003).
IV. Most injuries involve rupture of the medial and/or lateral collateral ligaments and the cranial and/or caudal cruciate ligaments.
   A. Most commonly affected ligaments are the medial collateral cranial cruciate ligament and the caudal cruciate ligament.

B. Lateral collateral ligament becomes lax with stifle joint flexion, which may spare it from damage.

Clinical Signs

I. Stifle effusion, pain, and angular deviation may be evident.
II. Damage to the medial collateral ligament results in a valgus instability.
III. Damage to the lateral collateral ligament results in a varus instability.
IV. Damage to the cruciate ligaments results in cranial and/or caudal drawer.

Diagnosis

I. Meticulous physical examination under anesthesia allows determination of which ligaments are involved.
II. Results of palpation may be confusing, and joint exploration is frequently required to confirm individual ligament involvement.

Differential Diagnosis

I. Cranial cruciate ligament rupture
II. Bacterial arthritis
III. Intraarticular or periarticular fracture

Treatment

I. Reconstruction of each of the involved ligaments
   A. The collateral ligaments can be primarily repaired, or a prosthetic ligament can be created from bone anchors or screws and heavy-gauge monofilament suture.
   B. The stifle can be stabilized as for cranial and/or caudal cruciate ligament rupture.
II. Transarticular stabilization
   A. Transarticular pin placement for small dogs or cats
   B. Rigid transarticular fixator application
   C. Hinged transarticular fixator placement
   D. External coaptation
   E. Arthrodesis

Monitoring of Animal

I. Institute medical management and monitoring for DJD.
II. A bandage may be placed to minimize postoperative swelling and edema after arthrotomy.
III. Evaluate limb function and stifle stability 6 to 8 weeks postoperatively.
IV. Low-impact activity is recommended, beginning at week 2 to 4 and continuing until lameness has resolved—typically by week 6 to 8.
   A. In animals treated with external skeletal fixation, remove the fixation device 4 to 6 weeks postoperatively.
   B. Institute low-impact activity after fixator removal.

Traumatic Joint Luxation

Definition and Causes

I. Traumatic joint luxation is the complete separation of two articulating joint surfaces.
II. Severe trauma is the typical cause of joint luxation.
III. Traumatic episode results in the disruption of the normal stabilizers of the joint, including the joint capsule, collateral ligaments, and other associated ligaments.
IV. Commonly affected joints include the shoulder, elbow, carpus, hip, stifle, tarsus, metacarpophalangeal and tarsophalangeal joints, and interphalangeal joints.

Clinical Signs and Diagnosis

I. Lameness of the affected limb can vary from mild to non–weight-bearing.
II. Clinical signs and history of trauma allow a presumptive diagnosis.
III. Physical examination findings are confirmatory in many cases.
   A. Discomfort with manipulation
   B. Excessive mobility
   C. Soft tissue swelling
   D. Abnormal limb length, with affected limb shorter
IV. Radiography confirms the luxation.

Differential Diagnosis

I. Intraarticular or periarticular fracture
II. Bacterial arthritis
III. Neoplasia

Treatment

I. Closed reduction and coaptation
II. Open reduction
III. Carpus
   A. Isolated collateral ligament injuries may be treated with primary repair or placement of a prosthetic ligament.
   B. Most injuries require partial carpal arthrodesis or pancarpal arthrodesis.
IV. Hip
   A. Closed reduction
      1. It is indicated for acute luxation (<3 to 5 days) in animals with normal hip conformation and no intraarticular fractures.
      2. Maintain reduction with an Ehmer sling for 3 to 4 weeks.
   B. Open reduction
      1. It is indicated when the femoral head does not seat well in acetabulum, the hip has reluxated after closed reduction, the hip has been chronically luxated, and intraarticular fractures or hip dysplasia are present.
      2. Open reduction techniques include toggle pin, extracapsular prosthesis, and iliofemoral suture.
   C. Salvage techniques
      1. FHO
      2. THA
V. Tarsus
   A. Isolated collateral ligament injuries may be treated with primary repair or placement of a prosthetic ligament.
   B. Many injuries require partial or total tarsal arthrodesis.
VI. Metacarpal, metatorsal, tarsophalangeal, and interphalangeal joints
   A. Closed reduction and external coaptation
   B. Primary ligamentous repair

C. Arthrodesis
D. Digit amputation

VII. Shoulder and elbow (see Congenital and Degenerative Disorders)

Monitoring of Animal

I. Instruct the owner to monitor bandages and slings SID-BID.
II. Restrict exercise for 4 to 8 weeks after bandage or sling removal to allow remodeling of ligamentous structures.
III. In surgical cases, obtain radiographs 6 to 8 weeks post-operatively to assess reduction, progression of osteoarthritis, and implant stability.

Physeal Injury

See Chapter 81.

CHAPTER 81

Diseases of Bone

Nicholas J. Trout

DEVELOPMENTAL DISORDERS

Panosteitis

Definition and Causes

I. Panosteitis is an acquired self-limiting disease that affects the long bones of rapidly growing, large-breed dogs.
II. The cause is unknown.
III. German shepherd dogs are one of several breeds that are predisposed (La Fond et al., 2002).

Pathophysiology

I. Increased osteoblast and fibroblast activity leads to degeneration and necrosis of bone marrow fatty tissue in the diaphyseal and metaphyseal regions, with replacement by fibrous connective tissue.
II. It is frequently associated with the nutrient foramen of long bones.
III. Medullary hypertension and vascular congestion may cause secondary endosteal and periosteal new bone formation (Demko and McLaughlin, 2005).
IV. New bone resorption returns the marrow to normal.

Clinical Signs

I. Typically a large- or giant-breed dog develops an acute lameness in a single limb or has a shifting, intermittent lameness.
II. Affected dogs are more commonly males, 5 to 18 months of age (range, 2 months to 5 years) (Montgomery, 2003).
III. Pain is elicited on deep palpation of the diaphysis and metaphysis of affected long bones.
IV. Most commonly affected bones are the ulna, radius, humerus, femur, and tibia, in that order.
V. Severely affected dogs may have pyrexia, anorexia, and lethargy.

Diagnosis

I. History, signalment, clinical signs, and physical examination findings suggest the condition.
II. Radiography may reveal several findings.
   A. "Cotton ball" appearance (radiodense blurring) of the trabecular pattern in the medullary canals and an endosteal reaction are seen.
   B. Smooth periosteal reaction gives the appearance of cortical thickening.
   C. Radiographs are frequently unrewarding because clinical signs precede these changes by 7 to 10 days.
III. Nuclear scintigraphy is a better diagnostic tool (Schwarz et al., 2004).

Differential Diagnosis

I. Elbow dysplasia
II. Hip dysplasia
III. Hypertrophic osteodystrophy
IV. Osteochondroses
V. Trauma

Treatment

I. Therapy consists of supportive care and analgesia.
II. Nonsteroidal antiinflammatory drugs (NSAIDs) are used during the acute phase of the disease, together with exercise restriction and weight reduction (if merited).
   A. Carprofen 2.2 mg/kg PO BID
   B. Meloxicam 0.1 mg/kg PO SID
   C. Deracoxib 1 to 2 mg/kg PO SID

Monitoring of Animal

I. Warn the owners that the lameness commonly shifts to another limb, but usually resolves permanently once the animal reaches skeletal maturity.
II. Secondary complications are rare.

Hypertrophic Osteodystrophy

Definition and Causes

I. Hypertrophic osteodystrophy (metaphyseal osteopathy) is a disease of the long bones of young, growing, large- and giant-breed dogs that causes metaphyseal trabecular disruption.
II. The cause is unknown.
III. The condition is not caused by a deficiency of vitamin C or excessive vitamin D, dietary mineral, or calories.
IV. Links to vaccination for canine distemper virus remain unproven (Harrus et al., 2002; Crumlish et al., 2006).

Pathophysiology

I. Disturbance of the metaphyseal blood supply leads to delayed ossification of the physeal hypertrophic zone.
II. Inflammation and necrosis may occur secondary to metaphyseal trabecular microfractures.

Clinical Signs

I. Metaphyseal limb swelling often involves all four limbs, but is more noticeable in the thoracic limbs.
II. Male dogs are affected more than female dogs and are usually 2 to 8 months of age.
III. In the acute form, transient, episodic, low-grade lameness occurs, with pyrexia and hot, swollen, painful limbs.
IV. Peracute cases may have lethargy, dehydration, and severe pain on palpation of the affected area.
V. Severe physeal damage rarely leads to angular limb deformities.

Diagnosis

I. History, signalment, clinical signs, and physical examination findings are often suggestive of the condition.
II. Radiographs reveal a pathognomonic pseudophyseal line adjacent to the physis on the metaphyseal side of the bone.
III. Laboratory findings are invariably unremarkable.
IV. Rare hypocalcemia is of unknown significance.

Differential Diagnosis

I. Panosteitis
II. Septic arthritis
III. Rickets
IV. Osteomyelitis
V. Trauma

Treatment

I. Therapy consists of supportive care and analgesia.
II. Correct an inappropriate diet and withdraw excessive supplements of vitamin C, vitamin D, or minerals.
III. NSAIDs are used during the acute phase of the disease.
   A. Carprofen 2.2 mg/kg PO BID
   B. Meloxicam 0.1 mg/kg PO SID
   C. Deracoxib 1 to 2 mg/kg PO SID
IV. Rest, confinement, use of soft bedding, and turning of the animal every 4 to 6 hours is done as necessary.
V. Severe cases may require more intensive management with prednisolone at 0.25 to 0.5 mg/kg PO SID (after ruling out the possibility of a bacterial infection), fluid therapy, and nutritional care.
VI. If lameness persists because of angular limb deformities, then surgical correction may be necessary.

Monitoring of Animal

I. Relapses can occur in growing dogs.
II. Most mild and moderate cases recover completely.
III. Owners may elect euthanasia of severely affected animals or ones that experience multiple relapses.

Craniomandibular Osteopathy

Definition and Cause

I. Craniomandibular osteopathy is a proliferative bone disease that primarily affects the mandible, zygomatic arches, and tympanic bullae of growing dogs.
II. The cause is unknown.

Pathophysiology

I. Existing lamellar bone undergoes resorption and replacement by new, woven bone.
II. Woven bone may be replaced by mature bone, but permanent distortion of bony architecture is common.

Clinical Signs

I. It is commonly seen in terrier breeds, 3 to 8 months of age, with males and females equally affected.
II. Difficult mastication, with secondary weight loss and dehydration, may occur.
III. Pain is detected when manually opening the animal's mouth and on deep palpation of affected flat bones.
IV. Decreased range of motion is present in the temporomandibular joint.
V. Intermittent fever may be observed.
VI. The disease may be seen in other breeds, such as the Pyrenean mountain dog, Shetland sheepdog, Labrador retriever, Great Dane, English bulldog, Doberman pinscher, and boxer.
VII. A similar condition, calvarial hyperostosis syndrome, is reported in the bullmastiff (Pastor et al., 2000; McConnell et al., 2006).

Diagnosis

I. History, signalment, clinical signs, and physical examination findings allow a tentative diagnosis.
II. Radiographs reveal bilaterally symmetrical, periosteal proliferation along the mandible and tympanic bullae.
III. Bone biopsy is rarely necessary; however, histopathologic examination demonstrates osteoclastic resorption of lamellar bone, replacement of bone marrow by vascular fibrous tissue, and formation of coarse trabecular bone.

Differential Diagnosis

I. Myositis
II. Temporomandibular joint malalignment or malformation
III. Osteomyelitis
IV. Neoplasia

Treatment

I. Treatment consists of supportive care and analgesics until the animal reaches skeletal maturity.
II. NSAIDs may be useful.
   A. Carprofen 2.2 mg/kg PO BID
   B. Meloxicam 0.1 mg/kg PO SID
   C. Deracoxib 1 to 2 mg/kg PO SID
III. Soft or liquefied food helps to reduce painful chewing.
IV. Gastrostomy or esophagostomy tubes may be necessary if the animal is unable to eat.
V. Rostral mandibulectomy allows affected dogs to lap gruel.
VI. Euthanasia may be indicated in severely affected dogs.

Monitoring of Animal

I. Schedule periodic physical and radiographic examinations of the animal (every 6 to 8 weeks) until skeletal maturity.
II. Warn owners of the possibility of relapses until skeletal maturity.

III. Prognosis is guarded when excessive bony proliferation of the bullae and mandible causes pain and poor condition.

Multiple Cartilaginous Exostoses

Definition and Causes

I. Multiple cartilaginous exostoses (osteochondromatosis) are proliferations of cartilage-capped exostoses arising from the surface of bones formed by endochondral ossification (Jacobson and Kirberger, 1996).
II. The exact cause is unknown, although a familial tendency has been reported in dogs (Chester, 1971).
III. Exostoses have been associated with feline leukemia virus infection in cats (Poole, 1993).

Pathophysiology

I. Chondrocytes displaced from the periphery of a long bone physis create an immature, independent growth plate perpendicular to the long axis of the bone.
II. In dogs, exostoses enlarge until skeletal maturity, when they stop growing.
III. In cats, exostoses can grow after skeletal maturity.

Clinical Signs

I. Exostoses only cause clinical signs if they have a compressive effect on adjacent structures.
II. Signs may be mild (e.g., lameness if they encroach on a tendon or ligament) or severe (e.g., paralysis from spinal cord compression).
III. Limb exostoses are often bilateral (Poole, 1993).
IV. Exostoses can be asymptomatic, incidental findings.
V. Affected dogs are typically young (6 to 18 months), whereas cats are older (2 to 4 years).

Diagnosis

I. Palpation of a firmly attached swelling associated with a rib, vertebrae, or long bone is characteristic.
II. Survey radiographs of the entire skeleton can be useful to locate smaller lesions before they become clinically significant.
III. Radiographs reveal the following:
   A. Outgrowths of bone contiguous with the periosteal surface from which they arise
   B. Varying amounts of hyaline cartilage within the exostoses producing a mottled appearance
   C. Smooth or irregular, sessile or pedunculated outgrowths
IV. Histological evaluation of a biopsy is characterized by a hyaline cartilage cap covering a base of cancellous bone.

Differential Diagnosis

I. Neoplasia
II. Trauma
III. Hypervitaminosis A (cats)
IV. Calcinosis circumscripta

Treatment

I. Although the heritable nature of the disease has not been proven, sterilization of affected animals is recommended.
II. Surgical removal is indicated if the exostosis produces secondary clinical signs from compression.
III. In cats, surgical excision may only be palliative because malignant transformation can occur.

Monitoring of Animal

I. In asymptomatic cases, perform a physical examination and radiographic evaluation every 6 months to define whether the lesion is static or enlarging.
II. Prognosis in dogs depends on the age of the animal at the time of diagnosis (more guarded if young animals with multiple lesions), as well as the number, location, and resectability of the lesions.
III. Prognosis in cats is poor because of the potential for malignant transformation.

Radial and Ulnar Growth Deformities

Definition and Causes

I. Radial and ulnar growth deformities occur as developmental abnormalities from total or partial fusion of the distal ulna, as well as from distal radial or proximal radial physes.
II. They can lead to asynchronous growth of the radius and ulna, with abnormal conformation of the forelimb.
III. Physeal abnormalities can arise from the following:
   A. Direct or indirect trauma
   B. Hypertrophic osteodystrophy: can bridge the growth plate
   C. Retained ulnar cartilaginous core
      1. Retarded endochondral ossification at the distal ulnar physis leads to slowed growth similar to a traumatic physeal closure.
      2. Retained ulnar cartilaginous cores do not always produce a disturbance in longitudinal growth.
   D. Chondrodystrophic breeds: relative retardation of the growth of the ulna compared with the radius
IV. Antebrachial angular and length deformities can affect the antebrachiocarpal joint and cubital joint, leading to subluxation and degenerative joint disease.

Pathophysiology

I. Proximal ulnar physis contributes only to olecranon length (15% of total length) and closes at 5 to 8 months of age; premature closure causes no significant abnormalities (Carrig and Wortman, 1981).
II. Distal ulnar physis contributes longitudinal growth distal to the elbow (approximately 85% of total length) and closes at 6 to 8 months.
III. Distal ulna physis grows more actively than the distal radius (>15%) and contributes as much growth as the proximal and distal radial physes combined.
IV. Proximal radial physis contributes 30% to 40% of total length and closes at 5 to 8 months of age (Carrig and Wortman, 1981).
V. Distal radial physis contributes about 60% to 70% of total length and closes at 6 to 9 months of age (Carrig and Wortman, 1981).

VI. As a paired set of bones, the radius and ulna must undergo synchronous, unrestricted growth to maintain proper alignment of the antebrachium and shared articular surfaces.

Clinical Signs

I. Signs include varying degrees of forelimb lameness, abnormal limb length, angulation (valgus, varus), and internal or external rotation along the long axis of the radius and ulna.
II. Joint pain, crepitus, and swelling with restricted range of motion are seen.
III. Signs are typically unilateral when initiated by trauma and are bilateral in young, large- or giant-breed dogs secondary to retained ulnar cartilaginous cores.

Diagnosis

I. Radiography is required to confirm the diagnosis and identify the exact lesions.
II. See Table 81-1 for diagnostic features.

Differential Diagnosis

I. Poor conformation
II. Carpal and elbow ligament and/or tendon laxity

Treatment and Monitoring

I. See Table 81-1 for therapeutic options.
II. Physical examination to assess limb conformation and range of movement in the elbow and antebrachiocarpal joints, together with radiographic evaluation of the bones and joints, is undertaken every 1 to 2 weeks in immature animals.
III. After corrective surgery, evaluate the animal clinically and radiographically every 2 to 4 weeks, depending on the underlying problem, type of surgery, and age of the animal.

INFECTIOUS DISORDERS

Osteomyelitis

Definition and Causes

I. Osteomyelitis is inflammation of bone marrow, cortex, and possibly periosteum (Johnson and Hulse, 2002; Herron, 1993)
II. Most commonly, bacteria cause osteomyelitis; however, other causes include fungi such as *Coccidioides immitis* (southwestern states) and *Blastomyces dermatitidis* (southeastern and central states), parasites, viruses, foreign bodies, and corrosion of metal implants.
III. Gram-positive organisms are more common in canine osteomyelitis (Dernell, 1999).
  A. *Staphylococcus* spp.
  B. *Streptococcus* spp.
  C. *Escherichia coli*
  D. *Proteus* spp.
IV. In the majority of cases a single organism is identified.
V. Anaerobic bacteria are uncommon isolates, but failure of standard treatments may reflect their presence.

Pathophysiology

I. Bacterial exposure may arise from exogenous contamination at the time of the original injury (e.g., puncture wound, open fracture, shearing injury), at the time of fracture repair, or from hematogenous seeding.
  A. Hematogenous infection is uncommon in small animals.
  B. Hematogenous infection can localize in the metaphysis of immature animals, in the epiphysis (sinusoidal venous sludging), or in the subchondral bone of adult animals.
II. Fungal infections usually occur secondary to pulmonary inoculation.
III. Factors affecting osteomyelitis secondary to exogenous sources include the following:
  A. Extent of soft tissue damage and alteration of blood supply
  B. Inoculation of bacterial flora
  C. Stability of fracture after repair
  D. Formation of a biofilm (glycocalyx): promotes bacterial attachment to bone or foreign bodies, and protects the bacteria from phagocytes, antibodies, and antibiotics
  E. Systemic or local factors that influence immune surveillance, metabolism, or local vascularity (Fossum and Hulse, 1992)

Clinical Signs

I. Acute osteomyelitis
  A. Signs are noted within 3 weeks (most often within 5 days) of injury, concurrent illness, or fracture repair.
  B. Soft tissue heat, swelling, pain, and lameness are common.
  C. Pyrexia, depression, and anorexia may be noted.
II. Chronic osteomyelitis
  A. Onset of signs months to years after an injury, previous illness or fracture repair
  B. Draining sinus tracts
  C. Pain and lameness
  D. Pyrexia, depression, anorexia uncommon

Diagnosis

I. History, clinical signs, radiography, and laboratory findings are suggestive.
II. Radiographic changes are generally not present until 2 weeks postinfection.
III. Radiography may reveal soft tissue swelling, irregular periosteal reactions, increased medullary density, and bony sequestration walled off by vascular new bone (involucrum).
IV. Fistulography may reveal a draining tract that leads to a bony lesion.
V. Leucocytosis with a neutrophilic left shift is expected with acute osteomyelitis but is often absent in chronic osteomyelitis.
VI. Deep, fine-needle aspirates or a biopsy is obtained for aerobic and anaerobic bacterial culturing.
VII. Do not take cultures from draining tracts.

TABLE 81-1

Frequency, Effects, and Treatment of Radius and Ulna Growth Deformities

	DISTAL ULNAR PHYSEAL CLOSURE	DISTAL RADIAL PHYSEAL CLOSURE	PROXIMAL RADIAL PHYSEAL CLOSURE
Frequency			
	Common	Uncommon	Very uncommon
Effects			
	Bowstring effect on radius causes cranial bowing, carpal valgus and external rotation of carpus, as well as humeroulna subluxation and carpal subluxation Degenerative joint disease	Entire physis closed (symmetrical): usually no growth deformity but can lead to bowstring effect on ulna with carpal varus, internal rotation of carpus, radial head subluxation (if closure occurs early) Closure of lateral physis (asymmetrical): produces a growth deformity from restriction of lateral growth and continued medial growth; distal subluxation of the radial head (associated with fragmented medial coronoid process*), proximal subluxation of the ulna, carpal valgus, dorsal subluxation of the radiocarpal joint Degenerative joint disease	Short radius, limb deformity unlikely, humeroradial subluxation, lateral displacement of the radial head, oblique angulation of radial joint surface Degenerative joint disease
Treatment of Immature Animals (< 6 to 8 months)			
	1. Normal elbow joint a. Partial distal ulna ostectomy with free fat graft in the bone defect b. Postoperative bandage/splint support 2. Humeroulnar malarticulation a. Proximal ulna osteotomy to allow dynamic improvement of elbow incongruency through triceps muscle pull b. Bone realignment with single intramedullary pin c. Postoperative bandage/splint support	1. Complete closure a. Midshaft radial osteotomy and distraction with external fixator† b. Partial, distal ulnar ostectomy to correct humeroradial malarticulation c. Multiple midshaft radial osteotomies, distractions, and bone plating to maintain limb length 2. Incomplete closure a. Resection of closed physis with interposition of free fat graft b. Radial osteotomy and distraction with external fixator† c. Dome osteotomy of distal radius and external coaptation‡	1. Transverse radial osteotomy and distraction with external fixator 2. Multiple radial osteotomies and bone plate fixation 3. Partial distal ulna ostectomy and fat interposition 4. Proximal ulna ostectomy with intramedullary pinning for mild radial shortening

Vet Surg 29:207, 2000.

VIII. When hematogenous osteomyelitis is suspected, obtain serial blood cultures.
IX. See Chapter 111 for diagnosis of fungal infections.

Differential Diagnosis

I. Implant failure and unstable fracture
II. Neoplasia

Treatment

I. Acute osteomyelitis
  A. Prepare the owner for long-term antibiotic treatment (4 to 6 weeks) based on bacterial culture and sensitivity testing, and preferably using minimal inhibitory concentration values.
  B. If bacterial cultures are negative, select antibiotics that have superior penetration of bone.
  C. Common antibiotic options include the following:
    1. Cephalexin 30 mg/kg PO BID
    2. Cefazolin 20 mg/kg IV, IM, SC QID
    3. Amoxicillin/clavulanic acid 22 mg/kg PO TID
    4. Clindamycin 11 mg/kg IV, IM, PO BID to TID
    5. Enrofloxacin 15 mg/kg PO BID (dogs)
    6. Metronidazole 15 mg/kg IV, PO BID
    7. Gentamicin 6 mg/kg IV, IM, SC SID
  D. See Chapter 111 for treatment of specific fungal diseases.
  E. Surgical procedures may be indicated in certain situations.
    1. Debridement, lavage, and drainage
    2. Delayed wound closure
    3. Ensuring fracture stability and removal of loose implants
II. Chronic osteomyelitis
  A. Antibiotic options are similar to those for acute osteomyelitis.
  B. Surgical removal of necrotic debris and dead bone may be warranted.
    1. Sequestrectomy followed by curettage and packing, with an autogenous cancellous bone graft to stimulate healing
    2. Removal of original implants
    3. Stabilizing fractures if necessary
  C. Antibiotic-impregnated polymethylmethacrylate beads or other biodegradable polymers can be used to deliver local, high levels of antibiotics, especially aminoglycosides (Dernell, 1999).
  D. Myocutaneous grafts can enhance local blood supply and soft tissue coverage of an extensive wound (Pavletic, 1999).
  E. In severe infections, limb amputation may be considered.

Monitoring of Animal

I. Physical examinations to evaluate wound healing and limb function are performed every 1 to 2 weeks, depending on the severity of the infection.
II. Serial radiographic evaluations are performed every 4 to 6 weeks until soft tissue and bone healing is complete.
III. Surgical debridement and appropriate antibiotic therapy can result in response rates in dogs approaching 90% (Budsberg and Kemp, 1990; Braden 1991).

IDIOPATHIC DISORDERS

Bone Cysts

Definition and Causes

I. Three main types of bone cysts exist.
  A. Subchondral: located in the epiphysis and adjacent to the joint
  B. Solitary: located in the metaphysis of juvenile long bones
  C. Aneurysmal: locally destructive, tumorlike lesions

II. Cysts can be single (monostotic) or multiple (polystotic).
III. Cause is usually unknown, although trauma can produce cysts that result from hematomas in subperiosteal locations.

Pathophysiology

I. Subchondral bone cysts are lined with a synovial membrane and filled with fibrous, myxoid, or serosanguineous fluid.
II. Solitary bone cysts are lined with fibrous connective tissue and filled with serosanguineous fluid.
III. Aneurysmal bone cysts are filled with vascular sinusoids (Montgomery, 2003).

Clinical Signs

I. Pain on palpation of affected bone
II. Lameness from the expansile nature of the cyst or pathologic fracture
III. Possibly asymptomatic

Diagnosis

I. Diagnosis is based on radiography, aspiration for bacteriological and cytological evaluation, and biopsy.
II. On plain radiographs, cysts may appear as expansile, radiolucent defects with thinning of cortical bone, and they may appear mottled from trabecular bone.
III. Aspirates are negative for bacteria and contain noninflammatory, acellular serosanguineous fluid or blood.
IV. Biopsy of the cyst wall reveals fibrous connective tissue, hemosiderin-laden macrophages, and mononuclear inflammatory cells (Halliwell, 1993).
V. Aneurysmal bone cysts have larger numbers of multinucleate cells and spicules of osteoid on histopathology.

Differential Diagnosis

I. Neoplasia
II. Trauma
III. Infection

Treatment

I. If clinically significant, solitary cysts can be drained, curetted, and packed with autogenous cancellous bone graft.
II. Weakened bone may require internal or external fixation until osteogenesis of the defect is complete.
III. Steroid injections into the cyst (Miura et al., 2003) and the use of bone cement to fill the defect (Sarierler et al., 2004) have been described.
IV. Aneurysmal bone cysts might be better treated by complete excision of the lesion whenever possible, because of the possibility of malignant transformation (Barnhart, 2002).

Monitoring of Animal

I. In asymptomatic animals, schedule periodic physical and radiographic evaluations.
II. Serial clinical and radiographic evaluations after cyst surgery are conducted every 6 weeks until bone healing is complete.
III. Most solitary cysts have a favorable prognosis.

Hypertrophic Osteopathy

Definitions and Causes

I. Hypertrophic osteopathy is a proliferative periosteal reaction in the distal extremities of long bones of dogs and, rarely, of cats (de Melo Ocarino et al., 2006).
II. Increased peripheral periosteal blood flow occurs secondary to a mass (neoplastic or infectious) in the thorax or abdomen and produces a periosteal reaction.

Pathophysiology

I. The mechanism by which a thoracic or abdominal mass increases peripheral blood flow is unknown, although an autonomic neurovascular reflex may be involved (Halliwell, 1993).
II. Increased peripheral blood flow may cause periosteal congestion and new bone formation in the distal extremities.

Clinical Signs

I. Acute or chronic, bilaterally symmetrical limb swelling, more noticeable in the forelimbs
II. Lethargy, with low-grade lameness
III. Incidental finding secondary to a thoracic or abdominal mass

Diagnosis

I. Physical examination findings of bilaterally symmetrical swelling of the extremities and lameness in mature animals are suggestive of the condition.
II. Complete blood count, serum biochemistry profile, and urinalysis are usually unremarkable or reveal changes related to the underlying thoracic or abdominal mass.
III. Radiographs of the extremities reveal palisades of periosteal new bone on the phalanges, metacarpi, metatarsi, tibia, fibula, radius, and ulna.
IV. Presence of a thoracic or abdominal mass is demonstrated on radiography or ultrasonography.

Differential Diagnosis

I. Primary or secondary bony neoplasia
II. Osteomyelitis: bacterial or fungal
III. Trauma
IV. Hypervitaminosis A (cats)

Treatment

I. Biopsy or definitive surgical resection of the underlying thoracic or abdominal mass is indicated.
II. NSAIDs are used to reduce limb swelling and discomfort.
   A. Carprofen 2.2 mg/kg PO BID
   B. Meloxicam 0.1 mg/kg PO SID
   C. Deracoxib 1 to 2 mg/kg PO SID
III. In cats, no NSAID is currently licensed for long-term use, although meloxicam 0.1 mg PO SID appears to be well tolerated (Robertson and Taylor, 2004).

Monitoring of Animal

I. Owners must be warned that clinical signs may persist for several weeks after treatment of the primary disease.

II. Bony lesions can take months to remodel, and complete resolution is unlikely.
III. Prognosis depends on whether the underlying thoracic or abdominal disease can be successfully treated.

NUTRITIONAL AND METABOLIC DISORDERS

Renal Secondary Hyperparathyroidism

Definition and Causes

I. Renal failure initiates secondary hyperparathyroidism through homeostatic mechanisms.
II. Renal insufficiency leads to hypocalcemia, hyperphosphatemia, parathyroid gland hyperplasia, elevated parathyroid hormone (PTH) levels, and bone resorption (Barber and Elliot, 1998).
III. Impaired renal function results in decreased conversion of inactive vitamin D_3 to its active form, which leads to decreased gastrointestinal absorption of calcium, decreased osteoclastic activity, and eventual osteomalacia (Cavanagh and Kosovsky, 1993).

Clinical Signs

I. Signs are predominantly associated with renal failure.
   A. Polydipsia, polyuria
   B. Dehydration, lethargy
   C. Vomiting, diarrhea
   D. Inappetence, weight loss
II. See Table 81-2 for other clinical features.

Diagnosis

I. Diagnosis is based on history, clinical signs, laboratory findings (see Table 81-2), and radiography.
II. Radiography reveals decreased bone density and loss of alveolar septa and lamina dura of the teeth, which gives them a floating appearance.

Differential Diagnosis

I. Nutritional secondary hyperparathyroidism
II. Hypovitaminosis D
III. Primary hyperparathyroidism (see Chapter 43)

Treatment and Monitoring

I. Address the underlying renal failure (see Chapter 48).
II. Parathyroidectomy is rarely considered for cases refractory to treatment of the renal disease.
III. Prognosis depends on the underlying cause of renal failure.

Nutritional Secondary Hyperparathyroidism

Definition and Causes

I. Diets low in calcium and high in phosphorus cause nutritional secondary hyperparathyroidism, which leads to elevation in PTH and metabolic disturbances.
II. Disease is rare but occurs in young animals fed an all-meat or all-grain diet (Kawaguchi et al., 1993; Tomsa et al., 1999).

Pathophysiology

I. It is most often associated with diets low in elemental calcium or having an inappropriately balanced calcium: phosphorus ratio (1:20 to 1:50).
II. Low-circulating vitamin D may originate from the diet or occur secondary to intestinal malabsorption.
III. Elevated PTH increases calcium resorption in the distal convoluted tubules of the kidneys and causes increased skeletal bone resorption.

Clinical Signs and Diagnosis

I. See Table 81-2 for clinical features.
II. Diagnosis is based on dietary history, clinical signs, laboratory findings (see Table 81-2), and radiography.
III. Generalized osteopenia is seen on survey skeletal radiographs and may be accompanied by pathologic or folding fractures.

TABLE 81-2

Clinical Features of Nutritional and Metabolic Diseases Causing Osteopenia

CLINICAL FEATURE	RENAL SECONDARY HYPERPARATHYROIDISM	NUTRITIONAL SECONDARY HYPERPARATHYROIDISM	HYPOVITAMINOSIS D
Lameness	Uncommon	Yes (especially young animals)	Yes
Bony deformities	Yes	Yes	Yes
Loose teeth ("rubber jaw")	Yes	No	No
Problems with mastication	Yes	No	No
Pathologic fractures	No	Yes (long bones or vertebrae)	Yes
Soft tissue calcification	Yes (lungs, kidney, heart, stomach)	No	No
Serum calcium	Decreased	Normal or decreased	Decreased
Serum phosphorus	Increased	Normal or increased	Increased
Parathormone level	Increased	Increased	Increased
Serum alkaline phosphatase	Normal or increased	Normal or increased	Normal or increased

Differential Diagnosis

I. Renal secondary hyperparathyroidism
II. Congenital bone defects
III. Disuse atrophy secondary to surgical implants, coaptation devices, or spinal paralysis
IV. Endocrine disorders: hyperthyroidism, diabetes mellitus, hyperadrenocorticism
V. Paraneoplastic hypercalcemia (see Chapter 73)

Treatment

I. Feed an appropriate diet and supplement calcium to achieve a 2:1 calcium:phosphorus ratio during the healing phase.
II. Restrict exercise to prevent further skeletal damage.
III. External coaptation may be necessary to prevent pathologic fractures.

Monitoring of Animal

I. Evaluate serum calcium, phosphorus, alkaline phosphatase, PTH, and radiographs of affected sites every 6 to 12 weeks.
II. In the absence of severe bony abnormalities, the prognosis is good.
III. Fractures may heal as a delayed union, taking >3 months.
IV. Spinal fractures may result in permanent paresis or paralysis despite healing.

Hypovitaminosis D

Definition and Causes

I. Hypovitaminosis D occurs secondary to inadequate ingestion and absorption of vitamin D in the diet or lack of sunlight, because ultraviolet radiation is necessary for the formation of active vitamin D_3.
II. Decreased vitamin D leads to decreased calcium absorption from the intestines, a compensatory increase in PTH, and calcium resorption from the skeleton.
III. Young animals develop abnormal endochondral ossification (rickets); mature animals develop osteomalacia.

Clinical Signs and Diagnosis

I. Diagnosis is based on history (diet and lifestyle), clinical signs, laboratory findings (see Table 81-2), and radiography.
II. Radiographs reveal a wider physis, metaphyseal flaring, and osteopenia in the long bones of young animals, and more generalized bone resorption in mature animals.

Differential Diagnosis

I. Nutritional secondary hyperparathyroidism
II. Renal secondary hyperparathyroidism
III. Hypertrophic osteodystrophy

Treatment

I. Provide a balanced diet with correct formulation of calcium, phosphorus, and vitamin D.
II. Surgical correction of angular limb deformities may be necessary in mature animals.

Monitoring of Animal

I. Evaluate serum calcium, phosphorus, alkaline phosphatase, PTH, and radiographs of affected sites every 6 to 12 weeks.
II. In the absence of severe bony abnormalities, the prognosis is good.
III. Fractures may heal as a delayed union, taking >3 months.

Hypervitaminosis A

Definition and Causes

I. Hypervitaminosis A is a metabolic disease caused by prolonged excessive intake of vitamin A through supplements or diet (e.g., raw liver, milk).
II. Hypervitaminosis A causes metaphyseal flaring, retards longitudinal growth of bone, and depresses periosteal osteoblastic activity (Herron, 1993).
III. Osteophytes and exostoses occur on the occipital bone and cervical and thoracic vertebrae, and they have been associated with sternebrae, ribs, and periarticular regions of lone bones.

Clinical Signs

I. Depression and reluctance to groom
II. Neck pain, ventriflexion
III. Lameness or paresis of one or both thoracic limbs

Diagnosis

I. Diagnosis is based on dietary history, clinical signs, laboratory findings, and radiography.
II. Serum vitamin A is usually elevated (normal range, 50 to 200 μg/dL) (Polizopoulou, 2005).
III. Radiographs reveal exostoses, cervical scoliosis, and ankylosis.

Differential Diagnosis

I. Mucopolysaccharidosis
II. Cervical disk disease
III. Osteochondromatosis

Treatment

I. Provide an appropriate, balanced diet from an elevated position to reduce cervical motion.
II. Meloxicam 0.2 mg/kg SC, PO once or 0.1 mg/kg PO SID for 3 to 4 days may provide temporary analgesia (Mathews, 2000).

Monitoring of Animal

I. Bony changes cease after the diet is corrected.
II. Some remodeling may occur over the long term, but epiphyseal damage and ankylosis are irreversible.
III. Periodic physical and radiographic evaluations are performed to monitor disease resolution.

Mucopolysaccharidosis Type VI

Definition and Causes

I. Mucopolysaccharidosis VI is an autosomal recessive, lysosomal storage disease of Siamese cats.

II. The enzyme responsible for the breakdown of glycosaminoglycans—an important component of cartilage and bone—is functionally impaired, which leads to skeletal abnormalities (Crawley et al., 2003).
III. Excessive amounts of glycosaminoglycans are excreted in the urine.

Clinical Signs

I. Signs in Siamese cats by 6 to 8 weeks of age
II. Smaller than littermates
III. Facial dysmorphia: broad face, short nose, small ears, enlarged head
IV. Progressive difficulty walking, with pelvic limb paresis or paralysis secondary to compressive exostoses affecting the spinal cord
V. Progressive degenerative joint disease

Diagnosis

I. Diagnosis is suggested by signalment, clinical signs, laboratory findings, and radiography.
II. Glycosaminoglycans are detected on urinalysis.
III. Cytological examination of blood smears reveals abnormal cytoplasmic granules within neutrophils.
IV. Radiography reveals generalized osteopenia, exostoses, vertebral fusion, and widespread degenerative joint disease.

Differential Diagnosis

I. Hypervitaminosis A
II. Osteochondromatosis

Treatment and Monitoring

I. No definitive treatment exists.
II. Bone marrow transplantation has been described (Beekman, 1993; Dial et al., 1997).
III. Affected cats may live for several years with supportive care; however, the disease is progressive and overall prognosis is poor.

NEOPLASIA

Definition

I. Bone tumors can be primary or secondary.
II. Secondary tumors include distant metastases or local extension of soft tissue tumors invading adjacent bone.
III. Most bone tumors are primary and malignant (Chun, 2005).

Causes and Classification

I. Primary bone tumors
  A. Osteosarcoma
    1. It is the most common bone tumor in dogs (90%) and cats (>70%) (Chun, 2005).
    2. In dogs, the most common appendicular locations include the distal radius, proximal humerus, distal femur, and proximal tibia.
    3. In dogs, the most common axial sites are the mandible and the maxilla.
    4. Osteosarcoma in small dogs tends to affect the axial skeleton most often (Chun and de Lorimer, 2003).
    5. Appendicular and axial lesions are evenly distributed in the cat.
  B. Chondrosarcoma
    1. Second most common bone tumor in dogs (approximately 10%)
    2. Rare in cats
    3. Flat bones more frequently affected than long bones
  C. Fibrosarcoma: uncommon in cats and dogs
  D. Hemangiosarcoma
    1. Rare in cats and dogs
    2. Usually a locally invasive muscular disease
  E. Multilobular tumor of bone (multilobular osteochondrosarcoma)
    1. Uncommon in dogs and rare in cats
    2. Locally invasive tumor
    3. Arises from the flat bones of the skull in middle-aged and older dogs
  F. Multiple myeloma
    1. Uncommon in dogs and rare in cats
    2. Systemic plasma cell malignancy (see Chapter 77)
II. Metastatic bone tumors
  A. Rare in cats and dogs
  B. More likely to involve the diaphysis than a primary bone tumor
  C. Most common: mammary gland carcinoma, transitional cell carcinoma, prostate carcinoma

Clinical Signs

I. Lameness in an affected limb can vary from mild to severe.
II. The potential exists for a pathologic fracture with minimal trauma.
III. Pain, palpable swelling, or a mass may be detected at tumor location.
IV. Paresis, paralysis, and pain may be associated with extradural or nerve root compression from spinal neoplasia.
V. Cachexia is possible.
VI. Dyspnea may arise secondary to metastatic disease.

Diagnosis

I. Signalment is suggestive for some tumors; for example, osteosarcoma typically occurs in mature, large- and giant-breed dogs.
II. Radiographic changes include cortical destruction, periosteal new bone formation, osteolysis, osteoproliferation, soft tissue swelling, and pathologic fractures.
III. No radiographic changes are pathognomonic.
IV. Three radiographic views of the thorax may reveal metastatic lung lesions.
V. Elevated levels of serum alkaline phosphatase at the time of diagnosis are a negative prognostic factor (Ehrhart et al., 1998; Garzotto et al., 2000).
VI. Definitive diagnosis is based on histopathologic evaluation of a bone biopsy.
  A. Obtain sample using a Michel bone trephine or Jamshidi bone biopsy needle (Straw, 1996).

B. Submit samples for bacterial culture and antibiotic sensitivity testing to rule out fungal or bacterial osteomyelitis.
C. Definitive tumor diagnosis using this combined technique occurs in >90% of cases (Waters, 1993).

VII. Skeletal nuclear scintigraphy is a sensitive tool to identify concurrent or early bony metastasis.

Differential Diagnosis

I. Osteomyelitis
II. Trauma
III. Bone infarcts (emboli)
IV. Benign cystic lesions

Treatment

I. Palliative therapy may include medical management with NSAIDs alone or in combination with narcotics.
A. Transdermal fentanyl patches (3 to 5 μg/kg) provide analgesia for 3 to 4.5 days.
B. Tramadol may be given at 1 to 4 mg/kg PO BID to TID.

II. Bisphosphonates may provide palliation in dogs with osteosarcoma (Tomlin et al., 2000; Milner et al., 2004).
III. Chemotherapy alone is ineffective in the face of gross disease (Ogilvie et al., 1993).
IV. See Tables 81-3 and 81-4 for chemotherapeutic and surgical options for osteosarcoma and other bone tumors.

Monitoring of Animal

I. Dogs treated palliatively are usually euthanized because of local recurrence or lack of pain control.
II. Because most animals with osteosarcoma succumb to diffuse pulmonary metastasis, three views of thoracic radiographs are performed every 3 to 6 months.
III. Animals undergoing chemotherapy require frequent complete blood counts, platelet counts, and serum biochemistry panels.

TABLE 81-3

Overview of Appendicular Osteosarcoma Therapy over the Past 15 Years

SURGERY AND CHEMOTHERAPY PROTOCOL	REFERENCE	MEDIAN SURVIVAL (1-YEAR AND 2-YEAR SURVIVAL)
Amp alone (n = 19)	Mauldin et al., 1988	175 days (21%, 0%)
Amp + DOX 30 mg/m^2 dL + cDDP 60 mg/m^2 day 21 × 2 doses (n = 19; 36 appendicular, 2 axial)	Mauldin et al., 1998	300 days (37%, 26%)
Amp + cDDP 50 mg/m^2 every 28 days × 2-6 doses (n = 19)	Shapiro et al., 1988	301 days (unknown, unknown)
Amp + cDDP 50 mg/m^2 every 28 days × 6 doses or until metastasis noted (n = 16)	Kraegel et al., 1991	413 days (62%, ≥18%)
Amp alone (n = 17)	Straw et al., 1991	119 days (11%, 4%)
Amp + cDDP 70 mg/m^2 every 21 days × 2 doses (n = 19)	Straw et al., 1991	262 days (38%, 18%)
Amp + cDDP 70 mg/m^2, 21 days preop and immediately postop (n = 35)	Straw et al., 1991	282 days (43%, 16%)
Amp alone (n = 15)	Thompson and Fugent, 1992	168 days (20%, unknown)
Amp + cDDP 60 mg/m^2 × 2 doses at 2 and 7 weeks postop (n = 15)	Thompson and Fugent, 1992	290 days (33%, unknown)
Amp alone (n = 162)	Spodnick et al., 1992 ,	134 days (11.5%, 2%)
Amp/limb sparing + cDDP 60 mg/m^2 every 21 days × 1-6 doses (n = 22; 17 = amp, 5 = limb sparing); survival data not divided for surgery types	Berg et al., 1992	325 days (45.5%, 20.9%)
Amp/limb sparing + DOX 30 mg/m^2 every 2 weeks × 5 doses (n = 35; 33 = amp, 2 = limb sparing); because 2-3 doses were given adjunctive to surgery, only patients with minimal clinical signs were included; survival date not divided for surgery types	Berg et al., 1995	366 days (50.5%, 9.7%)
Amp + carbo 300 mg/m^2 every 21 days × up to 4 doses (n = 48)	Bergman et al., 1996	321 days (35.4%, unknown)
Amp + DOX 15-20 mg/m^2 (1-2 hours before cDDP) + cDDP 60 mg/m^2 × 3 doses starting 2 (n = 53) or 10 (n = 49) days postop; twelve dogs died after first cycle	Berg et al., 1997	2 days postop group: 345 days (48%, 28.3%, 3 years: 15.3%) 10 days postop group: 330 days (46.2%, 27.5%, 3 years: 18%)
Amp + cDDP 50 mg/m^2 dL + DOX 15 mg/m^2 day 2 × 4 (n = 16) Also treated with empty liposomes	Chun et al., 2000	540 days (68.7%, 25%)

Modified from Chun R, de Lorimer LP: Update on the biology and management of canine osteosarcoma. Vet Clin North Am Small Anim Pract 33:491, 2003; with permission.

Amp, Amputation; *DOX,* doxorubicin; *cDDP,* cisplatin; *postop,* postoperative; *preop,* preoperative; *carbo,* carboplatin.

TABLE 81-4

Treatment Options for Bone Neoplasia

OSTEOSARCOMA	CHONDROSARCOMA	FIBROSARCOMA	HEMANGIOSARCOMA	MULTILOBULAR TUMOR	METASTATIC BONE TUMORS
Limb amputation: median survival of 5 months in dogs (Spodnik et al., 1992); mean survival of 17 months in cats (Heldmann et al., 2000) Radiotherapy alone: pain relief for 2-4 months (Green et al., 2002) Limb amputation and chemotherapy: see Table 81-3; 1-year survival rates of 35%-60%; median survival rate of 10-18 months in dogs (Chun et al., 2000) Limb-sparing surgery ± chemotherapy, radiotherapy: aims to maintain a functional limb without negative effect on survival Best sites: proximal scapula (Trout et al., 1995), distal radius (La Rue et al., 1989; Farese et al., 2004; Liptak et al., 2004), and distal tibia (Rovesti et al., 2002)	Limb amputation or aggressive surgical resection Benefits of adjunctive chemotherapy and radiotherapy uncertain	Limb amputation or aggressive surgical resection Adjunctive chemotherapy for high-grade disease (Dernell et al., 1998b) Adjunctive chemotherapy and radiotherapy for unresectable masses (Forrest et al., 2000)	Limb amputation ± chemotherapy	Aggressive surgical resection: median survival 630-797 days (Straw et al., 1989; Dernell et al., 1998a)	Surgical treatment unrewarding Palliative radiation Metastectomy to remove lung masses: possibly useful in dogs with <3 nodules in one lung and if >300 days after diagnosis (O'Brien et al., 1993)

TRAUMATIC DISORDERS

Fractures

Definition and Causes

I. A bone fracture is a disruption of the normal architecture of bone.
II. Fractures can be defined by the following:
  A. Location
  B. Direction
  C. Number of fracture lines
  D. Reducible or nonreducible
  E. Open or closed

Pathophysiology

I. Fractures occur when excessive or abnormal forces are applied to a bone.
  A. Axial compressive forces tend to produce oblique fractures.
  B. Tensile forces tend to produce transverse fractures, particularly avulsion fractures when a tendon or ligament is attached to the bone (e.g., greater trochanter, olecranon, tibial crest).
  C. Shear forces lead to fractures along lines of maximal shear stress (e.g., Salter-Harris type IV fracture of the lateral condyle in an immature animal) (Schwarz, 1991).
  D. Bending forces lead to compression on the concave surface of a long bone and tension on the convex surface, which typically leads to a transverse or short oblique fracture.
  E. Torsional forces lead to spiral fractures.
II. Most fractures result from a combination of disruptive forces.
III. Velocity of force affects fracture pattern.
  A. Low-velocity forces tend to produce single fractures and minimal soft tissue trauma.
  B. High-velocity forces tend to produce comminuted fractures and significant damage to the surrounding soft tissues.

Clinical Signs

I. Acute weight-bearing or non–weight-bearing lameness in appendicular bone fractures
II. Soft tissue swelling, pain on palpation, crepitation, abnormal limb posture or position
III. External skin trauma, puncture, laceration, shearing wounds that may communicate with the fractured bone
IV. Concurrent injury of vital systems secondary to the trauma (e.g., pulmonary contusions, ruptured bladder)
V. Compromised neurological integrity with spinal fractures or peripheral nerve trauma associated with a long bone fracture

Diagnosis

I. Diagnosis is based on history, clinical signs, physical examination findings, and radiographic changes.
II. Careful palpation helps the clinician avoid missing multiple fractures in an affected limb.
III. Radiography of the affected limb is performed under sedation or anesthesia, with a minimum of two divergent views.
IV. Computerized tomography, when available, can be useful for evaluating fractures of the axial skeleton.

Differential Diagnosis

I. Pathologic fracture from neoplasia
II. Metabolic bone disease
III. Joint luxation

Treatment

I. Address and stabilize life-threatening injuries in the traumatized animal.
II. Pain relief before and after fracture management is provided using a variety of analgesic agents.
  A. Epidural narcotics
    1. Preoperative administration reduces anesthetic requirements and provides immediate postoperative analgesia.
    2. In dogs, options include the following:
      a. Morphine (preservative free) 0.05 mg/kg plus 0.5% bupivacaine 1 mL/15 kg (pelvic limb fractures)
      b. Morphine (preservative free) 0.05 mg/kg plus 0.5% bupivacaine 1 mL/20 kg plus 0.9% saline 1 mL/20 kg (thoracic limb fractures)
    3. In cats, preservative-free morphine is used alone.
      a. Pelvic limb: 0.07 mg/kg
      b. Thoracic limb: 0.1 mg/kg in 0.1 mL/kg 0.9 % saline
    4. Local anesthetics are not used in cats because of the proximity of the cat's spinal canal to the epidural space.
  B. Selective and regional blockage of the brachial plexus
    1. Lidocaine 2% or bupivacaine 0.5% are preferred.
    2. A 22-gauge, 1- to 1.5-inch needle is inserted into the axillary space at the level of the shoulder before forelimb surgery.
  C. Systemic narcotics
    1. Morphine
      a. Dogs: 0.25 to 0.5 mg/kg IM, SC
      b. Cats: 0.05 to 0.1 mg/kg IM, SC
    2. Oxymorphone
      a. Dogs: 0.025 to 0.1 mg/kg IV, IM, SC
      b. Cats: 0.025 to 0.05 mg/kg IM, SC
    3. Butorphanol 0.1 to 0.2 mg/kg IM, SC
    4. Buprenorphine
      a. Dogs: 0.005 to 0.02 mg/kg SC, IM, IV
      b. Cats: 0.005 to 0.01 mg/kg SC, IM, IV
    5. Hydromorphone
      a. Dogs: 0.1 to 0.2 mg/kg IV
      b. Cats: 0.02 to 0.1 mg/kg IV
    6. Fentanyl patch 3 to 5 μg/kg
      a. Applied 18 to 24 hours before surgery
      b. Provides analgesia for 3 days
III. If necessary, fractures are temporarily stabilized to increase the animal's comfort.

A. Distal to the elbow or stifle, use a Robert Jones bandage, with or without a splint (metal or fiberglass).
B. Proximal to the elbow or stifle, use cage confinement.

IV. Animals with closed fractures are given perioperative antibiotics at the time of anesthetic induction.
A. Cephalosporin 22 mg/kg IV every 2 hours
B. Oxacillin 22 mg/kg IV every 2 hours

V. Animals with open, contaminated fractures are given broad-spectrum antibiotics or combinations of antibiotics (see Treatment of osteomyelitis) while awaiting the results of bacterial culture and antimicrobial sensitivity testing.

VI. Some fractures are amenable to cage rest, such as rib fractures, ulnar fractures with an intact radius, or a fibula fracture with intact tibia.

VII. Techniques for fracture repair include external splints or casts, internal implants, and external fixators (Table 81-5).

VIII. Autogenous bone grafts can provide live osteoblasts, are osteoinductive and osteoconductive, and serve as a scaffold for mechanical support.
A. Bone grafts can be obtained from the greater tubercle of the humerus, distal condyle of the femur, and the wing of the ilium.
B. They are packed into fracture gaps to promote healing.

TABLE 81-5

Fixation Devices for Fractures

DEVICES AND TECHNIQUES	USES
External coaptation	Closed fractures distal to the elbow or stifle
IM pin (single)	Never
IM pin with full cerclage	Long oblique or spiral fractures
IM pin with external fixator	Many diaphyseal and metaphyseal fractures
Rush pin technique	Metaphyseal, physeal, and epiphyseal fractures
Tension band fixation	Avulsion or iatrogenic fractures of bony prominences
Interlocking IM nail	Most diaphyseal fracture configurations
External fixators	Most diaphyseal and metaphyseal fractures
Circular fixators	Most fractures (experience needed)
Bone plate (anatomic)	Most fracture configurations because of varied plate design
Bone plate and rod	Buttressed fracture repairs
Ancillary devices Full cerclage wires Hemicerclage wires K-wires/crossed K-wires Lag screws	

From Roush JK: Management of fractures in small animals. Vet Clin North Am Small Anim Pract 35:1137, 2005; with permission.

IM, Intramedullary.

Monitoring of Animal

I. Postoperative radiographs are taken to assess fracture repair and provide comparisons for follow-up radiographs.

II. Confinement and/or cage rest are essential for periods of time, depending on the specific fracture, and are combined with early physical therapy to enhance limb function (see Chapter 83).

III. Animals are given NSAIDs during the first 7 to 10 days after surgery (see Treatment of Panosteitis).

IV. Adequate nutrition must be ensured; feeding may have to be supplemented via nasoesophageal or esophagostomy feeding tubes or by using IV parenteral nutrition.

V. Soft tissue injuries associated with fractures may require open wound management and closure as a separate surgical procedure.

VI. Certain fracture repair techniques (e.g., casts, splints, external and circular fixators) require regular physical examinations to monitor for repair-related complications (e.g., pressure sores, soft-tissue swelling, discharge at the skin–pin interface).

VII. Radiographic rechecks are performed around 4 weeks in young animals and 6 weeks in mature animals, then every 4 to 8 weeks until fracture healing is complete.

VIII. Prognosis for fracture healing is generally good; however, some predictably problematic cases occur.
A. Open fractures and comminuted fractures have a higher incidence of osteomyelitis, delayed union, malunion, and nonunion.
B. Distal radial fractures in small-breed dogs require internal or external fixation and should not be splinted or casted for definitive repair.
C. Compressive fractures of growth plates in immature animals may not be appreciated on initial radiographs, but can lead to premature closure of the physis with the potential for subsequent angular limb deformities.
D. Distal femoral fractures in immature dogs can produce excessive callus, causing adhesions to the quadriceps muscle group (leading to ankylosis and stifle hyperextension).

CHAPTER 82

Diseases of Muscle and Tendons

Brian S. Beale | Sorrel Langley-Hobbs | Nicholas J. Trout

CONGENITAL AND INHERITED DISORDERS

See Table 82-1.

DEGENERATIVE DISORDERS

Myositis Ossificans

Definition

I. Myositis ossificans is heterotrophic, nonneoplastic bone formation in the collagenous tissues of skeletal muscles.
II. Name is misleading because connective tissue (not muscle) is ossified, and evidence of inflammation is not always present.
III. It can be localized or generalized.
  A. Localized myositis ossificans
    1. Bone formation occurs in a single muscle or group of muscles.
    2. It is most common in large-breed, middle-aged, active dogs.
    3. It may be a separate entity in the Doberman pinscher, arising secondary to von Willebrand disease (Dueland et al., 1990).
  B. Progressive or generalized myositis ossificans
    1. Excessive fibrous connective tissue develops throughout skeletal muscles leading to muscle degeneration, dystrophic calcification, and ossification.
    2. It occurs in young to middle-aged cats and has rarely been reported in dogs (Guilliard, 2001; Asano et al., 2006).
    3. It is also known as *progressive ossifying fibrodysplasia* (Norris et al., 1980).

Causes and Pathophysiology

I. Cause is unknown.
II. Localized forms may be associated with one of the following:
  A. Acute or repetitive trauma
    1. Ossification of hematoma
    2. Tearing of periosteum, releasing osteoblasts
    3. Metaplasia of muscle and connective tissue to cartilage and bone
  B. Localized infection
  C. Microvascular bleeding from von Willebrand disease: Doberman pinschers
  D. Possible breed predisposition: German shepherd dogs
III. The progressive or generalized form may have a hereditary component and arise from a fibroblast defect in collagenous connective tissue, with secondary degeneration of muscle.

Clinical Signs

I. Localized form
  A. Palpable mass in affected muscle
  B. Exercise-induced muscle pain
  C. Lameness and stiffness: often in one limb
  D. Focal muscle atrophy
II. Progressive ossifying fibrodysplasia
  A. Lameness and stiffness is seen in one or more limbs, with pelvic limbs commonly affected.
  B. It may progress to decreased joint mobility and difficulty ambulating.
  C. Palpable, painful, firm nodules are seen, especially on the neck and back.
  D. It can progress over weeks to months to severe debilitation.

Diagnosis

I. Localized ossifying myositis
  A. Radiography can reveal the following:
    1. Stippled mineralized density in soft tissue (3 to 6 weeks), with mature bone detected 2 to 6 months after an injury
    2. ± Radiolucent core
    3. Possible adjacent periosteal reaction
  B. Ultrasonography and bone scintigraphy may be helpful.
  C. Biopsy findings are definitive.
    1. Central zone of spindle cells and hemosiderin-laden macrophages
    2. Intermediate zone of osteoid and immature bone
    3. Peripheral zone of mature bone, with resorption and remodeling that does not invade surrounding soft tissue
  D. Possible laboratory findings include the following:
    1. Elevated serum alkaline phosphatase
    2. Decreased von Willebrand factor, prolonged buccal bleeding times
II. Progressive ossifying fibrodysplasia

Text continued on p. 799.

TABLE 82-1

Congenital Myopathies

DISORDER AND DEFINITION	BREEDS AFFECTED	CAUSE AND INHERITANCE	CLINICAL SIGNS	DIAGNOSIS	DIFFERENTIAL DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Type II muscle fiber deficiency: predominance of type I and deficiency of type II muscle fibers, causing gait disturbance	Labrador retriever	Cause unknown Simple autosomal recessive	< 5 mo of age Initial gait abnormality progresses to generalized weakness, inability to hold head up. Exacerbated by exercise Marked skeletal muscle atrophy Stunted growth Progressive signs until maturity, then signs stabilize Megaesophagus Neurological examination normal or diminished tendon reflexes	Suspicious clinical signs in a Labrador Creatinuria* up to 30× normal; CK† less than normal Muscle biopsy: variable fiber diameter with increased endo- and perimysial connective tissue Deficiency of ATPase-staining type II fibers EMG may reveal myotonic discharges	Myasthenia gravis: older dogs; response to edrophonium chloride, EMG showing decremental response Nutritional myodegeneration: history of abnormal diet, progressive Congenital myotonia	None Diphenylhydantoin PO ineffective Diazepam PO may alleviate some signs Poor prognosis because lack of available treatment, but normal life span possible	Sharp et al. (1989) Gortel et al. (1996)
Muscular dystrophies, inherited myopathies	Alaskan malamute Golden retriever Groenendaeler shepherd Irish terrier Samoyed	Inability to produce dystrophin (cytoskeletal protein of muscle fibers) X-linked inheritance	*Dogs*: Onset at 6-8 wk of age Rapid progression of signs Difficulty swallowing and drooling	Compatible clinical signs in reported breeds Increased CK, aldolase, AST, ALT, and LDH	Congenital myotonia: myotonic dimple Hypokalemic myopathy of cats: elevated serum potassium	None Disease is progressive, but less rapidly after 6 mo of age (dogs)	Malik (1993) Robinson (1999) van Ham et al. (1993) Vos et al. (1986) Wetterman et al. (2000)

Modified from Davidson JR, Hosgood G: Disease of muscles and tendons. p. 806. In Morgan RV, Bright RM, Swartout MS (eds): Handbook of Small Animal Practice. 4th Ed. WB Saunders, Philadelphia, 2003; with permission.

CK, Creatine kinase; *EMG,* electromyography; *AST,* aspartate transaminase; *ALT,* alanine transaminase; *LDH,* lactate dehydrogenase.

*Normal = 0.1 to 1.6 mg/mL.

†Normal = 45 to 125 IU/dL.

TABLE 82-1

Congenital Myopathies—*cont'd*

DISORDER AND DEFINITION	BREEDS AFFECTED	CAUSE AND INHERITANCE	CLINICAL SIGNS	DIAGNOSIS	DIFFERENTIAL DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Muscular dystrophies—*cont'd*	Rottweiler Miniature schnauzer Welsh corgi Male cats	Males exhibit clinical signs Carrier females may have mild elevations in muscle enzymes without clinical signs Condition in golden retrievers is similar to Duchenne-type muscular dystrophy in humans	Stiff gait, rigid neck, adduction of hocks, abduction of elbows, tarsal flexor contraction, carpal hyperextension Hypertrophy of tongue and caudal thigh muscles Atrophy of other muscles, particularly truncal and temporal muscles Lumbar kyphosis Aspiration pneumonia from pharyngeal/esophageal dysfunction Exercise intolerance Normal neurological examination initially, with later proprioceptive deficits and hyporeflexia Dilated cardiomyopathy *Cats*: Onset at 12 mo of age Slow progression of signs Stiff, rigid neck Adduction of hocks Symmetrical muscular hypertrophy Lumbar kyphosis Reduced cardiac contractility and biventricular enlargement	Muscle biopsy variable: fiber necrosis and regeneration, hypertrophy (cat), fiber loss and fibrosis (dog), myofiber mineralization (both), and lack of dystrophia on immunostaining EMG: bizarre high-frequency discharges (golden retriever); diffuse, continuous myotonic discharge (Irish terrier) Normal nerve conduction velocity	Inherited myopathy of Devon rex cats: normal CK, AST, characteristic head and neck ventriflexion, megaesophagus, generalized muscle weakness and fatigue Immune-mediated polymyositis: characteristic cellular infiltrate in histological specimens	Poor prognosis	Bergman et al. (2002)

TABLE 82-1

Congenital Myopathies—*cont'd*

DISORDER AND DEFINITION	BREEDS AFFECTED	CAUSE AND INHERITANCE	CLINICAL SIGNS	DIAGNOSIS	DIFFERENTIAL DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Congenital myotonia: involuntary contraction of a muscle that persists after a voluntary effort or stimulation	Chow chow Cocker spaniel Labrador retriever Samoyed Staffordshire bull terrier West Highland white terrier Cats	Cause unknown Low membrane chloride conductance and accumulation of potassium in the tubular system may cause postexcitement depolarization of the muscle membrane and continued contraction of the muscle Autosomal recessive inheritance in the chow chow, but may have multifactorial etiology Thought to be heritable in cats	Abnormal stiff gait at 2-3 mo of age, lessens with exercise Abduction of forelimbs "Bunny hop" Arched back Muscle hypertrophy of all skeletal muscles, especially proximal appendicular muscles, tongue, and anal sphincter Normal muscle tone at rest Characteristic myotonic dimple persists for 30-40 sec after direct muscle stimulation (tongue or shaved limb) Dysphagia often observed	Typical clinical signs in a reported breed with myotonic dimple EMG: high-frequency myotonic a discharges with continuous insertional activity and possible decremental response Normal nerve conduction velocity CK may be elevated Muscle biopsy variable: hypertrophy, atrophy, and degeneration	Nutritional myodegeneration Cerebellar dysmyelinogenesis: also reported in young chow chows Animals with cerebellar disease can potentially recover, are not stiff, and have a continuous tremor of the head, neck, and trunk; they typically "bounce" repetitively on the hind limbs Inherited (X-linked) myopathy in cats	None Disease is not progressive Procainamide and quinidine may lessen initial weakness Diphenylhydantoin has no benefit Avoid prolonged exercise Fair to guarded prognosis Treatment not reported in cats because of potential drug side effects	Hickford et al. (1998) Toll et al. (1998) Hill et al. (1995)
Nemaline myopathy	Cats Border collie Schipperke	Cause unknown Thought to be inherited Only one report of several cats	Onset at 6-18 mo of age in cats and 6-24 mo in dogs Adult onset described in a dog Weakness, crouched, hypermetric gait Depressed patellar reflexes Progressive muscle atrophy	Muscle biopsy: nemaline rods in skeletal muscle fibers EMG: mild to moderate diffuse spontaneous activity		None Poor prognosis	Cooper et al. (1986) Delauche et al. (1998) Kube et al. (2006)

Continued

TABLE 82-1

Congenital Myopathies—*cont'd*

DISORDER AND DEFINITION	BREEDS AFFECTED	CAUSE AND INHERITANCE	CLINICAL SIGNS	DIAGNOSIS	DIFFERENTIAL DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Inherited myopathy of Great Danes	Great Dane	Cause unknown	Onset 6-19 mo of age No sex prediction Generalized tremors and collapse precipitated by exercise or excitement Generalized muscle atrophy, kyphosis, stiff pelvic gait Stunted Tucked position of pelvic limbs Progresses over 6-12 mo	EMG: fibrillation potentials and sharp waves Muscle biopsy: 50% of fibers contain a central core, fiber diameter variation, disruption of myofibrillar elements		None reported to be effective	Newsholme and Gaskell (1987) Targett et al. (1994) Feliu-Pasual et al. (2006)
Mitochondrial myopathy	Clumber spaniel Sussex spaniel German shepard dog Jack Russell terrier	Cause unknown Thought to be inherited Muscle mitochondria are unable to oxidize pyruvate	Onset 3-9 mo of age Collapse in sternal recumbency for 10-15 min with panting and tachycardia Progressive exerase intolerance Stilted gait	Metabolic acidosis after exercise CK possibly elevated		Correct lactic acidosis Prognosis is guarded	Breitschwerdt et al. (1992) Olby et al. (1997) Paciello et al. (2003)

A. Presence on plain radiographs of multiple mineralized densities distributed throughout muscles
B. Elevated serum creatine kinase (CK)
C. Biopsy findings in affected muscle
   1. Increased connective tissue between muscle fibers
   2. Mononuclear infiltration
   3. Muscle atrophy and degeneration

Differential Diagnosis

I. Neoplasia of bone or joints, including extraskeletal osteosarcoma
II. Dystrophic calcification, calcinosis circumscripta
III. Cartilaginous exostoses
IV. Callus formation secondary to bone healing
V. Radiopaque foreign body: teeth or bone fragments after bite wounds

Treatment and Monitoring

I. Localized ossifying myositis
   A. Treatment is indicated only for clinically significant lesions.
   B. Nonsteroidal antiinflammatory drugs may be helpful but must be avoided in dogs with bleeding tendencies.
      1. Carprofen 2.2 mg/kg PO BID
      2. Meloxicam 0.1 mg/kg PO SID
      3. Deracoxib 1 to 2 mg/kg PO SID
   C. Removal is recommended if the lesion is painful, if it restricts joint motion, or to obtain an excisional biopsy.
   D. Postoperative physical therapy is beneficial.
II. Progressive ossifying fibrodysplasia
   A. No specific, effective treatment is available.
   B. Corticosteroids, bisphosphonates, etretinate, and dietary changes have not alleviated the clinical signs or prevented disease progression.
   C. Prognosis is poor to guarded.

Fibrotic Myopathy

Definition and Causes

I. It is a chronic, progressive disorder of severe muscle contracture and fibrosis.
II. The exact cause is usually unknown.
III. Fibrotic myopathy may result from acute trauma, chronic repetitive trauma, autoimmune disease, drug reactions, infections, neurogenic disorders, and vascular abnormalities.
IV. Ischemia secondary to trauma may also lead to fibrosis.
V. Severely damaged muscle undergoes necrosis followed by fibrosis and contracture.
VI. Histologically, muscle is replaced by dense, collagenous connective tissue.

Clinical Signs

I. Muscles most often affected are the infraspinatus (infraspinatus contracture), quadriceps (quadriceps contracture), gracilis, and semitendinosus.
II. Signs are specific to the muscle or group of muscles affected.
   A. Quadriceps (Table 82-2)
   B. Gracilis, semimembranosus, semitendinosus
      1. Often affects active, mature, large-breed dogs, with German shepherd dogs overrepresented
      2. Short stride with a rapid medial rotation of the paw, external rotation of the hock, and internal rotation of the stifle during the middle to late phase of the stride.
      3. Possible reduction in passive movement of the thoracic limb and limb abduction
   C. Infraspinatus
      1. Usually a unilateral lesion, primarily in hunting or working breeds of dogs (Harasen, 2005; Devor and Sorby, 2006)
      2. Acute shoulder pain associated with exercise
      3. Progresses to a mechanical lameness 2 to 4 weeks after the initial injury, with adduction of the elbow, abduction of the thoracic limb, and external rotation of the antebrachium and carpus
      4. Lateral circumduction of the limb during each stride, with paw flipping forward

Diagnosis

I. Diagnosis is based on the history, clinical signs, physical examination findings, and diagnostic imaging.
II. The affected muscle may be palpably taut, hard, and usually nonpainful.
III. Diagnostic imaging may be helpful.
   A. Radiological findings may include the following:
      1. Patella lies more proximally than normal in cases of quadriceps contracture.
      2. Congenital stifle contracture produces stifle hyperextension, with both the distal femur and proximal tibia bending backwards (genu recurvatum).
      3. Occasionally streaks of mineralization may be seen in affected muscle groups.
   B. Ultrasonography may be able to differentiate other soft tissue abnormalities.
IV. Laboratory findings may include elevated levels of muscle enzymes in the early stages.

Differential Diagnosis

I. Neurological diseases
II. Hip dysplasia
III. Cranial cruciate ligament disease
IV. Lumbosacral disease

Treatment and Monitoring

I. Medical management is generally ineffective but may be acceptable for dogs with nondebilitating lameness.
II. Surgery aims to release the fibrous band(s) within the affected muscle.
   A. Quadriceps muscle: see Table 82-2
   B. Gracilis muscle: myotomy or myectomy of the affected muscle invariably leads to recurrence of clinical signs within 3 to 4 months
   C. Infraspinatus muscle: tenotomy results in immediate improvement in range of motion

III. Restrict activity for 2 weeks postoperatively.
IV. Prognosis depends on the affected muscle group.
  A. Quadriceps: guarded, considered a successful outcome if 50% to 75% use of affected limb returns
  B. Gracilis: guarded for recurrence, but affected animal makes an acceptable pet
  C. Infraspinatus: excellent for full recovery

INFECTIOUS DISORDERS

Protozoal Myositis

Definition and Causes

I. *Toxoplasma gondii* is the most common infectious cause of polymyositis.
  A. It may occur as part of a multisystemic infection in cats.
  B. In the dog, three clinical forms may occur.
    1. Generalized form that occurs in conjunction with canine distemper virus and may affect both the muscles and the central nervous system (CNS)
    2. Severe acute necrotizing myositis of adult dogs
    3. Polyradiculitis and polymyositis of young dogs (usually 3 to 6 months of age)
II. *Neospora caninum* can cause myositis and has been discovered in many dogs that were previously thought to have toxoplasmosis.

Clinical Signs

I. Severity of clinical signs is worse in very young (from 5 weeks of age) and immunosuppressed animals.
II. Several puppies in the same litter may be affected.
III. Gait abnormalities include hopping; progressive pelvic limb paresis; and acute, severe muscle pain (focal or generalized).
IV. *T. gondii* can produce a spastic hyperextension of the pelvic limbs, with severe muscle atrophy in dogs.
V. CNS and ocular signs include chorioretinitis, seizures, and stupor.
VI. Other clinical signs are cervical weakness; icterus, anorexia, and lethargy from liver dysfunction; dysphagia; and death.
VII. *N. caninum* is not usually associated with concurrent infections and more commonly produces a progressive ascending paralysis.

Diagnosis

I. Clinical signs compatible with polymyositis
II. Elevation of serum CK
III. Rising serum antibody titers to protozoal organisms (see Chapters 2 and 116)
IV. Mixed pleocytosis and a high protein count in cerebrospinal fluid (CSF) of animals with CNS signs
V. Histopathologic findings of muscle fiber atrophy, myonecrosis, and free or encysted organisms
VI. Tests to differentiate *T. gondii* from *N. caninum*
  A. Indirect fluorescent antibody tests on CSF, serum, or tissue
  B. Electron microscopy and immunohistochemical staining for *N. caninum*
  C. Polymerase chain reaction (PCR) assays

Differential Diagnosis

I. *Leptospira icterohaemorrhagiae*
II. Congenital myopathies
III. Nutritional myopathies
IV. Immune-mediated polymyositis
V. Hepatozoonosis (see Chapter 116)
VI. Sarcocystosis
  A. Pathogenic primarily in immunosuppressed animals
  B. Animals possibly seropositive for toxoplasmosis
  C. Specialized testing required for diagnosis (Vashisht et al., 2005)

Treatment and Monitoring

I. Antibiotic therapy is instituted, similar to that used for systemic toxoplasmosis.
  A. Clindamycin 10 to 20 mg/kg PO, IM BID to TID
  B. Trimethoprim-sulfadiazine 30 mg/kg PO BID, with pyrimethamine 0.25 to 0.5 mg/kg PO SID for 2 to 4 weeks in dogs or for 7 to 10 days in cats
II. Prognosis is guarded to poor because of concurrent diseases, immunosuppression, and CNS involvement.

Bacterial Myositis

Definition

I. Focal myositis may arise from direct infection of traumatized and devitalized muscle.
  A. Often associated with contamination of a wound
  B. May result from injection of bacteria into muscle (bite wounds)
II. Myositis may develop from hematogenous infections.

Causes

I. *Staphylococci* spp. and *Streptococci* spp.: most common in dogs
II. *Pasteurella multocida:* most common in cats
III. Other causes: *Clostridium tetani*, *Leptospira* spp. (especially *L. icterohaemorrhagiae*), *Corynebacterium* spp., gram-negative and anaerobic bacteria

Clinical Signs

I. Focal infection: localized muscle pain and swelling, lameness, ± fever
II. Diffuse myositis
  A. Generalized muscle pain, lethargy, malaise, fever
  B. Evidence of bacteremia and septicemia: injected mucous membranes, heart murmur, coagulopathies
  C. Death (possible in 24 hours)

Diagnosis

I. Diagnosis is suspected from compatible clinical signs, especially after muscle trauma.

II. Laboratory tests may be normal with focal disease; leukocytosis and elevated CK may be detected with diffuse disease.
III. Definitive diagnosis is based on identification of bacteria from affected tissue via aerobic or anaerobic culture or histopathology.

Differential Diagnosis

I. Focal myositis
  A. Subcutaneous abscess
  B. Muscle contusion or avulsion
  C. Parasitic myositis: *Dirofilaria immitis*
II. Diffuse myositis
  A. Toxoplasmosis, neosporosis, sarcocystosis (rare), trichinellosis (rare)
  B. Septicemia
  C. Streptococcal group G fasciitis (Naidoo et al., 2005)
  D. Other causes of fever, muscle and subcutaneous pain

Treatment and Monitoring

I. Localized myositis
  A. Wounds are surgically drained and lavaged.
  B. Warm, wet compresses TID to QID may be helpful.
  C. Broad-spectrum antibiotics are started and may be modified based on culture and sensitivity results.
  D. Prognosis is good, with resolution of signs within 7 to 10 days.
II. Diffuse myositis
  A. Parenteral antibiotics are indicated (see Chapter 113).
  B. Pain management and supportive care are instituted as needed.
  C. Prognosis is variable, depending on the degree of subcutaneous and systemic involvement, as well as the responsiveness of the causative bacteria to antibiotics.

METABOLIC MYOPATHIES

Feline Hypokalemic Polymyopathy

Definition and Causes

I. Chronic potassium depletion in cats produces a myopathy that causes acute onset of generalized weakness.
II. In many cats the cause is a total body depletion of potassium, usually from a combination of low dietary intake of potassium and increased urinary potassium loss (potassium-losing nephropathy).
III. Primary hyperaldosteronism associated with adrenocortical neoplasia may also cause persistent hypokalemia (Ash et al., 2005).
IV. A familial, inherited syndrome has been reported in Burmese cats.

Pathophysiology

I. Hypokalemia produces several effects on muscle cell membranes.
  A. Muscle cell hyperpolarization leads to increased sodium permeability of the sarcolemma and subsequent hypopolarization.
  B. Muscle cell hypopolarization causes muscle weakness.
  C. Hypokalemia may also affect muscle blood flow and lead to ischemic necrosis.
II. Depletion of potassium may occur for months before onset of clinical signs.

Clinical Signs

I. Acute onset of generalized weakness
II. Muscle pain, atrophy
III. Ventriflexion of the neck
IV. Stiff gait
V. Anorexia, weight loss
VI. Evidence of hypertension with primary aldosteronism

Diagnosis

I. Compatible clinical signs, with a normal neurological examination
II. Low serum potassium concentration (<3.5 mEq/L) and elevated CK (500 to 10,000 IU/L)
III. Low urine specific gravity and increased fractional urinary excretion of potassium with a nephropathy
IV. Elevated blood pressures with hyperaldosteronism
V. Electromyographic (EMG) abnormalities
  A. Increased positive sharp waves
  B. Fibrillation potentials
  C. Normal nerve conduction velocities
VI. Normal muscle histopathology on biopsy

Differential Diagnosis

I. Polymyositis
II. Polyneuropathies: diabetic neuropathy, vincristine-related neuropathy
III. Neuromuscular junction diseases: myasthenia gravis, certain toxicities
IV. Ethylene glycol toxicity
V. Severe anemia, other causes of weakness
VI. Thyrotoxicosis
VII. Thiamine deficiency
VIII. Hypernatremic myopathy
IX. Nemaline myopathy

Treatment and Monitoring

I. Potassium supplementation usually relieves the clinical signs.
  A. Potassium gluconate (more palatable and nonacidifying than potassium chloride [KCl]) is started at 5 to 8 mEq PO divided BID for cats with serum potassium <3 mEq/L.
  B. KCl in lactated Ringer's solution is administered IV at 0.4 mEq/kg/hr to severely hypokalemic cats.
    1. Measure serum potassium every 3 to 6 hours, and reduce infusion rates once potassium is >3.5 mEq/L.
    2. Monitor the electrocardiogram for arrhythmias and any catheterized veins for phlebitis.
    3. Monitor closely for potassium-related respiratory paralysis.

II. Dopamine (0.5 μg/kg/min IV) can induce a transient increase in serum potassium during life-threatening situations.
III. Monitor serum potassium SID until it returns to normal, then weekly.
IV. Once serum potassium stabilizes, a maintenance dose of potassium gluconate (2 to 6 mEq PO SID-BID) is usually effective.
V. A diet with adequate potassium (>0.6%) is also instituted.
VI. Prognosis for cats with hypokalemic myopathy is excellent with prompt diagnosis and treatment.

Exertional Myopathy in Greyhounds

Definition and Causes

I. Exertional myopathy is muscle damage that occurs primarily in greyhounds or working dogs after racing or exertion.
II. It is caused by acute muscle ischemia.
III. Exercise-induced muscle ischemia and lactic acidosis lead to lysis of muscle cell walls and release of myoglobin.
IV. Predisposing factors include the following:
   A. Lack of fitness
   B. Hot, humid conditions
   C. Overexcitement or exertion
   D. Excessive racing
V. Exertional myopathy may rarely develop secondary to prolonged seizure activity.

Clinical Signs

I. Mild cases have generalized muscle pain and swelling after strenuous exercise.
II. Signs in severe cases include the following:
   A. Distress, tachypnea
   B. Hard, painful swelling of affected muscles, especially of the trunk and limbs
   C. Myoglobinuria, possible hyperthermia
   D. Acute collapse, death within 48 hours from renal failure associated myoglobinuria

Diagnosis

I. Diagnosis is based on signalment, history, and clinical signs.
II. Myoglobinuria is a supportive finding.
III. Serum elevations of potassium, phosphorus, and muscles enzymes are common.
IV. Elevations of serum creatinine and blood urea nitrogen (BUN) occur with renal damage.
V. Postmortem histopathologic examination of muscles demonstrates multifocal hemorrhages and myonecrosis.

Differential Diagnosis

I. Heat stroke
II. Malignant hyperthermia
III. Certain toxicoses

Treatment and Monitoring

I. Intravenous fluids are started to prevent hypovolemia and promote renal excretion of myoglobin.
II. Sodium bicarbonate may be administered to combat muscle acidosis.
III. Enforced rest and cooling measures (see Chapter 135) are started.
IV. Diazepam is given at 0.5 mg/kg IV as a muscle relaxant.
V. Renal function and urine output are monitored.
VI. Prognosis is guarded for severe cases.

Malignant Hyperthermia

Definition and Causes

I. Malignant hyperthermia is severe elevation of the core body temperature from an abnormal physiological response to exercise or to certain drugs that produce peracute skeletal muscle hypercatabolism and contracture (Brunson and Hogan, 2004).
II. Drugs that may induce the condition in susceptible individuals include inhaled halothane and enflurane as well as injectable succinylcholine and lidocaine.
III. An autosomal dominant mutation in the gene encoding the skeletal muscle calcium release channel has been documented in mixed breed dogs (Roberts et al., 2001).
IV. A malignant, hyperthermia-like condition can occur in dogs after ingestion of hops (Duncan et al., 1997).

Pathophysiology

I. Malignant hyperthermia is associated with a hypersensitivity of calcium channels that allows the re-release of calcium in the sarcoplasmic reticulum.
II. Hypermetabolism of muscle depletes glycogen stores and generates heat, hypoxia, lactic acid, and carbon dioxide.

Clinical Signs

I. The condition is more common in males and heavily muscled dogs.
II. Mixed breed dogs, as well as the Labrador retriever, greyhound, and collie may be more commonly affected.
III. Initially tachycardia and tachypnea may be noted, followed by pyrexia.
IV. Muscle cramping and generalized rigidity ensue.
V. Occasionally contracture develops only of the masseter muscles.
VI. Respiratory distress from pulmonary edema and cardiovascular collapse may occur.
VII. Myoglobinuria and renal failure are often terminal events.

Diagnosis

I. Diagnosis is suggested from the clinical signs.
II. Laboratory findings include elevated serum levels of muscle enzymes, lactate, potassium, chloride, BUN, creatinine, and total protein, as well as decreased levels of calcium and bicarbonate.
III. Postmortem changes include the following:
   A. Immediate, generalized muscle rigidity
   B. Pale, soft, exudative musculature
   C. Variable muscle fiber size (hypertrophy common), increased numbers of internal nuclei on histopathology

Treatment

I. Discontinue all inciting drugs, stop anesthesia, and administer high flow rates of 100% oxygen.
II. Institute supportive therapy.
  A. Cooled 0.9% saline at 90 mL/kg/hr IV
  B. Sodium bicarbonate to correct acidosis
  C. Total body cooling (see Chapter 135)
  D. Shock doses of short-acting corticosteroids (see Chapter 132)
III. Dantrolene (skeletal muscle relaxant) is administered at 2 to 5 mg/kg IV.

Monitoring of Animal

I. Monitor renal function, urine output, and development of myoglobinuria.
II. Monitor electrolytes and acid-base status.
III. Monitor for cardiac arrhythmias.
IV. Prognosis is usually poor to guarded for dogs with the genetically mediated condition but may be good in dogs that are treated promptly for ingestion of hops.

Endocrine Myopathies

See Chapters 42 and 45.

IMMUNE-MEDIATED DISORDERS

Masticatory Myositis

Definition

I. Masticatory myositis is acute or chronic inflammation of the masticatory muscles that may lead to severe atrophy and difficulty opening the mouth.
II. It is the most common noninfectious, inflammatory myopathy of dogs.
III. It usually affects large-breed dogs.
IV. It is also referred to as *eosinophilic myositis, atrophic myositis,* and *cranial myodegeneration*.

Causes and Pathophysiology

I. Evidence indicates that autoantibodies to myosin cause the disease (Shelton and Paciello, 2006).
II. Masticatory muscles have a different embryologic origin (branchial arch) and are antigenically different (contain type 2M myofibers) from other skeletal muscle fibers.
III. Autoantibodies may be produced against these specific antigens.

Clinical Signs

I. Acute form
  A. Usually symmetrical swelling and pain of the muscles of mastication (temporalis, masseter)
  B. Difficulty opening the mouth (trismus)
  C. Anorexia from reluctance to open mouth
  D. Pyrexia
  E. Possible regional lymphadenopathy
  F. Exophthalmos from swelling of affected muscles, with secondary optic nerve stretching and blindness
II. Chronic form
  A. Progressive fibrosis and atrophy of muscles of mastication with inability to voluntarily or manually open the mouth (trismus)
  B. Difficulty with prehension, chewing and swallowing food, and weight loss
  C. Enophthalmos from atrophy of affected musculature

Diagnosis

I. Diagnostic findings include masticatory muscle swelling and pain or atrophy on physical examination, often with decreased ability to open the mouth.
II. Routine laboratory tests are often unrewarding but may reveal eosinophilia, as well as elevated serum globulin and muscle enzymes.
III. Serological testing for type 2M antibodies is the definitive test, but is not always positive.
IV. EMG findings may include the following:
  A. Positive sharp waves
  B. Fibrillation potentials
  C. Polyphasic motor unit potentials
  D. Electrical silence in areas of fibrosis
V. Histopathologic findings in muscle biopsies are helpful to identify both acute and chronic changes.
  A. Acute form: myofiber necrosis, diffuse and predominantly mononuclear cell infiltrates
  B. Chronic form: increased connective tissue and fibrosis, myofiber necrosis
VI. Radiographs of the temporomandibular joint help rule out other bony or joint diseases.
VII. Assays for autoantibodies against 2M fiber proteins may also be performed on frozen muscle specimens.

Differential Diagnosis

I. Polymyositis
II. Infectious myositis
III. Dermatomyositis
IV. Trigeminal neuropathy
V. Temporomandibular joint disease
VI. Retrobulbar inflammation
VII. Extraocular myositis (see Chapter 103)

Treatment and Monitoring

I. Immunosuppressive therapy is the treatment of choice.
  A. Prednisone is given at 1 to 2 mg/kg PO BID for 3 to 4 weeks, then tapered over 2 to 6 months.
  B. If the response to prednisone is poor, side effects are intolerable, or the drug cannot be tapered without relapses, then the following can be added:
    1. Azathioprine 2 mg/kg PO SID (dogs only), tapered once in remission
    2. Cyclophosphamide 1 to 2 mg/kg PO SID for 4 days on, 3 days off, for up to 3 weeks
  C. Continuously monitor the ability to open the jaw while on therapy.
  D. Relapses are common with premature tapering or withdrawal, and some dogs require prolonged therapy.
II. Insertion of a feeding tube may be considered in animals unable to eat.

III. Forced, manual opening of the jaw may be required in dogs when fibrosis and atrophy prohibits normal eating.
   A. Rib spreaders may be used to slowly tear the fibrosed muscles and open the jaw.
   B. An opening distance of 2 inches may be adequate in most animals.
   C. Excessive force may result in fractures of the teeth or jaw and must be avoided.
IV. Prognosis is most favorable when the diagnosis is made early in the course, before excessive fibrosis occurs.

Polymyositis

Definition and Causes

I. Polymyositis is a generalized inflammatory disease affecting one or more skeletal muscle groups.
II. Although the precipitating cause is unknown, the disease is a T cell–mediated immunological disease that results in muscle and fiber destruction and production of antimyosin autoantibodies (Neumann and Bilzer, 2006; Shelton and Paciello, 2006).
III. The condition can be seen in association with systemic lupus erythematosus (SLE) (Krum et al., 1977) and myasthenia gravis.
IV. Masticatory myositis may be a variant of polymyositis.

Clinical Signs

I. The disease may be acute and episodic or chronic and progressive.
II. It occurs in adult dogs of either sex and is characterized by the following:
   A. Weakness
   B. Anorexia, weight loss
   C. Stiff gait, reluctance to walk
   D. Muscle pain, pyrexia
   E. Dysphagia, dysphonia
   F. Regurgitation from megaesophagus
III. The muscles affected most commonly are those of the thoracic limbs, neck, esophagus, and pelvic limbs.

Diagnosis

I. Suspicion of polymyositis is initially based on clinical signs and a normal neurological examination.
II. Elevated serum CK is an inconsistent finding.
III. EMG may demonstrate generalized spontaneous electrical activity in affected muscles; however, if the disease is diffuse, it may be hard to localize testing sites.
IV. Muscle biopsy can be guided by EMG studies and usually reveals characteristic changes.
   A. Myofiber necrosis and phagocytosis
   B. Vacuolization and hyalinization
   C. Mononuclear infiltrates: lymphocytes, plasma cells
V. Serological testing for antimyosin antibodies is the definitive test, but is not positive in all cases.
VI. Antinuclear antibody assays and lupus erythematosus (LE) cell preparations may be positive, especially in cases with SLE.

Differential Diagnosis

I. Other immune-mediated disorders
   A. SLE
   B. Myasthenia gravis
   C. Polyarthritis
   D. Polyarteritis
II. Masticatory myositis
III. Polyneuropathies
IV. Infectious myopathies
V. Dermatomyositis
VI. Leptospirosis

Treatment and Monitoring

I. Immunosuppressive treatment is indicated.
   A. Prednisone is started at 1 to 2 mg/kg PO BID for 3 to 4 weeks, then tapered over 2 to 3 months.
   B. If the response to prednisone is poor, side effects are intolerable, or the drug cannot be tapered without relapses, then the following can be added:
      1. Azathioprine 2 mg/kg PO SID (dogs only), tapered once in remission
      2. Cyclophosphamide 1 to 2 mg/kg PO SID for 4 days on, 3 days off, for up to 3 weeks
II. Relapses are common with premature tapering or withdrawal, and some dogs require prolonged therapy.
III. Despite marked inflammation of muscles, regeneration, recovery, and reversal of fibrotic changes are possible in some dogs (Salvadori et al., 2005).
IV. Prognosis is guarded in cases with megaesophagus and SLE.

Dermatomyositis

Definition and Cause

I. It is an immune-mediated disease of dogs that causes inflammation of both skin and muscles.
II. The condition is familial in the Shetland sheepdog and collie, and may be an autosomal dominate trait with variable expressivity.
III. The disease also occurs in the Beauceron shepherd dog and possibly the Welsh corgi.

Clinical Signs

I. Onset is usually <6 months of age.
II. Alopecia, erythema, and scaling occur over areas of mechanical trauma, such as the muzzle, lips, tip of tail, around the eyes, pinnae, carpi, tarsi, and feet.
III. Pruritus of skin lesions is variable and may be related to secondary infections.
IV. Myositis may result in difficulty swallowing and chewing, a stiff gait, and reluctance to walk.
V. Regurgitation from megaesophagus may be noted.
VI. Severity of signs is variable, and signs may wax and wane.

Diagnosis

I. A combination of dermatological and myological signs, in a predisposed breed, is highly suggestive of the condition.

II. A serum biochemistry profile may reveal hyperglobulinemia and elevated CK.
III. Skin biopsy reveals the following:
  A. Follicular atrophy and perifollicular fibrosis
  B. Hydropic degeneration, apoptosis of basal cells
  C. Intrabasilar or subepidermal clefting
  D. Vasculitis
IV. Muscle fiber necrosis, atrophy, and inflammation are demonstrated on histopathology.
V. EMG shows positive sharp waves and fibrillation potentials in affected muscles of the head and limbs.
VI. Markers for the affected gene have been identified, making future genetic screening a possibility (Clark et al., 2005).

Differential Diagnosis

I. Other immune-mediated skin diseases: pemphigus complex, discoid lupus, vasculitis
II. Other immune-mediated myopathies: polymyositis, masticatory myositis

Treatment and Monitoring

I. Spontaneous resolution is possible in mildly affected dogs.
II. Minimize ultraviolet light exposure and trauma to affected areas.
III. Symptomatic therapy with topical sun blockers may be helpful.
IV. Pentoxifylline 25 mg/kg PO BID has induced partial and complete responses in some dogs (Rees and Boothe, 2003).
V. Vitamin E 200 to 800 IU PO BID to TID may be given for 2 to 3 months.
VI. Prednisone at 1 to 2 mg/kg PO SID may be tried for severe or unresponsive cases.
VII. Secondary skin infections are treated with appropriate antibiotics.
VIII. Prognosis is highly variable and related to the severity of the clinical signs.

NUTRITIONAL DISORDERS

Nutritional Myodegeneration

Definition and Causes

I. Nutritional myodegeneration resembles white muscle disease of large animals and is occasionally seen in dogs.
II. It has been produced experimentally by feeding selenium and vitamin E–deficient diets.

Clinical Signs

I. Generalized weakness
II. Difficulty rising, stiff gait
III. Swollen muscles
IV. Paraparesis
V. Dysphagia, dysphonia
VI. Sudden death in puppies with myocardial lesions

Diagnosis

I. History of abnormal diet
II. Elevated serum muscle enzymes
III. Abnormal findings on EMG
  A. Myopathic potentials
  B. Positive waves
  C. Fibrillation potentials
  D. Bizarre, high-frequency discharges
IV. Histopathologic abnormalities
  A. Pale muscles, with chalky longitudinal striations
  B. Myonecrosis, calcification of fibers, fiber regeneration and inflammation

Treatment and Monitoring

I. Supplement with selenium and vitamin E at 100 to 400 IU PO BID until the dog is clinically normal.
II. Correct the dietary abnormality.
III. Prognosis is usually poor if cardiac, diaphragmatic, and intercostals muscle are involved.

NEOPLASIA

Definition and Causes

I. Primary tumors of striated muscle
  A. Rhabdomyoma (Clercx et al., 1998; O'Hara et al., 2001)
  B. Rhabdomyosarcoma (Ginel et al., 2002)
  C. Primary skeletal muscle lymphoma (Harkin et al., 2000; Bennett et al., 2005)
  D. Common sites: appendicular muscles, larynx, muscles of head, heart
II. Metastatic (secondary) spread of tumors from distant sites
  A. Lymphoma
  B. Adenocarcinomas
  C. Hemangiosarcoma
  D. Malignant melanoma
III. Invasion of tumors in adjacent tissues
  A. Fibrosarcoma
  B. Osteosarcoma
  C. Mast cell tumor
  D. Hemangiopericytoma

Clinical Signs

I. Variable age of onset
II. Nonpainful swelling in affected muscle group
III. Lameness common when appendicular muscles affected

Diagnosis

I. Biopsy and histopathology are required for a definitive diagnosis.
II. Thoracic radiography and local lymph node biopsy are performed to stage the disease.

Treatment and Monitoring

I. For primary tumors, wide surgical excision is attempted to obtain clean surgical margins.
  A. Wide excision is often difficult.

Text continued on p. 814.

TABLE 82-2

Traumatic Muscle Injuries

INJURY	CAUSES AND PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Thoracic Limb					
Rupture of the serratus ventralis	Acute trauma, although also presented as chronic injury Reported in the dog and cat	Upward displacement of the scapula with forelimb lameness Usually unilateral	Clinical signs and history	Acute injuries are treated conservatively with a shoulder sling or other non–weight-bearing bandage for 3-4 wk Chronic injuries may require surgical repair of the muscle or fixation of the scapula to the ribs using wire Very good prognosis	Bloomberg (1995)
Disruption of the tendon of origin of the biceps brachii	Avulsion: acute trauma Avulsion of tendon of origin from the supraglenoid tubercle in young large-breed dogs (4-8 mo of age) Displacement: repetitive injury Medial displacement of the tendon of origin from the intertubercular groove in the racing greyhound; also reported in the miniature poodle and border collie	Weight-bearing lameness: acute for avulsion, chronic for displacement Pain on flexion and extension of the shoulder	Clinical signs and radiographs Avulsion: avulsed segment of bone (supraglenoid tubercle) may be seen on radiographs Displacement: palpation of medial displacement of the tendon during flexion of the shoulder or during extension of the elbow with the shoulder held in partial flexion	Avulsion: surgical reattachment of the tendon (pin and tension band or screw) associated with a good prognosis Displacement in athletic animals: surgical reconstruction of the intertubercular ligament using screws and figure-of-eight suture across the tendon as it sits in the groove Displacement in sedentary animals: rest and administration of anti-inflammatory drugs possibly successful Displacement with surgical stabilization has a good prognosis for return to function and fair prognosis for return to racing	Boemo and Eaton-Wells (1995)

Modified from Davidson JR, Hosgood G: Disease of muscles and tendons. p. 806. In Morgan RV, Bright RM, Swartout MS (eds): Handbook of Small Animal Practice. 4th Ed. WB Saunders, Philadelphia, 2003; with permission.

Traumatic Muscle Injuries—*cont'd*

INJURY	CAUSES AND PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Tenosynovitis of the biceps brachii tendon	Unknown, but likely secondary to trauma, overuse, and repetitive injury Middle-aged or older medium- and large-breed dogs No breed or sex predilection	Usually unilateral, but may be bilateral Intermittent, chronic, or progressive weight-bearing forelimb lameness that worsens after exercise and improves with rest Resistance to flexion and extension of the shoulder	History, clinical signs, and physical examination findings Acute pain elicited when pressure is applied directly to the bicipital tendon during flexion and extension of the shoulder Atrophy of the infraspinatus and supraspinatus muscles Radiographs (including craniodistal-cranioproximal flexed view) may identify dystrophic calcification of the tendon, osteophytes in the intertubercular groove, or a mineralized joint mouse within the tendon sheath Contrast arthrography may demonstrate filling defects along the tendon, adhesions between the tendon sheath and tendon, or joint mice No radiographic changes may be apparent in acute cases Cytological evaluation of synovial fluid consistent with DJD, but may be normal Diagnosis confirmed by exploratory arthrotomy and microscopic examination of biopsied tissue	Acute cases: nonsteroidal antiinflammatory medication with limited activity for 4-6 wk Severe or chronic cases: intrasynovial injection of 10-40 mg methylprednisolone acetate no more than every 2 wk; do not exceed 2 injections; rest for at least 2 wk after injection Arthroscopic tevotomy indicated for refractory cases (dogs that do not improve after 1 or 2 injections of corticosteroids) or for removal of joint mice if identified Prognosis for return to function is generally good	Kramer et al. (2001) Stobie et al. (1995) Wall and Taylor (2002) Esterline et al. (2005)

DJD, Degenerative joint disease.

Continued

TABLE 82-2

Traumatic Muscle Injuries—*cont'd*

INJURY	CAUSES AND PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Mineralization of the supraspinatus tendon	Cause unknown May be initiated by hypoxia of the tendon Mineralization deep in the tendon may cause mechanical irritation of the biceps tendon sheath	Role in causing lameness is unclear May have forelimb lameness or may be asymptomatic Must rule out all other causes of forelimb lameness (OCD, DJD, bicipital tendonitis, elbow pathology, etc.)	Mineralization seen on radiographs—often bilateral Contrast arthrography or arthrocentesis may rule out other causes of shoulder lameness Ultrasonography or nuclear scintigraphy may help differentiate between an actively inflamed tendon and asymptomatic mineralization	Conservative management with rest and nonsteriodal antiinflammatory drugs or local injection of methylprednisolone acetate If no response to conservative management, surgical removal of mineralization may resolve the lameness Mineralization may recur after surgery, but signs do not necessarily recur Therapeutic ultrasound	Kriegleder (1995) Laitinen and Flo (2000)
Rupture of the origin of the long head of the triceps	Typically racing greyhounds Avulsion of the origin from the posterior edge of the scapula	A hollow depressed area posterior and distal to the scapula	Based on clinical signs and history	Conservative management with rest may be sufficient Surgical reattachment of the muscle to the caudal scapula may be required Prognosis for return to racing is fair; same level of racing may not be attained owing to decreased range of motion of the shoulder	
Avulsion of the triceps tendon	Associated with trauma, local corticosteroid injection, or spontaneous avulsion Detachment of the triceps tendon occurs from its point of insertion on the olecranon Immature animals may have avulsion of the proximal epiphysis of the olecranon	Acute injury or chronic lameness Acute non–weight-bearing lameness with pain and reduced range of motion on flexion and extension of the elbow Chronic disruption associated with thickening and fibrosis over olecranon, muscle atrophy of affected forelimb	Based on clinical signs and radiographs Avulsed fragment of bone proximal to the olecranon may be seen on radiographs	Surgical repair of tendon using tension-relieving tendon sutures or reattachment of the olecranon epiphysis using a pin and tension band or screw is indicated Coaptation of the limb for 2 wk with physiotherapy and restricted exercise is advised for a further 3-4 wk Prognosis after acute injury is good, but joint motion may be restricted Prognosis after chronic injury is fair	Anson and Betts (1989) Davies and Clayton-Jones (1982) Gilmore (1984) Liehmann and Lorinson (2006)

OCD, Osteochondritis dissecans.

TABLE 82-2

Traumatic Muscle Injuries—*cont'd*

INJURY	CAUSES AND PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Injury of the flexor carpi ulnaris	Chronic, repetitive injury in racing greyhounds Transverse tears may occur through the tendon of the humeral head The insertion of the ulnar head and a bony fragment may avulse from the accessory carpal bone ("bowed tendon")	Poor performance Mild lameness After repeated injury, swelling and bruising are observed over the accessory carpal bone	Based on clinical signs and history	Transverse tears and avulsions should be surgically repaired Postoperative coaptation is required Prognosis for return to racing after transverse tears of the humeral head is good Prognosis for avulsion of the ulnar head is poor	
Injury to the digital flexor and extensor tendons	Lacerations above or below the metacarpal and metatarsal pads Digital extensor tendon injury is less critical owing to the many anastomoses of the tendon after they branch from the main tendon	Laceration may be accompanied by profuse hemorrhage Postural changes: superficial digital flexor injury alone may result in little change; deep digital flexor tendon injury results in flattening of one or more digits Chronic injury may result in excoriation of the metacarpal or metatarsal pads owing to prolonged postural changes	Based on clinical signs and surgical exploration of the laceration site Pressure, using the palm of the hand, on the bottom of the pads may allow detection of any postural change in the digits	Surgical repair is required if there are postural changes Coaptation is indicated if there are no postural changes Prognosis for acute injuries is good Prognosis for chronic injuries is poor owing to fibrosis and the inability to anastomose the tendon if there are extensive deficits	Williams et al. (1997)
Carpal laxity syndrome	Cause is unknown May be discrepancy in rate of growth between extensor and flexor muscle groups Reported in German shepherd dogs, boxers, Great Danes	Unilateral or bilateral carpal hyperflexion or hyperextension in puppies (<16 wk old)	Based on signalment and clinical signs	Exercise on grass Avoid use of splints Condition usually improves in 2-6 wk	Alexander and Early (1983) Shires et al. (1985)
Pelvic Limb					
Injury to the tensor fascia lata	Injury of racing greyhounds Tearing of the musculotendinous junction Most often the left rear leg of dogs racing in the United States	Weight-bearing lameness Palpable and visible depression in the proximal cranial area of the thigh	Based on clinical signs and palpation of thigh depression	Surgical repair is indicated Prognosis for return to racing after primary repair is good	

Continued

TABLE 82-2

Traumatic Muscle Injuries—*cont'd*

INJURY	CAUSES AND PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Rupture of the gracilis muscle	Injury of the racing greyhound, but also seen in working dogs Exact cause is unknown; sudden exercise in an unfit animal may predispose to injury Substantial hemorrhage can occur Unilateral injury is more common	Ventral displacement of the origin (or dorsal displacement of the insertion) is observed and palpated on the inside of the thigh Significant bruising over the inside of the thigh Pelvic limb lameness and difficulty rising, particularly 12-24 hr after the injury	Based on clinical signs and palpation of the muscle avulsion	Surgical repair or reattachment of the avulsed tendon to the bone may be indicated if return to racing is desired Prognosis for return to racing is fair Fibrosis at the surgical site may restrict motion	Eaton-Wells (1992)
Quadriceps contracture	Associated with inadequate fracture repair, osteomyelitis, severe trauma, or overzealous tissue handling Adhesions form between the quadriceps muscle and the femur Usually occurs in young animals Prolonged immobilization of the hind leg in extension or failure to bear weight soon after internal fixation may also be factors Also reported as a congenital disorder and in association with toxoplasmosis Disuse osteoporosis, irreversible DJD of the stifle, and growth disturbances can occur (hip luxation, bone hypoplasia, increased femoral torsion, medial patellar luxation, and limb shortening)	Pelvic leg held with the stifle and hock stiff in extension May be non–weight-bearing or use the leg as a peg leg The affected leg is held cranial with respect to the other hind leg Later clinical signs, if left untreated, include atrophy of the thigh muscles, bending of the stifle caudally in genu recurvatum with the hock extended, proximal positioning or medial luxation of the patella, and subluxation of the hip	Based on history and clinical signs In chronic cases, radiographs may reveal changes consistent with DJD of the stifle, hip luxation, or disuse osteoporosis of the long bones	Surgery is indicated to attempt to restore stifle joint mobility; adhesions between the quadriceps muscles and the femur are broken down and the stifle is flexed carefully to release any remaining fibrous tissue (excessive force could result in a Salter fracture of the distal femur or proximal tibia) Sliding myoplasty or Z-myoplasty of the quadriceps may be indicated Postoperative maintenance of stifle flexion using a 90-90 flexion sling, a Robinson sling, or an external pin splint for 4-5 days is indicated Physical therapy is also required Results are unpredictable; surgery may result in 50%-75% restoration of limb use If surgery is unsuccessful or there is advanced osteoarthritis of the stifle joint, stifle arthrodesis or amputation may be required	Bardet and Hohn (1984) Liptak and Simpson (2000)

TABLE 82-2

Traumatic Muscle Injuries—*cont'd*

INJURY	CAUSES AND PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Quadriceps contracture—*cont'd*				Prevention of this condition is preferable; femoral fracture repairs in young animals should be stable and allow early return to function Animals exhibiting signs of hyperextension following femoral fracture repair should have a flexion sling or dynamic flexion apparatus applied	
Disruption of the tendon of origin of the long digital extensor	Traumatic avulsion of the tendon of origin occurs in immature, large-breed dogs Displacement of the tendon occurs in young dogs	Avulsion causes mild weight-bearing lameness and pain on manipulation of the affected stifle Lateral soft tissue swelling may be present Displacement causes chronic, mild, weight-bearing lameness	Based on clinical signs and radiographs Radiographs may show avulsed bone and cartilage near the extensor fossa of the lateral femoral condyle, best observed on the lateral projection In a very young dog, the portion of bone may consist primarily of cartilage and not be visible on radiographs Diagnosis is confirmed by advanced imaging or exploratory arthrotomy Displacement can be palpated during extension and flexion of the stifle, which allows detection of the tendon moving in and out of the muscular groove	Surgical reattachment of the avulsed segment using bone screws is the treatment of choice Prognosis for return to function after acute injuries is good to excellent For displacement, surgical stabilization of the tendon by reconstruction of the supporting retinacular tissue, use of a staple to make a roof over the tendon, or tenotomy and transplantation of the tendon to the craniolateral aspect of the proximal tibia (as a last resort) is indicated Prognosis after surgery for displacement is variable	Fitch et al. (1997)

Continued

TABLE 82-2

Traumatic Muscle Injuries—*cont'd*

INJURY	CAUSES AND PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Avulsion of the lateral or medial head of the gastrocnemius muscle	Trauma Reported in the fox terrier, German shepherd dog, Labrador retriever	Weight-bearing lameness and soft tissue swelling over the caudal aspect of the stifle are apparent Hyperflexion of the stifle and hock is present	Based on clinical signs and radiographs revealing caudal and distal displacement of the fabella	Surgical reattachment of the tendon Prognosis for acute injuries is good	Robinson (1999)
Avulsion of the tendon of the popliteal muscle	Trauma	Weight-bearing lameness and soft tissue swelling over the lateral aspect of the stifle	Based on clinical signs and radiographs, which reveal displacement of the popliteal sesamoid bone and possibly a bony fragment from the lateral femoral condyle, positioned caudal to the point of attachment of the popliteal tendon	Surgical reattachment of the tendon Prognosis for acute injuries is good	Tanno et al. (1996)
Disruption of the Achilles mechanism (common calcaneal tendon, composed of three major musculotendinous units: (1) gastrocnemius muscle, (2) superficial digital flexor and (3) common tendon of the biceps femoris, semitendinosus, and gracilis muscles)	Rupture occurs primarily in mature working or racing dogs Injury has also been reported in cats Result of an animal jumping and landing on its rear legs May be bilateral Rupture secondary to parasitic disease of the gastrocnemius muscle also reported Disruption of the connective tissue over the superficial digital flexor tendon causes displacement of the tendon during weight bearing	Tarsal hyperflexion (<90°) and stifle hyperextension owing to the inability to extend the tarsus Degree of tarsal hyperflexion depends on the completeness of Achilles mechanism disruption The animal walks on the plantar surface of the tarsus Displacement of the superficial digital flexor tendon is associated with a mild, chronic, weight-bearing lameness with the hock slightly hyperflexed, but not to the same degree as with complete calcaneal tendon disruption	Clinical signs of tarsal hyperflexion and palpable flaccidity of the calcaneal tendon If the superficial digital flexor tendon is intact, the digits will flex when the tarsus is flexed Standing or stress radiographs may aid diagnosis, particularly in partial ruptures, because the entire tendon must be disrupted before excessive tarsal hyperflexion is present Ultrasonography may help localize the site of injury	Acute damage requires tenorrhaphy, or apposition of the muscle–tendon or tendon–bone junction Chronic rupture or injury can be treated by shortening the calcaneal tendon to reestablish function Prognosis for acute rupture or severance of the Achilles mechanism in most animals is good Prognosis in very large dogs, or in racing dogs for return to racing, is poor Prognosis for chronic injuries with fibrosis is less favorable, although function may be improved after surgery	Mauterer et al. (1993) McNichols et al. (2000) Reinke et al. (1993) Rivers et al. (1997) Mughannam and Reinke (1994) Parker and Cardinet (1984) Kramer et al. (2001) Moores et al. (2004) Ridge and Owen (2005) Nielson and Pluhar (2006)

TABLE 82-2

Traumatic Muscle Injuries—*cont'd*

INJURY	CAUSES AND PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT AND PROGNOSIS	REFERENCES
Disruption of the Achilles mechanism—*cont'd*		Tissue thickening around the tuber calcanei may be apparent	Displacement of the superficial digital flexor tendon is diagnosed on clinical signs, and by palpation of the tendon and thickened tissue to one side of the tuber calcanei	Arthrodesis of the tibiotarsal joint may be required if surgical repair is unsuccessful Prognosis for normal function after surgical stabilization of the superficial digital flexor tendon is very good	
Compartment syndrome	Interstitial pressure is elevated within a closed fascial compartment Causes of increased pressure include increased compartment volume (hemorrhage), post-ischemic tissue swelling, or external pressure (tight bandage)	Nonresolving swelling, pain, tense muscle Occurs in the craniolateral crural, caudal crural, caudal anterbrachial, and femoral compartments	Measure compartmental pressure with a catheter Contrast arteriography	Surgical decompression by fasciotomy	de Haan and Beale (1993) Radke et al. (2006) Bar-Am et al. (2006)

B. Amputation may be required for appendicular neoplasia.

II. In cases of metastatic or locally invasive neoplasia, treatment depends on the primary tumor.

III. Prognosis is related to whether the tumor is primary or secondary, the feasibility of complete excision, and the tumor's responsiveness to adjunctive chemotherapy or radiation therapy.

CHAPTER 83

Physical Therapy and Rehabilitation

Robert A. Taylor

GENERAL CONSIDERATIONS

Initial Assessment

I. Both the initial and subsequent physical assessments of the injured or affected body part are vital for developing physical therapy and rehabilitation plans and for providing an objective parameter to assess recovery and response.
II. Such parameters include weight-bearing status, limb circumference measurements, and determination of joint range of motion, in addition to a complete history and physical examination.

History

I. The nature of the injury, when it occurred, positive identification of the affected limb or body part, preexisting medical conditions
II. Methods of treatment already administered, including any surgical treatments
III. Response to previous conservative or surgical treatment
IV. Frequency of recurrence, any current supplements or nonprescription drug therapy

Physical Examination

I. A full orthopedic evaluation and a baseline neurological examination are conducted.
   A. Physical findings should match the diagnosis.
   B. For example, a dog with a 6-week-old, cranial cruciate ligament (CCL) injury typically has partial weight-bearing lameness, evidence of synovial effusion, medial buttressing, and instability.
   C. If the dog has non–weight-bearing lameness for 2 weeks, then other diagnostic considerations must be entertained.
II. The degree of muscle atrophy and decreased range of motion can help determine the chronicity of the injury and the length of time necessary for physical therapy and rehabilitation.
   A. In general, if an injury has been untreated with physical therapy for 6 weeks, then at least 12 weeks of therapy will be necessary.
   B. With an acute CCL injury, synovial and cartilage changes are evident by 3 to 4 weeks; muscle atrophy continues for at least 6 weeks.
III. Long-standing muscle atrophy, joint atrophy, and diminished weight bearing and range of motion result in the need for prolonged physical and rehabilitation therapy.
IV. Neurological and/or oncologic issues may mimic orthopedic problems, and they must be excluded during the diagnostic efforts.
V. See Table 83-1 for a list of common conditions to be ruled out by the clinician.

Monitoring of Progress

I. Response or lack of response to therapy is important.
II. Before beginning therapy, the clinician must have clearly delineated goals and measurable parameters of success.
   A. For example, goals that might be achievable when treating a postoperative case of CCL stabilization would include full range of motion, normal gait, full restoration of muscle mass, and return to function by 12 to 14 weeks.
   B. Achievable goals after physical therapy and rehabilitation for bilateral femoral head and neck osteotomy include pain-free range of motion and restoration of gluteal muscle strength.
III. If the animal's response to physical therapy and rehabilitation is inconsistent with expected results, then the clinician should reconsider the diagnosis.
   A. For example, a dog recovering from CCL stabilization should be ambulatory at a walking gait 4 weeks after surgery.
   B. By the sixth week of therapy, a persistent nonweight-bearing lameness and lack of progress regarding muscle mass restoration indicate the need for confirmation of diagnosis and evaluation of the lack of response to the physical therapy.

TYPES OF PHYSICAL THERAPY

Heat Therapy

Definition

I. Heat therapy is the application of a heat source to a body part.
II. Heat may be applied via direct transfer from a hot-water bottle, warmed fluid packs, ultrasound techniques, and diathermy.

TABLE 83-1

Common Conditions of the Pelvic Limbs That May Benefit from Physical Therapy

BODY LOCATION	COMMON CONDITIONS
Digits, pads, feet	Paronychia Lacerations of the interdigital skin or foot pads Luxations of the interphalangeal joints Luxations of the tarsometatarsal joint Fractures of the metatarsal bones Fractures of the phalanges Fractures of the sesamoid bones
Tarsus	Osteochondritis dissecans of the talus Fracture of the calcaneus Fracture of the central tarsal bone Fracture of the third or fourth tarsal bones Luxations of the tarsus with damage to the short or long tarsocrural ligaments Osteoarthritis Disruption of the common calcaneal tendon Rupture of the plantar ligaments
Tibia and fibula	Fractures of the tibia and fibula Panosteitis Traumatic periostitis Osteosarcoma
Stifle	Cranial cruciate ligament rupture Osteochondritis dissecans of the femoral condyles Injuries to the medial/lateral collateral ligaments Medial/lateral patellar luxation Medial/lateral meniscal damage Fractures Congenital absence of the patella Caudal cruciate ligament disruption Osteoarthritis
Femur	Fracture of the femur Panosteitis Osteosarcoma
Coxofemoral joint	Hip dysplasia Fracture of the acetabulum Fractures of the femoral head or neck Fracture/separation of the proximal capital femoral physis Legg-Calvé-Perthes disease Traumatic luxation of the coxofemoral joint Osteoarthritis

Reprinted with permission from Taylor RA: Orthopedic and neurologic evaluation. p. 185. In Millis DL, Levine D, Taylor RA (eds): Canine Rehabilitation and Physical Therapy. Elsevier Saunders, St. Louis, 2004.

Effects

I. Increases regional blood flow
II. Elevates pain threshold
III. Accelerates resolution of inflammation
IV. Causes vasodilation from stimulation of cutaneous thermoreceptors and the release of vasoactive peptides
V. Accelerates the rate of biochemical reactions
VI. Increases extensibility of collagenous tissues

Indications

I. Heat therapy is recommended after resolution of acute inflammation.
   A. In most orthopedic cases, heat therapy is used 2 weeks after surgery (after suture removal).
   B. Heat application is used after femoral head and neck excision, beginning the third postoperative week.
II. Application of heat to a body part or limb can enhance vasodilation as well as venous and lymphatic drainage.
III. Heat can be used after joint surgery to increase the extensibility of collagenous tissues and help regain joint range of motion.

Application Recommendations

I. Heat is usually applied during the second or third week after surgery or trauma.
II. Periincisional heat may be applied QID for 10 minutes.
III. When using heated water, care must be taken to avoid excessive temperatures (>42.2° C [108° F]).
IV. To avoid burns, do not use heat that is uncomfortable when placed on a human forearm.

Cautions and Contraindications

I. Superficial (or deeper) burns are easy to create with overaggressive use of heat.
II. Hot packs must be checked for leaks or thermal hot spots to avoid burning the animal, especially if heat is used while the animal is anesthetized, sedated, or has diminished nociception.
III. Avoid heat in the early phases of inflammation, because it may exacerbate edema and increase periincisional pain.
IV. Contraindications include use of heat on limbs or body parts with decreased sensation, during the first postoperative week, and when the animal does not tolerate the heat.

Cryotherapy

Definition

I. Cryotherapy is the application of cooling agents to regional areas of the body.
II. Cooling of tissues can be achieved by the local use of ice or ice packs, certain types of cryogens, or circulation of a coolant agent in a blanket or booty placed on the extremity.

Effects

I. Decreases blood flow via vasoconstriction
II. Decreases nerve conduction velocity of nociception fibers and can provide analgesia
III. Decreases pain and inflammation

IV. Increases tissue viscosity and stiffness
V. Effects mediated through decreased metabolism and local vasoconstriction

Indications

I. It may be used within the first 10 to 14 days of an injury or surgery to combat acute inflammation.
   A. Periincisional cooling for 7 to 10 days after surgery
   B. Regional cooling after joint manipulation
   C. Regional application over tendons and ligaments during physical therapy and rehabilitation
II. It can be used in emergency care for burns (see Chapter 134).
III. Cryotherapy provides postoperative analgesia and is used to reduce pain after joint mobilization procedures.

Application Recommendations

I. Ice packs are applied to periincisional tissues for 10 minutes QID for the first postoperative week.
II. A neoprene booty that cools via a refrigerant pumped through a network of tubes can reduce the need for postoperative analgesia after stifle surgery.

Cautions and Contraindications

I. Avoid excessive cryotherapy in regions of decreased sensation
II. Limit duration of cryotherapy to 20 minutes; thermal washout and reflex vasodilation will rewarm peripheral tissue within 20 minutes.

Passive Range-of-Motion Exercise

Definition

I. Exercise is often the mainstay of physical therapy.
   A. Exercise may involve active or passive activities.
   B. In most instances, the application of active "open-chain" activities, such as cycling, to animals is difficult, so most active therapeutic exercise involves "closed-chain" activities.
   C. Closed-chain activities usually revolve around normal canine activities such as sitting, standing, walking, trotting, or swimming.
II. Passive range of motion is an exercise activity that passively moves a joint through its normal arc of motion.
   A. In many acute or chronic problems, the range of motion is limited.
   B. After surgery of the extremities, passive range-of-motion exercises are a vital part of the immediate postoperative care.
   C. Such exercises are performed without active muscle contractions and are done to the limit of the animal's tolerance for motion.

Effects

I. Helps reduce loss of range of motion after extremity surgery
II. Helps mobilize tissue edema
III. Stretches ligaments, tendons, and joint capsules at the beginning and end of the available range of motion
IV. Decreases postoperative pain

Indications

I. Dogs recovering from CCL surgery receive 10 to 15 minutes of passive range-of-motion exercises three to four times daily.
II. Dogs recovering from cubital joint arthroscopy for fragmented coronoid removal receive passive range-of-motion exercises 10 to 15 minutes four to six times daily.
III. Early attention to passive range of motion minimizes the risk of joint contracture.

Application Recommendations

I. Passive range-of-motion exercises are done for 10 minutes QID, beginning the first day after joint or extremity surgery.
II. The affected limb is gently grasped while the dog is in a comfortable position.
   A. The joint is either flexed or extended, unless the joint is resistant or painful.
   B. The extremity is held in this position for 30 seconds and then moved in the opposite direction.
   C. At no time are vigorous manipulations done that create pain or discomfort for the dog.

Cautions and Contraindications

I. Passive range-of-motion exercises are contraindicated after unstable fixation of fractures, immediately after total joint replacement surgery, and after certain skin-grafting procedures.
II. Avoid overzealous motion after total elbow replacement, extensive skin-grafting procedures, or when extensive tension-relieving sutures are used for wound closure.

Therapeutic Exercise

Definition

I. Therapeutic exercise is active, participatory exercise done to improve muscle health and redevelopment, extend the range of motion of joints, and improve tissue atrophy.
II. The method and application of therapeutic exercise is customized based on the animal's needs and the resources of the hospital and staff members.
III. Treadmill walking involves the use of conventional treadmills for rehabilitation and physical therapy.
IV. Aquatic therapy involves the use of water as a medium for physical therapy.
   A. Its physical nature provides buoyancy of the animal's body, resistance to movement, and compression to body soft tissues.
   B. These properties can be exploited to provide earlier therapeutic exercise.
   C. Its resistance and viscosity provide resistance to motion and can be used to stimulate muscle contractions.

Effects

I. Treadmills are useful for patterning gait and to encourage early, postoperative weight bearing.
   A. The movement of the belt encourages the dog to walk.
   B. Activity may be awkward at first, but most dogs quickly acclimatize to its motion.

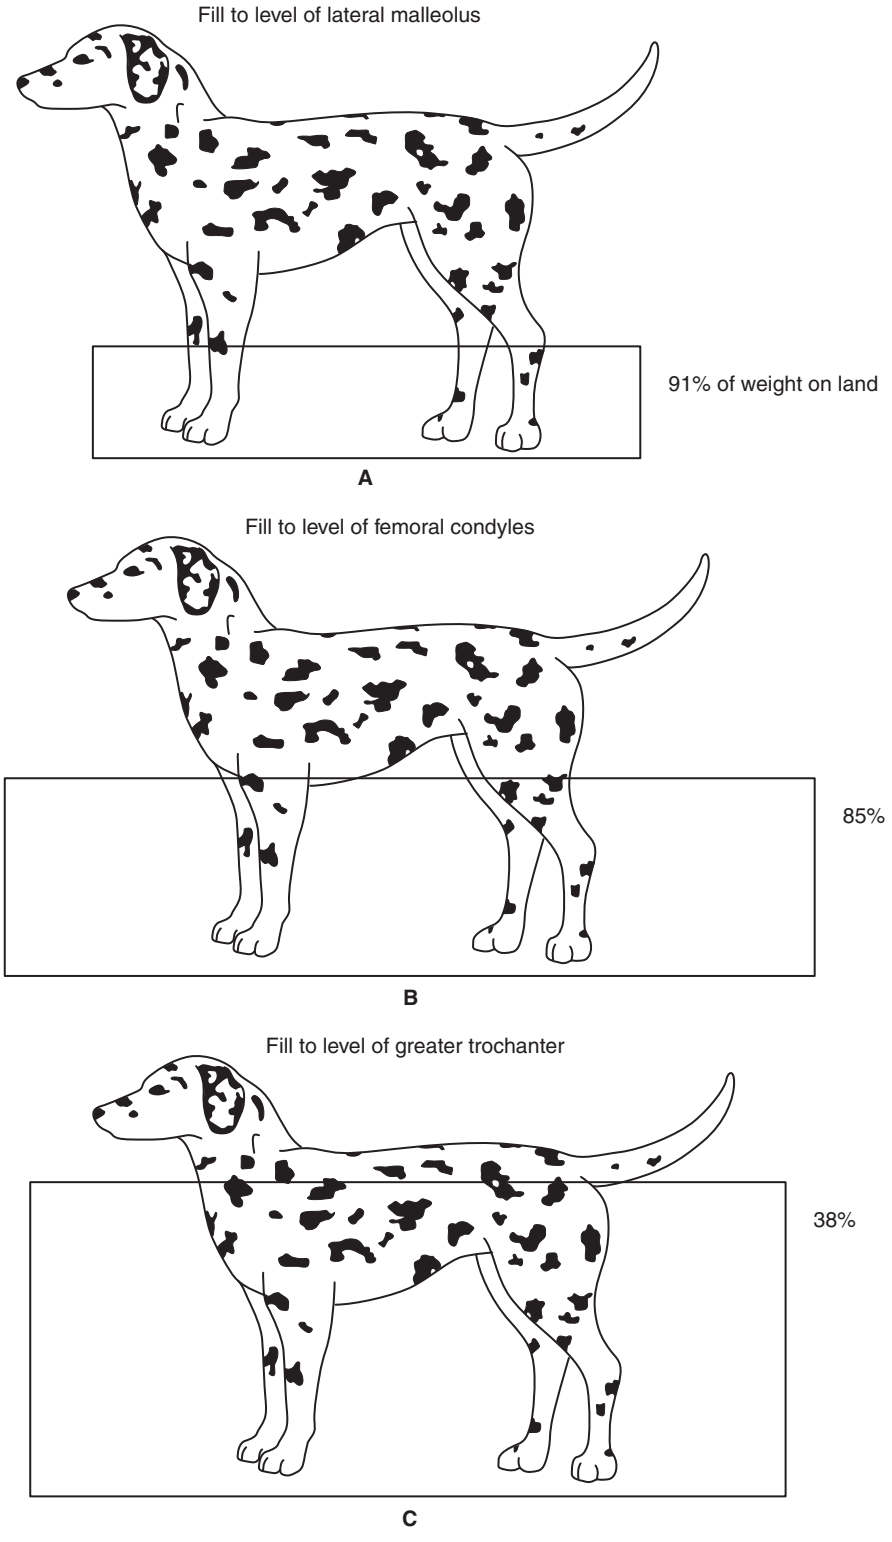

FIGURE 83-1 Dogs in water to the level of the lateral malleolus (**A**), lateral epicondyle (**B**), and greater trochanter (**C**), illustrating the amount (percent) of weight displacement that occurs with different levels of water. *Reprinted with permission from Taylor RA: Aquatic therapy. p. 265. In Millis DL, Levine D, Taylor RA (eds): Canine Rehabilitation and Physical Therapy. Elsevier Saunders, St. Louis, 2004.*

II. Aquatic therapy involves the use of water as a medium for physical therapy.
   A. Its physical nature provides buoyancy of the animal's body, resistance to movement, and compression to body soft tissues (Figure 83-1).
   B. These properties can be exploited to provide earlier therapeutic exercise.
   C. Water provides resistance to motion and can be used to stimulate muscle contractions.

Indications

I. Indications for treadmill exercise
   A. Treadmill exercise is used to restore muscle mass and full range of motion after most types of orthopedic procedures.
   B. It can be more effective than leash walking because the grade and speed of the treadmill can be adjusted to the animal.
   C. Specific indications include the following:
      1. Extremity surgery: cruciate surgery, total joint replacement
      2. Neurological and orthopedic surgery: intervertebral disc disease
      3. Fitness and agility training
      4. To provide strengthening in certain types of neuromuscular or orthopedic diseases

II. Indications for aquatic exercise
   A. Aquatic therapy increases strength and endurance, improves range of motion of joints, enhances the well-being of the animal, improves agility, and can reduce pain.
   B. Using the natural buoyancy of water allows for earlier weight bearing after trauma or surgery.
   C. Specific indications include the following:
      1. Certain orthopedic conditions: fracture repair, repair of CCL rupture, total hip replacement, treatment of tendonitis
      2. Certain neurological conditions: fibrocartilaginous emboli, intervertebral disc disease, polymyopathy, polyneuropathy, after repair of vertebral fractures or luxation

Application Recommendations

I. Beginning 3 to 6 weeks after CCL stabilization, level-grade treadmill walking is started at a speed of 1.5 miles per hour for 15 minutes and is gradually increased over the next 4 to 6 weeks.
II. Free swimming may be started after shoulder surgery for osteochondrosis.
III. Underwater treadmill therapy is useful after total hip replacement and CCL stabilization surgery.

Cautions and Contraindications

I. Treadmill exercise: unstable extremity fractures, fractious or unruly animals
II. Aquatic exercise: fear of water, open wounds, presence of external fixators, concurrent cardiovascular diseases, unstable diabetes mellitus

CHAPTER 84

Introduction

Rosanna Marsella

ORGANIZATION

I. This section is designed with a problem-based approach in mind.
II. The most common primary lesions, clinical presentations, and pertinent differential diagnoses are discussed.
III. When overlap exists between clinical disorders (i.e., the same disease may have multiple types of lesions), the reader is referred to another chapter for additional information.

HISTORY

I. Many lesions in dermatology are nonspecific (e.g., alopecia secondary to pruritus, scaling), so a through history is necessary to appropriately rank differential diagnoses.
II. It is important to note the age of onset and whether the disease has changed over time.
   A. Sudden-onset pruritus in a geriatric animal raises the concern for diseases other than allergies (e.g., cutaneous lymphoma), because allergies are more likely to develop in younger animals.
   B. Sudden-onset, intense pruritus in a very young animal raises the suspicion of diseases such as scabies, food allergy, and flea allergy, because they can affect animals at a very young age.
III. Seasonality of the condition also helps to rule in or rule out diseases.
   A. Animals that are pruritic only on a seasonal basis are more likely to suffer from flea allergic dermatitis or atopic dermatitis secondary to pollens.
   B. Contact allergy from plants that are only present on a seasonal basis is also possible.
IV. It is important to record whether pruritic diseases started with pruritus alone or whether lesions were present before the onset of the pruritus.
V. As the disease progresses, skin lesions commonly change; therefore it is important to know what lesions were present at the beginning of the disease.

DERMATOLOGIC EXAMINATION

I. It is important to examine all areas of the skin including ears, footpads, nails, and mucocutaneous junctions.
II. Attention is focused on the presence and type of primary lesions; often they provide a clue to the underlying disease.
   A. A macule is a circumscribed flat area of color change, and most are either erythematous or hyperpigmented.
   B. A papule is a small elevation of the skin ≤1 cm in diameter.
   C. Plaque is formed when multiple papules coalesce together.
   D. A pustule is a small elevation of the skin that contains purulent material.
   E. A nodule is a small solid elevation of the skin >1 cm that extends in to the deeper layers of the skin.
   F. A vesicle is an elevation of the epidermis that is filled with clear fluid.
   G. A bulla is a vesicle that is >1 cm in diameter.
   H. Secondary lesions evolve from primary lesions; in more chronic cases they may be the only lesions detectable.
   I. Epidermal collarettes are the remnants of pustules and present as a circular rim of scaling.
   J. Crusts are formed when exudate, serum, and/or blood become dried.
   K. Ulcers and erosions develop after the rupture of bullae and vesicles.
   L. Comedones result from plugging of hair follicles with keratin.
   M. Alopecia is often secondary to self-inflicted trauma.

N. Hyperpigmentation is frequently secondary to inflammation and indicates that the acute phase of the inflammatory process has resolved.

III. Distribution of lesions is also important when ranking differential diagnoses.
   A. Patchy hair loss on the trunk is more suggestive of types of folliculitis, such as superficial pyoderma, whereas patchy hair loss on the head and extremities is more suggestive of dermatophytosis and demodicosis.
   B. Pustular eruption primarily affecting the face (periocular region, pinnae, bridge of the nose) is highly suggestive of autoimmune diseases such as pemphigus foliaceous, whereas the same eruption affecting the ventral abdomen is more suggestive of a superficial pyoderma.

IV. Most dogs with skin problems develop secondary infections that may mask the underlying disease.
   A. In many cases the secondary infection must be addressed before the underlying disease can be diagnosed because infections may alter the clinical presentation and changes seen on histopathology.
   B. Once all the lesions have been recorded make a list of differential diagnoses, ranking them accordingly to the index of suspicion.
   C. Proceed with diagnostic tests.
   D. A minimum data base for an animal with skin problems includes a deep skin scraping to rule out demodicosis, cytological examination to investigate the presence of secondary infections and the types of inflammatory cells present, and a dermatophyte culture to rule out dermatophytosis.

CHAPTER 85

Pruritic Skin Diseases

Lisa Akucewich | Nicola Williamson

IMMUNE-MEDIATED DISORDERS

Flea Allergic Dermatitis

Definition and Causes

I. Pruritic, papular dermatitis arising from sensitization to the allergens produced by fleas (Scott et al., 2001c)
II. Follows exposure to fleas
III. No breed or sex predilection
IV. Age of onset: 6 months to 5 years
V. Most often seasonal, but nonseasonal in subtropical or tropical areas

Pathophysiology

I. Flea saliva and whole flea extract contain antigenic substances, including polypeptides, amino acids, aromatic compounds, and fluorescent materials (Scott et al., 2001c).
II. Flea allergic dermatitis arises from an adverse immunological response to the flea saliva (Moriello and Mason, 1995b).
III. It may be both an immediate and a late-phase Type I immunoglobulin (Ig) E mediated hypersensitivity response to flea saliva (Wilkerson et al., 2004).
IV. Type IV hypersensitivity has also been suggested.

Clinical Signs

I. Moderate to severe pruritus
II. Papules, erythema, self-inflicted trauma
III. Most common lesion locations in dogs: tail head, caudal thighs, antebrachial area of forelimbs
IV. Hair loss, excoriation, hyperpigmentation, scaling
V. Signs specific to cats
   A. Head and neck pruritus
   B. Eosinophilic granulomas complex
   C. Miliary dermatitis (Scott et al., 2001c)
VI. Flea feces and fleas: often not evident in cats because of excessive grooming behavior

Diagnosis

I. Suggestive history and physical examination findings, especially lesion distribution
II. Response to flea control
III. Intradermal skin testing with flea extract: false negatives common (Scott et al., 2001c)
IV. Presence of fleas and flea dirt, especially with use of flea comb

Differential Diagnosis

I. Other hypersensitivity reactions: adverse food reactions, atopic dermatitis
II. Drug reactions
III. Infectious diseases: *Malassezia* spp. dermatitis, bacterial folliculitis, dermatophytosis
IV. Parasitic disorders: demodicosis, scabies, cheyletiellosis, pediculosis

Treatment

I. Environmental flea control involves the following:
   A. Adulticides: synthetic pyrethrins (permethrin)
      1. Short-acting, with quick knockdown effect
      2. Toxic to cats in concentrations >0.5%
      3. Can be used indoors and outdoors
      4. Example: indoor room and area foggers
   B. Juvenile hormone analogue (ovicidal and larvicidal)
      1. Methoprene: insect growth regulator
         a. Sensitive to ultraviolet (UV) light, so used only indoors
         b. Example: *Precor 2000 Plus Premise Spray*
      2. Pyripoxyfen: insect growth regulator
         a. UV-light resistant
         b. Used indoors and outdoors
         c. Average duration of efficacy: 4 months
         d. Example: Virbac *Knockout Room* and *Area Fogger*
      3. Fenoxycarb
         a. Stable indoors for up to 40 weeks
         b. Used indoors and outdoors
         c. UV-light resistant
         d. Examples: *Insegan, Logic, Torus, Varikill*
   C. Miscellaneous ovicidal and larvicidal treatments
      1. *Steinernema carpocapsae* nematodes
         a. Biopesticides for outdoor flea control
         b. Flea larvae and pupae killed in grass and soil
         c. Replacement needed every few weeks; do not reproduce or move
         d. Need continuous moisture and shade
         e. Example: *Interrupt* (Veterinary Product Laboratories, Phoenix, Ariz.)

2. Sodium borate
   a. Nontoxic and applied to carpets
   b. Ovicidal and larvicidal by dehydration
   c. Professionally applied product guaranteed for up to 1 year

II. Numerous agents are available for individual flea control.
   A. Adulticides
      1. Fipronil
         a. Applied every 2 to 3 weeks, waiting 24 to 48 hours after bathing or swimming
         b. Examples: *Frontline Plus* (fipronil and methoprene), *Frontline Spray*
      2. Imidacloprid
         a. Applied every 2 to 3 weeks, waiting 24 to 48 hours after bathing or swimming
         b. Examples: Advantage, Advantix (imidacloprid and permethrin)
      3. Permethrin
         a. Applied every 2 to 3 weeks, waiting 24 to 48 hours after bathing
         b. Contains 45% to 60% permethrin
         c. Contraindicated in cats (high permethrin concentration)
         d. Cat and dog contact avoided until product completely dry
         e. Examples: *Bio-spot, Advantix*
      4. Selamectin
         a. Semisynthetic avermectin applied to skin for control of fleas, heartworm, ticks, certain intestinal and surface parasites
         b. Example: *Revolution*
      5. Permethrin 2%: adulticide, repellant
         a. Applied one to two times weekly, applied to a dry hair coat
         b. Used alone or in combination with spot-on treatments
         c. Used cautiously on dogs if cats in same household
         d. Contraindicated in cats (high permethrin concentration)
         e. Example: Virbac *Knockout Pet Spray*
      6. Neonicotinoid insecticides
         a. Act at the nicotinic acetylcholine receptor
         b. Rapidly acting, eliminated after oral administration
         c. Efficacy for 24 to 48 hours
         d. Example: *Capstar*
   B. Insect growth inhibitor: lufenuron
      1. Given monthly
      2. Several months are needed to obtain full benefit
      3. Examples: *Program, Sentinel*

III. Corticosteroids are recommended for short-term use only, in the absence of secondary infections.
   A. Prednisone 1 mg/kg PO SID for 5 days, then reduced to 0.5 mg/kg QOD
   B. Combination of prednisolone 2 mg and trimeprazine 5 mg *(Temaril-P)* (Plumb, 1999)
      1. Capsules given PO SID, and tablets given PO BID.
         a. Dog <5 kg: 1 capsule or 0.5 tablet
         b. Dog ≥5 to 10 kg: 2 capsules or 1 tablet
         c. Dog ≥10 to 20 kg: 4 capsules or 2 tablets
         d. Dog ≥20 kg: 6 capsules or 3 tablets
      2. After 4 days, dose reduced by 50% and adjusted as necessary.

IV. Topical glucocorticoids may be helpful.
   A. Triamcinolone 0.0125% *(Genesis Spray)* is applied SID for 7 days, then QOD and eventually discontinued.
   B. Hydrocortisone 1% *(ResiCORT Conditioner)* is applied one to two times weekly after bathing and not rinsed.
   C. Potential side effects with long-term use include cutaneous atrophy, comedones, demodicosis, calcinosis cutis (Hengge et al., 2006).

V. Weekly lime sulfur dips (4 oz lime dip/gal water) may decrease the pruritus.

VI. Secondary bacterial (see Chapter 86) and *Malassezia* spp. infections are treated accordingly (see Malassezia Dermatitis).

Monitoring of Animal

I. Environmental and individual flea treatments help control the disease, but it cannot be cured.

II. Prognosis is good to excellent with appropriate flea control.

Atopic Dermatitis

Definition and Causes

I. Atopy is a genetically inherited, recurrent, pruritic skin disease that is associated most commonly with IgE antibodies to environmental allergens.

II. Average age of onset is 1 to 3 years (Scott et al., 2001c).

III. Predisposed breeds include the boxer, Chihuahua, Gordon setter, Yorkshire terrier, Cairn terrier, Boston terrier, Chinese shar-pei, Labrador retriever, golden retriever, West Highland white terrier, English setter, Irish setter, English bulldog, American cocker spaniel, pug, Dalmatian, Scottish terrier, Wirehaired fox terrier, miniature schnauzer, Belgian tervuren, Shiba Inu, and Beauceron.

IV. No sex predilection exists.

V. No breed or sex predilection has been demonstrated in cats.

Pathophysiology

I. Type I hypersensitivity develops against environmental allergens.

II. Genetically predisposed dogs percutaneously absorb, inhale, or possibly ingest various allergens that provoke allergen-specific IgE or IgG production (Olivry and Hill, 2001).

Clinical Signs

I. Mild to severe pruritus of ears, face, axilla, feet, ventrum of body

II. Pruritus often generalized

III. Otitis externa common

IV. Secondary pyoderma and *Malassezia* spp. dermatitis common

V. Seasonal to perennial

Diagnosis

I. Diagnosis is often based on history, clinical signs, and the exclusion of other pruritic skin diseases.
II. Positive results on allergy testing are considered supportive.
III. Intradermal skin testing is the preferred method for diagnosis (Scott et al., 2001c), but certain medications must be withdrawn or they interfere with the test.
  A. Antihistamines: 10 to 14 days
  B. Oral and topical steroids: 30 to 45 days
  C. Injectable steroids: 60 days
  D. Oral fatty acids: 10 to 14 days
IV. Serum-based allergy tests have both false-positive and false-negative results.
  A. They are used when intradermal testing is unavailable, in animals in which withdrawal of medications cannot be done, and when sedation is risky.
  B. They are often performed in conjunction with intradermal testing.

Differential Diagnosis

I. Other allergic dermatoses: adverse food reactions, flea allergic dermatitis, contact allergy
II. Parasitic diseases: demodicosis, scabies
III. Infectious diseases: *Malassezia* spp. dermatitis, bacterial folliculitis, dermatophytosis
IV. Drug eruption

Treatment

I. Allergen-specific immunotherapy is preferred.
  A. Mechanism of hyposensitization is complex, several proposed hypotheses.
    1. Humoral desensitization: reduces levels of IgE
    2. Cellular desensitization: reduces reactivity of mast cells and basophils
    3. Immunization: induction of blocking antibody
    4. Generation of allergen-specific suppressor cells
  B. Allergen-specific vaccines are made based on results of the allergy test.
  C. Immunotherapy reduces pruritus, as well as skin and ear infections by 60% to 80%.
  D. It may take up to 1 year to see beneficial results.
II. Antihistamines can be used long term (Scott et al., 2001b).
  A. Diphenhydramine 2.2 mg/kg PO TID (dog)
  B. Chloropheniramine 0.4 mg/kg PO TID (dog) and 2 mg PO BID (cat)
  C. Hydroxyzine 2.2 mg/kg PO TID (dog) and 10 mg PO BID to TID (cat)
  D. Clemastine 0.05 to 0.1 mg/kg PO BID (dog) and 0.67 mg PO BID (cat)
III. Omega-3 fatty acids (docosahexanoic acid 240 mg and eicosapentaenoic acid 360 mg) are given at 1 capsule per 10 kg PO SID in both dogs and cats.
  A. Inhibition of arachidonic acid metabolism and generation of antiinflammatory mediators reduce pruritus.
  B. They are used in conjunction with other therapies.
IV. Antiinflammatory doses of prednisone (0.5 to 0.1 mg/kg PO QOD) are recommended for short-term therapy only, because of the potential cutaneous and systemic side effects.
V. Cyclosporine may control clinical signs in dogs at 5 mg/kg PO SID.
  A. Full effect may not be seen for 4 to 6 weeks.
  B. Pruritus can be controlled at QOD dosing in some dogs.
  C. Side effects include vomiting, diarrhea, gingival hyperplasia, papillomatosis, hirsutism, bacteriuria, nephropathy, bacterial skin infections, involuntary shaking, bone marrow suppression, and lymphoplasmacytoid dermatosis.
VI. Topical therapy for pruritus may also be tried.
  A. Triamcinolone 0.0125%
  B. Hydrocortisone conditioner 1%
  C. Lime sulfur dip
  D. Routine bathing to remove allergens every 7 days
VII. Secondary bacterial and *Malassezia* spp. infections are treated accordingly.
VIII. Individual and environmental flea control is instituted because 80% of atopic dogs also have flea allergic dermatitis (Scott et al., 2001c).

Monitoring of Animal

I. Atopy is a life-long disease and requires long-term management.
II. Control of secondary infections and exposure to fleas is important.
III. Recheck examinations are warranted to minimize flare-ups.

Contact Dermatitis

Definition and Causes

I. Contact dermatitis is an intensely pruritic, macular, papular dermatitis that usually affects sparsely haired skin after exposure to certain allergens.
II. Allergens include shampoos, soaps, topical medications (especially those containing antibiotics), insecticides, carpet, disinfects, and ants (Moriello and Mason, 1995).
III. In the southeastern United States (e.g., Florida), an allergic-contact dermatitis to plants of the Commelinaceae family is common in dogs (Marsella et al., 1996).
IV. No known sex or breed predilection exists.
V. Clinical signs generally occur in animals >6 months of age.
VI. Dogs are affected more often than cats.

Pathophysiology

I. Type IV hypersensitivity reaction is directed against small allergens (haptens) that are in contact with the skin (Marsella et al., 1996).
II. It involves two phases.
  A. Sensitization phase: initial exposure to the substance, without the development of an allergic reaction
  B. Elicitation phase: reexposure of sensitized the animal to the offending substance resulting in dermatitis

Clinical Signs

I. Intense pruritus occurs in areas of contact, especially the ventrum, face, pinnae, and feet (sparsely haired or bare areas).
II. Erythema and papular dermatitis of the ventrum, face, pinnae, and feet may also be noted.

Diagnosis

I. History and physical examination findings may be suggestive.
II. Clinical signs resolve if animal is confined away from the allergen.
III. Reexposure to the allergen leads to recurrence within 48 hours.
IV. Patch testing may be considered (Moriello and Mason, 1995b).
  A. Suspected allergens are applied directly to the skin.
  B. Test substance is suspended in petroleum jelly, applied to shaved skin, and covered with a bandage for 48 to 72 hours.
  C. Test sites are evaluated for erythema, induration, and vesication.
V. Obtain a biopsy of the lesion and submit it for dermatohistopathologic analysis.

Differential Diagnosis

I. Allergic dermatoses: adverse food reactions, flea allergic dermatitis
II. Parasitic diseases: demodicosis, scabies
III. Infectious diseases: *Malassezia* spp. dermatitis, bacterial folliculitis, dermatophytosis
IV. Systemic drug eruption

Treatment

I. Remove allergen from the environment and prevent access of affected animal to identified substances.
  A. Kennel or confine the animal to an uncarpeted room if carpet is suspected.
  B. Walk dogs only on dirt surfaces or paved roads if a contact allergy to *Commelinaceae* spp. is suggested.
II. Consider administering pentoxifylline at 15 to 20 mg/kg PO TID (Marsella et al., 1996).
  A. It is a methylxanthine derivative with immunomodulatory and rheologic effects.
  B. Side effects include gastrointestinal and central nervous system (dose related) signs.
III. Antiinflammatory doses of prednisone (0.5 to 0.1 mg/kg PO QOD) are recommended for short-term relief.
IV. Topical corticosteroid products (see previous discussion under Atopic Dermatitis) may be applied to affected areas.

Monitoring of Animal

I. Recheck animal in 10 to 14 days to evaluate resolution of lesions.
II. Avoid contact with offending allergen.
III. If exposure to allergen is difficult to avoid, continue regular bathing, topical corticosteroids for pruritus, and pentoxifylline 15 to 20 mg/kg PO BID to TID.
IV. Prognosis is excellent if the offending allergen can be avoided.

Adverse Food Reactions

Definition

I. Adverse food reaction (e.g., food allergy, food intolerance) is a nonseasonal, pruritic skin disorder of dogs and cats associated with ingestion of a substance found in the animal's diet (Rosser, 1993).
II. It can manifest as recurring, superficial bacterial infections and/or otitis externa and otitis media (Moriello and Mason, 1995a).
III. See also Chapter 122.

Causes and Pathophysiology

I. Beef, fish, chicken, eggs, and dairy products are the allergens to which dogs and cats most commonly develop adverse reactions.
II. No breed or sex predilection exists.
III. Reactions can occur at any age.
IV. Pathophysiology is unknown.

Clinical Signs

I. No pruritus to intense pruritus: nonseasonal
II. Macules, papules, pustules leading to alopecia, excoriation, scale, and crusts
III. Recurrent ear and skin infections: bacterial, yeast
IV. Gastrointestinal signs (10% to 15%): vomiting, diarrhea, increased frequency of bowel movements (Scott et al., 2001c)

Diagnosis

I. Perform a food trial by feeding a restricted, novel protein diet to which the animal has not been previously exposed (Rosser, 1993).
  A. Nutritionally balanced home-cooked diets are preferred for their lack of preservatives.
  B. Sources of proteins used include venison, rabbit, goat, beans, ostrich, and alligator.
  C. Many diets also contain white potato (see Chapter 122).
  D. Treat all secondary skin infections appropriately.
  E. Average length of food trial is 8 to 10 weeks.
  F. If infections (superficial pyoderma) recur, the diet trial time may require modification.
  G. For example, a 3-week relapse rate of superficial pyoderma may warrant antibacterials and extending the diet trial by approximately 5 weeks.
  H. Potato treats may be given.
II. Eliminate all other treats, including rawhide chew treats.
III. Heartworm prevention is changed from flavored tablets to unflavored tablets or topical selamectin.
IV. Clinical improvement is suggestive of the diagnosis; however, provocative challenge with the original diet is necessary to confirm the diagnosis (Rosser, 1993).

Differential Diagnosis

I. Allergic dermatoses: atopic dermatitis, flea allergic dermatitis, contact allergy
II. Parasitic diseases: demodicosis, scabies
III. Infectious diseases: *Malassezia* spp. dermatitis, bacterial folliculitis, dermatophytosis
IV. Drug eruption

Treatment and Monitoring

I. Avoid the offending food allergen or preservative.
II. Development of new food allergies is rare, but possible.
III. Outcome and prognosis are excellent if the offending allergen is identified and avoided.

INFECTIOUS DISORDERS

Acute Moist Dermatitis

Definition and Causes

I. Local irritation from a primary problem leads to self-trauma, which initiates an itch-scratch cycle (Moriello and Mason, 1995b).
II. No sex or age predilection exists.
III. It is common in animals with flea allergic dermatitis, otitis externa, and otitis media.
IV. Other underlying problems include other ectoparasites, atopic dermatitis, adverse food reactions, contact dermatitis, anal sac disease, and periocular diseases.
V. It is more common in hot and humid weather.
VI. Predisposed animals tend to have a dense undercoat, such as the golden retriever, Labrador retriever, German shepherd dog, and Saint Bernard (Scott et al., 2001a).

Clinical Signs

I. Highly pruritic to painful erosions of the skin surface develop rapidly and are associated with alopecia, exudation, and erythema.
II. Lesions typically affect the tail base area, lateral aspects of hind legs, trunk, neck, and face.
III. Lesions are often solitary, although multiple lesions can occur.
IV. Site affected may be related to the underlying cause.
   A. Lesions associated with flea allergic dermatitis often affect the dorsal rump and base of the tail area.
   B. Lesions associated with otitis externa occur on the neck and head.

Diagnosis

I. Diagnosis is based on history of acute onset and presence of a solitary intensely pruritic lesion.
II. Based on distribution of the lesion, look for the suggested cause.

Differential Diagnosis

I. Superficial pyoderma (bacterial folliculitis)
II. Dermatophytosis
III. Demodicosis

Treatment

I. Identify and treat the underlying cause.
II. Clip the area well, and remove all surface debris by gentle cleansing with dilute antimicrobial solutions (e.g. chlorhexidine, povidone-iodine).
III. Shampoo the area with topical benzoyl peroxide, which is left on for 10 to 15 minutes and then rinsed off; repeat the process two to three times weekly until lesions are resolved.
IV. Topical astringents (aluminum acetate 2% [*Domeboro* solution]) may be helpful.
V. Systemic glucocorticoids are used (see Atopic Dermatitis) to break the itch cycle.
VI. If evidence of folliculitis is noted at the periphery of the hot spot (papules), then systemic antibiotics are indicated for at least 3 weeks.
VII. Further trauma can be prevented by an Elizabethan collar.

Monitoring of Animal

I. Address predisposing factors to eliminate or modify self-trauma (e.g., flea allergic dermatitis, otitis externa).
II. Some dogs may have repeated episodes.
III. Pay attention to regular grooming, hygiene, flea control, and/or ear cleaning, especially during hot and humid weather conditions.
IV. If systemic antibiotic therapy is instituted, recheck the animal in 3 weeks.

Superficial Bacterial Folliculitis (Pyoderma)

See Chapters 86 and 88.

Bacterial Furunculosis

See Chapter 88.

Malassezia spp. Dermatitis

Definition

I. *Malassezia pachydermatis* is a commensal yeast that may overcolonize the skin of dogs.
II. Predisposition is reported in the basset hound, West Highland white terrier, dachshund, American cocker spaniel, English springer spaniel, and German shepherd dog, possibly because they have significantly more yeast on their skin (Matuosek and Campbell, 2002).

Causes

I. Antibiotic therapy may be a predisposing factor.
II. Other predisposing causes in dogs include the following (Matuosek and Campbell, 2002):
   A. Diseases of keratinization: primary seborrhea
   B. Immunosuppression: secretory IgA defects
   C. Endocrine diseases: hypothyroidism (especially Labrador retrievers), hyperadrenocorticism
   D. Possibly atopic dermatitis: role controversial
III. Generalized *Malassezia* spp. dermatitis in cats is usually associated with a systemic disease (e.g., metabolic disease, neoplasia) and is considered a serious finding.

IV. It is more common in the spring and summer, as well as in any months with high humidity.

Pathophysiology

I. For a commensal organism to become a primary pathogen, it must acquire virulence sufficient to overcome normal host defenses.
II. *Malassezia pachydermatis* has a symbiotic relation with commensal *Staphylococcus* spp.
   A. Both agents produce mutually beneficial growth factors.
   B. Growth of *Malassezia* spp. in vitro is enhanced by the presence of staphylococci.
   C. Inhibition of either agent does not inhibit the growth of the other.

Clinical Signs

I. Pruritus is a major and consistent sign.
II. Cats may have a waxy otitis, chin acne, or a generalized scaling dermatosis.
III. In dogs, dermatitis can be localized (external otitis, perianal, muzzle, periocular areas, feet) or generalized.
IV. Face rubbing, head shaking, foot licking, chewing, and scooting may occur.
V. Primary lesions (papules, pustules) are not usually seen unless a superficial folliculitis is also present.
VI. Erythema, lichenification, hyperpigmentation, alopecia, scaliness, and greasiness of the skin are common.
VII. A strong rancid odor (seborrhea-like odor) can occur, especially in dogs.
VIII. Folliculitis, furunculosis, and follicular sebaceous cysts (interdigital cysts) may also develop.

Diagnosis

I. Cytology is the most useful tool.
II. Acetate tape preparation cytology, swabs, or superficial skin scrapings are used to collect surface material.
   A. A glossy finish tape is recommended.
   B. After surface material is collected, the tape is stained with Diff-Quik.
   C. Tape is applied to a clean glass slide and examined under oil emersion.
   D. Yeast organisms stain purple and may appear oval, round, or peanut shaped.
III. Fungal culture on Sabouraud's agar may be used to diagnose *Malassezia* spp. but is not often necessary.
IV. Biopsy is not a reliable way to diagnose the disease.
   A. Yeast are evident only when present in large numbers and are easily lost with formalin fixation of the sample.
   B. Histopathological findings are characterized by the following:
      1. Superficial perivascular to interstitial dermatitis with irregular hyperplasia, diffuse spongiosis, and lymphocytic exocytosis of the epidermis and follicular infundibulum are typical.
      2. Parakeratosis is prominent.
      3. Lymphocytes, histiocytes, and plasma cells are the dominate dermal inflammatory cells.
      4. Yeast may be visualized in surface and/or infundibular keratin.

Differential Diagnosis

I. Allergic skin diseases: atopic dermatitis, food allergy, flea allergy, contact allergy
II. Drug eruption
III. Infectious diseases: superficial pyoderma, dermatophytosis
IV. Parasitic diseases: demodicosis, scabies
V. Neoplasia: mycosis fungoides

Treatment

I. Topical therapy
   A. Selenium sulfide 1% *(Selsun Blue)* is a keratolytic, antiseborrheic, degreasing agent (Scott et al., 2001b).
      1. It is recommended if the skin is greasy, waxy and scaly.
      2. It may be irritating in some animals and should not be used in cats.
      3. The frequency of use is dependent on severity of the condition (1 to 2 times weekly until resolution).
   B. Ketoconazole shampoo *(Nizoral, KetoChlor)* is effective in killing *Malassezia* spp.
      1. It is excellent for mild to moderate seborrhea oleosa.
      2. Use one to two times weekly until resolution.
      3. Ketoconazole shampoo is available over-the-counter.
   C. Chlorhexidine shampoo (3% to 4%) may be effective.
      1. Formulations can be drying and/or irritating.
      2. Chlorhexidine 2% in combination with miconazole 1% shampoo *(Malaseb)* is used one to two times weekly for yeast and bacteria.
   D. Enilconazole 0.2% rinse is also very effective (but not licensed for use in animals in the United States).
   E. Miconazole 1% *(Miconazole, ResiZOLE)* shampoo and conditioner may be applied one to two times weekly, depending on the severity of the condition.
   F. Vinegar-and-water (1:5 or 1:10) rinses are inexpensive and effective long-term treatments that help prevent relapses in some dogs (e.g., swimmers).
   G. Lime sulfur dip 2% can be used to relieve the itching and has mild antiyeast properties.
      1. The dip can be very drying to skin and hair coat.
      2. Use one to two times weekly.
II. Systemic therapy
   A. Ketoconazole 5 mg/kg PO BID is helpful in dogs.
      1. Side effects are nausea, vomiting, anorexia, and hepatotoxicity.
      2. It is avoided in cats because of nausea, vomiting, and anorexia.
      3. It is teratogenic in pregnant animals.
      4. Lightening of the hair coat may occur after 3 to 4 months of use but resolves after discontinuation.
   B. Itraconazole 5 mg/kg PO SID may be as effective but is more expensive.
      1. Side effects are nausea, vomiting, anorexia, and hepatotoxicity (lesser degree).

2. Vasculitis has been reported in doses at 10 mg/kg daily.

C. Fluconazole 2.5 mg/kg PO SID is used when concerns exist regarding liver toxicity.
1. Side effects are nausea, vomiting, abdominal discomfort, anorexia, and hepatotoxicity (lesser degree).
2. It does not suppress the adrenal corticotropic hormone axis.

D. Terbinafine 15 to 30 mg/kg PO SID may be considered.
1. Side effects are nausea, vomiting, abdominal discomfort, anorexia, and hepatotoxicity.
2. Neutropenia and pancytopenia have also been reported.

PARASITIC DISORDERS

Cheyletiellosis

Definition

I. It is an infection with a surface dwelling mite that results in variable pruritus.
II. It is also known as *walking dandruff*.

Causes

I. *Cheyletiella yasguri* is the species that affects dogs.
II. *Cheyletiella blakei* is the species that affects cats.

Pathophysiology

I. *Cheyletiella* spp. are obligate parasites.
II. Their 21-day life cycle is completed entirely on the host.
III. Ova are attached to hairs by fibrillar strands.
IV. Mites live in the keratin layer and create pseudotunnels in the epidermal debris.
V. Mites periodically attach to the epidermis and engorge themselves on fluid from the skin.

Clinical Signs

I. Highly contagious between dogs, cats, and humans.
II. Nonpruritic scale on the dorsum can progress to widespread scale and alopecia.
III. Pruritus may become severe.
IV. Cats may develop erythroderma and papular crusty eruptions.
V. Some cats only appear to overgroom the dorsum and have mild or no skin lesions.

Diagnosis

I. Identification of eggs (oval shaped, 200 μm) or mites (350 to 500 μm, four pairs of legs with combs and accessory mouth parts that look like hooks) is done by using superficial skin scrapings, acetate tape preparations, scale and hair collected with a flea comb, and sometimes fecal flotation.
II. Mites may be seen without magnification (appear as walking dandruff).

Differential Diagnosis

I. Cats: causes of seborrhea and military dermatitis, including liver disease and diabetes mellitus
II. Dogs
A. Bacterial pyoderma
B. Primary or secondary seborrhea
C. Demodicosis
D. Nutritional deficiency dermatoses
E. Intestinal parasitism
F. Hypersensitivity disorders: atopy, food allergy, flea allergy
G. Sarcoptic or otodectic mange
H. Pediculosis

Treatment

I. Treat all dogs, cats, and rabbits in contact with the infected animal.
II. Apply lime sulfur dips weekly for 6 weeks.
III. Apply a topical parasitical powder, dip, shampoo or spray weekly for 4 weeks.
IV. Consider administering ivermectin at 0.2 to 0.3 mg/kg SC, PO every 2 weeks for 3 doses (except in sensitive breeds of dogs).
V. Fipronil spot-on or spray (6 mg/kg) may be applied monthly for two treatments.
VI. Apply selamectin 6 to 15 mg/kg topically every 30 days; response may be improved by dosing every 2 weeks for three treatments.
VII. Treat the environment with an insecticide spray or fogger that is effective against fleas.

Monitoring of Animal

I. Prognosis is good; however, the mite is highly contagious among dogs, cats, rabbits, and humans.
II. Recheck the animal 3 to 4 weeks after starting treatment.

Notoedric Mange

Definition and Cause

I. *Notoedres cati* is a highly contagious mite that primarily infects cats, but dogs, foxes, and rabbits can also be infected.
II. *N. cati* is a surface-dwelling mite that causes papules, lichenification, thickening of the skin, and tightly adherent yellow-gray crusts.
III. The disease is also called *feline scabies*.
IV. The mite is zoonotic.

Clinical Signs

I. Lesions first appear on the medial, proximal margin of the pinnae.
II. Lesions rapidly spread to the rest of the ear, face, eyelids, and neck.
III. Feet and perineum may be affected, and lesions can become widespread.
IV. Lesions consist of thickened, wrinkled skin with tightly adherent gray to yellow crusts.
V. Intense pruritus may lead to self-mutilation and secondary bacterial infections.
VI. Peripheral lymphadenopathy may be present.

Diagnosis

I. Demonstration of the mite on skin scraping
II. Biopsy
  A. Thickened epidermis
  B. Focal, parakeratotic, hyperkeratosis and superficial perivascular dermatitis
  C. Mite segments seen in the stratum corneum

Differential Diagnosis

I. Otodectic mange, cheyletiellosis
II. Food allergy, atopy
III. Pemphigus complex
IV. Systemic lupus erythematosus

Treatment

I. All cats in the household are treated.
II. Crusts and debris are removed with a mild shampoo, then lime sulfur (2% to 3%) dip is applied weekly for six to eight treatments.
III. Ivermectin may also be given 0.2 to 0.3 mg/kg PO, SC every 2 weeks for three treatments.
IV. Selamectin can be applied topically for two applications, 4 weeks apart.

Monitoring of Animal

I. If no response to treatment is seen, then evaluate the animal for recurrence.
II. If recurrence has occurred, the animal may be reinfested from the environment or from untreated dogs, cats, or rabbits.

Sarcoptic Mange

Definition and Causes

I. Sarcoptic mange is a pruritic disease of dogs and foxes that is caused by the superficial burrowing mite, *Sarcoptes scabiei* var. *canis*.
II. Sarcoptic mites can transiently infect humans and cats.

Pathophysiology

I. Mites live in the stratum corneum and create burrows in which they lay eggs.
II. Pruritus is the result of a hypersensitivity reaction to the mite.
III. Life cycle is completed on the host.
IV. Mites can survive off the host for a minimum of 6 to 21 days.

Clinical Signs

I. Scabies is characterized by a nonseasonal intense pruritus.
II. Alopecia, erythema, papules, scales, and crusts are common.
III. Lesions are commonly found on the ear margins, elbows, hocks, and ventrum.
IV. With chronic infections, lesions become widespread, but the dorsum is usually spared.
V. Humans in contact with infected dogs may develop a pruritic papular reaction.
VI. Well-groomed animals may have intense pruritus, with minimal to no skin lesions.
VII. Generalized lymphadenopathy may be present.
VIII. Weight loss and lethargy may occur secondary to chronic pruritus and discomfort.

Diagnosis

I. High suspicion based on intense pruritus
II. Demonstration of mites, mite eggs, or fecal material on skin scrapings
  A. Multiple skin scrapings are best obtained from the elbows, hocks, lateral margin of the pinnae, and ventrum.
  B. Approximately 50% of infected dogs have negative skin scrapings.
III. Positive response to treatment for the mite
IV. Poor response to corticosteroids

Differential Diagnosis

I. Hypersensitivity disorders: atopy, food allergy, flea allergic dermatitis
II. Secondary bacterial or *Malassezia* spp. infections

Treatment and Monitoring

I. All dogs in contact with the infected dog must be treated.
II. Apply selamectin topically every 2 weeks for three treatments.
III. Fipronil spray may be applied every 2 weeks for three treatments.
IV. Ivermectin may be given 0.2 to 0.3 mg/kg PO, SC every 2 weeks for three treatments, except in ivermectin-sensitive breeds (e.g., collies, Shetland sheepdog, Old English sheep dog, Australian shepherd).
V. Milbemycin oxime may be administered 1.5 mg/kg PO every 2 weeks for three treatments.
VI. Lime sulfur dips may be done weekly for six treatments.
VII. In severe cases the environment must also be treated with parasiticide sprays.
VIII. Secondary infections must be appropriately treated.
IX. If the animal's pruritus has not decreased after 21 days of treatment, then perform further diagnostic tests and reevaluate treatments.

Otodectic Mange

Definition and Cause

I. Otitis and dermatitis in the dog and cat are caused by *Otodectes cyanotis*.
II. *Otodectes* spp. primarily infest the ear canal, but can live on adjacent skin.
III. The mite is spread between animals by direct contact or via fomites.
IV. Mites cause irritation and a hypersensitivity reaction.

Clinical Signs

I. Copious cerumen production usually occurs in both ears but can be unilateral.
II. Pruritus is common.

III. Alopecia and/or a papular crusting dermatitis can occur on the pinnae; around the ear, face, and neck; and on the dorsolumbar area.
IV. Some animals may be asymptomatic carriers.

Diagnosis

I. Direct visualization of the mite in the ear canal or in cerumen
II. Microscopic identification of mites in cerumen to which mineral oil has been added
III. Examination of superficial skin scrapings

Differential Diagnosis

I. Atopy, food allergy
II. Notoedric, sarcoptic mange
III. Pediculosis, chiggers
IV. Pelodera dermatitis
V. Flea allergy dermatitis

Treatment

I. Prognosis is excellent as long as all animals in contact with the infected animal are treated.
II. Ears are cleaned with a ceruminolytic agent.
III. Treatment includes the following:
   A. Pyrethrin ear drops SID for 7 days; repeated in 7 days
   B. Thiabendazole *(Tresaderm)* SID for 7 days; repeated in 7 days
   C. Ivermectin 0.01% otic solution *(Acarexx)* 0.5 mL in each ear once; repeated in 2 weeks
   D. Selamectin applied to the skin for two treatments, 30 days apart
   E. Fipronil two to three drops in the ear; repeated in 7 and 30 days (not approved for this use)
   F. Ivermectin 1% solution 0.2 to 0.4 mg/kg PO, SC every 2 weeks for three treatments (not approved for this use)
   G. Treatment of secondary infections
   H. Possible whole-body treatment

NEOPLASIA

Epitheliotropic Lymphoma (Mycosis Fungoides)

See Chapter 91.

CHAPTER 86

Disorders Causing Focal Alopecia

Robert A. Kennis

INFECTIOUS DISORDERS

Canine Demodicosis

Definition

I. Demodicosis is a folliculitis caused by proliferation of *Demodex canis* mites.
II. *D. canis* mites are passed from the mother to the offspring within the first few days of birth.
III. Dogs that develop clinical signs may have localized or generalized lesions.
IV. Adult-onset demodicosis is frequently associated with immunosuppression from an underlying cause.

Causes

I. Causative mite is *D. canis*, a follicular mite.
II. A long, slender mite has also been reported but is less common.

Pathophysiology

I. Pathogenesis of clinical demodicosis is poorly understood; however, stress may play a role.
II. Genetic predisposition exists in dogs that develop juvenile-onset generalized disease.
III. Dogs born by cesarean section and not allowed to nurse do not have mites.
IV. Dogs with no history of juvenile demodicosis may develop clinical signs at a later age.
    A. Possible underlying causes include the following:
        1. Hyperadrenocorticism
        2. Hypothyroidism
        3. Administration of immunosuppressive agents (corticosteroids)
        4. Neoplasia
    B. Some cases of adult-onset demodicosis are idiopathic.

Clinical Signs

I. Localized demodicosis
    A. Alopecia frequently occurs in a circumscribed pattern.
        1. Hair may epilate easily from the leading margin of the lesion.
        2. Broken hairs are not commonly associated with demodicosis.
    B. Comedones (plugged hair follicles) may be present.
    C. Pustules and papules may occur and indicate a secondary infection.
    D. Epidermal collarettes may be present.
    E. Dogs are rarely pruritic unless secondary infection is present.
    F. Feet and muzzle are frequently affected in juvenile-onset, localized demodicosis.
II. Generalized demodicosis
    A. Alopecia may be circumscribed, diffuse, locally or generally extensive, and possibly symmetrical.
    B. Hairs may epilate easily from the leading margins.
    C. Comedones may occur.
    D. Papules, pustules, hemorrhagic pustules, and draining tracts may be present.
    E. Development of crusting and scaling is variable.
    F. Pruritus is uncommon unless secondary infection is present.
    G. Odor from the skin surface may occur with secondary infection.

Diagnosis

I. Diagnosis is based on the observation of *D. canis* mites on skin biopsy, plucked-hair analysis (trichogram), or deep skin scraping from affected regions.
II. Deep skin scrapings are performed because the mite is located deep within the follicle.
    A. Pinching the skin may move mites to a more superficial location within the hair follicles.
    B. Skin is scraped with a scalpel blade or knife until hemorrhage is observed, indicating that the scraping is at the level of the dermis near the base of the hair follicle.
    C. Collected debris is mixed with mineral oil on a glass slide, and a coverslip is added to aid observation.
    D. Microscopic evaluation (×10) identifies mites.
    E. If mites are present, then the clinician documents whether they are alive or dead and determines the ratio of juvenile mites (egg, larvae, and nymph stages) to adult mites, which is beneficial for assessing response to treatment.
    F. Deep skin scrapings are the best way to diagnose demodicosis.
III. Plucked-hair analysis (trichogram) involves examining hairs from the leading margin of the lesion.

A. A hemostat or thumb forceps is used to grab the hairs near the skin surface.
B. Plucked hairs are placed on a glass slide containing a drop of mineral oil, with the hairs aligned for easier observation of the hair bulbs.
C. Microscopic evaluation (×10) reveals mites near the base of the hairs.
D. This diagnostic procedure is not as sensitive as deep skin scrapings.

IV. Biopsy and histopathology are useful for chronically inflamed skin and for demodicosis involving the feet.
A. Sedation and anesthesia may be needed if a local anesthesia of the sample site cannot be performed.
B. Skin is generally not aseptically prepared, but hair is clipped from the site to better access the selected lesion.
C. A 6-mm Baker biopsy punch can be used for collecting the sample, which should extend to the subcutaneous fat.
D. Collected samples are submitted in formalin, and special stains are not required to identify mites.

Differential Diagnosis

I. Localized demodicosis
A. Dermatophytosis
B. Bacterial folliculitis
C. Alopecia areata
D. Vaccination reaction
E. Pattern baldness

II. Generalized demodicosis
A. Dermatophytosis
B. Bacterial folliculitis
C. Alopecia areata
D. Pattern baldness
E. Cutaneous drug eruption
F. Anagen and telogen defluxion
G. Vasculitis
H. Neoplasia
1. Squamous cell carcinoma
2. Cutaneous lymphosarcoma
I. Sebaceous adenitis
J. Nutritional-related diseases
1. Zinc-responsive dermatosis
2. Vitamin A–responsive dermatosis
3. Hepatocutaneous syndrome
K. Autoimmune diseases
1. Pemphigus complex
2. Lupus and lupuslike reactions
L. Metabolic diseases
1. Hyperadrenocorticism
2. Hypothyroidism

Treatment and Monitoring

I. Localized demodicosis
A. Rotenone ointment (*Goodwinol;* containing botanical extract from orris root)
1. Apply SID to BID to the alopecic regions.
2. Warn the owner that the alopecic areas may become larger once treatment is started, from the mechanical epilation of hairs during application and the outward spreading of the mites.
B. Benzoyl peroxide gel (*Pyoben* gel, *Oxydex* gel)
1. Apply SID to the alopecic regions.
2. It does not kill or remove the mites from the follicles but helps to limit secondary infection, and unplugs hair follicles.
3. This product bleaches fabric; therefore it must be completely dry before animal is allowed on furniture and rugs.
4. Product has limited efficacy.
C. Observation only
1. Many cases of localized demodicosis are self-limiting, but secondary infection and underlying causes must be addressed.
2. Localized demodicosis may progress to a generalized form, so advise the owner to watch for new lesions or worsening of clinical signs.

II. Juvenile-onset generalized demodicosis
A. Treat all concurrent secondary bacterial and parasitic infections.
B. Correct any nutritional imbalances.
C. Spay or castrate dogs with generalized disease.
D. Treat the demodicosis with amitraz.
1. Amitraz *(Mitaban)* is the only licensed and approved product for the treatment of generalized demodicosis, and it can be used in dogs ≥12 weeks of age.
2. Remove all the hair to allow maximum skin contact with the dip.
3. Bathe the dog in a benzoyl peroxide–based shampoo and towel dry before dipping (may be done the day before).
4. Mix one bottle of the amitraz with 2 gallons of warm water.
5. Sponge the mixture onto the dog, making sure to wet all skin surfaces.
6. Allow the dog to air dry and keep it from getting wet between dips.
7. Continue dips every 2 weeks until two negative skin scrapings occur 2 weeks apart; follow with one more dip.
8. Sedation is a likely side effect.
9. Untoward side effects include bradycardia, hypothermia, seizures, coma, hyperexcitability, pruritus, vomiting, or diarrhea.
10. Small dogs are more susceptible to these side effects, probably because of their increased surface area:body weight ratio.
11. It is best to dip small dogs in the hospital and closely monitor them for 24 hours post-dipping.
12. Yohimbine may be used to reverse the adverse side effects associated with amitraz.
13. Tactik is an industrial-grade amitraz product that is not licensed or approved for use on dogs, so is not recommended.

III. Adult-onset generalized demodicosis
A. Treat all secondary infections, with the selection of antibiotics based on bacterial cultures for chronic cases.

1. Severe bacterial infections are treated to near-clinical remission before instituting amitraz dips.
2. Aggressive bathing and alternative miticide therapy can be considered during this time.

B. Treat any underlying cause, such as hypothyroidism, hyperadrenocorticism, and neoplasia.
C. Treat the demodicosis with amitraz as outlined previously.
   1. Dogs with demodicosis of the feet are allowed to stand in the solution for maximum contact.
   2. Refractory cases are sometimes treated with weekly dipping or dipping with double-strength solution (one bottle mixed with 1 gallon water) every 1 to 2 weeks.
D. Ivermectin 1% *(Ivomec)* is an alternative mitocide.
   1. Initial dosage is 0.1 mg/kg PO SID for 7 days, then increased to 0.2 mg/kg PO SID for 3 weeks if no side effects occur.
   2. Continue at the same dosage for 2 additional weeks if adequate improvement is seen.
   3. If live mites and juvenile stages are seen, increase to 0.3 mg/kg PO SID for another month, and reassess the animal.
   4. Doses can gradually be increased to 0.6 mg/kg PO SID if needed.
   5. Signs of toxicity include mydriasis, excessive salivation, lethargy, coma, and death.
   6. Ivermectin is contraindicated in the collie, Shetland sheepdog, Australian shepherd, border collie, and Old English sheepdog.
   7. Several precautions exist when using ivermectin for the treatment of demodicosis.
      a. Do not give to dogs <12 weeks old.
      b. Treatment may take months to achieve a clinical remission; therefore treatment should continue for 1 month beyond two negative skin scrapings taken 2 weeks apart.
      c. Relapses are common.
      d. Do not administer concurrently with amitraz.
      e. No reversal agent is available if ivermectin toxicity occurs—only supportive care.
      f. Idiosyncratic reactions have occurred in breeds other than those listed above, so obtain written consent from the owner before instituting this therapy.
E. Milbemycin *(Interceptor)* may also be tried.
   1. Dose is 1 to 2 mg/kg PO SID.
   2. It may be used in breeds for which ivermectin is contraindicated.
   3. If live mites and/or juvenile stages are seen after 1 month of therapy, then the dose may be doubled.
   4. Toxicities and side effects are uncommon, but the product may be cost-prohibitive for some clients.
   5. Complete remission may take many months.
   6. Treatment should continue for 2 months beyond two negative skin scrapings taken 2 weeks apart.
   7. Relapses are common.
   8. Milbemycin should not be used concurrently with either ivermectin or amitraz.

Dermatophytosis

Definition

I. Dermatophytosis is a fungal skin infection in dogs and cats that targets the growing anagen hairs and surface keratin of the skin.
II. The common name for this infection is *ringworm*.

Causes

I. The most common causes include the following:
   A. *Microsporum canis:* a zoophilic species
   B. *Microsporum gypsum:* a geophilic species
   C. *Trichophyton mentagrophytes:* a zoophilic species
II. Dermatophytosis of dogs and cats can be caused by other species found on food, zoo animals, and humans.
III. All dermatophytes are zoonotic.

Pathophysiology

I. Animals can develop dermatophytosis by coming into contact with active fungal spores from the environment, fomites, or an infected animal.
II. Dermatophytes only infect growing hairs, so when the hair stops growing or falls out, the infection resolves.
III. Host immunity (cell-mediated) is important for the prevention and resolution of dermatophyte infections.
IV. Drugs and diseases that suppress cell-mediated immunity increase the risk of dermatophytosis.
V. Trauma and skin maceration (e.g., bathing, grooming) may help establish dermatophyte infections.

Clinical Signs

I. Alopecia is variable, but is the classic lesion.
   A. Alopecia may be patchy to diffuse.
   B. Focal lesions may be well circumscribed as the infection spreads outward.
      1. Chronic lesions may have new hair growth in the center of an outward-spreading infection.
      2. Coalescing, circumscribed lesions may form a serpiginous leading margin.
   C. Affected hairs tend to break rather than epilate easily.
   D. Alopecia is usually asymmetrical.
II. Scaling is variable.
   A. Dry scaling areas (seborrhea sicca) may be associated with the alopecia.
   B. Epidermal collarettes may be present.
III. Primary lesions such as papules, pustules, or nodules may be seen.
IV. Secondary lesions may evolve from primary lesions or from trauma, and include scaling, excoriation, hyperpigmentation, crusts, collarettes, alopecia, and erythema.
V. Pruritus is variable.
VI. Because this disease is contagious, other pets and/or people within the same household may be affected.

Diagnosis

I. Definitive diagnosis is by fungal culture.
  A. Allows identification of the genus and species
  B. Allows for antifungal susceptibility testing
II. To obtain a fungal culture, do the following:
  A. Clean the affected areas with cotton soaked in alcohol to decrease bacterial contamination, and allow the area to air dry.
  B. Use a sterile hemostat or thumb forceps to grasp the hair near the skin surface.
    1. Select the leading margin of an active lesion.
    2. Place the hair, scale and crusts in a sterile Petri dish or sterile carrier for submission to a laboratory.
    3. Alternatively, place the collected hairs, scale and crust on the surface of a fungal culture plate or dermatophyte test media (DTM).
      a. Keep the sample in a dark, humid area at room temperature.
      b. Fungal growth is associated with a red color change in the DTM.
  C. A sterile tooth brush may also be used to collect the sample.
    1. Brush the entire animal and dispose of excess hair.
    2. Submit the toothbrush in a sealed bag to a reference laboratory.
    3. Alternatively, touch the tips of the brush to the DTM.
    4. Include any hair and scale that was collected.
    5. It is an excellent technique to use on animals with resolving lesions or on suspected asymptomatic carriers.
III. A trichogram may be helpful in identifying fungal infected hairs.
  A. Pluck hairs from the leading margin of the lesion.
  B. Place hairs on a glass slide with a drop of mineral oil and apply a cover slip.
    1. Potassium hydroxide solution may be used as a clearing agent instead of mineral oil to better visualize the fungal spores.
    2. Lactophenol blue may also be used to stain the slide.
  C. Observe under ×10 magnification with the light condenser turned down.
  D. Fungal-infected hairs appear fuzzy because of the damaged cuticle.
  E. Fungal spores may be seen on the hairs.
  F. A fungal culture is performed to identify the genus and species of the organism.
IV. Wood's lamp examination involves using a cobalt-blue light to identify dermatophytes that fluoresce.
  A. It only identifies some species of *Microsporum canis*.
  B. False negatives are common.
  C. False positives may occur from topical mediations.
  D. It does not identify an active infection because hairs may fluoresce that are no longer infectious.
  E. Best results are obtained if the lamp is allowed to warm for at least 10 minutes.
  F. It is only a screening tool and not a substitute for a fungal culture.

Differential Diagnosis

I. Bacterial folliculitis
II. Demodicosis
III. Alopecia areata
IV. Vaccine reaction
V. Pattern baldness
VI. Adverse drug reaction
VII. Vasculitis
VIII. Sebaceous adenitis
IX. Nutritional causes of alopecia and scaling
  A. Zinc-responsive dermatosis
  B. Vitamin A–responsive dermatosis
  C. Hepatocutaneous syndrome
X. Autoimmune disorders
  A. Pemphigus complex diseases
  B. Lupus and lupuslike reactions
XI. Ectoparasites
  A. *Cheyletiella* spp.
  B. Lice
  C. *Notoedres* spp.
  D. *Otodectes* spp.
  E. Fleas
XII. Metabolic disorders
  A. Hyperadrenocorticism
  B. Hypothyroidism
XIII. Neoplasia
  A. Squamous cell carcinoma
  B. Mast cell tumor
  C. Cutaneous lymphoma

Treatment and Monitoring

I. Lime sulfur dip
  A. Mechanism of action unknown
  B. Helps to decrease scale and pruritus
  C. May be used as a sole therapy or adjunctive therapy
  D. No age restrictions, but very young animals should be observed for hypothermia while the solution is drying
  E. Applied weekly until a negative fungal culture is achieved
  F. Precautions
    1. Do not allow cats to self-groom while the product is still wet.
    2. The product can tarnish jewelry and stain fabric.
    3. The strong sulfur odor is somewhat offensive, so owner compliance may be compromised.
II. Griseofulvin
  A. Dose for microsized product is 10 to 120 mg/kg PO SID or in divided doses.
    1. Initial dosage is 25 mg/kg PO BID.
    2. Decrease dose if the ultramicrosized formula is used.
  B. Continue for 2 weeks beyond a negative fungal culture.
  C. Precautions are numerous (Plumb, 1999).
III. Ketoconazole
  A. Dose range is 5 to 10 mg/kg PO SID to BID, with 10 mg/kg PO SID preferred in dogs.

B. Use with caution in cats.
C. Use for 2 weeks beyond a negative fungal culture.
D. Precautions are described under Treatment for Acute Moist Dermatitis in Chapter 85.

IV. Itraconazole
A. Dose range is 5 to 10 mg/kg PO SID to BID in both dogs and cats.
B. Use for 2 weeks beyond a negative fungal culture.

V. Fluconazole
A. Dose is 2.5 to 10 mg/kg PO SID to BID.
B. Use for 2 weeks beyond a negative fungal culture.

VI. Topical therapy for focal lesions
A. Topical medications with known efficacy include clotrimazole, ketoconazole, miconazole, enilconazole, and lime sulfur.
B. Topical medications with possible efficacy include thiabendazole, iodine products, and sodium hypochlorite (bleach).
C. Chlorhexidine and captan rinse are products with limited efficacy against dermatophytes.
D. Localized skin reactions may occur from these products.
E. When applying topical medications to cats, prevent oral ingestion.
F. Avoid products containing corticosteroids.
G. Efficacy of shampoo products is controversial.

Canine Superficial Bacterial Folliculitis

Definition

I. It is a bacterial skin infection leading to alopecia and inflammation of the hair follicles.
II. Follicular inflammation may predispose the follicle to bacterial infection.

Causes

I. Common associated bacteria include the following:
A. *Staphylococcus intermedius*
B. *Staphylococcus schleiferi*
C. *Staphylococcus epidermidis*
D. *Staphylococcus xylosis*
E. *Micrococcus* spp.
F. Gram-negative aerobes
G. *Streptococcus* spp.
H. *Bacillus* spp.
I. Various anaerobic species

II. Infections may arise from underlying cutaneous, metabolic, or immunological abnormalities.
III. Secondary infections are common and may be associated with the following:
A. Allergies
B. Seborrhea
C. Metabolic diseases: hyperadrenocorticism, hypothyroidism, diabetes mellitus
D. Iatrogenic causes: bathing, topical drugs or medications
E. Immunodeficiencies of immunoglobulin A, G, or M

Pathophysiology

I. Host factors allowing bacterial colonization
A. Changes in pH
B. Increased moisture
C. Altered cell turnover rate
D. Altered local cytokine production
E. Systemic illness

II. Predisposing causes of bacterial infection
A. Follicular inflammation
B. Follicular obstruction: seborrheic conditions, comedone formation
C. Follicular degeneration: endocrinopathy, corticosteroids
D. Other infections: dermatophytosis, demodicosis
E. Follicular damage from pruritus (allergy)

Clinical Signs

I. Alopecia
A. Circumscribed, outward spreading
B. Diffuse
C. Easy hair epilation owing to follicular inflammation

II. Papules, pustules
III. Epidermal collarettes, crusts
IV. Superficial moist dermatitis
V. Pyotraumatic folliculitis
VI. Chronic lesions: hyperpigmentation, lichenification
VII. Deep infections: nodules, hemorrhagic pustules, draining tracts

Diagnosis

I. Identification of increased/high numbers of bacteria on direct impression sample
A. A clean glass slide is applied to an affected lesion.
1. Pustules are gently ruptured.
2. Sample the leading margin of epidermal collarettes.
3. A cotton swab may be used to collect samples from highly exudative or draining lesions.

B. Stain the slide with a Modified Wright's stain.
C. A Gram stain may be helpful in identifying bacteria in highly exudative or hemorrhagic samples.
D. View with a ×100 oil immersion objective.
E. The presence of increased amounts of bacteria (both intra or extracellular) along with inflammatory debris or inflammatory cells is diagnostic.
F. NOTE: It is difficult to find bacteria on normal skin when direct impression samples are made.

II. Biopsy and histopathology
A. Local anesthesia with lidocaine is usually adequate.
B. A 6-mm Baker biopsy punch is recommended for primary lesions (papules or pustules).
C. Perform surgical excision with the long axis of the blade extending across the leading margin of the lesion.
D. Bacteria may be seen on histopathology but may require special stains.
E. Absence of bacteria does not rule out a bacterial cause of the problem.
F. The pattern of inflammation may help to elucidate the underlying cause of the infection.

G. Perifollicular dermatitis is suggestive of an underlying allergic cause, demodicosis, or a bacterial or dermatophyte infection.
H. In cases in which bacteria are present on cytology, consider treating the infection empirically before performing a biopsy.
I. A poor response to therapy indicates the need for a biopsy.

III. Bacterial culture and susceptibility testing
A. Primary lesions (pustules) are sampled directly.
1. The hair around the lesion is clipped away.
2. The pustule is ruptured with a sterile 25-gauge needle.
3. Pustule contents are collected on a sterile swab.
B. Secondary lesions (crusts, epidermal collarette) may also be cultured.
1. Gently lift the crust and scale with a sterile swab and culture the under side of the lesion.
2. Normal bacteria flora may be cultured with this technique, so it is important to correlate clinical findings and cytologic findings with culture results (false-positive results may occur).
C. Chronic and deep lesions are best cultured via biopsy and submitted for macerated tissue culture.
1. Aseptically prepare the skin and allow it to air dry before biopsy.
2. Place the biopsy sample in a culture medium or sterile Petri dish.
3. Request aerobic, anaerobic, and fungal cultures.
4. Submit a second sample for histopathologic analysis.
D. Antibiotics are withheld for at least 48 hours before sample collection.

Differential Diagnosis

I. Because most bacterial infections are secondary to an underlying problem, emphasis is placed on diagnosing the cause.
II. Clinical signs of bacterial folliculitis can resemble many diseases.
A. Dermatophytosis
B. Demodicosis
C. Primary or secondary seborrhea
D. Sebaceous adenitis
E. Endocrinopathies: hypothyroidism, hyperadrenocorticism, sex hormone imbalances
F. Vasculitis
G. Sterile panniculitis
H. Traumatic-induced dermatitis from pruritic causes (see Chapter 85)
I. Neoplasia

Treatment

I. Treat the underlying cause.
II. Institute topical and or systemic therapy.
A. Topical shampoos: benzoyl peroxide, chlorhexidine, ethyl lactate
B. Oral antibiotics (see Table 88-1)

Monitoring of Animal

I. Therapy is continued 1 week beyond clinical remission.
A. Three weeks is usually adequate for acute cases.
B. Bathing may speed resolution of the problem.
II. Poor response to therapy or intolerance of the selected medication requires additional steps.
A. Consider bacterial culture with susceptibility.
B. Consider biopsy with histopathology.
III. Recurrence after successful treatment is possible.
A. Treated for an inadequate time
B. Resistance to the selected antibiotic
IV. Seek the underlying cause of any recurrences.

INFLAMMATORY DISORDERS

Vaccine-Associated Vasculitis

Definition and Cause

I. Affected dogs develop an expanding focus of alopecia at the site of vaccination, especially a rabies vaccine.
II. Lesions may not develop for 2 to 4 months after vaccination.
III. The reaction leads to permanent, scarring alopecia.

Pathophysiology

I. Vasculitis develops at the injection site.
II. Ischemia of the hair follicles occurs.
III. Inflammation may or may not be visible during the acute phase.

Clinical Signs

I. Focal, complete alopecia is typical.
II. The lesion is usually circumscribed and erythematous.
III. The skin may become atrophic and/or hyperpigmented.
IV. Scaling is variable.
V. The lesion is usually nonpruritic.

Diagnosis

I. Diagnosis is made based on history and clinical findings.
II. Biopsy and histopathology may be helpful in ruling out other causes of alopecia.
III. Biopsy during the acute phase may indicate a vasculitis.
A. Lesions are usually not apparent: however, until alopecia develops and the vasculitis has subsided.
B. Other causes of vasculitis must be ruled out.

Differential Diagnosis

I. During the acute phase of the reaction
A. Spider bites
B. Systemic illness: ehrlichiosis, Rocky Mountain spotted fever
C. Adverse drug reaction
D. Neoplasia: lymphoma
E. Dermatomyositis
F. Burns: caustic or thermal
II. During the chronic phase of the lesion
A. Spider bite

B. Adverse drug reaction
C. Burns

III. Causes of epidermal collarettes
A. Bacterial folliculitis
B. Dermatophytosis
C. Demodicosis

Treatment and Monitoring

I. During the acute phase of the reaction, pentoxifylline may be used at 10 to 15 mg/kg PO BID.
II. If the lesion is cosmetically disfiguring, then it may be surgically excised.
III. Advantages and disadvantages of vaccination must be considered when future vaccinations are chosen, because reactions can worsen with repetitive use.
IV. Consider treatment with pentoxifylline at the time of injection and continue for several weeks afterward.

MISCELLANEOUS DISORDERS

Alopecia Areata

Definition and Causes

I. It is an uncommon disorder characterized by patchy to diffuse hair loss.
II. Skin is not grossly inflamed.
III. T lymphocytes and antifollicular antibodies may be present
IV. It may be multifactorial in origin.

Clinical Signs

I. Alopecia: focal to multifocal, diffuse to patchy, symmetrical or asymmetrical, sometimes well circumscribed
II. No clinical evidence of skin inflammation
III. Possible spontaneous hair regrowth

Diagnosis

I. Diagnosis is based on biopsy and histopathology.
II. Multiple biopsy samples are collected.
III. A trichogram may reveal dysplastic hairs.

Differential Diagnosis

I. Focal alopecia: vaccine reaction, follicular dysplasia, bacterial folliculitis, demodicosis, dermatophytosis
II. Symmetrical alopecia: endocrinopathies, pattern baldness, psychogenic alopecia in cats
III. Chronic oral or parenteral corticosteroid administration

Treatment and Monitoring

I. Affected animals may recover spontaneously.
II. No defined treatment exists.

CHAPTER 87

Disorders Causing Symmetrical Alopecia

Rudayna M. Ghubash

CONGENITAL/DEVELOPMENTAL DISORDERS

Pattern Baldness

Definition and Causes

I. Tardive hypotrichosis is a condition in which animals are born with normal hair coats and develop alopecia as they mature.
II. It is also known as *acquired-pattern alopecia*, *canine pinnal alopecia*, and *dachshund pattern baldness*.
III. Four separate syndromes have been reported.
  A. Pinnal alopecia of dachshunds
    1. It is more common in males.
    2. Alopecia usually starts between 6 and 9 months of age.
  B. Ventral and caudal alopecia of Boston terriers and dachshunds
    1. Also reported in the Chihuahua, whippet, greyhound, Italian greyhound, and Manchester terrier.
    2. Condition occurs primarily in females.
    3. Alopecia typically begins around 6 months of age.
  C. Bald thigh syndrome of greyhounds
  D. Pattern alopecia of Portuguese water dogs and American water spaniels: begins around 6 months of age

Pathophysiology

I. It is probably genetic in origin.
II. Specific hair follicle pathophysiology is unknown.

Clinical Signs

I. In general, all these conditions develop symmetrical alopecia that tends to be restricted to certain areas of the body.
II. Some animals have a thin, fine hair coat in affected areas.
III. With pinnal alopecia of dachshunds, the alopecia is symmetrical and involves the dorsal haired surface of the pinna and the caudal auricular area.
IV. Boston terriers and dachshunds develop symmetrical alopecia that occurs on the ventrum, ventral neck, caudal auricular area, and the medial aspect of the hind legs.
V. In bald thigh syndrome of greyhounds, symmetrical alopecia occurs on the caudal aspect of the hind legs.
VI. Pattern alopecia of Portuguese water dogs and American water spaniels is characterized by symmetrical alopecia of the ventral neck, the medial aspect of the hind legs, and potentially the entire tail.

Diagnosis

I. Pattern baldness is often diagnosed based on age of onset, breed, clinical signs, and exclusion of other diseases.
  A. Skin scrapings are performed to rule out parasitic causes, such as demodectic mange.
  B. Dermatophyte cultures are used to rule out dermatophytosis.
  C. If the alopecia is occurring in a middle-aged or older animal, then endocrine testing is conducted to rule out hypothyroidism and hyperadrenocorticism.
II. Diagnosis can be supported by histopathology of skin biopsies of the alopecic areas.
  A. Normal epidermis and dermis
  B. Diminutive hair follicles
  C. Hair follicles not in growth arrest cycle
    1. Not primarily in telogen or catagen
    2. Key difference from endocrine alopecias

Differential Diagnosis

I. Sex hormone dermatoses
II. Hypothyroidism
III. Hyperadrenocorticism
IV. Follicular dysplasia
V. Demodicosis
VI. Dermatophytosis
VII. Ear margin seborrhea

Treatment and Monitoring

I. No successful treatment has been developed.
II. Melatonin has been useful in some affected animals at 3 mg PO SID to BID for dogs <10 kg and at 6 mg PO SID to BID for dogs >10 kg.
  A. Main side effect of melatonin is gastrointestinal upset.
  B. If no evidence of hair regrowth is seen after 6 months, then melatonin can be stopped.
III. No monitoring is required because this is a self-limiting, aesthetic disease.

IDIOPATHIC DISORDERS

Cyclical Flank Alopecia

Definition and Causes

I. The disorder is also known as *seasonal flank alopecia* and *canine recurrent flank alopecia*.
II. It is a localized follicular dysplasia on the trunk that is usually symmetrical in nature, seasonal, and associated with a noninflammatory hyperpigmentation of the skin.
III. The syndrome is most common in the English bulldog, French bulldog, boxer, and Airedale terrier.
IV. It has also been documented in the miniature schnauzer, miniature poodle, Doberman pinscher, Bouvier de Flandres, Scottish terrier, Staffordshire terrier, Griffon Korthal, and Affenpinscher.

Pathophysiology

I. Underlying pathogenesis of this condition is poorly understood.
II. Because of higher incidences in certain breeds, a genetic influence is suspected.
III. Because of seasonality and higher occurrence in certain regions of the world, photoperiod and variations in regional climates probably also influence the hair follicle cycle.

Clinical Signs

I. Typically a bilateral, symmetrical alopecia develops in the thoracolumbar region, with hyperpigmentation of the underlying skin.
II. It can be unilateral.
III. The alopecia usually has a well-demarcated border.
IV. Spontaneous regrowth of hair usually occurs within 3 to 8 months.
V. Alopecia usually occurs every year around the same time.
   A. Some animals (20%) have a one-time occurrence (Scott et al., 2001a).
   B. Sometimes the occurrence of alopecia skips a year.
   C. The extent of the alopecia can vary from year to year.

Diagnosis

I. Diagnosis is based on occurrence in a compatible breed, seasonal history, clinical signs, ruling out other differential diagnoses, and histopathology of the skin.
   A. Skin scrapings to rule out demodicosis
   B. Fungal cultures to rule out dermatophytosis
   C. Endocrine testing to rule out hypothyroidism and hyperadrenocorticism
II. It can be difficult to diagnose with histopathology, depending on the timing of the disease when the biopsy is performed.
III. Several histological characteristics predominate.
   A. Significant follicular hyperkeratosis is usually present.
   B. Dilated hyperkeratotic infundibulum atop abnormally truncated hair follicles results in a "witch's foot" appearance that is unique to this disease.

Differential Diagnosis

I. Hyperadrenocorticism
II. Hypothyroidism
III. Alopecia X
IV. Follicular dysplasia
V. Sex hormone dermatoses
VI. If alopecia is not symmetrical
   A. Demodicosis
   B. Dermatophytosis
   C. Follicular dysplasia
   D. Sebaceous adenitis

Treatment and Monitoring

I. Hair typically regrows spontaneously at the end of the season.
II. Because this is only a cosmetic condition, therapy may be unnecessary.
III. Melatonin therapy is effective in some dogs.
   A. Mechanism of action is unknown.
   B. Melatonin has been useful in some affected animals at 3 mg PO SID to BID for dogs <10 kg and at 6 mg PO SID to BID for dogs >10 kg.
      1. The primary side effect of melatonin is gastrointestinal (GI) upset.
      2. Response to melatonin therapy is expected within 6 months.
   C. Melatonin therapy can be started before the historical season for alopecia in an attempt to prevent the condition from developing.

ENDOCRINE AND METABOLIC DISORDERS

Alopecia X

Definition and Causes

I. Alopecia X is a bilaterally symmetrical alopecia of unknown cause, with a poorly understood pathophysiology.
II. A great deal of confusion exists regarding this disorder.
III. It is also called *adult-onset growth hormone deficiency (hyposomatotropism), growth-hormone responsive alopecia, castration-responsive alopecia, biopsy-responsive alopecia, congenital adrenal hyperplasia-like syndrome,* and *pseudo-Cushing's disease.*
IV. It is also known colloquially as *black skin disease* and *coat funk.*
V. It often occurs in the Pomeranian, chow chow, Keeshond, and miniature and toy poodles.
VI. It has been reported in the Airedale terrier, dachshund, German wirehaired pointer, Alaskan malamute, and Portuguese water dog.

Pathophysiology

I. Alopecia X is most likely a defect in the ability of the hair follicle to cycle properly.
II. In the 1980s it was initially thought to be a growth hormone deficiency, although several reports refuted this theory.

A. One third of dogs evaluated with this condition had normal growth hormone concentrations in response to xylazine or gonadotropin-releasing hormone (Lothrop, 1988).
B. Affected dogs lack other signs relating to a growth hormone deficiency.
C. Selective deficiency of growth hormone from the pituitary gland would be rare.
D. Normal dogs can grow hair in response to growth hormone injections, so response to treatment does not indicate a deficiency.

III. One study proposed that the disease resulted from an adrenal steroid hormone imbalance (Schmeitzel and Lothrop, 1990).
A. Researchers thought that partial deficiency of the 21-hydroxylase enzyme resulted in an increase in adrenal steroid intermediate products, which interfered with the normal hair follicle cycle.
B. However, no systemic signs are associated with this disease.
C. Another study found no abnormalities in the 21-hydroxylase gene of alopecic Pomeranians (Takada et al., 2002).
D. Not all animals with this syndrome have the classic hormonal abnormalities that are expected with a 21-hydroxylase deficiency.

IV. A recent abstract investigated the change in hair follicle estrogen receptors in dogs treated with melatonin for this disease (Frank, 2006).
A. Of the dogs that regrew hair, none showed any changes in follicular estrogen receptors before and after response to treatment.
B. Up-regulation of follicular estrogen receptors is probably not the cause of this syndrome, because down-regulation of receptors did not occur in animals responding to treatment.

Clinical Signs

I. Bilaterally symmetrical alopecia of the flanks, neck, caudal hind legs, and perineum
II. Hyperpigmentation of the underlying skin
III. Lack of systemic signs
IV. Loss of primary hairs and a "puppy coat" appearance

Diagnosis

I. Perform skin scrapings to rule out demodicosis.
II. Submit fungal cultures to rule out dermatophytosis.
III. Endocrine testing is used to eliminate the possibility of hypothyroidism or hyperadrenocorticism.
IV. University of Tennessee sex hormone panel is helpful in diagnosing animals with abnormalities in intermediate forms of sex hormones, even though the exact relationship to the disease is unknown.
V. Skin histopathology is consistent with an endocrine alopecia, after other endocrine diseases have been eliminated as possibilities
A. Prominent flame follicles
B. Arrest of the hair follicles in telogen and catagen

Differential Diagnosis

I. Hyperadrenocorticism
II. Hypothyroidism
III. Sex hormone dermatoses
IV. Cyclical flank alopecia

Treatment and Monitoring

I. Melatonin can cause hair regrowth in some animals.
A. The mechanism of action is unknown.
B. Melatonin has been useful in some affected animals at 3 mg PO SID to BID for dogs <10 kg and at 6 mg PO SID to BID for dogs >10 kg.
1. Main side effect of melatonin is gastrointestinal upset.
2. If response occurs, hair growth is expected within 6 months.

II. Intact animals often respond to neutering, but debate continues regarding whether the condition in these animals is truly alopecia X or a sex hormone problem.
III. Mitotane can cause hair regrowth in some cases.
A. Dose recommendations vary from 15 to 25 mg/kg/day PO.
B. Treatment is not recommended because it involves treating an aesthetic disease with a drug that has potentially serious side effects.

IV. Trilostane has been effective.
A. In one study, trilostane resulted in hair growth in three Alaskan malamutes with Alopecia X (Leone et al., 2005).
1. Dose ranged from of 3.0 to 3.6 mg/kg/day PO.
2. Monitoring consisted of a complete blood count (CBC), chemistry panel, and adrenocorticotropic hormone (ACTH) stimulation tests at 2 weeks, 4 weeks, 3 months, and 6 months after initiating therapy.
3. No abnormalities on CBCs and chemistry panels were noted in any dogs, and cortisol assays were normal, indicating that excessive adrenal suppression did not occur.

B. Another study treated 16 Pomeranians and eight miniature poodles with Alopecia X (Cerundolo et al., 2004).
1. Most of the Pomeranians (85%) and miniature poodles (100%) grew hair within 4 to 8 weeks when treated SID to BID, with a mean daily dose of 10.85 mg/kg/day PO.
2. No adverse effects were noted.

V. It is debatable whether mitotane and trilostane are better options than no treatment at all because this is an aesthetic disease.

Hypothyroidism

Definition

I. Hypothyroidism is characterized by a deficiency of thyroid hormones from either structural or functional abnormalities of the thyroid gland.
II. Animals are typically affected during middle age.

III. Increased incidence of the disease has been reported in the Airedale terrier, beagle, American cocker spaniel, Great Dane, golden retriever, Labrador retriever, Irish setter, and Old English sheepdog.
IV. No difference in incidence has been detected between the two sexes.

Causes and Pathophysiology

I. The most common cause of canine hypothyroidism is lymphocytical thyroiditis, a genetically linked, immune-mediated disease of the thyroid glands.
II. Idiopathic atrophy of the thyroid glands also leads to a decrease in production of thyroid hormones (see Chapter 42).

Clinical Signs

I. Dermatological signs occur in many hypothyroid dogs.
II. Dogs are nonpruritic, unless the condition is complicated by secondary infection.
III. Bilaterally symmetrical alopecia is usually confined to areas of wear, such as the lateral trunk, ventral thorax, and tail.
IV. Alopecia typically spares the head and extremities.
V. Hair coat is dull and of poor quality.
VI. Some dogs exhibit a poor ability to heal from wounds.
VII. Seborrhea sicca, seborrhea oleosa, and secondary bacterial and yeast infections are common.
VIII. Comedones and hyperpigmentation may be noted.
IX. If myxedema is present, then the skin can be puffy or thickened (especially on the head).

Diagnosis

I. Histopathologic examination may be used initially to determine whether the cause of the alopecia is endocrine or nonendocrine.
   A. Significant follicular atrophy
   B. Vacuolated, hypertrophied arrector pili muscles
   C. Increased level of dermal mucin
   D. Hair follicles in growth cycle arrest
II. Certain abnormalities on routine blood work are supportive but not diagnostic.
   A. Mild nonregenerative anemia
   B. Hypercholesterolemia
   C. Hypertriglyceridemia
III. Measurement of thyroid hormones is used to definitively diagnose the disease, but results can be difficult to interpret.
   A. Total serum thyroxine (T_4)
      1. Normal T_4 almost always excludes the diagnosis of hypothyroidism.
      2. Decreased T_4 levels should be interpreted in conjunction with other tests.
      3. Nonthyroidal illnesses, drug administration, and breed variations (greyhounds) can cause low T_4 levels.
      4. Diestrus and pregnancy can cause elevated T_4 levels.
      5. One study found an overlap in T_4 levels between normal dogs, hypothyroid dogs, and nonhypothyroid dogs with concurrent illness (Nelson and Ihle, 1991).
   B. Free T_4 by equilibrium dialysis
      1. It is the most accurate representation of thyroid function, as it is the form of the hormone that can actively enter cells and bind to receptors.
      2. Free T_4 is less affected by sickness, serum protein concentration, and other conditions compared with total T_4.
   C. Thyroid-stimulating hormone (TSH) (Peterson et al., 1997; Ramsey et al., 1997)
      1. Useful in conjunction with other tests (not by itself)
      2. Elevated in 66% to 75% of hypothyroid dogs
      3. Normal in 25% to 33% of hypothyroid dogs
      4. Elevated in about 10% of euthyroid dogs

Differential Diagnosis

I. Hyperadrenocorticism
II. Sex hormone dermatoses
III. Alopecia X
IV. Cyclical flank alopecia
V. Follicular dysplasia
VI. Postclipping alopecia
VII. Telogen effluvium

Treatment

I. Supplementation with a brand name thyroxine product is recommended.
   A. Generic thyroid supplements sometimes contain a lower hormone level than listed on the bottle and may not always be reliable.
   B. Beginning dose recommendation is 0.02 mg/kg PO BID.
   C. Once the animal is controlled on the BID regimen, the dose can sometimes to be decreased to SID, with the same level of control.
II. Initial lower dose (0.01 mg/kg PO BID) may be used in animals with preexisting cardiac disease and then gradually increased over time.

Monitoring of Animal

I. Check postpill total T_4 level 4 to 6 weeks after starting thyroid supplementation to make sure the animal is receiving the proper dose.
   A. If an animal is receiving supplementation BID, collect a blood sample 4 to 6 hours after the previous dose for a peak level.
   B. This level should be at the high end of the reference range or slightly above normal, because this is the peak level of the day.
II. If the dog is receiving supplementation SID, then a trough total T_4 is checked just before the scheduled time to receive the medication.
   A. Level should be at the low end of the reference range.
   B. This is the lowest thyroid level of the day.
III. If adjustments are made to the dose, then T_4 levels are checked again 4 to 6 weeks later.
IV. Once the maintenance dose has been established, postpill thyroid levels are checked twice yearly.

V. Measuring total T_4 is sufficient for evaluating postpill levels.
VI. Thyrotoxicosis caused by oversupplementation, or supplementation of a nonhypothyroid dog, is rare.
  A. Incidence of toxicity is low because of rapid metabolism and excretion of thyroid hormones in dogs.
  B. Clinical signs include polyuria, polydipsia, excessive weight loss, and tachycardia.

Spontaneous Hyperadrenocorticism

Definition

I. Hyperadrenocorticism is characterized by excessive production of glucocorticoids by the adrenal gland, as a result of pituitary gland or adrenal gland dysfunction.
II. It is most common in middle-aged to older dogs.
III. A higher incidence has been reported in female dogs.
IV. Breeds with a higher incidence include the miniature and toy poodle, dachshund, Boston terrier, boxer, and beagle.

Causes and Pathophysiology

I. Pituitary-dependent hyperadrenocorticism
  A. Most cases (85%) are caused by a pituitary tumor that leads to excessive secretion of adrenocorticotropic hormone (ACTH) (Scott et al., 2001c).
  B. This excess of ACTH causes a bilateral hypertrophy of the adrenal glands and leads to increased production of cortisol.
  C. Tumor can be a microadenoma or macroadenoma.
II. Adrenal-dependent hyperadrenocorticism
  A. About 15% to 20% of affected dogs have a functional adrenal tumor that produces excessive cortisol (Scott et al., 2001c).
  B. Tumor can be an adenocarcinoma or adenoma.

Clinical Signs

I. Bilaterally symmetrical alopecia, typically of the trunk
II. Hyperpigmentation
III. Calcinosis cutis
IV. Comedones
V. Thin, hypotonic skin
VI. Skin that is easily bruised
VII. Secondary bacterial pyoderma, *Malassezia* spp. dermatitis, demodicosis

Diagnosis

I. See Chapter 45 for an in-depth discussion on the diagnosis of spontaneous hyperadrenocorticism.
II. History and the ACTH stimulation test can be used to differentiate between spontaneous and iatrogenic hyperadrenocorticism.
  A. Chronic use of oral corticosteroids or injectable steroids can predispose an animal to iatrogenic hyperadrenocorticism.
  B. Animals with iatrogenic hyperadrenocorticism show a minimal response to exogenous ACTH (ACTH stimulation test) because the adrenocortical axis is suppressed.
III. Skin biopsies are consistent with an endocrinopathy.
  A. Epidermal, follicular and sebaceous gland atrophy
  B. Dilation and hyperkeratosis of the hair follicles
  C. Hair follicles in growth cycle arrest
  D. Calcinosis cutis highly suggestive

Differential Diagnosis

I. Hypothyroidism
II. Sex hormone dermatoses
III. Alopecia X
IV. Cyclical flank alopecia
V. Iatrogenic hyperadrenocorticism

Treatment and Monitoring

I. See Chapter 45 for an in-depth discussion on the treatment of hyperadrenocorticism, including doses and monitoring.
  A. Mitotane *(o,p'-DDD, Lysodren),* an adrenocorticolytic agent that results in selective necrosis and atrophy of the adrenal cortex, is the most commonly used treatment for canine hyperadrenocorticism.
  B. Trilostane, a competitive inhibitor of the 3β-hydroxysteroid dehydrogenase enzyme in the adrenal glands, inhibits the production of progesterone and its end products and is efficacious in the treatment of canine pituitary-dependent hyperadrenocorticism.
  C. Ketoconazole lowers cortisol levels by inhibiting enzymes involved in steroid biosynthesis but is not very efficacious.
  D. L-Deprenyl (selegiline hydrochloride, *Anipryl*), a selective and irreversible monoamine oxidase type B inhibitor that restores central dopamine concentrations, is effective in 20% of canine pituitary-dependent hyperadrenocorticism cases (Reusch et al., 1999).
II. It can take several months for hair to grow and skin to normalize, and new hair growth can differ from its previous color and quality.
III. If calcinosis cutis is present, then the time until hair regrowth can be prolonged.
  A. A thin film of topical dimethyl sulfoxide (DMSO) can be applied to areas of calcinosis cutis SID to break down calcium deposits.
  B. Gloves must always be worn when handling DMSO.
  C. Baseline serum calcium levels are checked and repeated monthly in severe cases to monitor for hypercalcemia.

Iatrogenic Hyperadrenocorticism

Definition and Causes

I. Iatrogenic hyperadrenocorticism arises from exogenous administration of glucocorticoids, and clinical symptoms are similar to spontaneous hyperadrenocorticism.
II. Long-term oral, injectable, and topical glucocorticoids have all been implicated in this disease.

Pathophysiology

I. Excessive amounts of exogenous glucocorticoids produce similar effects on organs as they do in spontaneous hyperadrenocorticism.

II. This results in suppression of ACTH output by the pituitary gland, which leads to suppression of cortisol production by the adrenal glands.

Clinical Signs

I. Bilateral, symmetrical alopecia of the trunk
II. Hyperpigmentation
III. Calcinosis cutis
IV. Comedones
V. Thin, hypotonic skin
VI. Skin that is easily bruised
VII. Secondary bacterial pyoderma, *Malassezia* spp. dermatitis, demodicosis

Diagnosis

I. History of exposure to exogenous glucocorticoids is usually obtained.
II. Affected animals have a minimal response to exogenous ACTH (ACTH stimulation test) because the adrenocortical axis is suppressed.
III. Liver enzymes are often elevated.
IV. The low-dose dexamethasone suppression test cannot be used to diagnose this disease.

Differential Diagnosis

I. Hypothyroidism
II. Sex hormone dermatoses
III. Alopecia X
IV. Cyclical flank alopecia
V. Spontaneous hyperadrenocorticism

Treatment

I. Discontinue all glucocorticoids.
II. If the glucocorticoids have been given orally or topically, they are slowly tapered over several weeks to allow the adrenal glands to recover from the suppression and start producing endogenous cortisol.
III. If calcinosis cutis is present, then a thin film of topical DMSO can be applied to areas of calcinosis cutis SID to break down calcium deposits.
   A. Gloves must always be worn when handling DMSO
   B. Baseline serum calcium levels are checked and repeated monthly in severe cases to monitor for hypercalcemia.

Monitoring of Animal

I. Serial ACTH stimulation tests can be done while the glucocorticoids are being tapered, and then every 3 to 4 weeks after discontinuation of the glucocorticoids, until the test result returns to normal.
II. If no permanent damage has been done to any internal organs, the prognosis is good.

Sex Hormone Dermatoses in the Male Dog

Definition

I. Sex hormone dermatoses are a poorly defined group of diseases characterized by dermatological symptoms secondary to an underlying dysfunction of the sex hormones.
II. They are often secondary to neoplastic conditions of the reproductive tract.
III. They are usually seen in middle-aged to older animals.
IV. Increased incidence is reported in the boxer, collie, Shetland sheepdog, and Weimaraner.

Causes and Pathophysiology

I. In male dogs, Sertoli's cell tumors, interstitial cell tumors, and seminomas may cause an endocrine alopecia, with Sertoli's cell tumors being the most common.
II. Skin disease and feminization occur from an abnormal ratio of sex hormones or from hyperestrogenism.

Clinical Signs

I. Bilaterally symmetrical alopecia
II. Hyperpigmentation of the skin
III. Linear preputial dermatoses on the ventral caudal abdomen
IV. Alterations in coat color
V. Behavioral changes
VI. Feminization: pendulous prepuce, gynecomastia, enlarged nipples
VII. Signs of bone marrow suppression secondary to hyperestrogenemia: anemia, thrombocytopenia, pancytopenia

Diagnosis

I. Palpation of an enlarged scrotal testes or an abdominal mass in a cryptorchid dog
II. Advanced imaging to locate a testicular tumor
III. Biopsy and histopathologic examination of the testicle to confirm the presence of a tumor
IV. Laboratory assays to document increased estrogen levels
V. Hematological examination and bone marrow aspirate to evaluate a hypoplastic bone marrow (nonregenerative anemia, thrombocytopenia, leukopenia) secondary to estrogen toxicity
VI. Histopathologic examination of the skin similar to other endocrinopathies, especially hypothyroidism
   A. Arrest of hair follicle cycle
   B. Atrophy of the hair follicles

Differential Diagnosis

I. Hypothyroidism
II. Hyperadrenocorticism
III. Alopecia X
IV. Cyclical flank alopecia
V. Follicular dysplasia

Treatment and Monitoring

I. Bilateral castration is indicated.
II. In one study, 8% of Sertoli's cell tumors and 11% of seminomas metastasized, but interstitial cell tumors were usually benign (Scott et al., 2001c).
III. Evaluate for signs of metastasis before surgery because it affects the prognosis.
IV. Because micrometastasis may be present before surgery, monitor the animal for a relapse of dermatological symptoms and eventual metastasis of the tumor (see Chapter 56).

Hyperestrogenism in the Female Dog

Definition

I. Hyperestrogenism is an uncommon endocrine disease in the female dog and is the result of elevated estrogen levels or abnormal sex hormone ratios.
II. It is also known as *ovarian imbalance type I.*
III. It is usually seen in middle-aged, intact female dogs.
IV. There is a higher incidence in English and French bulldogs.

Causes and Pathophysiology

I. Cystic ovaries or a functional ovarian tumor cause abnormal hormone levels.
II. Hormonal imbalances interfere with normal hair follicle cycling and result in alopecia.

Clinical Signs

I. Bilaterally symmetrical alopecia primarily of the lateral flanks, inguinal, perineal regions
II. Possible alopecia of the neck, chest, caudal and medial hind legs
III. Comedones, especially affecting the vulva
IV. Gynecomastia, enlarged nipples and vulva
V. Hyperpigmentation
VI. Seborrhea
VII. Estrous cycle abnormalities
VIII. ± Endometritis, pyometra

Diagnosis

I. Abdominal ultrasonography or exploratory surgery identifies abnormal ovarian tissue.
II. Ovarian tissue is submitted for histopathologic examination.
III. Estrogen assays may show elevated blood estrogen levels.
IV. Hematological examination and a bone aspirate are indicated to evaluate a hypoplastic bone marrow (nonregenerative anemia, thrombocytopenia, leukopenia) secondary to estrogen toxicity.
V. Histopathological examination of the skin may reveal the following:
   A. Results are similar to other endocrinopathies, especially hypothyroidism and tumor-associated skin disease in male dogs.
   B. Hair follicles are in growth cycle arrest.
   C. Hairless telogen hairs are present in high numbers.
VI. Regrowth of hair occurs in response to ovariohysterectomy.
VII. If an ovarian neoplasm is suspected, then thoracic radiographs are done to evaluate for metastasis.

Differential Diagnosis

I. Hyperadrenocorticism
II. Hypothyroidism
III. Alopecia X
IV. Follicular dysplasia

Treatment and Monitoring

I. Ovariohysterectomy resolves the dermatological signs.
II. Because micrometastasis can be present before surgery, monitor the animal for a relapse of dermatological symptoms and eventual metastasis of any tumor.

MISCELLANEOUS CONDITIONS

See Table 87-1.

TABLE 87-1

Miscellaneous Disorders of Symmetrical Alopecia

CONDITION	CAUSES	SIGNALMENT/CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Color dilute alopecia (color mutant alopecia)	Dilutions of black and brown hair to blue and fawn, respectively, are caused by abnormalities of coat color genes	Common in blue and fawn Doberman pinschers but also reported in other breeds with dilute colored hair coats Affected animals have recurrent bacterial folliculitis and thinning of the hair coat, primarily on the dorsum	Histopathology of skin biopsies reveals abnormal deposition and distribution of melanosomes within the hair shaft and hair follicle	Recurrent bacterial folliculitis is treated with appropriate antibacterials Mild topical antibacterial and antiseborrheic products are recommended Melatonin can be used at 3 mg PO SID-BID for dogs <10 kg and at 6 mg PO SID-BID for dogs >10 kg

Continued

TABLE 87-1

Miscellaneous Disorders of Symmetrical Alopecia—*cont'd*

CONDITION	CAUSES	SIGNALMENT/CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Excessive shedding	Previously reported in the literature; condition is not a primary disease but is secondary to folliculitis, seasonal changes, etc.			
Feline acquired symmetrical alopecia	Previously reported in the literature; many dermatologists thought these cats were suffering from allergic disease or psychogenic alopecia		New cases are required to confirm this condition is a unique entity	
Feline psychogenic alopecia	Alopecia from excessive licking or grooming is associated with a primary anxiety disorder	No age or sex predilection exists Condition is most commonly reported in Siamese and Abyssinian cats Animal has symmetrical or patchy alopecia caused by excessive grooming	Diagnosis is made by ruling out other causes of feline pruritus Skin scrapings, fungal cultures, flea preventatives, elimination food trials, and evaluation for environmental allergies are performed Only 10% of cats referred to a behaviorist for this disease suffered from it, 76% were allergic, and 14% suffered from a combination of allergies and psychogenic alopecia (Waisglass et al., 2006)	If the underlying cause of the anxiety cannot be resolved, antianxiety medications can be attempted with amitriptyline 5 mg PO BID or clomipramine 1.25-2.5 mg PO SID
Short-hair syndrome of silky breeds	Previously reported in the literature; many dermatologists thought these dogs had color mutant alopecia		New cases are required to confirm this condition is a unique entity	
Telogen defluxion	Alopecia is caused by a sudden arrest of hair follicles in the anagen cycle, and synchronization into the telogen phase is caused by a stressful event	Animal has a history of a stressful condition, such as life-threatening illness, surgery, pregnancy, or anesthesia Alopecia usually develops over most of the body but tends to spare the head	Diagnosis is based on the history of a stressful experience and examination of affected hair follicles revealing telogen hair follicles (slightly clubbed and lacking root sheaths)	Condition resolves when the cause of the hair cycle arrest is removed Histopathology of skin lesions reveals that most hair follicles are in the telogen phase

CHAPTER 88

Papular, Pustular, and Subcutaneous Skin Diseases

Candace A. Sousa

GENERAL CONSIDERATIONS

Papule

Definition

I. A papule (Figure 88-1) is a solid circumscribed elevation of the skin that varies in diameter from 1 to 10 mm.
II. Papules are usually caused by an infiltration of inflammatory cells into the epidermis (intraepidermal) or dermis, subepidermal edema, or epidermal hypertrophy.
  A. They can be pink, red or black in color.
  B. They may or may not be associated with a hair follicle.
III. Papules can be classified by their location.
  A. A follicular papule occurs when the inflammatory infiltrate accumulates within the epidermis of the follicle or in the perifollicular dermis.
  B. A nonfollicular papule is located within the skin, but is not associated with a hair follicle.
  C. An interfollicular papule is a nonfollicular papule found only within the haired skin and in an interfollicular location.

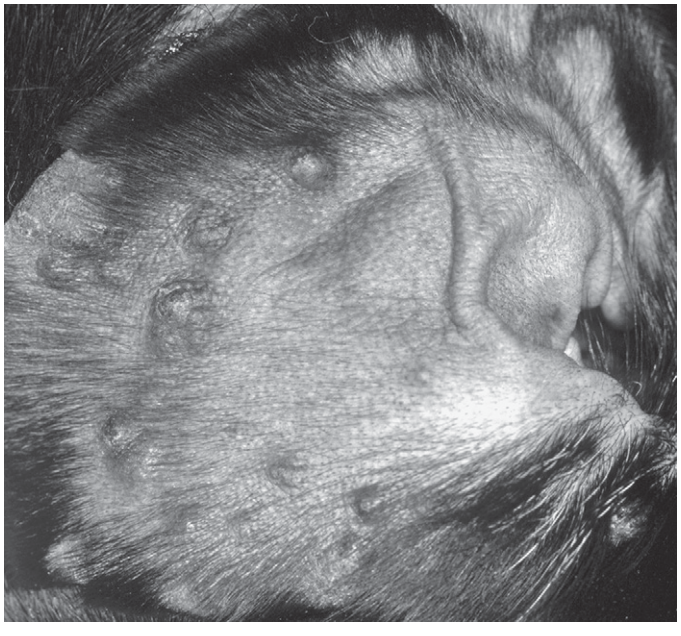

FIGURE 88-1 Papules on the inner aspect of the pinna, secondary to an infestation with *Sarcoptes scabiei.*

Causes

I. Follicular papule
  A. Staphylococcal folliculitis
  B. Demodicosis
  C. Dermatophytosis ("ringworm")
II. Nonfollicular or interfollicular papule
  A. *Sarcoptes scabiei*
  B. Flea bites
  C. Mosquito bites
  D. Contact hypersensitivity
  E. Pemphigus foliaceus
  F. Drug eruptions

Pustule

Definition

I. A pustule (Figure 88-2) is a small (<1 cm) circumscribed collection of purulent material.
II. Pus is a liquid inflammatory product composed of leukocytes.
III. Pustules may be intraepidermal, subepidermal, or follicular in location.
  A. They are usually yellow in color but may be white, green, or red.
  B. Most pustules contain neutrophils, but eosinophils can also be found.
  C. Most pustules are infectious in origin, but some may be sterile.

Causes

I. Infections
  A. Staphylococcal pyoderma and folliculitis
  B. Impetigo
II. Noninfected, sterile conditions
  A. Juvenile cellulitis
  B. Pemphigus foliaceus
  C. Acne
  D. Eosinophilic pustulosis
  E. Subcorneal pustular dermatosis

FIGURE 88-2 Pustule associated with impetigo in a puppy.

Diagnostic Approach to Papules and Pustules

I. Skin scraping
   A. Deep to rule out demodicosis
   B. Superficial to look for scabies
II. Surface cytology
   A. Identification of cocci (most likely *Staphylococcus* spp.) or other bacteria
   B. Identification of the predominant cell type (if any)
III. Wood's lamp examination
IV. Dermatophyte culture
V. Aspirate cytology of a pustule
   A. Identification of cocci (most likely *Staphylococcus* spp.) or other bacteria
   B. Identification of the predominant cell type (if any)
   C. Identification of the presence of acantholytic keratinocytes
VI. Response to therapeutic trial
   A. Minimum 21-day course of an antistaphylococcal antibiotic
   B. Treatment for scabies and fleas
VII. Bacterial culture and susceptibility
   A. If no response to appropriate antibiotic therapy is seen
   B. Before prescribing a drug that may be expensive or potentially dangerous
   C. To identify a sterile pustular disease
VIII. Skin biopsy

INFECTIOUS DISEASES

Superficial Staphylococcal Pyoderma and Folliculitis

Definition and Causes

I. They are infections within, or colonization of, the epidermis and hair follicle.
II. In dogs, *Staphylococcus intermedius* is isolated in >90% of the cases.
III. Other causes in dog include the following:
   A. *Staphylococcus aureus*
   B. *Staphylococcus schleiferi* subsp. *schleiferi*
   C. *Staphylococcus schleiferi* subsp. *coagulans*
IV. Staphylococcal pyoderma or folliculitis is very rare in cats.

Pathophysiology

I. *S. intermedius* is a normal inhabitant of the skin and hair coat, oral cavity, ear canal, and mucous membranes of dogs.
II. Colonization of the skin and hair follicles occurs secondary to changes in the cutaneous microclimate that result in conditions favorable to the growth of staphylococci.
III. The most common underlying causes are ectoparasitic infestations, pruritus from allergic dermatoses, and endocrinopathies.

Clinical Signs

I. Pustules: either interfollicular or follicular
II. Papules, erythema, scaling, epidermal collarettes, and/or hyperpigmentation
III. Short-coated dogs: only patchy alopecia
IV. ± Pruritus

Diagnosis

I. History of previous improvement after an appropriate course of antibiotic therapy
II. Compatible or suspicious clinical signs
III. Cytological identification of cocci (possibly with other bacteria) in a sample taken from a pustule, from the underside of a crust, or from the surface a lesion
IV. Bacterial culture of the contents of a pustule or material collected from a collarette
V. Elimination of the condition and a clinical cure after appropriate antibiotic therapy

Differential Diagnosis

I. Demodicosis with secondary staphylococcal pyoderma
II. Dermatophytosis
III. Pemphigus foliaceus

Treatment

I. Any underlying or predisposing factors are treated to maximize the chance of a clinical cure and minimize recurrences.
II. If only a few lesions are seen, then topical therapy alone can be used.

TABLE 88-1

Antibiotics Useful in Treating Canine Bacterial Pyoderma

DRUG	BRAND NAME	DOSE
Amoxicillin/clavulanate	*Clavamox*	13.75 mg/kg PO BID
Cephalexin	Generic forms	22 mg/kg PO BID
Cefadroxil	*CefaTabs*	22 mg/kg PO BID
Cefpodoxime	*Simplicef*	5-10 mg/kg PO SID
Clindamycin	*Antirobe*	5.5-33 mg/kg PO BID or 11 mg/kg PO SID
Difloxacin	*Dicural*	5-10 mg/kg PO SID
Enrofloxacin	*Baytril*	5-20 mg/kg PO SID
Erythromycin	Generic forms	10 mg/kg PO TID
Lincomycin	*Lincocin*	22 mg/kg PO BID or 15.4 mg/kg PO TID
Marbofloxacin	*Zeniquin*	2.75-5.5 mg/kg PO SID
Orbifloxacin	*Orbax*	2.5-7.5 mg/kg PO SID
Oxacillin	Generic forms	22 mg/kg PO TID
Sulfadimethoxine/ormetoprim	*Primor*	Day 1: 55 mg/kg PO SID, then 22 mg/kg PO SID
Trimethoprim/sulfamethoxazole	Generic forms	15 mg/kg PO BID
Trimethoprim/sulfadiazine	*Tribrissen*	15 mg/kg PO BID

A. Clean with an antiseptic shampoo that contains benzoyl peroxide, ethyl lactate, or chlorhexidine SID to QOD for 7 to 14 days.
B. Apply topical antimicrobial ointments or creams that contain mupirocin, neomycin, benzoyl peroxide, or chlorhexidine, SID to BID for 7 to 14 days.

III. If the lesions are widespread or do not improve with topical treatment, then administer systemic antibiotics for a minimum of 21 days (Table 88-1).

Monitoring of Animal

I. Recheck the animal 7 to 14 days after treatment is initiated, and continue therapy for at least 7 days after resolution of all signs.
II. Prognosis for complete resolution of the condition is good, especially if the underlying cause is controlled or eliminated.

Impetigo

Definition and Causes

I. Impetigo is an uncommon superficial bacterial infection of the sparsely haired regions of the body.
II. The lesions are caused almost exclusively by *Staphylococcus* spp.
III. The condition occurs most commonly in puppies and young dogs.
IV. In most cases no specific underlying cause can be identified, but a dirty environment, poor nutrition, and parasitism have been implicated in a few cases.
V. Pathophysiology is unknown.

Clinical Signs

I. Numerous small, nonfollicular papules, pustules, and yellowish crusts are concentrated in the glabrous areas of the inguinal and axillary regions of the body.
II. Lesions are not usually painful or pruritic.

Diagnosis

I. Tentative diagnosis is based on finding nonfollicular papules and pustules in a typical location in a young dog.
II. Cytologic examination of the contents of a pustule demonstrates neutrophils and coccoid bacteria.
III. Histopathologic examination of the skin demonstrates nonfollicular, subcorneal, or intragranular neutrophilic pustules; bacterial cocci may or may not be identified.
IV. Bacterial culture of a sample taken from an intact pustule most commonly grows *Staphylococcus* spp.

Differential Diagnosis

I. Demodicosis with secondary staphylococcal pyoderma
II. Dermatophytosis
III. Pemphigus foliaceus
IV. Flea bite hypersensitivity
V. Subcorneal pustular dermatosis

Treatment

I. Any underlying or predisposing factors are treated to maximize the chance of a clinical cure and to minimize recurrences.
II. If only a few lesions are seen, then topical therapy alone can be used.
A. Clean with an antiseptic shampoo that contains benzoyl peroxide, ethyl lactate, or chlorhexidine SID to QOD for 7 to 14 days.
B. Apply topical antimicrobial ointments or creams that contain mupirocin, neomycin, benzoyl peroxide, or chlorhexidine, SID to BID for 7 to 14 days.

III. If the lesions are widespread or do not improve with topical treatment, then administer systemic antibiotics for at least 21 days (see Table 88-1).

Monitoring of Animal

I. Recheck the animal 7 to 14 days after treatment is initiated and continue therapy for at least 7 days after resolution of the condition.
II. Prognosis for complete resolution of the condition is good.

Skin Fold Pyoderma (Intertrigo)

Definition and Causes

I. Intertrigo is an overgrowth or colonization of skin folds by normal skin bacteria ± yeast.

II. Skin folds develop as normal conformation (i.e., facial folds in brachycephalic breeds; lip folds, tail folds, vulvar folds in other breeds) or from obesity.
III. Moisture, sebum, secretions (tears, saliva) and exfoliated keratinocytes accumulate in these areas, which also have poor air circulation.
IV. Bacterial and yeast overgrowth occurs and leads to inflammation as well as the typical clinical signs.

Clinical Signs

I. ± Alopecia
II. Erythema, papules, maceration
III. Malodor

Diagnosis

I. Tentative diagnosis is based on the location of the lesion (within an area of skin-to-skin contact), particularly in a facial fold, lip fold, vulvar recess, tail fold, axillae, or on the ventral midline.
II. Cutaneous cytological examination demonstrates the presence of bacteria (predominantly cocci) and possibly yeast.
III. Cotton-tipped swabs can be used to sample material from affected areas to prove they are the source of the odor.

Differential Diagnosis

I. Superficial staphylococcal pyoderma
II. Demodicosis
III. Dermatophytosis
IV. *Malassezia* spp. dermatitis

Treatment and Monitoring

I. The fold is eliminated if possible.
   A. This can be accomplished by surgery, particularly with lip, facial, or vulvar recess folds.
   B. Weight reduction helps minimize folds in the axillae and ventral midline.
II. Institute maintenance cleaning every 1 to 3 days with an antiseptic shampoo that contains chlorhexidine, benzoyl peroxide, or ethyl lactate.
III. Apply topical antibiotic or antiseptic ointment, cream or spray that contains mupirocin, neomycin, benzoyl peroxide, or chlorhexidine SID.
IV. Prognosis for improvement is excellent, but the animal may need lifelong topical maintenance therapy if the folds are not removed surgically.

Deep Bacterial Pyoderma and Furunculosis

Definition and Causes

I. Deep bacterial pyoderma and furunculosis are infectious diseases involving the dermis or subcutaneous tissues.
II. They most commonly begin as a superficial staphylococcal pyoderma or folliculitis.
III. Once the hair follicle ruptures, furunculosis occurs, which results in a pyogranulomatous inflammation in the dermis.
IV. These conditions are usually secondary to another underlying condition (e.g., demodicosis, endocrinopathy, dermatophytosis).

Clinical Signs

I. Condition can be focal, multifocal, or generalized.
II. Papules, pustules, alopecia, hemorrhagic bullae, erosions, ulcers, ± crusts are common.
III. Often serosanguineous to purulent material drains from fistulous tracts.
IV. Lesions may be painful or pruritic.
V. Regional lymph nodes are often enlarged.

Diagnosis

I. History and typical physical examination findings
II. Neutrophils and bacteria on cytological examination
III. Dermatohistopathologic findings
   A. Suppurative folliculitis and furunculosis
   B. Bacteria (often difficult to identify)
IV. Bacterial culture identifies the bacterial pathogen or pathogens and aids in the selection of the proper systemic antibiotic.

Differential Diagnosis

I. Deep staphylococcal pyoderma secondary to demodicosis
II. Deep fungal infection
III. Mycobacteriosis
IV. Neoplasia

Treatment

I. Any underlying cause must be identified and treated.
II. Systemic antibiotics (see Table 88-1) are administered for a minimum of 4 weeks or for >2 weeks after complete resolution of clinical signs (often for a total of 6 to 12 weeks).
III. Antiseptic shampoos (e.g., benzoyl peroxide, chlorhexidine, ethyl lactate) are used once to twice weekly to aid in removal of the crusts and exudate, with a minimum contact time of 10 minutes before rinsing.

Monitoring of Animal

I. If the underlying cause can be corrected, then the prognosis for a complete clinical cure is good.
II. When the underlying cause cannot be identified or treated, then the condition usually recurs.
III. Fibrosis, scarring, and permanent alopecia may result.
IV. Some dogs must be treated continuously to keep the condition under control.

Subcutaneous Abscesses and Cellulitis

Definition and Causes

I. A subcutaneous abscess is a collection of inflammatory cells, usually neutrophils, within the subcutaneous tissue.
II. Cellulitis is a diffuse purulent inflammatory reaction within subcutaneous tissues.
III. The most common cause is a bacterial infection, although fungal infections and even sterile processes can cause a similar signs.

Pathophysiology

I. Bacteria are introduced into the subcutaneous tissues either through a breach in the epidermis, as a result of a

wound or injury, or after the rupture of a hair follicle (furunculosis).
II. In addition to *Staphylococcus* spp., other bacteria such as *Pasteurella multocida*, *Escherichia coli*, *Proteus* spp., or *Pseudomonas* spp. can be involved.
III. In some cases the infecting bacteria spread hematogenously to distant sites and organs (e.g., heart, kidneys).

Clinical Signs

I. Painful swelling of the skin
II. ± Draining tracts
III. Erythema and necrosis of overlying skin
IV. ± Pyrexia, anorexia, lethargy

Diagnosis

I. Tentative diagnosis is based on compatible clinical signs.
II. Aspiration and cytologic examination of material from the site demonstrates neutrophils and occasional bacteria.
III. Bacterial culture of material obtained via aspiration yields a positive culture, with one or more organisms.

Differential Diagnosis

I. Neoplasia
II. Sterile nodular panniculitis
III. Subcutaneous fungal or atypical mycobacterial infections

Treatment

I. If an abscess is identified, the abscess is surgically opened to provide drainage.
II. Necrotic tissue is removed, and the cavity is flushed with an antiseptic solution (e.g., chlorhexidine, betadine).
III. Antibiotics are given for a minimum of 14 days.
   A. A broad-spectrum antibiotic such as amoxicillin/clavulanate 15 to 22 mg/kg PO BID is started empirically.
   B. Choice of drug is then based on the results of a bacterial culture and susceptibility testing.

Monitoring of Animal

I. Complete healing of an abscess usually occurs within 2 weeks.
II. The cause of the deep infection (e.g., bite wounds, superficial pyoderma) must be identified and treated to prevent a recurrence.
III. Some lesions heal with a scar.

Dermatophytosis

See Chapter 86.

INFLAMMATORY AND IDIOPATHIC CONDITIONS

Canine Acne

Definition

I. Acne is an uncommon condition in young dogs (3 to 12 months of age) that may arise from abnormal follicular keratinization.
II. It is also known as *muzzle folliculitis* and *furunculosis*, or *chin pyoderma*.
III. It affects predominantly short-haired dogs.

Causes and Pathophysiology

I. An undetermined genetic predisposition followed by local trauma may be the initial cause.
II. Further trauma causes the short hairs to break below the skin surface, leaving the follicle open to bacterial colonization.
III. In some cases the infected follicle ruptures and introduces pieces of hair and skin into the dermis, which leads to furunculosis.

Clinical Signs

I. Lesions are seen most commonly on the chin and lips.
II. The condition is generally not pruritic or painful.
III. Lesions consist of alopecia and follicular papules that become pustular, then enlarge and ulcerate.
IV. Serosanguineous to seropurulent material drains from fistulas.
V. Suppurative folliculitis and furunculosis then develop.

Diagnosis

I. Presumptive diagnosis is based on clinical lesions in a short-haired breed of dog <1 year of age.
II. Cutaneous cytological examination of the contents of a pustule or the exudate from a draining fistula demonstrates neutrophils and bacterial cocci.
III. Definitive diagnosis is made by skin biopsy.
   A. Early lesions may have comedones.
   B. Late lesions have signs of deep pyoderma.
IV. If a bacterial culture is performed, *Staphylococcus* spp. is generally identified, although mixed bacterial infections are possible.

Differential Diagnosis

I. Superficial or deep bacterial pyoderma secondary to demodicosis
II. Dermatophytosis
III. Juvenile cellulitis

Treatment

I. Minimize trauma to the chin.
II. Early lesions are treated with topical antimicrobial shampoos or gels.
   A. The use of products that contain benzoyl peroxide can enhance the removal of debris from the hair follicle and decrease the number of bacteria on the hair coat and skin surface.
   B. Clean the chin or apply the gel SID until the condition is resolved.
   C. Antibacterial ointments that contain mupirocin can be applied SID until the infection is controlled.
III. In many cases, systemic antibiotic therapy is also needed.
   A. If pustules and evidence of secondary staphylococcal folliculitis are present, then antibiotics are given for a minimum of 21 days or >7 days beyond resolution of signs (see Table 88-1).

B. If hair follicles have ruptured and a resultant furunculosis occurs, then antimicrobial medications may be needed for >8 weeks.

IV. Dogs that are severely affected may benefit from topical or systemic glucocorticoids.
   A. Topical triamcinolone is applied SID for 14 days.
   B. Oral prednisone, prednisolone, or methylprednisolone (0.5 mg/kg PO SID) may be given for 7 days, then decreased to the lowest possible dose.

Monitoring of Animal

I. Instruct owners to keep the chin washed as long as there are visible lesions.
II. Antibiotic therapy is continued until the pustules are gone.
III. Most cases heal with scarring.

Feline Acne

Definition and Causes

I. Feline acne an uncommon disorder in cats arising from follicular hyperplasia and follicular keratinization.
II. Pathogenesis is unknown.

Clinical Signs

I. Early lesions consist of comedones, mildly erythematous crusted papules, and pustules on the chin.
II. Lesions may involve the skin adjacent to the upper and lower lips.
III. Lesions progress to nodules as the follicles rupture and lead to furunculosis.
IV. The chin then becomes swollen, with multiple draining fistulae or abscesses.
V. Lesions heal with alopecia and scarring.

Diagnosis

I. Diagnosis is based on the presence of compatible clinical signs and by ruling out other possible conditions.
II. On histopathologic examination, hair follicles are distended with keratin; some may be inflamed or ruptured.

Differential Diagnosis

I. Demodicosis
II. Dermatophytosis
III. *Malassezia* spp. colonization
IV. Facial excoriation associated with methimazole therapy

Treatment and Monitoring

I. Secondary bacterial folliculitis or furunculosis is treated with systemic antibiotics for 2 to 4 weeks.
II. Hair surrounding the lesions is clipped and the skin gently washed with a shampoo that contains benzoyl peroxide or ethyl lactate SID to QOD until the lesion heals (then as needed).
III. Topical antibacterial products such as 2% mupirocin, 0.75% metronidazole gel, or products that contain clindamycin or tetracycline may also be helpful.
IV. In very severe cases, oral vitamin A (8000 IU PO SID) or isotretinoin (2 mg/kg PO SID) may be tried.
V. Prognosis for improvement is good, but affected cats may require lifelong topical therapy.

Juvenile Cellulitis

Definition and Cause

I. Juvenile cellulitis is an uncommon, idiopathic form of panniculitis of young puppies, usually 3 to 16 weeks old.
II. It is most commonly seen in purebred dogs.
III. It has also been called *puppy strangles,* because the submandibular nodes are enlarged and appear to be strangulating the dog.
IV. Pathophysiology is unknown.

Clinical Signs

I. Sudden onset of pustules and discharge occurs on the lips, eyelids, and in the ear canals, as well as on the muzzle.
II. Lesions then fistulate and drain.
III. Submandibular lymphadenopathy is common.
IV. In rare cases, lesions appear on the trunk.
V. Many puppies are febrile, anorexic, and depressed, and some exhibit joint pain.

Diagnosis

I. Presumptive diagnosis is often made from the typical signalment and clinical signs.
II. Cytological examination of contents of pustules or draining lesions reveals pyogranulomatous inflammation, with no organisms.
III. Bacterial culture of an intact lesion yields no growth.
IV. Definitive diagnosis is made by skin biopsy, which demonstrates pyogranulomatous dermatitis and panniculitis.

Differential Diagnosis

I. Demodicosis with secondary bacterial pyoderma
II. Staphylococcal pyoderma

Treatment

I. Any secondary bacterial pyoderma is treated with appropriate systemic antibiotics (see Staphylococcal Pyoderma).
II. Gently wash affected areas SID with an antibacterial shampoo containing chlorhexidine or benzoyl peroxide to remove the crusts and exudate.
III. Give prednisone 2 mg/kg PO SID for 1 to 4 weeks until the condition is controlled, then taper slowly over several weeks.

Monitoring of Animal

I. Prognosis is good.
II. In severe cases, healing may be associated with permanent scarring.

Sterile Eosinophilic Pustulosis

Definition and Cause

I. It is a rare, sterile, superficial, pustular skin disease of dogs.
II. Cause and pathogenesis are unknown.

Clinical Signs

I. No breed, age, or sex predilection has been noted.
II. The disease manifests as an acute onset of multifocal to generalized papules and pustules that are follicular or interfollicular, and result in scaling and epidermal collarettes.
III. Lesions are generally concentrated on the trunk.
IV. Most dogs are pruritic.
V. Occasionally dogs are febrile, anorexic, or have peripheral lymphadenopathy.

Diagnosis

I. Other differential diagnoses are ruled out using appropriate diagnostic tests and therapies.
II. Cytological examination of a pustule reveals primarily eosinophils and occasional neutrophils.
III. Most dogs have circulating eosinophilia on a complete blood count.
IV. Bacterial culture of an intact pustule yields no growth.
V. Definitive diagnosis is made by skin biopsy, which reveals eosinophilic intraepidermal pustules, folliculitis, and (rarely) eosinophilic furunculosis.

Differential Diagnosis

I. Superficial bacterial pyoderma, impetigo, folliculitis
II. Pustular dermatophytosis
III. Demodicosis with secondary staphylococcal pyoderma
IV. Subcorneal pustular dermatosis
V. Pemphigus foliaceus
VI. Drug eruption

Treatment and Monitoring

I. Any secondary bacterial pyoderma is treated with appropriate systemic antibiotics (see Staphylococcal Pyoderma).
II. Prednisone 2 to 4 mg/kg PO SID to BID is given until lesions resolve, then tapered to the lowest effective dose and frequency.
III. Alternatively, dapsone 1 mg/kg PO TID can be used until the lesions resolve, then tapered.
IV. Prognosis is poor, but many dogs can be kept in remission with low doses of these medications.

Subcorneal Pustular Dermatosis

Definition and Cause

I. It is a rare, idiopathic, sterile, pustular dermatosis of dogs.
II. The cause is unknown.
III. The condition has been reported most commonly in the miniature schnauzer.
IV. In some cases the condition is associated with a reaction to shampoos.

Clinical Signs

I. It is a multifocal to generalized pustular disease primarily involving the head and trunk.
II. Secondary erythema, crusting, scaling, alopecia, and epidermal collarettes can be seen.
III. Systemic signs are rare.

Diagnosis

I. Tentative diagnosis is based on compatible clinical signs.
II. Carefully performed bacterial cultures of the contents of an intact pustule are usually negative, although a few colonies of nonpathogenic bacteria can occasionally be isolated.
III. Definitive diagnosis is made by skin biopsy, which reveals subcorneal pustular dermatitis without acantholysis.

Differential Diagnosis

I. Staphylococcal pyoderma, impetigo, folliculitis
II. Pemphigus foliaceus
III. Sterile eosinophilic pustulosis
IV. Autoimmune dermatoses: particularly pemphigus foliaceus, systemic lupus erythematosus

Treatment and Monitoring

I. The condition is poorly responsive to antibiotics or glucocorticoid therapy, which helps support a tentative diagnosis.
II. Dapsone is the therapy of choice.
   A. Dogs are given 1 mg/kg PO TID for 2 to 4 weeks.
   B. Once lesions resolve, the dose is tapered to the lowest effective dose and frequency.
   C. In some cases, therapy can be discontinued.
III. If no response occurs with dapsone, then treatment with high doses of oral corticosteroids may be effective (see Chapter 91).
IV. Prognosis is good if the animal responds to treatment with dapsone.

Contact Dermatitis

See Chapter 85.

PARASITIC DISORDERS

Demodicosis

See Chapter 86.

Sarcoptic Mange

See Chapter 85.

Flea Bite Hypersensitivity

See Chapter 85.

Mosquito Bite Hypersensitivity

Definition and Causes

I. It is a rare, seasonal condition of cats that have been sensitized to the bite of a mosquito.
II. Cats with dark hair on the pinnae or face may be at increased risk, because the pigment may act as an attractant for mosquitoes.
III. Thinly haired regions of the pinnae, face, and footpads may be more easily accessible to mosquitoes.
IV. Reaction may be both an immediate and a delayed hypersensitivity.

Clinical Signs

I. Papules, pustules, crusts, and erosions are concentrated on the haired portion of the dorsal muzzle and occasionally on the outer pinnae.
II. Occasionally the margins of the footpads are involved and can be swollen, crusted, fissured, or ulcerated.
III. Cats exhibit mild to severe pruritus.
IV. In advanced cases the muzzle can be swollen and alopecia develops, with or without nodules and pigmentary changes to the skin (hyperpigmentation and hypopigmentation).
V. Peripheral lymphadenopathy is variable.

Diagnosis

I. Tentative diagnosis is based on the history of dermatitis in a compatible location that coincides with the mosquito season.
II. Lesions should resolve when the cat is confined to a mosquito-free environment for 1 week.
III. Peripheral eosinophilia is common.
IV. Dermatohistopathologic examination helps rule out other differential diagnoses, but the findings are often nondiagnostic.
   A. Hyperplastic, superficial to diffuse perivascular dermatitis with eosinophils is seen.
   B. In some cases, eosinophils are found in the wall of the hair follicle and can even lead to eosinophilic furunculosis.

Differential Diagnosis

I. Adverse reaction to food
II. Dermatophytosis
III. Cutaneous herpesvirus dermatitis
IV. Autoimmune dermatoses: particularly pemphigus foliaceus
V. Flea bite hypersensitivity

Treatment

I. Cats are confined to a mosquito-free environment, particularly at dawn and dusk when mosquitoes are most active.
II. Water-based pyrethrin sprays are applied topically SID to the affected areas in an effort to repel mosquitoes.
III. If the cat is very pruritic or the lesions are very extensive, then prednisone 3 to 5 mg/kg PO SID for 1 to 3 weeks may be used, then tapered.
IV. Methylprednisolone acetate can be administered at 20 mg IM every 2 to 4 weeks, as needed during the mosquito season (for cats that cannot be medicated orally).

Monitoring of Animal

I. Prognosis for healing is good, but permanent scarring is possible.
II. The condition is likely to return in subsequent years unless the cat is confined to a mosquito-free environment or a mosquito repellent is applied daily.

IMMUNE-MEDIATED DERMATOSES

Pemphigus Foliaceus

See Chapter 91.

CHAPTER 89

Nodular Dermatoses

Stephen L. Lemarie

GENERAL APPROACH TO NODULAR DERMATOSES

Definition and Causes

I. A nodule is a circumscribed, solid, cystic or edematous elevation >1 cm in diameter that usually extends into the deeper layers of the skin (subcutis, panniculus, muscle).
II. Causes are numerous.
  A. Bacterial infections
  B. Fungal infections
  C. Parasitic infections
  D. Noninfectious inflammation
  E. Neoplasia

Pathophysiology

I. Cellular infiltrates may be inflammatory, reactive, and/or neoplastic.
II. Disruption of the overlying epidermis frequently occurs as a result of inflammation or ischemia.

Clinical Signs

I. Nodule consistency: firm, cystic, edematous
II. Nodule integrity: ulcerated, eroded, fistula
III. Depth of disease: dermal, subcutis, panniculus, muscle
IV. Distribution: solitary, multiple, generalized, mucous membrane involvement

Diagnosis

I. Cytology: draining tract exudates, fine-needle aspirate
II. Biopsy: multiple lesions, complete intact nodules
III. Culture and sensitivity: entire nodule or full-thickness section of lesion

Differential Diagnosis

See Box 89-1.

Treatment and Monitoring

I. Treatment is based on a complete diagnostic evaluation that establishes a definitive diagnosis.
II. Prognosis and monitoring is dependent on the diagnosis.
III. Monitoring considerations include whether the lesion is localized or systemic, the presence of any concurrent immunosuppressive disease, and potential for side effects from medical therapy.

Box 89-1

Differential Diagnosis for Nodular Dermatoses

Bacterial Infections

Staphylococcal furunculosis: see Chapter 86
Mycobacterial infections
Botryomycosis
Actinomyces spp. and *Nocardia* spp. infections

Fungal Infections

Dermatophytic granuloma: see Chapters 86 and 88
Blastomycosis
Histoplasmosis
Cryptococcosis
Coccidioidomycosis
Sporotrichosis

Miscellaneous Infections

Pythiosis
Protothecosis

Parasites

Demodicosis-related furunculosis: see Chapter 86
Leishmaniasis

Noninfectious Inflammation

Sterile eosinophilic pustolosis: see Chapter 88
Sterile nodular panniculitis
Xanthoma
Calcinosis cutis
Calcinosis circumscripta
Sterile nodular granuloma and pyogranuloma
Juvenile cellulitis: see Chapter 88
Nodular dermatofibrosis
Vasculitis: see Chapter 91

Neoplasia

Mast cell tumor
Others: see Tables 89-3, 89-4, 89-5

INFECTIOUS DISORDERS

Botryomycosis

Definition and Causes

I. Botryomycosis is an uncommon skin infection of dogs and cats in which bacterial organisms form macroscopic or microscopic tissue grains.
II. The causative organism is usually *Staphylococcus* spp., but occasionally other bacteria (*Streptococcus* spp., *Pseudomonas* spp., or *Proteus* spp.) are isolated.
III. Infections are associated with a presumed immunologic reaction to nonbranching bacteria and may be sequela to a penetrating injury or bite wound.

Clinical Signs

I. Single to multiple, firm, nonpainful, and typically nonpruritic nodules are seen.
II. Nodules may be fistulated.
III. Purulent discharge may contain white granules or grains.

Diagnosis

I. Cytological examination of exudates reveals suppurative inflammation (with or without granules) containing dense bacterial colonies.
II. Dermatohistopathologic examination reveals pyogranulomatous inflammation of the dermis that may extend into the superficial and deeper subcuticular areas.
III. Within pyogranulomas are discrete accumulations of bacteria that are imbedded in brightly eosinophilic material compatible with a Splendore-Hoeppli reaction (presumed to consist of antigen-antibody complexes).
IV. Bacterial culture of tissue and/or exudates with tissue grains yields the causative agent.

Differential Diagnosis

I. Actinomycosis, nocardiosis
II. Foreign-body reaction
III. Systemic mycoses
IV. Neoplasia
V. Atypical mycobacteriosis

Treatment

I. Surgical excision of nodules is performed.
II. Long-term antibiotic therapy (4 to 8 weeks) is based on culture and sensitivity results.
III. In most cases, antibiotic therapy alone is not effective.
IV. Prognosis is good with combined medical and surgical therapy.

Actinomycosis and Nocardiosis

Definition and Causes

I. Actinomycosis and nocardiosis are uncommon cutaneous and subcutaneous (and sometimes systemic) diseases of the dog and cat.
II. *Actinomyces* spp. are gram-positive, non–acid-fast, filamentous, anaerobic, and microaerophilic rods.
III. *Actinomyces* spp. are commensal inhabitants of the oral cavity and gastrointestinal tract of many mammals and may exist as saprophytes.
IV. *Nocardia* spp. are gram-positive, partially acid-fast, filamentous, aerobic, rods that are common saprophytes.

Pathophysiology

I. Infections are typically a result of wound contamination or inoculation of the agents into tissue.
II. Highest incidence is in outdoor dogs and cats, especially hunting dogs.
III. Disease is more common in immunosuppressed animals.

Clinical Signs

I. History of previous bite wounds or penetrating injury is common.
II. Clinical signs include solitary to multiple, intact or ulcerated dermal and subcutaneous nodules, cellulitis, fistulous tracts, and abscess formation.
III. Drainage can be serosanguineous to purulent.
  A. Tissue grains are most common with actinomycosis.
  B. *Nocardia asteroides,* the most common agent of nocardiosis, typically does not produce tissue grains.
IV. Lesions of actinomycosis are commonly present in the cervical, mandibular, and submandibular areas.
V. Lesions of nocardiosis typically occur on the feet, limbs, and trunk.

Diagnosis

I. Cytological examination of actinomyces exudate or aspirate
  A. Neutrophilic to pyogranulomatous inflammation
  B. Individual or aggregates of gram-positive, non–acid-fast, beaded, filamentous organisms with occasional branching
II. Cytological examination of nocardiosis exudate or aspirate
  A. Neutrophilic to pyogranulomatous inflammation
  B. Individual or aggregates of gram-positive, partially acid-fast, beaded, branching filamentous organisms
III. Histopathologic examination
  A. Deep punch or wedge biopsy of nodules or fistulous tracts is recommended.
  B. Pyogranulomatous inflammation with aggregates of bacterial organisms is usually detected.
  C. Special stains can be requested to help identify organisms.
IV. Bacterial culture and sensitivity
  A. Aerobic and anaerobic cultures are submitted.
  B. Organisms are often difficult to grow.

Differential Diagnosis

I. Atypical mycobacterial infection
II. Systemic mycoses
III. Opportunistic fungal infection
IV. Neoplasia

Treatment

I. Surgical excision and debulking of diseased tissue
II. Long-term antibiotics based on culture and sensitivity, if possible
  A. Actinomycosis
    1. Penicillin G (PO, SC, IM, IV) or penicillin V (PO) at ≥60,000 U/kg TID
    2. Minocycline 5 to 25 mg/kg IV, PO BID
    3. Clindamycin 5 mg/kg SC BID
    4. Amoxicillin 20 to 40 mg/kg IM, SC, PO QID
    5. Erythromycin 10 mg/kg PO TID
  B. Nocardiosis
    1. Sulfadiazine 80 mg/kg PO TID or 110 mg/kg PO BID
    2. Sulfamethazine 50 mg/kg PO TID
    3. Sulfisoxazole 50 mg/kg PO TID
    4. Trimethoprim-sulfadiazine 15 to 30 mg/kg PO, SC BID
    5. Ampicillin 20 to 40 mg/kg IV, IM, SC, PO QID
    6. Erythromycin 10 mg/kg PO TID
    7. Minocycline 5 to 25 mg/kg PO, IV BID

Monitoring of Animal

I. Prognosis for cure with both diseases is guarded.
II. Animals that are systemically ill are also evaluated for systemic disease.

Atypical Mycobacteriosis

Definition and Causes

I. Atypical mycobacteriosis is an uncommon nodular disease of dogs and cats caused by fast-growing, saprophytic mycobacteria present in the environment that are inoculated in the dermis and panniculus by trauma or contamination of a wound.
II. It is most often associated with infections of Runyon group IV mycobacteria.
  A. *Mycobacterium fortuitum*, *M. phlei*, *M. smegmatis*, *M. chelonei*
  B. Nonchromogenic, rapidly growing, gram-positive, acid-fast, aerobic, non–spore-forming bacilli
III. Group IV mycobacteria are ubiquitous in nature.

Pathophysiology

I. Cats appear to be more susceptible to the development of mycobacterial skin infections than other animals.
II. History of trauma is usually reported before the onset of clinical disease.
III. Rapidly growing atypical mycobacteria are rare causes of skin disease in dogs.

Clinical Signs

I. In the cat, skin lesions are most commonly found over the ventral abdomen and inguinal fat pads.
  A. Lesions are characterized by chronic or recurrent fistulous tracts and ulcers, as well as purpuric macules and nodules that ulcerate.
  B. Underlying adipose tissue is thickened, firm, and nodular on palpation.
  C. In some cases large cutaneous lesions are present that migrate along fascial planes.
  D. Most cats are unaffected systemically, and disseminated disease is rare.
II. Lesions in dogs are usually associated with trauma or fight wounds.
  A. Lesions are characterized by recurrent abscesses, draining tracts, and nonpainful subcutaneous nodules that ulcerate and drain.
  B. Prognosis for remission with medical and surgical intervention is better for dogs than cats.
  C. Pulmonary and disseminated disease associated with atypical mycobacteria (without cutaneous involvement) can occur in the dog.

Diagnosis

I. Submission of deep wedge biopsies for culture is necessary for diagnosis.
  A. Because of the low number of organisms usually present in the lesions, the need to repeat biopsies several times is not uncommon.
  B. When possible, intact nodules are selected for biopsy.
  C. Special culture media are requested.
  D. Dehiscence of the biopsy area is not uncommon.
II. *Mycobacterium fortuitum* is most commonly isolated, followed by *M. smegmatis*, *M. phlei*, and *M. chelonei*.
III. Cultures of exudate from draining lesions are typically negative.
IV. Cytological examination of exudate from lesions reveals pyogranulomatous inflammation, and organisms are rarely seen.
V. Tissue samples that include adipose tissue are submitted for culture and sensitivity testing and histopathology.
VI. Histopathologic findings consist of varying degrees of granuloma formation, pyogranulomatous dermatitis, cellulitis, and panniculitis.
VII. Acid-fast bacteria are observed in approximately 50% of cases and are usually present extracellularly in clear vacuoles surrounded by a rim of neutrophils (Greene, 1998).

Differential Diagnosis

I. Nocardiosis, actinomycosis
II. Systemic mycoses
III. Neoplasia

Treatment

I. Treatment is based on culture and sensitivity results.
II. Antibiotic treatment is typically prolonged; some animals are never cured and relapse once antibiotics are discontinued.
III. Fluoroquinolones and clarithromycin are the best choices for empiric treatment while culture and sensitivity results are pending.
  A. Higher than normal doses have been recommended for fluoroquinolones (10 to 20 mg/kg PO/day), although

caution must be exercised when administering enrofloxacin to cats (doses >5 mg/kg/day have been associated with blindness).
   B. Clarithromycin can be administered at 5 to 15 mg/kg PO BID.
IV. Wide surgical excision of lesions is helpful, although wound dehiscence is common if all affected tissue is not removed.

Canine Leproid Granuloma Syndrome

Definition and Causes

I. It is a poorly characterized mycobacterial disease of dogs in which nodular mycobacterial granulomas are present in the skin and subcutis.
II. The cause is an unidentified mycobacterial organism.

Pathophysiology

I. Pathogenesis is unknown; however, it has been speculated that biting flies may be responsible for inoculating mycobacteria into the skin of susceptible dogs.
II. The syndrome occurs most commonly in New South Wales, Australia, although worldwide distribution is likely.
III. The disease is most common in short-haired breeds, boxers, or boxer-cross dogs.

Clinical Signs

I. Single or multiple firm nodules are present that may ulcerate.
II. Nodules are not painful and are found most often on the head and dorsal surface of the pinnae.
III. Nodules may also occur on the distal limbs and trunk.
IV. Affected dogs are not systemically ill, and internal organ or lymph node involvement is not a feature of the syndrome.

Diagnosis

I. Diagnosis is made by submitting nodules for histopathology.
II. Organisms are infrequently identified on cytological examination of material collected by fine-needle aspiration of the nodules.
III. Lesions contain variable numbers of acid-fast bacilli surrounded by granulomatous inflammation.
IV. Culture and sensitivity of affected tissue should be attempted, but no mycobacterial organisms have been isolated to date.

Differential Diagnosis

I. Bacterial granulomas
II. Systemic mycoses
III. Neoplasia

Treatment and Monitoring

I. Favorable response to treatment with doxycycline or amoxicillin-clavulanate has been reported.
II. Some dogs have demonstrated spontaneous resolution of the nodules.
III. A small number of dogs develop chronic lesions despite treatment.
IV. Prognosis is usually good, with lesions typically regressing within 3 to 4 weeks.

Systemic Mycoses

Definition

I. Systemic mycoses with cutaneous manifestations include blastomycosis, histoplasmosis, coccidioidomycosis, and cryptococcosis.
II. Nodular lesions are a common cutaneous manifestation of systemic mycoses.

Causes

I. Blastomycosis is a systemic mycotic infection affecting numerous organ systems caused by *Blastomyces dermatitidis* (see Chapter 111).
II. Histoplasmosis is caused by the soilborne, dimorphic fungus *Histoplasma capsulatum*.
III. Coccidioidomycosis is caused by the soilborne fungus *Coccidioides immitis*.
IV. Cryptococcosis in dogs and cats is caused by *Cryptococcus neoformans*.

Pathophysiology

I. Blastomycosis
   A. Primary mode of infection is inhalation of spores from mycelial growth.
   B. Large-breed male dogs are most commonly infected; cats are rarely infected.
II. Histoplasmosis
   A. Free-living mycelial stage produces microconidia that are infective.
   B. Inhalation of the microconidia is the likely route of infection.
III. Coccidioidomycosis: inhalation of arthroconidia
IV. Cryptococcosis: inhalation of airborne organisms most likely route

Clinical Signs

I. Blastomycosis
   A. Cutaneous disease occurs in up to 40% of dogs (Greene, 1998).
   B. Lesions include intact or ulcerated nodules and plaques, subcutaneous abscesses, draining tracts, and large firm papules.
   C. Multiple lesions are usually present and can occur anywhere, although the face, nasal planum, and digits are commonly affected.
   D. Cats have similar lesions, with the digits and footpads most often affected.
II. Histoplasmosis
   A. Cats are a susceptible host, and most cases occur in cats <4 years of age.
      1. Skin disease is uncommon, but lesions are usually multiple and occur anywhere on the body.
      2. Lesions consist of draining tracts, papules, ulcers, and nodules.

3. The face, nose, and pinnae may be more commonly affected.

B. Most affected dogs are <4 years of age, and skin lesions are similar to those in cats.

III. Coccidioidomycosis
A. Skin lesions in dogs are usually multiple and almost always occur over bony prominences.
B. Lesions typically consist of nodules, papules, ulcers, draining tracts, and abscesses.
C. Lesions in cats consist of nodules, subcutaneous granulomas, draining tracts, and abscesses.
D. Skin lesions are the most frequent type of infection in cats and occur with or without underlying bony involvement.

IV. Cryptococcosis
A. Skin or subcutaneous lesions are present in up to 50% of feline cases (Greene, 1998).
1. Cutaneous lesions commonly consist of multiple papules to nodules of varying sizes, as well as abscesses, ulcers, and draining tracts.
2. Skin lesions are most common on the face, pinnae, and paws.
3. Nasal lesions are common and classically are firm to boggy swellings over the bridge of the nose or fleshly polypoid masses in the nostril.

B. In general, cryptococcosis is an uncommon disease in the dog; only 20% of cases have skin lesions (Greene, 1998).
1. Skin lesions may consist of abscesses, nodules, papules, ulcers, and draining tracts.
2. Lesions of the tongue, gums, and hard palate may also occur.

Diagnosis

I. Cytological and histopathologic examination of nodules show pyogranulomatous inflammation.
II. Blastomycosis organisms are round to oval yeast structures measuring 5 to 20 µm in diameter that demonstrate broad-based budding and have a thick refractile, double-contoured cell wall.
III. Histoplasmosis organisms are round yeast 2 to 4 µm in diameter that are often contained within macrophages.
IV. Coccidioidomycosis organisms can have two forms.
A. The spherule form is 20 to 200 µm in diameter, and the endospore form is 2 to 5 µm in diameter.
B. Spherules are often found in exudate from draining skin lesions.
V. Cryptococcosis organisms are round to elliptical organisms 2 to 20 µm in diameter that display narrow-based budding and have a thick, clear or refractile halo.
VI. For a discussion of serological testing for the systemic mycoses, see Chapters 2 and 111.

Differential Diagnosis

I. Neoplasia
II. Mycobacterial infection
III. Actinomycosis, nocardiosis

Treatment and Monitoring

I. See Table 89-1.
II. Treatment duration may be >6 months, and prognosis for some systemic mycoses is guarded.

Sporotrichosis

Definition and Causes

I. Sporotrichosis is a subcutaneous nodular dermatosis caused by a dimorphic fungus.
II. The causative agent, *Sporothrix schenckii*, exists as a saprophyte in soil and organic matter.

Pathophysiology

I. The organism has a worldwide distribution.
II. In most cases, sporotrichosis is acquired via inoculation of the organism into tissues.
III. Sporotrichosis can occur in three forms: cutaneous, cutaneolymphatic, and disseminated.
IV. More than one form may be present in an individual.

Clinical Signs

I. Skin lesions in dogs with the cutaneous form consist of multiple firm nodules and plaques.
A. Lesions favor the head, pinnae, and trunk but can occur anywhere.
B. Nodules may ulcerate and form draining tracts.
C. The cutaneolymphatic form arises as a nodule on a distal limb, with subsequent ascending infection via lymphatics.
D. Secondary nodules associated with regional lymph nodes may develop.

II. In cats, skin lesions consist of draining puncture wounds, abscesses, and cellulitis.
A. Lesions are often found on the head, distal limbs, and base of tail, and they are sometimes associated with fight wounds.
B. Lesions may become very exudative, with crusting, progressive ulceration, and necrosis that affect the underlying soft tissues.
C. Autoinoculation associated with grooming behavior can result in the development of additional lesions.

Diagnosis

I. Diagnosis can be made by cytological or histological identification of the organism.
II. Large numbers of organisms are usually present in the exudate of lesions from cats, but very low numbers of organisms are retrieved from canine lesions.
III. Organisms are cigar shaped, round or oval, measure 2 to 10 µm, and are found extracellularly or within phagocytic cells.
IV. Tissue may be submitted for culture.
V. In dogs, fluorescent antibody tests are helpful in establishing a diagnosis when the organism is not detected and fungal cultures are negative.

TABLE 89-1

Antifungal Therapies for Selected Deep Fungal Diseases in the Dog and Cat

	DRUG	SPECIES	DOSE (mg/kg)	ROUTE	INTERVAL	DURATION
Blastomycosis						
	Itraconazole	Dog	5	PO	SID	60 days
		Cat	5	PO	BID	60 days
	Fluconazole	Dog	5	PO	BID	60 days
	Amphotericin lipid complex	Dog	1	IV	3 times/week	Stopped when cumulative dose reaches 12 mg/kg
	Amphotericin	Cat	0.25	IV	3 times/week	Stopped if azotemia occurs or cumulative dose reaches 4 mg/ kg
		Dog	0.5	IV	3 times/week	Stopped if azotemia occurs or cumulative dose reaches 4-6 mg/ kg, then imidazole started Stopped when cumulative dose is 8-10 mg/kg if given alone
Coccidioidomycosis						
	Ketoconazole	Dog	5-10	PO	BID	8-12 months
		Cat	50 mg/dose	PO	SID-BID	12 months
	Itraconazole	Dog	5	PO	BID	12 months
		Cat	25-50 mg/dose	PO	SID-BID	12 months
	Fluconazole	Dog	5	PO	BID	12 months
		Cat	25-50 mg/dose	PO	SID-BID	12 months
	Amphotericin	Dog	0.4-0.5	IV	every 48-72 hrs	Until cumulative dose of 8-11 mg/kg reached
	Lufenuron	Dog	5	PO	SID	4 months
Cryptococcosis						
	Flucytosine	Cat	30	PO	QID	1-9 months *or*
			50	PO	TID	1-9 months *or*
			75	PO	BID	1-9 months
		Dog	50-75	PO	TID	1-12 months
	Amphotericin (deoxycholate)	Cat	0.1-0.5	IV	3 times/week	Until cumulative dose of 4-10 mg/kg reached
		Dog	0.25-0.5	IV	3 times/week	Until cumulative dose of 4-10 mg/kg reached
	Amphotericin (lipid complex)	Cat	0.5-0.8	SC	3 times/week	Each dose added to 400 mL of 0.45% saline, 2.5% dextrose to total cumulative dose of 8-26 mg/kg
		Dog	1	IV	3 times/week	With lipid complex drug, individual dose and cumulative dose may be increased until cumulative dose of 8-12 mg reached
	Ketoconazole	Cat	5-10	PO	BID	6-10 months *or*
			10-20	PO	SID	6-10 months
		Dog	5-15	PO	BID	6-10 months *or*
			30	PO	SID	6-10 months
	Itraconazole	Cat	5-10	PO	BID	6-10 months *or*
			10-20	PO	SID	6-10 months
	Fluconazole	Dog, cat	5-15	PO	SID-BID	6-10 months

TABLE 89-1

Antifungal Therapies for Selected Deep Fungal Diseases in the Dog and Cat—*cont'd*

DRUG	SPECIES	DOSE (mg/kg)	ROUTE	INTERVAL	DURATION
Histoplasmosis					
Itraconazole	Dog, cat	10	PO	SID-BID	4-6 months
Fluconazole	Dog, cat	2.5-5	PO	SID-BID	4-6 months
Amphotericin	Dog, cat	0.25-0.5	IV	QOD	Continued until cumulative dose of 5-10 mg/kg reached in dogs and 4-8 mg/kg in cats
Sporotrichosis					
SSKI (potassium iodide)	Dog	40	PO	TID	>2 mo
	Cat	20	PO	BID	>2 mo
Ketoconazole	Dog	5-15	PO	BID	>2 mo
	Cat	5-10	PO	BID	>2 mo
Itraconazole	Dog	5-10	PO	SID-BID	>2 mo
	Cat	5-10	PO	SID-BID	>2 mo

Differential Diagnosis

I. Systemic mycoses
II. Neoplasia
III. Mycobacterial disease
IV. Actinomycosis, nocardiosis

Treatment and Monitoring

I. See Box 89-1.
II. Treatment duration may be >6 months, and prognosis is guarded.
III. Because of the zoonotic potential of this organism, all individuals handling possible cases should wear gloves and properly dispose of contaminated material.

MISCELLANEOUS NODULAR DISEASES

See Table 89-2.

NEOPLASIA

Mast Cell Tumor

Definition and Causes

I. Mast cell tumors (MCTs) are malignant tumors that are the most common skin tumor of dogs and the second most common tumor of cats.
II. The etiology is unknown.
III. Researchers have proposed a viral etiology because many dogs with MCT have genetic mutations in c-kit, which may be responsible for the genesis and/or progression of MCT.

Clinical Signs

I. Most often reported in middle-aged to older animals
   A. It is occasionally found in dogs as young as 4 months.
   B. Breeds with a predilection include the boxer, Boston terrier, bull terrier, bull mastiff, Staffordshire bull terrier, fox terrier, English bulldog, dachshund, Labrador retriever, golden retriever, beagle, pug, Chinese shar-pei, Rhodesian ridge back, and Weimaraner.
   C. Siamese cats are predisposed.
II. All canine cutaneous MCTs are considered potentially malignant.
   A. Tumors are generally alopecic, erythematous, edematous nodules that vary in size from several millimeters to several centimeters.
   B. Lesions are common on the trunk, head, and extremities.
   C. Lesions on distal extremities and lips may occur as poorly defined areas of swelling.
   D. Massive degranulation of neoplastic mast cells may occasionally occur, resulting in generalized edema, altered coagulation, severe hypotension, and/or terminal hemorrhagic gastroenteritis.
III. MCTs in cats are usually discrete, firm, tan, alopecic papules and nodules, ranging in size from a few millimeters to 2 cm.
   A. Head, legs, upper thighs, and the dorsal tail are the most common areas affected.
   B. Most MCTs in cats are benign neoplasms, with low local recurrence rates.
   C. Atypical, poorly granulated MCTs sometimes recur as multiple miliary nodules that eventually regress spontaneously.
   D. Rarely, numerous and widespread papular to small nodular cutaneous MCTs arise from cutaneous spread of primary visceral mast cell neoplasia.

Diagnosis

I. Cytological examination
   A. Neoplastic round cells with eccentrically placed nuclei and abundant metachromatic cytoplasmic granules

TABLE 89-2

Miscellaneous Nodular Diseases

DISEASE/DEFINITION	SIGNALMENT/PATHOGENESIS	CLINICAL PRESENTATION	DIAGNOSIS	TREATMENT/PROGNOSIS
Leishmaniasis is a protozoal infection caused by numerous *Leishmania* spp.	Occurs in dogs and cats Rodents, other domestic and wild mammals can serve as reservoirs for disease Transmitted by sandflies *Phlebotomus* (Old World) and *Lutzomyia* (New World)	Clinical presentation includes the following: exfoliative dermatitis and silvery scale, nodular and pustular dermatitis, nasal and digital hyperkeratosis Numerous organ systems can be affected	Definitive diagnosis is by cytologic or histologic identification of amastigotes from lymph nodes or bone marrow ELISA, complement fixation, and indirect fluorescent antibody tests are available but do not confirm active disease PCR assays are also available	Meglumine antimonate 20-50 mg/kg SC BID or 200-300 mg/kg IV QOD Allopurinol 11-15 mg/kg PO SID Combination therapy may improve clinical response rates Prognosis is poor for cure Public health hazard often results in euthanasia of animal
Pythiosis is caused by an aquatic pathogen, *Pythium insidiosum*, a member of the class of Oomycetes	Disease occurs in dogs and rarely in cats Infection occurs after exposure and/or consumption of water contaminated with motile flagellate zoospores Most common in wet tropical and subtropical climates	Three forms of disease have been described: subcutaneous, nasopharyngeal, gastrointestinal Cutaneous lesions occur on the limbs of dogs and the trunk or back of cats Lesions consist of soft, boggy proliferative nodules that ulcerate and form draining tracts	Cytology: macerated tissue in 10% KOH sometimes reveals poorly septate, wide and branching hyphae Histopathology: pyogranulomatous dermatitis with eosinophils and hyphae Other tests: culture of affected tissues and ELISA serology	Early and complete surgical removal of affected tissue can be curative Therapy with antifungal agents is usually unsuccessful Prognosis is poor
Protothecosis is a saprophytic, achlorophyllous algae	Rare in dogs and cats Highest incidence reported in immunosuppressed animals Infection occurs via the gastrointestinal tract or through contact with injured skin	*Cats:* large, firm cutaneous nodules common over the distal extremities, head, and base of the tail *Dogs:* disseminated disease with multiorgan involvement, skin lesions consisting of nodules and draining tracts over the extremities, and mucocutaneous junctions	Cytology: pyogranulomatous inflammation with spherules that often contain endospores Histopathology: nodular to diffuse pyogranulomatous inflammation with large numbers of organisms	Wide surgical excision is done for localized lesions Systemic antifungal treatments are usually ineffective Prognosis is poor if the disease is disseminated or lesions are not resectable

ELISA, Enzyme-linked immunosorbent assay; *PCR,* polymerase chain reaction; *KOH,* potassium hydroxide.

TABLE 89-2

Miscellaneous Nodular Diseases—*cont'd*

DISEASE/DEFINITION	SIGNALMENT/PATHOGENESIS	CLINICAL PRESENTATION	DIAGNOSIS	TREATMENT/PROGNOSIS
Sterile nodular panniculitis is an idiopathic inflammatory disease of subcutaneous fat	Rare in dogs and cats Dachshunds and poodles may be predisposed	The trunk is most commonly affected, with deep cutaneous nodules Lesions may become cystic, ulcerate, and develop draining tracts Animals with multiple lesions may exhibit anorexia, lethargy, and pyrexia	Excisional biopsy: suppurative, pyogranulomatous, granulomatous, eosinophilic, necrotizing or fibrosing, septal or diffuse panniculitis Negative cultures for bacteria, mycobacteria, and fungi are supportive	Excision of a solitary lesion is performed Multiple lesions: tetracycline and niacinamide at 500 mg PO TID of each drug for dogs >10 kg or 250 mg PO TID of each drug for dogs <10 kg; cyclosporine 5 mg/kg PO SID until resolution, then tapered Severe or refractory cases: prednisone 2 mg/kg PO SID (dogs) or 4 mg/kg PO SID (cats) until resolution, then tapered Prognosis is good
Xanthoma is a benign granulomatous lesion associated with an abnormality in lipid metabolism	Causes in cats include hereditary hyperlipoproteinemia, idiopathic forms, feeding high-fat foods and/or treats, and diabetes mellitus	Condition consists of multiple whitish or yellow papules, and nodules or plaques that may be ulcerated Head, distal extremities, feet, and bony prominences are typically affected	Histopathology: nodular to diffuse infiltration of foamy macrophages and variable numbers of multinucleate histiocytic giant cells	Lesions resolve with resolution of underlying disease Low-fat diets are fed to cats with hypertriglyceridemia
Calcinosis circumscripta is a focal area of dystrophic calcification that occurs at sites of repetitive or previous trauma	Uncommon in dogs Highest incidence in young, large-breed dogs Described in association with hypertrophic osteodystrophy and polyarthritis Very rare in cats	Single, firm, haired or alopecic dome-shaped subcutaneous or deep dermal masses are seen that may ulcerate and discharge a white, gritty substance Elbows, metatarsal, and phalangeal areas are commonly affected	Cytology: amorphous, gritty white material Histopathology: multifocal accumulations of finely or coarsely granular, amorphous, basophilic debris in the deep dermal or subcutaneous tissue that is surrounded by granulomatous inflammation	Complete surgical excision is curative Resolution of associated disease may cause lesions to diminish Prognosis is good

Continued

TABLE 89-2

Miscellaneous Nodular Diseases—*cont'd*

DISEASE/DEFINITION	SIGNALMENT/PATHOGENESIS	CLINICAL PRESENTATION	DIAGNOSIS	TREATMENT/PROGNOSIS
Sterile granuloma and pyogranuloma are probably immune-mediated, but the exact pathogenesis is unknown	Uncommon in dogs Highest incidence in the collie, golden retriever, boxer, and other large, short-haired breeds	Nonpainful, nonpruritic firm dermal papules and nodules are seen that may become alopecic or ulcerated Most common location is over the muzzle, periocular areas, ear, pinnae, and feet	Cytology: pyogranulomatous inflammation with no microorganisms Histopathology: nodular to diffuse pyogranulomatous dermatitis Negative fungal, bacterial and mycobacterial cultures are supportive	Excision of solitary lesions Prednisone 1-2 mg/kg PO BID, then tapered Tetracycline and niacinamide 500 mg PO TID of each drug for dogs >10 kg or 250 mg TID for dogs <10 kg Azathioprine 2 mg/kg PO SID, then 2 mg/kg PO QOD for maintenance Prognosis is good, although continuous therapy is needed for some dogs
Nodular dermatofibrosis is associated with renal cystic disease and uterine leiomyomas	Rare in dogs Highest incidence in middle-aged to older German shepherd dogs It may have an autosomal dominant mode of inheritance	Sudden appearance of multiple firm, well-circumscribed nodules up to 4 cm Most common location is the limbs, head, and ears Skin disease can precede clinical signs of underlying cause by months to years	Histopathology: circumscribed dermal or subcutaneous mass composed of structurally normal collagenous bundles Radiography, ultrasonography or exploratory laparotomy may be needed to diagnose underlying renal or uterine disease	Removal of skin lesions may be done for cosmetic reasons Nephrectomy is indicated for unilateral kidney disease Ovariohysterectomy is done for uterine leiomyomas Long-term prognosis is poor

B. Possible agranular mast cells
C. Eosinophils common

II. Histopathologic examination
A. Dermal and/or subcutaneous masses composed of round cells arranged in sheets and cords
B. Round to oval cells with central round nuclei, abundant cytoplasm, and metachromatic granules
C. Variable numbers of eosinophils

III. Systemic evaluation
A. Prognostic factors
1. A worse prognosis has been associated with rapid growth, a deep and fixed position, ulceration, systemic signs, and location on a mucocutaneous junction, the muzzle, or ear.
2. Masses in the inguinal, preputial, or perianal regions may exhibit less aggressive behavior.

B. Staging
1. Staging tests for asymptomatic dogs with cutaneous MCTs are often normal.
2. The test that is positive most often is regional lymph node aspiration.
3. Buffy coat preparation and bone marrow aspiration are usually negative.
4. Ultrasonography is indicated to evaluate the liver, spleen, and sublumbar lymph nodes.
5. Thoracic radiography is done to evaluate the sternal lymph nodes.

Treatment

I. All MCTs are widely excised as early as possible, taking 2- to 3-cm lateral margins and one tissue plane deep to the tumor.

II. MCTs are very radiosensitive, and radiation therapy is a common adjunctive therapy when incomplete margins are detected after surgery.

III. Chemotherapy may be used for large tumors, residual microscopic disease after excision of grade II tumors, or for grade III tumors.
A. This treatment has limited value for disseminated disease.
B. Lomustine 60 to 90 mg/m^2 PO every 3 weeks for five doses is often given.
C. Vinblastine, vincristine, and chlorambucil can be considered.
D. Prednisone is given as a palliative measure.

IV. Ancillary therapy includes famotidine 0.5 mg/kg PO SID and diphenhydramine 2 mg/kg PO TID.

Monitoring of Animal

I. Reevaluate the animal every 3 to 4 months for presence of new cutaneous lesions and for metastasis to regional lymph nodes and/or internal organs.

II. For animals on lomustine, monitor for neutropenia, thrombocytopenia, and hepatotoxicity.

III. The Patnaik grading scheme has shown that 83%, 44%, and 6% of dogs with grade I, II and III tumors, respectively, were alive approximately 4 years after surgery (Bergman, 2005).

IV. Grading scheme is not useful for cats.

V. Prognosis for cats with primary cutaneous MCTs is good.

Epithelial and Hair Follicle Tumors

See Table 89-3.

Mesenchymal Tumors

See Table 89-4.

Histiocytic and Lymphocytic Tumors

See Table 89-5.

TABLE 89-3

Epithelial and Hair Follicle Tumors

TUMOR/DEFINITION	SIGNALMENT	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Squamous cell carcinoma: malignant neoplasm of keratinocytes	Common in dogs and cats Affects older animals Scottish terrier, Pekingese, boxer, poodles, and Norwegian elkhound predisposed	Solitary, proliferative, cauliflower-like lesions Often ulcerated Most common on unpigmented pinnae, nose, and eyelids of cats	Cytology: epithelial cells arranged individually or in clusters with retained nuclei and nuclear atypia Histopathology: poorly defined masses of neoplastic keratinocytes, common mitotic figures, ± keratin pearls	Wide surgical excision Laser ablation or cryotherapy for small, superficial lesions Radiation therapy for nonresectable lesions Prognosis variable Better prognosis for small, well-differentiated tumors Most tumors locally invasive and slow to metastasize Nail bed tumors more aggressive and metastasize more readily
Basal cell tumor: neoplasm of basal cells of the epidermis, hair follicles, sebaceous glands, or sweat glands	Common in older cats Siamese, Himalayan, and Persian cats predisposed Uncommon in older dogs Cocker spaniel, poodles, Shetland sheepdog, Kerry blue terrier, and Siberian husky predisposed	Common locations: head, neck, thorax, dorsum Lesions solitary, discrete, firm to fluctuant nodules Lesions may be pigmented or cystic	Cytology: cuboidal epithelial cells with scant blue cytoplasm, rare atypia Histopathology: lobulated intradermal to subcutaneous masses, cords, or nests of cells	Surgical excision usually curative Prognosis good as tumors exhibit benign behavior Basal cell carcinomas are low-grade malignancies; rarely metastasize
Trichoblastoma: benign hair follicle tumor arising from primitive hair germ epithelium	Common in older dogs and cats Poodles and cocker spaniels predisposed	Up to 2 cm in size Firm alopecic masses on the head and neck of dogs and cranial trunk of cats	Cytology: keratinized epithelial cells, free keratin Histopathology: ribbons to nodules of small, basophilic, undifferentiated basal cells	Surgical excision Prognosis good
Trichoepithelioma: benign hair follicle tumor from cells that differentiate into hair follicle or shaft structures	Older dogs and cats Uncommon Bassett hound, golden retriever, miniature schnauzer, standard poodle, spaniels, and Persian cats predisposed	Up to 2 cm in size Alopecic, firm, gray to white lobulated masses Most common on the trunk and legs of dogs and the tail and legs of cats	Cytology: see Trichoblastoma Histopathology: multiple well-circumscribed nodules of basal cells that resemble primitive follicular bulbs and contain central cystic areas of keratinization	See Trichoblastoma
Tricholemmoma: benign hair follicle tumor arising from follicular outer root sheath cells	Rare Occurs in middle-aged to older dogs and cats Afghan hound predisposed	Up to 7 cm in size Firm, discrete nodules Most common on the head and neck	Cytology: see Trichoblastoma Histopathology: well-circumscribed nodules of small polyhedral cells with clear cytoplasm, surrounded by a thick basement membrane	See Trichoblastoma

TABLE 89-3

Epithelial and Hair Follicle Tumors—*cont'd*

TUMOR/DEFINITION	SIGNALMENT	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Trichofolliculoma: likely a hamartoma because it resembles the entire follicular or folliculosebaceous unit	Uncommon in dogs Rare in cats	Solitary dome-shaped nodule <2 cm Possible central pore or depression	Cytology: see Trichoblastoma Histopathology: well-circumscribed dermal nodule composed of one or several primary follicles that are large, dilated, and keratinized through to the granular cell layer	See Trichoblastoma
Pilomatricoma: benign hair follicle tumor arising from germinative cells of the follicular matrix	Uncommon in dogs Occurs in middle-aged to older dogs Poodles, Kerry blue terrier, Old English sheepdog, Airedale terrier predisposed	Solitary, firm-to-hard, well-circumscribed masses up to 10 cm Most common over rump and shoulders	Cytology: see Trichoblastoma Histopathology: discrete nodule formed by multiple cystic structures lined by basilar epithelial cells, cysts containing keratinized ghost cells	See Trichoblastoma
Infundibular keratinizing acanthoma: benign hair follicle tumor of unknown cause	Uncommon in dogs Norwegian elkhound, Lhasa apso, Pekingese, Yorkshire terrier, and German shepherd dog predisposed	Up to 4 cm in size Solitary or multiple, partially alopecic nodules, usually with a central pore	Cytology: cornified squamous epithelial cells, and amorphous cellular debris Histopathology: well-circumscribed dermal nodule oriented around central cyst filled with laminated keratin	Surgical excision Prognosis good
Sebaceous adenoma: benign cutaneous neoplasm of glandular or combined ductal and glandular origin	Occurs in older dogs Cocker spaniel, Siberian husky, miniature poodle, coonhound, beagle, dachshund, and Persian cats predisposed	Lesions solitary or multiple, dome-shaped or papillated tumors that usually measure <1 cm	Cytology: normal-appearing sebaceous cells with foamy, pale-blue cytoplasm and small, dark nuclei Histopathology: multiple, large lobules of sebaceous cells that show normal maturation from the basal reserve cell layer to large, pale, lipid-laden central cells	Observation only or surgical excision Prognosis good
Sebaceous epithelioma: neoplasm that differentiates primarily into basal reserve cells of sebaceous glands	Common in dogs Rare in cats Predisposed breeds same as for sebaceous adenomas	Firm, nodular fungiform or plaquelike masses Range from several millimeters to several centimeters in size	Cytology: small, uniform, sometimes pigmented epithelial cells, with low numbers of sebaceous cells Histopathology: multiple, large, irregular islands of epithelial reserve cells, well-circumscribed smaller lesions, irregular and infiltrative larger masses	Observation or surgical excision Prognosis good

Continued

TABLE 89-3

Epithelial and Hair Follicle Tumors—*cont'd*

TUMOR/DEFINITION	SIGNALMENT	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Sebaceous carcinoma: rare, malignant neoplasm of sebocytes	Older dogs and cats Cocker spaniel, Cavalier King Charles spaniel, Scottish terrier, and Siberian husky predisposed	Solitary, firm nodules up to 7.5 cm in size Occur commonly on head of dogs and cats	Cytology: basophilic basal-type cells, with nuclear and cellular atypia Histopathology: irregular but circumscribed, multilobular dermal lesions with variable sebaceous differentiation, cytoplasmic vacuolation, and eosinophilic cytoplasm	Complete surgical excision Tumors locally invasive and lymph node involvement possible Prognosis guarded
Apocrine secretory adenoma: benign neoplasm arising from apocrine gland or ductal cells	Uncommon in dogs and cats Great Pyrenees, chow chow, malamute, and Old English sheepdog predisposed	Well-circumscribed, firm or fluctuant dermal nodules that are usually solitary Lesions in dogs typically 0.5-4 cm in size Usually <2 cm size in cats	Cytology: medium to round or oval epithelial cells that contain eccentric nuclei and large intracytoplasmic droplets of secretory product Histopathology: discrete dermal nodules comprised of multiple ducts, tubules, or cysts lined by cuboidal to columnar epithelium with clear or eosinophilic fluid, inflammation common	Complete surgical excision Prognosis good
Apocrine secretory adenocarcinoma: malignant neoplasm of apocrine gland or ductal cells	Uncommon in dogs and cats Usually in older dogs and cats Coonhound, Norwegian elkhound, and Siamese cat predisposed	Solitary, usually circumscribed masses Size ranges from 0.5-10 cm in dogs and 0.2-3 cm in cats Common on legs and head of dogs and on legs and abdomen of cats	Cytology: variably sized epithelial cells with scant basophilic cytoplasm Histopathology: similar to apocrine secretory adenoma, well-differentiated, composed of neoplastic glandular structures	Complete surgical excision Radiation therapy for incompletely excised lesions Prognosis guarded Tumors possibly locally invasive; can recur and/or metastasize after surgery

TABLE 89-4

Mesenchymal Tumors

TUMOR/DEFINITION	SIGNALMENT	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Melanocytoma: benign neoplasm arising from melanocytes	Common in dogs Uncommon in cats Highest incidence in canine breeds with dark pigmentation of the skin and in cats with black or gray coat color	Solitary, circumscribed, alopecic, fleshy, dome-shaped masses that are 0.5-4.0 cm in size Occur on head and pinnae of cats and trunk and head of dogs	Cytology: variably shaped cells, with brown to green-black pigment in the cytoplasm Histopathology: variably pigmented melanocytes arranged in clusters, cords or whorls, low mitotic index	Surgical excision Prognosis good
Melanoma: malignant dermal or junctional melanocytic tumor	Older dogs and cats Dogs with heavily pigmented skin and cats with black or gray hair coats predisposed	Sessile, polypoid, or plaquelike Up to 10 cm in size Gray, brown, or black in color Common on head and legs of dogs and head, thorax, and tail of cats	Cytology: see Melanocytoma Histopathology: invasive tumors with cellular atypia and frequent mitotic figures, common ulceration, and necrosis; spindle, round to polygonal, dendritic, epithelioid, and balloon cell types	Radical surgical excision Radiation therapy Palliative chemotherapy Prognosis poor Recurrence and metastasis common
Fibrosarcoma: malignant neoplasm arising from fibroblasts	Most common malignant mesenchymal neoplasm in cats Uncommon in dogs Gordon setter, Irish wolfhound, Brittany spaniel, golden retriever, and Doberman pinscher at higher risk	Firm, poorly circumscribed, often multilobular masses Size is 1-15 cm Alopecia and ulceration common Vaccine-induced fibrosarcoma in cats primarily a complication of rabies and feline leukemia virus vaccines	Cytology: variably shaped and sized mesenchymal cells, possible multiple nuclei Histopathology: ill-defined (infiltrative) margins, composed of large spindle cells arranged in interlacing bundles of varying Vaccine-induced tumors demonstrate peripheral inflammation, epithelioid macrophages, multinucleated giant cells (also contain bluish, amorphous material presumed to be adjuvant)	Treatment of choice is wide surgical excision or amputation Radiation therapy Chemotherapy for palliation Prognosis for small tumors good if completely removed Large, deep truncal vaccine-induced tumors have poor to guarded prognosis
Fibroma: benign fibrocytic neoplasm of dermis or subcutis	Uncommon in dogs and cats Doberman pinscher, boxer, and golden retriever predisposed	Solitary, firm or rubbery, circumscribed masses with an ovoid, dome-shaped or polypoid conformation Most common on head and legs of dogs and cats	Cytology: uniform spindle cells, round to oval nuclei, indistinct nucleoli Histopathology: bundles of collagen that are thick and have repetitive patterns, possible broad swirls of collagen, rare mitotic figures	Observation only or surgical excision Prognosis good

Continued

TABLE 89-4

Mesenchymal Tumors—*cont'd*

TUMOR/DEFINITION	SIGNALMENT	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Lipoma: benign tumor of lipocytes	Common in dogs Middle-aged to older dogs and cats Labrador retriever, Doberman pinscher, miniature schnauzer, cocker spaniel, dachshund, weimaraner, and Siamese cat predisposed	Well-circumscribed, ovoid or discoid masses with soft or rubbery consistency Most occur on trunk and legs	Cytology: oily aspirate, variable numbers of lipocytes with ballooning cytoplasm and a small, flat nucleus near the cell membrane Histopathology: well-circumscribed dermal or subcutaneous nodules composed of mature lipocytes, with a delicate capsule	Observation for small lesions Surgical excision for larger or rapidly growing tumors Prognosis generally good Infiltrative lipomas often recur and cause destruction of underlying tissues
Liposarcoma: malignant tumor of subcutaneous lipoblasts	Uncommon in dogs Very rare in cats Middle-aged to older animals Shetland sheepdog and beagle predisposed	Variably circumscribed, soft or fleshy masses that measure ≥2 cm Arise in the subcutis but frequently involve the dermis Most tumors involve axial region and proximal legs	Cytology: bizarre cellular morphology, indistinct cell margins, numerous lipid droplets Histopathology: well-circumscribed but unencapsulated; large round to polygonal cells arranged in solid sheets; low mitotic activity; hemorrhage, necrosis, fibrosis, and ulceration possible	Radical surgical excision Systemic chemotherapy Prognosis guarded to poor Tumors locally invasive Metastasis possible but rare
Hemangioma: benign neoplasm of blood vessel endothelial cells, possibly induced by chronic solar damage in dogs with light skin, thin hair coats	Uncommon in dogs Rare in cats Middle-aged to older animals Airedale terrier, Gordon setter, boxer, soft-coated wheaten, and wirehaired fox terriers predisposed to spontaneous lesions Whippet, beagle, Dalmatian, American bull terrier, and basset hound predisposed to solar-induced lesions	Well-circumscribed, dome-shaped or polypoid masses with red or red black coloration Solar-induced lesions alopecic with ulceration and hemorrhage; occur over ventral abdomen, inguinal region, medial thighs, and axilla	Cytology: blood with few (normal) endothelial cells Histopathology: well-circumscribed, nonencapsulated tumor composed of vascular spaces filled with erythrocytes	Surgical excision Avoidance of ultraviolet exposure Solar-induced lesions may undergo malignant transformation Prognosis generally good

TABLE 89-4

Mesenchymal Tumors—*cont'd*

TUMOR/DEFINITION	SIGNALMENT	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Hemangiosarcoma: malignant neoplasm of vascular endothelial cells; primary or metastatic sites; solar-induced lesions possible	Uncommon in older dogs and cats Italian greyhound, whippet, Irish wolfhound, vizsla, American bull terrier, and basset hound predisposed	Dermal or subcutaneous lesions Dermal lesions ill-defined, red to dark-blue plaques or nodules and ≤2 cm in size Subcutaneous lesions poorly circumscribed, dark-red or blue-black, spongy masses up to 10 cm in size	Cytology: neoplastic endothelial cells varying from normal in appearance to large pleomorphic cells with basophilic cytoplasm and prominent nucleoli Histopathology: plump endothelial cells aligned on delicate collagen trabeculae or dermal collagen bundles, vascular spaces not uniformly enclosed by endothelial cells, low to moderate mitotic activity Check for metastasis with radiography and ultrasonography	Radical surgical excision for dermal tumors Surgical excision and adjunctive chemotherapy (vincristine, doxorubicin, cyclophosphamide) for tumors that involve deeper structures Prognosis good for completely excised dermal lesions Prognosis guarded to poor for locally invasive tumors and metastases
Hemangiopericytoma: neoplasm of pericytes	Occurs in the dog Not reported in cats Exact incidence unknown Cannot be diagnosed without immunohistochemistry to rule out other cell types The term *canine spindle cell tumor with whorling pattern* is considered more accurate for tumors not evaluated by immunohistochemistry Large-breed dogs at greater risk Siberian husky, Irish setter, German shepherd dog, and mixed breeds predisposed	Solitary, deep dermal and subcutaneous, multinodular, fairly well-circumscribed masses with firm or slightly soft consistency Lesions favor trunk or legs	Cytology: small, spindle-shaped to stellate tumor cells with round to oval nuclei and wispy, light blue cytoplasm Histopathology: unencapsulated subcutaneous and/or dermal masses comprised of small spindle and polygonal cells arranged in interlacing bundles, sheets or concentric whorls	Radical surgical excision or amputation Radiation therapy Prognosis variable Tumors may recur locally; metastasis rare
Reactive fibrohistiocytic nodule: benign tumor of histocytes that may be macrophages or dendritic cells, suggestive of a reactive process	Uncommon in dogs Most affected dogs <3 years of age No breed or sex predilections	Solitary or occasionally multiple, firm cutaneous nodules measuring <1 cm Most often occur on face, scrotum, and legs See Chapter 77	Histopathology: circumscribed, unencapsulated dermal nodules composed predominantly of histiocytic cells arranged in solid sheets	Surgical excision Sublesional injection of methylprednisolone 10-40 mg for single lesions Prednisone 2-4 mg/kg PO SID until regression for multiple lesions Azathioprine 2 mg/kg PO QOD for refractory lesions Prognosis good

Continued

TABLE 89-4

Mesenchymal Tumors—*cont'd*

TUMOR/DEFINITION	SIGNALMENT	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Anaplastic sarcoma with giant cells: poorly differentiated mesenchymal neoplasm of various origins	Uncommon Older dogs and cats No known breed predilections	Solitary, large, firm, poorly circumscribed, subcutaneous and dermal masses Legs and shoulders most common sites	Cytology: pleomorphic, round to fusiform mesenchymal cells, giant multinucleate cells with dyskaryosis Histopathology: unencapsulated mass, variable amounts of collagen, spindle cells, large round cells and multinucleated giant cells forming dense bundles or sheets	Radical surgical excision or amputation Prognosis guarded Tumors locally invasive to underlying bone/muscle Metastasis possible
Transmissible venereal tumor: exact origin unknown; cells express vimentin, are mesenchymal in origin, and contain 58 or 59 chromosomes	Recognized only in dogs Transmission from infected dogs or bitches during coitus or by licking and rubbing Exact incidence unknown	Tumors vary in size from small nodules to large masses Nodular, pedunculated, papillary, or multilobular Mainly observed on genital skin or mucosa	Cytology: large pleomorphic round cells with vacuolated cytoplasm, nuclei with coarse chromatin, variable mitotic figures Histopathology: sheets and rows of round or polyhedral cells with indistinct cell boarders, large round granular to vesicular nuclei, large single nucleolus, numerous mitotic figures	Surgery for small localized lesions but recurrence possible Vincristine 0.025 mg/kg IV once weekly until remission Radiation therapy effective Prognosis good Metastasis rare Spontaneous regression possible

TABLE 89-5

Histiocytic and Lymphocytic Tumors

TUMOR/DEFINITION	SIGNALMENT	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Canine cutaneous histiocytoma: neoplasm of Langerhans' cells	Most common in dogs <3 years of age Head, neck, ears, and extremities most often affected Persistent or recurrent histiocytomas most common in the shar-pei and shar-pei–cross dog Rare in cats	Rapidly growing, erythematous, round nodules up to 2.5 cm in size Alopecia and ulceration common Persistent and recurrent lesions localized to one region or widespread	Cytology: large, round cells with moderate amounts of cytoplasm, round or kidney bean–shaped nuclei Histopathology: round to polygonal cells arranged in cords and dense sheets, obliteration of adnexal structures, moderate mitotic activity, lymphocytic inflammation in older lesions Persistent and recurrent histiocytomas: aggregates of plasma cells, neoplastic cells extending deeper into subcutaneous tissues, moderate to high mitotic activity	Observation only because most lesions regress spontaneously Surgical excision for lesions that do not regress Cryotherapy for lesions in locations where excision is difficult Prognosis good See Chapter 77
Cutaneous plasmacytoma: neoplasm of plasma cell origin	Uncommon in dogs; average age in dogs 10 years Rare in cats Cocker spaniel, Airedale terrier, Kerry blue terrier, Scottish terrier, and standard poodle predisposed	Sessile, firm, raised masses <2 cm Lesions numerous in some cases Pinnae, lips, digits, chin, and oral cavity common locations Occasionally exhibit malignant behavior and may metastasize	Cytology: round cell with perinuclear halo, moderate amounts of darkly basophilic cytoplasm, round eccentric nuclei, frequent mitoses and binucleate to multinucleate cells Histopathology: circumscribed but unencapsulated masses mostly confined to dermis, tumor cells occasionally extending to the epidermis, round cells with discrete borders and central to paracentral nuclei, common mitotic figures	Surgical excision Cryotherapy for lesions in locations where excision is difficult Prognosis good in dogs Prognosis guarded in cats because systemic disease and metastasis common See Chapter 77
Epitheliotropic lymphoma: malignant neoplasm arising from memory T cells	See Chapter 91	See Chapter 91	See Chapter 91	See Chapter 91
Nonepitheliotropic lymphoma: malignant neoplasm arising from T or rarely B lymphocytes	Uncommon in dogs and cats Weimaraner, boxer, St. Bernard, basset hound, Irish setter, cocker spaniel, German shepherd dog, golden retriever, and Scottish terrier predisposed	Solitary or multiple, discrete dermal and subcutaneous nodules or infiltrative plaques Rapid progression and metastasis to regional lymph nodes in most cases Subsequent systemic involvement common	Cytology: many large, round discrete cells, large and round nuclei, variable amounts of light-blue cytoplasm, variable size, shape, and number of nucleoli Histopathology: deep dermal and subcutaneous unencapsulated mass composed of sheets or nodular perivascular aggregates of relatively monomorphic cells Search for internal involvement	Surgical excision for solitary nodules Combination chemotherapy (may induce temporary remissions) Prognosis poor

CHAPTER 90

Regional Dermatoses

Emily Rothstein

CLAW DISEASE

Asymmetrical Claw Disease

Definition and Causes

I. Asymmetrical claw disease is an abnormality in one claw or multiple claws on one paw.
II. Secondary bacterial infections are the most common cause.
  A. Trauma to the claw may occur in the dog or cat and often leads to infection.
  B. Examples include bite wounds, crush injuries, torn claws, exposure to chemicals, and thermal burns.
  C. Arteriovenous fistulae may develop from penetrating wounds or after onychectomy.
III. Fungal infections are less common.
  A. *Trichophyton mentagrophytes:* dog
  B. *Microsporum canis:* cat
  C. *Candida* spp.: dog and cat
  D. *Blastomyces dermatitidis:* dog
  E. *Cryptococcus neoformans:* cat
  F. *Sporothrix schenckii:* cat
  G. *Geotrichum candidum:* dog
  H. *Malassezia pachydermatis:* more common in dogs
IV. Neoplasia may also affect the claws.
  A. Dog
    1. Squamous cell carcinoma: more likely in older dogs, black dogs (Labrador retriever, standard poodle, giant schnauzer, Bouvier de Flandres)
    2. Melanoma
    3. Mast cell tumor
    4. Keratoacanthoma
    5. Inverted papilloma
    6. Miscellaneous: atrichial sweat gland adenosarcoma, fibrosarcoma, leiomyosarcoma, lymphoma, myxosarcoma, nerve sheath tumor, osteosarcoma
  B. Cat
    1. Squamous cell carcinoma
    2. Metastasis of primary lung tumor (Scott et al., 2000)

Pathophysiology

I. Trauma or damage to the claw often creates abnormal growth and allows embedding of debris, leading to secondary infection.
II. Neoplasia damages the claw and/or third phalanx.

Clinical Signs

I. Lameness, pain, pruritus: varying degrees, dependent on cause
II. Paronychial changes
  A. Swelling and edema
  B. Hair loss
  C. Oozing and/or crusting
  D. Erosion, ulceration, and/or necrosis
  E. Hyperpigmentation, lichenification
  F. Brown discoloration of claws and surrounding hairs
III. Claw abnormalities
  A. Onychoclasis: breakage of claw
  B. Onychocryptosis: ingrown claw
  C. Onychodystrophy: abnormal claw formation
  D. Onychogryphosis: hypertrophy and abnormal claw curvature
  E. Onychomadesis: sloughing of claw
  F. Onychomalacia: softening of claw
  G. Onychorrhexis: longitudinal striations associated with brittleness and breakage of claw
  H. Onychoschizia: splitting and/or lamination of claw, usually beginning distally
IV. Regional lymphadenopathy possible
V. Occasionally only systemic signs: fever, depression, anorexia

Diagnosis

I. Possible trauma and/or previous surgical procedure
II. Cytological examination of claw fold debris
  A. Bacterial or fungal infections often induce pyogranulomatous to granulomatous inflammation, composed of degenerative neutrophils and macrophages.
  B. Look for organisms, such as cocci, rods, and/or yeast.
  C. Examine for neoplastic cells.
III. Culture and sensitivity
  A. Bacterial cultures are especially helpful if rods are seen on cytological examination.
  B. Fungal cultures can be submitted from proximal claw shavings or avulsed claw material.
IV. Radiography
  A. Radiographs of the foot are evaluated for bony changes of the corresponding digit if neoplasia or osteomyelitis is suspected.
  B. Thoracic radiographs may show evidence of a primary lung tumor, metastatic disease, or systemic fungal disease.

V. Laboratory tests
   A. They are usually normal and not very helpful.
   B. Complete blood cell count (CBC) may show evidence of inflammation.
VI. Histopathology of claw, including the third phalanx and claw fold
   A. It is the most helpful way to diagnose neoplasia.
   B. Two techniques are available and both require general anesthesia.
      1. Removal of the third phalanx and claw using the standard declaw procedure allows procurement of claw, claw fold, ungual crest, and the entire third phalanx.
      2. Onychobiopsy involves using an 8 mm biopsy punch to biopsy horizontally along the claw (Mueller and Olivry, 1999).
         a. Medially, the claw and bone are sampled.
         b. Laterally, the skin of the claw fold is sampled.

Treatment

I. Remove any broken, loose, and/or painful claws.
II. Start appropriate antimicrobial therapy.
   A. Antibiotics are administered for at least 4 to 8 weeks and 2 weeks beyond clinical cure.
   B. Empiric drugs for cocci include one of the following:
      1. Cephalexin 22 to 30 mg/kg PO BID
      2. Amoxicillin/clavulanate 13.75 mg/kg PO BID
      3. Potentiated sulfonamides (trimethoprim-sulfamethoxazole, trimethoprim-sulfadiazine) 15 to 30 mg/kg PO BID
   C. Fluoroquinolones are usually reserved for severe disease and/or presence of rods.
   D. If possible, the choice of antibiotic drugs is based on culture and sensitivity results for infections with rods.
III. Antifungal medications are typically administered once daily for at least 3 to 6 months.
   A. Ketoconazole 5 to 20 mg/kg PO SID with food
   B. Itraconazole 5 to 10 mg/kg PO SID with food
IV. Fungal infections are difficult to resolve and may require amputation of the third phalanx.
V. Foot soaks may make the pet more comfortable.
   A. Antimicrobial medications: diluted chlorhexidine diacetate or gluconate (0.5% to 4%), iodophor (povidone-iodine)
   B. Epsom salts: 2 tablespoons mixed in 1 qt of warm water
VI. Radical surgical excision of the third phalanx is indicated for melanoma and squamous cell carcinoma.

Monitoring of Animal

I. Antimicrobial drugs are continued for at least 2 weeks for bacterial infections and for at least 3 months beyond clinical resolution for fungal infections.
II. Dogs with squamous cell carcinoma have a longer survival time because these tumors metastasize rarely; however, monitoring of regional lymph nodes is indicated.

Symmetrical Claw Disease

Definition and Causes

I. It includes abnormalities of multiple claws on multiple paws.
II. Widespread claw disease is often associated with other underlying diseases.
   A. Congenital, developmental disorders
      1. Dermatomyositis of the Shetland sheepdog and collie
      2. Acrodermatitis of the bull terrier
   B. Systemic disorders
      1. Hypothyroidism: dog
      2. Hyperthyroidism: cat
      3. Hyperadrenocorticism
      4. Diabetes mellitus
      5. Atopic dermatitis
      6. Disseminated intravascular coagulation
      7. Metabolic epidermal necrolysis
      8. Acromegaly: dog
      9. Lymphoma: dog
      10. Zinc deficiency: dog
   C. Infections
      1. Demodicosis
      2. Feline immunodeficiency virus (FIV), feline leukemia virus (FeLV)
      3. Leishmaniasis
   D. Immune-mediated disorders
      1. Pemphigus foliaceus
      2. Pemphigus vulgaris
      3. Bullous pemphigoid: dog
      4. Systemic lupus erythematosus (SLE)
      5. Vasculitis
      6. Cold-agglutinin disease
      7. Symmetrical lupoid onychodystrophy: dog
   E. Miscellaneous conditions
      1. Idiopathic onychodystrophy of the dachshund, Siberian husky, and very old dogs (Scott et al., 2000)
      2. Idiopathic onychomadesis of the German shepherd dog, whippet, English springer spaniel (Scott et al., 2000)
      3. Keratinization defects, such as primary seborrhea of the American cocker spaniel (Scott et al., 2000, Angus, 2004)

Pathophysiology

I. Any disorder that affects the ungula crest also affects the production of the claw.
II. Neoplasia disrupts the crest and claw.
III. Immune-mediated diseases and lupoid onychodystrophy affect claw growth.
IV. Systemic diseases can affect the paronychial skin (leading to secondary infection) and the ungual crest, both of which affect claw formation.

Clinical Signs

I. Local signs are similar to asymmetrical claw disease, except that numerous claws on multiple paws are involved.

II. Systemic signs relating to the underlying disease process are also evident.

Diagnosis

I. Obtain a complete history, including exposure to drugs and recent vaccinations.
II. Perform a thorough physical examination, including the claws and claw folds.
III. Cytologically examine claw fold debris.
  A. With pemphigus foliaceus, numerous acanthocytes and/or neutrophils (with or without bacteria) and eosinophils may be present.
  B. Neutrophils (inflammation), microorganisms (infection), and neoplastic cells are sometimes found.
IV. Skin scrapings and plucked hairs are helpful to diagnose demodicosis.
V. Perform appropriate laboratory tests for possible underlying diseases.
VI. Antinuclear antibody (ANA) test may support the diagnosis of SLE but is not specific for this disease.
VII. Histopathology of the claw, including the third phalanx and claw fold is helpful for diagnosis.
  A. Third phalanx and claw may be removed using a standard declaw procedure.
  B. Onychobiopsy may be performed.

Differential Diagnosis

I. Loss of claws
  A. SLE
  B. Bullous pemphigoid
  C. Pemphigus vulgaris
  D. Vasculitis
  E. Idiopathic onychomadesis
II. Breakage, onychodystrophy
  A. Endocrine disorders: hypothyroidism, hyperadrenocorticism
  B. Infections: leishmaniasis, FeLV, FIV, infections secondary to diabetes mellitus or hyperadrenocorticism
  C. Idiopathic: dachshund, Siberian husky
  D. Lupoid onychodystrophy
  E. Nutritional: zinc deficiency

Treatment

I. Secondary infections are treated (see Asymmetrical Claw Disease).
II. Immune-mediated diseases, such as pemphigus complex, pemphigoid, SLE, and vasculitis require aggressive therapy.
  A. Corticosteroids
    1. Cats often respond better to prednisolone and triamcinolone than the other corticosteroids.
    2. Prednisone and prednisolone induction dose is 2.2 to 6.6 mg/kg PO SID, then tapered over weeks to months.
    3. Triamcinolone induction dose is 0.2 to 0.6 mg/kg PO SID.
    4. Dexamethasone induction dose is 0.2 to 0.6 mg/kg PO SID.
  B. Azathioprine dose (dogs only) is 1.5 to 2.5 mg/kg PO SID.
  C. Chlorambucil is especially helpful in feline diseases.
    1. Examples: SLE, pemphigus vulgaris, pemphigus foliaceus
    2. Dose: 0.1 to 0.2 mg/kg PO SID to QOD
  D. Tetracycline or doxycycline with niacinamide can take 6 to 12 weeks to take effect and can be used in conjunction with other drugs initially.
    1. Dose in dogs <10 kg: tetracycline 250 mg PO TID or doxycycline 100 mg PO SID and niacinamide 250 mg PO TID
    2. Dose in dogs >10 kg: tetracycline 500 mg PO TID or doxycycline 100 mg PO BID and niacinamide 500 mg PO TID
  E. Omega-6 and omega-3 fatty acid supplements are given at twice the manufacturers' dosing instructions.
  F. Pentoxifylline *(Trental)* may be used in dogs at 10 to 20 mg/kg PO BID to TID for vascultitis.
III. Treatment of symmetrical lupoid onychodystrophy involves several options.
  A. Food elimination trial for at least 8 weeks
  B. Omega-6 and omega-3 fatty acid supplements for at least 3 to 4 months
  C. Vitamin E 400 IU PO BID
  D. Tetracycline or doxycycline and niacinamide (described previously)
  E. Corticosteroids as described previously for immune-mediated diseases
  F. Removal of third phalanx and claw on all affected digits (Boord et al., 1997)
IV. Idiopathic disorders can be treated with the following:
  A. Gelatin (Knox) for strengthening claws
    1. Dachshund: 10 g PO BID
    2. Other dogs: 1 g/kg SID
  B. Biotin 5 µg/kg/day PO indefinitely
  C. Pentoxifylline 10 to 20 mg /kg PO BID in dogs to treat altered vasculature
  D. Removal of third phalanx and claw on all affected digits (Boord et al., 1997)
V. Neoplasia is treated with amputation of the affected toe or toes.

Monitoring of Animal

I. Claws grow very slowly (1 to 1.5 mm/wk); therefore they should be monitored for several months.
II. Immune-mediated diseases require specific monitoring measures.
  A. CBC: for blood dyscrasias from azathioprine and chlorambucil
  B. Biochemistry profile: for elevated liver enzymes with corticosteroids and azathioprine
III. With certain underlying causes or conditions, therapy is lifelong.

FOOTPAD DISEASE

Feline Plasma Cell Pododermatitis

Definition and Causes

I. It is a rare disease of the footpads of the cat that is characterized by the accumulation of plasma cells.
II. The cause is unknown, but thought to be immune-mediated.

Clinical Signs

I. No breed, age, or sex predilection exists.
II. Initially soft, nonpainful swelling of footpads occurs.
  A. More than one pad on more than one foot is typically involved.
  B. Digital pads are most commonly affected, followed by the metatarsal or metacarpal pads.
  C. Lightly pigmented pads may look violaceous (purple).
  D. Pads appear striated with white scale.
III. Later, the pads can become ulcerated and painful.
IV. Rarely, immune-mediated glomerulonephritis or plasma cell stomatitis also occurs.

Diagnosis

I. Clinical signs are suggestive.
II. Cytological examination of fine-needle aspirates of the pad often reveals numerous plasma cells.
III. Laboratory test results are variable.
  A. CBC can reveal neutrophilia and increased lymphocytes.
  B. Biochemistry profile often reveals elevated globulins.
  C. Serum protein electrophoresis may show a polyclonal gammopathy.
  D. Tests for FeLV and FIV are usually negative; however, one study showed 50% of cats tested were positive for FIV (Guaguere et al., 1992).
IV. Bacterial culture is negative, unless the ulcerated pad is secondarily infected.
V. Histopathologic examination of the footpad is usually diagnostic.
  A. Initial lesions show either a superficial or deep perivascular plasmacytic dermatitis.
  B. Later lesions are characterized by a diffuse accumulation of plasma cells.
  C. Presence of neutrophils is variable; they increase in the presence of ulceration.

Differential Diagnosis

I. Granuloma, pyogranuloma
  A. Infection with bacteria and fungal organisms
  B. Immune-mediated diseases
    1. Eosinophilic granuloma complex can exhibit similar pad swelling.
    2. Pemphigus foliaceus can begin as scaling or crusting of pads.
    3. Animals with mosquito bite hypersensitivity can have erythematous plaques that ulcerate or are crusty.
    4. Animals with vasculitis can experience ulceration of footpads.
II. Neoplasia
  A. Fibrosarcoma or malignant fibrous histiocytoma can appear as a nodular disease.
  B. Nodules are usually firm on palpation and affect only one footpad.

Treatment and Monitoring

I. No treatment needed: asymptomatic problem, with possible spontaneous regression in some cats
II. Corticosteroids
  A. Prednisolone 4.4 mg/kg PO SID until lesions resolve, then tapered
  B. Triamcinolone 0.4 to 0.6 mg/kg PO SID until lesions resolve, then tapered
  C. Dexamethasone 0.5 mg/kg PO SID until lesions resolve, then tapered
III. Chrysotherapy (gold salts)
  A. Aurothioglucose 1 mg/kg IM every 7 days until lesions resolve (2 to 3 months), then every 14 days for 2 to 3 treatments, then every 30 days for maintenance
  B. Monthly monitoring for anemia, thrombocytopenia, and glomerulonephritis
IV. Doxycycline 25 mg/day PO (Bettenay et al., 2003)
  A. Animal is encouraged to drink water; if this medication becomes lodged in the esophagus, it can cause erosive esophagitis.
  B. Improvement may take 6 to 8 weeks.
V. Surgery to remove single lesions

Canine Footpad Hyperkeratosis

See Nasal Planum Disorders.

NASAL PLANUM DISORDERS

Canine Nasal and Footpad Hyperkeratosis

Definition

I. Increased keratinization (an increase in the horny layer of the skin) of nasal planum
II. May occur on the footpads, especially in the Dogue de Bordeaux, Kerry blue terrier, and Irish terrier

Pathophysiology

I. Infectious agents typically affect the keratinocytes.
II. Metabolic and nutritional changes affect the production of the stratum corneum.
III. Anything that changes the maturation and/or cornification of the stratum corneum leads to hyperkeratosis.

Causes

I. Congenital, developmental disorders
  A. Nasal hyperkeratosis in the Labrador retriever (Page et al., 2003; Peters et al., 2003)
  B. Primary seborrhea of the American cocker spaniel (see Chapter 93)

C. Congenital hyperkeratosis of the Dogue de Bordeaux, Kerry blue terrier, and Irish terrier

II. Infections
A. Canine distemper virus
B. *Leishmania infantum*

III. Idiopathic disorders: usually geriatric or brachycephalic dogs

IV. Secondary to other systemic diseases: metabolic epidermal necrosis, hepatocutaneous syndrome, superficial necrolytic dermatitis (Scott et al., 2000)

V. Immune-mediated disorders
A. Pemphigus foliaceus: nasal changes accompanied by pad hyperkeratosis and diffuse crusting
B. Pemphigus erythematosus: nasal changes accompanied by depigmentation and crusting along bridge of nose
C. Discoid lupus erythematosus: nasal changes accompanied by depigmentation, loss of cobblestones, or bumpy texture to nasal planum
D. SLE: accompanied by numerous systemic clinical signs (see Chapter 76)

VI. Zinc-responsive dermatosis

VII. Trauma to paranasal gland

VIII. Neoplasia: cutaneous lymphoma

Clinical Signs

I. Nasal hyperkeratosis
A. Thickening and dryness of the nasal planum occurs.
B. Depending on the underlying cause, depigmentation, crusting, and erosions or ulcerations can be observed.

II. Pad hyperkeratosis
A. Hyperkeratosis usually involves the entire surface of all footpads.
B. In congenital disorders, it may be noted by 6 months of age.
C. Fissures may develop and lead to secondary bacterial infections and pain.

III. Possible systemic signs: SLE, occasionally pemphigus foliaceus, hepatocutaneous syndrome, infectious diseases

Diagnosis

I. Classical clinical signs: hyperkeratosis, ± depigmentation, crusting

II. Signalment suggestive
A. Congenital and nutritional disorders occur in younger animals.
B. Immune-mediated and metabolic disorders usually occur in mature animals.

III. Biopsy of lesions
A. Samples are obtained from affected tissues (haired skin, nasal planum, foot pads) without any surgical preparation.
B. Two to three samples are submitted.
C. Because the nasal planum and footpads are vascular and well innervated, biopsies from this area are done under general anesthesia.

IV. Histopathology
A. Epidermal hyperplasia (hyperkeratosis) is the classic lesion.
B. Epidermal pallor and necrosis are seen below the parakeratotic and hyperkeratotic areas in metabolic epidermal necrosis.
C. Follicular and epidermal parakeratosis and hyperkeratosis are seen with zinc-responsive dermatosis.
D. Acantholysis is seen with pemphigus foliaceus.
E. Lichenoid and/or hydropic interface dermatitis are found in SLE.
F. Pigmentary incontinence and apoptosis are also characteristic of immune-mediated disorders.

Differential Diagnosis

I. Young age of onset
A. Labrador nasal hyperkeratosis: typically 6 to 12 months
B. Canine distemper virus
C. Primary seborrhea of the American cocker spaniel
D. Footpad hyperkeratosis

II. Older, adult age of onset
A. Canine distemper virus
B. Idiopathic nasal hyperkeratosis

III. Depigmentation present
A. Immune-mediated disease
B. Lymphoma

Treatment

I. For primary seborrhea or idiopathic nasal hyperkeratosis, no treatment is needed.

II. Symptomatic therapy with keratolytic medications may help in congenital hyperkeratosis and idiopathic hyperkeratosis.
A. Urea and propylene glycol 5% gel *(KeraSolv)*
B. Petroleum jelly to soften the tissue
C. Salicylic acid gel
D. Trimming nonviable tissue away from the footpads

III. Oral immunosuppressive drugs are indicated for pemphigus foliaceus, SLE, and possibly pemphigus erythematosus (described previously).

IV. Topical immunosuppressive drugs may be tried for discoid lupus and pemphigus erythematosus.
A. Fluocinolone 0.01% and dimethyl sulfoxide 60% *(Synotic)* BID, then tapered
B. Betamethasone valerate 0.1% cream BID, then tapered
C. Tacrolimus 0.1% *(Protopic)* SID to BID

V. Supportive care may be needed for dogs with systemic signs.
A. Canine distemper virus
B. SLE

VI. Leishmaniasis is treated with meglumine antimonate 20 to 50 mg/kg SC BID or 200 to 300 mg/kg IV QOD or allopurinol 11 to 15 mg/kg PO SID (Lemarie, 2003)

VII. Zinc supplementation is usually administered lifelong for zinc-responsive dermatosis (see Chapter 93).

Monitoring of Animal

I. Prognosis is variable.

II. For idiopathic hyperkeratosis, prognosis is excellent because the disorder is purely cosmetic.

III. For the following conditions, prognosis is fair for control of the disease or the underlying cause:
   A. Primary seborrhea of the American cocker spaniel
   B. Pemphigus erythematosus, pemphigus foliaceus
   C. Discoid lupus erythematosus
IV. For many diseases, the prognosis is guarded.
   A. Metabolic epidermal necrosis, hepatocutaneous syndrome
   B. Leishmaniasis
   C. Canine distemper virus

Nasal Depigmentation

See Chapter 92.

CHAPTER 91

Erosive and Ulcerative Diseases of the Skin

Russell Muse | Nicola Williamson

INFECTIOUS DISORDERS

Mucocutaneous Pyoderma

Definition

I. Mucocutaneous pyoderma is a syndrome characterized by erythema, swelling, and adherent crusts around mucocutaneous junctions (Gross et al., 2005).
II. German shepherd dogs and their crosses may be at an increased risk, but dogs of any age, breed, or sex may be affected.

Causes and Pathophysiology

I. Bacterial overgrowth and infection develop and cause inflammation.
II. Additional immunologic factors increase the severity of the inflammation.
III. Underlying pathophysiology is not currently understood.

Clinical Signs

I. Initially swelling and erythema of the lips occur, especially at the commissures and lower lip folds.
II. Crust develops that entrap hairs, which allows erosions and fissures to form.
III. Purulent exudates may be seen, as well as variable pain, pruritus, and odor.
IV. Extension to the periocular areas, the nasal planum, nares, vulva, and philtrum may be noted.

Diagnosis

I. Cytological impression smear reveals intracellular and extracellular bacteria organisms (cocci, rod-shaped organisms, or mixed infection).
II. Ideally biopsy of erythematous noncrusted, nonulcerated tissue reveals several typical histopathologic changes.
   A. Perivascular to lichenoid infiltrate that is composed of plasma cells, neutrophils, and mixed mononuclear cells
   B. Lymphocytic exocytosis extending into the hair follicle
   C. Crusting, neutrophilic, and serocellular debris in older lesions

Differential Diagnosis

I. Lupus erythematosus
II. Pemphigus complex: pemphigus foliaceus, pemphigus erythematosus, or mucous membrane pemphigus
III. Lip fold pyoderma
IV. Zinc-responsive dermatitis
V. Drug eruption

Treatment

I. Clip the hair and clean the affected tissue with antimicrobial shampoos.
II. Apply topical antibiotics, such as mupirocin or polymyxin/neomycin combinations, BID for 2 to 4 weeks.
III. Oral antibiotics are often needed for 3 to 6 weeks.
   A. Antibiotic therapy may be chosen empirically when treating the cocci seen on cytologic impression smears.
      1. Clindamycin 5 mg/kg PO BID
      2. Cephalexin 22 mg/kg PO BID to TID
      3. Amoxicillin and clavulanate 13.75 mg/kg PO BID
   B. Antibiotic therapy is best when based on culture and sensitivity testing for treating rod-shaped bacteria or mixed infections.
IV. Corticosteroids may be needed to decrease the inflammatory response if antibiotic therapy does not completely resolve the condition.

Monitoring of Animal

I. Relapses are common.
II. Daily maintenance and routine cleaning with topical and oral antimicrobial agents may be needed for life.

IMMUNE-MEDIATED DISORDERS

Bullous Pemphigoid

Definition and Cause

I. It is a rare vesicobullous subepithelial disorder that involves the skin and mucous membranes of the dog and cat.
II. Genetic-related factors are probably involved.

Pathophysiology

I. Autoantibodies form principally against the basement membrane type XVII collagen molecule (also known as *bullous pemphigoid antigen 2* [BPAG2 or BP180]).
II. No gender, age, or breed predilections have been noted in dogs or cats.

Clinical Signs

I. Dogs
   A. Firm vesicles with irregular borders rupture and lead to erosions, ulcers, and crusting.
   B. Lesions may be located on the concave aspect of the pinnae, abdomen, axilla, and/or mucocutaneous junctions.
   C. Oral lesions are noted in <50% of the cases (Gross et al., 2005).
   D. Systemic signs are generally absent.
II. Cats: generally few lesions, erosions on the face

Differential Diagnosis

I. Pemphigus vulgaris
II. Epidermolysis bullosa (EB)
III. Erythema multiforme and toxic epidermal necrolysis
IV. Lupus complex disorders (vesicular and systemic)
V. Mycosis fungoides (cutaneous lymphoma)
VI. Drug eruption

Diagnosis

I. Routine laboratory tests (biochemistry profile, complete blood count [CBC]) are usually normal.
II. Histopathologic examination of biopsied skin reveals multiple changes.
   A. Subepidermal accumulation of neutrophils and eosinophils develops early, with subsequent vesicle formation.
   B. Intact and degenerating eosinophils are seen at the dermal-epidermal junction of preblistered and blistered areas, especially with Luna stains.
   C. Cutaneous cleavage occurs in the lamina lucida because type IV collagen is at the base of the dermal-epidermal cleft.
III. Direct immunofluorescence of tissue shows a linear and continuous deposition of immunoglobulin (Ig) G at the dermal-epidermal junction in 90% of dogs and cats; IgM and complement component 3 (C3) are also occasionally noted (Gross et al., 2005).
IV. Indirect immunofluorescence assays show variable titers of circulating IgG antibodies directed at the epidermal side of the split through the lamina lucida of the basement membrane (Gross et al., 2005).

Treatment

I. Immunosuppressive dose of prednisone and azathioprine are used in most cases (Table 91-1).
II. Tetracycline and niacinamide combination may be helpful in mild cases (see Table 91-1).

Monitoring of Animal

I. Some cases can be managed medically and maintained in remission.
II. Because many cases may require lifelong therapy, routine monitoring of immunosuppressive drug therapy is required.

Mucous Membrane Pemphigoid

Definition and Causes

I. It is a rare, chronic, autoimmune vesicobullous subepithelial autoimmune disease affecting the mucous membranes, mucocutaneous junctions, and haired skin of dogs and cats.
II. Autoantibodies are directed against various basement membrane proteins.
III. German shepherd dogs may be predisposed.

Pathophysiology

I. IgG Type 1 and 4 autoantibodies are directed against the epidermal side of the epithelium and target various segments of Type XVII collagen (Gross et al., 2005).

TABLE 91-1

TABLE 91-1

Rights were not granted to include this table in electronic media.
Please refer to the printed publication.

II. This attack leads to separation of the epidermis and the dermis and to vesicle formation.

Clinical Signs

I. Erosions with ulcers are the predominant clinical findings; however, vesicles may be found in nontraumatized skin.
II. Lesions are predominately located at the mucocutaneous junction of the lips, nasal planum, paranasal skin, periorbital skin, pinnae, genitalia, or anus.
III. Bulbar conjunctiva may also be affected.

Diagnosis

I. Diagnosis is based on histopathologic examination of affected skin.
   A. Subepidermal vesicles are seen, with variable inflammation consisting of predominantly red blood cells, neutrophils, and eosinophils.
   B. Superficial dermis may contain neutrophils, eosinophils, and lymphocytes in a lichenoid pattern in dogs.
II. Direct immunofluorescence of affected skin may reveal IgG at the basement membrane in dogs.
III. Indirect immunofluorescence assays may reveal circulating IgG antibodies in both dogs and cats (Gross et al., 2005).

Differential Diagnosis

I. Bullous pemphigoid
II. EB
III. Lupus complex: vesicular cutaneous lupus erythematosus, systemic lupus erythematosus (SLE)
IV. Pemphigus vulgaris
V. Mucocutaneous pyoderma
VI. Drug eruption

Treatment and Monitoring

I. Immunosuppression is the primary therapy (see Table 91-1).
II. Therapy is often lifelong.
III. Prognosis is good with appropriate therapy.
IV. Animal is monitored as for cutaneous, discoid lupus erythematosus (see following section).

Cold Agglutinin Disease

Definition and Causes

I. It is a cutaneous disease and type II hypersensitivity associated with the precipitation of proteins by cooling, with subsequent vascular insult.
II. It is associated with a cold-reaction (IgM) erythrocyte antigen.
III. Underlying causes that may precipitate this disorder include lead poisoning in dogs, and upper respiratory infections and lead poisoning in cats (Scott et al., 2001).
IV. Idiopathic forms also occur in both dogs and cats.

Pathophysiology

I. Cryoglobulins and cryofibrinogens precipitate from serum and plasma, respectively, on cooling and then dissolve on warming.
II. Cutaneous lesions result from vascular insufficiency and secondary circulatory stasis, thromboembolism, and vasculitis.

Clinical Signs

I. Skin lesions include erythema, purpura, necrosis, and ulceration.
II. Pain is usually noted.
III. Lesions usually involve the extremities, paws, pinnae, and tip of the tail.
IV. Lesions worsen with exposure to cold.

Diagnosis

I. History
II. Physical examination
III. Demonstration of titers of cold agglutinin
IV. In vitro autohemagglutination at room temperature
   A. Blood collected in tubes with heparin or ethylenediaminetetraacetic acid (EDTA) agglutinates when applied to a slide.
   B. Cooling exacerbates the agglutination.
V. Positive Coomb's test at 4° C

Differential Diagnosis

I. Vasculitis
II. SLE
III. Dermatomyositis
IV. Disseminated intravascular coagulopathy
V. Frostbite

Treatment and Monitoring

I. Identification and correction of any underlying precipitating factors
II. Avoidance of cold weather
III. Immunosuppressive therapy

Cutaneous Drug Eruptions

Definition

I. It is a reaction to a drug or its metabolite that occurs in a sensitized animal and causes cutaneous lesions.
II. Signs vary greatly between animals and usually do not resemble known pharmacological reactions.
III. Signs typically decrease within days to weeks of discontinuing the offending drug.

Causes and Pathophysiology

I. Two categories of reactions occur.
   A. Predictable reactions are dose dependent.
   B. Unpredictable reactions are related to the following:
      1. Immunologic responses
      2. Nonimmunologic responses
         a. Metabolic disorders or enzyme deficiencies
         b. Direct effect of mast cells, basophils, arachidonic acid, activation, or complement activation
         c. Drug interactions
         d. Exacerbation of preexisting skin disease

II. Inciting drugs may be administered via inhalation, orally, topically, or by injection.
III. Any medication can potentially cause a cutaneous drug reaction.
IV. Drugs reported to cause reactions include ampicillin, asparaginase, aurothioglucose, carprofen, cephalosporin, cyclosporine, diethylcarbamazine, doxorubicin, 5-fluorocytosine, griseofulvin, itraconazole, ketoconazole, levamisole, methimazole, penicillin, phenothiazines, prednisone, primidone, streptomycin, sulfonamides, tetracycline, trimethoprim-sulfa, and vaccines.

Clinical Signs

I. Reactions can mimic any dermatosis.
II. No age or sex predilection exists.
III. Some breeds of dogs are predisposed.
   A. Bichon frisé, Maltese terrier, Pekingese, poodle, and silky terrier are predisposed to local injection reactions.
   B. Doberman pinschers are predisposed to reactions from oral sulfonamides.
   C. Miniature schnauzers are predisposed to reactions from gold therapy, oral sulfonamides, and certain shampoos.
IV. Lesions include alopecia, altered pigmentation, urticaria, purpura, angioedema, erythroderma, maculopapular rash, self-induced trauma secondary to pruritus, erythema multiforme, and toxic epidermal necrolysis.
   A. Erythema multiforme is thought to be a host-specific T-cell hypersensitivity directed against keratinocyte-associated antigens that results in lymphocyte-induced cell death.
      1. Minor lesion: target lesions seen, only one mucosal surface affected, <10 % of body surface area affected
      2. Major lesion: >1 mucosal surface affected, 10% to 50% of body surface affected, <10% epidermal detachment
   B. Toxic epidermal necrolysis is a very rare disease in dogs and cats that is often rapidly progressive and life threatening.
      1. Cytotoxic T cells and mononuclear cells may cause apoptosis of keratinocytes.
      2. Cutaneous lesions are thought to be caused by toxic cytokines, especially tumor necrosis factor (TNF)-α.
   C. Stevens-Johnson syndrome is a severe form of erythema multiforme in which >50% of the body surface is affected and 10% to 30% epithelial detachment occurs.

Diagnosis

I. All other causes of similar skin lesions must be eliminated.
II. Most drug reactions occur within 1 to 3 weeks after initiation of therapy, while the drug is still being administered or remains in the body.
III. If the animal has had prior exposure to the drug, then reactions may occur within hours to days of readministration.
IV. Removal of the offending drug results in improvement within 5 to 14 days.
V. Rechallenge with the suspected drug is not recommended.
VI. Histologically, multiple changes are possible, including perivascular dermatitis, interstitial dermatitis, intraepidermal vesiculopustular dermatitis, interface dermatitis, subepidermal vesicular dermatitis, vasculitis and vasculopathy, and panniculitis.
VII. Laboratory abnormalities are usually nonspecific.

Treatment and Monitoring

I. The offending drug is discontinued, and all chemically related drugs are avoided.
II. Supportive care and symptomatic therapy are administered as needed.
III. Use of corticosteroids is controversial.
IV. Affected animals usually improve within 5 to 14 days of discontinuing the offending agent.
V. Some reactions may be life threatening.

Cutaneous or Discoid Lupus Erythematosus

Definition and Cause

I. Cutaneous lupus erythematosus is an ulcerative dermatosis involving the nasal planum of the dog and cat; the condition is part of the lupus complex of diseases.
II. Probably caused by a combination of genetic factors and photoactivation of the skin, which may induce an autoimmune response.
III. Collie, Shetland sheepdog, German shepherd dog, and Siberian husky may be predisposed.
IV. No sex or age predilections are noted.

Pathophysiology

I. Stimulation of B lymphocytes by autoreactive T cells causes antibody production against various nuclear and cytoplasmic proteins.
II. Basal layers of the epidermis are often targeted, ultimately causing cell death (apoptosis) and weakening of the dermal-epidermal junction.
III. This damage allows separation of the dermis and the epidermis, with secondary erosion and ulceration.

Clinical Signs

I. Early lesions include a progression of changes from erythema and depigmentation to loss of the cobblestone architecture of the planum nasale and variable scaling.
II. Further progression leads to erosion, ulceration, and crusting, with possible hemorrhage.
III. Residual scarring and leukoderma are common.
IV. Areas affected may include the following:
   A. Junction of the haired skin and the nasal planum
   B. Ventral and medial aspects of the alar folds
   C. Occasionally the lips, oral cavity (tongue, palate), pinnae, and genitalia

Diagnosis

I. Compatible history and signalment are suggestive.
II. Routine diagnostic tests are as follows:
   A. Skin scraping: negative

B. Dermatophyte culture: negative
C. Cytological impression smears: lack of acantholytic cells to distinguish from pemphigus complex diseases

III. Histopathologic examination of the affected skin reveals multiple changes.
A. Ideally, obtain biopsies from sites of recent depigmentation.
1. Basal cell apoptosis is typical.
2. Interface to lichenoid pattern may be seen, with lymphocytes and plasma cells predominating.
3. Pigmentary incontinence occurs from damage to melanocytes.
4. Focal thickening of the basement membrane zone may be seen.
B. Avoid obtaining biopsies from heavily crusted, ulcerated, or scarred areas.

IV. Direct immunofluorescence may reveal deposition of granular deposits of IgG, IgM, or C3 at the dermal-epidermal junction.
V. Indirect immunofluorescence assays of serum are generally negative.

Differential Diagnosis

I. Other lupus complex diseases: SLE, vesicular variant of cutaneous lupus erythematosus
II. Mucocutaneous pyoderma
III. Pemphigus foliaceus, pemphigus erythematosus
IV. Contact dermatitis
V. Mycosis fungoides
VI. Vogt-Koyanagi-Harada (VKH)-like syndrome
VII. Actinic dermatitis
VIII. Vitiligo
IX. Demodicosis or dermatophytosis: if the lesions are in haired areas

Treatment

I. Avoid exposure to the sun or use sunscreens to protect against aggravation of the lesion by ultraviolet light.
II. Topical therapy is indicated and may be successful in mild cases.
A. Topical corticosteroids
1. Begin with potent forms (e.g., betamethasone, fluocinolone) initially BID for 5 to 7 days.
2. Dose is then tapered to a lower frequency, and lower-potency products are used (e.g., triamcinolone, hydrocortisone).
B. Tacrolimus 0.1% *(Protopic)*
1. Can be applied BID for 14 days, then tapered to two to three times weekly
2. Can be used when corticosteroids are contraindicated or ineffective
C. Topical cyclosporine: some anecdotal success

III. Systemic therapy is indicated when topical therapy is ineffective or the case is severe (see Table 91-1).

Monitoring of Animal

I. After treatment has been initiated, animal is reexamined at 1 to 2 weeks to evaluate response to therapy.
II. Once clinical remission has been achieved, animal is reexamined at 1-month intervals as the drug doses are being tapered and then every 6 months while on maintenance therapy.
III. Baseline laboratory tests (biochemistry profile, CBC, urinalysis) are evaluated before starting corticosteroids, after 1 month, and then every 6 months.
IV. Urine cultures are performed yearly in animals on corticosteroids.
V. Animals on azathioprine or chlorambucil therapy require the following:
A. CBC and platelet counts are performed before therapy, then every 2 weeks for 12 weeks, and then every 6 months for life.
B. Biochemistry profile is submitted every 6 months to monitor for hepatotoxicity.
C. Urine cultures are performed yearly.

Exfoliative Cutaneous Lupus Erythematosus

Definition and Cause

I. It is an acquired, generalized exfoliative dermatopathy.
II. Previously reported as hereditary lupoid dermatosis of the German shorthaired pointer (Bryden et al., 2005).
III. The cause is poorly understood but is probably hereditary.

Pathophysiology

I. Findings are suggestive of a cytotoxic T-cell reaction and a major histocompatibility complex, cell-mediated immunologic reaction.
II. To date, the German shorthaired pointer is the only breed affected.
III. No specific age or sex predilections are known, although young (median age, 10 months) and female (ratio, 2:1) dogs were affected in one study (Bryden et al., 2005).

Clinical Signs

I. Scale, alopecia, follicular casting, crusting, and ulcerations occur in variable degrees on the muzzle, pinnae, and dorsal trunk; they may become generalized.
II. Lymphadenopathy, pain, pruritus, and pyrexia are variable.

Diagnosis

I. Compatible history and signalment are suggestive.
II. Typical physical examination findings are seen.
III. CBC reveals possible thrombocytopenia, lymphopenia, and anemia.
IV. Routine diagnostics (skin scraping and dermatophyte culture) are negative.
V. Histopathologic examination of affected skin reveals the following:
A. Generally a moderate to diffuse hyperkeratosis is present.
B. Moderate to marked multifocal lymphocytic interface dermatitis occurs, with focal apoptosis throughout the stratum spinosum.

C. Lymphocytic exocytosis of the epidermal and follicular epithelium may also be seen.

VI. Direct immunofluorescence of affected skin has revealed a deposition of IgG in the epidermal basement membrane.
A. Occasional presence of IgM, IgA, C3
B. IgG and IgM on basement membrane of the hair follicle (Bryden et al., 2005)

VII. Serum indirect immunofluorescence assays may reveal circulating antihair follicle IgG antibodies (Bryden et al., 2005).

VIII. Immunohistochemistry shows CD3- and CD8-positive T lymphocytes in the epidermis, superficial dermis, infundibulum of the hair follicle, and sweat glands.

Differential Diagnosis

I. Primary keratinization defects
II. Other lupus complex diseases: cutaneous lupus, SLE
III. Pemphigus foliaceus, pemphigus erythematosus
IV. Sebaceous adenitis
V. VKH-like syndrome
VI. Contact dermatitis
VII. Demodicosis, dermatophytosis
VIII. Drug eruption

Treatment

I. The disease is poorly responsive to therapy.
II. Topical therapy with antiseborrheic (sulfur, salicylic acid) shampoos is most helpful to remove excess scale.
III. Systemic therapy may be tried.
A. Fatty acid supplements and combination therapy with tetracycline and niacinamide have been used in many dogs without much success.
B. Prednisone 2.2 mg/kg PO SID in conjunction with topical therapy has resulted in some temporary remissions.
C. Azathioprine at varying doses has also been used with limited success (see Table 91-1).
D. Anecdotally, cyclosporine 5 mg/kg PO SID has resulted in improvement in some animals.

Monitoring of Animal

I. Therapy is usually only palliative, and a waxing and waning course is typical.
II. Euthanasia is a common outcome.

Vesicular Cutaneous Lupus Erythematosus

Definition

I. It is an ulcerative dermatitis described in the Shetland sheepdog and the collie.
II. The condition was formerly referred to as *idiopathic ulcerative dermatosis* (Jackson, 2006).
III. It is possibly a photosensitive vesicular variant of cutaneous, discoid lupus erythematosus, although the lesions are typically not in sun-exposed areas.

Causes

I. It is poorly understood but may involve genetic factors and photosensitivity.
II. To date, the Shetland sheepdog, collie, and their crosses have only been affected.
III. No age or sex predilections have been documented, although middle-aged to older dogs are usually affected.

Pathophysiology

I. Pathophysiology is not completely understood, but findings are suggestive of a lymphocyte-mediated attack on basal epidermal keratinocytes.
II. Autoantibodies targeting nuclear antigens have also been found.

Clinical Signs

I. Transient vesicobullous eruptions develop in areas of erythema and progress into ulcers with defined borders.
II. Groin and axillae are most commonly involved.
III. Other areas occasionally affected include the mucocutaneous junctions of the eyes, mouth, anus, as well as footpads and genitals.
IV. Pain, secondary pyoderma, and a concurrent myositis may be noted.

Diagnosis

I. History and signalment are helpful.
II. Complete physical examination is performed to look for typical clinical findings.
III. Routine diagnostic tests (skin scrapings, biochemistry profile, CBC) are normal.
IV. Antinuclear antibody (ANA) test is negative.
V. Impression cytology may show neutrophils in ulcerated areas, with intracellular bacteria indicative of a secondary pyoderma.
VI. Histopathologic examination reveals multiple changes.
A. Interface to lichenoid inflammation of predominantly lymphocytes
B. Vacuolization of the basal epidermis and apoptosis of the basal cell layer
C. Apoptosis in the suprabasilar layer, with satellitosis in the epithelium of the hair follicle
D. Subepidermal vesicles leading to dermal-epidermal separation

VII. Direct immunofluorescence of affected tissue has revealed IgG at the basal cell region and the basement membrane zone.

Differential Diagnosis

I. Bullous pemphigoid
II. Erythema multiforme and toxic epidermal necrolysis
III. Other lupus complex diseases: SLE, cutaneous lupus erythematosus
IV. Pemphigus vulgaris
V. Dermatomyositis

Treatment

I. Treatment is similar to cutaneous lupus erythematosus (see Table 91-1).
II. In addition, pentoxifylline 10 to 20 mg/kg PO TID has had some positive effects.

Systemic Lupus Erythematosus

Definition

I. SLE is a rare, multisystemic, autoimmune disease that involves the skin, urinary tract, joints, or hematologic system of the dog and cat (see also Chapter 76).
II. The skin is involved in 20% to 54% of cases (Gross et al., 2005; Helton-Rhodes, 2006).

Causes

I. Organ specific and nonspecific circulating autoantibodies are directed against a variety of tissue antigens (Gross et al., 2005).
II. Photoaggravation may also play a role.
III. Dogs that are predisposed include the Finnish spitz, collie, Shetland sheepdog, German shepherd dog, and poodle.
IV. Himalayan, Siamese, and Persian cats may be predisposed (Scott et al., 2001).

Pathophysiology

I. Tissue damage arises from immune complex deposition, direct cytotoxicity, or cell-mediated autoimmunity.
II. Pathogenesis of the skin lesions in SLE is unclear; however, multiple factors may be involved.
  A. Ultraviolet light may serve as a trigger for autoantigen expression once it penetrates to the level of the epidermal basal cells.
  B. Specific autoantibodies found in plasma attach to keratinocytes and induce cytotoxicity of keratinocytes.
  C. Injured keratinocytes release lymphocyte attractant and other cytokines, including interleukin (IL)-1, IL-2, and TNF-α.
  D. Apoptosis is inappropriately activated, and subsequent changes cause weakening and separation of the dermal-epidermal junction.

Clinical Signs

I. Clinical signs in dogs
  A. Ulcerative stomatitis is commonly seen.
  B. Mucocutaneous ulcerations develop from bullae in the mucocutaneous junction.
  C. Ulcers may also develop on the footpads.
  D. Panniculitis, urticaria, purpura, erythema, scale, crusting, and depigmentation may be noted.
  E. Face, ears, or distal extremities are commonly affected.
  F. See Chapter 76 for noncutaneous signs of SLE.
II. Clinical signs in cats
  A. Generalized seborrhea, exfoliative erythroderma, alopecia, scaling, and crusting are commonly seen.
  B. Footpads, face, neck, and limbs are commonly affected.
  C. Noncutaneous findings include fever, glomerulonephritis, hemolytic anemia, and weight loss (Gross et al., 2005).

Diagnosis

I. Biochemistry profile and CBC may reveal systemic or hematologic abnormalities.
II. Direct-impression smears of skin lesions are nondiagnostic.
III. ANA tests are positive in 85% to 90% of cases (Helton-Rhodes, 2006).
IV. Histopathologic examination may show multiple changes.
  A. The histopathologic pattern is similar to cutaneous lupus erythematosus.
  B. Evidence of vasculitis and panniculitis may also be present.
V. Direct immunofluorescence of affected tissue may show granular deposition of IgG or C3 at the basement membrane zone.

Differential Diagnosis

I. Other lupus complex diseases: discoid lupus, exfoliative cutaneous lupus
II. Bullous pemphigoid
III. Pemphigus vulgaris
IV. Panniculitis: infectious or sterile causes
V. Drug eruption
VI. Vasculitis
VII. Erythema multiforme and toxic epidermal necrolysis

Treatment

I. See Table 91-1.
II. Gold salts are avoided because of possible problems with concurrent glomerulonephritis.

Monitoring of Animal

I. Prognosis is guarded to poor.
II. Monitoring is similar to that for cutaneous, discoid lupus (see previous discussion).

Epidermolysis Bullosa

Definition and Causes

I. EB represents a group of mechanobullous diseases of various causes in dogs and cats.
II. A defect in the structural integrity of the epidermis or basement membrane zone results in loss of epithelial integrity and blister formation.
III. Various breeds are predisposed (Table 91-2).

Pathophysiology

I. Autoantibody formation develops against different structures, depending on the specific disease.
II. This results in loss of the skin integrity and subsequent blister formation.

Clinical Signs

I. Most subtypes of this disorder cause erosions and ulcerations of the pinnae, footpads, oral cavity, claws, and over the bony prominences of the face (see Table 91-2).
II. Lesions associated with dystrophic EB may be more severe and widespread than other forms.

TABLE 91-2

Clinical Features of the Various Forms of Epidermolysis Bullosa

DISEASE TYPE	EPIDERMAL STRUCTURE TARGETED	BLISTER LAYER	CLINICAL SIGNS	SPECIES/BREED	HISTOPATHOLOGIC FINDINGS	DIRECT IMMUNOFLUORESCENCE	INDIRECT IMMUNOFLUORESCENCE
Epidermolysis bullosa simplex	Intermediate filaments	Basal layer	Superficial erosions of the skin in axillae and groin	Collie, Shetland sheepdog	Although not definitively demonstrated in dogs and cats, histopathological pattern is similar to junctional epidermolysis bullosa	Unknown	None
Junctional epidermolysis bullosa (lethal and nonlethal forms)	Anchoring filaments	Lamina lucida of basement membrane zone	*Dogs:* erosions, ulcers on face, pinnae, footpads, and oral cavity *Cats:* shedding of claws with paronychia	Dogs: toy poodle, Beauceron, German shorthaired pointer Cats: Siamese	Vesicle (dermal-epidermal separation, sparse dermal inflammation) Basement membrane zone on floor of blister	Negative	Negative
Dystrophic epidermolysis bullosa	Anchoring fibrils of Type VII collagen	Beneath lamina densa	*Dogs:* footpad and oral ulcers, scarring of pinnae, tail *Cats:* loss of claw, ulcers of tongue, gums, footpads	Dogs: Akita, Beauceron, golden retriever Cats: domestic shorthair, Persian	Severe neutrophilic inflammation Fibrinous suppurative exudates Basement membrane on floor of blister	Negative	Unknown
Epidermolysis bullosa acquisita	Anchoring fibrils of Type VII collagen	Beneath lamina densa	Erythema occurs and develops into vesicles and ulcers in axillae, groin, oral cavity, mucocutaneous junction, and footpads	Great Dane possibly predisposed	Neutrophils increase in subepidermal skin before blister formation, then separation and necrosis occur Basement membrane zone on roof of blister	Positive IgG in a thick and continuous band at basement membrane	Positive IgG-1, IgG-4

Diagnosis

I. Diagnosis of EB can only reliably be made via biopsy.
II. Wedge section biopsies are recommended (as opposed to punch biopsies) to allow for complete removal of the intact blister for sectioning and histopathologic examination.
III. Histopathologic changes are noted in Table 9-2.
IV. Periodic acid–Schiff (PAS) stains can be used to highlight the lamina densa.
    A. Lamina densa is on the floor of the blister in junctional EB.
    B. Lamina densa is on the roof of the blister in dystrophic EB.

Differential Diagnosis

I. Bullous pemphigoid
II. Mucous membrane pemphigus
III. SLE
IV. Pemphigus vulgaris
V. Drug eruption
VI. Erythema multiforme

Treatment and Monitoring

I. Immunosuppressive therapy is warranted (see Table 91-2).
II. Levamisole 2.5 mg/kg PO QOD alone or in combination with corticosteroids may be helpful.
III. Therapy is variably successful.
IV. Prognosis is dependent on severity.

Feline Eosinophilic Granuloma Complex

Definition and Causes

I. Eosinophilic granuloma complex is a reaction pattern usually caused by a hypersensitivity response to an antigen.
II. Hypersensitivity reactions may arise from the following:
    A. Environmental allergens
    B. Foods
    C. Ectoparasites
        1. Fleas
        2. *Otodectes* spp.
        3. *Cheyletiella* spp.
        4. *Notoedres* spp.
        5. Lice
        6. Arthropod insects
    D. Drugs
    E. Bacterial infections
    F. Fungal infections
        1. Dermatophytosis
        2. *Malassezia* spp.
    G. Viral infections
        1. Feline leukemia virus
        2. Feline immunodeficiency virus
III. Eosinophilic granulomas, eosinophilic plaques, and indolent or rodent ulcers are included in the complex.

Clinical Signs

I. Eosinophilic granuloma
    A. Lesions may be linear and ulcerative.
    B. Typically nodules and/or plaques are alopecic, erythematous, eroded, or ulcerated.
    C. Pruritus is uncommon.
    D. The most common form is a nodular lesion of the mouth or chin (chin edema, "pouty" chin).
    E. Linear plaques may be found on the caudal thighs.
    F. Footpads and conjunctiva may also be affected.
II. Eosinophilic plaque
    A. It typically occurs as areas of alopecia, erosion, and/or ulceration.
    B. Lesions are commonly located on the ventral abdomen, medial thigh, axillary region, flexor surface of the elbows, neck, and dorsal aspect of the trunk.
    C. Pruritus is a common feature.
III. Indolent ulcer
    A. It is also known as a *rodent ulcer*.
    B. An erosive or ulcerated lesion is typically found in the middle of the upper lip or on the upper lip near the canine teeth.
    C. The hard palate may be involved.
    D. Lesions are not usually pruritic or painful.
    E. Regional lymphadenopathy can occur.

Diagnosis

I. Compatible history
II. ± Eosinophils on cytology
III. ± Peripheral eosinophilia
IV. ± Lymphadenopathy
V. Skin biopsy: diagnostic

Differential Diagnosis

I. Infections: bacterial, fungal, viral
II. Neoplasia

Treatment

I. Control any underlying allergies.
II. Consider administering systemic antibiotics for 2 to 4 weeks.
III. Use corticosteroids to induce remission.
    A. Prednisolone 2 to 4 mg/kg PO BID until lesions resolve (2 to 8 weeks), then gradually tapered to the lowest possible dose
    B. Methylprednisolone acetate 4 mg/kg or 20 mg IM, SC every 2 to 3 weeks until lesions resolve
        1. Dose is then decreased to every 2 to 3 months, only as needed.
        2. Improvement is usually seen within 2 to 4 weeks.
    C. Triamcinolone 0.8 mg/kg PO SID until resolution, then tapered
    D. Dexamethasone 0.4 mg/kg PO SID until resolution, then tapered
IV. Cases refractive to corticosteroids may respond to the following:
    A. Trimethoprim-sulfadiazine 125 mg PO BID
    B. Doxycycline 25 mg PO BID
    C. Cyclosporine 25 mg PO SID
V. Surgical excision may be considered for small, unresponsive lesions.
VI. Laser, cryotherapy, or radiation therapy are useful for unresponsive lesions.

Monitoring of Animal

I. Monitor body weight and appetite.
II. Monitor blood glucose and urinalysis for evidence of diabetes mellitus.
III. Monitor urine cultures for urinary tract infections.

Pemphigus Complex

Definition and Causes

I. The term *pemphigus complex* is used to describe an uncommon group of autoimmune diseases in the dog and cat.
II. Lesions are vesiculobullous to pustular in nature and arise from autoantibody-mediated disruption of desmosomes and intercellular adhesions between keratinocytes resulting in acantholysis.
III. Five forms have been identified in dogs and cats.
IV. The disorders are differentiated by clinical lesions, intraepithelial acantholysis, and the location of the desmosomes that are attacked.
   A. Pemphigus foliaceus: most common form in dogs and cats
   B. Pemphigus erythematosus
      1. Represents a mild form of pemphigus foliaceus
      2. May be a crossover between pemphigus foliaceus and SLE
   C. Pemphigus vulgaris: second rarest and most severe variant
   D. Pemphigus vegetans: rarest form, considered to be a benign variant of pemphigus vulgaris
   E. Paraneoplastic pemphigus: recently described in dogs with neoplasia

Pathophysiology

I. Type II (cytotoxic) hypersensitivity causes pemphigus lesions.
II. Pemphigus antibodies bind to desmosomal antigens, leading to the breakdown of cell-to-cell adhesion molecules, with acantholysis and blister formation.

Clinical Signs

I. Signalment: no sex or age predisposition
II. Pemphigus foliaceus
   A. Predisposed breeds include the dachshund, Schipperke, Finnish spitz, bearded collie, chow chow, Akita, and Newfoundland.
   B. Doberman pinschers and Labrador retrievers are overrepresented with drug-induced pemphigus foliaceus.
III. Pemphigus erythematosus
   A. Age: usually middle-aged animals
   B. Predisposed breeds: Shetland sheepdog, collie, German shepherd dog
IV. Specific clinical features
   A. Pemphigus foliaceus
      1. Typically includes scales, crusts, or pustular dermatitis.
         a. Crusts are often honey-colored to brown in appearance.
         b. It often begins on the face and ears.
         c. It is not a vesicular condition.
      2. Depigmentation of the nose is common, but oral cavity involvement is rare.
      3. Feet, footpads, nail beds, and the inguinal area may become affected.
      4. The disease generally progresses over 6 months.
      5. Cats tend to have paronychia and involvement of the nipples.
      6. The disease may wax and wane and be accompanied by secondary bacterial pyoderma, peripheral lymphadenopathy, lethargy, anorexia, and fever.
      7. Severe pain and pruritus are variable.
      8. Three clinical forms have been recognized.
         a. Spontaneous: Akita, chow chow
         b. Drug-induced (often after exposure to trimethoprim-sulfa drugs): Doberman pinscher, Labrador retriever
         c. Dogs with a history of chronic skin disease
   B. Pemphigus erythematosus
      1. Erythema and a pustular dermatitis are usually confined to the face and ears.
         a. Depigmentation of the nose may be the initial lesion.
         b. Depigmented noses are predisposed to photodermatitis, which may exacerbate the condition.
      2. Occasionally footpads or genitalia may be involved.
      3. Pain and pruritus are variable.
   C. Pemphigus vulgaris
      1. This form of pemphigus is a vesiculobullous disease and can progress to erosions and ulcers.
      2. Most cases have lesions in the oral cavity.
         a. Mucocutaneous junctions (eyelids, nostrils, lips, anus, prepuce, vulva) may be affected.
         b. Cutaneous lesions may also be evident, especially in the axillae and groin.
      3. Onychomadesis (sloughing of claws) or ulcerative paronychia (infection or inflammation of the claw folds) may be the only presenting sign.
      4. Positive Nikolsky's sign (the outer layer of the skin is easily removed when positive pressure is applied to the edge of a lesion) indicates poor cellular cohesion.
      5. Secondary bacterial pyodermas and lymphadenopathy may be present.
      6. Pain and pruritus are variable.
      7. Fever, anorexia, and depression may be noted in severely affected animals.
   D. Pemphigus vegetans
      1. Vesiculopustular disease that develops into papillomatous and verrucous lesions that may exude serum and be covered in pustules.
      2. Animals are generally healthy.
      3. Pain and pruritus are variable.
      4. Nikolsky's sign may be present.
      5. It may be a benign form of pemphigus vulgaris.
   E. Paraneoplastic pemphigus: possibly associated with lymphoma, splenic sarcoma, Sertoli cell tumor in the dog (Elmore et al., 2005)

Diagnosis

I. Hematological changes are nonspecific.
   A. Leukocytosis with a left shift may be evident if a secondary bacterial infection is present.
   B. Moderate normochromic, normocytic anemia, hyperglobulinemia, and hypoalbuminemia may also be detected.
II. In a low number of cases, ANA titers may be positive with pemphigus erythematosus.
III. Cytological examination of pustules may reveal numerous acanthocytes, neutrophils (nondegenerate unless secondary infection exists), and eosinophils.
   A. Acantholytic cells may form sheets or rafts.
   B. Secondary bacterial pyoderma can cause small numbers of acantholytic cells.
IV. Primary lesions (pustules, bullae and vesicles) are biopsied whenever possible.
   A. Acantholytic cells and intraepidermal clefting are present in all forms of pemphigus.
   B. Pemphigus foliaceus and pemphigus erythematosus have subcorneal or intraspinous clefts.
   C. Pemphigus vulgaris has suprabasilar clefting or vesicle formation secondary to acantholysis.
   D. Pemphigus vegetans may show epidermal hyperplasia and intraepidermal microabscesses that contain acantholytic cells and eosinophils, but controversy exists as to the typical lesion.
   E. Crusts may contain large numbers of acanthocytes that are secondary to pustule or vesicle rupture.
V. Immunofluorescence and immunoperoxidase testing are used to detect antibody deposition in tissues.
   A. Sensitivity of direct immunofluorescence testing in dogs is variable.
      1. Biopsies must be shipped in Michel's medium and maintained at a pH of 7.0 to 7.2.
      2. Lip samples are a possible tissue source.
      3. False-positive results are possible.
         a. Footpad and nose samples
         b. Samples from animals previously treated with corticosteroids
         c. Samples from secondary lesions
         d. Improper sample transportation
   B. Indirect immunofluorescence is not specific or sensitive.
   C. Immunoperoxidase tests may also be performed.
      1. Formalin-fixed samples can be used.
      2. False-positive results may be obtained from animals treated with corticosteroids.

Differential Diagnosis

See Box 91-1.

Box 91-1

Differential Diagnoses for the Pemphigus Complex Diseases

Disease	Differential Diagnoses
Pemphigus foliaceus	Bacterial folliculitis, dermatophytosis, demodicosis, primary or secondary seborrhea, pemphigus erythematosus, systemic lupus erythematosus, discoid lupus erythematosus, cutaneous drug reaction, dermatophilosis, zinc-responsive dermatitis, cutaneous T-cell lymphoma, necrolytic migratory erythema, subcorneal pustular dermatosis, eosinophilic pustulosis, leishmaniasis
Pemphigus erythematosus	Bacterial folliculitis, demodicosis, primary or secondary seborrhea, pemphigus erythematosus, systemic lupus erythematosus, discoid lupus erythematosus, benign familial pemphigus, cutaneous drug reaction, dermatomyositis, zinc-responsive dermatitis, epidermolysis bullosa simplex, uveodermatologic syndrome, leishmaniasis
Pemphigus vulgaris	Bullous pemphigoid, epidermolysis bullosa acquisita, systemic lupus erythematosus, drug reaction, toxic epidermal necrolysis, cutaneous T-cell lymphoma, erythema multiforme, candidiasis infection, ulcerative stomatitis (multiple causes)
Pemphigus vegetans	Pemphigus vulgaris, pemphigus erythematosus, bacterial folliculitis, fungal granulomas, cutaneous neoplasia, benign familial pemphigus
Paraneoplastic pemphigus	Systemic lupus erythematosus, pemphigus vulgaris, mucous membrane pemphigoid, bullous pemphigoid, epidermolysis bullosa acquisita, erythema multiforme, toxic epidermal necrolysis, bullous drug eruptions, vesicular cutaneous lupus erythematosus

Treatment

I. Pemphigus foliaceus and pemphigus vulgaris
   A. In dogs and cats the initial therapy of choice is immunosuppressive doses of oral prednisone (see Table 91-1).
   B. Cats that fail to respond to prednisone may respond to dexamethasone or triamcinolone.
   C. In the dog the addition of azathioprine may help achieve remission, but azathioprine is contraindicated in cats.
   D. Chlorambucil can be used in both cats and dogs as an alternative to azathioprine.
   E. Cyclophosphamide can be used in the dog in combination with prednisone.
   F. Gold therapy (aurothioglucose), although not always available, can be tried in conjunction with prednisone in dogs and cats that are refractory to the previously discussed therapies (see Table 91-1).
      1. All other therapies are discontinued for 4 weeks before initiating gold therapy.

2. Test dose is administered first.
   a. Animals <10 kg: 1 mg IM
   b. Animals >10 kg: 5 mg IM
3. If adverse effects are not detected, then a dose of 1 mg/kg IM is given 1 week later and repeated on a weekly basis.
4. If after 12 weeks no response is seen, then the dose may be increased to 1.5 to 2.0 mg/kg IM weekly.
5. Once remission is achieved, the dosing interval is increased to every 2 weeks, then to every 4 weeks for several months.
6. The oral form of gold *(Auranofin)* has not been efficacious in the dog and is expensive.
7. Gold therapy may take 6 to 12 weeks to be effective.
8. Prednisone may need to be continued at full strength during the initial 6 to 12 weeks of gold therapy.

G. Human immunoglobulin therapy (1 g/kg IV over 6 to 12 hours and given for 1 to 2 days) may also be tried.

II. Pemphigus erythematosus and pemphigus vegetans
   A. Treatment with topical corticosteroids and sun avoidance (especially between the hours of 10 AM and 4 PM) may achieve remission.
   B. Sunscreens with a sun protection factor (SPF) of ≥15 and containing titanium dioxide may be beneficial when applied BID to TID.
   C. Combination of tetracycline and niacinamide may achieve remission in 25% of dogs, but animals must be monitored for gastrointestinal side effects and seizures.
   D. Vitamin E (topically or systemically) may be of benefit.
   E. If the previous measures do not achieve a satisfactory result, or the animal comes out of remission, then the addition of corticosteroids may be beneficial.

III. Paraneoplastic pemphigus: treatment of the underlying neoplasia

Monitoring of Animal

I. All of the medications used to treat pemphigus have potential side effects that necessitate monitoring.

II. When administering prednisone, check a CBC and biochemistry panel every 2 weeks until remission is obtained or tapering begins.
   A. Side effects include a stress leukogram, elevated liver enzymes, and decreased globulins.
   B. Urine cultures are periodically performed to monitor for urinary tract infections secondary to immunosuppression.

III. With azathioprine, chlorambucil, or cyclophosphamide therapy, a CBC and chemistry panel are performed every 2 weeks initially.
   A. Side effects include bone marrow suppression (thrombocytopenia, anemia, leukopenia) and elevated liver enzymes (mild increases are expected).
   B. If side effects occur, then the dose of the medications is decreased.
   C. Urine cultures are periodically conducted to monitor for urinary tract infections secondary to immunosuppression.
   D. Urinalyses are also performed to monitor for drug-induced sterile hemorrhagic cystitis that develops in some dogs on cyclophosphamide for >2 months.

IV. While the animal is receiving chrysotherapy, a CBC and urinalysis are performed before each treatment to monitor for anemia, eosinophilia, and proteinuria; chemistry panels are done monthly to monitor for elevations in liver enzymes.

V. Animals on potent topical steroids are monitored similarly to those on systemic corticosteroids.

VASCULAR DISORDERS

Ischemic Dermatopathy

Definition and Causes

I. *Ischemic dermatopathy* is the term given to multiple cutaneous vasculopathies of dogs that are similar in clinical and histological appearance.

II. This group of diseases includes five separate disorders, with variable causes and clinical signs (Gross et al., 2005).
   A. Group 1 includes dermatomyositis, an inheritable, inflammatory disorder with a juvenile onset affecting skin and muscle; certain breeds are at increased risk.
   B. Group 2 includes a juvenile-onset, ischemic dermatopathy of dogs that is identical to dermatomyositis but has no proven breed or familial predisposition.
   C. Group 3 includes dogs that exhibit postrabies vaccination panniculitis.
   D. Group 4 includes dogs with more severe generalized cutaneous reactions after rabies vaccination.
   E. Group 5 includes dogs with adult-onset, generalized ischemic dermatopathy that have no correlative history of a vaccine reaction.

Pathophysiology

I. Cutaneous hypoxia leads to atrophy of the hair follicles and alopecia.

II. Vascular impairment may occur to the skin over bony prominences, with ulceration, erosions, and crusting.

III. Subsequent scarring may or may not be present.

IV. Breed predispositions are noted in some disorders (Table 91-3).

Clinical Signs

I. Groups I and II
   A. Transient papules with erythema and vesicles leading to ulcers, crusts, and alopecia
   B. Scarring with pigmentary abnormalities (hypopigmentation or hyperpigmentation)
   C. Aggravated by ultraviolet light
   D. No pain or pruritus, subtle involvement of muscles

II. Group III: focal scarring and alopecia at site of injection

III. Groups IV and V: similar lesions to Groups I and II but may be more severe

TABLE 91-3

Ischemic Dermatopathy Disorders of the Dog

DISORDER	BREEDS AFFECTED	AGE OF ONSET	DISTRIBUTION OF LESIONS	CAUSES
Dermatomyositis	Collie, Shetland sheepdog, and their crosses	Juvenile: <6 mo	Face, pressure points on extremities Can be generalized	Genetic predisposition Possible unknown environmental factors
Juvenile-onset ischemic dermatopathy	Chow chow, Welsh corgi, German shepherd dog, miniature schnauzer, dachshund, fox terrier, Maltese	Juvenile: <6 mo	Face, pressure points on extremities Occasionally generalized	Unknown
Postrabies vaccine panniculitis	Toy or miniature breeds	Any age	Site of injection or local extension	Rabies vaccine
Severe generalized vaccine-induced ischemic dermatopathy	Unknown	Adult onset	Generalized	Rabies vaccine
Generalized idiopathic ischemic dermatopathy	Unknown	Adult onset	Generalized	Unknown

From Gross TL, Ihrke PJ, Walder EJ et al: Erosive and ulcerative diseases of the epidermis. p. 116. In Gross TL, Ihrke PJ, Walder EJ et al (eds): Skin Diseases of the Dog and Cat Clinical and Histopathologic Diagnosis. 2nd Ed. Blackwell, Oxford, England, 2005.

Diagnosis

I. Routine diagnostic tests (skin scraping, dermatophyte culture) are negative.
II. Diagnosis is based on histopathology of affected skin.
  A. Scattered degeneration of basal cells (apoptosis) occurs in the epidermis and epithelium of the hair follicles.
  B. Epidermal and dermal pallor occur, as well as hypoxia of the follicles and adnexa.
  C. Lymphocytes and histiocytes predominate.
  D. Once ulceration develops, intense neutrophilia may be noted.
  E. Dermal scarring and atrophic hair follicles may be seen.
  F. Blood vessels may show a vasculitis of low cellularity.
  G. Skeletal muscle inflammation may be found with deep biopsies.
III. Differentiation of the various groups relies on history and signalment.

Differential Diagnoses

I. Demodicosis
II. Dermatophytosis
III. Bacterial pyoderma
IV. Discoid lupus
V. Drug eruption

Treatment and Monitoring

I. Treatment of most of the disorders generally requires immunosuppressive therapy (see Table 91-1).
II. Pentoxifylline 10 to 20 mg/kg PO TID may be helpful in some cases.

Vasculitis

Definition and Causes

I. Vasculitis is an inflammation of the walls of blood vessels and often results from deposition of immune complexes within the walls of the vessels (Type III hypersensitivity).
II. Vasculitis can occur as a primary disorder or arise secondary to exposure to drugs, neoplasia, infections, inflammation, or vaccines.
III. Cutaneous vasculopathies usually result from damage to the postcapillary venules.
IV. Multiple breeds may be predisposed and are represented in various syndromes.
  A. Proliferative thrombovascular necrosis of the pinnae: toy and small breeds
  B. Familial cutaneous vasculopathy: German shepherd dog
  C. Cutaneous and renal glomerular vasculopathy: greyhound
  D. Neutrophilic leukocytoclastic vasculitis: Jack Russell terrier
  E. Focal cutaneous vasculitis and alopecia at the site of rabies vaccines: miniature poodle, Yorkshire terrier, silky terriers

Pathophysiology

I. Activation of complement and other chemoattractants leads to the recruitment of neutrophils, which enzymatically degrade blood vessel walls.
II. Vessel occlusion and thrombosis may develop, causing hypoxic changes to the tissues.
III. Tissue hypoxia results in erosions, ulcers, and necrosis.

Clinical Signs

I. Clinical signs are numerous and variable, depending on the organs involved.
II. Initially macular erythema and edema progresses to papules, plaques, petechiae, and hemorrhagic bullae.
III. Ultimately, erosions, ulcers, and necrosis result.
IV. Affected areas tend to be associated with extremities (legs, footpads, claws), the pinnae, nasal planum, face, scrotum, and tail.
V. Additional systemic signs may include myopathy, polyarthropathy, hepatopathy, anorexia, pain, pruritus, anemia, and thrombocytopenia.

Diagnosis

I. Direct cytological impression smears are nondiagnostic.
II. Digital pressure on erythematous or purpuric lesions does not result in blanching.
III. Laboratory tests (biochemistry profile, CBC, urinalysis) results vary depending on the organ involved.
IV. ANA assay is usually negative.
V. Diagnosis relies on histopathology of affected skin.
   A. Neutrophilic leukocytoclastic vasculitis and inflammation involving the vessel walls
   B. Fibrinoid degeneration of blood vessel walls, with thrombosis
VI. Direct immunofluorescence may exhibit immunoglobulin or complement deposition in the vessel walls (and occasionally in the epidermal basement membrane).

Differential Diagnosis

I. SLE
II. Disseminated intravascular coagulopathy
III. Cold agglutinin disease
IV. Hypersensitivity reactions

Treatment

I. Identify and correct the underlying cause, if possible.
II. Immunosuppressive therapy is usually indicated (see Table 91-1).
III. Pentoxifylline 20 mg/kg PO TID may help combat inflammation and restore perfusion.
IV. Dapsone 1 mg/kg PO TID has been shown to be effective in some cases.
V. Sulfasalazine 20 to 40 mg/kg PO TID has also been effective in some cases.
VI. Cyclosporine 5 mg/kg PO SID has had anecdotal success in some cases.
VII. Prognosis depends on the specific disorder and the severity of the condition.

NEOPLASTIC DISORDERS

Cutaneous (Epitheliotropic) T-Cell Lymphoma

Definition and Causes

I. An uncommon cutaneous lymphoma affecting dogs and cats
II. Malignancy of T lymphocytes of the skin
III. Also known as *mycosis fungoides*

Pathophysiology

I. Pathophysiology is unknown.
II. The disorder is thought to arise from chronic antigenic stimulation of T cells in the skin.

Clinical Signs

I. Four clinical presentations in dogs
   A. Exfoliative erythroderma: pruritic erythema, scaling
   B. Mucocutaneous erythema, depigmentation, ulceration
   C. Solitary or multiple cutaneous plaques or nodules
   D. Infiltrative, ulcerative lesions of the oral mucosa (similar to chronic stomatitis) and hyperkeratotic, depigmented and/or ulcerated footpads
II. Possible peripheral lymphadenopathy, signs of systemic illness
III. Rarely in dogs: lesions only on the nasal planum, nasal philtrum, lips, anus
IV. Cats: well-circumscribed annular areas of alopecia, erythema, and scaling on the head and neck

Diagnosis

I. Suggestive history and signalment
II. Definitive findings on skin biopsy
   A. Epidermis and epithelium of hair follicles are infiltrated with neoplastic lymphocytes.
   B. Pautrier's microabscesses (focal aggregates of atypical, polymorphic lymphocytes within the epithelium) may occur.
   C. In dogs, a tropism for hair follicles and epitrichial sweat glands exists.

Differential Diagnosis

I. Atopic dermatitis
II. Food allergy
III. Vasculitis
IV. Sarcoptic mange
V. Other neoplasms
VI. Chronic stomatitis
VII. Autoimmune diseases: SLE or discoid lupus, pemphigus complex

Treatment and Monitoring

I. Prognosis is variable.
   A. Animals diagnosed late in the course may survive only 5 to 10 months.
   B. Mildly affected dogs may survive for longer periods.
II. Therapy of choice for some is lomustine (CCNU) 10 mg/kg PO every 3 weeks.
   A. Monitor CBC for thrombocytopenia, leukopenia, and anemia before each treatment.
   B. Monitor a biochemistry profile for elevations in liver enzymes before each treatment.
III. Topical nitrogen mustard has limited efficacy.
IV. Limited success has also occurred with combination chemotherapy of prednisone, cyclophosphamide, vincristine, chlorambucil, doxorubicin, and methotrexate.

Feline Thymoma–Associated Exfoliative Dermatitis

Definition and Causes

I. A rare exfoliative disease seen in cats with thymomas (see Chapter 73)
II. Thought to be associated with induction of autoreactive T cells

Clinical Signs

I. Exfoliative dermatitis occurs in middle-aged to older cats and has no sex predilection.
II. Erythema and exfoliation often start on the head, neck, and pinnae; the dermatitis then becomes generalized over weeks to months.
III. Alopecia and hyperpigmentation of the skin can occur.
IV. Accumulations of seborrheic debris may occur interdigitally and around claw beds.
V. Some cats become white from to loss of hair pigment (leukotrichia).
VI. Pruritus may be absent, minimal, or severe (rare).

Diagnosis

I. Biopsy of the skin reveals the following:
   A. The most consistent histological changes are hyperkeratosis and mild transepidermal and follicular apoptosis.
   B. Interface dermatitis may be present and involve follicles to the level of the isthmus.
   C. Basal cell apoptosis may be prominent.
   D. Sebaceous glands can be absent.
   E. Vacuolation of the dermal-epidermal junction may be seen.
   F. Pigmentary incontinence (macrophages filled with pigment) is a classic feature.
II. See Chapter 20 for diagnostic tests for thymomas.

Differential Diagnosis

I. SLE
II. Erythema multiforme
III. Epitheliotropic T-cell lymphoma
IV. Dermatophytosis
V. Demodicosis
VI. Pemphigus foliaceus
VII. Hyperadrenocorticism or diabetes mellitus, with associated bacterial, *Malassezia* spp., or dermatophyte infection

Treatment and Monitoring

I. Removal of the thymic mass is the treatment of choice.
   A. Noninvasive tumors have a good prognosis (median survival, 2 years).
   B. Invasive tumors (15%) have a poor prognosis, with survival rarely occurring beyond the immediate postoperative period.
II. Overall prognosis is poor when the tumor is not excised.
III. Most cats are euthanized within 4 to 5 months of initial onset of cutaneous lesions from worsening of the skin condition.

CHAPTER 92

Pigmentary Disorders of the Skin

Manon Paradis

DISORDERS OF HYPERPIGMENTATION

Lentigo

Definition and Cause

I. In Latin, *lentigo* (plural, *lentigines*) is the word meaning lentil-shaped spot.
II. *Lentigo* describes the well-circumscribed black macules observed in mature dogs.
III. The cause of these lesions is usually unknown.
IV. Hyperpigmented (Box 92-1) macules or patches result from increased numbers of melanocytes in the epidermis, without evidence of focal proliferation.

Clinical Signs

I. Several well-circumscribed black macules develop over several months.
II. Subsequently they become static and remain unchanged for the life of the dog.
III. The most common location is on the ventrum.
IV. The condition affects mature dogs.
V. It is asymptomatic.

Diagnosis

I. Diagnosis is usually based on history and clinical findings.

Box 92-1

Terminology Pertaining to Pigmentary Changes of Hair and Skin

Term	Definition
Hyperpigmentation or hypermelanosis	Increased pigmentation of the skin or hair coat in areas that should be less pigmented
Melanoderma	Skin hyperpigmentation
Melanotrichia	Hair hyperpigmentation
Hypopigmentation or hypomelanosis	Lack of (or decrease in) pigmentation of the skin or hair coat in areas that should be pigmented
Leukoderma	Depigmented skin or mucosa
Leukotrichia	Depigmented hair shaft

II. Dermatohistopathologic examination reveals an increased number of melanocytes in the epidermis and the presence of melanin pigment in most keratinocytes.

Differential Diagnosis

I. Pigmented neoplasms of the skin, especially melanocytomas and melanomas
II. Papillomavirus-induced lesions: characterized by slightly rough black-pigmented macules to plaques that may transform into squamous cell carcinoma
III. Pigmented epidermal nevi
IV. Lentigo profusa
   A. Hereditary form of lentigo previously reported in pugs
   B. May be papillomavirus-induced lesions or pigmented epidermal nevi
V. Aforementioned conditions: hyperkeratotic surface or thickening

Treatment and Monitoring

I. None indicated: cosmetic condition only
II. Benign skin change

Lentigo Simplex in Orange Cats

Definition and Causes

I. Multiple lentigines affecting mucocutaneous junctions, especially in orange cats
II. Cause unknown
III. Most likely genetically determined

Pathophysiology

I. Hyperpigmented macules or patches result from an increased number of skin melanocytes and a hypermelanosis of the keratinocytes of the basal cell layer of the epidermis.
II. Focal proliferation of epidermis is not evident.

Clinical Signs

I. Lesions start as tiny black spots on the lips and often spread to the nose, gingiva, and eyelids (Figure 92-1).
II. Lentigines progressively increase in size (range from 1 to 9 mm in diameter) and number with age and may eventually coalesce.
III. Lesions may start in orange cats <1 year of age.
IV. Lentigines are not symptomatic.

FIGURE 92-1 Lentigo simplex represented by multiple pigmented macules on the lips and nasal planum of an adult orange cat.

Diagnosis

I. Diagnosis is usually based on history and clinical findings.
II. Dermatohistopathologic examination reveals marked hypermelanosis, predominantly of the basal cell layer of the epithelium, and increased numbers of melanocytes.

Differential Diagnosis

I. Melanocytoma (benign melanoma)
II. Malignant melanoma

Treatment and Monitoring

I. None indicated
II. Cosmetic condition only

Postinflammatory Hyperpigmentation

Definition and Causes

I. Skin hyperpigmentation after inflammation is very common (especially in dogs), regardless of the inciting cause of the inflammation.
II. Hyperpigmentation is a common sequela to pyoderma, demodicosis, *Malassezia* spp. dermatitis, and dermatophytosis in dogs.
III. Dermatophytosis is one of the few skin diseases of cats in which hyperpigmentation may be seen.

Pathophysiology

I. Exact mechanism of hyperpigmentation after inflammation is unknown.
II. Hyperpigmentation associated with many pruritic diseases results from chronic irritation because of cutaneous friction in addition to inflammatory processes.

Clinical Signs

I. Postinflammatory skin hyperpigmentation can be focal and well circumscribed, patchy, or diffuse.
II. Focal postinflammatory melanotrichia is seen occasionally in adult dogs with silver or gray hair coats.
III. Cutaneous hyperpigmentation is uncommon in cats.

Diagnosis

I. Diagnosis is usually based on history and clinical findings.
II. Identification of an underlying cause is supportive.

Treatment and Monitoring

I. Identify and treat the underlying cause.
II. Melanoderma usually resolves slowly (over weeks to months), after the underlying cause has been corrected.
III. In most cases melanotrichia resolves at the next shedding cycle.

Hormonal-Associated Hyperpigmentation

Definition and Causes

I. Diffuse skin hyperpigmentation may result from endocrinopathies, such as hyperadrenocorticism, hypothyroidism, hyperestrogenism, and alopecia X.
II. The mechanism of hyperpigmentation is unknown.
III. Hyperpigmentation may result from direct and/or indirect effects of hormones on melanocytes.
IV. Tanning of alopecic skin exposed to ultraviolet light—the most potent stimulus for melanogenesis—may also be a contributing factor.

Clinical Signs

I. Diffuse melanoderma is seen, particularly of hypotrichotic or alopecic skin.
II. Melanotrichia is observed occasionally after treatment of canine hyperadrenocorticism.

Diagnosis

I. Diagnosis is usually based on history and clinical findings.
II. Identification of the underlying endocrinopathy is supportive.

Treatment and Monitoring

I. Identify and treat the underlying endocrinopathy.
II. Hyperpigmentation usually resolves slowly (over weeks to months), after the underlying endocrinopathy has resolved.

DISORDERS OF HYPOPIGMENTATION

Nasal Depigmentation

Definition and Causes

I. Acquired hypopigmentation of the nasal planum
II. Also known as *Dudley nose* or *snow nose*

III. Idiopathic disorder with genetic predisposition in golden retrievers, yellow Labrador retrievers, Siberian huskies and Alaskan malamutes
IV. Loss of pigment production by melanocytes of the nasal planum

Clinical Signs

I. Affected dogs are born with pigmented noses, but the black color of the nasal planum gradually lightens to a light brown (hypopigmentation) or pinkish color (depigmentation) (Figures 92-2 and 92-3).
II. Changes may be permanent or may wax and wane in some dogs.
III. Typically worse during the winter months (hence the colloquial name *snow nose*), with some increase in pigmentation in spring and summer.
IV. Other dermatologic lesions such as ulceration and crusts or pruritus are absent.
V. Normal cobble texture of the nasal planum is preserved, as opposed to autoimmune diseases in which the normal surface architecture is destroyed.

Diagnosis

I. Diagnosis is based on history and clinical findings.
II. Dermatohistopathologic examination reveals a marked reduction of epidermal melanin granules.

Differential Diagnosis

I. Vitiligo (see following section)
II. Cutaneous (discoid) lupus erythematosus
III. Pemphigus erythematosus
IV. Epitheliotropic lymphoma (mycosis fungoides)
V. Uveodermatologic syndrome (Vogt-Koyanagi-Harada–like syndrome; Table 92-1)

Treatment and Monitoring

I. No known treatment is available.
II. It is a cosmetic problem only.
III. The condition is considered a defect in show dogs.

Vitiligo

Definition and Causes

I. Vitiligo is an acquired disorder characterized by selective destruction of melanocytes in skin and hair matrix cells, which results in leukoderma and leukotrichia (see Box 92-1).
II. Vitiligo is presumed to be hereditary in some breeds, such as the Belgian shepherd, rottweiler, Doberman pinscher, and Siamese cat.

Pathophysiology

I. Various theories have been proposed to explain vitiligo, including the production of antimelanocyte antibodies.
II. In general, vitiligo is a spontaneous disorder and is not accompanied by inflammation.

Clinical Signs

I. One or several asymptomatic, possibly symmetrical, macular areas of leukoderma and/or leukotrichia develop, especially of the lips, buccal mucosa, muzzle, nasal planum, and footpads.
II. Depigmentation is usually permanent, but spontaneous repigmentation may occur.
III. It is usually first noted in young adulthood.
IV. The disorder is uncommon in dogs and rare in cats.

FIGURE 92-2 Depigmentation of the nasal planum in an adult Alaskan malamute (also called *Dudley nose* or *snow nose*).

FIGURE 92-3 Depigmentation of the nasal planum in an adult yellow Labrador retriever.

TABLE 92-1

Miscellaneous Acquired Pigmentary Disorders

DISORDER	DEFINITION AND CAUSE	DIAGNOSIS	CLINICAL SIGNS	TREATMENT AND MONITORING
Melanotrichia of feline acromelanism	Cats demonstrating acromelanism (dark extremities or points), such as the Siamese and Himalayan breeds, develop temporary coat color changes consisting of melanotrichia after inflammation or hair clipping	Diagnosis is based on compatible history and clinical findings Changes are confined to cats with acromelanism	Melanotrichia develops at the site of skin inflammation or after clipping of the truncal area	No treatment is required Melanotrichia usually resolves at the next shedding cycle
Acquired aurotrichia ("gilding syndrome")	Acquired pigment changes are seen in the hair coat of miniature schnauzers, presumably caused by a shift in eumelanins and pheomelanins	Diagnosis is based on compatible history and physical examination findings	Miniature schnauzers develop patches of golden hair in a previously normal, gray or black coat	No known treatment exists Spontaneous resolution occurs in 6-24 months
Malnutrition	Malnutrition is the cause—specifically trace element deficiencies such as copper and zinc, as well as low dietary tyrosine or phenylalanine	Diagnosis is based on suggestive history and physical examination findings	Black hair changes to reddish or brown hair	Feed a balanced diet Condition normally resolves when the underlying cause is removed
Endocrinopathies	Lightening of the hair coat occurs in dogs with Sertoli cell tumors, alopecia X, hypothyroidism, or hyperadrenocorticism	Diagnosis is based on suggestive history, physical examination findings, and appropriate diagnostic tests	Old retained hair shafts become dry, frizzy, and lighter in color	Treat the underlying cause Condition normally resolves when the underlying cause is removed
Environmental factors	Color changes occur after exposure to chronic ultraviolet light or other environmental elements (e.g., chlorine, detergents)	Diagnosis is based on suggestive history and physical examination findings	Old retained hair shafts become dry, frizzy, and lighter in color	Avoid excessive exposure to causative environmental factors Condition resolves when the underlying cause is removed
Uveodermatologic syndrome	It is considered an immune-mediated disease, with melanocytes as the target Hair, skin, and the uveal tract of the eyes are affected Alaskan sled dogs and oriental breeds are predisposed; also documented in the Australian shepherd, Irish setter, golden retriever, St. Bernard, and other breeds It may affect dogs of all ages	Diagnosis is based on compatible history and physical examination findings Histopathology of skin biopsies is diagnostic: lichenoid dermatitis with many macrophages, uncommon apoptotic cells in the basal cell layer, pigmentary incontinence in depigmented areas	Often acute onset of anterior or panuveitis occurs Possible retinal detachment, secondary glaucoma, and blindness may occur Depigmentation of eyelids, nose, lips, footpads, scrotum, and (sometimes) haired areas of the body is seen Oral and cutaneous ulcerations are possible in severe forms Mild cutaneous signs include depigmentation of skin and hair, as well as mild scaling and erythema of affected areas Generalized or focal vitiligo is a classic finding	Prednisone is administered 2 mg/kg PO SID or divided BID initially, then tapered once signs are controlled Azathioprine (1-2 mg/kg PO SID) may be needed in addition to prednisone for difficult to control cases See also Chapter 102

Diagnosis

I. History of acquired depigmentation of one or several macular areas of skin, mucosa, or hair, with no history of previous trauma is highly suggestive.
II. Dermatohistopathologic examination reveals normal skin except for the absence of melanocytes and melanin.

Differential Diagnosis

I. Nasal depigmentation (Dudley nose, snow nose)
II. Uveodermatologic syndrome (Vogt-Koyanagi-Harada–like syndrome)
III. Certain autoimmune diseases: cutaneous lupus erythematosus, pemphigus erythematosus, pemphigus foliaceus
IV. Alopecia areata: leukotrichia possibly seen in resolving lesions
V. Epitheliotropic lymphoma (mycosis fungoides)
VI. Postinflammatory or posttraumatic hypopigmentation

Treatment and Monitoring

I. No known treatment is available.
II. Vitiligo is a cosmetic disorder that does not affect the animal's quality of life.

Postinflammatory Hypopigmentation

Definition and Causes

I. It is an acquired hypopigmentation of previously normal skin and hair after destruction of melanocytes.
II. Potential causes include trauma, burns, and infection.
III. A number of inflammatory diseases may begin with hypopigmentation of the nose and occasionally the lips, such as cutaneous lupus erythematosus, pemphigus erythematosus, pemphigus foliaceus, and uveodermatologic syndrome.

Pathophysiology

I. Selective destruction of melanocytes occurs in skin and hair matrix cells.
II. Secondary leukoderma and leukotrichia develop.

Clinical Signs

I. Leukoderma and/or leukotrichia develop at a site of previous skin trauma.
II. Depigmentation is usually permanent.

Diagnosis

I. Acquired depigmentation occurs at the site of previous trauma, infection, or inflammation.
II. It can occur in any breed of dog or cat.

Differential Diagnosis

I. Vitiligo and other hypopigmenting disorders
II. Epitheliotropic lymphoma (see Chapter 91)

Treatment and Monitoring

I. Repigmentation may occur after treatment of the underlying cause.
II. Sunscreen applied before sun exposure may prevent sunburn in the hypopigmented skin.
III. Depigmented skin may be prone to sunburn and subsequent actinic dermatitis.

MISCELLANEOUS ACQUIRED PIGMENTARY DISORDERS

See Table 92-1.

CHAPTER 93

Crusting and Scaling Dermatoses

Nicola Williamson

CONGENITAL/DEVELOPMENTAL DISORDERS

Primary Seborrhea

Definition and Causes

I. Primary seborrhea is an inherited hyperproliferative disease in which the epidermal cell turnover time is approximately 8 days instead of the normal 21 days.
II. It may be an autosomal recessive trait in West Highland white terriers and Persian cats.

Pathophysiology

I. It is most commonly seen in the American cocker spaniel, West Highland white terrier, English springer spaniel, and basset hound.
II. Other reported breeds include the Jack Russell terrier, Cavalier King Charles spaniel, Wheaton terrier, Chinese shar-pei, dachshund, Doberman pinscher, German shepherd dog, Irish setter, and Labrador retriever.
III. It may also be seen in Persian, Himalayan, and exotic shorthaired cats.
IV. No sex predilection has been noted.

Clinical Signs

I. Dogs
  A. Pruritus is common.
  B. Dogs develop signs early in life that progress with age.
  C. The American cocker spaniel, West Highland white terrier, English springer spaniel, Chinese shar-pei, basset hound, and Labrador retriever tend to have a greasy seborrhea that involves the ventral neck, face, perineum, and feet.
  D. Doberman pinschers and Irish setters tend to have a dry, flaky hair coat.
  E. Ceruminous hyperplasic otitis externa may be noted.
  F. Greasy, malodorous coat may be present.
  G. Digital hyperkeratosis can be present.
  H. Brittle claws may occur.
  I. Lesions tend to be worse around the mouth, eyes, pinnae, axillae, groin, and feet.
II. Cats
  A. Most cats display clinical signs within the first 2 to 3 days of life.
  B. Less severe cases may become evident at 6 weeks of age.
  C. Hair appears dirty and sticks together.
  D. Over time the whole body becomes greasy, scaly, and alopecic.
  E. Waxy accumulations can occur in the ears and face folds.
  F. Rancid odor is often present.

Diagnosis

I. History of early age of onset
II. Histopathologic changes on skin biopsy
  A. Orthokeratotic or parakeratotic hyperkeratosis
  B. Follicular keratosis with variable dyskeratosis
  C. Hyperplasic, superficial, perivascular dermatitis
  D. Possibly bacteria and yeast within the keratin

Differential Diagnosis

I. Ichthyosis
II. Epidermal dysplasia
III. Vitamin A–responsive dermatitis
IV. Sebaceous adenitis
V. Causes of secondary seborrhea

Treatment

I. Dogs
  A. Institute good nutrition.
  B. Treat secondary bacterial and yeast infections on the skin and in the ears.
  C. Use topical antiseborrheic shampoos and emollients for bathing.
    1. Initially bathing may be required every 2 to 3 days for 2 to 3 weeks, until the seborrhea is controlled.
    2. Bathing can then be decreased to every 7 to 14 days.
  D. Fatty acid supplementation with eicosapentaenoic acid (EPA) 180 mg/5 kg PO SID may help control scaling and associated transepidermal water loss.
  E. Prednisone 1 to 2 mg/kg PO SID may be used for pruritus, then tapered to the lowest possible dose.
  F. Retinoid administration may slow keratinocyte differentiation.
    1. Vitamin A: maximum dose of 400 IU/kg/day PO indefinitely
    2. Etretinate 1 mg/kg PO SID indefinitely
    3. Acitretin 0.5 to 1 mg/kg PO SID indefinitely

G. Vitamin D_3 10 ng/kg PO SID may inhibit keratinocyte proliferation, but calcium levels must be closely monitored.

II. Cats
   A. No effective treatment is known.
   B. Periodic clipping, bathing, and grooming may keep the cat comfortable.
   C. Affected cats are often euthanized.

Monitoring of Animal

I. Prognosis depends on the severity of the seborrhea.
II. Seborrhea is a lifelong condition and is incurable.
III. Animals receiving prednisone are monitored for polydipsia, polyuria, polyphagia, weight gain, panting, dull hair coat, vomiting, diarrhea, pancreatitis, elevated liver enzymes, diabetes mellitus, gastrointestinal (GI) ulcerations, muscle wasting, behavioral changes, and secondary infections.
IV. Animals receiving retinoids are monitored for anorexia, vomiting, diarrhea, polydipsia, joint pain and stiffness, behavioral changes, cracked footpads, cutaneous erythema, swelling of the tongue, and keratoconjunctivitis sicca (KCS).
V. Animals receiving Vitamin D_3 are monitored for hypercalcemia.

Familial Footpad Hyperkeratosis

See Chapter 90.

Miscellaneous Congenital Crusting Disorders

See Table 93-1.

INFLAMMATORY DISORDERS

Secondary Seborrhea

Definition and Causes

I. Secondary seborrhea is a chronic skin disease that manifests as increased scale production, greasy coat or skin, and occasionally inflammation.
II. Potential causes include the following:
   A. Allergic disorders: atopy, food allergy, flea allergic dermatitis, contact allergy
   B. Endocrine disorders: diabetes mellitus, hyperadrenocorticism, hypothyroidism, sex hormone imbalances
   C. Infectious disorders: bacterial pyoderma, *Malassezia* spp. dermatitis, dermatophytosis, leishmaniasis
   D. Immune-mediated disorders: pemphigus foliaceus, pemphigus erythematosus, systemic lupus erythematosus, discoid lupus erythematosus, sebaceous adenitis, cutaneous drug reaction
   E. Nutritional disorders: dietary imbalance, zinc-responsive dermatosis, vitamin A–responsive dermatosis
   F. Parasitic disorders: cheyletiellosis, demodicosis, *Scabies* spp., *Otodectes* spp., pediculosis
   G. Metabolic disorders: superficial necrolytic dermatitis, malabsorption, maldigestion
   H. Neoplastic disorders: cutaneous epitheliotropic lymphoma

Diagnosis

I. Compatible history and signalment
II. Appropriate lab work to evaluate for cutaneous and systemic diseases
III. Histopathologic changes on skin biopsy
   A. Orthokeratotic or parakeratotic hyperkeratosis
   B. Follicular keratosis with variable dyskeratosis
   C. Hyperplasic, superficial, perivascular dermatitis
   D. Possibly bacteria and yeast within the keratin

Differential Diagnosis

I. Primary seborrhea
II. Ichthyosis
III. Epidermal dysplasia
IV. Vitamin A–responsive dermatosis
V. Sebaceous adenitis

Treatment and Monitoring

I. Determine and treat the underlying disorder.
II. See previous discussion of Primary Seborrhea.

IDIOPATHIC DISORDERS

Sebaceous Adenitis

Definition

I. An uncommon, idiopathic disease affecting the sebaceous glands of dogs
II. Rare in cats

Causes and Pathophysiology

I. Four theories exist as to the cause and pathogenesis.
   A. Inherited disease causing the destruction of sebaceous glands
   B. Cell-mediated response directed against the sebaceous gland
   C. Keratinization disorder that causes blockage of the sebaceous ducts, resulting in glandular inflammation
   D. Abnormality in dermal lipid production
II. It is thought to be an autosomal recessive trait in standard poodles.

Clinical Signs

I. Middle-aged dogs of either sex are affected.
II. Breed predilections include the standard poodle, vizsla, Samoyed, Akita, dachshund, German shepherd dog, Belgian shepherd, and mixed-breed dogs.
III. Lesions are usually bilaterally symmetrical and affect the head, face, pinnae, and trunk.
IV. Lesions initially develop on the dorsal surfaces of the previously mentioned areas.
V. Lesions can also develop on the tail and cause a "rat tail" appearance.
VI. Secondary bacterial infections may cause folliculitis and furunculosis.
VII. Short-coated breeds (vizsla, dachshund) demonstrate the following:
   A. Lesions are typically asymptomatic and appear as peripherally expanding areas of alopecia and scale.

Text continued on p. 911.

TABLE 93-1

Miscellaneous Congenital Crusting Disorders

DISORDER	SPECIES/BREED	CAUSE	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Idiopathic facial dermatitis	Persian, Himalayan cats	Idiopathic keratinization disorder	Median age of appearance is 12 months Black exudates appear on the skin and distal portions of the hair shafts with inflammation of the adjacent skin Black, waxy material is seen in the ears Mucoid ocular discharge is seen Lesions are confined to the head and neck, primarily on the chin, around the mouth, and eyes Variable pruritus, secondary infections, and submandibular lymphadenopathy may develop	Diagnosis is based on compatible signalment and history Biopsy results include the following: (1) orthokeratotic hyperkeratosis and crusting, (2) hyperplasia of the epidermis, (3) superficial to perivascular interface dermatitis, with neutrophils, eosinophils, and mast cells predominating, (4) bacteria and *Malassezia* spp.	Treatment is usually unsuccessful Rare reports have indicated positive response to cyclosporine *(Neoral)* at 6-7 mg/kg/day PO Secondary bacterial and *Malassezia* spp. infections are treated Partial control may be obtained with prednisone 1-3 mg/kg PO SID for 4 weeks, then decreased to 1-3 mg/kg PO QOD, or with methylprednisolone acetate 4 mg/kg SC, infrequently
Ichthyosis	Both dogs and cats: West Highland white terrier, golden retriever, Jack Russell terrier, Yorkshire terrier, Wheaton terrier	Congenital keratinization disorder causing excessive scaling Also called *fish scale disease* Autosomal recessive trait	Most of the body has tight adherent scale that flakes off in large sheets Erythematous, scaly patches may be prominent in flexor and interdigital areas Thickening of footpad margins and nasal planum is common Perioral and periocular hyperkeratosis may occur	Diagnosis is based on compatible signalment and history Biopsy results include the following: (1) orthokeratotic hyperkeratosis with hypergranulosis, (2) often numerous mitotic figures in keratinocytes, (3) follicular plugging and keratosis, (4) reticular degeneration	Condition is chronic, incurable, and difficult to manage No specific treatment exists Frequent bathing with antiseborrheic (salicylic acid or sulfur based) shampoos followed by emollient rinses is recommended Information regarding retinoid therapy is as follows: (1) sotretinoin has been ineffective, (2) acitretin *(Soriatane)* 1-2 mg/kg PO SID has helped some cases, and it may take up to 3 months for remission to occur, with administration then decreased to QOD

TABLE 93-1

Miscellaneous Congenital Crusting Disorders—*cont'd*

DISORDER	SPECIES/BREED	CAUSE	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Epidermal dysplasia	West Highland white terrier	Keratinization disorder Also called *armadillo skin* Autosomal recessive trait	Greasy coat, with mild to moderate pruritus initially affecting the face, ears, ventrum, limbs, and feet is seen Condition progresses to widespread alopecia, erythema, hyperpigmentation, lichenification, and crusting	Diagnosis is based on compatible signalment and history Biopsy results include the following: (1) epidermal hyperplasia and dysplasia with perivascular dermatitis; (2) excessive mitotic figures in the keratinocytes; (3) crowding of basal cell keratinocytes; (4) loss of polarity; (5) often budding yeast on or in the surface and superficial follicular keratin	No specific treatment exists Secondary infections are treated with systemic antibacterial drugs and then maintained with topical therapy
Exfoliative cutaneous lupus erythematosus	See Chapter 91	See Chapter 91	See Chapter 91	See Chapter 91	See Chapter 91
Jack Russell terrier vasculopathy	Jack Russell terrier	Vascular disorder of genetic origin Few cases occurred within 2-3 weeks of vaccination See Chapter 91	Small vessel vasculitis resulting in alopecic, crusting and ulcerated skin over bony prominences of the head and extremities is seen Punctate ulcers occur on the footpads V-shaped necrotic wedges of the pinnae are reported	Diagnosis is based on compatible signalment and history Biopsy results include the following: (1) cell-poor leukocytoclastic vasculitis; (2) apoptosis of basal cell layer; (3) pigmentary incontinence; (4) ischemic degeneration of hair follicles	The following drugs have been used alone and in conjunction with each other: (1) prednisolone 1 mg/kg PO SID; (2) dapsone 1 mg/kg PO TID; (3) vitamin E 200-400 IU PO SID NOTE: Relapses are common with drug withdrawal

Continued

TABLE 93-1

Miscellaneous Congenital Crusting Disorders—*cont'd*

DISORDER	SPECIES/BREED	CAUSE	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PROGNOSIS
Acrodermatitis	Bull terrier	Inherited autosomal recessive lethal disease of white bull terriers (rare) Abnormalities in zinc and copper metabolism	No sex predilection exists Condition is seen shortly after birth At birth the skin color is lighter than normal Usually by 6-8 weeks, an erythematous, exfoliative, papulopustular dermatitis is present at mucocutaneous junctions and the distal extremities Ulcers and crusts are usually prominent on the pinnae and muzzle Feet are splayed, with abnormal cornification of the pads (exfoliation, villous hypertrophy, and fissures) Claws may be dystrophic and paronychia is usually present Hard palate may be abnormally arched Secondary pyodermas, *Malassezia* spp. dermatitis, candidiasis, and otitis can occur Other signs include growth retardation, abnormal behavior, bronchopneumonia, and diarrhea Average lifespan is 7-8 months, although some affected animals may live up to 3 years	Diagnosis is based on compatible signalment and history Biopsy results include the following: (1) diffuse compact layers of massive parakeratosis; (2) focal crusting; (3) possible laminar pallor	No cure exists Secondary infections are treated Zinc supplementation is usually ineffective Parents of affected dogs should not be bred because they are carriers; littermates should not be bred Normal littermates may experience zinc-responsive dermatosis

B. Scale is typically nonadherent and fine.
C. Swelling of the eyelids, muzzle, and lips can occur.

VIII. In the standard poodle, lesions start as hyperkeratosis and progress to alopecia.
A. Silver-white scale is present along with a dull, dry coat.
B. Follicular casts are common.
C. In some cases the initial signs may be changing of hair coat color and straightening of the hair.
D. Lesions typically are on the head, pinnae, and eventually involve the neck and dorsal trunk.

IX. Akitas usually have generalized, erythematous, and greasy changes to their coats.
A. Matting of the hair, scale, yellow-brown greasy keratosebaceous debris, papules, pustules, and hair casts are common.
B. Undercoat may be lost.
C. Secondary pyoderma is common.
D. Fever, malaise, and weight loss can occur.

X. German shepherd dogs have lesions that usually start on the tail and advance cranially.

XI. Samoyeds have dull, brittle, and broken hairs.
A. Follicular casts are common.
B. Moderate to severe truncal scaling and alopecia may occur.

XII. Most dogs are not pruritic unless a secondary bacterial infection occurs.

XIII. Nonpredisposed breeds may have an acute onset of intense pruritus and generalized exfoliative erythroderma that progresses to nonpruritic alopecia.

XIV. No breed, age, or sex predilection exists in the cat.
A. Lesions typically begin on the head, neck and pinnae and progress caudally over the body.
B. Lesions are comprised of broken hairs, alopecia, scales, crusts, and hair casts.

Diagnosis

I. Suggestive history and signalment in a predisposed breed

II. Diagnosis confirmed with skin biopsy
A. Early lesions
1. Varying degrees of granulomatous or pyogranulomatous sebaceous adenitis are seen.
2. Usually sebocytes are no longer visible.
3. The disease is diagnosed by identifying discrete perifollicular granulomas in an area where a sebaceous gland would normally be found.
4. Early involvement of adnexa is not seen.
B. Chronic lesions
1. Sebaceous glands are absent and replaced by fibrosis.
2. Orthokeratotic hyperkeratosis of the epidermis and hair follicles is common.
3. Hair follicles are often atrophied.

Differential Diagnosis

I. Bacterial pyoderma

II. Causes of secondary seborrhea

III. Demodicosis

IV. Dermatophytosis

V. Follicular dysplasia

VI. Vitamin A–responsive dermatitis

VII. Endocrinopathies, especially hypothyroidism

Treatment

I. Secondary infections are treated.

II. Mild cases may respond to keratolytic shampoos and emollient rinses.
A. Propylene glycol 50% to 75% rinses are used initially SID, then reduced to every 2 to 3 days once clinical signs are controlled.
B. Baby oil solution (1:1 mixture with water) can be applied to the skin for several hours, then washed off with shampoo.

III. Combination of tetracycline and niacinamide is an option.
A. Dogs <10 kg
1. Tetracycline 250 mg and niacinamide 250 mg PO TID or
2. Tetracycline 500 mg and niacinamide 250 mg PO in the morning; tetracycline 250 mg and niacinamide 500 mg PO in the evening
B. Dogs >10 kg
1. Tetracycline 500 mg and niacinamide 500 mg PO TID or
2. Tetracycline 1000 mg and niacinamide 500 mg PO in the morning; tetracycline 500 mg and niacinamide 1000 mg PO in the evening

IV. Some dogs respond to omega-3 and omega-6 fatty acid supplementation.

V. Corticosteroid therapy is of no benefit.

VI. Severe cases may warrant systemic retinoid administration.
A. Etretinate 1 to 2 mg/kg PO SID
B. Acitretin 0.5 to 1.0 mg/kg PO SID

VII. Cyclosporine 5 mg/kg PO BID may help when retinoid administration fails.

VIII. Spontaneous remission is rare.

IX. In cats, one report suggests the of use of cyclosporine 5 mg/kg PO SID initially, then tapered to 5 mg/kg PO QOD (Noli and Thomas, 2006).

Monitoring of Animal

I. Because inflammation of the sebaceous glands cannot be stopped, treatment is aimed at controlling the signs.

II. Animals receiving retinoid therapy are monitored for anorexia, vomiting, diarrhea, polydipsia, joint pain and stiffness, behavioral changes, cracked footpads, cutaneous erythema, swollen tongue, and KCS.

III. Animals receiving cyclosporine are monitored for anorexia, vomiting, diarrhea, weight loss, myelosuppression, and elevations in liver enzymes, blood urea nitrogen (BUN), and creatinine.

Pinnal Seborrhea

Definition and Causes

I. Seborrheic disorder of the ear margins

II. Dachshunds possibly predisposed

III. Occurs in dogs with pendulous ears
IV. Pathophysiology unknown

Clinical Signs

I. Ear margins are the only site affected.
II. Keratinous debris is initially noted along the ear margins.
III. Ear margins can develop alopecia, crusting, fissures, and ulcerations.
IV. Condition is exacerbated by dry heat.

Diagnosis

I. Compatible signalment, history, and clinical signs
II. Orthokeratotic and/or parakeratotic hyperkeratosis and follicular keratosis on biopsy of affected areas

Differential Diagnosis

I. Vasculitis (see Chapter 91)
II. Sarcoptic mange (see Chapter 85)
III. Causes of secondary seborrhea

Treatment

I. No specific therapy known
II. Symptomatic care
  A. Wash ear margins with salicylic acid, sulfur, or benzoyl peroxide–containing shampoos SID to QID until all debris is removed.
  B. Once debris is removed, wash areas with shampoo as needed.
  C. Moisturizer is applied after shampooing.
III. Possible helpful measures
  A. Pentoxifylline 10 to 15 mg/kg PO BID to TID
  B. Topical retinoid therapy
  C. Essential fatty acid supplementation
IV. Severe cases: topical or systemic steroids, surgical excision of affected areas

Monitoring of Animal

I. Initial improvement may be noted 4 to 6 weeks after initiation of symptomatic treatment.
II. If topical therapy does not reduce the amount of scale, then pentoxifylline may be considered.
III. One month after starting pentoxifylline, decreased ulceration and/or scale may be noted.
IV. Once the pinnae have normalized (may take 4 to 12 months) pentoxifylline can be decreased to SID, then QOD, and eventually stopped if the condition does not worsen.

INFECTIOUS DISORDERS

Leishmaniasis

See Chapter 89.

PARASITIC DISORDERS

See Chapter 85.

NUTRITIONAL DISORDERS

Zinc-Responsive Dermatosis

Definition and Causes

I. Zinc-responsive dermatosis is hyperkeratosis of the skin as a result of zinc deficiency.
II. Syndrome I occurs in Alaskan malamutes and Siberian huskies.
III. Syndrome II arises from a zinc-deficient diet, interference of zinc absorption from excessive calcium or phytates in the diet, or essential fatty acid deficiency (generic dog food disease).
IV. Any breed may be affected, and lesions may vary within a litter.

Pathophysiology

I. Syndrome I: genetic defect resulting in decreased intestinal zinc absorption
  A. Lesions usually develop during puberty but may be exacerbated with illness, estrus, or pregnancy.
  B. Age of onset varies from 0.5 to 10.5 years, with 41% developing clinical signs before 2 years of age (Columbini, 1999).
  C. Lesions often develop between September and April.
  D. No sex predilection has been identified.
II. Syndrome II: zinc-deficient diet

Clinical Signs

I. General signs
  A. Anorexia, growth retardation, poor wound healing
  B. Reproductive disorders
  C. Lethargy, pyrexia, lymphadenopathy, cutaneous lesions
II. Cutaneous lesions of syndrome I
  A. Focal alopecia and erythema occur early and progress to scaling and crusting.
  B. Lesions are typically seen around the eyes, mouth, footpads, perianal region, and at pressure points.
  C. Hair coat may be dull and dry, with excessive sebum production.
  D. Secondary bacterial and/or *Malassezia* spp. infections are common.
  E. Pruritus is common.
III. Cutaneous lesions of syndrome II
  A. Lesions are similar to syndrome I.
  B. Lesions primarily occur on the head and pressure points of the extremities.

Diagnosis

I. Compatible history, signalment, and clinical signs
II. Skin biopsy
  A. Severe, diffuse epidermal and follicular parakeratosis, superficial perivascular dermatitis
  B. Secondary infections common

Differential Diagnosis

I. Autoimmune diseases: pemphigus complex, discoid or systemic lupus erythematosus

II. Bacterial pyoderma
III. Demodicosis
IV. Dermatophytosis
V. Metabolic epidermal necrosis

Treatment and Monitoring

I. Syndrome I requires lifelong elemental zinc supplementation.
   A. Zinc sulfate 10 mg/kg/day PO; crush tablets and mix with food to enhance absorption
   B. Zinc gluconate 5 mg/kg/day PO
   C. Zinc methionine 1.7 mg/kg/day PO
II. Syndrome II requires correction of nutritional imbalances.
   A. Zinc supplementation (previously discussed) speeds resolution of symptoms.
   B. Once resolution of clinical signs occurs, discontinue zinc supplementation.
III. If no response to treatment is seen within 4 weeks, then the zinc dose is increased by 50% and/or low-dose prednisone may be started at 0.5 mg/kg/day PO to enhance zinc absorption.
IV. Adding an essential fatty acid supplement also helps zinc metabolism.
V. Dogs that do not respond to these therapies may need injectable zinc sulfate (10 to 15 mg/kg IV).
   A. Injections are given weekly for a minimum of 4 weeks.
   B. Maintenance injections may be needed every 1 to 6 months to prevent relapses.
VI. Treat secondary bacterial infections.

Vitamin A–Responsive Dermatosis

Definition and Causes

I. Rare disease affecting cornification
II. Most commonly seen in American cocker spaniels
III. Possible hereditary origin

Clinical Signs

I. Adult-onset disorder
II. Lesions most commonly on lateral and ventral chest and abdomen
III. Mild to moderate pruritus
IV. Dull, dry, disheveled hair coat
V. Easily epilated hair
VI. Alopecia, papules, crusts, scale
VII. Severe follicular plugging, with follicular fronds or casts
VIII. Concurrent ceruminous otitis

Diagnosis

I. Adult age of onset
II. Skin biopsy
   A. Severe follicular keratosis
   B. Follicular fronds
   C. Furunculosis

Differential Diagnosis

I. Primary seborrhea
II. Sebaceous adenitis
III. Zinc-responsive dermatosis
IV. Causes of secondary seborrhea

Treatment and Monitoring

I. Administer Vitamin A 10,000 IU PO SID with a fatty meal.
   A. Improvement may take 4 to 6 weeks, and remission may require 8 to 10 weeks of therapy.
   B. Lifelong therapy is usually needed to maintain remission.
II. Antiseborrheic shampoos and emollients may be used several times weekly until remission, then 2 to 4 times monthly for maintenance.

CHAPTER 94

Introduction

Rachel D. Ring

GENERAL CONSIDERATIONS

I. Ocular discomfort or vision loss in animals often evokes emotional responses in owners and prompts presentation to the veterinarian.
II. Common presenting complaints include loss of vision, ocular discomfort or discharge, and/or changes in the appearance of the eye.
III. Presenting complaints can be restricted to the eye or include systemic manifestations.
IV. Common clinical signs are exhibited for both minor and potentially blinding ocular disorders.

EXAMINATION PROCEDURES

I. Obtain a pertinent history.
  A. Animal signalment
  B. Onset and duration of problem
  C. Any concurrent systemic signs or illness
  D. Current and previous environment
  E. Current and/or previous therapy and response
  F. Preventative health status
II. Observe the animal in the examination room.
  A. Initial assessment of vision
  B. Ability to negotiate room and objects
  C. Assessment of adnexal and ocular positioning before handling
  D. Determination of behavioral, neurological, or other impairments that may contribute to or imply visual disorders
III. Perform an adnexal examination.
  A. Direct visual examination with penlight or transilluminator
  B. Palpation of lids, orbital rim, and globe positioning in orbit (retropulsion)
  C. Examination under magnification with slit lamp biomicroscopy or otoscope lens (or magnifying glass)
IV. Assess cranial nerve reflexes (see Chapter 105).
  A. Pupillary light response (PLR)
    1. Assesses retina and optic nerve and tracts, as well as oculomotor nerve and iris pupillary musculature
    2. Subcortical, does not determine vision
    3. Requires bright penlight or transilluminator
  B. Dazzle response
    1. Retina and optic nerve and tracts assessed, as well as facial nerve and lid musculature
    2. Subcortical, does not determine vision
    3. Can provide basic assessment of retinal function when unable to visualize or elicit PLR
  C. Menace response
    1. Retina, optic nerve and tracts, and visual cortex assessed, as well as facial nerve and lid musculature
    2. False-positive test when tactile air currents created
    3. Learned reflex: absent in young animals
V. Consider other routine testing.
  A. Schirmer's tear test (STT) (see Chapter 97)
    1. Filter paper measurement of tear production in millimeters per minute (mm/min)
    2. Important test to determine borderline to low tear production
  B. Fluorescein dye test (see Chapter 98)
    1. Corneal epithelium is hydrophobic, whereas the stroma is hydrophilic.
    2. Stain retention by exposed stroma indicates corneal erosion or ulceration.
  C. Tonometry (see Chapter 100)
    1. Measurement of intraocular pressure in millimeters of mercury (mm Hg)
    2. Indentation or applanation methods
    3. Important in diagnosis of glaucoma and uveitis.
VI. Perform an intraocular examination.
  A. Direct visual examination with penlight or transilluminator
  B. Magnified examination with slit lamp biomicroscopy

C. Funduscopy
   1. Examination with a direct ophthalmoscope provides the most magnification.
   2. Indirect examination with a light source and indirect lens provides the best panoramic view.

ANCILLARY DIAGNOSTIC TESTS

I. Maze testing (obstacle course)
   A. Observed ability to negotiate obstacles
   B. Dimmed and normal lighting
   C. Each eye patched, if necessary
II. Laboratory diagnostics
   A. Indicated for suspected systemic involvement or preanesthetic workup
   B. Complete blood count and serum chemistries as appropriate for problem and age
   C. Serological testing for regional infectious organisms
   D. Bacterial and/or fungal cultures
   E. Cytological and/or histopathologic examination
III. Electrodiagnostics
   A. Electroretinogram
      1. Used to evaluate retinal function
      2. Important for diagnosis of retinal disease and preoperative workup before cataract surgery (see Chapters 101 and 102)
   B. Visual evoked potential
      1. Used to evaluate optic nerve, optic tract, and occipital cortex
      2. Distinguishes between visual problems of ocular versus visual pathway origin (see Chapter 105)
IV. Ocular and orbital imaging
   A. Radiography
      1. Plain films are helpful for evaluation of orbit and sinuses.
      2. Contrast radiography is performed for nasolacrimal, orbital, and fistulous and cystic disorders.
   B. Ultrasonography
      1. A-scan, B-scan, or color Doppler techniques
      2. B-scan most useful in opaque eyes and for evaluation of orbital soft tissues
   C. Computed tomography (CT)
      1. Often used with orbital or visual pathway disorders
      2. Provides good imaging of orbital soft tissue and bony structures
   D. Magnetic resonance imaging
      1. Application similar to CT
      2. Excellent imaging of intraocular and extraocular soft tissue structures
      3. Less precise resolution of bony structures

CHAPTER 95

Diseases of Eyelids

Stacy E. Andrew

CONGENITAL/DEVELOPMENTAL DISORDERS

Dermoid

Definition and Causes

I. Dermoid is a congenital mass with normal epidermal components located in an abnormal place.
II. It is usually an incidental finding.
III. The condition is heritable in some breeds of dog (Dalmatian, German shepherd dog, Saint Bernard) (Bedford, 1999).
IV. It can result from inclusion or arrest of epidermal and connective tissues during fetal cleft closure (Cook, 1999).

Pathophysiology

I. Can include stratified squamous epithelium, hair follicles, sebaceous glands, adipose tissue, sweat glands, and (rarely) cartilage or bone
II. Unilateral or bilateral, and may be multiple in number
III. May involve the eyelid, conjunctiva, and/or cornea
IV. Variable irritation depending on the size of lesion and the component tissues

Clinical Signs

I. Clinical signs are associated mainly with corneal and conjunctival irritation from hairs.
   A. Blepharospasm
   B. Epiphora
   C. Conjunctival hyperemia
   D. Corneal ulceration
II. Normal blinking may be disrupted.

Diagnosis

I. Complete ophthalmic examination reveals presence of abnormally located epidermal tissue.
II. Excisional biopsy and histopathologic examination of submitted tissue are conclusive.

Differential Diagnosis

I. Scar tissue
II. Neoplasia

Treatment

I. If the lesion is small and no clinical signs exist, then no treatment is necessary.
II. Small eyelid lesions (less than one fourth the length of the palpebral fissure) are removed by wedge resection.
III. Larger lesions often require sliding skin grafts or skin transposition techniques (Bedford, 1999).

Monitoring of Animal

I. If surgery is performed, sutures are removed in 10 to 14 days.
II. Stain the cornea with fluorescein to ensure that corneal ulceration has not occurred.

Eyelid Agenesis

Definition

I. Also referred to as *eyelid coloboma*
II. Failure of development of the eyelid, with focal absence of skin, conjunctiva, and fornix

Causes

I. The cause is unknown.
II. It is much more common in cats than dogs.
III. Ventromedial eyelid agenesis may be related to failure of optic fissure closure.

Pathophysiology

I. Upper eyelids develop from the frontonasal process (Cook, 1999).
II. Eyelid epidermis, cilia, and conjunctiva arise from surface ectoderm; the dermis and tarsus arise from neural crest mesenchyme.
III. The condition is usually bilateral, involving the lateral portion of the upper eyelid; however, it may be unilateral.
IV. Other ocular tissues (iris, sclera, optic nerve) can also be involved.

Clinical Signs

I. Proportional to amount of eyelid missing
II. Related to inability to cover the cornea or to contact from trichiasis hairs touching the cornea
III. Possibly asymptomatic
IV. Epiphora, blepharospasm
V. Exposure keratitis: vascularization, ulceration, scarring, pigmentation
VI. Visual deficits if other ocular defects present

Diagnosis

I. Diagnosis is based on the absence of eyelid tissue.
II. Rule out concurrent ocular anomalies.
  A. Iris, scleral, and/or optic nerve colobomas
  B. Keratoconjunctivitis sicca or lacrimal gland deficiency

Differential Diagnosis

I. Entropion
II. Corneal ulceration
III. Symblepharon

Treatment

I. Very young kittens and mature animals with small lesions that are asymptomatic need periodic monitoring for corneal irritation.
II. Topical lubricating ointment is used as needed in animals with only minor clinical signs (e.g., epiphora).
III. Carbon dioxide laser therapy or cryotherapy is useful to remove trichiasis hairs.
IV. Reconstructive blepharoplasty (surgical reconstruction of the eyelid margin and upper eyelid) is indicated for larger defects with keratitis.
  A. Primary goals are to provide a cosmetic, functional upper eyelid and corneal protection (Glaze and Gelatt, 1999).
  B. One technique (Roberts and Bistner, 1968) involves rotating a pedicle of skin and muscle from the lower eyelid to the defect and suturing conjunctiva to the ventral margin.
  C. Trichiasis from the resulting misdirected lower lid hairs is treated (see discussion under Trichiasis).
  D. Techniques can also be performed using conjunctiva transposed from the palpebral side of the third eyelid (Dziezyc and Millichamp, 1989).
  E. H-Plasty using skin from above the lesion is another surgical option.

Monitoring of Animal

I. Asymptomatic animals or those treated medically are monitored periodically to ensure that corneal irritation and keratitis are not developing.
II. Sutures are removed 10 to 14 days after surgery, and additional surgical procedures for trichiasis may be scheduled several weeks to months later.
III. Animals are reevaluated immediately if they exhibit squinting, tearing, or discomfort.

Entropion

Definition

I. Inward rolling of a portion or the entire eyelid
II. Two categories of entropion
  A. Developmental
  B. Acquired
    1. Spastic: resulting from ocular pain
    2. Cicatricial: resulting from trauma or chronic inflammation

Causes

I. Genetic basis of developmental entropion is not understood.
II. In some dogs, developmental entropion is likely inherited in a simple dominant mode with complete penetrance (Bedford, 1999).
III. Breed predispositions include the American cocker spaniel, bullmastiff, chow chow, Clumber spaniel, English bulldog, Great Dane, Labrador retriever, miniature and toy poodles, rottweiler, shar-pei, and Saint Bernard.
IV. Cicatricial entropion is acquired after chronic inflammation or trauma.
V. Squinting as a result of ocular irritation causes spastic entropion (e.g., ulcerative keratitis, anterior uveitis, trichiasis, foreign body).

Pathophysiology

I. Developmental entropion is related to globe size, eyelid muscle tone (often lax), and palpebral fissure length (often excessive).
II. Chronic blepharitis or eyelid trauma can cause fibrosis of the eyelid and secondary cicatricial entropion.
III. Ocular irritation causes squinting via increased orbicularis oculi muscle tone and concurrent enophthalmos from retractor bulbi muscle activity.

Clinical Signs

I. Clinical signs range from absent to severe.
II. Signs are based on the degree and type of entropion, amount of associated trichiasis, and presence of corneal ulceration.
III. Signs include blepharospasm, epiphora, and corneal disease (e.g., pigmentation, vascularization, ulceration).

Diagnosis and Differential Diagnosis

I. Diagnosis is usually straightforward.
  A. Eyelid margin is not discernible in the resting position.
  B. Eyelid hairs (trichiasis) are usually seen in contact with the cornea.
II. Developmental entropion is differentiated from spastic entropion by placing topical anesthetic on the eye, which resolves any spastic component.
III. The cornea is fluorescein stained to rule out corneal ulceration or keratitis.
IV. Other causes of ocular irritation and pain are also ruled out.
  A. Primary trichiasis, ectropion, ectopic cilia
  B. Primary ulcerative keratitis, corneal foreign body
  C. Anterior uveitis, glaucoma

Treatment

I. Medical treatment
  A. Treat causes of spastic entropion.
  B. Treat superficial corneal ulceration with broad-spectrum topical antibiotic agents ± atropine (for cycloplegia).
  C. Use topical lubricating ointment to provide temporary corneal protection before surgery.
II. Temporary tacking: animals <6 months old

A. Use 3-0 or 4-0 nonabsorbable suture material in a vertical mattress pattern.
B. First bite is taken 1 to 2 mm from the eyelid margin, and the second bite is taken through the skin over the orbital rim.
C. Sutures are left in place for 2 to 3 weeks.
D. Alternatively, use skin staples or skin glue.
E. Temporary lateral tarsorrhaphy may also be used for lower eyelid entropion in young dogs (Bedford, 2000).

III. Permanent procedures for mature animals
A. Many surgical procedures are available to correct entropion, and the choice is determined by the cause, location, and extent of the entropion.
B. The most useful surgical procedure is a modified Hotz-Celsus procedure (Figure 95-1).
C. Other entropion procedures to consider are as follows:
1. Arrowhead modification of Hotz-Celsus procedure for lateral canthal eversion
2. Medial canthal V-plasty for medial canthal entropion correction
3. Fornix-based suture placement (Williams, 2004) for lower-eyelid entropion
4. Stades procedure for excessive upper-eyelid skin and sagging brow (Stades, 1987)
5. Brow suspension (Willis et al., 1999), stellate rhytidectomy (Stuhr et al., 1997), or coronal rhydectomy (McCallum, 2004) for entropion and redundant skinfolds
6. Y-V plasty for cicatricial entropion correction (Bedford, 1999)

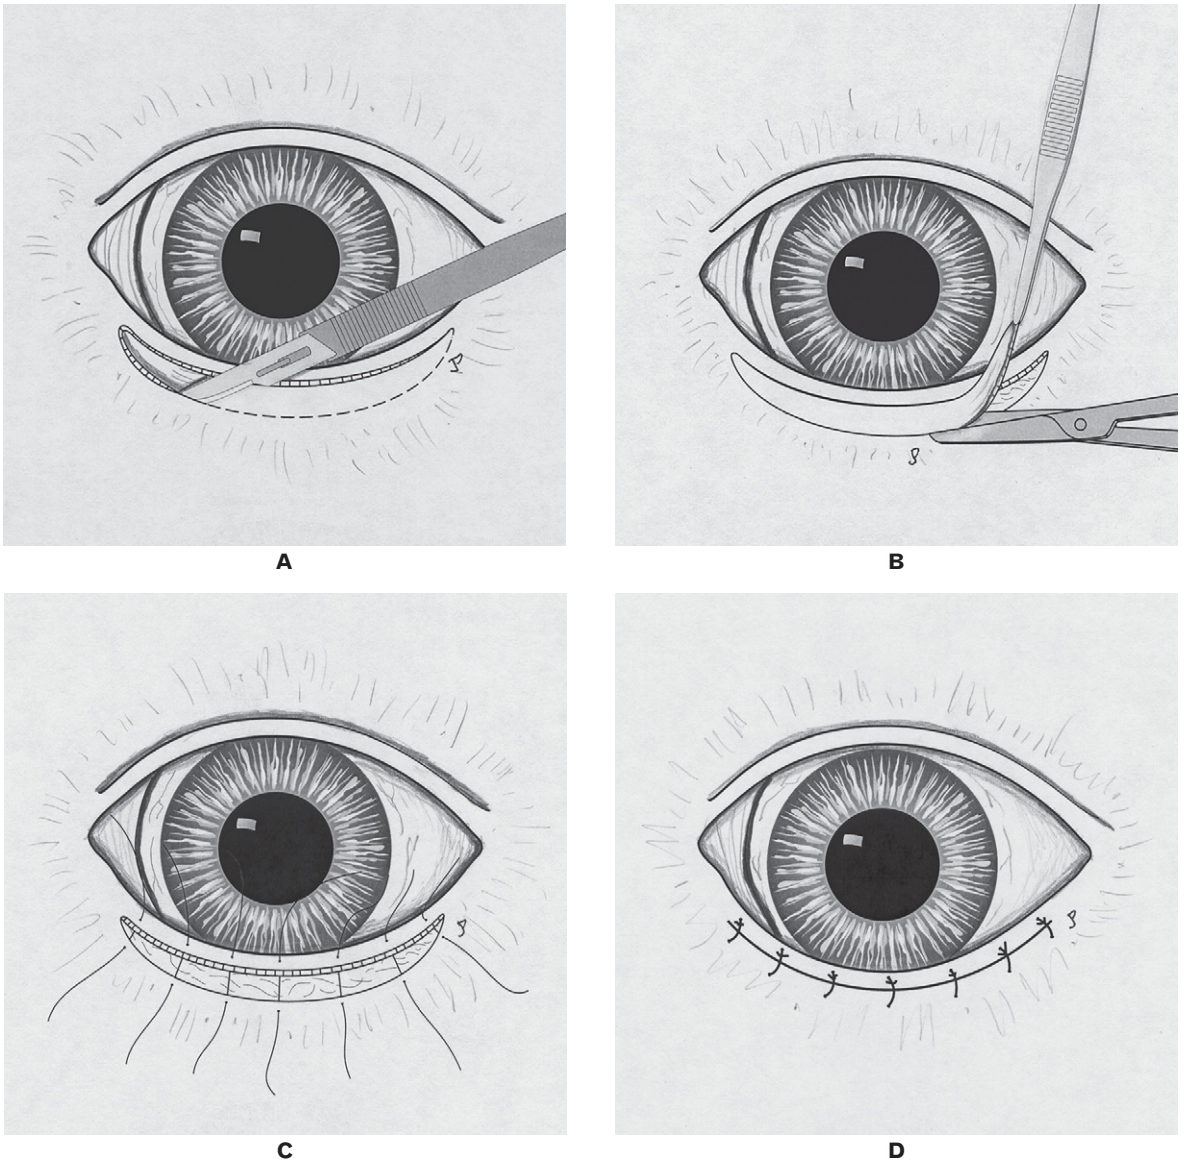

FIGURE 95-1 Modified Hotz-Celsus procedure for entropion of the lower central eyelid. **A,** The first incision is parallel to and 2 mm away from the eyelid margin. A second incision is made, distal to the first one, and incorporates enough skin to correct the entropion. **B,** The tissue is then removed using small tissue scissors. **C,** Simple interrupted, 5-0 or 6-0, nonabsorbable skin sutures are placed to oppose the skin edges. **D,** The first suture is placed in the midpoint of the incision and subsequent sutures are placed to halve the remaining distances. *From Gelatt KN, Gelatt JP: Small Animal Ophthalmic Surgery. Butterworth-Heinemann, Oxford, 2001; with permission.*

Monitoring of Animal

I. Topical ophthalmic antibiotic agent BID to TID
II. Elizabethan collar until suture removal
III. Suture removal in 10 to 14 days
IV. Fluorescein staining to ensure a suture-induced corneal ulcer has not occurred if blepharospasm noted

Ectropion

Definition

I. Outward rolling of a portion or the entire eyelid
II. Occurs most frequently in the lower eyelid

Causes

I. Developmental
   A. Often congenital
   B. Common breeds: American cocker spaniel, basset hound, bloodhound, Clumber spaniel, Great Dane, mastiffs, Newfoundland, Saint Bernard
II. Acquired
   A. Cicatricial: from previous eyelid damage or surgery
   B. Senile: from decreased orbicularis oculi muscle tone
   C. Physiological: from facial muscle fatigue after exercise in hunting breeds
   D. Paralytic: after damage to the branches of cranial nerve VII

Pathophysiology

I. May or may not be clinically significant
II. Desired trait or breed standard in many breeds of dog

Clinical Signs

I. Animals may be asymptomatic.
II. Clinical signs vary with the extent of ectropion.
   A. Conjunctivitis
   B. Epiphora
   C. Debris accumulation in the lower fornix
   D. Keratitis if severe
III. It may be combined with entropion.

Diagnosis

I. Complete ophthalmic examination, including fluorescein staining of the cornea
II. Breed predisposition

Differential Diagnosis

I. Other eyelid diseases: entropion, distichiasis, trichiasis, blepharitis
II. Corneal and conjunctival disease: conjunctivitis, corneal ulcer
III. Nasolacrimal system obstruction

Treatment

I. Medical treatment
   A. Clean accumulated discharge daily.
   B. Apply topical lubricant ointment to exposed conjunctiva and/or cornea BID to TID.
II. Surgical treatment is necessary only if keratitis or severe conjunctivitis is present.
   A. Full-thickness wedge resection at the lateral canthus for cases of excessive laxity (Bedford, 1999)
   B. Kuhnt-Szymanowski technique to shorten the lower eyelid and increase lateral canthal stability (Bedford, 1999)
   C. Kuhnt-Hembolt technique to shorten the lower eyelid (Bedford, 1999)
   D. Wharton-Jones or V-Y plasty (Donaldson, 2005) and other tissue-relaxing procedures for cicatricial ectropion correction (Hamilton et al., 1998)

Monitoring of Animal

I. Postoperative topical antibiotic ointment BID to TID
II. Elizabethan collar until suture removal
III. Suture removal in 10 to 14 days
IV. Fluorescein staining of the cornea if blepharospasm or epiphora occurs

Macropalpebral Fissure

Definition

I. An abnormally large palpebral fissure
II. Also called *euryblepharon* and *macroblepharon*

Causes

I. Brachycephalic conformation in both dogs and cats results in a relative exophthalmos, with a breed predisposition in the Boston terrier, Lhasa apso, pug, and shih tzu.
II. Excessive eyelid length and poor support of eyelids by the globe are often a cause in the bloodhound, Clumber spaniel, and Saint Bernard.
III. It may be accompanied by lagophthalmos.

Pathophysiology

I. The shallow orbit causes protrusion of the eye through the palpebral fissure, and predisposes to proptosis.
II. Excessive lid length and lack of support of the palpebral fissure are accompanied by entropion, ectropion, and/or excessive facial folds.
III. Abnormal precorneal tear film dynamics may result in corneal and conjunctival signs.

Clinical Signs

I. In brachycephalic breeds
   A. Visible sclera around the entire eye
   B. Keratitis: pigmentary or ulcerative
   C. Failure to close eyelids completely while blinking or sleeping
II. In dogs with excessive lid length
   A. Exposure conjunctivitis or keratitis
   B. Mucoid or mucopurulent ocular discharge
   C. Failure to close eyelids completely while blinking or sleeping

Diagnosis

I. Visualization of large palpebral fissure
II. Signalment

III. Complete ophthalmic examination: Schirmer tear test (STT), fluorescein staining, testing of blink reflexes

Differential Diagnosis

I. Acquired exophthalmos (see Chapter 103)
   A. Orbital neoplasia
   B. Orbital cellulitis and abscessation
II. Other eyelid diseases
   A. Entropion
   B. Ectropion
   C. Combination entropion and ectropion
III. Buphthalmos
IV. Cranial nerve VII paralysis

Treatment

I. Medical therapy: topical lubricating ointment TID to QID
II. Surgical therapy (Bedford, 1999)
   A. Lateral permanent tarsorrhaphy (Figure 95-2)
   B. Roberts-Jensen pocket technique (Jensen, 1979)
   C. Wyman and Kaswan lateral canthoplasty (Gelatt and Gelatt, 1994)
   D. Modified Fuchs lateral canthoplasty (Gelatt and Gelatt, 1994)
   E. Bedford lateral canthoplasty (Bedford, 1998)
   F. Combination procedures (van der Woerdt, 2004)

Monitoring of Animal

I. Postoperative topical antibiotic ointment BID to TID
II. Elizabethan collar until suture removal
III. Suture removal in 10 to 14 days
IV. Fluorescein staining of cornea if blepharospasm or epiphora occurs

Distichiasis

Definition

I. Cilia that arise from undifferentiated meibomian gland tissue and exit from the normal meibomian gland opening at the lid margin
II. May occur on both upper and lower eyelids

Causes and Pathophysiology

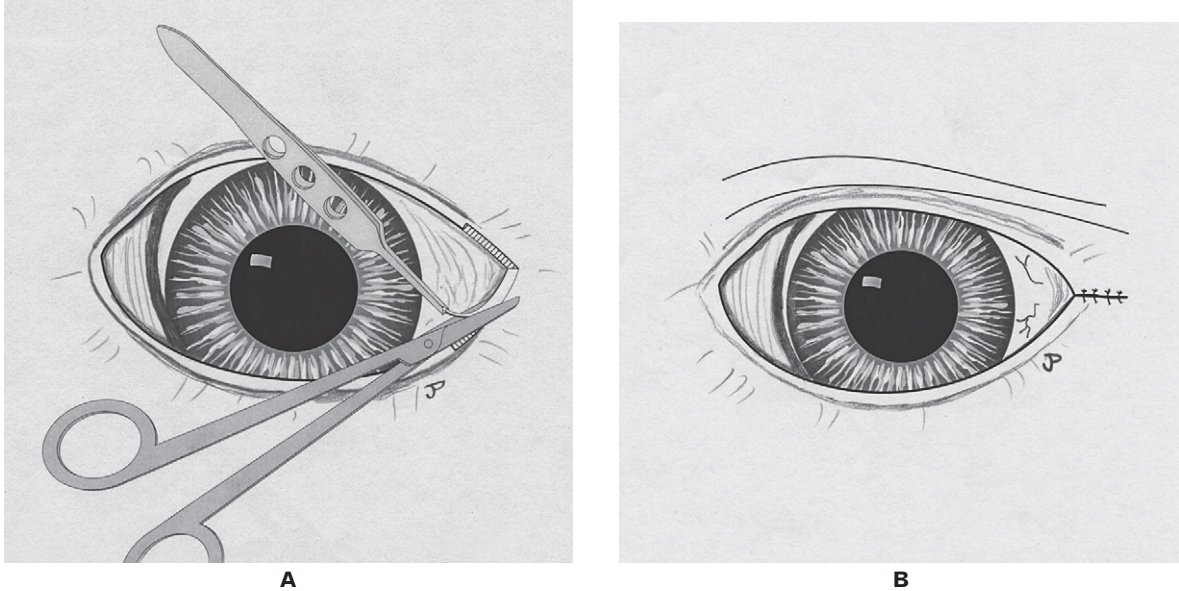
I. Genetic causes have not been determined, but it is probably a heritable trait.
II. Breeds commonly affected include the American cocker spaniel, Bedlington terrier, boxer, golden retriever, miniature longhaired dachshund, miniature and toy poodles, Pekingese, Saint Bernard, Shetland sheepdog, and Yorkshire terrier.
III. Distichiasis may be congenital or secondary to chronic meibomitis that results in glandular metaplasia.
IV. Misdirected hairs can cause corneal irritation and possibly ulceration.

Clinical Signs

I. Asymptomatic, especially American cocker spaniels
II. Symptomatic in some dogs
   A. Epiphora
   B. Blepharospasm
   C. Conjunctivitis
   D. Mucus accumulation
   E. Possible keratitis: ulcerative, pigmentary, vascular

Diagnosis

I. Direct visualization of hairs exiting the meibomian gland openings (easier to visualize with focal illumination and magnification)



A B

FIGURE 95-2 Permanent lateral canthoplasty to reduce the size of the palpebral fissure. **A,** The lower and upper eyelid margins and the lateral canthal margins are excised. **B,** A two-layer closure is used. The tarsoconjunctiva is apposed using 6-0 absorbable suture, and the skin and muscle layer is then apposed using 5-0 or 6-0 nonabsorbable suture material. The canthal margin is closed first using a figure-eight suture (see Figure 95-3, *C*). *From Gelatt KN, Gelatt JP: Small Animal Ophthalmic Surgery. Butterworth-Heinemann, Oxford, 2001; with permission.*

II. Disturbance of tear film at the eyelid margin (Bedford, 1999)
III. Removal of hairs (epilation) to determine if clinical signs resolve
IV. STT and fluorescein staining

Differential Diagnosis

I. Other eyelash or eyelid abnormalities: trichiasis, ectopic cilia, entropion, ectropion
II. Other causes of conjunctivitis or keratitis: keratoconjunctivitis sicca, allergies

Treatment

I. None in asymptomatic animals
II. Medical treatment
  A. If only a few distichia present, if problem is minor, or if animal is poor surgical candidate
  B. Topical lubricant ointment TID to QID
  C. Epilation of hairs with topical anesthesia and cilia forceps for temporary relief
III. Surgical treatment
  A. Cryosurgery (double freeze-thaw) works well, but usually results in transient depigmentation of the lid margins.
  B. Basal meibomian gland cautery destroys the base of the meibomian glands and the germinal hair bulb of the distichia.
  C. Partial tarsal plate resection is used to remove a wedge of tissue containing the affected glands and hairs.
  D. Electrolysis involves inserting a fine needle along the hair shaft to the root and using heat to destroy the follicle, but it is not recommended if distichia are numerous, because of the secondary damage it creates.

Monitoring of Animal

I. Postoperative complications include recurrence of distichia and scarring of the eyelid, with or without cicatricial entropion.
II. Use topical ophthalmic antibiotics postoperatively BID to TID.
III. Apply an Elizabethan collar for the first 5 to 7 days postoperatively.
IV. Stain the cornea with fluorescein if blepharospasm or epiphora occurs.
V. After cryotherapy, lid depigmentation may last as long as 6 months and may be permanent.
VI. Hair regrowth is possible with most procedures, and new hairs can erupt at any time.

Trichiasis

Definition and Causes

I. It is defined as normal eyelid or facial hairs that come into contact with the cornea and conjunctiva.
II. Primary forms are as follows:
  A. Brachycephalic breeds of dogs and cats with medial canthal entropion and nasal fold trichiasis
  B. Genetics undetermined
III. Secondary forms arise from the following:
  A. Entropion
  B. Eyelid agenesis
  C. Dermoid
  D. Previous injury and scar formation

Pathophysiology

I. Hairs from normally located follicles are directed toward and contact the eye.
II. These hairs can induce corneal or conjunctival irritation with resulting clinical signs.

Clinical Signs

I. May be asymptomatic
II. Epiphora and chronic moist dermatitis of nasal folds or affected areas
III. Conjunctivitis and possibly mucoid discharge
IV. Pigmentary keratitis

Diagnosis

I. Visualization of hairs contacting cornea
II. Remainder of ophthalmic examination normal

Differential Diagnosis

I. Keratoconjunctivitis sicca
II. Entropion, ectropion
III. Distichiasis, ectopic cilia
IV. Corneal ulceration

Treatment

I. None for asymptomatic animals
II. Medical therapy
  A. To temporarily relieve clinical signs
  B. Trimming of facial hairs
  C. Application of mustache wax or petroleum jelly to force hairs to lay in proper direction
  D. Use of topical lubricating ointment to temporarily decrease corneal irritation
III. Surgical therapy
  A. Various surgical procedures depending on the area affected
  B. Hotz-Celsus resection (see Figure 95-1)
  C. Stades procedure (Stades, 1987) and brow suspension (Willis et al., 1999), especially for shar-peis
  D. Medial canthoplasty (Yi et al., 2006; see Figure 95-2)
  E. Nasal fold resection (Gelatt and Gelatt, 1994)

Monitoring of Animal

I. Postoperative topical antibiotics BID to TID
II. Elizabethan collar until suture removal
III. Suture removal in 10 to 14 days
IV. Fluorescein staining if blepharospasm or epiphora occurs

Ectopic Cilia

Definition and Cause

I. Cilia grow from the meibomian gland but exit through the palpebral conjunctiva.
II. Cause is unknown, but probably similar to those for distichiasis.

Pathophysiology

I. Corneal irritation from hair rubbing
II. May be single or multiple
III. May be unilateral or bilateral

Clinical Signs

I. Ocular (corneal) pain: squinting, tearing
II. Chronic or recurrent erosions in the central, dorsal cornea

Diagnosis

I. Evert the eyelid.
II. Use magnification to visualize cilia coming through the conjunctiva.
III. Cilia are usually located at the 12 o'clock position in the center of the upper eyelid.
   A. Found several millimeters from lid margin
   B. Often emerge from nonpigmented island in pigmented conjunctiva or from a pigmented island in nonpigmented conjunctiva

Differential Diagnosis

I. Foreign body: corneal, conjunctival, third eyelid
II. Blepharitis
III. Conjunctivitis
IV. Refractory corneal ulcer

Treatment

I. Tarsoconjunctival resection is preferred.
II. Ectopic cilia recur frequently after electroepilation.

Monitoring of Animal

I. If concurrent corneal ulceration is present, then the animal is treated appropriately with topical antibiotic agent BID to TID ± atropine.
II. Reevaluate the animal if blepharospasm or epiphora occurs.
   A. Additional cilia can erupt from the same or additional sites.
   B. Fluorescein stain is applied to the cornea to rule out a corneal ulcer.

INFLAMMATORY DISORDERS

Symblepharon

See Chapter 96.

Neonatal Ophthalmia

Definition

I. An infection that occurs under the totally or partially closed eyelids of neonatal animals
II. Bilateral or unilateral

Causes

I. Cat
   A. Feline herpesvirus 1
   B. *Chlamydia psittaci (Chlamydophila felis)*
   C. *Mycoplasma felis* and *Mycoplasma gatae*
   D. Other miscellaneous causes of conjunctivitis
II. Dog: *Staphylococcus* spp. or other normal adnexal flora

Pathophysiology

I. Normally the eyelids in puppies and kittens remain closed until 10 to 14 days after birth (ankyloblepharon).
II. Conjunctival infection results in the production of ocular discharge, which accumulates under the closed palpebral fissure.

Clinical Signs

I. Distended eyelids
II. Ocular discharge (mucopurulent)

Diagnosis and Differential Diagnosis

I. Based on clinical signs in a neonatal animal
II. Other congenital eyelid conditions ruled out
III. Culture and sensitivity of discharge

Treatment

I. Warm compress applied to area will soften adherent exudate.
II. Open the palpebral fissure with traction or small, dull scissors (Glaze and Gelatt, 1999) to allow drainage.
III. Flush fornices with saline.
IV. Apply topical antimicrobials TID to QID for 7 to 10 days.
   A. Neomycin-polymyxin-bacitracin for puppies
   B. Oxytetracycline or erythromycin for kittens

Monitoring of Animal

I. Resolution of the problem usually occurs after treatment.
II. Evaluate corneas (fluorescein stain) after eyelid opening.
III. Affected animals can develop globe rupture and other serious consequences.
IV. Reevaluate 6 to 8 weeks posttherapy (external examination with focal light source and STT) to ensure that secondary complications such as symblepharon, corneal scars, and keratoconjunctivitis sicca have not occurred.

Blepharitis

Definition

I. Inflammation of the eyelids
II. Granulomatous inflammation of the meibomian glands: chalazion or internal hordeolum
III. Inflammation of the glands of Zeis and Moll: stye or external hordeolum

Causes

I. Blepharitis can be focal or diffuse, unilateral or bilateral, and can affect any or all eyelids.
II. Blepharitis may be a component of or the presenting complaint with many disorders (Table 95-1).

Pathophysiology

I. With parasitic, fungal, bacterial, and viral forms, the animal is exposed to the organism and an infection is established.

TABLE 95-1

Causes of Blepharitis

DISEASE TYPE	DOG	CAT
Parasitic	Localized *Demodex canis* *Sarcoptes scabiei* var. *canis* *Onchocerca* spp. Insect bite	*Demodex cati* and *Demodex gatoi* *Notoedres cati* *Cuterebra* spp. Insect bite
Fungal	*Microsporum canis, Microsporum gypseum* *Trichophyton mentagrophytes* Dermatophytosis *Malassezia* spp. Systemic blastomycosis, cryptococcosis, histoplasmosis, aspergillosis	*M. canis, M. gypseum* *T. mentagrophytes* Dermatophytosis Histoplasmosis
Bacterial	Bacterial folliculitis (*Staphylococcus* spp.) Juvenile cellulitis (puppy "strangles") Cervicofacial *Actinomyces viscosus*	Tuberculosis
Protozoal	Neosporosis Leishmaniasis	Leishmaniasis
Viral	Canine distemper virus	Cat pox Feline herpesvirus 1
Immune-mediated	Bullous pemphigoid Pemphigus foliaceus Pemphigus vulgaris Pemphigus erythematosus Discoid lupus erythematosus Systemic lupus erythematosus Vitiligo Uveodermatologic syndrome Canine familial dermatomyositis Vasculitis Erythema multiforme Canine necrolytic migratory erythema	Pemphigus vulgaris Pemphigus erythematosus Systemic lupus erythematosus Erythema multiforme
Idiopathic	Seborrhea and bacterial folliculitis Chronic ulcerative medial canthal blepharitis Hypereosinophilic syndrome Idiopathic periocular alopecia Topical-steroid alopecia	Facial dermatitis: Persian, Himalayan Periocular leukotrichia: Siamese Hypereosinophilic syndrome
Allergic	Atopy Contact allergies Food hypersensitivity	Atopy Contact allergies Food hypersensitivity
Miscellaneous	Self-trauma Food hypersensitivity Zinc-responsive dermatosis Solar dermatitis Topical steroid–related alopecia	Self-trauma Eosinophilic plaques Hypereosinophilic syndrome
Neoplastic form	Epitheliotropic lymphoma	

Data from Donaldson D, Day MJ: Epitheliotropic lymphoma (mycosis fungoides) presenting as blepharoconjunctivitis in an Irish setter. J Small Anim Pract 41:317, 2000; Donohue DE, Brightman AH: Cervicofacial *Actinomyces viscosus* infection in a Brazilian Fila: a case report and literature review. J Am Anim Hosp Assoc 31:501, 1995; Scott DW, Miller WH Jr, Griffin CE (eds): Muller & Kirk's Small Animal Dermatology. 6th Ed. WB Saunders, Philadelphia, 2001.

A. Often toxin production results in inflammation.
B. Young animals are predisposed, and genetic influences are possible in the cat (Scott et al., 2001).

II. With immune-mediated diseases, autoantibodies or immune complex deposition leads to cutaneous changes.

Clinical Signs

I. Any combination of signs possible
   A. Mucoid discharge
   B. Erythema
   C. Pruritus
   D. Hair loss
   E. Change in pigmentation
II. Often concurrent systemic dermatoses
III. Types of signs with specific disorders
   A. Parasitic
      1. Small, circumscribed, scaly alopecic areas
      2. Possible pruritus, especially with secondary bacterial infection, demodicosis
   B. Fungal
      1. Patchy alopecia and variable scaling
      2. Minimal pruritus
      3. Folliculitis and furunculosis mimicking pemphigus
   C. Bacterial
      1. Alopecia
      2. Eyelid thickening or swelling
      3. Pustules, crusts, ± fistulas
      4. Juvenile cellulitis
         a. Young dog, ± febrile
         b. Regional lymphadenopathy
         c. Eyelid, muzzle, and ear alopecia
         d. Crusts, erythema
         e. Possibly painful, self-trauma
   D. Viral
      1. Alopecia
      2. Pustules and erosions
      3. Ocular discharge, especially with canine distemper virus
   E. Immune-mediated
      1. Pemphigus group: pustular dermatitis, crusts, ulceration, inflammation, depigmentation of the eyelids
      2. Lupus group: alopecia, erythema, vesicles, ulcers
      3. Dermatomyositis: alopecia, scaling, ulceration
   F. Idiopathic
      1. Feline facial dermatitis manifests with inflammation, pruritus, and accumulated black debris around the eyelids.
      2. Periocular leukotrichia includes lightening of hair around the eyes.
      3. Eosinophilic blepharitis manifests with focal masses and erythema of the eyelids.
   G. Allergic
      1. Contact allergies can manifest as acute-onset edema and hyperemia.
      2. Eyelid swelling is common with insect bites.
      3. Atopic dogs demonstrate facial pruritus and periocular hyperemia.
      4. Food-allergic animals exhibit facial and ear pruritus.
   H. Self-trauma: excoriations, thickening, erythema
   I. Drug eruption
      1. Especially with sulfonamides and cephalosporins
      2. Drug-induced pemphigus
      3. Alopecia, crusting, ulceration of eyelids
      4. More severe signs with erythema multiforme
   J. Nutritional
      1. Young dogs: oversupplementation with zinc in large-breed, fast-growing dogs
      2. Zinc-responsive dermatosis in Siberian husky and Alaskan malamute: middle-aged dogs with zinc deficiency
      3. Crusting and erythema
      4. Scaling, alopecia, and hypo- or hyperpigmentation
   K. Epitheliotropic lymphoma (mycosis fungoides)
      1. Recurrent conjunctivitis
      2. Mucoid ocular discharge
      3. Depigmentation of eyelid margins

Diagnosis

I. History, clinical signs, concurrent drug administration, and seasonality are very important to the diagnosis.
II. Stain the cornea with fluorescein to rule out corneal ulceration before use of topical corticosteroid medications.
III. Perform a Wood's lamp examination and fungal cultures to rule out dermatophytes.
IV. Skin scraping and trichograms may identify parasitic causes.
V. Cytological analysis and culture/sensitivity are indicated for possible bacterial and fungal causes.
VI. Skin biopsy and histopathologic examination help confirm immune-mediated, nutritional, neoplastic, and idiopathic causes.
VII. Intradermal skin testing and food trials are helpful with atopic and food-allergic animals.

Differential Diagnosis

I. Conjunctivitis
II. Neoplasia of eyelids

Treatment

I. With all types of blepharitis: prevention of self-trauma with an Elizabethan collar
II. Parasitic blepharitis
   A. *Demodex* spp.
      1. Most cases of localized demodicosis resolve spontaneously in 6 to 8 weeks.
      2. For persistent cases, use systemic ivermectin 0.2 to 0.4 mg/kg PO once weekly for 3 weeks (not recommended for use in collie-type dogs, Shetland sheepdog–type dogs, or microfilaria-positive dogs).
   B. Sarcoptic mange
      1. Topical selamectin 6 to 12 mg/kg is applied every 2 weeks for 3 treatments.
      2. Milbemycin may also be used at 2 mg/kg PO every 7 to 14 days for three treatments.

3. Unresponsive cases may be treated with the following:
   a. High-dose ivermectin is administered 0.4 to 0.6 mg/kg PO once daily (not recommended for use in collie- or Shetland sheepdog–type dogs).
   b. Milbemycin is administered 2 mg/kg PO SID for 1 to 2 months beyond the point that negative skin scrapings are found.

III. Fungal blepharitis
   A. Clip the hair.
   B. Apply topical antifungal cream (clotrimazole, miconazole).
   C. Institute systemic antifungal therapy for generalized disease (see Chapter 111).

IV. Bacterial blepharitis
   A. Systemic antibiotic therapy is instituted based on culture and sensitivity results.
      1. Lincomycin 20 mg/kg PO BID, cephalexin 22 mg/kg PO BID to TID, or cefpodoxime proxetil 5 to 10 mg/kg SID is administered for a minimum of 3 weeks.
      2. Recurrent cases may require treatment with a broader-spectrum antibiotic.
      3. Some dogs with staphylococcal hypersensitivity also require systemic corticosteroids (prednisone 1 mg/kg PO BID, tapered over 3 to 4 weeks).
   B. Topical antibiotic agents with hydrocortisone are also applied BID.
   C. Systemic corticosteroid and antibiotic drugs are administered for juvenile cellulitis (see Chapter 88).

V. Viral blepharitis
   A. Supportive care of systemically ill animals: fluid therapy ± broad-spectrum antibiotic agents
   B. Topical triple-antibiotic ointment with hydrocortisone BID to TID

VI. Immune-mediated diseases
   A. Topical neomycin-polymyxin B-dexamethasone ointment TID to QID
   B. Immunosuppressive doses of prednisone at 2 to 4 mg/kg PO SID to BID, tapered over 3 to 4 weeks
   C. Azathioprine 2.2 mg/kg SID to QOD for unresponsive cases (dogs only)
   D. No effective treatment for dermatomyositis

VII. Idiopathic diseases
   A. No effective treatment exists for feline facial dermatitis (Scott et al., 2001).
   B. No treatment is required for periocular leukotrichia.
   C. Eosinophilic blepharitis is treated with topical and/or systemic corticosteroids.

VIII. Allergic diseases
   A. Removal of offending allergen, if determined
   B. Topical antibiotic and corticosteroid agent TID to QID for 5 to 7 days in dogs
   C. Hyposensitization and possibly hypoallergenic diet
   D. Systemic antihistamines (e.g., hydroxyzine 2.2 mg/kg PO BID to TID)
   E. Cyclosporine 5 mg/kg SID for 2 to 4 weeks, then tapered

IX. Nutritional disorders
   A. Correct any dietary imbalance.
   B. Supplement with oral zinc (see Chapter 93).

Monitoring of Animal

I. Animals on corticosteroids, especially immunosuppressive doses, are closely monitored for systemic side effects.
II. Many cases of blepharitis take weeks to months to resolve.
III. Some cases need lifelong therapy.

IDIOPATHIC DISEASES

See Table 95-2.

NEOPLASIA

Definition and Causes

I. Progressive multiplication and growth of skin, conjunctiva, or gland of the eyelids
II. Can be benign or malignant
III. Primary, secondary, and metastatic forms

TABLE 95-2

Idiopathic Eyelid Disorders

DISEASE	SPECIES	CLINICAL SIGNS	DIAGNOSIS	TREATMENT
Idiopathic granulomatous disease*	Dog	Multiple, bilateral tan, firm, cutaneous lower eyelid granulomas	Histopathology	Intraperitoneal polyethylene glycol-modified L-asparaginase
Apocrine hidrocystomas†	Cat	Multiple cysts in medial canthus, upper and lower eyelids	Histopathology	Surgical excision Trichloracetic acid
Periorbital epidermal cyst‡	Dog	Slowly enlarging medial canthal mass	Histopathology	Surgical excision

*Collins BK, MacEwen EG, Dubielzig RR et al: Idiopathic granulomatous disease with ocular adnexal and cutaneous involvement in a dog. J Am Vet Med Assoc 201:313, 1992.

†Chaitman J, vanderWoerdt A, Bartick TE: Multiple eyelid cysts resembling apocrine hidrocystomas in three Persian cats and one Himalayan cat. Vet Pathol 36:474, 1999; Yang SH, Lin CH, Hsu CD et al: Use of chemical ablation with trichloracetic acid to treat eyelid apocrine hidrocystomas in a cat. J Am Vet Med Assoc 230: 1170, 2007.

‡Davidson HJ, Blanchard GL: Periorbital epidermoid cyst in the medial canthus of three dogs. J Am Vet Med Assoc 198:271, 1991.

Pathophysiology

I. Most canine eyelid tumors are benign (Table 95-3).
II. Tumors in dogs that appear histologically malignant tend to be infiltrative but rarely metastasize.
III. Eyelid tumors in cats are far less common than in dogs, but they are much more likely to be malignant.
IV. Eyelid neoplasms destroy normal eyelid tissue at varying rates and degrees.
V. Secondary effects can occur with all types of tumors.
   A. Extension into orbit
   B. Ocular discharge
   C. Hemorrhage from mass

TABLE 95-3

Classification of Eyelid Tumors in the Dog and Cat

TUMOR TYPE	CLINICAL FEATURE
Dog	
Sebaceous gland adenoma (meibomian gland adenoma)	Most common eyelid tumor Usually occurs in older dogs Slow-growing mass at or near lid margin Visible through conjunctival surface, extends onto the eyelid margin
Papilloma	Usually occurs in young dogs May be associated with oral papillomas Viral forms regress over time
Sebaceous adenocarcinoma	Usually occurs in older dogs Locally invasive, slow-growing mass at or near lid margin Rare
Melanoma (benign or malignant)	Dark, superficial, well-demarcated nodules Tend to occur at eyelid margin
Histiocytoma	Usually seen in young dogs Raised, hairless, pink nodules that often regress over time
Mast cell tumor (mastocytoma)	See Chapter 89
Basal cell carcinoma	Ulcerative, invasive mass
Squamous cell carcinoma	Rare in the dog Rapidly growing, ulcerative, invasive mass
Fibrosarcoma	Aggressive, invasive mass
Apocrine gland adenocarcinoma	Very invasive
Lobular orbital adenoma	Swollen, hyperemic eyelids
Cat	
Squamous cell carcinoma	Most common eyelid tumor Slightly raised or depressed ulcerated lesion On or adjacent to eyelid margin Locally invasive, malignant
Lymphosarcoma	Conjunctival invasion Primary or multisystemic manifestations
Fibrosarcoma	Focal, nodular, ulcerated Aggressive, invasive
Basal cell carcinoma	Round, well-circumscribed, ulcerated lesion Generally benign
Mast cell tumor (mastocytoma)	Single or multiple Dermal, epidermal, or subcutaneous Variable appearance See Chapter 89
Adenoma/adenocarcinoma	Rare in the cat
Melanoma	Often darkly pigmented (but not always)

Data from Glaze MB, Gelatt KN: Feline ophthalmology. p. 997. In Gelatt KN (ed): Veterinary Ophthalmology. 3rd Ed. Lippincott Williams & Wilkins, Philadelphia, 1999; Headrick JF, Bentley E, Dubielzig RR: Canine lobular adenoma: a report of 15 cases with distinctive features. Vet Ophthalmol 7:47, 2004; Hirai T, Mubarak M, Kimura T et al: Apocrine gland tumor of the eyelid in a dog. Vet Pathol 34:232, 1997; Krehbiel JD, Langham RF: Eyelid neoplasms of dogs. Am J Vet Res 36:115, 1975; McLaughlin SA, Whitley RD, Gilger BC et al: Eyelid neoplasms in cats: a review of demographic data (1979-1989). Vet Clin North Am Small Anim Pract 27:1011, 1997; Roberts SM, Severin GA, Lavach JD: Prevalence and treatment of palpebral neoplasms in the dog: 200 cases (1975-1983). J Am Vet Med Assoc 189:1355, 1986.

D. Eyelid deformation
E. Corneal ulceration and irritation

Clinical Signs

I. A mass-type lesion is present on the eyelid margin or eyelid skin.
II. Appearance of the various tumors is listed in Table 95-3.
III. Ulcerative keratitis occurs, depending on the tumor size and location.

Diagnosis

I. Signalment and clinical signs
II. Thorough ocular examination
III. Cytological examination of fine-needle aspirate or impression smears
IV. Histopathologic examination: essential
V. Lymph node aspiration and thoracic radiography: recommended with some malignant tumors

Differential Diagnosis

I. Granulation tissue
II. Chalazion
III. Foreign body
IV. Ulcerative blepharitis
V. Trauma
VI. Eosinophilic granuloma in Siberian huskies (Vercelli et al., 2005)

Treatment

I. Wedge resection (Figure 95-3)
A. For removal of neoplasms that are less than one third the length of the eyelid margin

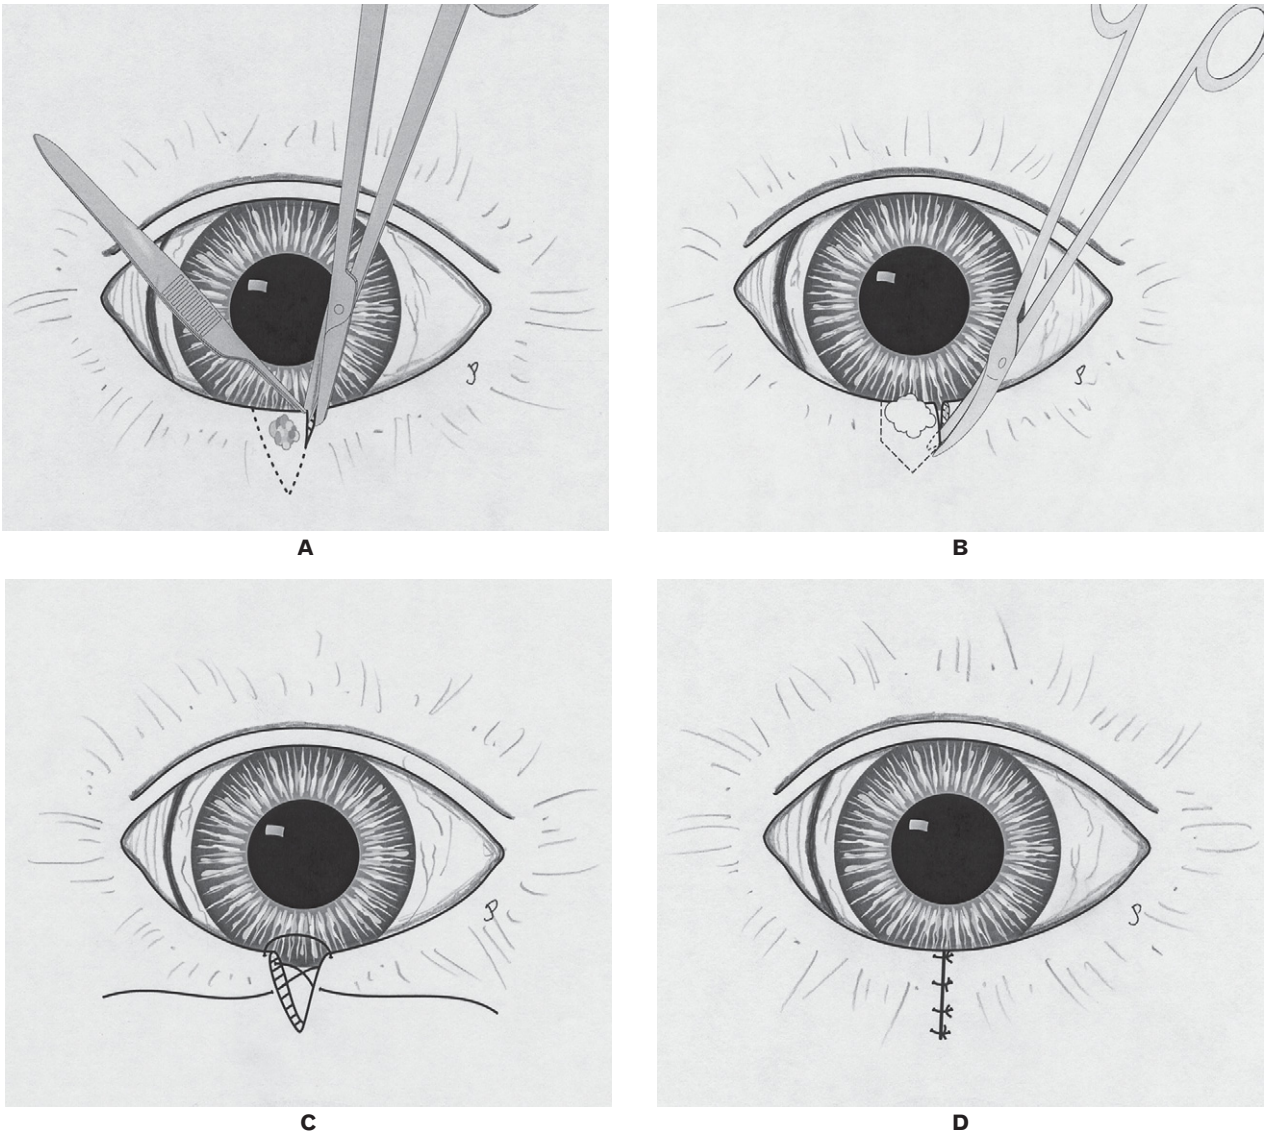


FIGURE 95-3 Full-thickness wedge excision for eyelid tumor removal. **A,** A V-shaped wedge of tissue is excised. The clinician should ensure that the sides of the incision are of equal length and can be full or partial thickness. **B,** For slightly larger lesions, a four-sided incision is recommended. **C,** A two-layer closure is used. The tarsoconjunctiva is apposed using 6-0 absorbable suture, and the skin and muscle layer is then apposed using 5-0 or 6-0 nonabsorbable suture material, starting at the eyelid margin using a figure-eight suture. **D,** The remainder of the incision is closed with simple interrupted sutures. *From Gelatt KN, Gelatt JP: Small Animal Ophthalmic Surgery. Butterworth-Heinemann, Oxford, 2001; with permission.*

B. Precise alignment of the eyelid margin, skin, and conjunctiva (essential)
C. Postoperative care
1. Topical cold compress during recovery ± warm compresses for 2 to 4 days postoperatively
2. Elizabethan collar until suture removal in 10 to 14 days
3. Broad-spectrum topical antibiotic agent BID to TID for 5 to 7 days

II. Split-thickness or full-thickness sliding skin graft (Figure 95-4)
A. Used for lesions that encompass more than one third of the eyelid margin.
B. Precise alignment of the eyelid margin, skin, and conjunctiva is essential.
C. Postoperative care is the same as for wedge resection.

III. Multiple other pedicle and rotating grafts for large lesions (Bedford, 1999; Schmidt, 2005)

IV. Carbon dioxide laser ablation (Bussieres et al., 2005)
A. Uses a defocused beam for adnexal tumors
B. May be cost prohibitive

V. Diode laser ablation: useful for pigmented masses

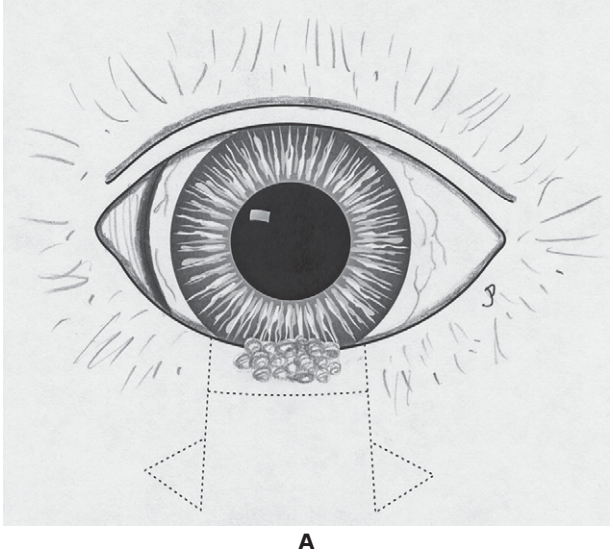
VI. Cryotherapy
A. Used as adjunctive or primary therapy for some eyelid masses (e.g., squamous cell carcinoma).
B. Especially useful for tumors that are too large for resection.

VII. Chemotherapy
A. Rarely used for eyelid neoplasms
B. May be of benefit for mast cell tumors or lymphosarcoma
C. May be useful to reduce mass size before other therapies are conducted (e.g., surgical resection)

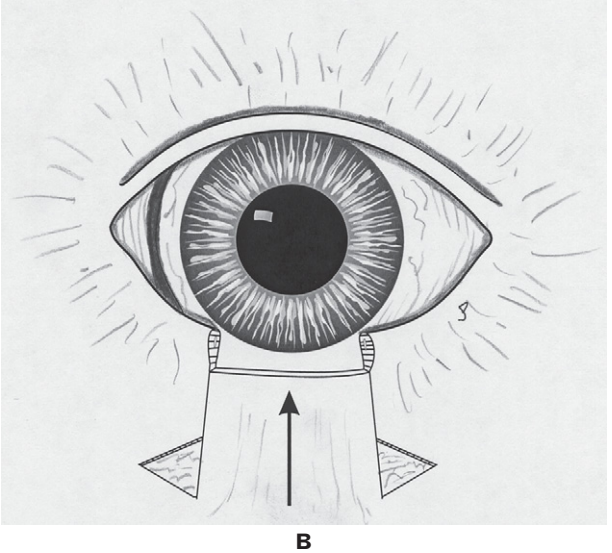
VIII. Radiation therapy
A. It is most useful for squamous cell carcinoma.
B. Reducing the tumor burden via surgical debulking increases the effectiveness of radiation.

Monitoring of Animal

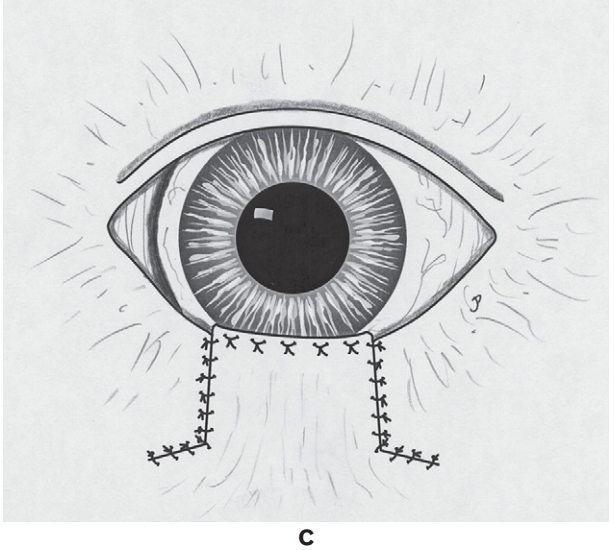
I. Most canine lid tumors are cured by local excision.
A. Skin sutures are removed in 10 to 14 days.



A



B



C

FIGURE 95-4 H-plasty or sliding skin graft for treatment of large eyelid margin lesions. **A,** Two slightly diverging incisions are made in the skin. A third incision is made parallel to the eyelid margin and serves as the distal margin of the mass removal. The length of the diverging incisions is twice the height of the tissue to be excised. A Burow's triangle of skin is excised from each side of the distal incision. **B,** The lid mass is excised and the skin flap is dissected from underlying subcutaneous tissues and advanced into the defect. The posterior aspect of the graft must be lined with mucosa. **C,** The leading edge of the graft is positioned 0.5 to 1.0 mm above the adjacent normal eyelid margin. Nonabsorbable 5-0 to 6-0 simple interrupted sutures are placed first at the junction of the graft with the eyelid margin, then at the edges of the previous Burow's triangles. The conjunctival tissue is attached to the edge of the skin using simple interrupted sutures that do not contact the cornea. *From Gelatt KN, Gelatt JP: Small Animal Ophthalmic Surgery. Butterworth-Heinemann, Oxford, 2001; with permission.*

B. Animals are evaluated sooner if the owner reports excessive squinting or tearing that could indicate a suture-induced corneal ulcer.

II. Malignant tumors are likely to recur and may eventually metastasize.

III. Monitoring frequency depends on the histological diagnosis.

TRAUMA

Eyelid Laceration

Definition and Causes

I. A partial-thickness or full-thickness tear in the eyelid

II. Most commonly traumatic: associated with bite wounds or other traumatic events

Pathophysiology

I. Sharp or blunt wound to the eyelid causes skin, muscle, tarsal plate, and/or conjunctiva to be torn.

II. Ineffective blink and corneal exposure can result.

III. Keratitis ensues, especially if the eyelid margin is disrupted.

Clinical Signs

I. Tear in the upper or lower eyelid: partial or full thickness

II. Associated hemorrhage and swelling

III. Epiphora, especially with injury to ventral lacrimal punctum or canaliculus

IV. Granulation tissue formation: possible in chronic wounds

V. Keratitis from ineffective blink or from causative agent

Diagnosis

I. Complete physical and ophthalmic examinations are performed to evaluate for other injuries.
   A. Animal is examined for globe rupture, proptosis, pneumothorax, or additional bite wounds.
   B. Cornea is fluorescein stained to evaluate the integrity of the corneal epithelium.

II. Nasolacrimal system is also evaluated for damage, especially with medial canthal injuries.

Differential Diagnosis

I. Dehiscence of eyelid surgery repair

II. Neoplasia: similar in appearance to chronic lacerations that have granulated closed

III. Eyelid or eyelash abnormalities: entropion, ectropion, trichiasis

Treatment

I. Eyelids are highly vascular and have a great capacity to heal and resist infection.

II. Partial-thickness lacerations may be treated medically or surgically.
   A. Wound is cleaned and topical antibiotic ointment is applied.
   B. Tissue is kept moist before surgical repair.
   C. Gentle cleansing with dilute povidone-iodine (1:50 *Betadine* in saline) is performed.

III. With surgical repair, minimal debridement is needed because of the good vascular supply.
   A. Do not excise eyelid tissue flaps.
   B. Direct closure and healing by primary intention provide the best results.

IV. It is imperative to precisely align the eyelid margin, skin, and conjunctiva.
   A. Two-layer closure is stronger than one layer.
   B. Tarsal plate and conjunctiva are closed starting at the lid margin with a buried mattress suture (5-0 or 6-0 absorbable suture).
   C. Remainder of the conjunctiva and muscle layer is closed in a partial-thickness, buried, simple continuous pattern, ensuring that suture is not rubbing on the cornea.
   D. Eyelid margin skin is apposed and sutured in a figure-eight fashion with monofilament material (5-0 or 6-0 nonabsorbable) (see Figure 95-3, *C*).
   E. Remainder of the skin is closed with simple interrupted or cruciate sutures.

V. Postoperative care includes the following:
   A. Topical ice packs during recovery ± warm compresses for 2 to 4 days postoperatively
   B. Elizabethan collar until suture removal
   C. Broad-spectrum topical and systemic antibiotics for 5 to 7 days

Monitoring of Animal

I. Skin sutures are removed in 10 to 14 days.

II. Animal is evaluated sooner if excessive squinting or tearing occurs, which could indicate a suture-induced corneal ulcer.

CHAPTER 96

Disorders of the Conjunctiva and Third Eyelid

Harriet J. Davidson

CONGENITAL/DEVELOPMENTAL DISORDERS

Encircling Third Eyelid

Definition and Cause

I. The lateral edge of the third eyelid extends dorsotemporally around the eye.
II. Genetic predisposition exists in American cocker spaniels.

Clinical Signs

I. Eye and conjunctival tissues are normal, with the exception of the extra layer of tissue surrounding the eye.
II. The leading edge of the third eyelid is frequently pigmented.

Diagnosis

I. Clinical appearance is pathognomic.
II. Movement of the third eyelid using a cotton-tipped applicator after the application of topical anesthetic helps to identify the eyelid margin as normal.
III. Cytology of the eyelid margin reveals normal epithelial cells, with or without melanin granules.

Differential Diagnosis

I. Conjunctivitis
II. Melanoma

Treatment and Monitoring

I. Therapy is not necessary.
II. This condition has no effect on the third eyelid movement or gland function.

Dermoid and Choristoma

Definition

Dermoid or choristoma is a growth of normal epithelial cells (most often skin) in an abnormal location, in this case the conjunctiva.

Causes

I. It may occur as an unusual finding in any breed.
II. Breed predisposition is as follows:
   A. Dogs: dachshund, Dalmatian, Doberman pinscher, German shepherd dog, Saint Bernard
   B. Cats: Birman (Hendy-Ibbs, 1985)

Clinical Signs

I. The abnormal tissue has the appearance of hairy or nonhairy skin.
II. It is raised and irregular.
III. The most common locations are at the temporal or dorsal conjunctiva.
IV. It may grow over the corneal surface.

Diagnosis and Differential Diagnosis

I. Biopsy of the tissue reveals normal epithelial layers and/or components of skin and hair.
II. The primary differential consideration is neoplasia.

Treatment and Monitoring

I. Complete surgical resection of the dermoid is usually curative.
II. Sharp dissection of the surface of the dermoid is completed with a scalpel blade, whereas blunt dissection of the deeper tissues is accomplished with a blade or scissors.
III. Closure of the conjunctival tissues may not be necessary for a small dermoid, but large wounds are closed with a continuous pattern of 6-0 absorbable suture.
IV. Treat postoperatively with ophthalmic steroid and antibiotics TID for 2 weeks.
V. Ophthalmic antibiotic agents are used alone if a corneal ulcer has been created from the surgery.
VI. Examine the animal 2 to 6 weeks postoperatively to confirm there is no recurrence.
VII. Failure to remove all the tissue may result in regrowth at the same location.

Prominent Third Eyelid

Definition

I. The third eyelid protrudes across the surface of the eye, altering the normal appearance.
II. The third eyelid itself is not inflamed.

Causes

I. Neurological diseases
   A. Horner's syndrome: loss of sympathetic innervation

B. Haw's syndrome (Muir et al., 1990)
   1. Seen in cats
   2. Specific cause unknown
   3. Possibly diarrhea as an accompanying clinical sign

II. Pain or malaise
   A. Ocular pain: corneal ulcer, uveitis, glaucoma
   B. Systemic illness or malaise

III. Loss of orbital tissue
   A. Dehydration
   B. Fat or muscle atrophy
   C. Microphthalmia or phthisis bulbi

IV. Orbital space–occupying mass
   A. Neoplasia
   B. Orbital abscess, cellulitis

V. Tetanus

Pathophysiology

I. Passive upward movement of the third eyelid when the eye moves deeper into the orbit
   A. Loss of sympathetic innervation (Horner's syndrome)
   B. Contraction of the extraocular muscles
      1. Pain from ocular disease results in contraction of the extraocular muscles, pulling the globe deeper into the orbit in an effort to protect the eye.
      2. Overstimulation of the extraocular muscles can occur, as with tetanus.
   C. Loss of orbital structures allowing the globe to fall deeper into the orbit
      1. Microphthalmic globe: congenitally abnormal small eye, often nonvisual
      2. Phthisical globe: shrunken in size, acquired, usually nonvisual
      3. Loss of fat or muscle within the orbit

II. Physical displacement by a space-occupying mass or inflammation within the orbit

Clinical Signs

I. The condition may be uni- or bilateral.
II. The third eyelid is usually physically normal.

Diagnosis and Differential Diagnosis

I. Bilateral condition: dehydration, fat or muscle atrophy, generalized pain or malaise, tetanus, haws
II. Unilateral condition: orbital neoplasia or infection, ocular pain, Horner's syndrome
III. Complete physical examination
IV. Examination of the face for evidence of a symmetry
V. Thorough ophthalmic examination: pupillary light reflexes, Schirmer's tear test (STT), fluorescein stain, intraocular pressure, retropulsion of globe to evaluate the orbit
VI. Possibly pharmacologic testing to determine the cause of Horner's syndrome (see Chapter 105)

Treatment and Monitoring

I. Treat any underlying condition.
II. No treatment may be required; the presence of the third eyelid across the eye is not detrimental to the animal.
III. Topical application of 1% to 5% phenylephrine or 0.1% to 0.5% epinephrine ophthalmic solution may be applied as needed to cause retraction of the eyelid.
IV. The leading edge of the eyelid can be tattooed to make the eyelid less noticeable.

Prolapsed Gland of the Third Eyelid

Definition

I. The gland of the third eyelid prolapses and is no longer lying in the normal position.
II. The gland is exposed while still under the conjunctiva and the third eyelid is folded over.

Causes

I. The ligament that holds the gland in place breaks and allows the distal end of the gland to slip forward while still remaining under the conjunctival tissue.
II. Subsequent exposure results in swelling and inflammation of the glandular tissue.
III. Some breeds are predisposed.
   A. Dogs: American cocker spaniel, basset hound, beagle, English bulldog, Lhasa apso, poodle, and brachycephalic breeds in general
   B. Cats: Burmese (Koch, 1979)
IV. It may also be associated with an everted third eyelid cartilage.

Clinical Signs

I. Smooth, rounded, soft mass under the conjunctiva on the third eyelid
II. Possibly mucoid discharge
III. Unilateral or bilateral
IV. Predominantly in dogs <1 year of age

Diagnosis

I. Clinical appearance is usually diagnostic.
II. Palpate the third eyelid to rule out everted cartilage.
III. The mass can often be gently pushed back into place (transiently), behind the third eyelid.
IV. Consider fine-needle aspiration with cytological examination to rule out neoplasia, proliferative conjunctivitis, or episcleritis.

Differential Diagnosis

I. Neoplasia
II. Proliferative conjunctivitis: plasmacytic conjunctivitis (PC), ligneous conjunctivitis (LC) (see Inflammatory Disorders, later in this chapter)
III. Everted third eyelid cartilage
IV. Prominent third eyelid
V. Subconjunctival cyst
VI. Episcleritis (see Chapter 98)

Treatment

I. Surgical restoration of the normal gland position.
   A. Administer topical ophthalmic antibiotic and steroid preparations TID 1 week before surgery and ophthalmic

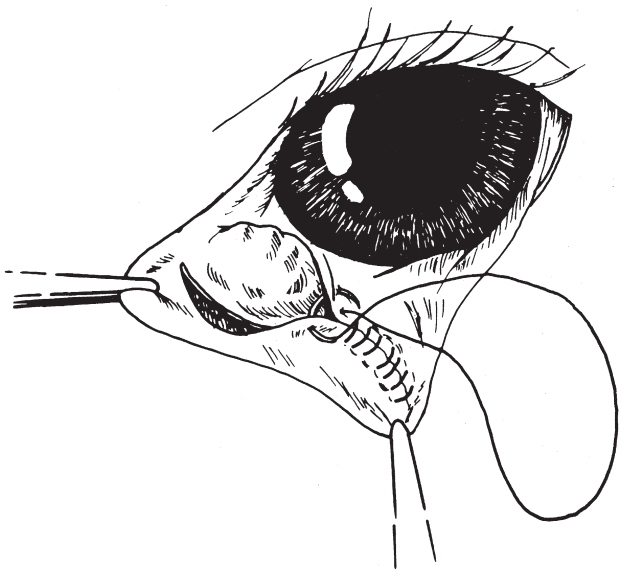

FIGURE 96-1 Repair of a prolapsed third eyelid gland using a pocket technique. One-centimeter incisions are made on the posterior surface of the third eyelid on either side of the prolapsed gland parallel to the free margin. The far sides of each incision are sutured together with 6-0 absorbable suture. *From Morgan RV, Duddy JM, McClurg K: Prolapse of the gland of the third eyelid in dogs: a retrospective study of 89 cases (1980-1990). J Am Anim Hosp Assoc 29:56, 1993; with permission.*

antibiotic alone TID for 2 weeks after surgery to help decrease inflammation and improve surgical success.

B. With a unilateral prolapse, consider surgery of the opposite eye to prevent future prolapse.

C. A pocket, imbrication technique may be performed (Figure 96-1).
   1. The third eyelid is pulled forward, exposing the bulbar surface.
   2. One-centimeter incisions are made on either side of the gland parallel with the free edge.
   3. The far edges of the two incisions are sutured together using an absorbable 6-0 suture in a continuous pattern.
   4. The gland is tucked down into the pocket as the suture line is closed.

D. A modified orbital rim tacking technique may be considered (Figure 96-2).
   1. Double-armed, nonabsorbable 2-0 to 4-0 suture is used.
   2. A 5-mm skin incision is made along the ventral orbital rim.
   3. A 5-mm conjunctival incision is made inside the eyelid, matching the skin incision.
   4. Suture is passed through the skin incision and the periosteal orbital rim and exits the conjunctival incision.
   5. The same suture is then passed through the conjunctiva and exits the dorsal surface of the gland.
   6. The same suture is then passed back into the dorsal surface of the gland and exits the conjunctiva close to the original position.
   7. The second arm of the suture is passed through the skin incision and the periosteal orbital rim, and exits the conjunctival incision (same as the first suture arm).
   8. The two arms of the suture are tied together, pulling the gland downward and anchoring it to the orbital rim.

E. A modified purse-string procedure is used in selected cases (Figure 96-3).
   1. It is recommended for puppies with acute prolapse of the gland.
   2. Absorbable 6-0 suture is used.
   3. Initially the suture is inserted in the bulbar conjunctiva within the ventral fornix (between the gland and the limbus).
   4. Then the suture is passed between the free edge of the third eyelid and the gland.
   5. Finally, the suture is passed into the bulbar conjunctiva of the ventral fornix.
   6. The suture is tied together, drawing the gland downward as the purse string is closed.

II. Surgical removal of the gland is considered only as a last resort.
   A. It is not an ideal therapy because removal of the lacrimal gland tissue predisposes the dog to development of keratoconjunctivitis sicca (KCS) (Morgan et al., 1993).
   B. Amputation of the exposed portion of the prolapsed gland can be completed with mild sedation and a topical or short-acting anesthetic.
   C. Sharp dissection of the gland is used, with no closure of the conjunctival tissues.

Monitoring of Animal

I. Reexamine the affected eye in 1 to 2 weeks.
   A. To ensure no corneal damage has resulted from surgical trauma or exposure
   B. To ensure proper healing of the incision

II. Reexamine the animal again in 1 to 3 months.
   A. To ensure proper position of the gland
   B. To ensure normal tear production (see Chapter 97)

Everted Third Eyelid Cartilage

Definition

I. The base of the T-shaped cartilage curls and protrudes anteriorly.

II. The rest of the third eyelid is usually normal with primary eversion of the cartilage.

Causes

I. Genetic predisposition in large-breed dogs

II. Genetic predisposition in German shorthaired pointers (Martin and Leach, 1970)

III. Reported in conjunction with prolapsed gland of the third eyelid in a Burmese cat (Albert et al., 1982)

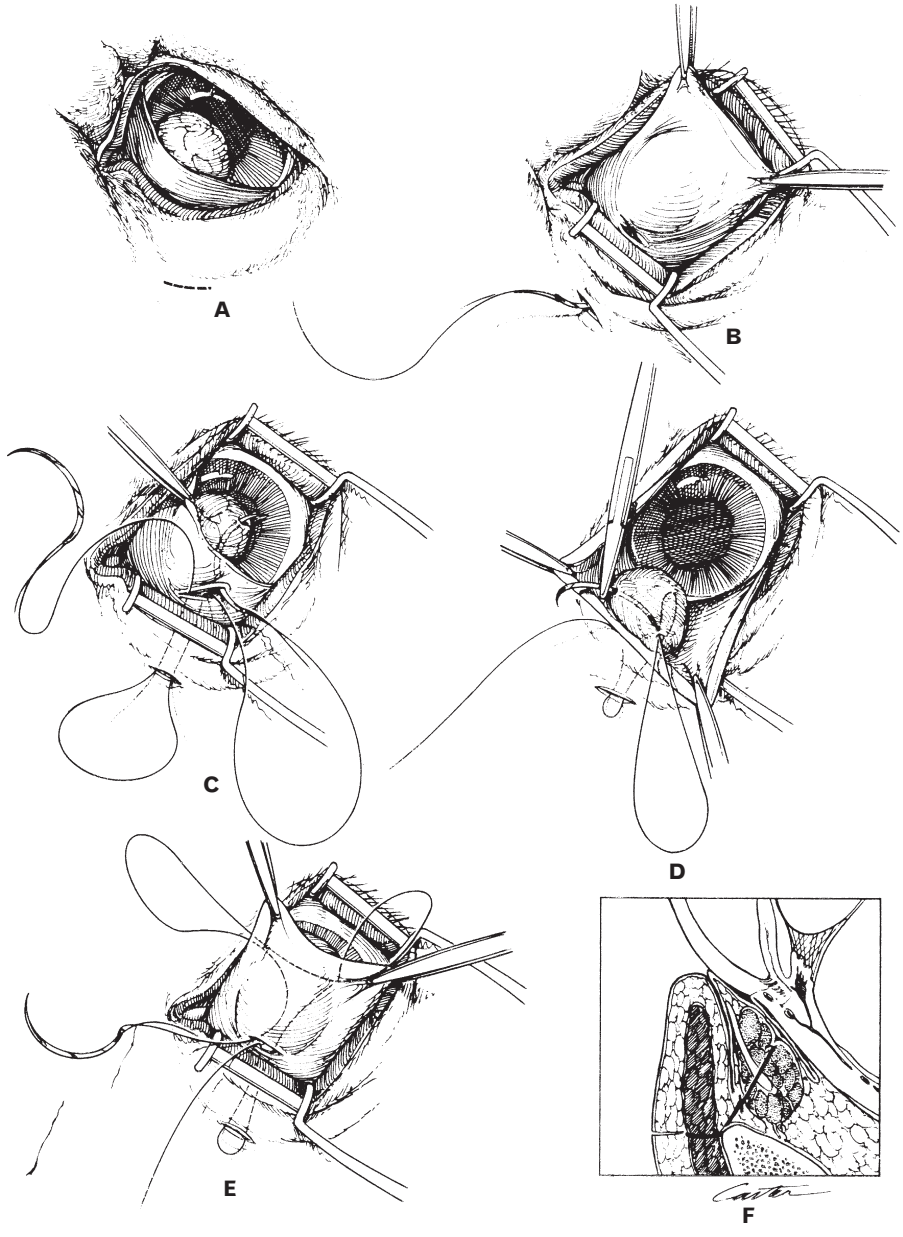

FIGURE 96-2 Diagram of a modification of the orbital rim anchorage method for surgical replacement of the gland of the third eyelid in dogs. A 5-mm skin incision is made parallel and subjacent to the ventral periorbital rim (**A**). A second incision is made parallel to the skin incision in the ventral conjunctival fornix. Nonabsorbable, monofilament suture (2-0 to 4-0 nylon, depending on the size of the dog) on a 3/8 circle cutting needle is passed through the skin, the periosteal rim, and the conjunctival incision (**B**). This is repeated with a second needle attached to the other end of the same suture. The first needle is passed through the conjunctiva and emerges through the dorsal gland (**C**). The needle is passed back through the gland (**D**) and then back out the conjunctival incision (**E**). A knot is tied securing the repair (**F**). Neither conjunctiva nor skin is sutured. *From Stanley RG, Kaswan RL: Modification of the orbital rim anchorage method for surgical replacement of the gland of the third eyelid in dogs. J Am Vet Med Assoc 205:1412, 1994; with permission.*

Pathophysiology

I. It is believed to result from rapid growth of the posterior portion of the cartilage compared with the anterior portion (Martin and Leach, 1970).
II. It may occur secondary to chronic prolapse of the gland of the third eyelid, which may weaken the cartilage.

Clinical Signs

I. Appearance of the third eyelid may change acutely.
II. Firm, thin, linear scroll of tissue is present on the palpebral surface of the free margin of the third eyelid.
III. Palpation of the third eyelid allows identification of the cartilage borders.

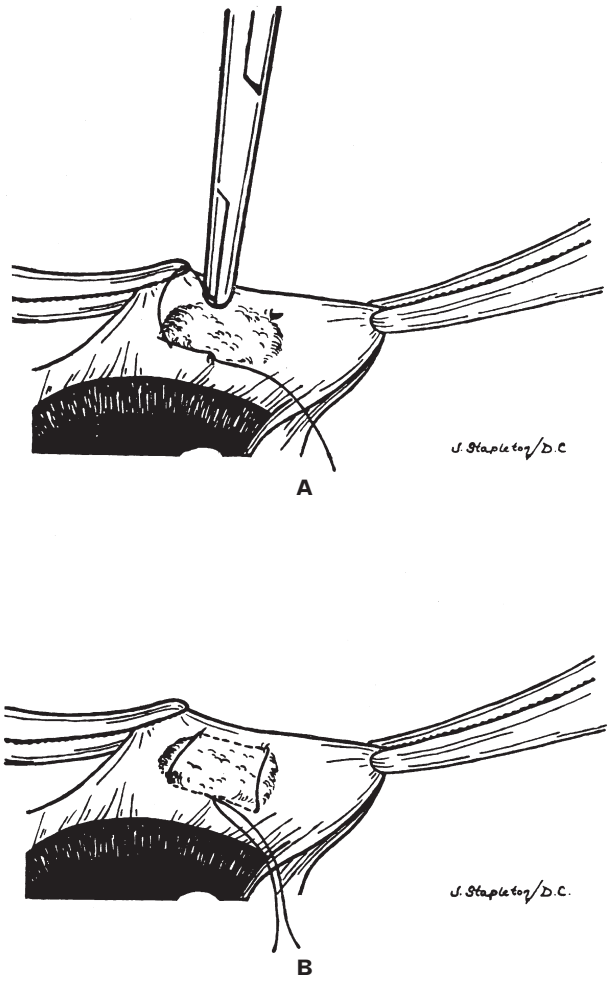

FIGURE 96-3 Placement of a modified purse-string suture around the prolapsed third eyelid gland. The initial bite is taken in the ventral fornix at the base of the third eyelid, and the second bite is taken between the body of the gland and the free margin of the third eyelid **(A).** The modified purse-string is completed when that final bite is placed back into the fornix to exit near the point of initial entry, drawn together, and tied **(B).** To stimulate adequate adhesion, the conjunctiva over the prolapsed gland is scarified before suture placement. *From Moore CP: Imbrication technique for replacement of prolapsed third eyelid gland. p. 126. In Bojrab MJ (ed): Current Techniques in Veterinary Surgery. 3rd Ed. Lea & Febiger, Philadelphia, 1990; with permission.*

IV. It is not usually painful, but mild conjunctivitis may develop.

Differential Diagnosis

I. Prolapsed gland of the third eyelid
II. Prominent third eyelid
III. Neoplasia of the third eyelid

Treatment

I. Surgical removal of the everted portion of the cartilage may be performed if the eye is symptomatic.
II. A single incision is made on the bulbar surface of the third eyelid conjunctiva.
III. The curled portion of the cartilage is bluntly dissected from the surrounding tissue using scissors or scalpel blade.
IV. Conjunctiva does not usually require closure.
V. In breeds that are predisposed to prolapse of the gland of the third eyelid, closure of the incision with 6-0 absorbable suture in a continuous pattern may prevent prolapse of the gland.
VI. After surgery a topical ophthalmic antibiotic is applied TID for 2 weeks.

Monitoring of Animal

I. Reexamine the animal in 1 to 2 weeks to ensure normal healing and no corneal ulceration secondary to surgical manipulation.
II. Reexamine the animal in 2 months to ensure normal position of gland of the third eyelid.

DEGENERATIVE DISORDERS

Subconjunctival Cyst

Definition

An epithelial cell-lined, fluid-filled sac forms as a result of an abnormal accumulation of glandular cells beneath the conjunctival surface.

Causes

I. Congenital abnormal location of glandular tissue
II. Chronic conjunctivitis
III. Trauma
IV. Surgical malpositioning of a prolapsed gland of the third eyelid

Clinical Signs

I. Soft, pliable swelling beneath the conjunctiva
II. Minimal discomfort

Diagnosis

I. Fine-needle aspiration of the mass reveals clear to golden, acellular, proteinaceous fluid.
II. Lacrimal duct flushing confirms no connection exists with the lacrimal canaliculus or sac.
III. Ultrasonography reveals a circumscribed mass with a hypoechoic center.

Differential Diagnosis

I. Neoplasia
II. Prolapse of the gland of the third eyelid
III. Prolapsed orbital fat
IV. Foreign body granuloma
V. Dacryoadenitis

Treatment and Monitoring

I. Surgical removal of the entire cyst
   A. Enlarged area of the conjunctiva is incised along one edge of the structure, followed by blunt dissection and removal of the entire cyst.
   B. If the cyst is ruptured, then identifying all the tissues is difficult; however, every effort is made to remove all the glandular tissue.

C. Conjunctival tissue is closed over the wound using 6-0 absorbable suture in a continuous pattern.
D. Failure to completely remove the cyst may result in local recurrence.

II. Ophthalmic antibiotics TID for 2 weeks to prevent infection

III. Reexamination postoperatively
A. At 1 to 2 weeks to ensure no corneal damage occurred secondary to surgical trauma and to ensure proper healing of the conjunctival wound
B. At 3 to 6 months to ensure no recurrence of the cyst

INFLAMMATORY DISORDERS

Conjunctivitis

Definition

I. Inflammation of the conjunctival tissues

II. May involve bulbar conjunctiva overlying the globe and on the posterior surface of the third eyelid

III. May affect palpebral conjunctiva lining the external eyelid and on the anterior surface of the third eyelid

Causes

I. Infectious agents
A. Bacteria and other organisms
1. *Chlamydia psittaci (Chlamydophila felis):* common in cats
2. *Mycoplasma felis:* common in cats, frequently accompanies viral respiratory disease
3. Gram-positive bacteria: *Staphylococcus* spp., *Bacillus* spp., *Corynebacterium* spp.
B. Viruses
1. Feline herpesvirus 1: chronic or recurrent conjunctivitis, with or without concurrent corneal ulceration
2. Calicivirus: frequently associated with signs of upper respiratory infections and oral ulceration in cats
3. Canine distemper: nonspecific conjunctivitis during acute disease
C. Parasites
1. Uncommon
2. *Thelazia* spp.
3. *Cuterebra* spp.
4. *Dirofilaria* spp. larvae
D. Systemic infections
1. *Blastomyces dermatitidis*
2. *Histoplasma capsulatum*
3. *Borrelia burgdorferi*

II. Immune-mediated disorders
A. Atopy, type I hypersensitivity
B. Cell-mediated inflammation
1. Eosinophilic conjunctivitis (EC): cats
2. Ligneous conjunctivitis (LC): dogs
3. PC (or pannus-associated conjunctivitis): dogs, most common in German shepherd dogs or related breeds

III. Irritative conditions
A. Drying of tissue from exposure or KCS (see Chapter 97)
B. Abnormal hairs: distichia, ectopic cilia, entropion, or trichiasis rubbing on the conjunctival surface
C. Environmental irritants: chemicals, smoke, dust, foreign bodies, others

IV. Trauma

V. Conditions accompanying other ocular diseases: uveitis, episcleritis, glaucoma, or corneal ulceration

Pathophysiology

I. Vasodilation occurs from any of the nonspecific causes, resulting in edema and inflammatory cell infiltration.

II. Chemotaxins stimulate increased inflammatory cell migration in the tissues, and these inflammatory cells increase the inflammatory cascade.

III. Specific causes of EC, LC, and PC are unknown.
A. EC has been associated with feline herpesvirus (Larocca, 2000).
B. LC may result from excessive vascular permeability that arises from an immune-mediated condition (Ramsey et al., 1996).
C. PC may be a hypersensitivity reaction and is related to excessive ultraviolet light stimulation (Eichenbaum et al., 1986).

Clinical Signs

I. Discharge
A. Epiphora: overflow of tears from increased lacrimation
B. Mucoid: from increased stimulation of goblet cells
C. Purulent: bacterial infections resulting in degenerate neutrophils

II. Chemosis: swelling of the conjunctiva

III. Hyperemia (engorgement of vessels)
A. Conjunctival vessels lie on the surface of the globe, can easily be moved across the globe, and blanch with topical ophthalmic epinephrine.
B. Scleral vessels are deep, usually a darker color, and move with the globe beneath the conjunctiva.
C. Hemorrhaging may also occur beneath the conjunctiva.

IV. Possible blepharospasm

V. Proliferative changes
A. Swelling of conjunctival lymphoid follicles: pink to clear, smooth swellings with a cobblestone appearance
B. EC: white to pink to red, raised, irregular tissue
C. LC: membranous white to pink tissue that may encircle the entire eye and obscure the cornea
D. PC: most often involving the third eyelid or the lateral aspect of the globe, producing a raised, red, cobblestone or "hamburger meat" appearance

Diagnosis

I. Complete ophthalmic examination to determine causes or rule out other conditions
A. Diagnostic tests
1. STT
2. Fluorescein stain
3. Intraocular pressure

B. Areas to examine
1. Eyelids for entropion, distichiasis, ectopic cilia, trichiasis, and foreign bodies
2. Cornea for evidence of keratitis or ulceration
3. Anterior chamber and iris for signs of intraocular inflammation or glaucoma

II. Cytology
A. Technique
1. Apply topical ophthalmic anesthetic to the conjunctival surface.
2. Retract the eyelid to expose the inflamed surface.
3. Use a blunt instrument (e.g., Kimura spatula, blunt edge of a scalpel blade) to scrape the surface several times.
4. Transfer cells to a glass slide; dry and stain the cells.
B. Normal cytology
1. Cell types: epithelial cells, melanin granules, mucin strands, blood cells
2. Bacteria: variable depending on the type of animal; mainly gram-positive such as *Staphylococcus* spp., *Bacillus* spp., and *Corynebacterium* spp. (in the dog)
C. Abnormal cytology
1. Degenerative and nondegenerative neutrophils with abundant bacteria suggest infections.
2. Intracytoplasmic inclusion bodies suggest *Chlamydophila* spp. or *Mycoplasma* spp.
3. Eosinophils (especially if more present than would be seen in a normal peripheral blood smear) and/or mast cells are suggestive of EC.
4. Amorphous, fibrillar hyaline-like material is a common finding in LC.
5. Abundant plasma cells are a prominent feature of PC.

III. Identification of organisms
A. Culture
1. Bacteria: aerobic culture
2. Mycoplasma: requires special media and growth conditions
B. Immunofluorescent antibody testing: herpesvirus and chlamydophilia
1. False positives may occur when fluorescein stain has been used before sample collection.
2. False negative occurs when an adequate sample is not obtained.
C. Polymerase chain reaction: herpesvirus, chlamydial or mycoplasmal agents

IV. Biopsy
A. Reserved for severe or unresolved conjunctivitis
B. Technique
1. Topical ophthalmic anesthetic is applied to the conjunctival surface.
2. Excise the most severely affected tissues with scissors.
3. Stop any bleeding with gentle pressure or application of topical ophthalmic epinephrine or phenylephrine.

Differential Diagnosis

I. Keratitis and corneal ulcers
A. Examine cornea to ensure it is clear and healthy.
B. Stain cornea to rule out ulcers (see Chapter 98).

II. Scleritis
A. Inflammation of the tissue beneath the conjunctiva confirms diagnosis.
B. Moving the conjunctiva across the surface of the inflamed tissue can help to localize it.

III. Uveitis
A. Measure intraocular pressure because it may be low with acute uveitis.
B. Examine the anterior chamber, iris, lens, and fundus for signs of inflammation (see Chapter 99).

IV. Glaucoma
A. Vascular engorgement often accompanies glaucoma.
B. Measure the intraocular pressure because it will be elevated with glaucoma (see Chapter 100).

Treatment

I. Infection (Table 96-1)
A. *Chlamydophila* spp. and *Mycoplasma* spp.: topical ophthalmic chloramphenicol, tetracycline, or erythromycin QID until resolution of clinical signs
B. Gram-positive bacteria: broad-spectrum topical ophthalmic antibiotic agent QID until resolution of clinical signs
C. Herpesvirus
1. Topical antiviral medications
a. Initial treatment must be five or more times daily.
b. Frequency is decreased as the clinical signs regress.
c. Choices include trifluorothymidine, idoxuridine, and vidarabine.
2. Oral L-lysine
a. Dose variable: 250 to 500 mg PO SID to BID
b. Used to decrease clinical signs and prevent recurrence
c. Unproven clinical efficacy
D. Parasites
1. Systemic therapy for the specific condition
2. Topical ophthalmic steroids BID to QID for inflammation (see Table 96-1)

II. Immune-mediated diseases
A. Atopy
1. Isolate and remove the cause, if possible.
2. Rinse eyes with sterile eyewash.
3. Administer topical steroids BID to QID (see Table 96-1).
4. Consider ophthalmic antihistamines (see Table 96-1) BID to QID in place of, or in conjunction with, ophthalmic steroid.
B. Eosinophilic conjunctivitis
1. Ophthalmic steroidal preparations (see Table 96-1)
a. Administer BID to QID depending on severity of the condition.
b. Decrease frequency as the condition improves.
c. Low-level topical steroid therapy (SID, QOD, or once weekly) is often required for life to prevent recurrence.
2. Megestrol acetate
a. Used specifically for EC in the cat.

TABLE 96-1

Medications Available for the Treatment of Conjunctivitis

DRUG	BRAND NAME (MANUFACTURER)	ROUTE	RECOMMENDED DOSE	MECHANISM AND USE
Antiviral Drugs				
Vidarabine (adenine arabinoside)	*Vira-A* (Monarch)	Ointment	5-8 times daily	All three products inhibit viral replication of herpesvirus
Idoxuridine	*Herplex* (Allergan)	Solution	5-8 times daily	
Trifluorothymidine	*Viroptic* (Burroughs Wellcome)	Solution	5-8 times daily	
Topical Steroidal Drugs				
Prednisolone acetate 1% Prednisolone $NaPO_4$ 1% Dexamethasone 0.1% Hydrocortisone 1% Betamethasone 0.1%	Multiple manufacturers	Solution and ointment	BID-QID	These drugs suppress inflammatory responses: EC, LC, PC, atopy, irritative, noninfectious, and nonulcerative conjunctivitis
Antiinflammatory Drugs				
Ketorolac 0.5%	*Acular* (Allergan)	Solution	BID-QID	Inhibits prostaglandin synthesis: atopy
Naphazoline 0.027%/ pheniramine 0.315%	*Opcon-A* (Bausch & Lomb)	Solution	BID-QID	Causes vasoconstriction, antihistamine
Cyclosporine 0.2%	*Optimmune* (Schering)	Ointment	BID	Causes T-cell suppression: LC
Olopatadine 0.1% Ketotifen fumarate 0.025%	*Patanol* (Alcon) *Zaditor* (Ciba Vision)	Solution Solution	BID-TID BID-TID	These drugs are H_1-receptor antagonists, prevent mast cell degeneration
Antibiotic Drugs				
Chloramphenicol 1%	Multiple manufacturers	Solution and ointment	TID-QID	These four drugs are bacteriostatic: *Chlamydophila* spp. and *Mycoplasma* spp.
Erythromycin 0.5%	Multiple manufacturers	Ointment	TID-QID	
Tetracycline	*Achromycin* (Storz/Lederle)	Ointment	TID-QID	
Oxytetracycline-polymyxin	*Terramycin* (Pfizer)	Ointment	BID-TID	
Bacitracin-neomycin-gramicidin and bacitracin-neomycin-polymyxin	Multiple manufacturers	Solution and ointment	TID-QID	Broad-spectrum antibiotic drugs
Antibiotic-Steroid Combinations				
Neomycin-polymyxin-dexamethasone	Multiple manufacturers	Solution and ointment	TID-QID	These drugs are broad-spectrum antibiotic-steroid combinations: prevent infection and inflammation
Bacitracin-neomycin-polymyxin-hydrocortisone	Multiple manufacturers	Ointment	SID-QID	
Gentamicin-betamethasone	*Durafilm* (Schering)	Solution	SID-QID	

EC, Eosinophillic conjunctivitis; *LC,* ligneous conjunctivitis; *PC,* plasmacytic conjunctivitis; H_1, histamine$_1$.

b. Although topical ophthalmic steroidal preparations are effective in the treatment of EC, such preparations may aggravate a concurrent viral infection (Larocca, 2000).
c. The mechanism of action in the resolution of this disease is unknown.
d. Use of megestrol acetate is controversial because of known side effects, including diabetes, adrenocortical suppression, and mammary neoplasia, and is considered a treatment of last resort.

C. Ligneous conjunctivitis (Ramsey et al. 1996)
1. No single therapy is effective in all cases.
2. Surgical debulking of membranes is combined with topical steroid or oral antiinflammatory medications to prevent recurrence.
3. Prednisolone may be given at an initial dose of 2 mg/kg PO SID, then decreased to 0.5 mg/kg PO SID to QOD.
a. Systemic side effects, including hyperadrenocorticism, pancreatitis, and diarrhea, may occur.
b. Low dose of prednisolone may be needed for life to maintain remission of the disease.
4. Azathioprine is given at an initial dose of 2 mg/kg PO SID and then decreased to 0.5 to 1.0 mg/kg PO QOD.
a. This is an immunosuppressive drug, and the dog must be systemically evaluated with a complete blood and platelet count to look for bone marrow suppression, as well as urinalysis to test for secondary infection.
b. Therapy may be needed for the lifetime of the animal to maintain remission of the disease.
5. Topical ophthalmic medications may be tried.
a. Prednisolone 1% BID to TID may be used in conjunction with other therapies.
b. Cyclosporine 2% solution or 0.2% cyclosporine ointment may be used BID in conjunction with other therapies.

D. Plasmacytic conjunctivitis
1. Ophthalmic steroidal preparations (see Table 96-1)
a. Apply these medications BID to QID, depending on severity of clinical signs.
b. Dose is decreased as condition improves.
c. Low level of therapy may be necessary for life to keep the condition from progressing to involve the cornea.
2. Ophthalmic cyclosporine (0.2% to 2.0%) BID alone or in conjunction with topical steroidal preparations
3. Ophthalmic tacrolimus (0.02% to 0.03%) BID alone or in conjunction with topical steroids

III. Irritative conditions
A. Remove or treat the source of the irritation.
B. Use topical steroidal preparations BID to QID until condition is resolved.

IV. Trauma: topical steroidal preparations BID to QID until conjunctivitis is resolved

V. Primary ocular diseases
A. Treat the specific underlying ocular disease.
B. Ophthalmic steroids may be used as needed BID to QID.
C. Treatment of conjunctivitis is not necessary if corneal ulceration (see Chapter 98) is the primary disease.

Monitoring of Animal

I. Monitor the animal biweekly until complete resolution of signs.
II. If clinical signs do not regress or if they return rapidly after discontinuation of therapy, perform a complete ophthalmic examination to ensure other ocular diseases are not present.
III. Chronic conjunctivitis may require a biopsy to rule out uncommon forms of the disease or hidden neoplasia.

Symblepharon

Definition

I. Symblepharon is the development of adhesions between apposing epithelial surfaces.
II. It most often involves the bulbar and palpebral surfaces, but can involve the cornea or the third eyelid (adhering to the cornea and/or eyelid).
III. Cats are affected more frequently than dogs.

Causes

I. Herpesvirus infection in kittens is the most common cause.
II. Conjunctival surface trauma from chemical irritants or severe abrasion may also result in symblepharon.

Pathophysiology

I. Abrasion of the epithelial surface results in fibrosis and adhesion of the conjunctiva to the conjunctiva, eyelids, or the cornea.
II. Adhesion of the conjunctival surfaces may cause damage to lacrimal tissues, with a loss of normal tear function.
III. Normal movement of the eyelids may be impaired.
IV. Vision may be obscured from decreased palpebral fissure size, conjunctival tissue covering the cornea, or secondary keratitis.

Clinical Signs

I. It may appear similar to conjunctivitis.
II. Epiphora or mucopurulent discharge is common.
III. Eyelid movements may be decreased.
IV. Corneal opacification or ulceration may also be present.

Diagnosis

I. Physical examination reveals the conjunctival surfaces are adherent to themselves, the eyelids, or cornea.
II. Apply a topical ophthalmic anesthetic and then use a cotton-tipped applicator to move the conjunctival surfaces.
A. Normal conjunctiva is easily moved in multiple directions.
B. With symblepharon, a loss of tissue mobility occurs.

III. Stain the cornea with fluorescein to identify corneal ulceration, especially if herpesvirus infection is suspected.

Treatment and Monitoring

I. Treat any underlying active condition.
   A. Herpesvirus is treated with antiviral medications.
   B. Chemical irritants are rinsed with copious amounts of sterile eyewash followed by antibiotic agents to prevent secondary bacterial infections and steroidal preparations to decrease further inflammation.
II. Corneal opacities are treated as follows:
   A. Corneal ulcers (stain fluorescein positive) are treated with topical antibiotics QID to prevent secondary bacterial infections (see Chapter 98).
   B. Scars (stain fluorescein negative) may be treated with topical steroids BID to TID to attempt to decrease the opacification.
III. Decreased tear production requires specific therapy.
   A. Topical cyclosporine BID may be beneficial in improving natural tear production and decreasing corneal vascularization.
   B. Artificial tear solutions BID to QID are used to supplement natural tears.
   C. If KCS results in chronic corneal disease, then further treatment may be necessary (see Chapter 97).
IV. Surgical intervention is necessary to break down the adhesions.
   A. Although several techniques have been described, a high rate of readhesion exists (Gelatt and Gelatt, 1994).
   B. Results of surgery are often disappointing.

NEOPLASIA

Definition

I. Primary growth of neoplastic cells in the conjunctiva, third eyelid, or both
II. Invasion of secondary neoplasia
   A. Spread of local neoplasia from adjacent tissues (eyelid or orbit) into the conjunctiva
   B. Metastatic spread of neoplastic cells (rare)
III. Uncommon

Causes

I. Cellular origin of primary neoplasia
   A. Epithelial: squamous cell carcinoma, papilloma
   B. Melanocytic: melanoma, amelanotic melanoma
   C. Vascular: hemangioma, hemangiosarcoma, angiokeratoma
   D. Glandular: adenoma, adenocarcinoma
   E. Round cell origin: histiocytoma, mastocytoma, lymphosarcoma
II. Secondary neoplasia
   A. Adenocarcinoma: local invasion from the lacrimal glands
   B. Melanoma: local invasion from limbal neoplasia
   C. Lymphosarcoma: often multifocal disease

Clinical Signs

I. Appearance of the tissues varies depending on the type of neoplasm.
II. Tumors of the conjunctiva and third eyelid are raised, irregular, and often develop rapidly.
III. Concurrent conjunctivitis may be present.

Diagnosis

I. Cytological examination
   A. After application of proparacaine, a blunt instrument (Kimura spatula or the blunt end of a scalpel blade) is used to scrape the surface several times.
   B. Cells are transferred to a glass slide, dried, and stained.
II. Biopsy under topical anesthesia
III. Excisional biopsy under general anesthesia

Treatment

I. Surgical resection of entire mass with clean margins
II. Diode laser ablation for melanoma
III. Adjunctive therapy
   A. Cryotherapy: squamous cell carcinoma, papilloma, melanoma, adenoma, adenocarcinoma
   B. Radiation therapy: squamous cell carcinoma, melanoma, hemangiosarcoma
   C. Hyperthermia: squamous cell carcinoma
IV. Concurrent treatment of systemic neoplasia
V. Topical antibiotic-steroid combinations TID for 2 weeks to prevent secondary infection and inflammation postoperatively

Monitoring of Animal

I. Reexamine the animal in 2 weeks to ensure proper healing of surgical site.
II. Failure to remove all neoplastic cells may result in local recurrence.
   A. Malignant melanoma
      1. High rate of local recurrence
      2. Guarded to poor prognosis
   B. Papilloma
      1. Self-limiting
      2. Good prognosis
   C. Squamous cell carcinoma
      1. Focal mass: good prognosis
      2. Extensive masses: poor prognosis
   D. Hemangioma and angiokeratoma: good prognosis
   E. Hemangiosarcoma: guarded to poor prognosis unless small and completely excised
   F. Adenoma: good prognosis
   G. Adenocarcinoma: guarded to poor prognosis
   H. Histiocytoma and mastocytoma: good prognosis
III. Metastatic spread of conjunctival neoplasia is rare.
   A. Melanomas may metastasize.
   B. Secondary conjunctival neoplasia may be associated with metastatic disease elsewhere.
IV. Reexamine in 2 to 3 months to ensure no recurrence of the tumor.

CHAPTER 97

Disorders of the Lacrimal and Nasolacrimal System

Robert J. Munger

CONGENITAL/DEVELOPMENTAL DISORDERS

See Table 97-1.

DEGENERATIVE DISORDERS

Keratoconjunctivitis Sicca

Definition

I. Keratoconjunctivitis sicca (KCS) is an ocular surface disorder arising from a deficiency of aqueous tear secretion.
   A. Primary KCS: results from failure of lacrimal secretion
   B. Secondary KCS: results from obstruction of ductules from the lacrimal glands and failure of tears to reach the eye
II. Deficiency of aqueous tears causes desiccation and inflammation of the cornea and conjunctiva.

Causes

I. Primary KCS
   A. Immune-mediated inflammation of the lacrimal glands and the ocular surface
      1. Possible genetic influences and breed-related predisposition
         a. Includes the American cocker spaniel, English bulldog, Lhasa apso, shih tzu, West Highland white terrier, Cavalier King Charles spaniel, and others (Moore, 1999)
         b. Breeds similar to those with atopic disease
      2. Lymphocytic infiltrates in lacrimal glands and conjunctiva
      3. Positive response to topical cyclosporine (T-cell suppressor)
   B. Neurohormonal factors
      1. Age and neutering predispose to KCS.
      2. Spayed females may predominate.
   C. Drug toxicity
      1. Sulfonamides: including trimethoprim and sulfa combinations
      2. Phenazopyridine
      3. Atropine: topical or parenteral (Hollingsworth et al., 1992)
      4. Anesthesia-induced (Herring et al., 2000)
      5. 5-Aminosalicylic acid
      6. Etodolac *(EtoGesic)*
   D. Excision of prolapsed gland of third eyelid
      1. Especially in canine breeds predisposed to KCS
      2. Burmese cats
   E. Neurogenic: decreased secretion associated with loss of parasympathetic stimulus of the lacrimal glands
   F. Trauma
      1. Damage to lacrimal glands or their innervation
      2. Orbital damage or proptosis with exposure of globe
   G. Infectious diseases
      1. Canine distemper virus may affect the lacrimal glands.
      2. Feline herpesvirus 1 is incriminated in most cases of feline KCS, but the mechanism is unclear and may be secondary to scarring of ductules.
   H. Radiation-induced damage to the lacrimal glands
      1. Especially during cancer treatment for neoplasia of the head
      2. Becoming more common with advances in oncology
   I. Congenital alacrima (see Table 97-1)
II. Secondary KCS
   A. Severe and/or chronic conjunctivitis causes scarring and occlusion of the ductules leading from the lacrimal glands to the conjunctival sac.
   B. Causes include infections (bacterial, chlamydial, viral), allergy, and chemical irritation.
   C. Obstruction can be permanent with severe scarring.

Pathophysiology

I. Hypersensitivity and altered ocular surface immunity contribute to inflammation of the ocular surface and lacrimal glands (Kaswan et al, 1985; Bistner, 1994; English, 1999).
   A. Accumulation of lymphocytes in glands and the subepithelial layer of the conjunctiva alters glandular and conjunctival cellular architecture and physiology, thereby adversely affecting lacrimal secretions.
   B. Altered corneal epithelium participates in antigen presentation to T-helper cells and recruitment of immune cells.
   C. Release of inflammatory mediators adds to the process.
      1. Diffuse infiltration of subconjunctival tissues with neutrophils and lymphocytes
      2. Keratitis
         a. Superficial inflammation progressing to deep stromal inflammation

TABLE 97-1

Congenital/Developmental Disorders of the Nasolacrimal System

DISORDER	DEFINITION	CAUSES	CLINICAL FEATURES	DIAGNOSIS	DIFFERENTIAL DIAGNOSIS	TREATMENT
Congenital alacrima	Congenital absence of tearing from lacrimal gland from hypoplasia or agenesis	Breed related: pug, Yorkshire terrier (Aquirre et al., 1971; Grahn, 1999); or anomalous development	Severe drying of ocular surface with corneal scarring/pigmentation, conjunctival hyperemia Copious mucopurulent discharge Usually unilateral	Clinical signs typical of neonatal KCS Confirmed by low Schirmer tear test	KCS from neonatal ophthalmia with secondary damage to lacrimal gland	Tear replacements: lacrimal stimulation not effective Topical antibiotics Parotid duct transposition if salivary production is normal
Lacrimal cysts	Rare, fluid-filled cystic swelling originating from orbital lacrimal gland or nictitans gland	Congenital or developmental defect of the glands or their ductules, or acquired from duct obstruction arising from trauma and/or inflammation Secretory stasis leads to dilated acini and ductules with epithelial atrophy Cyst wall lined with flattened cuboidal epithelium ± inflammation	Soft, fluctuant swelling within orbit or at medial canthus Possible distention of conjunctiva with protrusion into palpebral fissure Possible displacement of globe, third eyelid, and orbital structures Epiphora or impaired secretion of tears may be present	Based on: identification of orbital and/or subconjunctival cyst with orbital ultrasound or MRI	Orbital cellulitis: swelling is usually painful and responsive to antibiotics Orbital neoplasm	Surgical excision usually curative Topical and systemic antibiotics to prevent postoperative infection Monitor tear production with Schimer tear test
Imperforate puncta	Lacrimal punctal aplasia: a congenital absence of the opening of the upper and/or lower lacrimal punctae Usually presents as membrane over the position of the punctum	Genetic or breed related factors: most commonly seen in American cocker spaniel, Bedlington terrier, golden retriever, miniature and toy poodles, and Samoyed (Rubin, 1989)	Epiphora from impaired drainage into NLD with wetting and reddish brown staining of periocular hair Secondary dermatitis with bacterial infection when wetting is severe Stasis of tears in NLD may lead to dacryocystitis Epiphora may be absent if only upper punctum involved	Examination with magnification to visualize site of punctae Failure of fluorescein passage to nares is not diagnostic Flushing nasolacrimal system (19-gauge or smaller canula) usually results in bulging of the membrane occluding the punctum	Epiphora from any impaired drainage: 1. Scarring of punctae or NLD 2. NLD atresia or attenuation 3. Dacryocystitis or acquired obstruction from foreign body or infection 4. Micropunctum or punctal malposition (congenital or with entropion or ectropion)	Surgical opening of punctum: best performed under anesthesia with tenting of the occluding conjunctival veil by NLD flushing or passage of pigtail probe or lacrimal duct probe Topical antibiotic-steroid drops TID-QID for 2-3 weeks

KCS, Keratoconjunctivitis sicca; *MRI,* magnetic resonance imaging; *NLD,* nasolacrimal duct.

TABLE 97-1

Congenital/Developmental Disorders of the Nasolacrimal System—*cont'd*

DISORDER	DEFINITION	CAUSES	CLINICAL FEATURES	DIAGNOSIS	DIFFERENTIAL DIAGNOSIS	TREATMENT
					Diverted drainage or overflow of tears from trichiasis, distichiasis, entropion, shallow or scarred lacrimal lake Excessive lacrimation from ocular disease	Prevent closure by cannulation of duct with monofilament flexible tubing, such as silastic, polyethylene, or polyvinyl tubing (Slatter, 2006b)
Micropunctum	Incomplete development or stricture of the lacrimal punctum	Congenital malformation or cicatricial stenosis	Epiphora and stasis of tear flow, as for imperforate lacrimal punctum	The presence of epiphora and identification of small, punctal opening confirm the diagnosis	As for imperforate lacrimal punctae (see earlier)	Enlarge punctum with punctal dilator or by incision/excision of surrounding conjunctiva and maintain opening with cannulation as described earlier (Grahn, 1999)
Malpositioned punctae and canaliculi	Congenital misplacement of the lower punctum and canaliculus or displacement of the punctum by medial lower lid entropion	Congenital development of the punctum and canaliculus in an abnormal position Displacement occurs commonly in toy and brachycephalic breeds in association with tight medial canthal ligaments and/or medial entropion and trichiasis	May be asymptomatic Chronic epiphora and periocular staining Medial canthal trichiasis may be present	Direct examination of punctal position With medial entropion, eversion of the lid will rotate the punctum into a normal position	Same as for imperforate punctum and micropunctum	None if asymptomatic Cannulation, dissection, and repositioning of the punctum and canaliculus after careful incision and dissection of the surrounding conjunctiva (Grahn, 1999) Correction of medial lower lid entropion

Continued

TABLE 97-1

Congenital/Developmental Disorders of the Nasolacrimal System—*cont'd*

DISORDER	DEFINITION	CAUSES	CLINICAL FEATURES	DIAGNOSIS	DIFFERENTIAL DIAGNOSIS	TREATMENT
Dacryoma	A cyst formed by the accumulation of tears in an obstructed canaliculus or NLD Sometimes confused in the literature with dacryops, which refers to a constant presence of an excess of tears in the eye owing to narrowing of the lacrimal punctum	Embryonic malformation of the canaliculus or NLD can cause obstruction and dilation of the ductular structures Acquired obstruction of NLD or canaliculus may occur secondary to trauma of inflammation	Epiphora varies depending on degree of obstruction Fluctuant medial canthal swelling that may distort the medial canthus Cysts are lined by epithelium	Impaired flow of tears to nares NLD flushing: obstruction varies from none to complete, and cyst swelling may increase if NLD communicates with cyst Skull radiographs may reveal nasal or sinus cavity cysts, bony changes from pressure on adjacent bone, or other primary diseases blocking NLD (e.g., abscessed teeth, foreign body, neoplasm) Positive contrast dacryocystorhinography may reveal ductule abnormalities or communication with sinuses or adjacent cysts Other modalities include ultrasonography and MRI	Structural abnormalities including dacryocystitis, acquired stenosis, adjacent orbital disease (cellulitis, zygomatic mucocele or adenitis, myositis, neoplasia), other congenital anomalies (see earlier) Functional impairment of tear drainage (see earlier) Excessive lacrimation from extraocular or intraocular or irritation	Surgical excision or marsupialization of the cyst is done, with careful dissection from the duct and cannulation if possible during closure to prevent stenosis of the duct; curettage may be adequate if removal is not possible Complications include scarring with permanent obstruction and epiphora, and recurrence of the cyst Creation of new drainage route may be required in the event of scarring (dacryocystorhinostomy or conjunctival buccostomy)

b. Superficial corneal vascularization and pigmentation
c. Neutrophilic and lymphocytic cellular corneal infiltration

II. Loss of lacrimal secretions leads to pathologic changes.
A. Commingling of lipid and mucoid layers of the tear film
1. Hypertonicity of the tear film
2. Accumulation of mucopurulent discharge (worse with chronicity)
B. Altered cleansing, lubrication, and nutrition of the ocular surfaces
1. Accumulation of environmental irritants
2. Accumulation of bacteria and cellular debris
3. Altered gas and nutrient exchange
C. Acute decline in tear production often leading to corneal ulceration and secondary bacterial infection
1. Keratomalacia
2. Descemetocele
3. Corneal perforation

III. Chronicity produces secondary surface changes.
A. Pigmentation and scarring of cornea
B. Conjunctival hypertrophy and goblet cell proliferation
C. Irregular corneal surface and altered wettability

Clinical Signs

I. Acute KCS
A. Blepharospasm, intense conjunctival hyperemia, protrusion of the third eyelid, dull and/or irregular corneal surface
B. Exudates: mucoid to mucopurulent (mild to moderate)
C. Corneal ulceration
1. May progress rapidly to keratomalacia
2. Possible perforation of the cornea, with secondary uveitis
D. Early corneal vascularization: more severe if decline in tear secretion is preceded by other causes of keratoconjunctivitis

II. Chronic KCS
A. Conjunctival hyperemia, thickening (hypertrophy), chemosis
B. Exudates: copious, ropy mucopurulent
1. Yellow to green in color
2. Heavy accumulations in conjunctival sac and on lids: may interfere with lid opening after periods of sleep
3. Often confused with primary infection
C. Corneal changes
1. Corneal vascularization and scarring progressing to corneal opacification (deep and superficial)
2. Corneal pigmentation that progresses with time
3. Irregular corneal surface, ± dried exudates on the surface
4. Corneal ulcers: less common than with acute KCS
D. Decreased vision secondary to severe corneal changes
E. Blepharitis: variable incidence
F. Less ocular pain
G. Lagophthalmos, especially in brachycephalic breeds
H. Cats: clinical signs less severe, little discharge

III. Unilateral versus bilateral disease
A. Usually bilateral
B. Unilateral: particularly in early stages of primary KCS, any time with secondary KCS

IV. Dry nares and nostril (xeromycteria)
A. May occur on affected side(s)
B. Possibly from concurrent involvement of nasal glands (Slatter, 2006b) and/or pterygopalatine nerve damage (Scagliotti, 1999)
C. Dried exudate in nostril, occluding nostril in severe cases

Diagnosis

I. Based on clinical signs
A. Some animals with borderline KCS appear normal.
B. Discharge and ocular irritation warrant Schirmer tear test (STT) evaluation.

II. Schirmer tear test
A. Standard method for quantifying aqueous tear production
B. Normal values
1. Dog: ≥15 mm/min (19.8 ± 5.3 mm/min) (Slatter, 2006a)
2. Cat: 16.9 ± 5.7 mm/min (Slatter, 2006a)
a. Marked variation in tear production depending on stress
b. Interpretation difficult and closely linked to clinical signs
C. Abnormal values
1. Marginal or early subclinical KCS: clinical signs minimal or absent
a. Dog: 11 to 14 mm/min
b. Cat: 5 to 11 mm/min
2. Mild to moderate KCS
a. Dog: 6 to 10 mm/min
b. Cat: 5 to 11 mm/min
3. Severe KCS
a. Dog: <5 mm/min
b. Cat: <5 mm/min
c. Both species: 0 to 2 mm/min, associated with guarded prognosis
D. Technique and materials
1. Commercially available test strips may vary in absorbency.
a. Use same brand for repeated measurements in same animal.
b. Color-impregnated strips are available with calibrations for easy reading of results.
2. Strip is bent at notch and placed over lower lid (preferably laterally).
3. Remove excessive mucopurulent discharge before testing.
4. Perform test before instillation of other solutions or medications (e.g., local anesthetics, mydriatics).
5. Repeated testing is indicated for evaluation of transient versus permanent KCS.

III. Phenol red thread tear test (Brown et al., 1997)

IV. Ancillary testing
  A. Conjunctival bacterial culture and sensitivity testing
  B. Fluorescein staining for erosions and ulceration of cornea
  C. Polymerase chain reaction testing for feline herpesvirus 1
  D. Rose bengal staining
    1. For detection of devitalized epithelial cells
    2. May have a toxic effect on the epithelial cells with repeated use

Differential Diagnosis

I. Primary conjunctivitis and keratoconjunctivitis: allergic, bacterial, viral, traumatic
II. Dacryocystitis
  A. Mucoid to mucopurulent discharge in medial canthus
  B. STT normal
  C. Nasolacrimal duct flushing: discharge flushed from punctae and nares
III. Facial and lid paralysis and lagophthalmos
IV. Trigeminal nerve dysfunction
  A. Low STT from loss of reflex stimulation, without significant conjunctivitis or discharge
  B. Loss of palpebral and corneal blink responses
V. Idiopathic, low STT in cats associated with stress or unknown factors

Treatment

I. Tear replacement and lubrication
  A. Applied pending recovery of normal tear secretion
  B. Designed to replace one or more of the tear film components (mucin, aqueous, and/or lipid layers)
    1. May be combined with electrolytes and other medications
    2. Applied 4 to 12 times daily as needed
    3. Single-dose preparations, preservative free to reduce toxicity to the cornea
  C. Various types of tear replacements (Table 97-2).
II. Tear stimulation
  A. Topical cyclosporine A
    1. Lacrimogenic action incompletely understood
      a. Inhibits T-helper cells in lacrimal tissue
      b. Restores dominance of T-suppressor cells in sustaining normal lacrimal function
      c. Influences prolactin production and neurohormonal control of lacrimal secretion
    2. Antiinflammatory and immunomodulating effects
      a. Decreases cytokine production
      b. Decreases recruitment of immune cells and release of inflammatory mediators
      c. Preserves normal cellular architecture and function of both the lacrimal glands and the ocular surface
    3. Preparations
      a. Cyclosporine 0.2% ointment *(Optimmune)*
      b. Cyclosporine 1% to 2% solution in corn, mineral oil, or medium-chain triglyceride solution
    4. Therapeutic use
      a. Recommended BID (TID in severe cases)
      b. May require 6 to 12 weeks for response, especially in severe cases
      c. Therapy usually lifelong: 85% recurrence when discontinued (Moore, 1999; Slatter, 2006b)
      d. Controlled studies lacking for indications and safety in cats

TABLE 97-2

Types of Tear Replacement Preparations

CLASS	PROPERTIES	ACTION	EXAMPLES
Carboxycellulose and methylcellulose preparations	Water soluble and viscous	Prolonged contact time and increased surface wettability	*Celluvisc, Biovy Tears, Tears Naturale, Refresh*
Polyvinyl alcohol	Less viscous than methylcellulose but good corneal adhesion	Increased adhesion and contact with cornea, with increased wettability	*AKWA Tears, Artificial Tears,* other generics
Prolonged contact polymers (e.g., dextran, polyvinylpyrrolidine, carbopol)	Mucinous	Combined with aqueous preparations to replace mucin and aqueous tears and increase contact time	*Genteal Gel, Refresh Liquigel, Lubrithal*
Viscoelastics (methylcellulose, glycosaminoglycans—sodium hyaluronate and chondroitin sulfate)	Mucinous and viscous	Increase tear viscosity Prolong tear retention Enhance lubrication and comfort Protect corneal surface	*UltraTears, I-Med Plus, Hyoptic, Blink*
Ophthalmic lubricating ointments (petrolatum)	Mimic action of lipids from meibomian glands	Prevent tear evaporation Prolong contact time for medications Sustained release of medication	*Lacrilube, Refresh PM, Genteal PM, Puralube,* other generics

B. Tacrolimus 0.02% to 0.03% ointment or solution BID to TID (Chambers et al., 2002; Berdoulay et al., 2005)
1. Action and efficacy similar to topical cyclosporine
2. Anecdotal reports of efficacy when topical cyclosporine fails

C. Pilocarpine 1% to 2% ophthalmic solution
1. Administration of one to four drops on food PO BID to TID has been used for its parasympathomimetic action on lacrimal glands.
2. Efficacy is questionable; best indication for use is neurogenic KCS (Smith et al., 1994).

III. Antimicrobial therapy to prevent secondary infections

IV. Antiinflammatory therapy
A. Topical corticosteroids and nonsteroidal antiinflammatory drugs
B. Possibly systemic corticosteroids: severe inflammation, allergic keratoconjunctivitis

V. Mucinolytic and anticollagenase therapy
A. Formulations
1. Acetylcysteine 5% to 10% applied topically BID to QID
2. Acetylcysteine added to Severin's KCS solution: artificial tears, pilocarpine, antibiotics (Severin, 1996)

B. Actions
1. Break down and remove excess mucus
2. Anticollagenase activity to prevent enzymatic degradation of the corneal stroma

C. Disadvantages
1. May be irritating, especially with prolonged use
2. Expensive, degrades rapidly

VI. Surgical therapy
A. Parotid duct transposition
1. When tear stimulation fails and tear replacement therapy is inadequate
2. Case selection critical
a. Functional parotid gland and duct must be present; check for adequate salivation.
b. Corneal and conjunctival infection and ulceration must be controlled before surgery.
c. Normal lid structure and function are essential.

B. Punctal occlusion via implants or cauterization
1. Act to retard drainage of tears from lacrimal sac
2. Efficacy in animals unproven
3. Require basal tear production for adequate benefit
4. Cautery of punctae irreversible: last resort therapy

Monitoring of Animal

I. Medical therapy
A. Prognosis after treatment with cyclosporine and tacrolimus
1. Good in dogs when treatment is initiated early (66% to 75% improvement) (Moore, 1999; Slatter, 2001b)
2. Poor when STT is 0 to 2 mm/min, especially if duration prolonged

B. Complications and side effects rare
1. Cyclosporine 2% solution in corn oil can affect systemic cellular immunity (Gilger et al., 1995, 1996).
2. Occasional blepharoconjunctivitis can occur in dogs with either formulation.
3. Compounded corn oil solutions are easily contaminated by bacteria.
4. Compounded tacrolimus has similar complications and side effects to cyclosporine.

II. Surgical therapy: parotid duct transposition
A. Postoperative care
1. Administer topical antibiotic and steroidal medications, ± systemic antibiotic agents.
2. Stimulate salivation frequently with food treats.
3. Monitor for corneal irritation and ulcers from sutures.

B. Postoperative complications
1. Excessive wetting of face and lids from saliva
a. It may lead to bacterial dermatitis and blepharitis.
b. Frequent cleansing helps to reduce bacteria.
c. Possible resolution is achieved with partial ligation of the duct to reduce secretion.
2. Salivary and mineral precipitates on lids and ocular surface
a. Possible irritation, pain, blurred vision
b. Topical 1% disodium ethylenediamine tetraacetic acid (NaEDTA) in artificial tears BID to QID to reduce precipitates
c. Frequent cleansing: possibly as demanding as tear replacement therapy
3. Corneal ulceration with delayed healing

Qualitative Tear Film Abnormalities

Definition

I. Abnormalities in the quality and/or volume of the mucin or lipid layers of the tear film

II. Result in tear film instability with inadequate distribution and adherence of tear film over the cornea despite sufficient aqueous secretion

Causes

I. Lipid abnormalities
A. Inflammation of the meibomian glands and lid margin
1. Marginal blepharitis, blepharoconjunctivitis, and meibomian gland adenitis cause deficient production of lipids and production of abnormal lipids (Moore, 1999; Moore and Collier, 1990).
a. Bacterial infections: *Staphylococcus* spp. most common
b. Yeast infections: *Candida* spp., *Malassezia* spp.
2. Lipid secretions from damaged glands are released into lid tissues, causing further inflammation.

B. Autoimmune diseases affecting lid margins and lipid secretion

C. Generalized seborrhea in dogs, with altered meibomian gland secretions

II. Mucin abnormalities (Moore and Collier, 1990; Davidson and Kuonen, 2004)
A. Loss of conjunctival goblet cells with chronic inflammation from infectious and immune-mediated diseases

B. Severe ulceration and scarring of the conjunctiva with goblet cell loss
C. Vitamin A deficiency, with squamous metaplasia and keratinization of the conjunctiva (experimental)

Pathophysiology

I. Lipid deficiency and lipid abnormalities
  A. Altered distribution of tear film over the eye
  B. Increased evaporation and premature dispersion of aqueous tears
  C. Increased friction between ocular surface and abnormal lid margins during blinking
  D. Corneal and conjunctival toxicity from abnormal lipids and inflammatory products
II. Mucin deficiency
  A. Premature breakup of tear film from altered distribution and binding of tears over cornea
    1. Tear film breakup time is decreased.
    2. Dry spots appear on cornea from a relative deficiency of aqueous tears despite normal production and volume.
  B. Progressively altered conjunctival architecture and differentiation of goblet cells leading to progressive mucin deficiency

Clinical Signs

I. Many similarities regardless of type of abnormality
  A. Keratitis and keratoconjunctivitis with superficial vascularization and scarring of cornea
  B. STT normal unless chronicity has affected lacrimal glands
II. Lipid abnormalities
  A. Hyperemic swollen lid margins with prominent openings of meibomian glands; openings plugged
  B. Lipid granulomas, multiple chalazia
  C. Dried exudates on lids
  D. Perimarginal lid ulceration and fistulation
  E. Corneal epithelial irregularities, ± fluorescein retention
III. Mucin abnormalities
  A. Relative absence of discharge
  B. Corneal ulceration: multifocal erosions or deep ulcers, variable severity and duration
  C. Multifocal corneal desiccation and opacities: lackluster appearance to cornea
  D. Conjunctival thickening

Diagnosis

I. Lipid disorders
  A. Eyelid examination for typical changes
  B. Evaluation of meibomian gland secretions
    1. Culture and sensitivity
    2. Cytology: bacteria, inflammatory cells
    3. Secretions thick, opaque, inspissated, cream-cheese consistency
II. Mucin deficiency
  A. Tear film breakup time
    1. Instill one to two drops of fluorescein in conjunctival sac, blink lids once, then hold lids open to prevent blinking.
    2. Record time from last blink to appearance of first dry (dark) spot in fluorescein film.
    3. Normal is 19 ± 5 seconds.
    4. Irregularity of corneal surface, tractability of the animal, and other factors disrupting the tear film affect reliability.
  B. Conjunctival biopsy to confirm deficiency or absence of goblet cells
    1. Under topical local anesthesia, obtain sample from ventral conjunctival fornix anterior to base of the third eyelid.
    2. Normal ratio of goblet cells to epithelial cells in this area is 0.3.

Differential Diagnosis

I. Keratoconjunctivitis sicca
II. Keratoconjunctivitis: infectious, allergic, traumatic

Treatment

I. Lipid abnormalities
  A. Ocular lubricating ointments: reduce friction between lids and cornea, decrease evaporation of tears
  B. Topical antibiotic/steroid therapy for infection and inflammation (in absence of corneal ulceration), ± systemic antibiotics
  C. Possible surgical curettage of chalazia
  D. Warm compresses and lid washing with soaps formulated for the eye to remove crusts, exudates, and bacteria
  E. Cyclosporine ointment
    1. Petrolatum and corn oil base: lubricates and decreases evaporation of aqueous tears
    2. Stimulates tearing: improves health of ocular surfaces
    3. Antiinflammatory effects
II. Mucin deficiency
  A. Topical artificial tear solutions with mucinous and/or viscoelastic properties
  B. Control of infection and inflammation with topical antibiotic and corticosteroid drugs
  C. Cyclosporine ointment as for lipid abnormalities

Monitoring of Animal

I. Long-term therapy and monitoring are required if permanent loss or impairment of tear film components exists.
II. Reexamine SID to QOD in acute or severe cases (especially with corneal ulceration) until stable.
III. Educate owner regarding importance of treatment compliance in chronic cases.

INFLAMMATORY DISORDERS

Dacryocystitis

Definition and Causes

I. Dacryocystitis is inflammation of the lacrimal sac and nasolacrimal duct.

II. Causes are varied.
  A. Infection
    1. Primary: bacteria (most common), fungi (rare)
    2. Secondary: dental (tooth root abscesses) or nasal diseases
  B. Foreign bodies lodged in nasolacrimal duct: seeds, grass awns, other plant material
  C. Trauma
  D. Stasis of tear flow through duct: stenosis, adhesions, cysts

Pathophysiology

I. Abnormalities of the punctae, canaliculi, and/or nasolacrimal duct (congenital or acquired) impair tear flow and allow microbial proliferation.
II. Foreign bodies provide nidus for infection and inflammation.

Clinical Signs

I. Unilateral or bilateral involvement
II. Epiphora ± medial canthal dermatitis
III. Conjunctivitis: usually mild, ± recurrent
IV. Mucoid to mucopurulent discharge
  A. Discharge accumulates in the medial canthus.
  B. Discharge is expressed from punctae with pressure at medial canthus or after nasolacrimal irrigation.
V. Local pain: especially with medial canthal abscess (rare) or cyst formation

Diagnosis

I. Typical clinical signs
II. Expression or flushing of exudates and/or foreign bodies from punctae
III. Dacryocystorhinography using a positive contrast agent
  A. Demonstrates sites of stenosis and cyst formation; may outline foreign bodies
  B. Recommended in recurrent cases before surgical intervention
IV. Computerized tomography (CT) and magnetic resonance imaging (MRI) (Giuliano et al., 2006)

Differential Diagnosis

I. Keratoconjunctivitis sicca
II. Conjunctivitis
III. Epiphora from functional impairment of drainage, medial canthal excoriation
IV. Dental disease with fistula formation near medial canthus

Treatment

I. Flushing of nasolacrimal duct to remove foreign bodies and improve patency
  A. Sterile saline or water flushed through nasolacrimal cannula
    1. Dogs: 23-gauge lacrimal cannula
    2. Cats: 27-gauge lacrimal or air injection cannula
  B. Occlude opposite punctum while flushing
  C. Retrograde flushing from nose also possible
  D. May require anesthesia
    1. Especially with difficult obstructions requiring repeated flushing to dislodge foreign material
    2. When animal is in pain
  E. Bacterial culture and sensitivity testing on effluent flushed from duct
II. Broad-spectrum topical antibiotic or antibiotic/steroid therapy
  A. Based on results of culture and sensitivity testing
  B. Solutions preferred for optimal access to duct system
  C. Frequent applications (every 4 to 6 hours) for several weeks
III. Systemic antibiotics for nasolacrimal and dental abscesses, severe dermatitis, fistulous tracts
IV. Systemic antifungal therapy when mycotic disease confirmed
V. Indwelling nasolacrimal catheterization (Slatter, 2006b) in recurrent or persistent cases
  A. Polypropylene or nylon sutures (2-0 or 3-0)
  B. Polyethylene, polyvinyl, or silastic tubing
  C. Sutured to skin below medial canthus and near the nares
  D. Left in place for 2 to 3 weeks
VI. Dacryocystotomy to remove foreign bodies or explore lacrimal sac swelling (Grahn, 1999; Slatter, 2006b)
  A. Skin incision over the lacrimal bone and lacrimal sac adjacent to medial canthus and parallel to the lower lid
  B. Incision into the lacrimal sac parallel to the lumen for removal of foreign material and inspissated pus
  C. Silastic tubing cannulation of duct
VII. Dacryocystorhinostomy (Giuliano et al., 2006)
  A. Skin incision (3.5 cm) is made from level of infraorbital foramen dorsocaudally over the lacrimal and maxillary bones toward the medial canthus.
  B. Maxillary bone is exposed with sharp dissection and opened with an air drill.
  C. Nasolacrimal sac is sharply incised and evacuated.
  D. Silicone stent is passed from superior lacrimal punctum to lacrimal sac and into nasal cavity.
  E. Soft tissue and skin are closed over the opened nasolacrimal sac.
VIII. Adjunctive procedures: dental extractions for tooth root abscesses

Monitoring of Animal

I. Repeat nasolacrimal flushing and cytology every 1 to 2 weeks until cytology and/or culture are normal.
II. Continue antimicrobial therapy for 1 to 2 weeks past resolution of clinical signs and demonstration of normal nasolacrimal flushing.
III. Warn owners that recurrences (early or late) are common.

NEOPLASIA

Definition and Causes

I. New and uncontrolled growth of abnormal and/or undifferentiated cells derived from the lacrimal glands

(primary), or by extension or metastasis from other sites (secondary).

II. Primary tumors are as follows:
  A. Lacrimal gland: adenoma, adenocarcinomas (Rebuhn and Edwards, 1977; Wilcock and Peiffer, 1988)
  B. Third eyelid gland (see Chapter 96)

III. Primary neoplasia of the nasolacrimal duct has not been documented, but metastasis from distant sites and by local extension from adjacent sites may compress or obliterate the duct.

Pathophysiology

I. May decrease aqueous tear production
II. May displace globe and/or third eyelid
III. May extend into other orbital structures
IV. Possible local extension of neoplasia from the orbit, nasal cavity, or paranasal sinuses, with compression or invasion of the nasolacrimal duct
V. Increasing incidence with age

Clinical Signs

I. Space-occupying, nonpainful mass of orbit, base of third eyelid
  A. Protrusion of third eyelid and enophthalmos when third eyelid gland involved
  B. Superotemporal swelling when orbital lacrimal gland involved
  C. Exophthalmos with retrobulbar tumors

II. Epiphora from compression of lacrimal lake or nasolacrimal duct by the tumor or globe (exophthalmos)
III. KCS in rare cases
IV. Possible ipsilateral involvement of the nasal cavity
  A. Mucoid, mucopurulent, and/or serosanguinous ocular and nasal discharge
  B. Ipsilateral obstruction of airflow through nasal passage

Diagnosis

I. Suspicious ocular and orbital findings
  A. Evidence of an orbital mass (see Chapter 103)
  B. Firm mass at base of third eyelid
  C. Possible palpable orbital rim abnormalities
  D. Possible enlargement of regional lymph nodes or swelling in oral cavity (especially behind last upper molar)

II. Radiography
  A. Plain radiographs of skull usually normal except with extension to bone
  B. Thoracic radiographs to check for metastasis
  C. Ultrasonography
    1. Depiction of mass: location, size, echogenicity
    2. Guidance of percutaneous biopsy or fine-needle aspiration
  D. CT and MRI: provide best resolution and delineation of mass
  E. Contrast studies for involvement of nasolacrimal duct

III. Biopsy and fine-needle aspirates for histopathology and cytology
IV. Orbital exploration and biopsy when previous tests nondiagnostic

Differential Diagnosis

I. Other causes of orbital neoplasia
II. Granulomatous inflammation of orbit from foreign body, mycotic infection, pseudotumor
  A. Chorioretinal granulomas may be found with systemic mycoses.
  B. Radiolucent foreign bodies may be identified with ultrasonography, CT, or MRI.
  C. Fistulous tracts may be present with foreign bodies.

III. Zygomatic adenitis or mucocele (especially dog and ferret)
IV. Orbital cellulitis
V. Orbital lacrimal cysts

Treatment

I. Early excision (treatment of choice)
  A. Early removal of primary third eyelid adenocarcinomas may be curative.
  B. Neoplasia is one of the rare indications for complete excision of the third eyelid.
  C. Orbital exenteration is indicated when tumor extends beyond the third eyelid or when the orbital lacrimal gland is involved.

II. Adjunctive therapy
  A. Radiation for orbital lacrimal adenocarcinomas
  B. Systemic antibiotics for secondary infections
  C. Systemic antiinflammatory therapy
    1. Palliative therapy to reduce inflammation and swelling around the tumor
    2. Piroxicam 0.3 mg/kg PO SID to QOD in dogs
  D. Topical cyclosporine therapy
    1. KCS is present or anticipated from removal of the lacrimal gland.
    2. Lacrimal gland is in the path of the radiation beam or the target radiation therapy.

Monitoring of Animal

I. Neoplasia of the third eyelid gland (see Chapter 96)
II. Primary lacrimal gland adenocarcinomas
  A. Prognosis is usually poor, because tumor has often extended into the orbit.
  B. Local recurrence is common within 3 to 6 months.

III. Neoplasia involving the nasolacrimal duct
  A. Long-term prognosis is usually poor, because tumors are usually carcinomas or adenocarcinomas extending from the nasal cavity or paranasal sinuses.
  B. Recurrence is common within 6 to 18 months after radiation therapy.

CHAPTER 98

Diseases of the Cornea and Sclera

Ruth Marrion

CONGENITAL DISORDERS

See Table 98-1.

ACQUIRED NONINFLAMMATORY OPACITIES

See Tables 98-2 and 98-3.

INFECTIOUS DISEASES

Feline Herpesvirus Keratitis

Definition and Causes

I. Superficial corneal ulcers caused by infection with feline herpesvirus 1 (FHV)
II. May also produce stromal keratitis without ulceration

Pathophysiology

I. FHV infects cells of corneal and conjunctival epithelium (Nasisse et al., 1989a).
II. Necrosis of corneal epithelium results in superficial corneal ulcers.
   A. Geographic (maplike) corneal ulcers: large, superficial, irregularly shaped areas of ulceration most common
   B. Branching dendritic ulcers: less common
   C. Possibly recurrent from latent infections (Gaskell and Povey, 1979; Gaskell et al., 1985)

Clinical Signs

I. Superficial corneal ulceration in either a geographic or dendritic pattern is a typical finding.
II. Geographic, corneal ulceration appears clinically identical to a canine indolent ulcer, but basement membrane disease does not cause it.
III. Ulcers may be associated with a painful conjunctivitis, producing conjunctival hyperemia and mild chemosis.
IV. Ulcers may become secondarily infected with bacteria and appear identical to other infected ulcers.

Diagnosis

I. Nontraumatic corneal ulcers in a cat are often presumed to be caused by FHV.
II. Polymerase chain reaction (PCR) and virus isolation are the best tests to confirm the presence of FHV.
   A. These tests have a high incidence of false positives and negatives (Maggs et al., 1999).
   B. They are also expensive and not readily available.
III. Immunofluorescent antibody tests are less sensitive than PCR tests.

Differential Diagnosis

I. Ulcers from irritants such as distichia: uncommon in cats
II. Trauma from cat scratches, other exogenous sources
III. Lagophthalmos, medial canthal trichiasis, and entropion in brachycephalic breeds
IV. Dry eye: may be associated with FHV infection

Treatment

I. Antiviral therapy
   A. Antiviral drugs are virustatic and not virucidal; therefore they must be used frequently.
   B. These medications may be toxic to host cells if used long term.
   C. Available drugs cannot eradicate latent infections; therefore owners must be warned of possible recurrences.
II. Specific antiviral medications
   A. Idoxuridine
      1. Not commercially available; may be compounded
      2. Used topically four to six times daily for 1 week past resolution of clinical signs
   B. Trifluridine
      1. Most effective virucidal agent in vitro (Nasisse et al., 1989b)
      2. Commercially available but expensive
      3. May burn or sting upon administration
      4. Used topically four to six times daily for 1 week past resolution of clinical signs
   C. Acyclovir
      1. Dosage: 200 mg PO BID to QID for 2 weeks
      2. *Caution:* not labeled for use in cats; potentially toxic
         a. Check complete blood count and chemistry profile after 1 week of use.
         b. A low incidence of blood dyscrasias and renal problems is associated with this medication.

TABLE 98-1

Congenital Disorders of the Cornea and Sclera

DISORDER	CAUSES	CLINICAL APPEARANCE	DIAGNOSIS	TREATMENT AND PROGNOSIS
Neonatal superficial corneal opacities	Not known; may arise from incomplete development of the corneal epithelium at the time of lid opening or subsequent to metabolic deficiencies of the neonatal cornea	Faint multifocal gray opacities within the superficial cornea, usually in the interpalpebral region	Based on clinical appearance in puppies <4 mo old, the absence of history or signs of prior disease, the absence of pain, and lack of fluorescein uptake	No treatment is indicated; most lesions disappear by 3-6 mo of age
Deep stromal and endothelial opacities	Persistent pupillary membranes (PPMs; see Chapter 99) attach to corneal endothelium, resulting in a gray or pigmented dense plaque; inherited in many dog breeds (e.g., basenji, Australian shepherd dog, Welsh corgi, Yorkshire terrier)	PPMs result in a white, gray, or pigmented opacity usually not involving >25% of the corneal surface	Opacities associated with PPMs often exhibit a strand of tissue originating from the iris collarette	No effective treatment is available Corneal opacities associated with PPMs may appear to get smaller as the eye/cornea grows
	Anterior segment dysgenesis (see Chapter 99) results in disordered development of the mesenchyme destined to form the cornea and anterior uvea; inherited in Doberman pinschers, Saint Bernards (Bergsjo et al., 1984)	Anterior segment dysgenesis may result in a cornea that is focally or diffusely opaque Other abnormalities, including blindness, microphthalmia, glaucoma, and lenticular dysgenesis, may be present	Signs of anterior segment dysgenesis in a young dog	Cases of anterior segment dysgenesis with glaucoma may need enucleation
Dermoid	Breed predisposition in the dachshund, dalmation, Doberman pinscher, German shepherd dog, Saint Bernard; sporadic in other breeds and in cats	An area of the cornea and/or sclera containing tissue covered by keratinized skin, with or without hair	Clinical appearance in a young dog or cat	Superficial keratectomy generally results in resolution; some scarring may remain

D. Famciclovir
   1. Dosage: one fourth of a 125 mg tablet PO BID for 8 days or more
   2. Most information anecdotal (Sapienza, 2002)

E. L-Lysine
   1. Slows replication of the virus by virtue of its chemical similarity to arginine (an amino acid found at high concentration in the virus)
   2. Dosage: 250 to 500 mg PO SID to BID long-term

Bacterial and Fungal Keratitis

Definition

I. Bacterial keratitis: an ulcer that is primarily or secondarily infected with bacteria

II. Fungal keratitis: an ulcer that becomes secondarily infected with fungi (Marlar et al., 1994; Glaze and Gelatt, 1999)

Causes

I. Common bacterial pathogens: *Staphylococcus* spp., *Streptococcus* spp., *Corynebacterium* spp., *Enterococcus* spp., *Pasteurella multocida* (Massa et al., 1999), *Pseudomonas aeruginosa* (Tolar et al., 2006)

II. Fungal pathogens: *Aspergillus* spp. most common (Marlar et al., 1994)

Pathophysiology

I. Usually a primary event results in loss of corneal epithelium (e.g., trauma, exposure, FHV infection).

II. Bacteria or fungi colonize the corneal stroma.

TABLE 98-2

Acquired Noninflammatory Opacities

LESION	CAUSES	CLINICAL SIGNS AND DIAGNOSIS	TREATMENT
Lipid keratopathy	Accumulation of lipid in anterior corneal stroma Inherited (see Table 98-3) Postinflammatory Associated with metabolic diseases causing hypercholesterolemia	White, shiny crystalline infiltrate in superficial corneal stroma Often present as a dense perilimbal infiltrate (arcus lipoides cornea) when associated with hypercholesterolemia and hypothyroidism	None for inherited lipid infiltrates Identify and treat any underlying metabolic disease Lower blood cholesterol with a low-fat diet
Calcium infiltration	Calcium accumulation in the superficial corneal stroma, especially in interpalpebral space May be secondary to chronic keratitis or systemic diseases (e.g., chronic renal disease, hyperadrenocorticism), or following previous corneal trauma	Dense white corneal stromal deposits, often in the axial cornea Disruption of the overlying corneal epithelium may cause chronic and/or recurrent ulceration.	Identify and treat underlying cause, if present Topical 1% NaEDTA solution in artificial tears BID-TID or lubricating ointments may be helpful Superficial keratectomy may be necessary if medical treatment does not alleviate discomfort
Endothelial dystrophies and degenerations	Hereditary endothelial dystrophy: Boston terrier, Chihuahua (Martin and Dice, 1982), Manx cat (Bistner et al., 1976), and domestic shorthair cat (Crispin, 1982) Senile endothelial degeneration Feline bullous keratopathy (Glover et al., 1994)	Endothelial dystrophy: progressive corneal edema that may lead to blindness, corneal bullae and ulceration; occurs in middle-aged to older dogs and as early as 4 mo (Manx) or 3-4 wk (domestic shorthair) in cats Senile endothelial degeneration: appears similar to familial canine endothelial dystrophy Bullous keratopathy: severe corneal edema that may result in bulla formation and subsequent ulceration	Topical hypertonic ointment or solution (5% sodium chloride or 40% glucose) applied 4-6 times daily may reduce bullae formation and subsequent ulceration. Conjunctival flap or thermokeratoplasty may be indicated for cases with recurrent ulceration. Penetrating keratoplasty may be performed for cases of bullous keratopathy or marked opacity.

EDTA, Ethylenediamine tetraacetic acid.

III. Collagenases from bacteria and host leukocytes digest the corneal stroma, resulting in progressively more loss of stroma.
IV. Presence of bacteria stimulates elaboration of inflammatory mediators, resulting in signs of secondary uveitis.
V. Fungal infections are rare and are most likely to occur after use of topical corticosteroid medications, cyclosporine, or antibiotics (Marlar et al., 1994).

Clinical Signs

I. Positive fluorescein stain retention
II. Marked pain with severe epiphora and blepharospasm
III. White stromal infiltrates in area of ulcer from presence of bacteria, leukocytes
IV. Stromal abcessation if epithelialization occurs over the infected area
V. Evidence of secondary uveitis, especially hypopyon
VI. Corneal edema
VII. Peripheral corneal vascularization ("brush border")
VIII. Corneal plaque, ± satellite lesions in cases of fungal keratitis

Diagnosis

I. Cytological examination of corneal scraping
   A. Gram and/or Diff-Quik stain
   B. Bacteria and numerous neutrophils in bacterial keratitis
   C. Fungal elements ± leukocytes in fungal keratitis
II. Aerobic bacterial and fungal culture and sensitivity testing
   A. False-negative culture or cytology occurs in some cases of infected ulcers.
   B. Consider initiating treatment based on finding the previously listed clinical signs.

TABLE 98-3

Canine Corneal Dystrophies

BREED	AGE	LOCATION	APPEARANCE	OTHER DATA
Shetland sheepdog	>4 mo	Epithelial-subepithelial	Multiple small focal spots or rings	Recurrent erosions common; may be associated with distichia, tear film deficiency
Cavalier King Charles spaniel	Any age	Central anterior stroma	Oval gray opacity with "ground glass" appearance	Composed of lipids; no associated systemic disease
Beagle	>3 yr	Central anterior stroma	Solid oval or doughnut-shaped gray opacity	Composed of various lipids; no associated systemic disease
Siberian husky, Samoyed	>6 mo	Anterior, mid, and deep stroma	Gray/tan hazy oval opacity in anterior stroma, or refractile crystals in deep stroma; often clearer centrally	Recessive inheritance; composed of lipids
Airedale terrier	> 6 mo	Starts centrally, progresses toward limbus	Dense milky infiltrate, usually clear at the limbus	Can cause blindness; composed of lipids; no associated systemic disease
American cocker spaniel	>1 yr	Endothelium, Descemet's membrane	Multifocal gray spots, patches, or streaks	May be dominant genetic trait; no associated corneal edema
Boston terrier, Chihuahua	> 5 yr	Starts temporally, progresses nasally	Gray reticulated opacity typical of corneal edema	Severe edema may result in corneal bullae and/or recurrent erosions

From Kirschner SE: Diseases of the cornea and sclera. p. 1007. In Morgan RV (ed): Handbook of Small Animal Practice. 3rd Ed. WB Saunders, Philadelphia, 1997; with permission.

Differential Diagnosis

I. Traumatic, aseptic ulcers
II. Persistent erosions
III. Viral-induced ulcers

Treatment

I. Hospitalization is recommended for the following reasons:
   A. Facilitates frequent application of medications
   B. Allows frequent reevaluation of cornea
   C. Allows rapid surgical intervention as needed
II. Apply topical antibiotic solutions every 2 to 4 hours.
   A. Variety of products are available.
   B. Most isolates are sensitive to ciprofloxacin or a combination of a cephalosporin and tobramycin (Tolar et al., 2006), but topical cephalosporin is not available commercially.
III. Administer topical autologous serum every 2 to 4 hours.
   A. Serum contains numerous protease inhibitors, including α_2-macroglobulin, the universal protease inhibitor (Berman et al., 1975).
   B. Acetylcysteine is an alternative but is expensive and may not be readily available.
IV. Topical atropine is given to effect (every 2 to 4 hours).
   A. Solutions may cause profuse salivation in cats, so consider use of an ointment.
   B. Solutions are preferred for deep stromal lesions.
V. Systemic nonsteroidal antiinflammatory agents are used in dogs for treatment of secondary uveitis.
   A. Aspirin 10 mg/kg PO BID
   B. Carprofen 2 mg/kg PO BID
VI. Systemic antimicrobials are indicated, especially if a penetrating wound is noted or suspected.
   A. Presence of hypopyon does not confirm bacterial endophthalmitis because the hypopyon is generally sterile.
   B. Consider use of amoxicillin 22 mg/kg PO BID.
VII. Subconjunctival antibiotics may be helpful.
   A. Amikacin 25 to 125 mg
   B. Ampicillin 50 to 100 mg
   C. Cefazolin 100 mg
   D. Gentamicin 20 to 40 mg
VIII. Antifungal agents are indicated for fungal keratitis.
   A. Natamycin is the only drug currently approved for ocular use and is effective but expensive.
   B. Nystatin is fungistatic, not fungicidal, and is made by mixing 50,000 U soluble powder in 1 mL saline.
   C. Intravenous fluconazole or miconazole may be used topically.
   D. Itraconazole 1% in dimethyl sulfoxide has been used in horses (Ball et al., 1997).
   E. Miconazole vaginal cream and silver sulfadiazine cream have also been used in horses.
IX. Surgery (placement of a conjunctival flap, corneoscleral transposition, or corneal lamellar graft) is indicated in the following circumstances:
   A. Descemetoceles
   B. Deep stromal ulcers
   C. Rapidly progressive ulcers

Monitoring of Animal

I. Monitor for improvement in clinical signs.
   A. Depth of ulcer
   B. Secondary uveitis: degree of miosis, aqueous flare, hypopyon
II. Consider changing antibiotics and/or increasing frequency of application if signs worsen.
III. Consider surgical intervention if signs worsen.

INFLAMMATORY DISORDERS

Corneal Ulceration

Definition

I. Superficial erosion is a loss of the corneal epithelium only.
II. Stromal ulceration involves loss of both the epithelium and some portion of stroma.
III. With a descemetocele, stroma is lost down to Descemet's membrane.
IV. Perforation is a wound in Descemet's membrane, with leakage of aqueous humor and/or iris prolapse.

Causes

I. Trauma
   A. External sources: cat scratch, foreign body, others
   B. Eyelid disease: distichiasis, ectopic cilia, entropion
II. Tear film disease
   A. Keratoconjunctivitis sicca (KCS)
   B. Goblet cell deficiency
   C. Lipid tear film abnormality from meibomian gland pathology (Moore, 1999)
III. Lagophthalmos
   A. Macropalpebral fissure
   B. Exophthalmos: pathologic or conformational
   C. Buphthalmos
   D. Decreased blink frequency
      1. It may occur from corneal denervation after trigeminal nerve injury.
      2. Brachycephalic dogs have relatively few corneal nerves and often an incomplete blink.
   E. Palpebral nerve palsy
IV. Infections
   A. Bacterial (Tolar et al., 2006; see previous discussion)
   B. Fungal: aspergillosis (Marlar et al., 1994; see previous discussion)
   C. Viral: FHV (see previous discussion)
      1. Infection may be primary or may be a recurrence of latent infection.
      2. Infection may be more common in immunosuppressed or stressed cats.
V. Thermal or chemical burns
   A. Detergent agents
   B. Acids
   C. Alkaline agents
VI. Immune-mediated disease: marginal keratitis (Parshall and Kellum, 1987)
VII. Secondary to other corneal disease
   A. Calcium infiltrates
   B. Edema (especially bullous keratopathy)
   C. Corneal epithelial basement membrane disorder

Pathophysiology

I. One of the causative events results in damage to the corneal epithelium, with focal or widespread loss.
II. In some cases, corneal stroma is lost as well.
III. Epithelial cell mitosis and migration occur, covering the wound in several days.
IV. Continued presence of an inciting cause (e.g., trauma, lagophthalmos) or a secondary factor (e.g., basement membrane disease, secondary bacterial infection, FHV infection) may prevent healing.

Clinical Signs

I. Superficial erosions
   A. Blepharospasm
   B. Epiphora
   C. Congestion of conjunctival vessels
   D. Miosis in some cases
II. Stromal ulcers
   A. All of the signs of superficial erosions
   B. Visible defect in the stroma
   C. Mucopurulent discharge
   D. Aqueous flare, with or without hypopyon
   E. Perilimbal vascularization (brush border)
III. Descemetoceles
   A. All the signs of stromal ulcers are usually present.
   B. Exposed Descemet's membrane is smooth and clear, not edematous like stroma, does not retain fluorescein stain.
IV. Perforated corneal ulcers
   A. All the signs of descemetoceles, plus intense blepharospasm
   B. Fibrin or pigmented mass (iris prolapse) in the ulcer bed
   C. Possibly fluid leaking from the wound
V. Herpesvirus keratitis
   A. Young kittens
      1. Signs of upper respiratory infection
      2. Ocular discharge associated with corneal ulceration
   B. Adult cats
      1. Signs of upper respiratory infection are rarely seen.
      2. Very small epithelial linear or dendritic lesions, or erosions and ulcers of any size and shape may be found.
      3. Secondary KCS may be present.

Diagnosis

I. Stain the cornea with fluorescein to determine the presence of an ulcer (Descemet's membrane will not stain).
II. Test palpebral nerve function and ability to blink completely.
III. Perform a Schirmer tear test (STT) unless obvious epiphora is present.

IV. Carefully examine the adnexa to determine whether the ulcer is from an endogenous or exogenous irritant.

Differential Diagnosis

I. Anterior uveitis may also cause pain, epiphora, miosis, and congestion of episcleral vessels; however, a fluorescein dye test is negative.
II. Glaucoma may cause pain, epiphora, and episcleral vessel congestion; however, the pupil is usually dilated, unresponsive.
  A. Lack of normal menace reflex occurs.
  B. The fluorescein dye test is negative.
III. Entropion, distichiasis, and ectopic cilia may cause pain, epiphora, and conjunctival hyperemia, with or without a concurrent corneal erosion or ulcer.
IV. KCS or conjunctivitis may cause pain and conjunctival hyperemia.
  A. Epiphora is not present in cases of KCS, and the STT is abnormally low.
  B. Fluorescein dye test is negative.

Treatment

I. Topical antibiotics
  A. Apply TID to QID for superficial erosions, 4 to 12 times a day for stromal ulcers.
  B. Stromal ulcers are treated with antibiotics that are bactericidal and broad spectrum.
  C. Neomycin is used with caution in cats because of the potential for anaphylactic reactions (Plunkett, 2000).
  D. Fluoroquinolones and tobramycin should *not* be used prophylactically but are reserved for rapidly progressive ulcers, as discussed previously.
II. Topical atropine
  A. Give to effect.
  B. Usually SID to QID is sufficient, but some cases require a higher frequency.
  C. Also indicated for anterior uveal inflammation as manifested by miosis, aqueous flare, and hypopyon.
III. Systemic nonsteroidal antiinflammatory agents in dogs
  A. Indicated if uveitis is present
  B. Aspirin 10 mg/kg PO BID
  C. Carprofen 2 mg/kg PO BID
IV. Systemic antibiotic medications
  A. Indicated for corneal perforations
  B. Amoxicillin 22 mg/kg PO BID
V. Contact lenses
  A. Soft contact lenses are indicated for superficial nonhealing erosions and are contraindicated in infected corneal ulcers.
  B. Collagen contact lenses can be rehydrated in topical antibiotic solution and used in infected corneal ulcers (last 24 to 72 hours).
VI. Surgical therapy (Table 98-4)
  A. Third eyelid flaps
    1. Useful to protect ulcers secondary to lagophthalmos, decreased blink frequency, poor lid conformation, and KCS
    2. Contraindicated in rapidly progressive ulcers because they prevent monitoring of the condition
  B. Conjunctival flaps
    1. They are indicated for descemetoceles or for deep stromal ulcers.
    2. They act as a graft with an intact blood supply rather than a bandaging effect.
    3. The graft is cut at the base 6 to 8 weeks after surgery to interrupt blood supply and reduce scarring.
  C. Primary closure
    1. It is used for descemetoceles and for ruptured corneal ulcers <2 to 3 mm in diameter.
    2. If performed in larger wounds, it may distort the cornea excessively.
  D. Corneoscleral transposition and lamellar grafts (Brightman et al., 1989)
    1. Used for closure of descemetoceles and perforated corneal ulcers too large to close primarily
    2. Require adjacent healthy cornea to transpose
  E. Swine intestinal submucosa (SIS) (Bussieres et al., 2004)
    1. Has been used for perforated ulcers, deep stromal ulcers, and corneal abscesses
    2. Requires adjacent healthy cornea to which to suture
VII. Therapy of FHV (see previous discussion)
VIII. Therapy of bacterial fungal ulcers (see previous discussion)
IX. Therapy of persistent erosions (see following section)

Monitoring of Animal

I. Recheck visits are important.
  A. Superficial erosions: in 5 to 7 days
  B. Stromal ulcers: every 2 to 3 days until reepithelialized or until no purulent discharge is seen
II. Watch for signs of infection (change from epiphora to purulent discharge, increased depth of the lesion).
  A. Culture the wound.
  B. Increase antibiotic frequency and/or change antibiotics.
  C. Consider surgical intervention.
III. If not healed in 1 to 2 weeks, then a thorough ocular examination is repeated to rule out any previously undiagnosed cause.
IV. Postoperative rechecks are scheduled every 2 to 3 days for a week, then every 1 to 2 weeks until the cornea is healed.
V. Herpesvirus keratitis is controllable but not curable; periodic flare-ups are common.

Persistent Corneal Erosions

Definition

I. A corneal ulcer that does not heal within 2 weeks despite appropriate treatment
II. Also known as *nonhealing ulcer, indolent ulcer, boxer ulcer,* and *spontaneous chronic corneal epithelial defect* (SCCED)

TABLE 98-4

Surgical Therapies for Corneal Ulcers

SURGERY	INDICATIONS	CONTRAINDICATIONS	TECHNIQUE	REFERENCE
Third eyelid flap	Ulcers associated with exposure keratitis or KCS	Rapidly progressive ulcers	Use mattress pattern to suture third eyelid to superior bulbar conjunctiva or to upper lid.	Slatter (1990)
Conjunctival flap	Descemetoceles, deep stromal ulcers, rapidly progressive ulcers	Corneal perforations in which the anterior chamber is difficult to maintain (must use additional means of corneal support)	Use tenotomy scissors to dissect thin flap (pedicle, bridge, 180°, 360°) of conjunctiva from the limbus, based in the fornix. Suture to ulcer wall (pedicle flap), to normal cornea (bridge or 180° flap), or to conjunctiva (360° flap) using 6-0 to 8-0 suture. Reform anterior chamber if necessary.	Hakanson and Merideth (1987)
Corneoscleral transposition, corneal lamellar graft	Descemetoceles, deep stromal ulcers, perforated ulcers	No normal cornea exists	Make partial-thickness corneal flap, free lamellar graft, or corneal flap attached to conjunctival pedicle flap, using a scalpel blade (cornea) and tenotomy scissors (conjunctiva). Slide the prepared graft over the defect and suture in place with 7-0 or 8-0 absorbable suture, thus sealing the wound. Reform the anterior chamber if necessary.	Slatter (1990), Brightman et al. (1989)
SIS graft	Descemetoceles, deep stromal ulcers, perforated ulcers	No normal cornea to which to suture SIS	Use punch biopsy to prepare graft 2.0 mm wider than recipient bed. Rehydrate graft in sterile saline and suture graft onto defect using 8-0 to 10-0 absorbable suture.	Featherstone et al. (2001), Bussieres et al. (2004)
Primary closure	Small decemetoceles and perforations (<3 mm)	Large defects	Close with simple interrupted or mattress sutures of 7-0 to 8-0 absorbable material. Reform anterior chamber if necessary.	Slatter (1990)

KCS, Keratoconjunctivitis sicca; *SIS,* swine intestinal submucosa.

Causes and Pathophysiology

I. Ulcer does not heal because of inadequate adhesion between the corneal epithelium and the stroma (Kirschner et al., 1989).
II. Defects in the epithelial basement membrane are present in some cases.
  A. The basement membrane is thickened and misshapen.
  B. Hemidesmosomes are decreased in number.
  C. An acellular, hyalinized zone may be present in superficial stroma (Bentley, 2005).
III. Endothelial disease is causative in some cases.
  A. Endothelial disease results in stromal edema, and subsequently in epithelial cell and intercellular edema.
  B. Corneal epithelial cells are unable to adhere and migrate normally.

Clinical Signs

I. Occur in middle-aged to older dogs
II. Epiphora, conjunctival hyperemia, variable blepharospasm
III. Superficial erosion with no stromal loss
IV. Pathognomonic: loose epithelium that is easily debrided from the edge of the ulcer
V. Possibly corneal vascularization
VI. Possibly corneal edema
  A. Localized if basement membrane disease is underlying cause
  B. Generalized if endothelial disease is present

Diagnosis

I. Presence of a superficial erosion with loose epithelial margins
II. Exclusion of other causes of corneal erosions

Differential Diagnosis

I. Determine if other causes of corneal ulceration are present, such as trauma, entropion, lagophthalmos, KCS, distichiasis, ectopic cilia.
II. Corneal ulcers caused by FHV appear clinically similar, and indolent erosions from basement membrane disease have not been documented in cats.

Treatment

I. Initial treatment
  A. Debridement is essential.
    1. Under topical anesthesia ± sedation, all loose epithelium is carefully removed with a sterile cotton swab, spatula, or scalpel blade.
    2. This procedure may result in removal of the entire corneal epithelium.
  B. Topical antibiotics are used BID to QID.
  C. Topical atropine is used to effect for blepharospasm and anterior uveitis (miosis, photophobia).
  D. Elizabethan collars are used in all cases.
  E. Many erosions heal within several weeks using this therapeutic regimen.
II. Ancillary therapies
  A. Used if debridement does not result in healing of the ulcer
  B. Superficial punctate keratotomy (Champagne and Munger, 1992)
    1. Debride all loose epithelium as described previously.
    2. Create a series of shallow punctures in the anterior corneal stroma, using a 22- to 25-gauge needle.
    3. Perform the punctures in the ulcerated area and the surrounding normal cornea.
    4. Nearly 90% of persistent erosions heal within 2 weeks of this procedure.
  C. Grid keratotomy (Stanley et al., 1998)
    1. Debride all loose epithelium.
    2. Create a crosshatch pattern in the anterior corneal stroma, using a 22- to 25-gauge needle.
    3. Perform the keratotomy starting in normal cornea, then extending into the ulcerated area and back into normal cornea.
    4. More than 80% of persistent erosions heal within 2 weeks of this procedure.
  D. Superficial stromal keratectomy (Stanley et al., 1998)
  E. Soft contact lenses
    1. They may be applied after debridement, keratotomy, or keratectomy.
    2. Lenses are left in place for 2 to 6 weeks.
  F. Third eyelid flap
    1. Provides a bandage over the cornea
    2. May be placed after debridement, keratotomy, or superficial keratectomy
  G. Hypertonic ophthalmic solutions and ointments
    1. Dose: 5% sodium chloride (NaCl) or 40% glucose SID to TID
    2. Indicated if edema is present
  H. Collagen shields
    1. Provide short-term protection (3 days)
    2. Questionable benefit for indolent ulcers
  I. Chondroitin sulfate and antibiotic solutions (Ledbetter et al., 2006)
    1. Chondroitin sulfate 100 mg/mL and tobramycin 3 mg/mL TID to QID
    2. Chondroitin sulfate 100 mg/mL and ciprofloxacin 3 mg/mL TID to QID
    3. Chondroitin sulfate solutions: possibly beneficial after debridement
  J. Thermokeratoplasty for refracting ulcers in edematous corneas

Monitoring of Animal

I. Recheck 7 to 14 days or sooner if additional signs occur.
II. If not healed in 2 weeks, consider an additional therapy as outlined previously.
III. Many erosions associated with basement membrane disorders heal within 2 to 4 weeks with debridement, application of an Elizabethan collar, and contact lens placement.
IV. Cases with corneal edema or extensive granulation tissue are more refractory.
  A. Ancillary therapy may be needed.
  B. Some cases take ≥10 weeks to heal.

Pannus

Definition

I. Pannus is infiltration of the cornea with lymphocytes, plasma cells, neutrophils, melanocytes, and granulation tissue.
II. It is also known as *chronic superficial keratitis* or *Uberreiter's syndrome*.
III. Atypical pannus, or plasmoma, is a variation of pannus involving the third eyelid (see Plasmacytic Conjunctivitis in Chapter 96).

Causes and Pathophysiology

I. Thought to be immune-mediated
II. Breed predisposition
  A. German shepherd dog (primarily)
  B. Other herding dogs: Belgian Tervuren, border collie, Australian shepherd dog
  C. Golden retriever, greyhound, rottweiler
III. Exacerbated by ultraviolet radiation and pollution (Chavkin et al., 1994)

Clinical Signs

I. A red to grey, irregular infiltrate begins in the inferotemporal and inferonasal cornea.
II. The infiltrate may cover the entire cornea in severe cases.
III. Melanin often accompanies the infiltrate.
IV. The lesion is usually fluorescein negative.
V. Redness, irregular thickening, and focal depigmentation of the third eyelid often occurs.
VI. The condition is often bilaterally symmetrical.

Diagnosis

I. Diagnosis is based primarily on clinical signs, especially in a predisposed breed.

II. Conjunctival or corneal scrapings demonstrating lymphocytes, plasma cells, and neutrophils are confirmatory.
III. Rule out the presence of other ocular diseases with a thorough ocular examination.

Differential Diagnosis

I. Corneal granulation tissue: history of prior trauma, ± obvious cause
II. Pigmentary keratitis: usually in brachycephalic breeds or dogs with underlying eyelid or tear film disease, absence of inflammatory corneal infiltrate
III. Corneal squamous cell carcinoma (SCC): rare in dogs, may be ulcerative, usually unilateral

Treatment

I. Topical corticosteroid medications
   A. Initially, 0.1% dexamethasone or 1% prednisolone acetate is used.
   B. Frequency is based on the severity of the disease (i.e., from once daily in mild cases to six to eight times daily in severe cases).
II. Topical cyclosporine (Williams et al., 1995)
   A. Commercially available 0.2% ointment BID
   B. Used in conjunction with topical steroidal medications
   C. Effective in cases with nictitans involvement (Read, 1995)
III. Subconjunctival corticosteroid medications for severe or refractory cases
   A. Betamethasone 1 to 2 mg
   B. Triamcinolone 4 to 8 mg
   C. Methylprednisolone acetate 4 to 8 mg
IV. Beta radiation and cryosurgery for severe cases (Rickards, 1980; Whitley, 1991)

Monitoring of Animal

I. Warn owners of chronicity and need for lifelong therapy.
II. Exacerbation of signs may occur in the summer or winter.
   A. Frequency of topical steroid treatment may need to be increased to up to six to eight times daily.
   B. Topical cyclosporine ointment may be added to treatment regimen as needed.
   C. Consider subconjunctival steroidal agents for refractory cases.
III. Schedule rechecks every 3 to 4 months, especially in the summer months.

Pigmentary Keratitis

Definition and Causes

I. Accumulation of melanin pigment in the corneal stroma
II. Result of chronic irritation of the cornea
   A. Distichia or trichiasis hairs
   B. Exposure of cornea from lagophthalmos
   C. Keratoconjunctivitis sicca
   D. Exophthalmos
   E. Buphthalmos
   F. Macropalpebral fissure
   G. Decreased blink frequency
   H. Palpebral nerve palsy

Pathophysiology

I. Pigment is produced in the corneal epithelium and superficial stroma in response to chronic irritation.
II. Pigment is often associated with keratitis and vascularization.

Clinical Signs

I. Corneal pigmentation is present and may be accompanied by vascularization.
II. It is not associated with corneal ulceration.
III. In severe cases, dogs are visually impaired from the corneal opacity.
IV. Corneal melanosis is most common in the Pekingese, pug, and other brachycephalic breeds.

Diagnosis

I. Appearance is diagnostic.
II. Location of pigment is often indicative of the source of chronic irritation.
   A. Exposure keratopathy from lagophthalmos results in central horizontal pigmentation.
   B. Irritation from medial canthal or nasal fold trichiasis results in pigmentation of nasal cornea.
III. Thorough ocular examination is performed with emphasis on the following:
   A. Blink frequency (normal, four blinks per minute)
   B. Ability to completely close the lids
   C. Presence of entropion, trichiasis, distichiasis
   D. STT results
   E. Tear film breakup time (normal, 19 ± 5 seconds)

Differential Diagnosis

I. Corneal lamellar scarring and fibrosis
II. Corneal/scleral melanoma

Treatment

I. Correct the underlying contributing cause.
   A. Administer topical cyclosporine BID for KCS.
   B. Topical tacrolimus BID may be more effective than cyclosporine for KCS (Berdoulay et al., 2005).
   C. Protect the cornea with topical lubricants BID to QID indefinitely.
   D. Surgically correct any eyelid abnormalities, and consider performing a medial canthoplasty to narrow the palpebral fissure.
II. Cyclosporine may decrease the amount of corneal pigment.
III. Surgical removal is generally not indicated because an exaggerated inflammatory response occurs postoperatively, with a rapid return of pigment.

Monitoring of Animal

I. Reexamine the animal every 3 to 6 months.
II. If pigmentation progresses, then increase the frequency of medical treatment, reevaluate the underlying cause, and perform a medial canthoplasty.

III. Eventual success of treatment is dependent on correction of the underlying cause; often the condition is incurable, only controllable.
IV. Because long-term topical corticosteroids suppress the adrenocortical axis and carry the risk of corneal ulceration, they must be used cautiously.

Feline Eosinophilic Keratitis

Definition

I. It is an infiltrative disease of the feline cornea, characterized by the presence of lymphocytes, plasma cells, eosinophils, and sometimes neutrophils and mast cells.
II. It may be unilateral or bilateral.

Causes

I. The exact cause of this disorder is unknown.
II. Many affected cats have concurrent FHV infection (Nasisse et al., 1996).
III. The relationship of eosinophilic keratitis to feline dermatologic eosinophilic granuloma complex is unknown.

Clinical Signs

I. Elevated pink or white vascularized lesions occur on the corneal surface, most often located temporally.
II. Often a yellow-white, caseous exudate clings to the surface of the lesion.
III. The condition is often nonpainful, but mild blepharospasm and mucoid discharge may be seen, particularly if the eyelids are abraded or the cornea is ulcerated.
IV. Fluorescein dye tests may reveal patchy ulceration of the surface of the lesion or of the adjacent cornea.

Diagnosis

I. Diagnosis is based on the presence of eosinophils or mast cells in corneal or conjunctival scrapings.
II. In a proliferative variant of the disease, scrapings reveal only lymphocytes or plasma cells.
III. Consider testing for FHV infection.

Differential Diagnosis

I. Feline herpesvirus stromal keratitis
II. Corneal granulation tissue secondary to prior corneal disease
III. Chronic corneal ulceration
IV. Limbal SCC

Treatment

I. Institute therapy with topical corticosteroid medications.
   A. Apply topical dexamethasone or prednisolone acetate two to six times a day until the cornea becomes clear, then as needed to prevent recurrence.
   B. In severe cases, consider subconjunctival corticosteroid administration (see Pannus).
II. Topical antiviral medications are administered for concurrent herpesvirus infection.
III. In refractory cases, consider the following drugs:
   A. Prednisone 5 to 10 mg/day PO for 7 to 14 days
   B. Megestrol acetate 0.5 mg/kg PO SID for up to 2 weeks, then as needed; used with caution and close monitoring for diabetes mellitus

Monitoring of Animal

I. Eosinophilic keratitis is often an incurable condition (only controllable).
II. Recheck the cat every 2 weeks until the cornea is clear, then every 2 to 3 months to monitor for recurrence.
III. If lesions return, then reinitiate or increase the frequency of therapy.

Feline Corneal Sequestration

Definition

I. Coagulative necrosis of the corneal stroma
II. Characteristic brown to black corneal lesion

Causes

I. The cause is multifactorial.
   A. Following corneal ulceration
   B. Secondary to corneal irritation
II. FHV is a potential underlying cause.

Pathophysiology

I. Sequestrum formation is initiated by damage to the cornea.
II. Sequestra occur in areas of chronic corneal ulceration and irritation.
III. Pigment may be absorbed from the tear film by exposed corneal stroma; this may be melanin (Featherstone et al., 2004).

Clinical Signs

I. Brown or black lesion in the cornea, often round and located in the axial cornea
II. May be associated with corneal edema and vascularization
III. Possible corneal ulceration
IV. Possible pain and ocular discharge

Diagnosis

I. Clinical appearance in a cat is diagnostic.
II. Samples may be submitted for detection of herpesvirus via culture or PCR assay; however, false positives and negatives are common (Maggs et al., 1999).
III. Assess tear function with a STT.
IV. Determine if eyelid conformation is a contributing factor.
   A. Brachycephalic cats may be lagophthalmic.
   B. Entropion may be present as a primary or secondary condition.

Differential Diagnosis

I. Pigmentary keratitis (rare in cats)
II. Corneal foreign body
III. Corneal ulceration

Treatment

I. Topical antibiotics are indicated if active ulceration is present.
   A. Use medications TID to QID.
   B. Neomycin-polymyxin-bacitracin ointment is used with caution in cats because it has been associated with fatal anaphylactic reactions (Plunkett, 2000).
II. Antiviral treatment is indicated if FHV is suspected as an underlying cause (see Feline Herpesvirus Keratitis).
III. Some lesions may be superficial and may be manually debrided or slough off of their own accord.
IV. Lubricating ointments may help decrease discomfort.
V. Surgery to remove the sequestrum is considered if the cat is painful or if the lesion persists and enlarges (Whitley, 1989).
   A. Superficial keratectomy is performed to remove the abnormal portion of the cornea.
   B. Adjunctive surgical therapies may be performed to protect the cornea after keratectomy.
      1. Conjunctival graft (Blogg et al., 1989)
      2. Corneoscleral transposition (Andrew et al., 2001)
      3. SIS graft (Featherstone et al., 2001)
      4. Third eyelid flap or contact lens (Morgan, 1994)
VI. Goals of postoperative care are to prevent infection, relieve pain, and prevent recurrence.
   A. Topical antibiotic medications TID to QID
   B. Atropine to effect (usually SID to BID)
   C. Lubricants as needed if tear production is decreased

Monitoring of Animal

I. Schedule recheck examinations every 3 to 4 weeks if surgery is not performed.
   A. The sequestrum may slough of its own accord.
   B. Watch for development of ulcers and treat with topical antibiotics as outlined previously.
II. Correct and/or treat and monitor any underlying problems.
   A. Long-term lubricants may be indicated, especially in brachycephalic, lagophthalmic cats.
   B. Entropion and other conformational problems are corrected if present.
III. Monitor for recurrences and development of new sequestra.
   A. Recurrence develops in a few cases after keratectomy (Morgan, 1994).
   B. Sequestrum formation may also occur in the fellow eye.

Episcleritis

Definition

I. Inflammation of the episcleral tissue ± involvement of the adjacent cornea
II. Occurs in focal and diffuse forms in the dog
III. Also known as *nodular fasciitis, nodular granulomatous episclerokeratitis,* and *fibrous histiocytoma* when a focal mass is produced

Causes and Pathophysiology

I. Idiopathic; possibly immune mediated
II. Proliferation of histiocytes, fibroblasts, lymphocytes, and plasma cells
III. Collies predisposed

Clinical Signs

I. Focal episcleritis
   A. This form is seen in collies, collie-like dogs, and a wide variety of breeds.
   B. Smooth, raised, red to white masses generally occur at the temporal limbus.
   C. Lesions are occasionally found in the conjunctiva, external eyelids, third eyelid, and oral gingiva.
II. Diffuse episcleritis
   A. This variation is most often seen in American cocker spaniels, Airedale terriers, and rottweilers (Slatter, 1990).
   B. Episcleral tissue is diffusely thickened and hyperemic.
   C. The temporal limbus is most often involved.
III. Signs common to both forms
   A. Episcleritis is characterized by lack of pain and ocular discharge.
   B. Corneal edema and vascularization may accompany the lesion.
   C. Corneal stromal lipid deposition may be noted at the leading edge of the lesion.

Diagnosis

I. Clinical findings are suggestive, especially in predisposed breeds.
II. Definitive diagnosis is based on biopsy with characteristic cytological or histopathologic findings.

Differential Diagnosis

I. Neoplasms such as lymphoma, mast cell tumor, SCC, viral papilloma
II. Granuloma
III. Idiopathic granulomatous disease with adnexal and cutaneous involvement (Collins et al., 1992)

Treatment

I. Topical 1% prednisolone or 0.1% dexamethasone is used QID for several weeks beyond resolution of signs.
II. Subconjunctival corticosteroid administration (see Pannus) is often required initially in severe cases.
III. Systemic prednisone (1 to 2 mg/kg/day PO) may be indicated if an adequate response is not noted with topical and subconjunctival steroidal medications.
IV. Oral azathioprine may also be indicated if remission is not achieved with steroidal agents (Latimer et al., 1983).
   A. Dose is 2 mg/kg/day PO for 5 to 30 days, then tapered to three times a week until the lesion has regressed.
   B. Complete blood count and chemistry profile are performed at initiation of therapy, 2 weeks later, and at regular intervals.

1. Azathioprine may cause leukopenia and/or thrombocytopenia.
2. Gastrointestinal disturbances and elevation of liver enzymes may also be noted.

V. Focal lesions may respond to cryotherapy.
VI. Tetracycline and niacinamide may be an alternative treatment (Rothstein et al., 1997).
   A. Dose is 250 mg of each TID for dogs <10 kg; 500 mg of each TID for dogs >10 kg.
   B. It may take up to 8 weeks to observe a response.
   C. Both tetracycline and niacinamide have immunomodulatory properties.
VII. Chronic therapy may be required in refractory or recurrent cases.

Monitoring of Animal

I. Long-term use of topical steroidal agents may be required to keep the lesion in remission.
II. Schedule recheck examinations every 2 to 3 weeks until lesions resolve, then every 4 to 6 months.

NEOPLASIA

Limbal Melanoma (Melanocytoma)

Definition

I. Brown to black, focal raised masses located at the limbus
II. May be locally expansile, but do not tend to metastasize (Wilcock and Peiffer, 1986)

Causes and Pathophysiology

I. Stromal melanocytes located at the limbus are the cell of origin.
II. Cells undergo transformation to a benign neoplasm.
III. The tumor may be aggressive, grow rapidly, and invade the globe in young (<4 years) dogs (Martin, 1981).
IV. Tumors are generally slow growing in older (>8 years) dogs and cats (Martin, 1981; Harling et al., 1986).

Clinical Signs

I. Smooth, black, raised mass located at the limbus, often temporally
II. Seen most commonly in the German shepherd dog, Labrador retriever, and golden retriever (Martin, 1981; Sullivan et al., 1996; Donaldson et al., 2006)
III. Possible corneal stromal lipid or neoplastic infiltrates at the leading edge of the lesion

Diagnosis

I. The clinical appearance is highly suggestive, especially in a German shepherd dog.
II. It must be differentiated from the scleral extension of a uveal neoplasm by thorough ocular examination with gonioscopy.
III. Diagnosis is based on biopsy and histopathologic examination.

Differential Diagnosis

I. Outward growth of an anterior uveal melanoma through the sclera
II. Limbal staphyloma

Treatment

I. Surgical removal or cryotherapy is indicated in young dogs with progressive lesions.
II. No treatment may be needed for small, slow-growing lesions in older animals.
III. Full-thickness sclerocorneal resection is indicated for large lesions (Martin, 1981; Wilkie and Wolf, 1991).
   A. Decreases chance of recurrence
   B. May use autologous or heterologous cornea, cartilage of third eyelid, synthetic graft material, or SIS to fill the defect created (Lewin, 1999)
   C. Histopathology required to identify cases with malignant potential (Donaldson et al., 2006)
IV. Photocoagulation by neodymium:yttrium-aluminum-garnet (Nd:YAG) or diode laser may be effective in some cases (Sullivan et al., 1996).
   A. Advantage: noninvasive procedure
   B. Disadvantage: higher recurrence rate

Monitoring of Animal

I. If the mass is not removed surgically because it is small and/or the animal is older, then recheck every 3 to 4 months.
   A. Perform gonioscopy to watch for extension of tumor into the anterior chamber.
   B. Perform tonometry, especially if the filtration angle is involved.
II. After surgical removal, recheck every 1 to 3 weeks until healing is complete, then every 3 to 6 months to check for recurrence.
III. If surgical removal is complete, the long-term prognosis is good.

Squamous Cell Carcinoma

Definition

I. SCC is the neoplastic transformation of corneal or conjunctival epithelial cells, resulting in tumor development.
II. Most commonly, the neoplasm originates from the conjunctiva or limbus and extends onto the cornea secondarily.

Causes and Pathophysiology

I. Ultraviolet damage to epithelium predisposes to development of SCC by inducing squamous metaplasia.
II. Lack of ocular pigment predisposes to development of SCC.

Clinical Signs

I. Tumors are often red, irregularly raised, and may be erosive.

II. Secondary bacterial infection can occur and be associated with areas of necrosis.
III. Ocular discharge and pain may be present, especially if the tumor is necrotic.
IV. The mass may extend to the conjunctiva, eyelid, third eyelid, and orbital tissues.

Diagnosis

I. Clinical appearance is suggestive.
II. Cytological analysis is often misleading because of the concurrent presence of necrosis and bacterial infection.
III. Definitive diagnosis requires biopsy and histopathologic examination.

Differential Diagnosis

I. Feline eosinophilic keratitis or conjunctivitis
II. Corneal granulation tissue
III. Chronic superficial keratitis (pannus)
IV. Viral papilloma (young dogs)
V. Corneal lymphoma

Treatment

I. Local excision by lamellar keratectomy and/or conjunctival resection is undertaken initially.
II. Recurrence after excision is common.
III. Several adjunctive therapies may be attempted to decrease likelihood of recurrence.
   A. Radiation therapy (Rebhun, 1990)
   B. Cryotherapy (Schoster, 1992)
   C. Hyperthermia
   D. Ablation with carbon dioxide lasers (English et al., 1990)
IV. Enucleation is performed if the lesion is too large to excise or if it extends to other ocular tissues.
V. Exenteration is indicated for orbital and/or lid involvement.

Monitoring of Animal

I. Recheck every 3 months in cases of small lesions; recheck every 3 weeks if lesions are large or advanced.
II. Skull radiography, computed tomography scans, or magnetic resonance imaging is indicated to monitor possible orbital recurrence.
III. Prognosis for long-term survival is guarded to poor because of the likelihood of local recurrence.

CHAPTER 99

Diseases of the Anterior Uveal Tract

A. Michelle Willis

CONGENITAL/DEVELOPMENTAL ABNORMALITIES

Persistent Pupillary Membranes

Definition and Causes

I. Persistent pupillary membranes (PPMs) are remnants of the mesodermal sheet carrying blood vessels that partially fill the anterior chamber during fetal development.
II. PPMs are inherited in the Basenji breed, but the mode of inheritance is unclear (Roberts and Bistner, 1968).
III. Cause is unknown in other breeds of dogs and cats.
  A. Familial occurrence with suspicion of inheritance in other commonly affected breeds
  B. Examples: collie, chow chow, Pembroke Welsh corgi, mastiff breeds
IV. PMMs can also occur as a sporadic, presumably non-inherited event.

Pathophysiology

I. In the developing fetus, the pupillary membrane arises from the collarette region or minor arterial circle of the iris and provides a vascular supply to the developing lens.
II. Atrophy of this membrane begins during fetal life, but may not be complete until the puppy is 4 to 8 weeks of age.
III. Incomplete resorption of this embryonic vasculature and mesenchymal tissue results in retained iris strands.
IV. PPMs may be associated with multiple ocular defects (e.g., microphthalmia, dyscoria, corneal opacification, cataract, retinal dysplasia).
V. Total persistence of the fetal pupillary membrane is rare and associated with other severe ocular anomalies.

Clinical Signs

I. Affected animals are typically asymptomatic, although thick and numerous strands may cause opaque lesions in the cornea and lens, with visual impairment.
II. Several variations of PPMs exist, such as iris-to-iris, iris-to-lens, and iris-to-cornea as well as free-floating strands in the anterior chamber.
  A. Focal pigment deposition on the anterior lens capsule or corneal endothelium may occur with no observable remaining PPM strands.
  B. Iris-to-cornea PPMs can affect the corneal endothelium, with edema or stromal fibrosis occurring at or adjacent to the site of corneal attachment.
  C. Iris-to-lens strands may cause a focal capsular and subcapsular cortical cataract.

Diagnosis

I. Examination of the anterior segment
  A. PPMs originating from collarette zone of the iris
  B. Pigmented strands in anterior chamber
  C. Punctate foci of pigment on anterior lens capsule or corneal endothelium
  D. Other congenital defects, particularly microphthalmia
II. No evidence of trauma or inflammation

Differential Diagnosis

I. Iris synechia
  A. Postinflammatory or posttraumatic
  B. Originate from pupil margin and typically accompanied by other signs of active or prior ocular inflammation (see Anterior Uveitis)
II. Senile iris sphincter muscle atrophy
  A. Strands of iris at the pupillary margin
  B. Possible iris stromal thinning
III. Fibrin strands or vitreous migration
  A. Both are weblike opacities in the anterior chamber and can contact lens or cornea.
  B. Fibrin is associated with anterior uveitis.
  C. Anterior chamber vitreous strands are associated with vitreous degeneration and/or lens instability.
IV. Other congenital abnormalities of the anterior uvea (Table 99-1)

Treatment

I. Usually none required
II. Transection of iris-to-cornea or iris-to-lens PPMs
  A. Intraocular hemorrhage from incised vascularized membranes is the biggest risk.
  B. Electrocautery minimizes bleeding.
  C. Laser surgery may simultaneously rupture and photocoagulate PPM.
III. Penetrating keratoplasty in combination with severing of PPMs

TABLE 99-1

Selected Developmental Abnormalities of the Anterior Uvea

OCULAR DEFECT	DEFINITION	PATHOPHYSIOLOGY	CLINICAL FINDINGS	TREATMENT/COMMENTS
Aniridia	Near or complete absence of iris	Presumed arrested differentiation of optic cup	Widely dilated pupil with rudimentary iris tissue ± photophobia	Use tinted goggles in tolerant dogs for outdoor activity Do not breed animal
Anterior segment dysgenesis	Anomalous development of the cornea, iridocorneal angle, iris, and ciliary body	Primary defect in formation of the neuroectodermal optic cup and abnormal induction of mesenchyme	Congenital blindness with variable microphthalmia, opaque cornea, and absent anterior chamber; occasional congenital glaucoma and buphthalmia	No treatment Inherited in Doberman pinschers, sporadic in other breeds Do not breed animal
Congenital dyscoria	Abnormally shaped pupil	Anomaly of iris stroma and/or musculature	Abnormal pupil shape; minor degree of dyscoria common	No treatment
Coloboma of iris	Incomplete sector of iris *Typical* refers to defect at 6 o'clock position	Incomplete closure of embryonic fissure	Variable-sized notch in iris that may also involve ciliary body and choroid	No treatment Inherited in Australian shepherd dogs
Heterochromia irides	Congenital color difference between two irises or difference in color in same iris	Hypopigmentation of iris; generally correlated with hair-coat color genetics	Blue-colored iris or portion of iris; may be associated with iris stromal hypoplasia and/or deafness (Waardenburg's syndrome)	No treatment Do not breed deaf animals

Modified from Davidson MG: Disorders of the anterior uveal tract. p. 1021. In Morgan RV (ed): Handbook of Small Animal Practice. 3rd Ed. WB Saunders, Philadelphia, 1997.

A. May be indicated if vision is impaired by extensive corneal edema associated with iris-to-cornea PPMs
B. Rarely performed in dogs

IV. Cataract extraction in combination with transection of PPMs
A. It is indicated for PPMs causing complete cataracts and vision loss.
B. Use ultrasonography and electroretinography to confirm that the retina and vitreous are healthy.

Monitoring of Animal

I. Inform the owner of the potential for more serious forms of the condition in the offspring of affected animals.
II. Breeding of affected dogs is discouraged.

Anterior Uveal Cysts

Definition

I. Anterior uveal cysts are epithelial-lined, pigmented structures arising from the posterior, pigmented epithelium of the iris or the ciliary body epithelium.
II. These cysts are either congenital or acquired.

Causes

I. Congenital
A. Failure of two layers of embryonal neuroectoderm to fuse, with fluid accumulation between these contiguous epithelial layers
B. May not be recognized until animal is several years old
C. Commonly affected breeds: Boston terrier, golden retriever (Cocoran and Koch, 1993)
D. Cats: rare

II. Acquired
A. Spontaneous
B. After chronic uveal inflammation or irritation
C. Secondary to uveal degeneration

Clinical Signs

I. Cysts appear as spherical, oval, or elongated, pigmented, intraocular structures.
II. They may be single or multiple.
III. Cysts are variably pigmented, typically pale to dark brown.
IV. They may be attached to the pupillary margin (common in cats) or be free-floating in the anterior chamber, or (occasionally) the vitreous.
V. Cysts attached to the ciliary body are often difficult to visualize without pupillary dilation.
VI. Rupture of uveal cysts may result in pigment deposition on the anterior lens capsule or corneal endothelium.
VII. They may predispose to the development of glaucoma in the golden retriever (Deehr and Dubielzig, 1998; Sapienza et al., 2000) and Great Dane (Spiess et al., 1998).

Diagnosis

I. A spherical, pigmented structure is free-floating in the anterior chamber or attached to the iris margin.
II. Cysts are fluid-filled and typically transilluminate with a bright light source.
III. Large cysts may alter the contour of the iris.
IV. Ultrasonography can differentiate a cyst from a solid mass lesion when the cyst is heavily pigmented.

Differential Diagnosis

I. Anterior uveal melanoma
  A. Solid, variably pigmented, cannot be transilluminated
  B. Alters structure and contour of the anterior uveal tissue
II. Focal pigment deposition on cornea or lens
  A. Postinflammatory or posttraumatic synechia: usually other evidence of prior uveitis or perforating corneal scars
  B. PPMs: congenital

Treatment

I. None required if no interference with vision or impingement on other tissues
II. Removal indicated if cysts interfere with vision or impinge on the corneal endothelium
  A. Neodymium:yttrium-aluminum-garnet (Nd:YAG) or diode laser therapy is used to puncture and ablate cyst wall.
    1. May require general anesthesia
    2. Less invasive than aspiration techniques
    3. Potential for laser damage to lens, iris, or retina
  B. Aspiration of cyst requires general anesthesia.
    1. Make a small limbal incision.
    2. Insert a blunt, 20-gauge needle or automated irrigation-aspiration unit to evacuate cyst contents.

Monitoring of Animal

I. Monitor for enlargement of cysts and associated problems.
  A. Visual deficits
  B. Impingement on corneal epithelium
II. Monitor intraocular pressure (IOP) in golden retrievers and Great Danes.

DEGENERATIVE DISORDERS

Iris Atrophy

Definition and Causes

I. Progressive thinning of the stroma or pupillary portion of the iris
II. Typically associated with aging (senile iris atrophy)
III. May develop after inflammatory conditions of the iris (secondary iris atrophy)
IV. Common in miniature poodles, miniature schnauzers, and Chihuahuas

Clinical Signs

I. Sphincter muscle atrophy
  A. Scalloped or "moth-eaten" pupillary margin
  B. Pigmented strands attached to dyscoric pupillary margin
  C. Typically bilateral but commonly asymmetrical
II. Iris stromal atrophy
  A. Age-associated color change in iris
  B. Fading of natural iris color
  C. Possible foci of hyperpigmentation as stroma lost and pigmented epithelium exposed
    1. Large holes in central iris as pigment epithelium of iris atrophies
    2. Appearance of fundic or tapetal reflex through stromal defects with transillumination
III. Dyscoria, mydriasis
IV. Anisocoria if atrophy is asymmetrical
V. Occasional pseudopolycoria
VI. Incomplete to absent pupillary light responses (PLRs) in advanced cases
VII. Occasional photophobia in bright light
  A. Associated with reduced ability to constrict pupil
  B. Usually subclinical

Diagnosis

I. Clinical appearance and location of iris strands at the pupillary margin allow a presumptive diagnosis.
II. Differentiate from neurological efferent mydriasis with topical miotic drug challenge.
  A. Use a topical, direct-acting, parasympathomimetic agent (2% pilocarpine).
  B. A functional pupillary sphincter muscle responds with significant miosis.
  C. An atrophied iris sphincter does not respond and the pupil remains dilated.

Differential Diagnosis

I. PPMs: congenital, arising from collarette zone of iris
II. Congenital iris coloboma causing dyscoria
III. Postinflammatory synechiae impairing pupil shape and function: usually other indicators of active or prior uveitis
IV. Neurological lesions resulting in mydriasis and an incomplete PLR (see Chapter 105)

Treatment and Monitoring

I. No specific treatment is available or usually warranted.
II. Reduce bright light exposure in animals exhibiting photophobia or consider fitting tolerant dogs with shaded goggles when outdoors.
III. Atrophy is typically progressive, so monitor for bright light sensitivity.

Altered Iris Pigmentation

Definition

I. Benign pigmentary changes in the iris
II. Classification of changes
  A. Ectropion uvea
  B. Iris freckle
  C. Iris nevus
  D. Benign iris melanosis

Causes and Pathophysiology

I. Ectropion uvea
  A. Prominence or proliferation of the pigmented posterior epithelium of the iris with anterior extension through the pupil
  B. Causes
    1. Epithelial hyperplasia with concurrent iris stromal atrophy
    2. Contraction of inflammatory exudates or preiridal fibrovascular membranes on the anterior iris surface, associated with chronic uveal inflammation, creating eversion of the pupillary margin
II. Iris freckle: hyperpigmentation of resident melanocytes, without an increase in cell numbers
III. Iris nevus
  A. More cellular than freckles
  B. Histologically similar to benign iridal melanoma in dogs (Diters et al., 1983)
IV. Benign iris melanosis
  A. Benign, diffuse increase in iridal pigmentation
  B. Possibly associated with chronic uveitis

Clinical Signs and Diagnosis

I. Appearance of lesion
  A. Ectropion uvea
    1. Heavily pigmented, curled edge at pupillary margin
    2. Other signs of uveitis
    3. Commonly seen with hypermature cataract
  B. Iris freckle
    1. Single or multifocal
    2. Absence of a discreet mass or nodule
  C. Iris nevus
    1. More cellular than freckles
    2. May be raised above iris surface, extend into iris stroma, or cause mild iris thickening
  D. Benign iris melanosis
    1. Diffuse pigmentary change in iris
    2. May be associated with chronic uveitis
II. Other ocular examination findings
  A. Normal pupil size and shape
  B. Gonioscopy and IOP
    1. Typically no involvement of iridocorneal angle
    2. Normal IOP
  C. Signs of prior or active uveitis: ectropion uvea

Differential Diagnosis

I. Early or small iridal melanoma
II. Iris atrophy
  A. Natural iris color fades.
  B. Foci of hyperpigmentation may be noted as stroma is lost and pigmented epithelium is exposed.
III. Pigmentary glaucoma (see Chapter 100)

Treatment and Monitoring

I. Reevaluate every 3 to 6 months to assess progression.
II. It is helpful to photograph the affected eye to compare changes at sequential visits.
III. Laser photocoagulation may be tried in progressive lesions of dogs (Cook and Wilkie, 1999) but remains controversial in cats (see Neoplasia).

INFLAMMATORY DISORDERS

Anterior Uveitis

Definition

I. Inflammation of the iris and ciliary body (anterior uveal tract)
II. May occur alone or in conjunction with posterior uveitis

Causes

I. Ocular causes
  A. Lens-induced uveitis
    1. Phacolytic uveitis is a nongranulomatous uveitis caused by resorption of a rapidly progressive or hypermature cataract.
    2. Phacoclastic uveitis is associated with disruption of the lens capsule and release of an excessive amount of lens protein into the anterior chamber that overwhelms the intraocular immune system.
  B. Ocular trauma
    1. Blunt trauma with uveal contusion
    2. Perforating corneal wounds
    3. Septic corneal ulcer or stromal abscess
    4. Surgical manipulation of the anterior segment
  C. Primary ocular neoplasia (see Neoplasia)
II. Systemic infectious diseases
  A. Systemic mycoses
    1. Blastomycosis
    2. Histoplasmosis
    3. Cryptococcosis
    4. Coccidioidomycosis
    5. Candidiasis
  B. Rickettsial infections
    1. Rocky mountain spotted fever (RMSF): *Rickettsia rickettsii*
    2. Ehrlichiosis: *Ehrlichia canis, Ehrlichia platys, Ehrlichia equi*
  C. Protozoal infections
    1. Toxoplasmosis
    2. Neosporosis
    3. Leishmaniasis
  D. Bacterial infections
    1. Septicemia of any cause
    2. Dogs: brucellosis, leptospirosis, Lyme borreliosis
    3. Cats: *Bartonella henselae;* possibly *Yersinia* spp. infection
  E. Viral infections
    1. Canine adenovirus (CAV)
    2. Canine herpesvirus (puppies)
    3. Feline infectious peritonitis (FIP)
    4. Feline immunodeficiency virus (FIV)
    5. Feline leukemia virus (FeLV)
    6. Feline herpesvirus 1 (FHV) (Maggs et al., 1999)
  F. Algal infections in dogs: *Prototheca* spp.

G. Parasitic agents
   1. Aberrant nematode larval migration
      a. Toxocariasis
      b. Dirofilariasis
      c. Ancylostomiasis
      d. Angiostrongylosis
   2. Ophthalmomyiasis interna with dipterous fly larvae (*Cuterebra* spp.)

III. Uveodermatologic or Vogt-Koyanagi-Harada (VKH)–like syndrome
   A. Presumed immune-mediated panuveitis associated with hair and skin lesions
   B. More common in young adult dogs (1 to 4 years old)
   C. Predisposed breeds: Asian or Arctic Circle breeds, such as Akita, chow chow, Samoyed, Siberian husky, Alaskan malamute

IV. Idiopathic anterior uveitis
   A. Diagnosis of exclusion when appropriate diagnostic investigation fails to identify a specific causative agent
   B. Common in older male cats
   C. Syndrome in golden retrievers often associated with iridociliary cysts (Deehr and Dubielzig, 1998; Sapienza et al., 2000)

V. Secondary ocular neoplasia

VI. Miscellaneous causes of disruption of the blood-aqueous barrier
   A. Systemic hypertension
   B. Hyperviscosity syndromes: multiple myeloma, ehrlichiosis
   C. Therapeutic radiation to the head
   D. Reflex uveitis secondary to corneal and scleral diseases

Pathophysiology

I. Lens-induced uveitis
   A. Both humeral and cell-mediated immune responses occur in response to lens antigens.
   B. Phacolytic uveitis develops as follows:
      1. Occurs in response to the release of lens proteins through an intact lens capsule of a cataractous lens
      2. Develops sooner in young dogs and is more difficult to treat than in older dogs (van der Woerdt et al., 1992)
   C. Phacoclastic uveitis has specific characteristics.
      1. Follows massive and sudden release of lens proteins from a ruptured lens capsule
      2. Results in a reversal of T-lymphocytic tolerance

II. Infectious agents
   A. Cause uveitis by direct intraocular replication or intraocular migration of organisms
   B. Stimulate an immune-mediated inflammatory response in uveal tissues
   C. Peculiar response to CAV infection
      1. Acute uveitis is related to intracellular viral replication causing a direct cytopathic effect.
      2. Subacute findings occur from anterior uveal and corneal endothelial immune complex deposition (type III hypersensitivity).
      3. The condition occurs more often with natural infection and the use of modified live CAV-1 vaccine (7 to 21 days after vaccination), although anterior uveitis may occur after the use of the CAV-2 vaccine.
   D. Reflex uveitis from septic corneal disease
      1. Corneal damage stimulates an axonal reflex, resulting in release of substance P, which produces vascular dilatation, altered permeability, and chemotaxis of neutrophils.
      2. Chemical mediators of inflammation are released by the anterior uvea in response to corneal inflammation associated with rapid colonization of the cornea by infectious agents.

III. Uveodermatologic syndrome
   A. Suspected to be an immune-mediated reaction to components of melanocytes in the eyes and skin
   B. Characterized histopathologically by a granulomatous inflammation of ocular tissues and a lichenoid inflammatory cell infiltrate pattern in dermal tissues (see Chapter 92)

IV. Idiopathic uveitis
   A. Presumed to be immunologically mediated
   B. Histopathology of affected tissues: lymphocytic and plasmacytic cellular infiltration
   C. At least partial response to antiinflammatory or immunosuppressive therapy

Clinical Signs

See Table 99-2.

Diagnosis and Differential Diagnosis

I. Complete physical examination

II. Complete ophthalmic examination

III. Complete blood count, biochemistry profile, urinalysis

IV. Thoracic radiography if fungal or neoplastic disease suspected

V. Abdominal radiography and ultrasonography if neoplasia suspected

VI. Serological testing
   A. Evaluation of cats with uveitis
      1. *Toxoplasma gondii* immunoglobulin (Ig)M and G
      2. Viral tests: FIP, FeLV, FIV
      3. *Cryptococcus neoformans* antigen
      4. *Bartonella henselae* IgG
   B. Evaluation of dogs with uveitis
      1. *Blastomyces dermatitidis* and *Histoplasma capsulatum* serology in the southern, midwestern, and mideastern states
      2. *Coccidioides immitis* serology in the southwestern states
      3. *E. canis, E. platys, E. equi, Rickettsia rickettsii*, and *Borrelia burgdorferi* serology in areas endemic for tickborne disease
      4. *Brucella canis* tests particularly in intact animals
      5. Serology for leptospirosis in endemic areas

VII. Aqueocentesis
   A. It may support a diagnosis of ocular toxoplasmosis, intraocular FHV or *Bartonella* spp. infection in cats by comparison of aqueous and serum antibody levels.

TABLE 99-2

Clinical Signs of Anterior Uveitis

CAUSES OR TYPE OF UVEITIS	SIGNS
Nonspecific Signs	
Acute	Conjunctival and scleral injection Photophobia Aqueous flare Miosis Edematous and hyperemic iris Corneal edema: diffuse, perilimbal Decreased intraocular pressure Hypopyon Hyphema
Chronic	Posterior synechia Secondary glaucoma Secondary cataract Keratic precipitates Iris hyperpigmentation Rubeosis iridis Vitreous syneresis Vitreous cellular infiltrate, debris on lens capsule Asteroid hyalosis
Lens-induced uveitis	Presence of hypermature cataract, although may accompany immature but rapidly progressive cataract in young or diabetic dog Hyperpigmentation of iris Pupil resistant to dilation with short-acting mydriatic
Systemic Infectious Diseases	
Canine adenovirus	Typically unilateral Corneal edema obscures anterior chamber Miosis and normal intraocular pressure distinguishes uveitis from glaucoma
Feline immunodeficiency virus	Pars planitis (inflammation of caudal ciliary body) is seen with white infiltrates in anterior vitreous
Fungal	Posterior segment findings predominate with secondary anterior uveitis
Rickettsial, protozoal, and bacterial	Anterior and posterior uveitis are often both present
Uveodermatologic syndrome	Chorioretinitis, retinal detachment, and progressive nontapetal choroidal depigmentation May be preceded or accompanied by depigmentation of fur and skin (see Chapter 92 for description of skin lesions)
Idiopathic Uveitis	
Cats	Cataract formation, lens luxation, and secondary glaucoma are common sequelae
Golden retrievers	Hallmark is pigment on anterior lens capsule, often deposited in a radial pattern Uveal cysts common

   B. Submit cytological testing, culture, or latex agglutination testing for *C. neoformans.*
   C. Culture for *B. henselae*.
   D. Perform polymerase chain reaction assays for *T. gondii, B. henselae* (Powell and Lappin, 2001).

VIII. Vitreocentesis
   A. Submit aspirate for cytological testing, culture, specific antigen testing, or antibody titers.
   B. Risks include hemorrhage from ciliary body or choroid, retinal detachment, lens trauma, and endophthalmitis.
   C. Primarily done in blind eyes when other tests fail to yield a diagnosis.

IX. Cerebrospinal fluid analysis
   A. Recommended in cases with concurrent central nervous system signs

B. Fungal (e.g., *C. neoformans*) or viral (e.g., distemper) titers measured
X. Skin biopsy if uveodermatologic syndrome suspected

Treatment

I. Specific therapy for underlying disease
II. Topical antiinflammatory therapy
  A. Corticosteroid agents
    1. Highly soluble prednisolone acetate 1% ophthalmic solution is the optimal choice.
    2. Prednisolone sodium phosphate and dexamethasone are additional options.
    3. Frequency (three to six times daily) depends on severity of clinical signs, with cautious tapering after resolution and control of signs.
  B. Nonsteroidal antiinflammatory medications
    1. Flurbiprofen 0.03%, suprofen 1%, diclofenac 0.1%
    2. Dose: BID to QID
    3. Synergistic with topical corticosteroid agents, so may help reduce frequency of topical corticosteroid medications
    4. May increase IOP
III. Topical mydriatic and cycloplegic therapy
  A. Reduces risk of posterior synechiae formation and decreases painful iridociliary muscle spasm
  B. Parasympatholytic agents
    1. Atropine 1% to affect pupillary dilation
      a. Frequency is SID to QID.
      b. It may exacerbate preexisting glaucoma or keratoconjunctivitis sicca (KCS).
    2. Tropicamide 1%
      a. Has a short-acting duration (1 to 4 hours)
      b. Useful if secondary glaucoma or KCS is a concern
  C. Sympathomimetic agents
    1. Phenylephrine 2.5% to 10% in conjunction with atropine two to six times daily
    2. May induce tachycardia or arrhythmias, especially in small animals
IV. Subconjunctival corticosteroid
  A. Does not replace use of topical steroidal medications but may have adjunctive effect in severe cases
  B. Long-acting choices are as follows:
    1. Triamcinolone 4 to 8 mg
    2. Methylprednisolone acetate 4 to 8 mg
  C. Not used in cases of corneal infection, ulceration, or suspected fungal uveitis
V. Systemic antiinflammatory therapy
  A. Warranted if posterior segment inflammation is present or if anterior uveitis is not controlled by high-frequency topical steroid administration
  B. Prednisone
    1. Antiinflammatory dose: 0.25 to 0.5 mg/kg PO BID, tapered once clinical signs are controlled
    2. Immunosuppressive dose: 1 to 2 mg/kg PO BID for certain forms of immune-mediated uveitis (e.g., VKH syndrome) or golden retriever uveitis (Sapienza et al., 2000)
    3. Used *only* after complete diagnostic evaluation has ruled out infectious disease
  C. Systemic nonsteroidal antiinflammatory drugs
    1. Helpful when systemic steroidal agents are contraindicated (e.g., diabetes mellitus, certain infectious diseases)
    2. Aspirin
      a. Dogs: 10 to 25 mg/kg PO BID for 1 to 3 weeks
      b. Cats: 6 mg/kg PO every 72 hours
    3. Carprofen: 2 mg/kg PO BID in dogs
    4. Meloxicam (Giuliano, 2004)
      a. Dogs: 0.2 mg/kg PO once, followed by 0.1 mg/kg PO SID
      b. Cats: 0.2 mg/kg PO once, followed by 0.1 mg/kg PO every 2 to 3 days
  D. Azathioprine
    1. It helps to reduce or eliminate the dose of corticosteroid medications required long-term to control immune-mediated uveitis.
    2. Dose is 2 mg/kg PO SID initially, then tapered to QOD.
    3. Dose is tapered based on response to therapy and blood parameters (can cause myelosuppression and hepatotoxicity).
VI. Surgical therapy
  A. Lensectomy for phacolytic or phacoclastic uveitis
  B. Enucleation
    1. Recommended in blind, painful eyes with chronic uveitis or secondary glaucoma that are unresponsive to medical therapy.
    2. Indicated to remove nidus of chronic mycotic infection in blind eyes unresponsive to therapy.

Monitoring of Animal

I. Reevaluate frequently (every 3 to 5 days) until control of inflammation is achieved.
II. Monitor for sequelae of chronic uveitis (secondary glaucoma, cataract formation).
III. Monitor for onset or resolution of posterior segment lesions.
IV. Prognosis varies depending on the underlying cause of the uveitis.
  A. Lens-induced uveitis
    1. Phacolytic uveitis is typically responsive to topical steroid therapy if instituted early.
    2. Phacoclastic uveitis is poorly responsive to medical therapy; surgical removal of all lens material shortly after lens capsule rupture carries a more favorable prognosis (Davidson et al., 1991).
  B. Infectious uveitis
    1. Fungal infection
      a. Fair to good prognosis: focal granulomatous chorioretinal lesions and mild anterior uveitis present
      b. Poor prognosis: advanced disease present
    2. Rickettsial uveitis
      a. Excellent prognosis: RMSF
      b. Fair prognosis: *E. canis*

3. Bacterial infections: good prognosis if primary disease resolves
4. Protozoal uveitis
   a. Toxoplasmosis: generally favorable prognosis
   b. Leishmaniasis: response of uveitis highly correlated with systemic response to therapy (Pena et al., 2000)
5. CAV-induced uveitis
   a. Prognosis is variable but often favorable.
   b. Vision may be compromised by persistent corneal edema or glaucoma.
6. Uveodermatologic syndrome
   a. Maintaining remission is challenging; recurrences are common.
   b. Side effects of high-dose corticosteroid therapy can be problematic.
   c. Long-term prognosis for vision is guarded to poor.
7. Idiopathic uveitis
   a. Recurrences are common, as are secondary sequelae.
   b. Prognosis is variable and dependent on response to antiinflammatory therapy.

HYPHEMA

Definition

I. Hyphema is blood in the anterior chamber.
II. It may be clotted or unclotted.

Causes

I. Developmental abnormalities
   A. Persistent hyperplastic tunica vasculosa lentis
   B. Persistent hyaloid artery
   C. Collie eye anomaly
   D. Vitreoretinal dysplasia
II. Blunt or penetrating ocular trauma
III. Coagulopathies
   A. Thrombocytopenias and thrombocytopathies
   B. Clotting factor deficiencies
   C. Disseminated intravascular coagulation
IV. Hyperviscosity syndromes
   A. Polycythemia vera
   B. Multiple myeloma, ehrlichiosis
V. Systemic hypertension
VI. Primary or metastatic neoplasia
VII. Uveal or retinal neovascularization
   A. Chronic uveitis
   B. Chronic glaucoma
VIII. Iatrogenic
   A. Diagnostic paracentesis
   B. Intravitreal injection
   C. Intraocular surgery
   D. Transscleral laser cyclophotocoagulation

Clinical Signs

I. Red blood cells circulating in or settled ventrally in the anterior chamber
II. Blood clot in anterior chamber
   A. Blood from trauma or uveitis usually clots.
   B. Blood from immune-mediated thrombocytopenia or warfarin toxicity rarely clots.
III. Possible rebleeding episode with contraction of clot

Diagnosis

I. If other signs of bleeding are seen, then rule out coagulopathy (see Chapters 67 and 68).
II. Systolic blood pressure is measured to rule out hypertension.
   A. Systolic pressure >170 mm Hg in both cats and dogs is compatible with hypertension.
   B. Investigate causes of hypertension (see Chapter 48).
III. Serology for infectious diseases associated with vasculitis is also indicated.
   A. *Ehrlichia* spp.
   B. *Rickettsia rickettsii*
   C. *Borrelia burgdorferi*
IV. Ocular ultrasonography helps identify the following:
   A. Intraocular tumor
   B. Retinal detachment
   C. Lens dislocation
V. Skull radiographs may reveal orbital fractures or metallic projectiles.

Treatment and Monitoring

I. Treat underlying disease if possible.
II. Limit activity to reduce risk of rebleeding.
III. Administer topical corticosteroid agent three to six times daily until resolution.
   A. Prednisolone acetate 1%
   B. Dexamethasone 0.1%
   C. Prednisolone sodium phosphate 1%
IV. Consider topical phenylephrine 2.5% to 10% to promote vasoconstriction and mydriasis.
V. Consider topical atropine.
VI. Consider intracameral tissue plasminogen activator for fibrinous clots.
   A. Inject 25 μg (0.1 mL of a 250 μg/mL solution) (Martin et al., 1993).
   B. It is most effective within the first 48 hours.
   C. Main risk is rebleeding.
VII. Monitor for secondary glaucoma from the following:
   A. Fibrin deposition in iridocorneal angle
   B. Posterior synechia and iris bombe
VIII. Prognosis for vision is variable and depends on the amount of bleeding and the underlying cause.

NEOPLASIA

See Table 99-3.

TABLE 99-3

Neoplasia

TYPE OF TUMOR	PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT	PROGNOSIS
Primary					
Anterior uveal melanoma	Arises from melanocytes in uveal tract Most common primary ocular tumor in dog and cat Forms: 1. Nodular in dog 2. Diffuse or nodular in cats	Pigmented mass in iris or, less commonly, ciliary body: 1. Amelanotic variants possible 2. Alteration in iris contour 3. Dyscoria with diffuse stromal involvement 4. Possible pigmentation of sclera adjacent to involved region of iris	Finding a mass on examination Systemic work-up: 1. Physical exam 2. CBC 3. Chemistry profile 4. Urinalysis 5. Thoracic and abdominal radiographs 6. Ultrasound: ocular and abdominal 7. Aspiration of cells 8. Histopathology	Laser ablation: small pigmented masses in dogs not involving iridocorneal angle or impinging on corneal endothelium 1. For localized iris or ciliary mass 2. High risk for hemorrhage Enucleation	Low metastatic potential in dogs High metastatic potential in cats: 1. Prognosis poorer with invasion of ciliary body or secondary glaucoma 2. Quarterly examination in cats: lymph node palpation, hepatic enzyme evaluation, thoracic radiography and abdominal US
Adenoma/ adenocarcinoma	Arise from iridociliary epithelium	More common in dog than cat Pink mass in iris or ciliary body protruding through pupil Adenocarcinoma more likely to invade sclera	As above	Enucleation is recommended in most cases because progressive expansion of tumor results in uveitis, glaucoma, and blindness	Both have low metastatic potential
Medulloepithelioma	Arises from embryonal neuroepithelial tissue	Typically present in younger dogs, but may go undiagnosed for years	As above	Enucleation is recommended in most cases because progressive expansion of tumor results in uveitis, glaucoma, and blindness	Low metastatic potential
Feline intraocular sarcoma	Occurs in eyes with previous penetrating trauma	Usually associated with lens capsule rupture Time from trauma to recognition of tumor variable (1-10 yr)	As above	Enucleation is treatment of choice.	Aggressive intraocular destruction and scleral/ extrascleral extension are common
Osteosarcoma	Osteoid-producing mesenchynal tumor	Associated corneal changes; inflammation and glaucoma may prelude specific evaluation of uveal tract	As above	Enucleation	Guarded

CBC, complete blood count; *US,* ultrasound.

TABLE 99-3

Neoplasia—*cont'd*

TYPE OF TUMOR	PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT	PROGNOSIS
Secondary					
LSA	Usually a component of multicentric disease	± Pink mass in uvea ± Lymphadenopathy or signs of systemic disease	As above	Specific chemotherapy Topical steroid therapy to control inflammation Palliative enucleation for painful eye nonresponsive to therapy	Variable depending upon systemic involvement
Metastatic	Hematogenous spread from distant primary	Often similar clinical appearance regardless of type Bilateral involvement more common than with primary tumor.	As above	As above	Guarded
TVT	Venereal transmission; hematogenous or lymphatic metastasis	Pale white-pink mass in iris or ciliary body Involvement of other mucosal surfaces	As above	Specific chemotherapy	Guarded to poor, especially with secondary ocular disease
All Tumors					
		Nonspecific: 1. Secondary glaucoma: a. Tumor invasion of iridocorneal angle b. PIFM development over irido corneal angle 2. Lens displacement 3. Anterior uveitis 4. Hyphema			

LSA, Lymphosarcoma; *TVT,* transmissible venereal tumor; PIFM, preiridal fibrovascular membrane.

CHAPTER 100

Glaucoma

Ian P. Herring

Definition

I. Glaucoma is a multifactorial disease characterized by an elevation of intraocular pressure (IOP) beyond that which is compatible with the health of the eye.
II. Glaucoma results in permanent vision loss through death of retinal photoreceptors, retinal ganglion cells, and their axons (i.e., optic nerve).

Causes

I. Primary and breed-related glaucoma (Bedford, 1975)
   A. Primary glaucoma is a heritable condition with certain breed predispositions (Table 100-1).
   B. Overall prevalence of primary breed-related glaucoma in purebred dogs has recently been estimated at approximately 0.89%, with the prevalence in certain breeds exceeding 5% (Gelatt and Mackay, 2004).
   C. IOP elevation occurs from a spontaneous increase in aqueous outflow resistance at the level of the iridocorneal angle and ciliary cleft.
   D. Glaucoma is often categorized based on gonioscopic appearance of the filtration angle.
      1. Open angle
         a. Angle appears normal before and in the early stages of glaucoma.
         b. Angle collapse and closure occurs late in the disease.
      2. Narrow to closed angle (most common form of canine primary glaucoma)
         a. Pectinate ligaments appear shortened or nonexistent.
         b. Base of iris is in apposition (or nearly so) to the peripheral cornea.
      3. Pectinate ligament dysplasia and mesodermal goniodysgenesis
         a. Individual pectinate ligaments, if visualized, are short and wide.
         b. In some cases a solid sheet of tissue with occasional "flow holes" spans the filtration angle.
         c. Concurrent narrowing or closure of the angle may be noted.
   E. Bilateral disease potential exists.
      1. Both eyes usually do not become affected at the same time.

TABLE 100-1

Dog Breeds Predisposed to Primary Glaucoma

BREED	GONIOSCOPIC FILTRATION ANGLE APPEARANCE
Alaskan malamute	Not defined
Akita	Narrow to closed
American cocker spaniel	Narrow to closed
Basset hound	Narrow to closed/mesodermal goniodysgenesis
Beagle	Open
Boston terrier	Not defined
Bouvier des Flandres	Narrow/pectinate ligament dysplasia
Bullmastiff	Not defined
Chow chow	Narrow to closed
Dalmatian	Not defined
English cocker spaniel	Narrow to closed
English springer spaniel	Narrow to closed
Fat-coated retriever	Narrow to closed
Giant schnauzer	Not defined
Great Dane	Not defined
Greyhound	Not defined
Italian greyhound	Not defined
Miniature pinscher	Not defined
Miniature schnauzer	Not defined
Norwegian elkhound	Open
Poodle	Open/narrow to closed
Samoyed	Narrow to closed
Shar-pei	Narrow to closed
Shih tzu	Not defined
Shiba Inu	Narrow to closed/pectinate ligament dysplasia
Siberian husky	Narrow to closed/pectinate ligament dysplasia
Smooth-haired fox terrier	Not defined
Welsh springer spaniel	Narrow to closed
Wirehaired fox terrier	Not defined

2. The exception to this is open-angle glaucoma, in which bilateral onset is common.

F. Although filtration angle malformations are congenital, most animals are clinically afflicted at 3 to 10 years of age.

G. Primary glaucoma occurs in cats, but is rare.

II. Secondary glaucoma

A. It often affects only one eye.

B. It may be bilateral if the inciting condition affects both eyes.

C. Common causes are as follows:

1. Uveitis
   a. Acute uveitis, if severe enough, may cause IOP elevations related to blockage of aqueous drainage by iridal swelling, fibrin, hyphema, or hypopyon.
   b. With chronicity, uveitis of any cause has the potential to cause glaucoma.
   c. Chronic uveitis is the most common cause of glaucoma in cats (Wilcock et al., 1990).
2. Hyphema
   a. Hyphema may be associated with trauma, coagulopathies, uveitis, intraocular neoplasia, hypertension, and retinal detachment.
   b. Glaucoma is likely in dogs with hyphema secondary to retinal disease (Nelms et al., 1993).
3. Lens luxation (Curtis, 1990)
   a. Distinct breed predisposition exists for spontaneous lens luxation in dogs.
   b. Luxation may also occur in association with hypermature cataracts, chronic uveitis, or senile degeneration of lens zonules.
   c. Severe secondary glaucoma can occur rapidly after anterior lens luxation and is the major reason to recommend early surgical removal of displaced lenses.
   d. Animals with lens subluxation and posterior lens luxation are also at risk for development of glaucoma, but less so than animals with anterior lens luxation (Glover et al., 1995).
4. Intraocular neoplasia
   a. It may cause glaucoma through mechanical compression of the filtration angle, obstruction of the angle with tumor cells, preiridal fibrovascular membrane formation, or hyphema.
   b. Diffuse iris melanoma is a common cause of glaucoma in cats (Wilcock et al., 1990).
5. Melanocytic glaucoma (Peterson-Jones, 1991)
   a. It occurs in middle-aged to older Cairn and Scottish terriers.
   b. Pigmented cells accumulate in the filtration angle and within the scleral venous plexus.
6. Aqueous humor misdirection (Czederpiltz et al., 2005)
   a. Anterior displacement of the lens resulting in a shallow anterior chamber is a prominent feature of the condition.
   b. It occurs in older cats and is often unilateral at initial presentation.
7. Trauma
   a. Blunt ocular trauma can occasionally result in acute, severe elevations in IOP.
   b. Hyphema after blunt trauma may predispose to glaucoma.
8. Aphakia
   a. Glaucoma may occur after lens removal surgery (Paulsen et al., 1986; Biros et al., 2000; Lannek and Miller, 2001).
   b. It may develop early in the postoperative period or months to years after surgery.

D. Breed-related conditions resulting in secondary glaucoma in the dog are as follows:

1. Lens luxations in terrier breeds
2. Ocular melanosis in Cairn and Scottish terriers
3. Iridociliary cysts and uveitis in golden retrievers
4. Vogt-Koyanagi-Harada (VKH)–like syndrome in Arctic Circle and other breeds

III. Congenital glaucoma

A. It is rare in dogs and cats.

B. It is related to extensive maldevelopment of the anterior segment of the eye, including the filtration angle.

C. IOP elevation occurs within the first few months of life.

Pathophysiology

I. Normal IOP and aqueous humor dynamics

A. The range of normal IOP in dogs and cats is approximately 10 to 25 mm Hg.

B. IOP is primarily determined by (1) the balance between aqueous humor production by the nonpigmented epithelium of the ciliary body and (2) aqueous humor outflow through the conventional (trabecular) and unconventional (uveoscleral) routes.

II. Aqueous outflow obstruction

A. Outflow obstruction in primary glaucoma is related to poorly understood biochemical and ultrastructural changes at the level of the filtration angle and ciliary cleft that may include the following:

1. Altered or increased glycosaminoglycan deposition within the aqueous outflow pathway in open-angle glaucoma
2. Reverse pupillary block (Miller et al., 2003)
3. Anterior segment inflammation and pigment dispersion (Reilly et al., 2005)
4. Physical closure of the filtration angle (Gum et al., 1993)

B. Outflow obstruction in secondary glaucoma may be related to a number of mechanisms (Peiffer et al., 1990; Smith et al., 1993).

1. Preiridal fibrovascular membrane formation associated with uveitis, chronic retinal detachment, or intraocular neoplasia may occlude the filtration angle.
2. Cellular deposition may occlude the filtration angle in glaucoma secondary to inflammation, hyphema, melanosis, and intraocular neoplasia.

3. Peripheral anterior synechiae may form and close the filtration angle in glaucoma secondary to uveitis, anterior lens luxation, or intraocular neoplasia.
4. Pupillary block may occur from annular posterior synechia, anterior vitreous herniation, and subluxated lenses.
   a. Aqueous humor is unable to flow through the blocked pupillary aperture.
   b. Pressure builds behind the iris, causing it to balloon forward and close the filtration angle.

III. Mechanisms of ocular pathology in glaucoma
   A. Direct pressure effects
      1. Corneal endothelial cell decompensation and death resulting in corneal stromal edema
      2. Stretching of globe (buphthalmos)
      3. Iris sphincter paralysis resulting in mydriasis
      4. Optic nerve compression and shearing at the lamina cribrosa resulting in axonal death
   B. Effect of abnormal aqueous humor composition and flow
      1. Cataract formation
      2. Corneal endothelial decompensation and death resulting in corneal stromal edema
   C. Excitotoxic amino acids (e.g., glutamate)
      1. Glutamate is neurotoxic to retinal ganglion cells and axons of the optic nerve.
      2. Elevated intravitreal glutamate levels have been demonstrated in affected dogs (Brooks et al., 1997).
      3. Histologic evidence of retinal glutamate toxicosis has been documented in dogs with primary glaucoma (McIlnay et al., 2004).
   D. Microcirculatory disturbance
      1. Optic nerve head microcirculatory autoregulation mechanisms may be defective in primary glaucoma.
      2. IOP-induced ischemia results in retinal ganglion cell death or increases the cells' susceptibility to excitotoxic amino acids.
   E. Permanent vision loss
      1. It is related primarily to damage to the ganglion cell layer of the retina and the optic nerve.
      2. Rapidity of onset is related to the severity and duration of IOP elevations.

Clinical Signs

I. Acute
   A. Ocular pain manifested by blepharospasm and/or rubbing eye
   B. Ocular redness from conjunctival hyperemia and/or episcleral injection
   C. Ocular discharge
   D. Corneal edema
   E. Dilated pupil
   F. Vision loss
   G. Optic nerve and peripapillary retinal edema and hemorrhage
   H. Behavioral changes related to vision loss and ocular discomfort

II. Chronic
   A. Possibly any acute sign
   B. Buphthalmos: enlargement of globe
   C. Haab's striae: gray to white linear corneal opacities caused by breaks in Descemet's membrane related to corneal stretching
   D. Lens subluxation and aphakic crescent: secondary to lens zonule rupture as the globe enlarges
   E. Cataract
   F. Peripapillary tapetal hyperreflectivity or hyperpigmentation
   G. Optic nerve cupping and atrophy

Diagnosis

I. Suggestive clinical signs
II. High likelihood in predisposed breeds of dogs (see Table 100-1)
III. IOP measurement (tonometry)
   A. IOP is measured by applanation, indentation, or rebound tonometry.
      1. Indentation tonometers (e.g., Schiotz) are very affordable and provide a reasonably accurate estimation of IOP, but they can be difficult to use in uncooperative animals.
      2. Applanation tonometers are more expensive but are convenient to use and are more accurate than indentation tonometers.
      3. Rebound tonometers are also expensive, but are convenient to use and correlate well with applanation tonometers (Gorig et al., 2006).
      4. Topical ophthalmic anesthetic is required for indentation and applanation tonometry, but is not used for rebound tonometry.
      5. Digital (palpation) estimation of IOP is unreliable.
   B. IOP is measured in both eyes for comparison.
   C. Animals with clinical disease usually have an obvious IOP elevation on presentation, although an elevation in pressure of >5 mm Hg in the affected eye compared with the normal eye is also suggestive of glaucoma.
   D. A single reading may not reflect the true status of IOP, because IOP in glaucoma may vary widely during the day, as well as from day to day.
   E. Several factors may lead to artifactual elevation in tonometric readings.
      1. Animal excitement or fear
      2. Excessive restraint, particularly with pressure around the neck
      3. Blepharospasm
      4. Inadvertent digital pressure on the eye when opening the eyelids
IV. Gonioscopy
   A. Gonioscopy is visualization of the filtration drainage angle using a goniolens.
   B. It is useful in distinguishing primary from secondary glaucoma.
   C. It may be difficult to perform in affected eyes because of corneal edema.

D. Filtration angle abnormalities are common in the unaffected eye of animals with primary glaucoma.

Differential Diagnosis

I. Uveitis
II. Corneal edema from other causes
III. Scleritis
IV. Exophthalmos
V. Lagophthalmos

Treatment

I. General concepts
  A. Control of IOP is the only known means by which the vision loss can be delayed.
  B. No known cure exists for glaucoma.
  C. At best, the disease can be controlled for a period.
  D. Glaucoma must be treated aggressively with a combination of medical and surgical therapy.
II. Goals of therapy
  A. Preservation of vision in affected eyes
  B. Prophylactic therapy for unaffected, at-risk eyes
  C. Resolution of pain
III. Treatment strategies
  A. In visual or recently visual eyes with significantly elevated IOPs (>35 to 40 mm Hg), emergency treatment with hyperosmotic medications or topical ophthalmic prostaglandin analogues is indicated.
    1. Maintenance medications are administered concurrently.
    2. Early surgical treatment is also considered.
  B. With signs consistent with glaucoma but IOPs <35 mm Hg, hyperosmotic treatment is unnecessary.
    1. Other medical antiglaucoma treatments are instituted immediately.
    2. Early surgical treatment may also be considered.
  C. In eyes that are blind and buphthalmic from chronic, end-stage glaucoma, a salvage procedure is recommended, because such eyes do not regain vision after control of IOP and benefit minimally from prolonged medical therapy.
  D. In primary glaucoma cases, prophylactic medication of the unaffected eye is recommended (Miller et al., 2000).
  E. Cases of secondary glaucoma must be treated for both the glaucoma and the underlying condition.
IV. Medical antiglaucoma therapy
  A. Emergency treatment
    1. Topical ophthalmic prostaglandin analogue (e.g. latanoprost), one drop to the affected eye
      a. Repeated in 5 to 10 minutes
      b. Often results in a dramatic IOP reduction within 20 to 40 minutes
      c. Contraindicated if glaucoma is secondary to anterior lens luxation
      d. Can combine with hyperosmotic therapy, but this is generally unnecessary
    2. Mannitol 1 to 2 g/kg IV over 20 to 40 minutes
      a. This medication is hyperosmotic.
      b. Water is withheld for 1 to 2 hours to possibly increase its effect.
      c. It is contraindicated in animals with congestive heart failure.
      d. Avoid use in dehydrated animals and those with renal failure.
      e. Dose may be repeated in 2 to 4 hours if needed.
    3. Glycerin 1 to 2 g/kg PO
      a. This medication is hyperosmotic.
      b. It is less effective than IV mannitol.
      c. It is contraindicated in diabetics and animals with congestive heart failure.
      d. Common gastrointestinal side effects are seen.
    4. Anterior chamber centesis
      a. Centesis is generally not recommended as a therapeutic procedure.
      b. The IOP reduction achieved via centesis is short-lived.
      c. Potential complications include laceration of iris or lens, hyphema, and introduction of infection.
  B. Maintenance medications
    1. In most animals, a combination of medications is required to achieve and maintain satisfactory control of IOP.
    2. Carbonic anhydrase inhibitors are generally considered the most effective medications for IOP reduction in the dog, and topical agents have largely replaced the oral forms.
      a. Dorzolamide *(Trusopt),* one drop to affected eye BID to TID
      b. Brinzolamide *(Azopt),* one drop to affected eye BID to TID
      c. Dorzolamide combined with timolol *(Cosopt),* one drop to affected eye TID
      d. Methazolamide 2 to 4 mg/kg PO BID to TID
      e. Acetazolamide 5 to 10 mg/kg PO BID to TID; CAUTION: Often avoided because side effects common
    3. Miotic drugs are moderately to highly effective, but they are contraindicated in the presence of anterior lens luxation and will exacerbate uveitis.
      a. Pilocarpine 2%, one drop to affected eye TID to QID
      b. Demecarium bromide 0.125%, one drop to affected eye BID
        (1) No longer commercially available
        (2) Can be obtained from compounding pharmacies
        (3) Should not be used in cats
    4. Prostaglandin analogues are moderately to highly effective but are contraindicated in the presence of anterior lens luxation and may exacerbate uveitis.
      a. Latanoprost *(Xalatan),* one drop to affected eye SID to BID
      b. Bimatoprost *(Lumigan),* one drop to affected eye SID to BID
      c. Travoprost *(Travatan),* one drop to affected eye SID to BID

d. Also effective emergency antiglaucoma medications
e. Ineffective in cats

5. Beta-adrenergic blocking agents are mildly to moderately effective, but cannot often be relied on as the sole medical therapy.
   a. Timolol maleate 0.5%, one drop to affected eye BID
   b. Betaxolol 0.5%, one drop to affected eye BID
6. Sympathomimetics are only mildly effective and cannot be relied on as the sole medical therapy.
   a. Epinephrine 1% or 2%, one drop to affected eye BID to QID
   b. Dipivalyl epinephrine (dipivefrin), one drop to affected eye BID to QID

C. Prophylactic medication (Slater et al., 1986; Miller et al., 2000)
1. Medicating the clinically unaffected eyes of dogs with primary glaucoma delays the onset of clinical disease.
2. Topical β-adrenergic blocking agents and topical miotic agents (demecarium bromide) appear equally effective at delaying disease onset (Miller et al., 2000).
3. Other treatments (topical carbonic anhydrase inhibitors, topical prostaglandin analogues) may also be useful.

D. Potential future medical treatment modalities
1. Excitatory amino acid antagonists
2. Calcium channel blockers

E. Contraindicated medication
1. Use of topical mydriatic agents, particularly atropine, is contraindicated in glaucomatous animals.
2. When treating other ophthalmic conditions (e.g., uveitis) in dogs predisposed to primary glaucoma, topical atropine must be used with caution.

F. Topical corticosteroid medications
1. For underlying uveitis and inflammation
2. When the cornea is not ulcerated

V. Surgical therapy

A. In visual or potentially visual eyes, surgery is recommended early in the disease process when the animal has the most to gain.

B. Prophylactic surgery in normotensive, at-risk eyes is controversial and generally not recommended.

C. Surgery is rarely, if ever, curative, and most animals continue to require some level of medical therapy for optimal IOP control.

D. Surgical procedures are designed to increase aqueous humor outflow or decrease aqueous production.

E. Procedures that increase aqueous humor outflow include the following aqueous humor shunting procedures (Peiffer et al., 1977; Gelatt et al., 1987; Bedford, 1989; Bentley et al., 1996, 1999; Cullen, 2004):
1. Gonioimplants
   a. Aqueous humor is diverted from the anterior chamber via synthetic tubing to an explant in the subconjunctival space.
   b. Aqueous humor diversion to the frontal sinus has also been reported recently.
   c. Synthetic implants may be nonvalved or may use a valve that opens only above a specific pressure to prevent postoperative ocular hypotony.
   d. Several subconjunctival explant configurations have been devised to increase the absorptive surface area for diverted aqueous humor.
   e. Gonioimplants are the most common and successful aqueous shunting procedure in use today.
2. Iridencleisis
   a. In this procedure, a radial section of iris is positioned under the bulbar conjunctiva through a limbal incision, allowing drainage of aqueous humor to the subconjunctival space.
   b. Because of low success rates, this procedure is uncommonly performed.
3. Cyclodialysis
   a. Sclerotomy is performed posterior to the limbus beneath the bulbar conjunctiva.
   b. By inserting a spatula through the sclerotomy site between the iris and ciliary body and the overlying sclera, a fistula is then created between the anterior chamber and the sclerotomy site, allowing an alternate route for aqueous egress.
   c. Cyclodialysis may be combined with an iridencleisis procedure.
   d. Because of low success rates, this procedure is uncommonly performed.
4. Acute complications
   a. Severe iridocyclitis and hyphema are the most common complications.
   b. Complication rates and severity of complications are lowest with gonioimplants.
5. Long-term complications
   a. They include shunt failure from occlusion by fibrin, cellular debris, or bleb fibrosis.
   b. Tissue plasminogen activator may be used to dissolve fibrin in a blockage.
   c. Intraoperative use of antifibrotic medications (e.g., mitomycin C) may delay fibrosis at the surgical site, but improved long-term bleb function associated with this treatment remains unsubstantiated.
   d. Surgical resection of fibrotic tissue may also prolong success.

F. Procedures that reduce aqueous humor production include the following:
1. Cyclophotocoagulation involves partial laser ablation of ciliary body epithelium.
   a. Neodymium:yttrium-aluminum-garnet (Nd:YAG) and diode lasers are both effective.
   b. Laser energy is applied transsclerally with the probe placed over the region of the pars plicata of the ciliary body.
   c. Potential complications include corneal ulceration, hyphema, cataract formation, iridocyclitis, and postoperative IOP elevations.

2. Cyclocryotherapy involves application of extreme cold to the surface of the globe over the region of the ciliary body to cause partial destruction of the ciliary body.
   a. Liquid nitrogen and nitrous oxide are both effective cryogens.
   b. Complications include uveitis and postoperative IOP spikes that may be prolonged and severe, limiting the usefulness of this technique in visual eyes.

G. Combination surgical procedures using laser cyclophotocoagulation and anterior chamber shunts are commonly performed (Bentley et al., 1999; Sapienza and van der Woerdt, 2005).

VI. Salvage procedures for end-stage glaucomatous eyes
   A. Goals
      1. After vision is lost, the primary goal of therapy is animal comfort.
      2. Surgical procedures to maintain control of IOP are rarely curative, and many animals become refractory to medical therapy.
      3. Medical therapy is also expensive and has potential side effects.
      4. Salvage procedures are considered for most blind eyes.
   B. Enucleation
      1. Surgical removal of the globe relieves discomfort associated with glaucoma and has few complications.
      2. Ancillary procedures to prevent inward sagging of eyelids into an empty orbit may be performed to improve postoperative cosmesis.
         a. Orbital implant of silicone or methylmethacrylate (Nasisse et al., 1988b)
         b. Nonabsorbable suture mesh implant (Hamor et al., 1993)
         c. Reconstruction using autogenous tissues (Mughannam and Reinke, 1994)
   C. Evisceration with intrascleral prosthesis (Brightman et al., 1977)
      1. Intraocular contents are removed and replaced with a silicone prosthetic sphere.
      2. Significant corneal scarring usually results, but animals are eventually comfortable and owner satisfaction with cosmesis is high.
      3. Intrascleral prosthesis is contraindicated in glaucoma secondary to intraocular neoplasia and has a high complication rate in cases with preexisting corneal ulceration or keratoconjunctivitis sicca.
   D. Intravitreal gentamicin injection in dogs (Moller et al., 1986)
      1. Gentamicin (15 to 25 mg) injected into the vitreous destroys the ciliary epithelium.
      2. Agent is toxic to lens and retina; therefore the procedure is only performed on blind eyes.
      3. Concurrent intravitreal injection of dexamethasone (0.25 to 0.5 mg) and/or topical treatment with ophthalmic corticosteroid medications is required to control postoperative intraocular inflammation.
      4. Volume of aqueous humor or vitreous equal to the gentamicin and dexamethasone injection volume is removed from the eye by centesis before injection.
      5. Inadvertent lens laceration during injection results in severe lens-induced uveitis.
      6. Outcome is difficult to predict and may include a normotensive and cosmetic eye, recurrence of glaucoma, or phthisis bulbi.
      7. Procedure is *not* performed in cats, because of their potential for forming posttraumatic ocular sarcomas.

VII. Treatment of the underlying disease process in secondary glaucomas
   A. Intracapsular lens extraction is indicated in cases of anterior lens luxation.
   B. Appropriate treatment for uveitis with elucidation and treatment of underlying diseases is required in cases of glaucoma secondary to uveitis.
   C. Enucleation is recommended for eyes with glaucoma secondary to intraocular neoplasia.

VIII. Prognosis
   A. Long-term prognosis for maintenance of vision in eyes affected with primary glaucoma is guarded to poor.
   B. Visual prognosis in eyes with secondary glaucoma is guarded and depends partly on the success of managing the underlying condition.

Monitoring of Animal

I. Once the disease is under control, IOP is monitored regularly (every 3 to 4 weeks) by tonometry.

II. It is unclear what level of IOP is safe in glaucomatous eyes.
   A. In an affected but visual eye, a high-normal IOP (20 to 25 mm Hg) may lead to continued vision loss and indicates a need for more aggressive medical and/or surgical measures.
   B. Ideal IOP in visual eyes is ≤15 to 20 mm Hg to prevent continued optic nerve damage.

III. Permanent vision loss, especially with concurrent loss of IOP control, is an indication for a salvage procedure.

IV. Educating the owner about the clinical signs of glaucoma may improve early detection of rising IOP or pressure spikes, especially in the normal eye.

V. Monitoring IOP of the unaffected eye in primary glaucoma cases is performed regularly (every 6 to 12 weeks) to allow early detection of IOP elevation.

CHAPTER 101

Diseases of the Lens and Vitreous

Carmen M.H. Colitz

CONGENITAL/DEVELOPMENTAL DISORDERS

See Table 101-1.

ACQUIRED DISORDERS

Cataracts

Definition

I. Any opacity of the lens regardless of the cause
II. Classification of cataracts (Davidson et al., 1990; Davidson and Nelms, 1999)
  A. By degree of opacification of lens and stage of maturity
    1. Incipient: <10% of tapetal reflection obstructed
    2. Early immature: 10% to 50% of tapetal reflection obstructed
    3. Late immature: 51% to 99% of tapetal reflection obstructed
    4. Mature: 100% of tapetal reflection obstructed
    5. Hypermature
      a. Cortical lens material may undergo liquefaction, and part of the tapetal reflex may be seen.
      b. Lens capsule may be wrinkled, with multifocal, dense, white plaques.
      c. Anterior chamber depth may be increased.
      d. Signs of lens-induced uveitis may be noted.
      e. Resorption of lens material with restoration of functional vision is uncommon except in dogs <1 year of age.
    6. Morgagnian: type of hypermature cataract wherein the nucleus falls into the ventral portion of the lens capsule
  B. By location
    1. General locations for opacities are as follows:
      a. Anterior or posterior capsule
      b. Anterior or posterior cortex
      c. Nucleus
      d. Equator
    2. Progression of cortical and equatorial cataracts more likely than capsular and nuclear cataracts
  C. By age of onset (does not imply cause)
    1. Congenital: present at birth
    2. Juvenile: few months to 6 years
    3. Senile: dog >6 years in large breeds and >10 years in small breeds

Causes

I. Congenital
  A. Opacification of lens present at birth
    1. From abnormal formation of primary or secondary lens fibers
    2. From exposure of the dam to toxic or infectious agents (Carmichael et al., 1965; Koch and Rubin, 1967)
  B. Inherited in some breeds (Table 101-2)
II. Inherited
  A. See Table 101-2 for affected breeds.
  B. Specific mutations have not been identified in most breeds of dog.
  C. Recently, mutations in the HSF4 gene have been identified in cataracts occurring in three breeds of dogs (Mellersh et al., 2006).
    1. Australian shepherd: inherited as an autosomal dominant trait
    2. Staffordshire bull terrier and Boston terrier: inherited as an autosomal recessive trait
III. Nutritional
  A. Arginine deficiency
    1. Puppies and kittens fed milk replacer
    2. Begins during third week after birth
  B. Other amino acid deficiencies: rare in dogs and cats
IV. Metabolic
  A. Hyperglycemia
    1. Elevated glucose levels saturate hexokinase and activate sorbitol pathway, allowing glucose to accumulate in the lens, leading to rupture of the lens fibers and opacification.
    2. Diabetes mellitus is a common cause of cataracts in dogs.
  B. Hypocalcemia
    1. Associated with renal failure, primary hypoparathyroidism, or secondary hypoparathyroidism
    2. Bilaterally symmetrical, multifocal, punctate opacities in outer cortex that progress to coalescing lamellar cortical opacities (Paterson and Delamere, 1992)

TABLE 101-1

Congenital and Developmental Disorders of the Lens

LESION	DEFINITION	CAUSE	CLINICAL FINDINGS	DIAGNOSTICS	TREATMENT
Aphakia	Absence of lens	Developmental anomaly	Absence of lens or lens capsule	Dilated ophthalmologic examination	None
Microphakia	Small lens	Developmental anomaly	Reduced lens diameter, elongated ciliary processes and zonules, whole lens visible in pupil aperture	Dilated ophthalmologic examination	No treatment is indicated, but monitor for changes in lens position and opacification; if either occurs, then extract lens
Lens coloboma of equatorial lens	Notchlike defect of equatorial lens	Developmental anomaly	Typically see notch at ventral aspect of lens	Dilated ophthalmologic examination	No treatment is indicated unless lens luxates or cataract occurs, then extract lens
Lenticonus/ lentiglobus	Cone-like deformity of lens/cone-like deformation of globe	Developmental anomaly	Usually see posterior protrusion of lens into vitreous; cataract may be present; may be associated with microphthalmia	Ophthalmic examination with dilated pupil; ultrasonography	Lensectomy if cataract present with vision impairments
Persistent hyperplastic tunica vasculosa lentis (PHTVL)	Embryonic vasculature around lens fails to regress	Developmental anomaly; may be inherited in the Doberman pinscher	Leucocoria, cataract, ± abnormal pupil function; inability to visualize fundus	Slit-lamp examination; ultrasonography	Indicated if vision impaired: lens extraction and anterior vitrectomy
Persistent hyperplastic primary vitreous (PHPV)	Embryonic vasculature extending from the optic nerve to the posterior lens capsule	Developmental anomaly; may be inherited in the Doberman pinscher	Leucocoria; cataract, inability to visualize fundus	Dilated ophthalmologic examination; ultrasonography	Indicated if vision is impaired: lens extraction and anterior vitrectomy
Persistent hyaloid artery	Failure of regression of a portion or all of the hyaloid artery	Developmental anomaly	A tubular vessel-like structure located between the lens and optic nerve that may or may not contain blood; usually seen as a tubular vessel-like structure adhered to the posterior lens capsule	Ophthalmic examination with dilated pupil and slit-lamp biomicroscopy	No treatment is indicated

TABLE 101-2

Characteristics of Selected Hereditary Cataracts in Dogs

BREED*	AGE OF ONSET	MODE OF INHERITANCE	LOCATION	PROGRESSION	ASSOCIATED FINDINGS†
Afghan	Juvenile	Not defined	Equatorial	Progressive	None
Akita	Congenital	Not defined	Nuclear and cortical	Variable progression	Microphthalmia, retinal dysplasia
Alaskan malamute	Juvenile	Not defined	Posterior subcapsular	Variable progression	None
American cocker spaniel	Juvenile or adult	Autosomal recessive	Cortical	Progressive	None
Australian shepherd dog	Congenital or juvenile	Autosomal dominant	Nuclear and cortical	Nonprogressive	Microphthalmia, retinal dysplasia, colobomas
Basenji	Congenital	Not defined	Anterior capsular	Nonprogressive	Persistent pupillary membranes (PPM)
Beagle	Congenital	Not defined	Anterior capsular	Nonprogressive	PPM
Boston terrier	Congenital or juvenile	Autosomal recessive	Nuclear and cortical	Progressive	None
	Adult	Not defined	Equatorial, subcapsular	Slow progressive	None
Cavalier King Charles spaniel	Congenital	Not defined	Nuclear and cortical	Progressive	Microphthalamia, lenticonus
Chesapeake Bay retriever	Juvenile or adult	Not defined	Posterior subcapsular	Variable progression	None
Chow chow	Congenital	Not defined	Nuclear and cortical	Variable progression	Microphthalmia, PPM, retinal dysplasia, nystagmus
Collie	Congenital	Not defined	Nuclear and cortical	Unknown	Microphthalmia, retinal dysplasia, colobomas
Doberman pinscher	Congenital	Dominant with incomplete penetrance	Posterior subcapsular	Variable progression	Persistent hyperplastic primary vitreous or tunica vasculosa lentis
English cocker spaniel	Congenital	Not defined	Anterior capsular	Nonprogressive	PPM, microphthalmia, retinal dysplasia
Flat-coated retriever	Juvenile or adult	Not defined	Posterior subcapsular	Nonprogressive	None
German shepherd dog	Congenital	Autosomal dominant	Nuclear	Nonprogressive	None
	Juvenile	Autosomal recessive	Posterior Y suture	Variable progression	None
Golden retriever	Juvenile or adult	Not defined	Perinuclear	Progressive	None
	Juvenile or adult	Not defined	Posterior subcapsular	Nonprogressive	None
Labrador retriever	Congenital	Incomplete dominance	Nuclear and cortical	Variable progression	Vitreoretinal dysplasia, skeletal chondrodysplasia
	Juvenile or adult	Not defined	Perinuclear	Progressive	None
	Juvenile or adult	Not defined	Posterior subcapsular	Nonprogressive	None
Miniature schnauzer	Congenital	Autosomal recessive	Nuclear and cortical	Variable progression	Posterior lenticonus, microphthalmia
Old English sheepdog	Congenital	Not defined	Nuclear and cortical	Progressive	PPM, microphthalmia, retinal dysplasia
Poodle					
Toy and miniature	Juvenile or adult	Not defined	Cortical	Progressive	None
Standard	Juvenile	Not defined	Equatorial	Progressive	None

Modified from English RV: Diseases of the lens and vitreous. p. 1036. In Morgan RW (ed): Handbook of Small Animal Practice. 3rd Ed. WB Saunders, Philadelphia, 1997 with permission.

*All dogs with cataracts should be evaluated for retinal degeneration.

†These findings may or may not be present.

TABLE 101-2

Characteristics of Selected Hereditary Cataracts in Dogs—*cont'd*

BREED*	AGE OF ONSET	MODE OF INHERITANCE	LOCATION	PROGRESSION	ASSOCIATED FINDINGS†
Rottweiler	Juvenile or adult	Not defined	Posterior subcapsular and cortical	Nonprogressive	None
Samoyed	Congenital	Autosomal recessive	Nuclear and cortical	Variable progression	Retinal detachment, skeletal chondrodysplasia
Siberian husky	Juvenile	Not defined	Posterior subcapsular, equatorial	Variable progression	None
Staffordshire terrier	Congenital Congenital	Not defined Not defined	Nuclear and cortical Posterior subcapsular	Progressive Nonprogressive	None Persistent hyperplastic primary vitreous or tunica vasculosa lentis
Welsh springer spaniel	Juvenile	Autosomal recessive	Cortical	Progressive	None
West Highland white terrier	Congenital Juvenile	Autosomal recessive Not defined	Nuclear and cortical Posterior Y suture	Progressive Nonprogressive	Microphthalmia None

C. Hypercalcemia: abnormalities in lens metabolism that cause lens epithelial cell death (Paterson and Delamere, 1992)

V. Exposure to toxins
  A. Most toxic cataracts begin in the cortical region near the equator or in the Y-suture regions.
  B. Drugs administered at much higher doses than normal can cause such cataracts.
    1. Diazoxide (Schiavo, 1976)
    2. Phenylpiperazine (Susick et al., 1991)
    3. Dinitrophenol (Martin, 1975)
    4. Long-term ketoconazole administration at 6.0 to 13.9 mg/kg/day (da Costa et al., 1996)
    5. Chronic oral administration of dimethyl sulfoxide at 2.5 to 40 g/kg
    6. Other examples: naphthalene, ouabain, digitalis, heavy metals, chlorpromazine, diquat, and hygromycin B (Sanford et al., 1981; Davidson and Nelms, 1999)

VI. Environmental or physical injury
  A. Blunt trauma (Davidson et al., 1991)
    1. Blunt injury causes contrecoup or compressive forces that damage lens epithelium and lens fiber cells.
    2. It may also cause lens capsule rupture and phacoclastic uveitis (see Chapter 99).
  B. Sharp trauma (Davidson et al., 1991)
    1. Penetrating ocular trauma that disrupts the anterior lens capsule
    2. Causes cataractous changes and phacoclastic uveitis
  C. Irradiation
    1. Orthovoltage irradiation (Jamieson et al., 1991; Paterson and Delamere, 1992)
    2. Megavoltage irradiation (Roberts et al., 1987; Paterson and Delamere, 1992)
    3. Ultraviolet irradiation
  D. Electric cord shock (Reddy, 1999)
  E. Microwave exposure (Michaelson et al., 1971)

VII. Secondary to inflammation (Engle and Spencer, 1995)
  A. Moderate to severe uveitis, regardless of cause, can result in anterior subcapsular or equatorial cataracts.
  B. Inflammatory mediators may diffuse across the lens capsule and disrupt normal metabolism of the lens epithelial cells.
  C. Resorbing, typically hypermature, cataracts cause lens-induced (phacolytic) uveitis, although any stage of cataract can cause uveitis.

VIII. Secondary to retinal degeneration (Zigler and Hess, 1985)
  A. Cataractous changes from release of water-soluble dialdehydes from peroxidation of photoreceptor lipid membranes are toxic to lens cellular membranes.
  B. These cataracts begin at the posterior subcortical region and progress anteriorly.

IX. Secondary to other ocular defects
  A. Persistent pupillary membranes (Barnett and Knight, 1969)
  B. Persistent tunica vasculosa lentis (Boeve et al., 1992)
  C. Persistent hyperplastic primary vitreous (Boeve et al., 1992)
  D. Anterior segment dysgenesis (Cook, 1995)
  E. Lens instability (subluxation or luxation)

X. Senility (Davidson and Nelms, 1999)
  A. Secondary to age-related changes in lens metabolism
  B. Equatorial cortical opacities common

Pathophysiology

I. Normal lens metabolism is directed toward maintaining transparency.

II. Any abnormality in the metabolism of the lens may result in a cataract through the following mechanisms:
  A. Changes in the ratio of lens protein types
  B. Alterations in metabolic pumps on the cell membranes
  C. Alterations in antioxidant activity
  D. Degradation of lens proteins

Clinical Signs

I. Age and breed of dog may indicate an inherited predisposition.

II. Visual impairment may be difficult for the owner to assess.
  A. Dogs often compensate for vision loss from slowly progressive cataracts.
  B. Dogs also compensate well with unilateral cataracts.

III. Leukocoria (change in color of the lens to white or blue) may be the first sign noticed.

IV. History may include the following:
  A. Previous uveitis
  B. Previous trauma
  C. Milk replacer fed when very young
  D. Variable visual impairment based on stage and location of cataracts
    1. Incipient: no change in vision
    2. Early immature: no change in vision
    3. Late immature: may see impairment on affected sides
    4. Mature: impairment on the affected sides
    5. Hypermature: impairment on affected sides unless resorption allows return of vision

V. Clinical signs of lens-induced uveitis may be present.
  A. Corneal edema, conjunctival hyperemia
  B. Aqueous flare
  C. Possibly miosis
  D. Blepharospasm and photophobia
  E. Associated with most stages of cataract
  F. Not always clinically evident

VI. Signs of secondary glaucoma may also occur.
  A. Clinical signs similar to those of lens-induced uveitis
  B. Scleral injection
  C. Possibly buphthalmia
  D. Elevated ocular pressure

VII. Lens luxation is uncommon except in hypermature cataracts, but subluxation may be evident with buphthalmia.

Diagnosis

I. Complete ophthalmic examination
  A. Slit lamp biomicroscopy with a dilated pupil to locate and stage the cataract, and to assess the cornea and anterior chamber
    1. Incipient cataracts are very small and difficult to locate without dilation and slit lamp biomicroscopy.
    2. Immature cataracts are more evident but still require magnification to characterize.
    3. Fundic examination is still possible with all early-immature and some advanced, late-immature cataracts.
    4. Mature cataracts involve the entire lens and do not allow the fundus to be visualized.
    5. Hypermature cataracts have an irregular anterior lens capsule, often with wrinkles or dense white plaques; with resorption, small areas of fundic reflex are seen (Colitz et al., 1999).
    6. Morgagnian cataracts allow some fundic reflex to be seen, and the nucleus of the lens is in the ventral portion of the lens capsule.
  B. Fundic examination (if possible) to rule out retinal diseases
  C. Measurement of intraocular pressure via tonometry
    1. Low pressures with uveitis
    2. High pressures with glaucoma
  D. Electroretinography to rule out retinal degeneration
  E. Ultrasonography to assess vitreous for degeneration and retina for detachments
II. Complete laboratory workup
  A. Rule out diabetes mellitus and other systemic illnesses.
  B. Diagnosis of inherited cataracts is based on signalment, location of cataracts, and exclusion of other causes, so laboratory tests are usually normal.

Differential Diagnosis

I. Nuclear sclerosis
  A. It begins in dogs at approximately 6 to 7 years of age and progresses slowly; does not cause visual impairment in the early stages.
  B. Homogeneous bluish appearance to the nucleus of the lens with clear cortex is seen.
  C. Fundus is still visible.
II. Other causes of leukocoria
  A. Persistent tunica vasculosa lentis
  B. Persistent hyperplastic primary vitreous
  C. Vitreal inflammation, pars planitis
III. Other causes of opacification within the eye
  A. Corneal edema or other corneal opacities (see Chapter 98)
  B. Aqueous flare, ± hypopyon
  C. Lipid flare with high serum triglyceride levels
  D. Intraocular neoplasia

Treatment

I. Medical therapy to stabilize underlying causes or associated conditions
  A. Dietary correction in young puppies and kittens
  B. Medical management of lens-induced uveitis (see Chapter 99)
    1. Topical corticosteroids, such as 1% prednisolone acetate or 0.1% dexamethasone
    2. Topical nonsteroidal antiinflammatory drugs in diabetic dogs
    3. Topical atropine or tropicamide for ciliary spasm and miosis, as well as to prevent posterior synechia
II. Criteria for surgical removal of lens
  A. Animal is in good health.
  B. Diabetes mellitus and associated hyperlipidemia are moderately to well controlled.
  C. Lens-induced uveitis is under control (although lensectomy and antiinflammatory agents are best approach).
  D. No evidence of secondary glaucoma is found, although concomitant endolaser ciliary ablation can be performed if vision is still present.
  E. No retinal degeneration or detachment discovered with electroretinography and ultrasonography, respectively.
  F. Preferably an immature cataract is present, although any stage of cataract may be operable.
III. Surgical options
  A. Phacoemulsification
    1. Ultrasonic energy breaks up the cataract so that it can be aspirated through a phacoemulsification needle (Gilger, 1997).
    2. Preferred technique for removal of all cataracts, except subluxated lenses.
    3. Insertion of an intraocular lens prosthesis into the capsular bag returns the eye to normal vision.
  B. Extracapsular lens extraction
    1. Rarely undertaken
    2. Requires a larger incision, with potential for more postoperative inflammation
  C. Discission and aspiration
    1. Feasible only in highly liquefied lenses
    2. Replaced by phacoemulsification
IV. Postoperative care
  A. Postsurgical therapy is vital to a successful outcome.
  B. Administer topical corticosteroids four or more times daily for 2 weeks, then taper per ophthalmologist's recommendations.
  C. Use topical antibiotics QID to prevent infection.
  D. Topical, short-acting, mydriatic agents (tropicamide) may be used to encourage pupil movement and prevent posterior synechia.
  E. Oral antibiotic therapy is often used in diabetic animals or if the posterior capsule has been breached.
  F. Oral nonsteroidal antiinflammatory agents may be used if uveitis is moderate to severe.
V. Postoperative complications
  A. Wound dehiscence and self-inflicted trauma are decreased with use of an Elizabethan collar.
  B. Uveitis is expected postoperatively and is worse with hypermature cataracts and in cases of presurgical lens-induced uveitis (van der Woerdt et al., 1992).
  C. Hyphema and vitreal hemorrhage are uncommon.

D. Ocular hypertension may occur 3 to 12 hours postoperatively and can often be managed with antiglaucoma medications (Smith et al., 1996).
E. Endophthalmitis is a rare complication (Taylor et al., 1995).
F. Retinal detachment and secondary glaucoma are potential long-term sequelae (Nassise and Davidson, 1999; Sigle and Nassise, 2005).
G. Posterior capsular opacification (secondary cataract) is the most common long-term complication of canine cataract surgery (Glover and Constantinescu 1997; Wilkie and Colitz, 2006).

Monitoring of Animal

I. Likelihood of progression of cataracts
   A. Nuclear cataracts and capsular cataracts are unlikely to progress.
   B. Cortical and equatorial cataracts will likely progress.
II. Success rate of surgeries
   A. Short-term success rate for animals undergoing phacoemulsification approaches 95% (Nasisse and Davidson, 1999).
   B. Short-term success rates are lower for animals with hypermature cataracts.
   C. Success rates diminish with time from opacification of the remaining lens capsule, detachment of the retina, and delayed onset of glaucoma.
III. Animals that are not candidates for surgery are examined two to three times yearly to monitor for lens-induced uveitis, secondary glaucoma, and lens subluxation or luxation.

Lens Subluxation and Luxation

Definition

I. Luxation is a total dislocation of the lens from its normal location within the patellar fossa, either anteriorly (into anterior chamber) or posteriorly (into vitreous chamber).
II. Subluxation is partial dislocation of the lens in any direction.

Causes

I. Congenital luxations: rare
II. Primary inherited luxations
   A. Usually bilateral but asymmetrical in presentation
   B. Dogs between 3 and 7 years of age (Curtis, 1990)
   C. Occurs in many terrier breeds: Sealyham, Jack Russell, wirehaired fox terrier, others (Curtis 1990; Davidson and Nelms, 1999; Morris and Dubielzig, 2005)
   D. Other predisposed breeds: border collie, German shepherd dog, certain spaniels, Chinese shar-pei (Curtis and Barnett, 1980; Foster et al., 1986)
III. Luxations secondary to other ocular conditions
   A. Glaucoma
   B. Chronic uveitis
   C. Hypermature, resorbing cataracts
   D. Trauma (rare)
   E. Intraocular neoplasia
IV. Idiopathic: older dogs or cats with no obvious predisposing causes

Pathophysiology

I. Pathophysiology of primary lens luxations is not completely understood; however, an inherited defect affects the zonules of the lens, resulting in zonular fiber dysplasia (Morris and Dubielzig, 2005).
II. With secondary luxations, the pathophysiology depends on the cause.
   A. Buphthalmia associated with glaucoma results in stretching and rupture of the zonules.
   B. Chronic uveitis may cause zonulolysis and is common in cats with chronic uveitis (Nasisse and Glover, 1997).
   C. Hypermature cataracts that are resorbing become smaller, thereby stretching the zonules.
   D. Zonulolysis from lens-induced uveitis may also cause zonule rupture in cases of hypermature cataracts.
   E. Traumatic causes can produce severe sight-threatening injuries, although breeds predisposed to lens luxation do not require extensive trauma to cause luxation (Nasisse and Davidson, 1999).

Clinical Signs

I. Signs with anterior luxations
   A. Acute changes
      1. Blepharospasm, epiphora
      2. Corneal edema, episcleral injection
      3. Blindness from either glaucoma or retinal detachment
   B. Chronic changes: corneal edema from endothelial damage, cataract, anterior uveitis, glaucoma
II. Signs with posterior luxations
   A. Variable blepharospasm
   B. Conjunctival hyperemia
   C. Possibly corneal edema, blindness
   D. Chronic changes: anterior uveitis, cataract, glaucoma, retinal detachment
III. Signs with subluxations
   A. Possibly no clinical signs
   B. Cataract
   C. Corneal edema, signs of uveitis or glaucoma

Diagnosis

I. Anterior luxation
   A. Painful, often cloudy eye
   B. Evidence of lens movement into anterior chamber
      1. Shallow anterior chamber
      2. Lens trapped in pupil
      3. Lens sitting anterior to iris
      4. Vitreous herniation into anterior chamber
   C. Increased intraocular pressure (often 30 to 90 mm Hg)
   D. Blindness
      1. Acute cases: secondary to acute glaucoma
      2. Chronic cases: secondary to chronic glaucoma, retinal detachment, and/or cataract formation
II. Posterior luxation

A. Deep anterior chamber with posterior movement of the iris
B. Iridodonesis (quivering of the iris)
C. Visualization of lens in the vitreal cavity
D. Possible vitreous herniation into anterior chamber

III. Subluxation
A. Aphakic crescent: a portion of the pupil is devoid of the lens, allowing visualization of the fundus or fundic reflex
B. Iridodonesis and phacodonesis (quivering of the lens with eye movement)
C. Vitreous herniation into anterior chamber around portions of the lens

IV. Ancillary tests
A. Fundic examination (if possible) to evaluate health of retina and optic nerve
B. Electroretinogram and ultrasonography to assess health of retina if cannot be visualized

Treatment

I. Anterior lens luxations require immediate medical and surgical intervention, on an emergency basis.
II. Posterior lens luxations are not considered an emergency.
III. Animals with glaucoma are treated with parenteral and topical drugs to lower their intraocular pressures as quickly as possible (see Chapter 100).
IV. Surgery for anterior and posterior lens luxations involves an intracapsular lens extraction, with or without introduction of a sulcus intraocular lens prosthesis (Glover et al., 1995; Nasisse and Glover, 1997).
V. Some surgeons perform phacoemulsification, carefully using a two-handed technique to avoid the large incision necessary for intracapsular lens extraction, with insertion of a foldable sulcus intraocular lens implant.
A. Prognosis is better if glaucoma is not present before surgery.
B. The most common causes of failure to save vision are secondary glaucoma and retinal detachment.
C. Greater success is achieved if surgery is performed before damage occurs to aqueous outflow pathways and the retina.

VI. Surgical intervention for subluxated lenses depends on degree of subluxation.
A. If a significant number of zonules are present, then lens extraction via phacoemulsification may be attempted.
B. If the lens is significantly subluxated, then intracapsular lens extraction is indicated after breakdown of the rest of the zonules (Nasisse and Davidson, 1999); alternatively, a two-handed phacoemulsification approach may be attempted.
C. A posteriorly subluxated lens may require no therapy, particularly in blind animals with quiet eyes; evaluate the animal periodically for secondary glaucoma; however, topical prostaglandin analogs are often used to cause miosis and trap the lens in the vitreous cavity, which will control intraocular pressure.
D. If unremitting glaucoma and blindness are present, then enucleation or evisceration with an intrascleral prosthesis is indicated.

Monitoring of Animal

I. Nonsurgical cases (blind, nonglaucomatous, posterior luxation, quiet eye) are monitored periodically for the following:
A. Elevations in intraocular pressure and institution of appropriate therapy
B. Signs of uveitis and administration of appropriate medical therapy
C. Consideration of enucleation, evisceration with intrascleral prosthesis, or chemical ciliary ablation with gentamicin (dogs only) if intraocular pressure elevation or uveitis develop or become intractable

II. Postoperatively, these cases require frequent monitoring for a successful outcome.
A. Weeks to months of administration of topical corticosteroid medications
B. Frequent monitoring of intraocular pressure for late-onset glaucoma and treatment of ocular hypertension as needed
C. Periodic monitoring for retinal detachments

DEGENERATIVE DISORDERS

See Table 101-3.

INFLAMMATORY DISORDERS

Vitritis and Hyalitis

Definition

I. Secondary infiltration of inflammatory cells into the vitreous from adjacent affected structures
II. May be associated with hemorrhage into the vitreous

Causes

I. Any cause of anterior or posterior uveitis (see Chapters 99 and 102)
II. Neoplasia
III. Blunt or perforating trauma
IV. Parasites

Pathophysiology

I. The vitreous has no direct vascular or nerve supply; therefore inflammatory or neoplastic cellular infiltrates develop secondary to neighboring inflammatory reactions (Boeve and Stades, 1999).
II. Traumatic incidents and inflammation can cause hemorrhage into the vitreous from the uvea or retina.
III. Hemorrhage in the vitreous is destructive to the gel structure, resulting in liquefaction, and may lead to vitreal fibrinous membranes that can cause retinal detachments (Miller et al., 1986; Boeve and Stades, 1999).
IV. Parasitic larva of *Dirofilaria immitis, Toxocara canis, Echinococcus* spp., and certain flies may migrate into the vitreous,

TABLE 101-3

Degenerative Disorders of the Vitreous

DISORDER	DEFINITION	CAUSES	CLINICAL SIGNS	DIAGNOSIS	TREATMENT
Synchysis scintillans	Cholesterol particles in liquefied vitreous that are mobile but do not return to their initial positions after movement	Associated with posterior uveitis and retinal degeneration	No visual impairment associated with this disorder	Ophthalmic examination with dilated pupil	No treatment necessary
Syneresis	Degeneration of the vitreous resulting in separation of the liquid and solid components	Aging, inflammation, or unknown causes	No visual impairment associated with this disorder, but predisposed to retinal detachment	Ophthalmic examination with dilated pupil	No treatment necessary
Asteroid hyalosis	Multiple, small particles of calcium or phospholipids in the vitreous that are mobile but return to their initial position after movement	Associated with retinal degeneration or posterior uveal changes; often no apparent cause	No visual impairment associated with this disorder	Ophthalmic examination with dilated pupil	No treatment necessary

causing a local inflammatory reaction, uveitis, or cysts (Boeve and Stades, 1999).

Clinical Signs

I. Variable visual impairment
II. Hemorrhage and/or cloudy (exudate) vitreous
III. Signs of anterior uveitis
  A. Corneal edema
  B. Aqueous flare
  C. Miosis, blepharospasm
IV. Signs of posterior uveitis
  A. Hyporeflective lesions in tapetal fundus
  B. Retinal hemorrhages
  C. Subretinal transudate or exudate
V. Signs of secondary glaucoma (see Chapter 100)

Diagnosis

I. Ocular examination under pupil dilation using slit lamp biomicroscopy and indirect ophthalmoscopy
II. Ultrasonography if anterior ocular media are opaque
III. Complete blood count and serum biochemistry profile to rule out systemic disease
IV. Serology for infectious agents capable of causing uveitis (see Chapter 99)
V. Radiography of chest and abdomen for signs of infectious or metastatic disease
VI. Careful vitreous aspirate if other tests are nondiagnostic and the eye is blind

Treatment and Monitoring

I. Treat the underlying cause.
II. Noninfectious diseases may benefit from systemic corticosteroid medications or other antiinflammatory agents.
III. Treat infectious diseases with appropriate antimicrobial and antiinflammatory agents.
IV. Cellular turnover rates are extremely slow in the vitreous compartment, so resolution and clearing may take weeks or months.
