CHAPTER 102

Disorders of the Posterior Segment

Robert D. Larocca

CONGENITAL/DEVELOPMENTAL DISORDERS

Retinal Dysplasia

Definition

I. Retinal dysplasia is an abnormal development and differentiation of the retina that results in folds of the sensory retina.
II. Severity of the retinal dysplasia varies from simple folds to geographic lesions and retinal detachment.
III. The disease is nonprogressive and unilateral or bilateral.
IV. It may affect vision, depending on the severity.

Causes

I. Inherited forms
  A. Variable inheritance patterns from autosomal recessive to dominant
  B. Component of multiple ocular anomalies: microphthalmos, colobomas, persistent hyperplastic primary vitreous
II. Acquired forms
  A. Infectious causes
    1. Canine adenovirus
    2. Canine herpesvirus
    3. Canine parvovirus
    4. Feline panleukopenia
    5. Feline leukemia virus
  B. Nutritional causes: vitamin A deficiency
  C. Toxins
  D. Radiation (x-ray) damage in newborns (Shively et al., 1972)
  E. Intrauterine trauma

Pathophysiology

I. Five theories have been suggested for spontaneous retinal dysplasia (Silverstein et al., 1971; Appleyard et al., 2006).
  A. Hyperplastic extension of neural retina into abnormal sites away from the pigmented epithelium
  B. Secondary to detachment of the neural retina from the retinal pigment epithelium (RPE) during development
  C. Occurs in areas without pigment epithelium
  D. Dysplastic processes without evidence of separation from the RPE
  E. Reduced levels of nuclear and mitochondrial transcripts in the retina and RPE of affected miniature schnauzers, suggesting lower energy supply to the retina and RPE (Appleyard et al., 2006)
II. Retinal dysplasia from exposure to physical, chemical, or infectious agents may result from efforts of the retina to regenerate, thereby producing gliosis, pigment cell migration, disorganization of retinal layers, and rosette formation.

Clinical Signs

I. Mild forms have no effect on vision.
  A. Folds and geographic lesions: usually no significant visual loss
  B. Retinal detachment: blind, dilated unresponsive pupils
II. Skeletal chondrodysplasia with a stunted appearance may be seen in certain breeds.
  A. Labrador retriever
  B. Samoyed
III. Retinal dysplasia is an autosomal recessive condition associated with persistent hyperplastic primary vitreous in the miniature schnauzer (Grahn et al., 2004).

Diagnosis

I. Because the condition is a congenital defect, dysplasia can be seen as early as the eyes can be examined via a fundic examination.
II. Geographic retinal dysplasia may not be visible until after 10 weeks of age (Holle et al., 1999).
III. Extent of the funduscopic changes varies.
  A. Retinal folds
    1. Tapetal region: small, linear or round, dark-gray hyporeflective lesions
    2. Nontapetal region: small, white-gray, round or linear vermiform streaks
  B. Geographic dysplasia
    1. Hyperreflective to hyperpigmented lesions
    2. Usually located in the dorsal tapetum at the region of the bifurcation of the major dorsal retinal vein
  C. Retinal detachment
    1. Retina free-floating
    2. Partial detachments possible
    3. Possible hemorrhage with the detachment

Differential Diagnosis

I. A condition similar to retinal folds can be detected at an early age in many breeds.
   A. These folds are believed to arise from a disparity in growth of the inner and outer retinal layers and, therefore, are not a true dysplasia.
   B. They typically appear as white vermiform streaks in the nontapetal retina, often near the optic disc.
   C. These folds resolve as the eye grows in size.
   D. True retinal dysplasia does not resolve with time.
II. Multifocal folds and geographic dysplasia can resemble postinflammatory chorioretinal scarring.

Treatment and Monitoring

I. Retinal dysplasia is usually a nonprogressive condition for which no treatment exists.
II. If retinal folds of uncertain etiology are diagnosed at an early age (<16 weeks), the dogs are rechecked again at 1 year of age to determine if the folds are true dysplasia or physiologic folds.
III. Affected animals with any form of retinal dysplasia are not to be used for breeding.

Collie Eye Anomaly

Definition and Cause

I. Collie eye anomaly (CEA) is an abnormal development of the posterior vascular and fibrous tunics of the eye.
II. CEA is a bilateral disease of rough- and smooth-coated collies, the Shetland sheepdog, Australian shepherd, and border collie.
III. The extent of the lesions can vary between the two eyes, but both eyes usually have choroidal hypoplasia.
IV. Defects of the sclera, vasculature, choroid, retina, and optic nerve can be seen.
V. Inheritance pattern is autosomal recessive (Yakeley et al., 1968; Bedford, 1982; Lowe et al., 2003).

Pathophysiology

I. Abnormal mesodermal differentiation results in colobomas of the sclera, choroid, and optic disc.
II. Colobomas may originate from embryologic deformities in the primitive epithelial papilla or from an abnormality in the closure of the fetal fissure.
III. Hemorrhage is thought to be caused by fragility of retinal neovascularization that extends into the vitreous (Barrie et al., 1981).
IV. Retinal detachments may be secondary to colobomatous defects from accumulation of fluid between the RPE and neural retina.

Clinical Signs

I. Only the major forms of CEA (i.e., large optic disc colobomas, retinal detachment, severe hemorrhage) affect vision.
II. Severely affected, blind puppies may exhibit pendular nystagmus or strabismus.

Diagnosis

I. Diagnosis is made via a fundic examination.
   A. Choroidal hypoplasia
      1. Area temporal to the optic disc in which a lack of pigment in the RPE and absence of tapetal tissue exist
      2. Maldevelopment of the choroidal vasculature
      3. Region temporal to the disc with increased exposure of the sclera (white appearance) and a scarcity of choroidal vessels
   B. Posterior polar coloboma
      1. Usually seen as a pit in the temporal or nasal side of the optic disc
      2. Gray to pink indentations or "blurry areas"
      3. Disappearance of adjacent retinal vessels into the defect
   C. Retinal vessel tortuosity
   D. Retinal detachment
      1. Partial or total
      2. Dilated, unresponsive pupils with complete detachments
   E. Hemorrhages
      1. Retinal or vitreal hemorrhage
      2. Hyphema: rare
II. Dogs are evaluated at an early age (6 to 7 weeks).
   A. Mild choroidal hypoplasia defects may disappear later (3 to 7 months of age) from a proliferation of pigment in the RPE.
   B. These dogs are termed *go normals*.
III. Merle-colored dogs can be difficult to evaluate.
   A. They lack pigment in the RPE and choroid.
   B. Evaluate these dogs carefully in the region temporal to the disc for a decrease in the choroidal vasculature.
IV. A DNA-based test is now available to detect CEA in the Australian shepherd, border collie, Lancashire heeler, collie, Shetland sheepdog, and Nova Scotia duck tolling retriever.
   A. Test can identify normal, carrier, and affected dogs.
   B. All affected dogs, regardless of severity, are homozygous for the same mutant gene.

Differential Diagnosis

I. Other primary colobomas from failure of the optic fissure to close may appear similar but are not accompanied by choroidal hypoplasia.
II. Central optic disc coloboma can be difficult to differentiate from a normal, deep physiologic cup.
III. Retinal detachment associated with retinal dysplasia can be difficult to differentiate from that of CEA.

Treatment and Monitoring

I. CEA is not a progressive disease, although severe defects such as large colobomas or vitreal changes may result in inflammation, hemorrhage, or detachment at a later date.
II. Most retinal detachments occur before 1 year of age.
III. Laser photocoagulation is rarely used to treat retinal detachments associated with CEA (Roberts, 1966; Kottow, 1982).
IV. Dogs with colobomas, retinal detachment, or hemorrhages are not to be bred.

V. Because of the high prevalence of CEA in the collie breed, owners find it difficult to stop breeding mildly affected animals (although this is ideal).

Optic Nerve Hypoplasia and Micropapilla

Definition and Cause

I. Optic nerve hypoplasia (ONH) is a congenital defect of the optic nerve that results in blindness.
II. Micropapilla is a small-appearing optic nerve that does not result in blindness.
III. ONH is an inherited condition in miniature and toy poodles and can be seen in many breeds (Kern and Riis, 1981; Rubin, 1989).
IV. ONH can be unilateral or bilateral.

Pathophysiology

I. The origin of ONH may be abnormal differentiation of the retinal ganglion cell layer or premature ganglion cell death (Collins, 1996).
II. Some of the nerve fibers fail to reach the disc, resulting in a small optic disc.
III. Micropapilla may be a milder form of hypoplasia not severe enough to significantly affect vision.

Clinical Signs

I. A unilateral condition may go unnoticed unless mydriasis is present.
II. Bilateral ONH results in blindness from birth.
  A. Affected puppies may circle or wander aimlessly.
  B. Mydriasis and absent menace reflexes are present in the affected eye(s).
III. Dogs with micropapilla have apparent normal vision.

Diagnosis

I. Micropapilla
  A. Fundic examination reveals a small optic disc in the affected eye, but vasculature and other structures are normal.
  B. The eye is visual, with normal pupillary light responses.
  C. Electroretinogram (ERG) and visual evoked potentials (VEPs) are normal.
II. Optic nerve hypoplasia
  A. Optic disc is small and dark, and the vasculature and other retinal structures appear normal.
  B. Eye is blind, often with a dilated, slow to unresponsive pupil.
  C. ERG shows normal *a* waves, slightly decreased amplitude and duration of *b* waves, and the VEPs are abnormal.

Differential Diagnosis

I. Optic nerve aplasia
  A. No optic disc is visible, and the retinal vasculature is often abnormal on fundic examination.
  B. ERG and VEPs are absent.
II. Optic nerve atrophy secondary to inflammatory events
  A. Animal previously visual and became blind in affected eyes
  B. May have circumpapillary inflammatory changes on funduscopy
III. Optic nerve atrophy secondary to glaucoma
  A. Optic nerve has cupped appearance.
  B. Other signs or findings are suggestive of glaucoma.
IV. Optic nerve atrophy secondary to progressive retinal atrophy (PRA)
  A. Significant evidence of retinal atrophy and optic nerve atrophy (see Generalized Progressive Retinal Atrophy)
  B. Animal previously visual

Treatment and Monitoring

I. These are congenital defects and are nonprogressive.
II. No corrective therapy is possible.
III. Do not breed affected dogs.

DEGENERATIVE DISORDERS

Generalized Progressive Retinal Atrophy

Definition and Causes

I. PRA encompasses an inherited group of retinal degenerations that leads to vision loss.
II. Most forms of PRA are inherited in an autosomal recessive manner, except for the following:
  A. X-linked PRA in the Siberian husky and Samoyed
  B. Autosomal dominant forms in the Abyssinian cat
  C. Dominant PRA in the English mastiff and bull mastiff
III. Two general types of PRA exist: early onset and late onset.
  A. Early-onset disorders are characterized by photoreceptor dysplasias in which certain photoreceptors fail to develop normally.
  B. Late-onset disorders are characterized by premature degeneration of the photoreceptors after they have developed normally.

Pathophysiology

I. Many forms of PRA exist, based on the enzymatic cause.
  A. Rod-cone dysplasia 1 (rcd1): early-onset disorder of Irish setters (Aguirre et al., 1978; Ray et al., 1995)
  B. Rod-cone dysplasia 2 (rcd2): early-onset disorder of collies (Chader et al., 1981)
  C. Rod-cone early-onset retinal degeneration: Persian cats (Rah et al., 2005)
  D. Photoreceptor dysplasia (pd): miniature schnauzers (Parshall et al., 1991)
  E. X-linked PRA: Siberian huskies (Acland et al., 1994)
  F. Early retinal degeneration (erd): Norwegian elkhounds (Acland and Aguirre, 1987)
  G. Progressive rod-cone degeneration 1 (prcd1)
    1. It is a late-onset PRA that affects many breeds.
    2. Affected breeds include toy, miniature, and standard poodles; American and English cocker spaniels; Labrador retrievers; and Portuguese water dogs (Aguirre et al., 1982; Aguirre and Acland, 1988, 1989).

H. Progressive rod-cone degeneration 2 (prcd2): an early-onset PRA of Tibetan terriers (Millichamp et al., 1988; Gould et al., 1995)
I. Dominant PRA of mastiffs
   1. It is the only dominant form of canine PRA.
   2. A single copy of the mutant gene causes the disease (no carrier state).
J. Cone degeneration: early-onset disorder of German shorthaired pointers

II. Photoreceptor metabolism and function are affected by abnormal cyclic guanosine 3′,5′-monophosphate metabolism or failure of photoreceptor outer segment renewal.
III. Pathophysiology of PRA in many breeds remains unknown.

Clinical Signs

I. All forms of PRA that affect the rod photoreceptors first have the same initial development of nyctalopia (night blindness).
II. Most cases lead to complete blindness because the cones are also eventually affected.
III. PRA is a bilateral disease and affects both eyes equally.
IV. Age of onset and rate of progression vary among breeds (Table 102-1).

Diagnosis

I. Diagnosis is based on clinical signs of nyctalopia along with fundic examination findings.
   A. Signs of night blindness can be evaluated by maze testing in both photopic and scotopic conditions.
   B. Navigational deficiency is noted in dim light.
   C. Pupillary light responses are generally slow.
II. Fundic findings are diagnostic at various stages of PRA (see Table 102-1).
   A. Tapetal hyperreflectivity
   B. Retinal vascular attenuation
   C. Optic nerve atrophy (dark appearance)
III. PRA can be detected via ERG.
   A. ERG detects retinal photoreceptor abnormalities before visible fundic changes (see Table 102-1).
   B. ERG findings depend on the specific type of PRA.
   C. Most forms of PRA result in a faster progression of rod degeneration.
   D. ERG changes consist of reduced amplitudes and prolonged implicit times of the waveforms, especially the *b* wave.
IV. DNA testing via a blood sample detects PRA in many breeds (Optigen LLC, Ithaca, N.Y. [607-257-0301], www.optigen.com).
   A. DNA tests for all forms of PRA are mutation-based tests; no marker-based tests are available at this time.
   B. The rcd1 PRA test is used to identify normals versus carriers and confirms the affected status of Irish setters.
   C. Dominant PRA test detects the actual mutation affected mastiffs.
   D. The prcd PRA test identifies the specific DNA mutation causing prcd-PRA.
      1. It detects normal dogs (homozygous normal).
      2. It detects carriers (heterozygous).
      3. It detects affected dogs (homozygous mutant).

TABLE 102-1

Summary of Fundic and Electroretinographic Findings in Generalized Progressive Retinal Atrophy and Hereditary Distrophy

BREED	DISORDER	EARLIEST FUNDIC LESION	EARLIEST ERG ABNORMALITY
Akita	Degeneration	6 mo-3 yr	1.5-2.0 yr
American cocker spaniel	prcd Degeneration	2-5 yr	9 mo
Briard	Retinal dystrophy	4-6 yr	5 wk
Collie	rcd2 Dysplasia	16 wk	6 wk
English cocker spaniel	prcd Degeneration	3-8 yr	1.5-3.0 yr
Irish setter	rcd1 Dysplasia	16 wk	6 wk
Labrador retriever	prcd Degeneration	3-6 yr	1.0-1.5 yr
Miniature longhaired dachshund	Degeneration	6 mo	4 mo
Miniature schnauzer	Degeneration	1.5-5.0 yr	6 wk
Norwegian elkhound	erd Degeneration	6 mo-1 yr	5-6 wk
	Rod dysplasia (rd)	5 mo-1 yr	6 wk
Papillon	Degeneration	1-5 yr	9 mo-1.5 yr
Toy, miniature, standard poodles	prcd Degeneration	3-5 yr	9 mo
Portugese water dog	prcd Degeneration	3-6 yr	1.5 yr
Samoyed	Degeneration	2-5 yr	1.5-2.0 yr
Siberian husky	X-linked degeneration	6 mo-2 yr	1.0-1.5 yr
Tibetan terrier	Degeneration	1.0-1.5 yr	10 mo

ERG, Electroradiogram; *prcd*, progressive rod-cone degeneration; *rcd2*, rod-cone dysplasia type 2; *rcd1*, rod-cone dysplasia type 1; *erd*, early retinal degeneration.

4. Dogs that test as homozygous normal can be bred to any other dog.
5. If a dog is suspected of having PRA based on fundic examination, then it must test as a homozygous mutant to truly be PRA.
6. Dogs that can be tested with the prcd PRA test include the Chesapeake Bay retriever, American cocker spaniel, American Eskimo dog, Australian cattle dog, Australian stumpy tail cattle dog, Chinese crested, Entlebucher Mountain dog, Finnish Lapphund, Kuvasz, Lapponian herder, miniature poodle, Nova Scotia duck tolling retriever, Swedish Lapphund, toy poodle, English cocker spaniel, Labrador retriever, and Portuguese water dog.

E. X-linked PRA test is a mutation-based test that identifies normals, carriers, and affected Siberian huskies and Samoyeds.
F. Type A PRA test is a specific mutation-based test for the miniature schnauzer.
   1. Type A PRA appears to have partial dominance expression, because some carriers appear affected via clinical or ERG findings.
   2. Because carriers may have signs of disease, researchers recommend that only homozygous normal schnauzers are used for breeding.
G. The rcd3 PRA test is a mutation-based test involving the PDE6A gene of Cardigan Welsh corgis.

Differential Diagnosis

I. RPE dystrophy or central PRA (Table 102-2)
II. Hereditary retinal dystrophy in briards (see following section)
III. Neuronal ceroid lipofuscinosis (see Table 102-2)
IV. Mucopolysaccharide storage diseases (see Chapters 65 and 81)
V. Retinal degeneration secondary to chorioretinitis
VI. Retinal degeneration secondary to optic neuritis
VII. Retinal degeneration secondary to chronic glaucoma
VIII. Sudden acquired retinal degeneration (SARD) (see later in this chapter)

Treatment and Monitoring

I. No treatment is available for PRA.
II. Because affected animals develop a progressive loss of vision, instruct owners on how to protect and care for blind pets.
III. Secondary cataracts are a frequent finding and may require medical treatment for lens-induced uveitis (see Chapters 99 and 101).
IV. Do not breed animals diagnosed with PRA.

Hereditary Retinal Dystrophy

Definition and Cause

I. Hereditary retinal dystrophy is a congenital disorder previously known as *congenital stationary night blindness* (CSNB).
II. Dogs are night-blind from birth and have a variable progression to complete blindness (Wrigstad et al., 1994).
III. An autosomal recessive inheritance pattern is suspected in the briard (Narfstrom et al., 1994).

Pathophysiology

I. Disorientation of the rod outer segments is seen histologically at 5 weeks of age.
II. The RPE develops inclusions, mainly located in the central and midperipheral tapetal regions, at 3.5 months of age.
III. Inclusions increase in number and spread peripherally with age.
IV. Rod photoreceptor degeneration is apparent in the peripheral tapetal retina histologically at 7 months of age.
V. At 7 years of age, the photoreceptor degeneration progresses from the central and midperipheral tapetal retina to the peripheral fundus (Wrigstad et al., 1994).
VI. A defect in retinal polyunsaturated fatty acid metabolism is suspected (Anderson et al., 1997).

Clinical Signs

I. Dogs are night-blind from birth.
II. Rapid horizontal nystagmus is seen frequently in puppies.
III. Pupils are generally mydriatic.
IV. Fundic examinations are normal early in the disease.

Diagnosis

I. Diagnosis is based on suspicious clinical signs in the briard breed.
II. DNA-based testing is currently available.
   A. A mutation in the RPE65 gene results in retinal dysfunction and RPE accumulation of lipid vacuoles (Aguirre et al., 1998).
   B. This mutation was found in both dogs with CSNB and dogs with retinal dystrophy, suggesting the two disorders are molecularly identical.
   C. A mutation-based gene test can identify normal, carriers, and affected dogs via a simple blood test.
III. ERG helps characterize the disorder.
   A. Absent *a* and *b* waves are detected in the dark-adapted state at 7 to 12 months of age.
   B. Reduction of 50% to 70% is present in the 30-Hz flicker fusion in the light-adapted state (Nilsson et al., 1992).

Differential Diagnosis

I. PRA (see previous section)
II. RPE dystrophy (see Table 102-2)

Treatment and Monitoring

I. Dogs that are only night-blind at birth frequently retain some sight until 6 to 7 years of age.
II. DNA-based test allows for selection of breeding dogs that will not produce affected puppies.
III. Recent studies using gene therapy offer hope for restoring vision to animals with this disease (Acland et al., 2001).

TABLE 102-2

Miscellaneous Retinal Degenerations

DISORDER	DEFINITION	BREEDS AFFECTED	CLINICAL SIGNS	DIAGNOSIS	PROGNOSIS
Hemeralopia	Day blindness from a selective cone degeneration	Alaskan malamute, German shorthaired pointer	Loss of vision in bright light	Clinical signs and ERG revealing absent cone function	Most animals retain dim-light vision
Central PRA (retinal pigment epithelial dystrophy, RPED)	A primary disease of the RPE with secondary retinal degeneration Occurs predominantly in the United Kingdom Very rare in the United States	Briard, Labrador retriever, golden retriever, English cocker spaniel, English springer spaniel, border collie, rough- and smooth-coated collie, Shetland sheepdog, Chesapeake Bay retriever	Vision loss is not noticed until late in the disease process Peripheral vision is usually spared until late	Ophthalmoscopic findings of multifocal pigment spots within the tapetal retina	Vision loss is not apparent until late in the disease
Neuronal ceroid lipofuscinosis	Inherited and progressive lipid storage disease that results in retinal degeneration and encephalopathy	English setter, Dalmatian, border collie, Tibetan terrier, Polish owczarek nizinny, miniature schnauzer	Progressive blindness usually occurring at 1 yr of age Neurological signs of ataxia, muscle weakness, and dementia usually develop	Diagnosis usually based on clinical signs and signalment Definitive diagnosis requires histopathology	Poor prognosis because the neurological disease is progressive and usually fatal
Vitamin E deficiency retinal degeneration	A slowly progressive visual loss resembling RPED; secondary to vitamin E deficiency	Any breed is susceptible	Progressive blindness beginning at 3-5 yr of age Neurologic, muscular, and reproductive defects may also be seen	Ophthalmoscopic findings reveal a mottled tapetal fundus with multiple discrete yellow-brown pigment spots and bars A deficiency in serum vitamin E also detected	Poor prognosis because progressive retinal degeneration leads to complete blindness if the deficiency is not corrected very early
Fluoroquinolone-induced retinal degeneration	A degeneration to the retina of cats attributed to a toxic affect from enrofloxacin	All cats	Dilated pupils and blindness	Ophthalmoscopic findings of retinal degeneration along with recent use of enrofloxacin	Poor prognosis; blindness usually irreversible
Borzoi chorioretinopathy	An acquired condition that initially manifests as focal retinal edema and loss of choriocapillaris and tapetum With time the retina degenerates and becomes hyperreflective, with RPE hyperpigmentation and clumping	Borzoi	No significant visual impairment for up to 7 years	Ophthalmoscopic findings of focal, peripheral, tapetal, hyperreflective and pigmented areas	Poor owing to progressive retinal changes that may result in visual impairment

ERG, Electroretinogram; *PRA*, progressive retinal atrophy; *RPED*, retinal pigment epithelial dystrophy; *RPE*, retinal pigment epithelium.

INFLAMMATORY AND INFECTIOUS DISORDERS

Chorioretinitis

Definition and Causes

I. Chorioretinitis is an inflammation of the posterior uvea (choroid) that also spreads to include the retina.
II. Chorioretinitis can be unilateral or bilateral.
III. It is usually a manifestation of a systemic disease process.
IV. Causes are numerous (Box 102-1; see Tables 104-5 and 104-7).

Pathophysiology

I. Inflammation of the retina and choroid often starts as an infiltrate of inflammatory cells surrounding blood vessels.
II. As the inflammation and vascular response increases, the retina becomes edematous (translucent appearance).
III. Accumulation of exudates between the photoreceptors and the RPE results in a detachment of the neural retina.
IV. Inflammation of the RPE causes a release of pigment, and the RPE can become hyperplastic, forming fibrouslike membranes.
V. Inflammation may lead to hemorrhage from retinal or choroidal vessels.

Clinical Signs

I. Ocular clinical signs vary depending on the severity of the inflammation and whether bilateral disease is present.
   A. Loss of vision is apparent if severe inflammation results in detachment or involves most of the retina.
   B. Such animals have dilated and minimally responsive pupils.
   C. Many animals also have signs of anterior uveitis (e.g., aqueous flare, scleral injection, squinting).
II. Many animals with chorioretinitis have clinical signs of a systemic illness.

Diagnosis

I. Funduscopic findings help differentiate active from inactive chorioretinitis.
   A. Active lesions have raised, fluffy, and irregular edges.
      1. Tapetal retina: dark gray-brown lesions
      2. Nontapetal retina: white-gray raised lesions
      3. Tortuosity or dilatation of blood vessels, hemorrhages, perivascular edema
      4. Subretinal granuloma formation or retinal detachment
   B. Inactive lesions have flat, sharp borders.
      1. Tapetal retina: hyperreflective scars, with or without areas of hyperpigmentation
      2. Nontapetal retina: flat, white-gray depigmented scars
      3. Possible vascular attenuation
      4. Possible optic nerve atrophy
II. Systemic causes are evaluated by a thorough physical examination, complete blood count, serum biochemistries, urinalysis, serology, radiography, ultrasonography, cytology, and histopathology of lesions, as indicated.

Box 102-1

Causes of Chorioretinitis

Infections

Viral: canine distemper virus, canine herpesvirus, feline infectious peritonitis, feline leukemia virus
Rickettsial: canine ehrlichiosis, Rocky Mountain spotted fever
Fungal: aspergillosis, blastomycosis, cryptococcosis, histoplasmosis, coccidioidomycosis, geotrichosis, pseudallescheriasis, acremoniasis
Bacterial: brucellosis, bartenellosis, leptospirosis, tuberculosis, any agent capable of inducing septicemia
Algal: protothecosis (dogs)
Protozoal: toxoplasmosis, neosporosis, leishmaniasis
Parasitic: *Toxocara canis, Angiostrongylus vasorum*, ophthalmomyiasis

Immune-Mediated

Thrombocytopenia
Autoimmune hemolytic anemia
Systemic lupus erythematosus
Uveodermatologic syndrome or Vogt-Koyanagi-Harada-like syndrome
Granulomatous meningoencephalitis

Metabolic Conditions

Diabetes mellitus
Hyperviscosity syndromes
Systemic hypertension
Anemia
Uremia

Immunological or Neoplastic Conditions

Lymphosarcoma
Choroidal melanoma
Retinoblastoma
Metastatic tumors
Malignant histiocytosis
Monoclonal gammopathies

Toxins

Enrofloxacin in cats

Trauma

Blunt
Surgical
Penetrating foreign bodies

Differential Diagnosis

I. Retinal dysplasia can appear similar to postinflammatory retinal scars, especially geographic dysplasia, in which an area of hyperreflectivity occurs with hyperpigmentation.
II. Multifocal hyperpigmented lesions associated with RPE dystrophy can appear similar to chorioretinitis.

III. End-stage PRA can appear similar to end-stage chorioretinal scarring.

Treatment

I. Treatment of chorioretinitis involves treating the underlying cause.
II. If anterior uveitis accompanies the chorioretinitis, then this condition is also treated (see Chapter 99).
III. If no infectious agents are identified, then systemic anti-inflammatory therapy is used.
  A. Prednisone 2.2 mg/kg PO SID, then tapered as a positive response is noted
  B. Azathioprine 2.2 mg/kg PO SID for immune-mediated disorders in dogs
IV. Systemic antibiotic therapy is indicated if an infectious cause is determined.
  A. Broad-spectrum antibiotics
    1. Dogs: chloramphenicol 25 to 50 mg/kg PO TID
    2. Cephalexin 22 to 30 mg/kg BID to TID
    3. Amoxicillin/clavulanic acid 20 mg/kg PO BID
    4. Dogs: enrofloxacin 2.5 to 5.0 mg/kg PO BID
  B. Rickettsial infections
    1. Tetracycline 22 mg/kg PO TID in dogs and 15 mg/kg PO TID in cats
    2. Doxycycline 5 to 10 mg/kg PO SID
  C. Fungal infections
    1. Itraconazole 5 to 10 mg/kg PO SID to BID for 6 to 12 months
    2. Amphotericin 0.5 mg/kg IV three times weekly until maximum dose of 6 mg/kg
    3. Dogs: fluconazole 2.5 to 5.0 mg/kg PO SID for 8 to 12 weeks
    4. Ketoconazole 10 to 15 mg/kg PO BID for 3 to 6 months
  D. Toxoplasmosis
    1. Clindamycin 10 to 20 mg/kg PO BID
    2. Trimethoprim-sulfadiazine 15 to 30 mg/kg PO BID and pyrimethamine 0.25 to 0.5 mg/kg PO SID for 7 to 10 days
V. Pars plana vitrectomy can be used for the treatment of ophthalmomyiasis interna posterior (Ollivier et al., 2006).

Monitoring of Animal

I. Repeated fundic examinations are used to assess response to therapy.
II. Resolution of chorioretinal inflammation, granulomas, or retinal detachments suggest successful therapy.
III. Chorioretinal inflammation frequently leads to retinal scarring.
IV. Prolonged therapy (6 to 12 months) is usually needed for fungal infections.

Optic Neuritis

Definition

I. Optic neuritis is an inflammation of the optic nerve.
II. Optic neuritis may be either unilateral or bilateral.
III. The optic papilla and/or the retrobulbar optic nerve may be affected.

Causes

I. Infectious diseases
  A. Canine distemper virus
  B. Blastomycosis
  C. Histoplasmosis
  D. Cryptococcosis
  E. Toxoplasmosis
  F. Neosporosis
  G. Tickborne infections: ehrlichiosis, Rocky Mountain spotted fever, Lyme borreliosis, tickborne encephalitis virus
II. Idiopathic forms
III. Immune-mediated diseases (see Box 102-1)
IV. Trauma
  A. Proptosis
  B. Surgical trauma of contralateral optic nerve via traction during enucleation
  C. Probing or biopsy of retrobulbar tissues
V. Granulomatous meningoencephalitis
VI. Vitamin A deficiency (rare)

Clinical Signs

I. Clinical signs are dependent on whether the disease is unilateral or bilateral.
II. Bilateral optic neuritis results in acute blindness with dilated and unresponsive pupils.
III. Other neurological signs may be noted.

Diagnosis

I. Funduscopy is often helpful if the papilla is affected.
  A. Swollen optic disc with blurring of margins and evidence of raised vessels over the surface of the disc
  B. Hyperemia or hemorrhage of disc
  C. Loss of physiologic cup within the disc
  D. Possible peripapillary retinal edema and detachment
II. Retrobulbar optic neuritis may not affect the optic disc, so the retina appears normal on funduscopy.
III. The cause of the optic neuritis must be evaluated.
  A. Complete laboratory data base, serological tests
  B. Thoracic radiography to evaluate for systemic fungal infection
  C. Cerebrospinal fluid analysis (see Chapter 23)
  D. Serum vitamin A levels
IV. ERG and VEPs are performed in cases of suspected retrobulbar optic neuritis to differentiate it from SARD.

Differential Diagnosis

I. Passive papilledema associated with increased intracranial pressure
II. Pseudopapilledema
  A. It is a normal variant in which there is an abundance of myelination of optic nerve axons beyond the anterior lamina cribrosa, resulting in a raised appearance of the optic disc.

B. The physiologic cup is still visible with pseudopapilledema.
III. Optic nerve neoplasia or neuropathy
IV. SARD
V. Blindness from central nervous system diseases

Treatment

I. Treatment is aimed at the underlying cause if one can be found.
II. Treat immune-mediated or idiopathic causes with prednisone 2.2 mg/kg PO SID, then taper as a positive response is noted.
III. See other therapies as outlined for chorioretinitis (see previous section).
IV. Vitamin A supplementation is used if deficient.

Monitoring of Animal

I. Repeated fundic examinations are used to assess response to therapy.
II. Optic neuritis frequently leads to permanent blindness from secondary atrophy of the optic nerve.

Retinal Detachments

Definition

I. Retinal detachment is a separation between the neurosensory retina and the RPE.
II. Subretinal fluid accumulates in the potential space that is a remnant of the embryonic optic vesicle.
III. Retinal detachments can be partial or complete and unilateral or bilateral.

Causes

I. Three types of retinal detachments exist, and each has different causes.
II. Rhegmatogenous detachments are associated with tears or breaks in the retina that allow liquefied vitreous to enter the subretinal space.
   A. Retinal tears can be caused by vitreal traction (e.g., vitreal degeneration, vitreal prolapse, lens luxation, posterior capsule tears).
   B. Hypermature cataracts and secondary vitreal degeneration can result in secondary tears.
   C. Blunt trauma to the eye infrequently results in retinal detachment.
   D. Spontaneous detachment occurs in Shih Tzus (Vainisi et al., 1990).
III. In nonrhegmatogenous detachments, subretinal fluid or blood usually accumulates from inflammation or hemodynamic causes.
   A. Systemic diseases: hypertension, infections, hyperviscosity, immune-mediated diseases, neoplasia
   B. Vitreal hemorrhage, degeneration, or movement
IV. Congenital or developmental detachments are conditions in which the neurosensory retina never attached to the underlying RPE or failed to remain attached.
   A. Retinal dysplasia
   B. CEA
   C. Persistent hyperplastic primary vitreous (see Chapter 101)

Pathophysiology

I. The pathogenesis of rhegmatogenous retinal detachments requires a break in the retina and an abnormal vitreous.
   A. Most retinal detachments occur in the peripheral retina where the vitreous has the strongest attachment to the retina.
   B. Traction frequently leads to a break in the retina and liquefied vitreous moves into the subretinal space, resulting in the detachment.
II. Nonrhegmatogenous retinal detachments arise from effusion of an exudate, hemorrhage, or transudate into the subretinal space, resulting in separation of the neurosensory retina from the RPE; a tear is not present.

Clinical Signs

I. Partial retinal detachments frequently go unnoticed.
II. Complete retinal detachments result in loss of vision.
   A. Pupils are dilated and minimally responsive or fixed.
   B. A "floating veil" of vessels may be visualized within the pupil with a simple penlight.

Diagnosis

I. Fundic examination is frequently diagnostic.
   A. Veil or funnel-like film attached to the optic disc
   B. Focal or generalized area of raised tissue or vessels
   C. Possible retinal hemorrhages
   D. Possible opaque inflammatory lesions or granulomas
II. Peripheral retinal tears frequently require the aid of scleral depression to be visualized.
III. Ocular ultrasonography is used to evaluate the posterior segment when the anterior segment is opaque.
IV. When any acquired retinal detachment is diagnosed, a systemic cause must be ruled out.
   A. Serous detachments in older cats are most commonly associated with systemic hypertension.
      1. Measure systemic blood pressure.
      2. Evaluate blood tests and urinalysis for causes of hypertension (see Chapter 48).
   B. Test for the following if exudative and granulomatous detachments are found:
      1. Cats: feline infectious peritonitis virus
      2. Cats, dogs: systemic fungal infections, neoplasia
      3. Dogs: protothecosis
      4. See Chorioretinitis, earlier in this chapter
   C. A subretinal aspirate can be performed in severe cases, if other diagnostic tests are inconclusive.

Treatment and Monitoring

I. Treatment is based on the cause and type of detachment.
II. Nonrhegmatogenous retinal detachments are treated medically.
   A. Treat the underlying systemic disease (see Chapters 48, 111, 112, 115, and 116).

B. Effective treatment of systemic hypertension often results in reattachment of the retina, with variable return of vision.
C. Fungal-induced detachments frequently lead to blindness from retinal damage and scarring, despite systemic therapy.
D. Immune-mediated or inflammatory detachments treated with prednisone at 2.2 mg/kg PO SID may reattach and regain function.

III. Rhegmatogenous retinal detachments require surgical treatment to correct the detachment.
A. The goal of surgical correction is to reappose the retina and the RPE and seal the breaks by creating a chorioretinal adhesion.
B. Retinal breaks are treated via laser photocoagulation, transscleral cryopexy, or scleral buckling.
C. Retinal breaks with small areas of subretinal fluid surrounding them can be treated with laser photocoagulation or transscleral cryopexy.
D. If vitreous pathology or traction accompanies the detachment, then a vitrectomy is needed in addition to the previous procedures.
E. Detachments from large bullous lesions and large tears frequently require a vitrectomy and infusion of either silicone oil or pneumatic gas to tamponade the retina against the RPE before a pexy procedure (Vainisi and Packo, 1995).

IDIOPATHIC DISORDERS

Sudden Acquired Retinal Degeneration

Definition

I. SARD is degeneration of the entire retina that results in complete blindness.
II. SARD occurs in adult dogs of any breed, with large-breed dogs, dachshunds and miniature schnauzers predisposed.

Causes

I. The cause of SARD is unknown.
II. Several theories have been suggested.
A. Autoimmune mechanism, though unlikely (Bellhorn et al., 1988; Gilmour et al., 2006; Keller et al., 2006)
B. Faulty fat metabolism (Moore, 1984)
C. Elevated vitreal glutamate levels suggesting excitotoxicity (Abrams et al., 1995)
III. Retinal degeneration associated with SARD involves an apoptic event involving the outer nuclear layer (Miller et al., 1998).

Pathophysiology

I. Acute dysfunction of the photoreceptor outer segments (both rods and cones) occurs and is followed by degeneration of the other layers of the retina.
II. All areas of the retina appear to be affected equally, and the changes are irreversible.

Clinical Signs

I. Major clinical sign is acute vision loss without signs of ocular inflammation.
II. Pupils are usually dilated and slow or unresponsive.
III. Many dogs also exhibit signs of polyuria and polydipsia, polyphagia, and recent weight gain.

Diagnosis

I. History of acute onset of blindness with no other apparent ocular changes is suggestive of SARD.
II. Fundic examination is often normal in acute disease.
III. Fundic examination in chronic cases resembles that of PRA (retinal degeneration).
IV. Definitive diagnosis is based on complete extinguishing of the ERG.
V. Other findings may include the following:
A. Elevated serum levels of alkaline phosphatase, aminotransferases, cholesterol, and bilirubin
B. Cortisol response test results suggestive of hyperadrenocorticism

Differential Diagnosis

I. Optic neuritis
A. Dogs with retrobulbar optic neuritis can have a normal fundic examination.
B. ERG findings are usually normal; VEPs are abnormal.
II. Cortical blindness
A. ERG is normal; VEPs are abnormal.
B. Fundic examination and pupillary light responses are usually normal.
III. End-stage PRA
A. PRA has a prolonged, progressive course of visual loss.
B. Late-stage SARD is indistinguishable funduscopically or on ERG from PRA.

Treatment and Monitoring

I. No treatment for SARD exists; it results in permanent blindness.
II. If polyuria, polydipsia, and weight gain are present, then testing for hyperadrenocorticism is performed and monitoring continues for several months.
III. Most of these signs subside without treatment in several weeks to months.

METABOLIC DISORDERS

Hypertensive Retinopathy

Definition

I. Retinal pathology associated with systemic hypertension is known as *hypertensive retinopathy*.
II. *Systemic hypertension* is defined as a systolic arterial blood pressure >170 mm Hg (Stiles et al., 1994).
III. Most ocular lesions are seen when the systolic pressures are >200 mm Hg.
IV. Ocular changes may include retinal edema, retinal hemorrhages and vessel alterations, retinal detachment, and hyphema.

Causes

I. Cat
  A. Chronic renal failure
  B. Hyperthyroidism
  C. High-salt diets (Turner et al., 1990)
  D. Hyperglycemia induced by megestrol acetate (Glaze and Gelatt, 1999)
  E. Primary, essential hypertension (rare)
II. Dog
  A. Chronic renal failure
  B. Hyperadrenocorticism
  C. Pheochromocytoma
  D. Renin-secreting renal tumors
  E. Polycythemia
  F. Diabetes mellitus
  G. Hypothyroidism and associated hypercholesterolemia
  H. Primary, essential hypertension (rare)

Pathophysiology

I. Precapillary vasoconstriction of the retinal arterioles occurs with systemic hypertension via autoregulation and results in ischemia and retinal degeneration with chronicity (Stiles et al., 1994).
II. As the endothelial cells and vascular smooth muscles deteriorate, serum and blood cells leak into the surrounding retinal tissue.
III. Ocular lesions that arise (e.g., retinal edema, serous exudates, retinal vessel tortuosity, hemorrhage, complete detachment) are dependent on the extent of vascular injury and the degree of hypertension.
IV. Retinal detachment may develop from choroidal vascular damage and leakage of fluid into the subretinal space (Spencer, 1985).
V. Retinal hemorrhages, edema, and intraretinal edema most likely occur secondary to retinal vascular damage.
VI. Retinal vessels can develop a "boxcar" appearance following vascular smooth muscle necrosis and focal dilatations.

Clinical Signs

I. Retinal detachment and severe retinal hemorrhage can lead to acute blindness.
II. Many small hemorrhages, retinal vessel tortuosity, and mild retinal edema go unnoticed.
III. Many animals exhibit signs of systemic illness associated with the cause of the hypertension.

Diagnosis

I. Funduscopic findings of one or more lesion compatible with hypertension along with repeated measurements of systemic blood pressure >170 mm Hg systolic are diagnostic for hypertensive retinopathy.
II. Once the diagnosis is confirmed, a search is undertaken for the underlying cause (see Chapter 48).

Differential Diagnosis

I. Clotting disorders
  A. Immune-mediated thrombocytopenia
  B. Myelophthisic neoplasia
  C. Estrogen-induced bone marrow suppression
  D. Infections: ehrlichiosis
  E. Toxins: warfarin type compounds
II. Hyperviscosity syndrome
III. Neoplasia of the posterior segment causing hemorrhage or detachment
IV. Polycythemia
V. Systemic lupus erythematosus

Treatment and Monitoring

I. Control of systemic blood pressure is the primary goal (see Chapter 48).
II. Treatment of the underlying disease (e.g., renal, hyperthyroid diseases) is also pursued.
III. If anterior segment inflammation or hemorrhage is also present, then topical prednisolone acetate 1% is instituted.
IV. Prognosis for return of vision with successful control of hypertension is fair in the dog and guarded in the cat.

NUTRITIONAL DISORDERS

Vitamin E Deficiency (Retinal Degeneration)

See Table 102-2.

Taurine Deficiency Retinopathy

Definition and Cause

I. Taurine retinopathy—or feline central retinal degeneration (FCRD)—is a specific retinal degeneration of cats induced by low levels of taurine.
II. The degeneration is bilaterally symmetrical and involves the central sensory retina.
III. Dietary content of 500 to 750 ppm of taurine is needed to prevent retinal pathology (Glaze and Gelatt, 1999).
IV. Cats fed dog food can develop FCRD from inadequate taurine levels in dog foods (Aguirre, 1978).
V. Taurine deficiency has been found in a group of Newfoundlands, although none of these animals showed signs of retinal degeneration (Backus et al., 2003).

Pathophysiology

I. Taurine is an essential dietary amino acid in cats because they have limited ability to synthesize it.
II. Dietary deficiency or malabsorption of taurine results in low plasma and retinal taurine levels within 5 weeks (Glaze and Gelatt, 1999).
III. Taurine acts as a neurotransmitter and functions to maintain cell membranes (Glaze and Gelatt, 1999).
IV. Taurine acts as an antioxidant, and taurine supplementation is known to alleviate oxidative stress in the retina (Militante and Lombardini, 2004).
V. Retinal cone dysfunction occurs within 10 weeks of onset of taurine deficiency, with cell death occurring in another 10 weeks (Schmidt et al., 1976).
VI. Cone photoreceptors are affected first and most severely.
VII. Taurine deficiency also causes dilated cardiomyopathy (see Chapter 10).

Box 102-2

Posterior Segment Neoplasia

Classification	Clinical Signs	Diagnostic Tests	Treatment	Prognosis
Primary tumors				
Adenomas/ adenocarcinomas Medullepithelioma Retinoblastoma/ glioma Astrocytoma Choroidal melanoma	Obvious mass within the eye, hyphema, uveitis, glaucoma, enlargement of the eye, dilated and non-responsive pupil, blindness	Ocular ultrasound is helpful with an opaque media. Evaluate for signs of other primary sources and with various imaging techniques. Consider aspirate of intraocular mass, or blind vitreal aspirate. Enucleated globes must be evaluated microscopically.	Smaller focal posterior segment tumors may be treated with laser or cryosurgery (rare). Large primary tumors are treated with enucleation. Enucleation is also considered when secondary glaucoma, uveitis/hyphema, blindness, or chronic pain are present or to reach a diagnosis. Intraocular lymphoma can be treated with systemic chemotherapy. Other secondary tumors are treated as appropriate for the primary tumor.	Most primary intraocular tumors are considered to be benign but locally destructive. Secondary tumors are considered metastatic lesions and therefore have a much more guarded prognosis for general health.
Secondary tumors Lymphoma Mammary gland adenocarcinoma Thyroid adenocarcinoma Pancreatic adenocarcinoma Renal carcinoma Neurogenic sarcoma Hemangiosarcoma				

Clinical Signs

I. No apparent clinical signs are noted early in the disease.
II. If the deficiency continues, then a complete degeneration can occur with blindness.

Diagnosis

I. Funduscopic findings are often diagnostic for FCRD.
   A. Earliest lesion, Stage 1: granularity in the area centralis in the tapetal retina
   B. Stage 2: an elliptical hyperreflective lesion in the tapetal retina temporal to the optic disc
   C. Stage 3: a second hyperreflective lesion appears nasal to the optic disc
   D. Stage 4: coalescence of the two elliptical lesions to form a band of hyperreflectivity
   E. Stage 5: generalized hyperreflectivity, vascular attenuation, optic nerve atrophy
II. Many cats develop a static lesion that does not progress, indicating a focal incident of taurine deficiency that has resolved.
III. Measurement of plasma or blood taurine levels confirms the disease.
IV. Also rule out a concurrent dilated cardiomyopathy.

Differential Diagnosis

I. Stage 5 taurine retinopathy is similar in appearance to end-stage PRA.
   A. ERG is attenuated in both conditions.
   B. Plasma taurine values are normal with PRA.
II. Blindness associated with enrofloxacin administration in cats has a more rapid onset and produces more generalized retinal degeneration at the onset (Gelatt et al., 2001).

Treatment and Monitoring

I. An appropriate taurine-supplemented diet is given.
II. Also supplement taurine at 250 to 500 mg PO SID to BID.
III. If treated early enough, retinal dysfunction and progression of the disease can be stopped.
IV. If retinal degeneration (photoreceptor cell death) has already occurred, it cannot be reversed.

NEOPLASIA

See Box 102-2.

CHAPTER 103

Diseases of the Orbit

Albert J. Mughannam

CONGENITAL DISORDERS

Microphthalmos

Definition

I. The globe is congenitally smaller than normal.
II. Potential concurrent abnormalities include cataract, anterior segment abnormalities, and retinal dysplasia.

Causes and Pathophysiology

I. Exposure to teratogen or abnormality during development of the eye in utero
II. Often idiopathic
III. Inherited in the miniature schnauzer, Australian shepherd, collie, Shetland sheepdog, Doberman pinscher, Cavalier King Charles spaniel
IV. Associated with excessive white coat color in some breeds

Clinical Signs

I. The globe is abnormally small in size.
II. Depending on its size, the microphthalmic globe may not fill the orbit completely, resulting in protrusion of the third eyelid, enophthalmos, and drooping of the lower lid.
III. Excessive accumulation of mucus and debris can occur and lead to chronic conjunctivitis.
IV. Associated conditions include cataract, anterior segment abnormalities, and retinal dysplasia.
V. Microphthalmia can be unilateral or bilateral.
VI. Vision is variable, depending on the degree of deformity.

Diagnosis

I. Diagnosis is based on the abnormally small size of the eye.
II. Measure the diameter of the cornea and compare it with the fellow eye.
III. Diagnosis is difficult in a young animal with bilaterally small eyes.

Differential Diagnosis

I. Phthisis bulbi
II. Enophthalmos
    A. Secondary to ocular pain
    B. Loss of retrobulbar fat
    C. Horner's syndrome

Treatment and Monitoring

I. Microphthalmia alone does not require treatment.
II. If entropion is severe, consider entropion surgery.
III. If clinical signs are noted and the eye is blind, consider enucleation.
IV. Cataract extraction is indicated in selected cases.
    A. Cornea must be clear enough to allow complete visualization of the lens.
    B. Adequate retinal function must be present.
        1. Evaluate light reflexes (pupillary light and dazzle reflexes).
        2. Electroretinography quantifies function of the retina.

DEGENERATIVE DISORDERS

Phthisis Bulbi

Definition

I. Globe atrophied (smaller than normal) secondary to chronic inflammation
II. Acquired, not congenital

Causes

I. Trauma
II. Inflammation
    A. Chronic uveitis, prior hyphema
    B. Previous intraocular surgery with complications

Pathophysiology

I. Chronic uveal inflammation has several deleterious effects.
    A. Fibrotic membrane formation occurs, as well as atrophy of uvea.
    B. Uvea ceases to produce aqueous humor.
    C. Intraocular pressure decreases and the globe shrinks.
II. Tissue contraction leads to disorganized, atrophied globe.

Clinical Signs

I. Abnormally small globe
    A. Subsequent enophthalmos
    B. Chronic conjunctivitis caused by accumulated mucus
II. Corneal scarring, edema, vascularization, or persistent uveitis
III. Evidence of discomfort while inflammation is active
    A. Blepharospasm

B. Pawing at the eye
IV. Uveitis: aqueous flare, conjunctival hyperemia, iridal hyperemia
V. Blindness

Diagnosis

I. Abnormally small globe
II. History of trauma, chronic uveitis, prior hyphema
III. Supportive evidence of skull trauma, penetrating foreign body
IV. Low intraocular pressure on tonometry

Differential Diagnosis

I. Microphthalmos
II. Enophthalmos

Treatment

I. Topical antiinflammatory medication for persistent uveitis
   A. Prednisolone acetate 1% or sodium phosphate BID to QID
   B. Neomycin-polymyxin-dexamethasone BID to QID
II. Enucleation if discomfort persists
   A. Chronic uveitis
   B. Chronic conjunctivitis
   C. Secondary entropion

Monitoring of Animal

I. Regular recheck examinations (every 2 to 3 months) to evaluate for discomfort while on medication
II. None required if no inflammation or discomfort present

Orbital Fat Prolapse

Definition

I. Normal retrobulbar fat is located caudal and ventral to the globe.
II. Orbital fat may prolapse rostrally into the subconjunctival space, thereby causing the conjunctiva to balloon outward.

Causes and Pathophysiology

I. The cause is usually unknown.
II. Orbital fat is normally separated from the subconjunctival space by orbital fascia.
   A. Senile degeneration of this fascia may allow fat herniation.
   B. Chronic inflammation may also weaken the orbital fascia.

Clinical Signs

I. Soft, noninflamed swelling of the conjunctiva is seen.
II. Pain is uncommon.
III. Prolapse may be intermittent.
IV. Exophthalmos, enophthalmos, and protrusion of the third eyelid are variable depending on the position of the prolapsed fat.
V. Globe position can be normal.
VI. This condition is only reported to be unilateral.

Diagnosis and Differential Diagnosis

I. Fine-needle aspirate reveals adipocytes.
II. Histological examination of excised tissue is conclusive.
III. Retropulsion of the globe is minimally inhibited.
IV. Cellulitis and abscessation, orbital hemorrhage, and masticatory myositis are painful.
V. A vascular lesion, although nonpainful, is likely to be pulsatile; color flow Doppler ultrasonography will identify abnormal blood flow.
VI. Orbital neoplasia, although typically nonpainful, is usually slowly progressive and occurs in older animals.
VII. Mucocele or cyst reveals saliva on fine-needle aspirate.

Treatment and Monitoring

I. Because this condition is not painful and is unlikely to predispose to more serious consequences, treatment is usually not necessary.
II. Surgical excision can be curative but may also predispose to further fat prolapse unless the orbital fascia is closed securely.

INFLAMMATORY DISORDERS

Mucoceles and Cysts

Definition

I. A salivary mucocele is a cavity filled with accumulated mucous secretion from leakage of saliva from the zygomatic salivary gland or its duct.
II. A retention cyst results from persistent glandular secretion.
III. The zygomatic salivary gland lies within the ventrolateral aspect of the orbit.

Causes and Pathophysiology

I. Inflammation, obstruction, or rupture of the salivary duct obstructs salivary flow.
II. Inflammation of the oral mucosa obstructs salivary outflow.
III. The cause of a retention cyst is unknown.

Clinical Signs

I. Fluctuant swelling of the conjunctiva
   A. If diseased tissue is caudal to globe: exophthalmos and third eyelid protrusion
   B. If diseased tissue is rostral to globe: enophthalmos
   C. Location of swelling variable: dorsal or medial to globe, within lower lid stroma, associated with third eyelid
II. Possible change in position of globe (Table 103-1)
III. Minimal pain on opening the mouth or palpation of the globe
IV. Unilateral
V. Possible swelling of the soft palate adjacent to the ipsilateral upper left molar teeth
VI. Conjunctival or oral swelling usually slowly progressive and nonpainful
VII. Retropulsion of globe almost normal

TABLE 103-1

Clinical Signs Associated with Orbital Disease

CLINICAL FINDING	POSSIBLE CAUSES
Exophthalmos	Rostral protrusion of the globe from a space-occupying lesion caudal to the equator May be confused with buphthalmos (defined as enlargement of the globe)
Protrusion of the third eyelid	From a space-occupying lesion caudal to the globe Could also be caused by enophthalmos, Horner's syndrome, tetanus, or idiopathic protrusion of the third eyelid
Enophthalmos	From a space-occupying lesion rostral to the equator May result from microphthalmos, phthisis bulbi, loss of orbital fat, Horner's syndrome, or retraction of the globe from pain
Conjunctival hyperemia	From vascular congestion or inflammation Nonspecific sign seen with many ocular diseases
Swelling of the soft palate caudal to the last molar tooth	The ventral floor of the orbit is composed of soft tissue. The medial aspect of the orbital floor lies immediately above the soft palate caudal to the last molar tooth.
Strabismus	From fibrosis or inflammation of the extraocular muscles
Vision loss or decreased pupillary light reflex	From optic nerve damage
Changes in retinal morphology	Indentation of the globe by the orbital process

Diagnosis

I. Ultrasonography reveals a fluid-filled mass (Table 103-2).
II. Fine-needle aspiration reveals saliva, which may be blood stained.
III. Retrograde sialography with radiographic contrast material shows filling of the lesion.
IV. Computed tomography (CT) or magnetic resonance imaging (MRI) provides more detail.

Differential Diagnosis

I. Cellulitis and abscessation, orbital hemorrhage, and masticatory myositis are painful.
II. Orbital neoplasia usually occurs in older animals.
III. Ultrasonographic findings of fluid-filled mass tend to rule out orbital fat prolapse and vascular lesions.

Treatment and Monitoring

I. Surgical excision of the affected gland and mucocele is curative.
II. Orbitotomy may be necessary.
III. Lid paresis from inadvertent incision of the palpebral nerves can occur postoperatively.
IV. Diminished aqueous tear production (keratoconjunctivitis sicca) can arise from interruption of innervation to the lacrimal gland if the palpebral nerves are damaged.

Cellulitis and Abscessation

Definition

I. Cellulitis is diffuse inflammation of the orbital tissues from infection or primary inflammation.
II. Abscessation is a localized collection of purulent material.

Causes and Pathophysiology

I. Usually idiopathic
II. Extension of infection from nearby structures: sinuses, zygomatic salivary gland, molar and premolar tooth roots
III. Infection: hematogenous, usually bacterial; fungal or parasitic causes rare (*Toxocara canis* in dogs)
IV. Foreign material: plant matter migrating from mouth
V. Steroid-responsive conditions
   A. Sialadenitis in dogs (Simison, 1993)
   B. Eosinophilic infiltrate in cats (Dziezyc et al., 1992)

Clinical Signs

I. Exophthalmos with protrusion of third eyelid; enophthalmos rarely
II. Pain and inability to retropulse globe
III. Pain on opening mouth from pressure of the ramus of the mandible on the orbital tissues
IV. Systemic signs: lethargy, inappetence, fever
V. Possibly an inflammatory leukogram
VI. Possible swelling and erythema of the soft palate adjacent to the ipsilateral molar teeth
VII. Possible conjunctivitis and increased intraocular pressure from tamponade
VIII. Usually unilateral
IX. Onset usually acute
X. Corneal ulceration or keratitis from exposure

Diagnosis and Differential Diagnosis

I. Diagnosis is primarily based on clinical signs.
   A. Acute onset
   B. Pain
   C. Unilateral condition

TABLE 103-2

Modalities for Diagnosis of Orbital Disease

DIAGNOSTIC MODALITY	ADVANTAGE	POTENTIAL DISADVANTAGE
General physical examination, including oral and dental examination	Aids in diagnosis of those conditions that affect other parts of the body, such as neoplasia and bleeding disorders	None
Systemic evaluation: chest and abdominal radiographs, laboratory testing	Aids in diagnosis of those conditions that affect other parts of the body, such as neoplasia and bleeding disorders	None
Digital retropulsion of globes	Aids in localization of the lesion, characterization of orbital disease (e.g., soft cyst vs. firm), and detection of pain	Results possibly inconclusive
Skull radiography	Allows evaluation of bony portions of orbit, nasal cavity, and teeth Detects radiodense foreign bodies	General anesthesia usually required
Ultrasonography	Allows imaging of the orbital soft tissues Particularly good for abscesses Doppler capabilities may help distinguish vascular lesions	Expense or availability of equipment
Computed tomography	Allows superior imaging of orbital tissues, particularly bone	Expense and availability of equipment General anesthesia required
Magnetic resonance imaging	Allows superior imaging of orbital tissues, particularly soft tissues	Expense and availability of equipment General anesthesia required
Fine-needle aspiration	Can offer cellular diagnosis Three potential locations for aspiration: 1. Into the ventral aspect of the orbit via the soft palate caudal to the last molar tooth 2. Medially along the bony orbital wall via the medial canthus 3. Laterally at the junction of the orbital ligament and zygomatic arch	Requires at least heavy sedation and often general anesthesia There is risk of piercing the globe, vessels or nerves. Introduction of infection possible
Trucut biopsy	Can offer precise tissue diagnosis	Requires at least heavy sedation and often general anesthesia Risk of piercing the globe, vessels, or nerves Introduction of infection possible

II. See Table 103-2 for diagnostic options.
   A. Ultrasonography is ideal.
   B. Inflammatory conditions are usually located laterally, whereas neoplasms are usually located medially (Mason et al., 2001).
III. Orbital hemorrhage is also usually painful, unilateral, and associated with an acute onset.
   A. Periocular tissues may be bruised, and frank bleeding may be noted.
   B. See Chapters 68 and 124 for discussion of bleeding disorders, particularly from rodenticide toxicity.
IV. Masticatory myositis is painful; however, the condition is usually bilateral.
V. Orbital neoplasia is usually not painful, is of relatively slow onset, and tends to occur in older animals.

Treatment

I. Focal orbitotomy via an oral approach is performed (Table 103-3).
   A. If abscessation is suspected, then drainage must be attempted.
   B. Cellulitis may respond solely to medical therapy.
   C. On attempted drainage, if frank pus is encountered, then bacterial culture and gentle lavage are considered.
   D. Vigorous lavage forces purulent material deeper into the orbit and must be avoided.
   E. Lack of purulent discharge does not necessarily rule out infection.
II. Following antibiotics may be used:
   A. Ampicillin 22 mg/kg PO TID

TABLE 103-3

Surgical Treatment of Orbital Disease

PROCEDURE	TECHNIQUE/RATIONALE
Enucleation of globe	Allows direct exploration of the orbit Performed if the eye is blind, irreversibly painful, or severely proptosed such that repositioning is not possible
Exenteration	Removal of all orbital contents May be the procedure of choice for an orbital neoplasm
Orbitotomy	
1. Oral approach	Incision is made into the mucosa of the soft palate caudal to the last molar tooth; a hemostat is then bluntly advanced through the medial pterygoid muscle into the ventral aspect of the orbital; drainage of fluid (usually pus) or biopsy is then possible
2. Zygomatic arch resection	Zygomatic arch is approached surgically and then removed via osteotomy Allows access to the lateral, dorsal, or ventral aspects of the orbit (Slatter and Abdelbaki, 1979; Gilger et al., 1994)
3. Dorsal approach	Skin incision is made lateral to the sagittal crest to allow undermining and reflection of the frontalis muscle Allows access to the dorsomedial and caudomedial aspects of the orbit (Ramsey and Fox, 1997)
4. Conjunctival approach	Incision is made directly into the conjunctiva Allows access to lesions rostral to the equator of the globe

B. Amoxicillin 22 mg/kg PO BID
C. Amoxicillin 22 mg/kg with clavulanic acid 13.75 mg/kg PO BID
D. Cephalexin 22 mg/kg PO BID

III. A single antiinflammatory dose of dexamethasone 0.5 to 1.0 mg/kg SC may be given to help reduce swelling and control pain.
IV. If the globe is inflamed or excessively exposed as a result of the exophthalmos, then an antibiotic ointment is applied to prevent infection and provide lubrication.

Monitoring of Animal

I. Improvement in clinical signs is usually noted within 2 to 3 days.
II. Complete resolution can take 2 to 4 weeks.
III. Lack of improvement indicates the need for further diagnostic tests (see Table 103-2).
A. Ultrasonography
B. Radiography
C. MRI or CT

Myositis

Definition

I. Masticatory myositis is inflammation of the masticatory muscles (i.e., temporalis, masseter, and pterygoideus muscles).
II. Extraocular myositis is inflammation of the extraocular muscles.

Causes

I. Immune-mediated cause is suspected.
A. Most skeletal muscles in the dog are types 1 and 2A.
B. Masticatory muscles in the dog are composed of type 2C muscle fibers, and this unique characteristic may explain the susceptibility of these muscles to immune-mediated inflammation.
II. Some breeds are predisposed to these disorders.
A. Masticatory myositis: German shepherd dog, Weimaraner, Labrador retriever, golden retriever (Gilmour et al., 1992)
B. Extraocular myositis: golden retriever most common, also Doberman pinscher, German shepherd dog, and other large-breed dogs (Ramsey et al., 1995)

Pathophysiology

I. Muscle tissues become infiltrated with inflammatory cells.
II. Swollen masticatory muscles fill the orbit and impinge on the globe, resulting in exophthalmos.
III. Swollen extraocular muscles impinge directly on the globe, resulting in exophthalmos.

Clinical Signs

I. Masticatory myositis (see Chapter 82)
A. Bilateral exophthalmos, protrusion of the third eyelid, conjunctivitis during the early stages
B. Pain on opening the mouth
C. Trismus (difficulty opening the mouth)
D. Pain on palpation of the temporal muscles and on globe retropulsion
E. Acute onset
F. Fever and anorexia common
G. Muscle fibrosis, atrophy, and subsequent enophthalmia with chronicity
H. Sudden vision loss possible (Glauberg and Beaumont, 1979)

I. Age of onset 3.1 years in one study (Gilmour et al., 1992)

II. Extraocular myositis
   A. Exophthalmos usually bilateral; excessive sclera showing circumferentially; protrusion of the third eyelid rare
   B. Not painful
   C. Often normal retropulsion of globes
   D. No systemic manifestations
   E. Vision loss uncommon
   F. Muscle fibrosis, atrophy, and subsequent enophthalmia with chronicity (Ramsey et al., 1995)
   G. Mean age of onset 13.5 months in one study (Ramsey et al., 1995)

Diagnosis

I. Bilateral exophthalmos is a characteristic feature.
II. Complete blood count may reveal eosinophilia with masticatory myositis, although this finding is nonspecific.
III. In masticatory myositis, electromyography often shows waveforms consistent with active inflammation, or atrophy in later stages of the disease.
IV. Muscle biopsy reveals predominantly lymphocytes and plasma cells in either condition, with histiocytes, eosinophils, and neutrophils noted less frequently.
V. Orbital imaging may reveal muscle swelling.
   A. Ultrasonography
   B. CT or MRI

Differential Diagnosis

I. Cellulitis and abscessation: painful but usually unilateral
II. Orbital hemorrhage: painful but usually unilateral, with periocular hemorrhage
III. Neoplasia: usually nonpainful and unilateral

Treatment

I. Institute systemic corticosteroid drugs at immunesuppressive doses (prednisone 2.2 mg/kg PO BID) for both types of myositis.
   A. Initially treat for 3 to 4 weeks, followed by a slow, tapering schedule.
   B. Lower dose and/or shorter duration are unlikely to be effective.
II. Azathioprine may be considered.
   A. As an adjunct to lower the dose of prednisone over the long term
   B. Dosage: 2.2 mg/kg PO SID; reduced to 1 to 2 mg/kg QOD for maintenance
   C. Found to be of limited benefit for extraocular myositis in one study (Ramsey et al., 1995).
III. Forcing open the jaws under anesthesia may be necessary for fibrotic masticatory myositis; however, a potential exists for fracturing the jaw.

Monitoring of Animal

I. Long-term medication is necessary for both conditions to maintain remission of clinical signs.
II. Side effects from medications must be monitored.
   A. Liver damage from long-term steroidal agents
   B. Bone marrow suppression from azathioprine
III. Fibrosis and atrophy of affected muscles may cause enophthalmos and strabismus.

VASCULAR DISORDERS

Definition

I. Two types of orbital vascular lesions are reported in small animals.
II. A varix is an enlarged and tortuous vein or artery.
III. An arteriovenous fistula is an abnormal communication between an artery and vein.

Causes and Pathophysiology

I. Congenital
II. Posttrauma
III. Precise cause difficult to establish in most cases

Clinical Signs

I. Intermittent and pulsating nonpainful exophthalmos, protrusion of the third eyelid, and/or conjunctival mass
II. More pronounced exophthalmos when the head is ventral to the heart because of positional hypertension
III. Systolic murmur or "bruit" with a fistula; none with a varix
IV. History of trauma
V. Lesion only unilateral

Diagnosis

I. The intermittent and pulsatile nature of the exophthalmos, third eyelid protrusion, and/or conjunctival swelling are highly suggestive.
II. Ultrasonography, particularly with color flow Doppler, helps identify the lesion.
III. MRI and CT can provide further detail.
IV. Contrast arteriography and venography are rarely performed.

Differential Diagnosis

I. Orbital fat prolapse may be intermittent but is not pulsatile.
   A. It is less likely to be associated with third eyelid protrusion or exophthalmos.
   B. Cytological findings include of adipocytes on aspirate.
II. Other orbital conditions rarely produce intermittent exophthalmos.

Treatment and Monitoring

I. Surgical excision is risky because hemostasis is difficult.
II. Orbital exenteration with meticulous hemostasis is curative for a fistula (Rubin and Patterson, 1965).
III. Coil embolization may be undertaken (Adkins et al., 2005).

NEOPLASIA

Definition and Causes

I. Neoplasms can arise from any orbital tissue (Table 103-4).
II. Local extension from neighboring structures and metastasis are common.

TABLE 103-4

Orbital Neoplasms

TUMOR ORIGIN	REFERENCES
Primary	
Adenoma	Headrick et al., 2004
Osteosarcoma: most frequent in dog	Kern, 1985; Cottrill et al., 1987; Hendrix and Gelatt, 2000
Mast cell tumor	Kern, 1985
Reticulum cell sarcoma	Kern, 1985
Fibrosarcoma	Kern, 1985; Hendrix and Gelatt, 2000
Chondrosarcoma	Magrane, 1965
Chondroma rodens (parosteal osteoma)	Jones et al., 1997
Hemangiopericytoma	Beltran et al., 2001
Meningioma of optic nerve	Mauldin et al., 2000
Neurofibrosarcoma	Kern, 1985; Andrew, 1999
Rhabdosarcoma (skeletal extraocular muscles)	Siebold, 1974
Lymphoma	Aquino et al., 1999
Liposarcoma	Hamor et al., 1999
Astrocytoma	Martin et al., 2000
Hemangiosarcoma	Gwin et al., 1982; LeCouteur et al., 1982
Secondary by Extension	
Regional adenocarcinoma	
Nasal	Kern, 1985; Hendrix and Gelatt, 2000
Salivary gland (usually zygomatic)	Ratto, 1991
Lacrimal	Rebhun and Edwards, 1977
Zygomatic gland adenoma	Giudice et al., 2005
Squamous cell carcinoma (from sinuses, eyelids, mouth; more common in cats)	Kern, 1985; Gilger et al., 1992
Melanoma (extension from globe, lids)	Gwin et al., 1982; Roels, 1998
Myxoma/myxosarcoma	
Metastatic	
Multicentric lymphoma	Kern, 1985; Gilger et al., 1992
Adenocarcinoma	
Uterus	Bellhorn, 1972
Mammary gland	Bellhorn, 1972
Kidney	Bellhorn, 1972
Thyroid	Barron et al., 1963
Sweat gland	Moise et al., 1982
Hemangiosarcoma	Gilger et al., 1992
Squamous cell carcinoma	Hamilton et al., 1984
Melanoma	Barron et al., 1963; Hyman et al., 2002
Transitional cell carcinoma	Szymanski et al., 1984
Meningioma	Perez et al., 2005
Fibrosarcoma	Gilger et al., 1992

Modified from Cook CS: Diseases of the orbit. p. 1076. In Morgan RV (ed): Handbook of Small Animal Practice, 3rd Ed. WB Saunders, Philadelphia, 1997; with permission.

Clinical Signs

I. Signs and signalment are often suggestive of orbital neoplasms.
   A. Usually occurs older animals (Hendrix and Gelatt, 2000; Attali-Soussay et al., 2001)
      1. Average age in dogs is 8.2 to 8.7 years.
      2. Average age in cats is 12.5 years.
   B. Usually slowly progressive and nonpainful
   C. Likely to occur medially and/or ventrally from tumor extension from neighboring tissues

II. If the mass is located caudal to the globe, then exophthalmos and protrusion of the third eyelid are seen.

III. If the mass is located rostral to the globe, then enophthalmos is seen.

IV. Vision loss with mydriasis occurs if the optic nerve is affected.
V. Corneal ulceration or keratitis from exposure is possible.

Diagnosis

I. Radiography is sometimes helpful.
   A. To assess involvement of bony orbit
   B. Thoracic radiographs to assess for metastasis
II. Ultrasonography may reveal a soft-tissue mass.
III. MRI and CT provide the greatest detail.
IV. Biopsy is required to obtain a definitive diagnosis.

Differential Diagnosis

I. Orbital cellulitis and abscessation: acute, painful, ± fever
II. Orbital cyst, mucocele: fluid-filled mass on ultrasonography
III. Orbital hemorrhage: acute, painful, tissues appear hemorrhagic, associated with systemic bleeding disorder
IV. Myositis: bilateral
   A. Masticatory myositis: painful
   B. Extraocular myositis: young dogs, globes retropulse easily
V. Idiopathic sclerosing pseudotumor in cats (Billson et al., 2006)
   A. Pseudotumor: an idiopathic mass lesion with accompanying inflammation
   B. Initial unilateral orbital involvement that progresses to bilateral
   C. Onset and progression over weeks to months
   D. Progressive immobility of normal orbital structures
   E. Clinical signs: exophthalmos, reduced ocular and eyelid motility, conjunctivitis, exposure keratitis
   F. No known cause or successful treatment

Treatment

I. General principles
   A. Most orbital neoplasms are malignant.
   B. Most orbital neoplasms are primary in dogs and secondary in cats.
      1. The most common tumor types in dogs are osteosarcoma, fibrosarcoma, and nasal adenocarcinoma.
      2. The most common tumor type in cats is the squamous cell carcinoma.
   C. Prognosis is usually poor.
II. Surgery
   A. Enucleation (removal of globe) with removal of neoplasm
      1. Procedure of choice if the globe is invaded by neoplasm
      2. Appropriate if the eye is blind or irreversibly painful
      3. May be necessary if the eye is visual, to allow access to the neoplasm
   B. Exenteration (removal of orbital contents)
      1. Procedure of choice if the neoplasm invades the globe and orbital structures
      2. More invasive than enucleation
         a More likely to induce hemorrhage
         b. Comprehensive knowledge of orbital anatomy required
   C. Orbitotomy
      1. Includes various surgical approaches that are based on the location of lesion (see Table 103-3).
      2. Ideal procedure if the lesion can be removed completely while preserving the globe; however, the surgeon may need to convert to exenteration during surgery if the neoplasm is extensive.
      3. Preoperative CT or MRI is recommended to help select a surgical approach.
III. Adjunctive therapy
   A. Chemotherapy may be used alone for lymphoma and mast cell tumors.
   B. Doxorubicin has been used for orbital sarcoma (Schoster and Wyman, 1978).
   C. Radiation therapy may be beneficial for nasal tumors (Adams et al., 1987; Roberts et al., 1987; Evans et al., 1989).

Monitoring of Animal

I. Surgical excision offers palliation, but recurrence is usually expected within several months.
II. Adjunctive therapy may delay recurrence.
III. Indications for euthanasia include the following:
   A. Neoplasm too extensive for surgical excision
   B. Systemic disease evident from metastasis

TRAUMA

Traumatic Proptosis

Definition

Proptosis is movement of the globe beyond the bony orbital rim occuring secondary to trauma.

Causes and Pathophysiology

I. Proptosis is caused by some type of trauma, such as blunt trauma or a dog fight.
II. Proptosis occurs very easily in brachycephalic breeds, because the orbit is shallow.
III. In cats and nonbrachycephalic dogs, severe trauma is required to cause proptosis.

Clinical Signs

I. Acute extreme exposure of globe
II. Corneal ulceration or keratitis from exposure
III. Mydriasis if the optic or oculomotor nerves are damaged
IV. Miosis from severe uveitis or sympathetic nerve damage
V. Conjunctivitis, chemosis, and/or conjunctival hemorrhage
VI. Lateral strabismus from rupture of medial rectus, ventral oblique, and ventral rectus muscles

Diagnosis and Differential Diagnosis

I. Diagnosis is based on history of trauma and acute onset, with classic clinical findings.
II. Perform a general physical examination to rule out other injuries.
III. Orbital hemorrhage may appear very similar clinically (acute onset, painful); therefore rule out possible rodenticide

exposure or other bleeding abnormalities (e.g., von Willebrand disease).

IV. Orbital abscessation and cellulitis, although painful and often acute in onset, rarely cause proptosis.

V. Orbital neoplasia rarely results in acute proptosis.

Treatment

I. Replace the globe into the orbit promptly to possibly restore vision.

II. Under general anesthesia, lubricate the globe with sterile ophthalmic ointment.

III. Using digital pressure or the flat surface of a scalpel handle and concurrent traction on the eyelid margins via forceps or sutures (preplacement of horizontal mattress sutures for temporary tarsorrhaphy), gently reposition the globe into the orbit.

IV. Horizontal mattress sutures are used to perform partial temporary tarsorrhaphy (closure of palpebral fissure).
   A. Sutures must be placed accurately.
      1. Sutures placed too deeply will rub the cornea.
      2. Shallow placement causes the eyelid margins to invert and rub the cornea.
   B. Place the suture directly into the orifices of the meibomian glands.
   C. A small portion of the palpebral fissure is left open medially for observation and medication administration.
   D. Two or three sutures are ideal.

V. A single antiinflammatory dose of dexamethasone 0.5 to 1.0 mg/kg SC may be given to help reduce swelling and control pain.

VI. Topical antibiotics are used BID to TID to prevent infection.

VII. Systemic antibiotics are used if infection is likely (dog bite or other penetrating injury).
   A. Ampicillin 22 mg/kg PO TID
   B. Amoxicillin 22 mg/kg PO BID
   C. Amoxicillin 22 mg/kg with clavulanic acid 13.75 mg/kg PO BID
   D. Cephalexin 22 mg/kg PO BID

VIII. Analgesics and antiinflammatory medications are given as needed.
   A. Aspirin at 5 to 10 mg/kg PO BID for dogs, and at 6 mg/kg PO QOD for cats
   B. Carprofen for dogs 2.2 mg/kg PO BID
   C. Butorphanol 1 mg/4.54 kg PO BID (dog or cat)

Monitoring of Animal

I. In the immediate postoperative period, monitor for the following:
   A. Excessive swelling at tarsorrhaphy site
      1. Possible need to revise tarsorrhaphy sutures
      2. Cold compresses to reduce swelling
   B. Protective collar to prevent self-inflicted trauma

II. Sutures are removed within 1 to 2 weeks pending resolution of orbital swelling.

III. Prognosis for vision is usually poor.
   A. Good prognostic indicators include proptosis in a brachycephalic dog, positive pupillary light reflex (direct or indirect), normal posterior segment examination findings, and presence of vision at the time of initial examination.
   B. Poor prognostic indicators include proptosis in nonbrachycephalic breeds or cats, hyphema, no visible pupil, facial fractures, optic nerve damage, and avulsion of three or more extraocular muscles.
   C. Enucleation at presentation is considered if clinical signs are catastrophic.
      1. Rupture of most or all extraocular muscles
      2. Globe rupture

IV. After removal of tarsorrhaphy sutures, monitor for the following:
   A. Recurrent proptosis
      1. Indicates irreversible damage to multiple extraocular muscles
      2. Either enucleation or permanent partial tarsorrhaphy indicated
   B. Permanent globe deviation from extraocular muscle avulsion
   C. Keratoconjunctivitis sicca secondary to lacrimal gland or duct damage
   D. Corneal anesthesia from nerve damage that predisposes to corneal ulceration

CHAPTER 104

Ocular Manifestations of Systemic Disease

Charles M. Stuhr | Emilia F. Wood

INTRODUCTION

I. The vascular nature of the eye combined with its clear media allows visualization of signs that may otherwise be masked in other tissues.
   A. These signs are commonly, but not always, bilateral.
   B. They alert the clinician to a list of differential diagnoses and a series of tests that may lead to a definitive diagnosis.

II. The goal of this chapter is to list common or prominent systemic diseases by the most obvious clinical sign noted on an ophthalmic examination.
   A. Clinical signs are grouped into the following categories:
      1. Eyelid and periocular symptoms (Table 104-1)
      2. Corneal opacities (Table 104-2)
      3. Red eye
         a. Inflammation with a prominent mucoid or mucopurulent discharge consistent with conjunctivitis or keratitis (Table 104-3)
         b. Inflammation with a mild serous or mucoid discharge consistent with uveitis (Table 104-4)
      4. Ocular hemorrhage (Table 104-5)
      5. Cataract formation (Table 104-6)
      6. Fundic lesions with or without visual deficits (Table 104-7)
   B. No one clinical sign is pathognomonic for any one disease.
   C. If primary ocular disease is ruled out or systemic signs accompany the ocular abnormalities listed, then consider the diagnostic tests described.
   D. These lists are not all-inclusive and specifically exclude the rare storage diseases and experimental toxicities.

TABLE 104-1

Systemic Diseases Associated with Eyelid and Periocular Symptoms

SPECIES	CLINICAL SIGNS	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Dog, cat	Periocular alopecia ± pruritus; crusting	Demodicosis, scabies	Skin scrape	Demodicosis is easier to diagnose than scabies with skin scraping
Dog, cat	Periocular alopecia ± pruritus; crusting	Dermatophytosis	Wood's lamp, culture	Transmissable to and from people
Dog	Periocular alopecia ± pruritus; crusting	Leishmaniasis	Skin scrape, biopsy	See Table 104-4
Dog > cat	Narrow palpebral fissure	*Clostridium tetani*	Anaerobic culture	Nictitans protrusion, "sardonic grin" History of penetrating wound
Dog > cat	Muscle spasms	Strychnine toxicity	Color of vomitus can be green or pink from dye marker in bait	Inducible tetanic convulsions Vomiting and diarrhea
Dog	Depigmentation	Vogt-Koyanagi-Harada disease	Biopsy	Also seen on face, feet, and scrotum, with rare ulceration Intraocular symptoms (see Table 104-4)
Cat	Depigmentation	Chédiak-Higashi syndrome	Blood smears Hair analysis	Inborn error of metabolism Photophobia Intraocular depigmentation
Dog > cat	Crusting, ulceration	Pemphigoid complex	Skin biopsy	Associated atopy common
Dog	Crusting, ulceration	Systemic lupus erythematosus	Skin biopsy	Keratoconjunctivitis sicca and anterior uveitis reported
Dog, cat	Crusting, ulceration	Drug eruption	Skin biopsy History of recent drug administration	Topical or parenteral use
Dog > cat	Edema, urticaria pruritus	Atopy/allergy	Intradermal skin test Enzyme-linked immunosorbent assay	Seasonal history important
Dog	Purulent discharge; crusting, alopecia, and erythema	Juvenile cellulitis	Cytology	Primarily in puppies less than 3 months old Bilateral

>, More commonly affected than.

TABLE 104-2

Systemic Diseases Associated with Corneal Opacities

SPECIES	CLINICAL SIGNS	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Dog, cat	Multifocal granular haze	Inborn errors of metabolism	See discussion of primary disease (Chapters 23 and 81)	Mucopolysaccharidosis with associated facial dysmorphism Lysosomal storage diseases Multifocal retinal spots can be observed

TABLE 104-2

Systemic Diseases Associated with Corneal Opacities—*cont'd*

SPECIES	CLINICAL SIGNS	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Dog > cat	Arcus lipoides, multifocal punctate anterior stromal deposits	Hyperlipidemia	Fasting serum triglycerides and cholesterol, free thyroxine, thyroid-stimulating hormone levels	Lipemia retinalis and lactescent aqueous humor are also possible Rule out hypothyroidism Primary disease in schnauzers
Dog	Arcus lipoides, lipid keratopathy	Hypothyroidism	Same for hyperlipidemia	Peripheral neuropathies, keratoconjunctivitis sicca, and blepharitis possible
Dog	Central corneal calcium deposits	Hyperadrenocorticism	Low-dose dexamethasone suppression test Adrenocorticotropic hormone (ACTH) stimulation test	Corneal erosions possible over deposits
Dog	Generalized edema	Infectious canine hepatitis	Enzyme-linked immunosorbent assay	Immune-mediated effects on uvea and corneal endothelium See Table 104-4
Dog	Multifocal punctate deposits	Corticosteroid associated	History of use ACTH stimulation test preferred	More often associated with topical than parenteral administration May develop rapidly

>, More commonly affected than.

TABLE 104-3

Systemic Diseases Associated with a Red Eye: Inflammation with a Prominent Mucoid or Mucopurulent Discharge Consistent with Conjunctivitis or Keratitis

SPECIES	CLINICAL SIGNS	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Dog	Conjunctivitis, KCS	Distemper	Conjunctival cytology and IFA test Serology of CSF or serum	Retinochoroiditis (active and inactive) Optic neuritis
Dog	KCS	Sulfonamide toxicity	Schirmer tear test	Increased risk with smaller dogs (Berger et al., 1995)
Cat	Conjunctivitis, keratitis, KCS, corneal erosions, sequestrum, plaques	Herpesvirus-1	Conjunctival or corneal PCR test IFA Conjunctival cytology with intranuclear inclusions	Current or prior upper respiratory infection Signs recur with stress Unilateral lesions more common in adults
Cat	Conjunctivitis	*Chlamydophila felis*	PCR IFA Conjunctival cytology with intracytoplasmic inclusions	Organisms are difficult to culture or observe Typically unassociated with corneal disease Cytological abnormalities noted in first 2 weeks of active disease
Cat	Conjunctivitis	*Mycoplasma felis* and *Mycoplasma gatae*	PCR IFA Conjunctival cytology with cell membrane inclusions	Organisms are difficult to culture or observe Typically unassociated with corneal disease

KCS, Keratoconjunctivitis; *IFA,* immunofluorescent antibody; *CSF,* cerebrospinal fluid; *PCR,* polymerase chain reaction.

TABLE 104-4

Systemic Diseases Associated with a Red Eye: Inflammation with a Mild Serous or Mucoid Discharge Consistent with Uveitis

SPECIES	CLINICAL SIGNS	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Dog, cat	Uveitis, glaucoma, retinal detachment	Metastatic neoplasia	Dependent on clinical signs	Lymphoma is most common, but many neoplasms spread to the eye and orbit
Dog > cat	Uveitis, keratitis, corneal edema, conjunctivitis, chorioretinitis, orbital cellulitis, glaucoma, retinal granulomas, optic neuritis, retinal detachment	Blastomycosis, histoplasmosis, coccidioidomycosis	Cytology Biopsy Serology (see Chapter 111)	Geographic location markedly affects relative risk of each agent With blastomycosis, posterior segment signs are more dominant than anterior segment signs (Bloom et al., 1996) Concurrent systemic signs almost always occur with histoplasmosis With coccidioidomycosis, unilateral ocular infection can occur with no obvious systemic signs (Angell et al., 1987)
Cat > dog	Chorioretinitis, retinal detachment, optic neuritis, mild anterior uveitis	Cryptococcosis	Cryptococcal capsular antigen assay Cerebral spinal fluid serology	Posterior segment more affected Possible history of exposure to pigeon feces
Dog	Granulomatous posterior uveitis, exudative retinal detachment	Protothecosis	Culture Cytology Immunofluorescent assay	Rare Associated with hemorrhagic diarrhea Fatal to date
Cat	Mild anterior uveitis, iridal swelling, secondary glaucoma	Feline leukemia virus	ELISA	Intraocular and orbital masses with associated uveitis are more common than finding aqueous flare alone
Cat	Anterior uveitis, luxated lens, secondary glaucoma	Feline immunodeficiency virus	ELISA	Pars planitis Most common infectious agent associated with secondary lens luxation
Cat	Anterior uveitis, retinal detachment, keratic precipitates	Feline infectious peritonitis virus	No definitive test (see Chapter 112) Clinical signs, elevated serum immunoglobulins	More commonly seen in young than old cats with the "dry" form
Cat	Anterior uveitis, retinal hemorrhage	Hemoplasmosis (haemobartonellosis)	Cytology of blood smear Packed cell volume PCR	Ocular signs are mild Anemia is primary source of systemic illness
Cat	Anterior uveitis, conjunctivitis	Bartonellosis (tentative)	Western Blot ELISA PCR	Concurrent stomatitis gingivitis
Cat > dog	Anterior uveitis, keratic precipitates	Toxoplasmosis	Serology (immunoglobulins G and M)	Chorioretinitis less common History of hunting Rare chorioretinitis and optic neuritis in the dog
Dog	Anterior uveitis	*Neospora caninum*	Serology (see Chapter 116)	Primarily in puppies via transplacental infection Associated neurologic disease

>, More commonly affected than; *ELISA*, enzyme-linked immunosorbent assay; *PCR*, polymerase chain reaction.

TABLE 104-4

Systemic Diseases Associated with a Red Eye: Inflammation with a Mild Serous or Mucoid Discharge Consistent with Uveitis—*cont'd*

SPECIES	CLINICAL SIGNS	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Dog	Anterior uveitis, glaucoma, retinal detachment	Vogt-Koyanagi-Harada syndrome	Skin biopsy	Depigmentation Akitas are the prototypical breed See Table 104-1
Dog	Alopecia, conjunctivitis	Leishmaniasis	Cytology of bone marrow or nodes Serology ELISA or PCR of bone marrow	Ocular lesions occur in 25% of cases (Pena et al., 2000) See Table 104-1
Dog	Anterior uveitis	*Anaplasma platys*	Serology (see Chapter 115)	Mild uveitis Hemorrhagic component is minimal
Dog	Anterior uveitis, hyphema, retinal hemorrhage and detachment	*Ehrlichia canis*, *Anaplasma phagocytophilum*	Serology (see Chapter 115)	Hemorrhagic component in anterior and posterior segment can be prominent See Table 104-5
Dog	Anterior uveitis, retinal hemorrhage, chemosis, conjunctivitis	*Rickettsia rickettsii*	Serology (see Chapter 115)	Signs similar to *E. canis* but less severe See Table 104-5
Dog	Anterior uveitis	*Borrelia burgdorferi*	Lyme Western blot ELISA PCR	Minimal documentation of associated ocular signs with Lyme disease (Cohen et al., 1990)
Dog	Corneal edema, anterior uveitis	Infectious canine hepatitis	Serology (see Chapter 112)	Reaction occurs 7-21 days postvaccination with canine adenovirus-1
Dog	Anterior uveitis	Dirofilariasis	Heartworm antigen	Mobile larva visualized in aqueous humor Removal via a limbal incision
Dog	Anterior uveitis, hyphema	Brucellosis	Serology (see Chapter 113)	More common in intact, breeding animals Zoonotic potential

TABLE 104-5

Systemic Diseases Associated with Ocular Hemorrhage

SPECIES	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Coagulopathies			
Dog, cat	Clotting factor deficiencies	PT Activated PTT	Orbital, conjunctival, and retinal hemorrhages Hyphema von Willebrand disease most common in the dog
Dog, cat	DIC	Fibrin degradation products Antithrombin III Platelet count D-Dimer assay	Orbital, conjunctival, and retinal hemorrhages Hyphema DIC portends a guarded prognosis Look for primary cause

PT, One-stage prothrombin time; *PTT,* partial thromboplastin time; *DIC,* disseminated intravascular coagulation.

Continued

TABLE 104-5

Systemic Diseases Associated with Ocular Hemorrhage—*cont'd*

SPECIES	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Dog, cat	Platelet abnormalities	Platelet count and function tests (e.g., buccal mucosal bleeding time)	Conjunctival and intraretinal hemorrhages Look for petechiae on any mucous membrane or skin
Dog, cat	Vitamin K–associated toxins	PT, PTT	Orbital, conjunctival, and retinal hemorrhages Hyphema History of rat poison ingestion
Infectious Agents			
Dog, cat	Bacterial septicemia	Culture Complete blood count	Conjunctival and retinal hemorrhages Animal usually febrile and depressed
Dog > cat	*Borrelia burgdorferi*	Lyme Western blot ELISA PCR	Retinal hemorrhages Mild uveitis and conjunctivitis See Table 104-4
Dog	*Ehrlichia canis, Anaplasma phagocytophilum*	Serology	Orbital, conjunctival, intraretinal, and subretinal hemorrhages Hyphema Acute phase associated with marked intraocular inflammation Chronic phase less robust See Table 104-4
Cat	Feline infectious peritonitis	Clinical signs Elevated serum immunoglobulins	Retinal hemorrhages Most common in kittens See Table 104-4
Cat	Hemoplasmosis	Blood smear PCR	Punctate retinal hemorrhages from anemia
Dog	*Rickettssia* spp.	PCR/serology	Petechiae of conjunctiva, iris, and retina Milder inflammation than noted with *E. canis*
Dog	*Toxocara canis*	Fecal flotation	Retinal hemorrhages Uncommon, but reported in active working dogs
Systemic Hypertension			
Dog, cat	All types of hypertension	See below	Primary differential diagnosis in old cats presenting with acute blindness May or may not have positive pupillary light reflexes Intraretinal, subretinal, vitreal, and conjunctival hemorrhages Hyphema
Dog > cat	Primary hypertension	BP	Diagnosis by exclusion
Cat > dog	Renal disease	BP Serum biochemistry panel Urinalysis	Polyuria/polydipsia Urinalysis important
Cat	Hyperthyroidism	BP Serum thyroid hormone assays	Weight loss in the presence of healthy appetite
Dog	Pheochromocytoma	BP Ultrasonography	Diagnosis may require exploratory laporotomy
Dog	Hyperadrenocorticism	Low-dose dexamethasone suppression test Adrenocorticotropic hormone simulation test	May resolve with control of disease

>, More commonly affected than; *ELISA,* enzyme-linked immunosorbent assay; *PCR,* polymerase chain reaction; *PCV,* packed cell volume; *BP,* blood pressure.

TABLE 104-5

Systemic Diseases Associated with Ocular Hemorrhage—*cont'd*

SPECIES	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Immune-Mediated Diseases			
Dog > cat	Hemolytic anemia	Coombs' test Reticulocyte count Blood smear	Conjunctival, iridal, and retinal hemorrhages Middle-aged, spayed females overrepresented
Dog > cat	Thrombocytopenia	Platelet count	Conjunctival, iridal, and retinal hemorrhages Generally platelet count < 50,000/μL needed for petechiae to develop
Other Vasculopathies			
Dog, cat	Polycythemia	PCV Erythrocyte count	Primary or secondary forms
Dog, cat	Hyperviscosity syndrome	Elevated serum immunoglobulins Serum protein electrophoresis	Screen for malignant neoplasia (i.e., multiple myeloma), ehrlichiosis

TABLE 104-6

Systemic Diseases Associated with Cataract Formation

SPECIES	SEVERITY/LOCATION OF CATARACT	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Dog	Immature to mature	Diabetes mellitus	Fasting serum glucose Urinalysis	Cataract typically rapid in onset Can occur even if diabetes appears controlled
Persian cats	Posterior subcapsular	Mannosidosis	See Chapter 23	Rare inborn error of metabolism
Dog, cat	Incipient to mature	Uveitis from any cause	See Chapter 96	Very common; progression and size are varible
Dog, cat	Multifocal punctate and linear	Hypocalcemia	Serum calcium and parathormone levels	Vision usually unaffected
Dog, cat	Incipient cortical; equatorial vacuoles to immature	Corticosteroid-associated	History of high dose and/or prolonged usage	Rare with either topical and parenteral use
Cat	Cortical and nuclear	Riboflavin deficiency	History of poor diet Serum riboflavin	Associated with a high-fat or raw fish diet

TABLE 104-7

Systemic Diseases Associated with Fundic Lesions with or without Visual Deficits

SPECIES	CLINICAL SIGNS	DISORDER	DIAGNOSTIC TESTS	COMMENTS
Cat	Tapetal hyper-reflectivity	Taurine deficiency	Plasma taurine levels	Progresses from a linear streak superior to the optic disc to generalized changes
Cat	Serous retinal detachment	Feline infectious peritonitis	No definitive test	See Table 104-4
Cat	Retinal tracks	*Cuterebra* spp.	Direct observation	Tracks are suspected larval migration
Cat, dog	Retinal detachment ± hemorrhage	Systemic hypertension	Blood pressure	Retina can attach and reattach, leading to altered reflectivity of fundus See Table 104-5
Dog	Normal retina (with vision loss)	Sudden acquired retinal degeneration	ERG	Central blindness or optic nerve disease are ruled out if ERG is extinguished Pupillary light reflexes are usually present
Dog	Subretinal granuloma	*Toxocara canis*	Fecal flotation	Lesions range from granulomas and retinal detachment to quiet areas of tapetal hyperreflectivity
Dog	Retinal detachment and depigmentation	Vogt-Koyanagi-Harada syndrome	Biopsy of skin lesions	See Table 104-4
Dog	Multifocal to diffuse chorioretinitis	Caine distemper	Serology	Associated conjunctival disease See Table 104-3
Dog, cat	Swollen optic papilla	Optic neuritis	Computed tomography, magnetic resonance imaging, cerebral spinal fluid analysis Normal ERG	Blind, quiet eye with fixed dilated pupils Retina may be normal in appearance
Dog, cat	Chorioretinitis, granulomatous retinal detachment, ± optic neuritis	Systemic mycoses, protothecosis, toxoplasmosis	Depends on suspected organism, serology	See Table 104-4
Dog, cat	Retinal hemorrhage ± detachment	Tick-borne diseases, coagulopathy, anemia, platelet dysfunction, metastatic neoplasia	Depends on etiology	See Tables 104-4 and 104-5

ERG, Electroretinogram.

CHAPTER 105

Neuroophthalmology

Annajane B. Marlar

DISORDERS OF THE EYELIDS AND ADNEXA

Facial Nerve Paralysis

Definition

I. Facial nerve paralysis is a lack of motion of muscles innervated by motor branches of the facial or seventh cranial nerve (CN VII).
II. Paralysis can be complete or partial, depending on the extent of the lesion.

Causes

I. Lesions affecting either the facial nucleus (medulla) or individual branches of the facial nerve
II. Peripheral neuropathy: endocrine secondary to diabetes mellitus, hypothyroidism, or hyperadrenocorticism; myasthenia gravis
III. Trauma to the nerve
IV. Idiopathic forms
V. Inflammation: granulomatous meningoencephalitis (GME), otitis interna and media, polyneuritis
VI. Iatrogenic: most commonly after lateral ear canal resection, ear ablation procedures, orbital exploration, lateral canthotomy
VII. Toxins: botulism
VIII. Neoplasia

Pathophysiology

I. Lesions can occur anywhere along the course of the facial nerve.
   A. Facial nucleus: ventrolateral medulla
   B. Trapezoid body: close proximity to abducens nucleus and trigeminal nucleus and tract
   C. Internal acoustic meatus of the petrosal bone: close proximity to CN VIII
   D. Facial canal, stylomastoid foramen
   E. Near muscles of facial expression: ears, eyelids, nose, cheeks, lips
II. Other cranial nerves or central nervous system (CNS) signs may occur, depending on location of the lesion.
III. Lesions can be unilateral or bilateral, partial (paresis), or complete (paralysis).

Clinical Signs

I. Lesions of nucleus and nerve before termination in individual muscle groups
   A. Eyelid paresis and paralysis: absent or decreased menace reflex (CN II or VII lesion) and palpebral reflex (CN V or VII lesion), ± wide palpebral fissure
   B. Possible ear droop on affected side
   C. Lip droop to affected side ± drooling
   D. Abnormal position of philtrum of nose: pulled toward the normal side
   E. Hemifacial spasm
      1. Lip and nose are pulled caudally on affected side.
      2. Palpebral fissure is smaller.
   F. Possibly Horner's syndrome or vestibular signs if other cranial nerves are affected
   G. Keratoconjunctivitis sicca (KCS)
II. Lesions along individual branches to different muscle groups
   A. Auriculopalpebral nerve: paresis and paralysis of ear and eyelid
   B. Buccal nerves: paresis and paralysis of lips and nose, loss of depression of lower eyelid

Diagnosis

I. Observation of facial asymmetry and position of ears, nose, and lips
II. Abnormal or absent palpebral reflex (Table 105-1)
III. Abnormal or absent menace reflex from inability to blink
IV. Possibly low tear production on Schirmer tear test
V. Tests to determine underlying cause (see Chapters 23 and 25)
VI. Evaluation of other cranial nerves

Differential Diagnosis

I. Lid retraction from scarring or trismus
II. Conformational macroblepharon
III. Exophthalmos and proptosis

Treatment and Monitoring

I. No definitive treatment exists, except to correct any underlying causes.
II. Lateral canthal closure is considered in lagophthalmic animals or in animals in which neurotrophic keratitis or KCS is also present.

TABLE 105-1

Neuroophthalmic Examination

TEST	TECHNIQUE	PATHWAY/STRUCTURE ASSESSED	NORMAL RESPONSE
Menace response	Present a sudden visual stimulus to each eye without touching or causing air movement near animal (i.e., stimulating CN V); eyes may need to be covered to prevent stimulus from contralateral eye	CN II and CN VII CN VI may be involved if globe is retracted; this is only likely if CN VII deficit is present	Eyelids close in response to stimulus; this is a learned reflex and does not develop until 12-16 weeks of age
Visual motion detection	Objects with minimal scent are moved into the visual fields; each eye is tested individually as well as together; move or throw cotton ball in front of the animal	Retina, CN II, visual pathways including visual cortex and motor pathways	Animal follows or attempts to retrieve object; movement of eyes or head occurs; this technique may be used by owners to monitor vision in the home environment
Dazzle response	Shine a very bright light (fiberoptic is best) into each eye individually	Retina, CN II, visual pathways to the subcortical level, motor pathways	Normal response is closure of the eyelids and/or retraction of the globe; the animal may move to avoid the stimulus
Pupillary shape and symmetry (performed before dilation or PLRs)	From a distance in ambient and dim light, visualize both eyes at once; observe shape and size of the pupil, as well as position	By observing pupils, assess for dyscoria, anisocoria, strabismus, lid position; it is important to assess which is the normal vs. abnormal pupil	Pupils should be symmetrical and an appropriate shape for species
Direct PLR	In darkened room, shine a light directly into the eye and observe the movement of this pupil	Retina, optic nerve, optic tract, pretectal area, anteromedian nucleus (CN III)	As light is directed into the eye, the pupil constricts
Indirect (consensual) PLR	In darkened room, shine light into one eye and observe the pupillary response of the contralateral eye	As for direct PLR	As light is directed into one eye, the contralateral pupil constricts, sometimes to a lesser degree
Swinging flashing test	In darkened room, shine light into one eye; after a few seconds, direct the light source to the contralateral eye	Retina, optic nerve, and prechiasmal lesions This test is most useful in assessing lesions anterior to the optic chiasm	Test is positive (i.e., abnormal) if, when light shifts, stimulus is insufficient to maintain constriction or if pupil dilates under direct stimulation
Blink reflex	Gently touch lateral and medial palpebral fissure; it is important not to stimulate visual pathways instead of tactile pathways	CN V and CN VII Medial canthus: ophthalmic branch CN V Lateral canthus: maxillary branch CN V	Eyelids close in response to tactile stimulus; degree of eyelid closure depends on several factors (e.g., globe position)
Corneal reflex/ sensation	Without touching the eyelids, gently touch the unanesthetised cornea with a sterile cotton-tipped applicator; a Cochet-Bonnet aesthesiometer can also be used	CN V, CN VI, CN VII Ophthalmic branch CN V	The eyelids close and the globe is retracted; this test can be used to assess CN V in the absence of normal CN VII function
Mase testing	In both scotopic (dark) and photopic (light) conditions, the animal is tested with randomly placed obstacles	Entire visual pathway and motor pathways; particularly useful in testing for nyctalopia	Normal animal is able to avoid obstacles even in a dimly lit room; scotopic vision is better in small animals than humans

CN, Cranial nerve; *PLR*, pupillary light response.

Continued

TABLE 105-1

Neuroophthalmic Examination—*cont'd*

TEST	TECHNIQUE	PATHWAY/STRUCTURE ASSESSED	NORMAL RESPONSE
Visual placing	Carry the animal toward the edge of a table	Entire visual pathway and motor pathways to forelimbs	The visual animal will reach for the edge of the table prior to touching it
Vestibulo-ocular reflex/ oculocephalic reflex, doll's head reflex	Move the head in all directions and observe for movement of the globe	Assesses vestibular system and motor pathways to extrocular muscle (i.e., CN II, IV, VI)	Eyes follow the direction of head movement, so that anterior gaze remains parallel to nose; ocular movements are bilateral and symmetrical

III. Tear supplements can be used to decrease the risk of corneal erosion.
   A. Ointments or gels are preferable because of increased contact times.
   B. Applications are often required TID to QID.
IV. Acupuncture may benefit animals with idiopathic forms (Jeong et al., 2001).
V. In some instances, paresis and paralysis may resolve with time.

Protrusion of Third Eyelid

See Chapter 96.

Neurogenic Keratoconjunctivitis Sicca

See Chapter 97.

Fibrosing Strabismus

Definition

I. Fibrosing strabismus is a syndrome characterized by a convergent esotropia (medial or ventral strabismus).
II. It can lead to decreased vision in severe cases because of altered eye position.

Causes

I. Unknown
II. Seen in different breeds: shar-pei, Akita, white German shepherd dog

Pathophysiology

I. Selective fibrosing myopathy affecting certain extraocular muscles, particularly the medial rectus, ventral rectus, and ventral oblique
II. Rotation usually ventromedial

Clinical Signs

I. Severe unilateral or bilateral, medial and ventromedial rotation of the globe is noted.
II. With forced duction, the globe cannot be moved into normal position.

Diagnosis

I. Suggestive findings on ophthalmic examination and forced duction testing
II. Imaging of orbital soft tissues with ultrasonography, magnetic resonance imaging (MRI), and computed tomography (CT)
   A. To identify affected muscles
   B. To rule out other orbital abnormalities, such as loss of retrobulbar fat

Differential Diagnosis

I. True esotropia (Table 105-2)
II. Deviation of globe from retrobulbar disease

Treatment and Monitoring

I. Surgical exploration with incision of fibrotic bands is not very successful at correcting the condition.
   A. The condition usually recurs.
   B. When the condition recurs, it does so within a short period of time and continues to progress.
II. Prognosis for returning the eye to the normal position is guarded.

Neurotrophic Keratitis

Definition

I. A keratopathy that develops from damage to the ophthalmic, sensory branches of the trigeminal nerve (CN V)
II. Usually unilateral

Causes

I. Trauma (most common): after partial or complete proptosis of the globe
II. Inflammatory and infectious diseases: GME, feline herpesvirus 1
III. Neoplasia

Pathophysiology

I. Normal corneal homeostasis depends on normal innervation.

TABLE 105-2

Lesions Affecting Eye Position

CLINICAL SIGNS	ABNORMALITY
Divergent strabismus, ptosis, inability to rotate eye nasally, dorsally or ventrally (external ophthalmoplegia)	Complete lesion of occulomotor nerve/nucleus (CN III)
As above but with ipsilateral dorsal rectus dysfunction	Central lesion involving CN III nucleus
Dysfunction of dorsal oblique muscle: unable to rotate upper aspect of the eye toward the nose	Ipsilateral trochlear nerve or contralateral trochlear nucleus (CN IV)
Dysfunction of lateral rectus: medial strabismus	Ipsilateral abducens nerve (CN VI)
Dysfunction of retractor bulbi: exophthalmos and abnormal ocular motility	Ipsilateral abducens nerve or accessory abducens nucleus (CN VI)
Convergent strabismus and pendular nystagmus in cats	Abnormality in axonal projections to visual cortex: congenital; most common in Siamese or albino animals; no treatment required
Ventrolateral strabismus (sunset sign); other neurologic signs usually present	Hydrocephalus: congenital
Skew (unilateral) deviation (ventral or ventrolateral)	Ipsilateral peripheral vestibular disease
"Jerk" nystagmus: horizontal or rotatory with quick phase away from the side of lesion	Peripheral vestibular disease
Vertical or positional nystagmus: direction changes with head position	Central vestibular disease

CN, Cranial nerve.

II. Denervation of the cornea causes a loss in corneal sensation and often leads to chronic erosive disorders.

Clinical Signs

I. Decrease in corneal sensation (see Diagnosis and Table 105-1)
II. Recurring or unresponsive corneal erosions that are not painful
III. Cranial nerve deficits if other nerves are affected (especially facial nerve)

Diagnosis

I. Lack of corneal sensation is evaluated by touching a cotton-tipped applicator to the cornea.
   A. Perform this test before application of topical anesthetic.
   B. Expected response is blinking, retraction of globe, and/or movement of the third eyelid.
   C. Alternatively, a Cochet-Bonnet aesthesiometer is used to quantify the degree of corneal sensation.
II. Diffuse stippling of fluorescein retention often occurs in the cornea and early in the course.
III. Animals with decreased corneal sensation must be evaluated carefully for KCS and facial nerve paralysis and paresis.
IV. Perform other tests for isolating and identifying a cause.

Treatment and Monitoring

I. Institute appropriate treatment of corneal erosions with topical antibiotics (see Chapter 98).
II. Consider performing temporary or permanent canthoplasties to prevent recurrence of proptosis and to protect the cornea.
III. Administer appropriate therapy for KCS, if present (see Chapter 97).
IV. After proptosis, especially in eyes with trigeminal nerve deficits, topical corticosteroids are contraindicated because they often predispose to corneal erosions, even if fluorescein staining is negative before their use.
V. Prognosis for healing of these lesions is poor, and recurrences are common.

DISORDERS OF THE PUPIL

Afferent Mydriasis

Definition

I. Afferent mydriasis is a relative dilation of the pupil resulting from a lesion affecting the retina, the optic nerve (CN II), the optic chiasm, or, uncommonly, the optic tract.
II. Abnormalities in pupillary light response (PLR) and menace reflex depend on the extent and site of the lesion.
III. After dark adaptation, the pupil is almost maximally dilated.
IV. It may be unilateral or bilateral.
V. Afferent defects are often described as prechiasmal, chiasmal, or postchiasmal.

Causes

I. Retinal lesions
   A. Retinal degeneration and atrophy: inherited degeneration, taurine deficiency, glaucoma, toxicities
   B. Retinal detachment
   C. Chorioretinitis
   D. Sudden acquired retinal degeneration (SARD)
II. Optic nerve lesions
   A. Congenital lesions: hypoplasia, coloboma
   B. Neoplasia: meningioma, lymphoma, glioma
   C. Inflammatory disorders: GME, infections (particularly fungal), immune-mediated optic neuritis, toxoplasmosis
   D. Trauma: proptosis, surgical trauma after enucleation of opposite globe, or incision and drainage of retrobulbar space

III. Optic chiasm and optic tract lesions
  A. Congenital anomaly: hydrocephalus, hypoplasia of optic nerve
  B. Neoplasia: meningioma, lymphoma, masses involving pituitary or structures of the hypophyseal fossa
  C. Inflammation: GME, immune-mediated meningitis
  D. Infections: systemic mycoses, viruses (distemper), bacterial meningitis, toxoplasmosis and other parasites
  E. Trauma: head injury
  F. Vascular lesions

Pathophysiology

I. Afferent arm of pupillomotor control has been classified as either a two- or three-neuron pathway (Figure 105-1).
  A. Signals arising in the retinal photoreceptors synapse on the bipolar cells.
  B. Bipolar cells synapse on the ganglion cells (fibers from these cells compose the optic nerve).
  C. Pupillary light fibers pass through the lateral geniculate nucleus (LGN) to synapse in the pretectal nuclei.
    1. Information from the pretectal nuclei decussates again via the caudal commissure.
    2. Information then passes to the parasympathetic nucleus of oculomotor nerve III, which is located near the Edinger-Westphal nucleus.

II. Lesions anywhere along the pathway can interrupt the normal PLR.

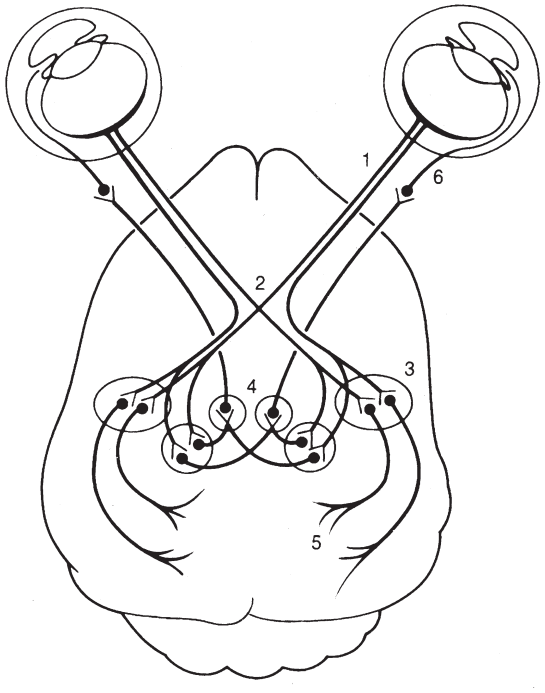

FIGURE 105-1 Pathways involved in pupillary light response (PLR) and vision. *1,* Optic nerve; *2,* optic chiasm; *3,* lateral geniculate nucleus (LGN); *4,* pretectal nucleus, near nucleus of Edinger-Westphal; *5,* optic radiation to occipital cortex; *6,* efferent, postganglionic component of parasympathetic innervation of the iris. *From Peiffer RL: Small Animal Ophthalmology: A Problem-Oriented Approach. 3rd Ed. WB Saunders, Philadelphia, 2001, p. 109; with permission.*

III. Fibers in the optic nerve carrying visual information synapse in the LGN and then travel on to the occipital cortex via the optic radiations.

Clinical Signs

I. Retinal lesions
  A. Variable menace response and visual deficits
  B. Diminished direct and consensual PLRs
  C. Positive swinging flashlight test (see Table 105-1)
  D. ± Visible fundic lesions
    1. Retinal detachment and/or retinal atrophy
    2. Chorioretinitis
    3. No lesions with SARD (see Chapter 102)

II. Optic nerve lesions
  A. Diminished direct and consensual PLRs
  B. Variable menace response and vision deficits
  C. Positive swinging flashlight test
  D. ± Funduscopic abnormalities
    1. Optic nerve swelling: papilledema, optic neuritis, elevated cerebrospinal pressure
    2. Hyperemic optic disc: optic neuritis
    3. Optic nerve cupping: coloboma or glaucoma
    4. Gray discoloration of optic nerve or small size: atrophy, hypoplasia

III. Optic chiasm lesions
  A. Diminished direct and consensual PLRs
  B. Variable menace response and vision deficits
  C. Possible systemic clinical signs: polyuria and polydipsia, polyphagia if lesion is pituitary in origin

IV. Optic tract lesions
  A. Variable direct and consensual PLRs, depending on the extent of the lesion
  B. Variable menace response and vision deficits (e.g., hemianopia)
  C. Other neurological signs depending on effect of the lesion on adjacent structures

Diagnosis

I. Complete ophthalmic examination
  A. Rule out intraocular or visible retinal and optic nerve disease.
  B. Include tonometry to rule out glaucoma.
  C. Afferent mydriasis is always accompanied by diminished or absent vision; visual deficits may be subtle to profound.

II. Neurological examination to evaluate for other deficits that aid in localization of lesion

III. PLR testing (see Table 105-1)
  A. With afferent lesions, both pupils dilate equally and maximally under dark adaptation.
  B. Because of unequal decussation of fibers at the chiasm and caudal commissure, dogs and cats may exhibit a physiological resting anisocoria.

IV. Swinging flashlight test
  A. Positive test is pathognomonic for retinal or prechiasmal lesions.

B. Lesions must be differentiated from pupillary escape—a normal phenomenon occurring when a normal pupil dilates slightly after the initial contraction as a result of adaptation of the retina.

V. Electrodiagnostics
   A. Electroretinogram (ERG) helps identify retinal diseases such as SARD or progressive retinal atrophy (PRA) (see Chapter 102).
   B. Visual evoked potentials (VEPs) are used to evaluate responses from ganglion cells to the occipital cortex.

VI. Advanced imaging techniques
   A. Ultrasonography allows visualization of the optic nerve and lesions affecting the retrobulbar area.
   B. MRI allows superior imaging of the optic nerve, chiasm, and optic tracts, as well as the brain.

VII. Cerebrospinal fluid analysis is indicated if optic pathway or CNS lesions are suspected.

Differential Diagnosis

I. Efferent mydriasis
II. Pharmacological blockade via iris sphincter paralysis (e.g., atropine)
III. Intraocular diseases
   A. Glaucoma
   B. Iris atrophy
   C. Early lens luxation
      1. Mild to moderate pupillary dilation with anterior position of lens
      2. ± Shallow anterior chamber

Treatment

I. Treat any underlying conditions (see Chapter 23).
II. Treatment of the pupillary abnormality alone is not warranted.

Monitoring of Animal

I. Prognosis depends on the underlying cause.
II. Monitor for additional ocular or neurological symptoms.

Efferent Mydriasis

Definition

I. Paralysis of the efferent parasympathetic pupillary pathway affects the iris sphincter and ciliary body.
II. Efferent mydriasis is also called *internal ophthalmoplegia*.

Causes

I. Orbital disease: trauma, space-occupying lesions, inflammation
II. Cavernous sinus syndrome (see Chapter 23)
III. Dysautonomia
IV. Midbrain or cerebellar lesions: infectious, inflammatory, anomalous, traumatic, neoplastic disorders
V. Pharmacologic blockade of iris sphincter: parasympatholytic agents (atropine, belladonna), sympathomimetics
VI. Idiopathic forms

Pathophysiology

I. Lesions along this two-neuron pathway affect the parasympathetic axons, with or without disrupting oculomotor nerve function to the extraocular muscles.
II. Cell bodies of the first-order neurons are located in the anteromedian nucleus at the rostral border of the oculomotor nucleus (CN III) and ventral tegmental area.
   A. Axons exit the mesencephalon in close proximity to the motor efferent fibers of the oculomotor nerve.
   B. Parasympathetic fibers travel superficially and medially.
   C. The fibers separate from motor efferent fibers just proximal to where they synapse within the ciliary ganglion.
III. Second-order or postganglionic parasympathetic fibers travel lateral to the optic nerve and become part of the short ciliary nerves (see Figure 105-1).

Clinical Signs

I. Mydriasis ipsilateral to lesion under normal lighting conditions
II. Normal vision and menace response in affected eye
III. Abnormal PLRs
   A. Affected eye: negative direct, positive indirect PLR
   B. Unaffected eye: positive direct, negative indirect PLR
IV. External ophthalmoplegia (see Table 105-2)
   A. It is a syndrome caused by lesions affecting the motor efferent fibers of the oculomotor nerve (CN III).
   B. It may occur if the lesion is proximal to the ciliary ganglion.
   C. Ipsilateral ptosis may occur but is often very subtle.
   D. Resting esotropia occurs from denervation of extraocular muscles innervated by CN III.

Diagnosis

I. Clinical ophthalmic examination
   A. Pupil on the affected side is dilated, with no direct PLR; however, a normal indirect PLR to the opposite eye is present.
   B. If internal ophthalmoplegia alone is seen, then the ophthalmic examination is otherwise normal.
   C. No visual deficit is detected.
   D. No history of pharmacological blockade of the iris sphincter is noted (e.g., atropine administration).
II. Neurologic examination
   A. Presence or absence of neurological deficits depends on the location of the lesion.
   B. Cavernous sinus syndrome often causes deficits in CNs IV, V, and VI.
   C. Other cranial nerve functions are usually normal if the lesion is confined to CN III.
III. Pharmacological testing (Table 105-3)
   A. To differentiate neurological lesions from iris sphincter disease
   B. To differentiate between preganglionic and postganglionic lesions

TABLE 105-3

Pharmacological Testing for Efferent Mydriasis

DRUG	MODE OF ACTION	FIRST-ORDER (PREGANGLIONIC) LESION	SECOND-ORDER (POSTGANGLIONIC) LESION	IRIS SPHINCTER DISEASE (INTRINSIC)
0.5% physostigmine	Indirect-acting parasympathomimetic	Constriction	No constriction	No constriction
0.1% pilocarpine	Direct-acting parasympathomimetic	No pupillary constriction	Constriction within 20 min	No constriction
2% pilocarpine	Direct-acting parasympathomimetic	Constriction within 20 min	Constriction within minutes	No constriction

Differential Diagnosis

I. Afferent mydriasis: vision deficit present
II. Dysautonomia: bilateral mydriasis, other ocular abnormalities (see Dysautonomia) with other systemic signs
III. Cerebellar disease: ± contralateral mydriasis
IV. Intraocular diseases
  A. Iris atrophy: no pupillary constriction with topical pilocarpine, other neurological signs absent
  B. Glaucoma: ruled out using tonometry, ophthalmic examination, and visual testing (see Chapter 100)
  C. Early lens subluxation: careful examination of anterior chamber depth and iris position usually diagnostic; ± elevations in intraocular pressure
  D. Posterior synechiae: visible adhesions between the iris and lens restricting iris movement
  E. Developmental anomalies of the iris sphincter: hypoplasia, coloboma, persistent pupillary membrane visible on examination of anterior segment

Treatment

I. Treatment is directed against any underlying neurological or orbital diseases.
II. If the mydriasis is caused by prior administration of parasympatholytic drugs, then consider discontinuing their use.
III. Dilute topical pilocarpine may be used for symptomatic relief in animals with dysautonomia (see later in this chapter).

Monitoring of Animal

I. Efferent mydriasis associated with focal CN III lesions may be permanent but is not life threatening.
II. Lesions of the midbrain and caudal brainstem warrant a guarded to grave prognosis.
III. Mydriasis from atropine and other parasympatholytic agents usually subsides within 7 to 14 days.
IV. Idiopathic efferent mydriasis may be transient and slowly resolve within several weeks.

Horner's Syndrome

Definition

I. Horner's syndrome is caused by a loss of sympathetic innervation to the eye and periorbita.
II. The causes are classified as central, preganglionic, or postganglionic.

Causes

I. Central (first-order) lesions
  A. Trauma
  B. Vascular diseases
  C. Neoplasia
  D. Inflammatory or infectious meningoencephalitides (e.g., GME, canine distemper)
II. Preganglionic (second-order) lesions
  A. Neoplasia
    1. Mediastinal lesions: lymphosarcoma, thymoma, metastatic tumors, anterior lung lobe tumors
    2. Cervical tumors: thyroid, parathyroid, soft tissue sarcomas
  B. Trauma
    1. Bite wounds to neck
    2. Automobile crashes with brachial plexus avulsion
    3. Surgical trauma
  C. Inflammation of cervical soft tissue structures adjacent to vagosympathetic trunk
  D. Abscess formation in soft tissues adjacent to neurons or ganglion
  E. Iatrogenic: jugular venipuncture or intravenous catheters
III. Postganglionic (third-order) lesions
  A. Idiopathic: common cause
  B. Middle ear disease: otitis media, petrositis
  C. Head trauma
  D. Neoplasia: middle ear, retrobulbar area
  E. Iatrogenic: bulla osteotomy, ear cleaning
  F. Cavernous sinus syndrome: vascular or neoplastic causes

Pathophysiology

I. Lesions may occur anywhere along the sympathetic efferent pathway.
II. First-order neurons develop as follows:
  A. Cell bodies reside in the hypothalamus and midbrain.
  B. Axons traverse the brainstem and spinal cord via the lateral tectotegmental spinal tracts.

C. They synapse with second-order neurons in the intermediate gray matter of the first three thoracic cord segments.

III. Second-order neurons exit the spinal cord via the thoracic spinal nerves.
   A. They travel with the sympathetic trunk across the cranial thorax.
   B. They continue through the cervicothoracic and middle cervical ganglion without synapsing and join the vagus nerve to form the vagosympathetic trunk.
   C. They synapse with third-order neurons in the cranial cervical ganglion.

IV. Third-order neurons arise in the cranial cervical ganglion (ventromedial to tympanic bulla), and their axons travel in close proximity to the internal carotid artery.
   A. They join the tympanic branch of the glossopharyngeal nerve (CN IX) in the middle ear.
   B. Axons travel from the middle ear through the cavernous sinus to join the ophthalmic branch of the trigeminal nerve (CN V).
   C. Axons enter the orbit through the orbital fissure and enter the globe via the long ciliary nerve.

Clinical Signs

I. Clinical signs ipsilateral to the lesion
II. Miosis and anisocoria more noticeable after dark adaptation
III. Third eyelid protrusion
   A. Passive: secondary to enophthalmos
   B. Active: denervation to smooth muscles of the third eyelid, particularly in the cat
IV. Enophthalmos
   A. Decrease in tone of smooth muscle encircling and within periorbital cone
   B. Allows increased retraction of globe by extraocular muscles, particularly retractor bulbi
V. Ptosis
   A. Secondary to denervation of Müller's muscle in the superior eyelid
   B. Rarely, a reverse ptosis (narrowing of palpebral fissure) if the inferior lid is involved
   C. Secondary to changes in globe position (enophthalmos)
VI. Possibly other signs associated with specific causes
   A. Laryngeal hemiplegia possible with lesions affecting second-order neurons
   B. CNS signs with first-order neuron disease
   C. Forelimb paralysis with anterior thoracic trauma
   D. Head tilt or facial nerve paralysis with middle ear disease

Diagnosis

I. Clinical history often indicates an acute onset and may identify an underlying cause (e.g., trauma, ear disease).
II. Careful ophthalmic and neurological examinations usually confirm the presence of Horner's syndrome.
   A. Three of the four ophthalmic signs are required (in the absence of other ophthalmic abnormalities that could produce these clinical signs).
   B. Perform a complete neurological examination to rule out other neurological deficits.
III. Thorough physical examination aids in the localization of any neurological and causative lesions.
IV. Pharmacological localization may be tried (Table 105-4).
   A. Controversy exists over the correct and most reliable testing protocols to use.
   B. Pharmacological testing may give helpful information but often yields inconsistent results.
   C. Denervation hypersensitivity of third-order neurons occurs after 7 to 14 days.
   D. Testing done in the absence of other ophthalmic manipulations (topical anesthetics and drugs affecting the pupils) is most reliable.
   E. Optimum minimal interval between applications of different test agents is 24 hours.
V. Other diagnostic aids include the following:
   A. Complete ear examination in postganglionic cases, ± fiber-optic scoping, myringotomy
   B. CT or MRI of the head and neck or radiography of the chest, depending on clinical signs
   C. Complete blood count, biochemistry profile, thyroid function tests
   D. Cerebrospinal fluid analysis for suspected central disease

TABLE 105-4

Pharmacological Testing for Horner's Syndrome

DRUG	MODE OF ACTION	CENTRAL LESION	PREGANGLIONIC LESION	POSTGANGLIONIC LESION
1% hydroxyamphetamine*	Indirect sympathomimetic—causes release of norepinephrine	Normal dilation	Normal dilation	No dilation
1% phenylephrine or 0.1% epinephrine	Direct-acting sympathomimetic	No dilation	No dilation	Dilation within 20 min
2.5% phenylephrine or 1% epinephrine	Direct-acting sympathomimetic	No dilation	Dilation within 20 min	Dilation within minutes

*This agent is no longer available commercially but can be compounded.

Differential Diagnosis

I. Third eyelid protrusion
  A. Ocular pain
  B. Enophthalmos
  C. Haw's syndrome
  D. Tetanus
  E. Dysautonomia
  F. Keratoconjunctivitis sicca
II. Miosis
  A. Ulcerative keratitis
  B. Anterior uveitis
  C. Drug-induced
  D. Spastic pupil syndrome (see later in this chapter)
  E. Central neurological lesions
III. Enophthalmos
  A. Ocular pain
  B. Decrease in orbital contents

Treatment

I. Treat any underlying cause.
II. Control of miosis in postganglionic lesions can be achieved using topical phenylephrine but is only recommended for those dogs in which vision is impaired by marked protrusion of the third eyelid.

Monitoring of Animal

I. Many postganglionic and idiopathic cases resolve spontaneously over a 6- to 8-week period.
II. If no cause is identified, then counsel owners to monitor for onset of other neurological signs.
III. Horner's syndrome associated with anterior thoracic lesions, brachial plexus injuries, and CNS disease is usually permanent.

Dysautonomia (Key-Gaskell Syndrome)

Definition

I. Key-Gaskell syndrome is characterized by a generalized failure of autonomic nerve function.
II. The disorder affects both sympathetic and parasympathetic systems.
III. The syndrome is most commonly recognized in the United Kingdom, but sporadic cases occur in the United States.
IV. Cats are affected most often in the United Kingdom, but dogs are affected more often in the United States.

Causes

I. The cause is unknown.
II. The syndrome closely resembles "grass sickness" in horses.
III. The disease does not appear to be contagious, but certain risk factors have been identified in dogs (Berghaus et al., 2001; Harkin et al., 2002).
  A. Young, outdoor dogs
  B. Rural location
  C. Dogs with access to pasture, farm ponds, and cattle
  D. Dogs consuming wildlife
IV. Previous theories that this syndrome is related to toxicity from flea products have been dismissed.

Pathophysiology

I. Necrosis and degeneration of autonomic ganglia and neurons occur and are most severe in acute to subacute cases.
II. Minimal inflammatory cellular infiltrates are noted.
III. CNS lesions involve a variety of locations.
  A. Various nuclei: CN III, V, VII, and XII; dorsal vagal nucleus; nucleus ambiguus
  B. Spinal cord ventral horn cells and intermediolateral gray matter
IV. Peripheral nervous system lesions are also widespread.
  A. Autonomic ganglia: both sympathetic and parasympathetic
  B. Dorsal root ganglia and ganglia of cranial nerves

Clinical Signs

I. Ophthalmic signs
  A. Keratoconjunctivitis sicca
  B. Bilateral third eyelid protrusion
  C. Mydriasis without visual deficits
  D. Occasional anisocoria
II. Systemic signs
  A. Dry mucous membranes
  B. Depression, anorexia, weight loss
  C. Constipation, fecal incontinence from decreased sphincter tone
  D. Megaesophagus with dysphagia, regurgitation, vomiting
  E. Possible bradycardia
  F. Dysuria, bladder atony

Diagnosis

I. Clinical history and physical examination findings are usually suggestive.
II. Pharmacological testing may be tried.
  A. Miosis occurs after topical administration of pilocarpine 0.05% to 0.1% or echothiophate iodide 0.06% (variable response in severe cases).
  B. Bethanechol 0.0375 mg/kg SC may result in voluntary urination.
III. Obtain a thoracic radiograph to evaluate for megaesophagus.
IV. Biochemistry, hematological findings, and urine tests are usually normal.
V. Definitive diagnosis requires histopathologic examination of autonomic ganglia.

Differential Diagnosis

I. Other causes of efferent mydriasis (see earlier in this chapter)
II. Other causes of third eyelid protrusion (see Chapter 96)
III. Other causes of KCS (see Chapter 97)

Treatment

I. Supportive therapy
  A. Parenteral nutrition, ± gastrostomy tube placement
  B. Manual bladder expression
  C. Fluid therapy

II. Topical ophthalmic pilocarpine (0.1% or 1%) or physostigmine (0.25%) BID to TID to stimulate pupillary constriction, as well as lacrimal and oronasal secretions
III. Bethanechol 2.5 to 5.0 mg PO BID to TID or 0.0375 mg/kg SC
   A. Monitor for denervation hypersensitivity to these drugs and adjust doses accordingly.
   B. Response often diminishes over time, requiring increased dose or change in route of administration (0.1 to 0.5 times normal dose).

Monitoring of Animal

I. Partial or full recovery is unlikely and may take months.
II. Abnormalities often persist, such as mydriasis, megaesophagus, and bladder atony.
III. Death from the disease or euthanasia is common.

Spastic Pupil Syndrome

Definition and Cause

I. Spastic pupil syndrome is a static or alternating anisocoria seen in cats with an absence of other neurologic deficits.
II. Feline leukemia virus infection is considered the cause.
   A. C-type viral particles are present in the ciliary ganglia and short ciliary nerves, suggesting direct viral invasion or an immunological reaction.
   B. Infiltration of these structures or iris stroma by neoplastic cells (lymphosarcoma) may also occur.

Clinical Signs

I. Anisocoria is noted over time and may alternate between eyes at various intervals.
II. Pupils may behave normally between episodes.
III. No other visual or iris abnormalities exist.

Diagnosis and Differential Diagnosis

I. Take a thorough history and perform a complete ophthalmic examination to rule out vision or iris disorders.
II. Also rule out Horner's syndrome and afferent PLR lesions.
III. Test for feline leukemia virus; may need repeated serology or testing of bone marrow.

Treatment and Monitoring

I. No treatment is available.
II. Prognosis is poor.
III. Other clinical signs of feline leukemia usually occur within a few years of diagnosis.

DISORDERS OF VISUAL PATHWAYS

Definition

I. Vision is decreased from lesions occurring in one or more of the structures involved in vision, such as the retina, optic nerve, optic chiasm, optic tracts, lateral geniculate body, rostral colliculus, optic radiation, parietal cortex, striate cortex, and extrastriate cortex.
II. Visual behavior relies not only on pathways that lead to processing of visual stimuli but also on the animal's ability to orient the eyes in such a way as to acquire those visual stimuli.
III. In animals, localization of more complex central visual deficits is often made difficult by the limitations of working with a nonverbal patient in conditions of varied stimuli and expected responses.
IV. It is important to note that a positive PLR is not indicative of vision.

Causes

I. Retina
   A. Retinal degenerations: PRA, SARD
   B. Retinal detachment
   C. Inflammatory disease, retinal toxins (see Chapter 102)
II. Optic nerve and chiasm
   A. Optic nerve hypoplasia, atrophy, coloboma
   B. Dysfunction from exposure to toxins (Table 105-5)
   C. Degeneration (e.g., glaucoma, trauma), inflammation, compression
   D. Anomalous misdirection of axons: Siamese cats, Belgian shepherd dogs
   E. Neoplasia
III. Optic tracts
   A. Inflammation, trauma
   B. Anomalies, vascular abnormalities
   C. Neoplasia
IV. LGN, rostral colliculus, optic radiation, visual cortices
   A. Inflammation, vascular disorders
   B. Drug-induced lesions, metabolic diseases
   C. Anomalous LGN abnormalities in albinos
   D. Anesthesia, certain toxicities
   E. Trauma, neoplasia

TABLE 105-5

Examples of Neuroophthalmic Toxicants

AGENT	NEUROOPHTHALMIC SIGNS
Cholinesterase inhibitors (e.g., carbamate, organophosphate)	Miosis
Ivermectin	Mydriasis, vision deficits, ± papilledema, ± retinal folding
Many plants (e.g., black locust, lantana, dogbanes)	Mydriasis
Metronidazole	Nystagmus
Sassafras	Mydriasis
Marijuana	Mydriasis
Cocaine	Mydriasis
Morphine	Miosis followed by mydriasis
Amphetamines	Mydriasis
Arsanilic acid	Blindness
Atropine	Mydriasis, decreased tear production

Pathophysiology

I. The afferent visual pathway involves multiple neurons as described previously (see Afferent Mydriasis and Figure 105-1).
II. Lesions may be bilateral or unilateral, partial, or complete.

Clinical Signs

I. Changes in visual behavior depend on the location and extent of lesions.
II. Wandering (pendular) nystagmus is indicative of a congenital or very early onset of blindness.
III. Retinal lesions are characterized by the following:
  A. Ipsilateral afferent mydriasis
  B. Abnormal menace and dazzle responses
  C. Visual deficits
  D. Funduscopic abnormalities in some conditions (e.g., PRA) but not in others (e.g., SARD)
IV. Optic nerve lesions often exhibit the following signs:
  A. Ipsilateral afferent mydriasis
  B. Visual deficits
  C. Abnormal menace response and dazzle response
  D. Ophthalmoscopic lesions in some cases: optic nerve atrophy, papillitis
  E. Possible cranial nerve deficits, other signs of orbital disease
V. Traits of optic chiasm lesions vary.
  A. Early rostral lesions cause decreased vision in the ipsilateral eye and progress to deficits in both visual fields (heteronymous).
  B. In some cases, other systemic abnormalities are present (e.g., polyuria, polydipsia) from expanding pituitary masses or other causes.
VI. Optic tract lesions have more subtle signs.
  A. Subtle or no anisocoria: dilated pupil contralateral to lesion
  B. Negative swinging flashlight test
  C. Contralateral homonymous visual field loss
VII. LGN lesions induce varying degrees of visual field deficits with normal PLRs.
VIII. Optic radiation lesions produce partial or complete vision loss with normal PLRs.
IX. Rostral colliculus lesions are characterized by partial or complete vision loss, visual deficits, and other neurological abnormalities.
X. With diffuse visual cortex disorders, menace response is usually absent.
  A. Changes in conjugate eye movement and vision may occur.
  B. The dazzle response is often positive, and PLRs are normal.

Diagnosis

I. Ophthalmic examination to identify vision, PLR, and other abnormalities
II. Neurological examination to elucidate cranial nerve and other deficits
III. Testing of oculomotor pathways via visual placing reactions, conjugate eye movements
IV. ERG to identify retinal disease
V. VEPs to detect postretinal lesions
VI. Diagnostic imaging to examine visual pathways
  A. MRI provides superior imaging of visual pathways and good delineation of CNS lesions.
  B. CT is good for localizing extracranial and intracranial nonocular disease.
  C. Ultrasonography is useful in imaging the retrobulbar space for compressive optic nerve lesions.
  D. Introduction of functional MRI may help to further delineate intracranial lesions.

Treatment and Monitoring

I. Treatment is aimed at any underlying cause.
II. Counseling the owner is recommended.
  A. Blindness, regardless of cause or reversibility, is traumatic for many owners.
  B. Visual impairment alone does not necessitate euthanasia of the animal.
  C. Alternative training techniques, such as scent training, voice commands, and/or clicker training, can help during the adjustment phase.
  D. Prognosis for return of vision from many conditions is guarded.
III. In many cases other neurological deficits are present or develop as the underlying disease progresses.

CHAPTER 106

Introduction

Lynette K. Cole

GENERAL INFORMATION

I. Ear diseases are common in animals, with reported incidences of otitis externa between 10% and 20% in the dog and 2% and 10% in the cat (Logas, 1994).
II. Chronic recurrent otitis externa develops if any primary underlying dermatologic condition is not diagnosed and treated.
III. Infectious otitis media is common in dogs with chronic recurrent otitis externa and often prevents resolution of the otitis.
IV. End-stage otitis occurs after months or years of chronic, recurrent otitis externa and usually requires surgical intervention consisting of a total ear canal ablation and bulla osteotomy.
V. Clinical signs of otitis interna consist of a head tilt to the affected side, spontaneous horizontal or rotary nystagmus, and asymmetrical limb ataxia.
VI. Deafness may be either acquired or congenital, with both requiring electrodiagnostics to evaluate hearing objectively.

ANATOMY OF THE EAR

I. Pinna
  A. The auricular cartilage expands to form the pinna, with the skin of the concave portion of the pinna adhering tightly to this cartilage.
  B. The pinna has vastly different breed conformations in the dog, whereas, there is little breed variation in the cat.
  C. The pinna is a mobile structure designed to localize and collect sound waves and transmit them to the tympanic membrane.
  D. The cartilage of the pinna becomes funnel shaped at the opening of the external ear canal.
II. External ear canal
  A. The opening of the external ear canal is bounded by the helix (the free, slightly folded margin of cartilage at the base of the pinna) rostrally, the tragus laterally, and the antitragus caudally.
  B. The vertical ear canal runs for about 1 inch, extending ventrally and slightly rostrally before taking a medial turn and forming the horizontal ear canal.
  C. The horizontal ear canal is composed of auricular and annular cartilage. The deeper portion of the annular cartilage of the horizontal ear canal overlaps with the osseous external acoustic meatus and articulates via ligamentous tissue.
  D. The ear canal is lined by skin that contains sebaceous glands, ceruminous glands (modified apocrine glands), and hair follicles. These adnexal structures are more numerous in the vertical ear canal than the horizontal ear canal of the dog.
III. Middle ear
  A. The middle ear is composed of the air-filled tympanic cavity, which is connected to the nasopharynx by the auditory (eustachian) tube.
    1. The tympanic membrane closes off the tympanic cavity at the level of the external acoustic meatus.
    2. The tympanic cavity is divided into three portions and contains the three auditory ossicles.
  B. The tympanic membrane separates the external ear canal from the middle ear.
    1. It is a semitransparent membrane that is thin in the center and thicker at the periphery.
    2. It is divided into two sections—the small upper pars flaccida and the larger lower pars tensa.
    3. The pars flaccida is the pink, small, loosely attached region forming the upper quadrant of the tympanic membrane that contains small blood vessels.
    4. The pars tensa, a thin, tough, pearl-gray structure with radiating strands, occupies the remainder of the membrane.

5. The pars tensa is attached firmly to the surrounding bone by a fibrocartilaginous ring, known as the *annulus fibrocartilaginous,* which is in turn attached to the osseous ring of the external acoustic meatus by fibrous tissue.
6. The manubrium of the malleus attaches to the medial surface of the tympanic membrane.
7. The outline of the manubrium of the malleus (the stria mallearis) may be visualized when the tympanic membrane is viewed externally.

C. The tympanic cavity may be divided into three portions.
1. The epitympanic recess is the smallest of the three areas and is occupied by the head of the malleus and the incus at their articulation.
2. The tympanic cavity proper is adjacent to the tympanic membrane.
   a. The caudal portion of this region contains the cochlear (round) window.
   b. The auditory tube connects the nasopharynx to the rostral portion of the tympanic cavity proper.
   c. The promontory, which houses the cochlea, lies opposite the tympanic membrane.
3. The largest region of the tympanic cavity, the ventral portion, is contained within the tympanic bulla.

D. The three auditory ossicles—the malleus, incus, and stapes—are the bones that transmit and amplify air vibrations from the tympanic membrane to the inner ear.

E. The footplate (base) of the stapes is attached to the vestibular (oval) window, which is in direct contact with the perilymph fluid.

IV. Inner ear

A. The main functions of the inner ear are to transmit sound and maintain balance.

B. The inner ear consists of an osseous and membranous labyrinth.

C. The osseous labyrinth contains a fluid, perilymph, and encloses the membranous labyrinth, which contains its own fluid, endolymph.

D. The membranous labyrinth contains a series of fluid-filled ducts and chambers.
1. It has three semicircular ducts, each in a separate plane.
2. Each semicircular duct has an ampulla with a sensory crista.
3. The labyrinth also houses the utriculus and sacculus, which contain sensory maculae.
4. Both the maculae and cristae conduct impulses for balance via the vestibular nerve.
5. The most highly developed portion of the membranous labyrinth is the cochlear duct.
6. Within the cochlear duct lie the organ of Corti, tectorial membrane, vestibular membrane, and sensory cells, all of which are involved in the transduction and transmission of sound impulses via the cochlear nerve to the brain.

E. The bony labyrinth surrounds the membranous labyrinth and consists of a perilymphatic space or vestibule, three semicircular canals, and a spiral cochlea.

DISEASES OF THE EAR

I. The ear diseases have been divided into three chapters.

II. Diseases of the external ear pinna are discussed in Chapter 107.

III. Diseases of the middle and inner ear are covered in Chapter 108.

IV. Chapter 109 examines the subject of deafness.

CHAPTER 107

Diseases of the External Ear and Pinna

Dawn E. Logas | Jamie R. Bellah

OTITIS EXTERNA

Definition

I. Otitis externa is an inflammation of the external ear canal.
II. Many times the pinna, middle ear, or both are also involved.

Causes

I. Causes of otitis externa are divided into predisposing, primary, and perpetuating factors.
II. Predisposing factors include anything that alters the delicate microenvironment of the external ear canal, allowing the canal to be overwhelmed by opportunistic or pathogenic microorganisms.
  A. Conformational abnormalities
    1. Gross anatomical variations
      a. Dogs with pendulous ears have significantly more otitis than dogs with erect ears.
      b. Dogs with congenital (e.g., Chinese shar-pei) or acquired (e.g., extraluminal neoplasias, abscessation) stenosis of the ear canal have increased incidence of otitis.
    2. Microanatomic variations
      a. Certain breeds, such as the Labrador retriever, American cocker spaniel, and English springer spaniel, have increased numbers of apocrine glands (ceruminous glands) and increased wax production.
      b. The aforementioned breeds and other heavily coated breeds (e.g., poodle, Lhasa apso) also have a higher density of compound hair follicles in the ear canal that allows for the excess accumulation of debris and wax in the canal.
      c. These microanatomical changes can lead to higher resident microbial populations and higher incidence of otitis externa compared with greyhounds and mongrel dogs.
  B. Ear canal epithelial compromise
    1. Increased moisture in the ear canal causes rehydration of corneocytes, maceration of the epidermis, and breakdown of the protective barrier (stratum corneum), allowing opportunistic microbes to colonize the ear canal and initiate otitis.
      a. Excessive wetting of the ear canal during bathing or swimming
      b. Chronic use of an aqueous-based ear cleaner
      c. High ambient humidity, temperature, and rainfall.
    2. Mechanical trauma to the ear canal leads to damage of the outer defenses of the otic epithelium and colonization by opportunistic pathogens.
    3. Overzealous ear cleaning with potent drying agents, use of cotton swabs or other objects to remove wax, and vigorous hair plucking are all potentially traumatic to the otic canal.
  C. Systemic diseases
    1. By impairing cell-mediated immunity, feline leukemia virus, feline immunodeficiency virus, canine parvovirus, and canine distemper virus predispose the ear to microbial overgrowth and subsequent otitis.
    2. Hyperadrenocorticism, hypoadrenocorticism, and diabetes mellitus are infrequently associated with otitis externa.
III. Primary factors directly cause otic inflammation.
  A. Parasites
    1. *Otodectes cynotis* is responsible for 50% of otitis externa cases in the cat and 5% to 10% in the dog, particularly in animals <1 year of age (Griffin, 1993).
      a. Otitis is secondary to direct irritation of ceruminous glands and sensitization of the host to the mite's salivary antigen.
      b. In cases of hypersensitivity, severe inflammation occurs with very few mites.
    2. *Demodex* spp. infestation can cause a severe ceruminous otitis in both dogs and cats, and otitis may be the first, only, or persistent sign of infestation.
    3. *Sarcoptes* spp., *Notoedres* spp., *Eutrombicula alfreddugesi,* hard ticks, fleas, flies, and lice mainly affect the pinna, although *Sarcoptes* spp. and *Notoedres* spp. can occasionally be found deep in the canal.
    4. The spinous ear tick, *Otobius megnini,* can cause severe, painful inflammation of the canal.
  B. Foreign bodies
    1. Grass awns, foxtails, dirt, and debris
    2. Dried medication, loose hair, and impacted wax

C. Hypersensitivity reactions
   1. The most common cause of persistent bilateral otitis externa in the dog
   2. Atopy
      a. Greater than 50% of atopic dogs have otitis externa at some time (Griffin, 1993).
      b. Otitis externa may be the first and only evidence of atopic disease.
      c. In uncomplicated cases of atopic otitis, only the pinnae and vertical canals are affected while the horizontal canals remain virtually normal.
   3. Food allergy
      a. Otitis externa may be present in up to 88% of food allergic dogs (Rosser, 1993).
      b. Otitis may be the first and only clinical sign.
      c. In uncomplicated cases, only the pinnae and vertical canals are affected.
   4. Contact allergy
      a. Contact allergy to topical therapy is suspected in any case that worsens or does not improve with appropriate therapy.
      b. Contact allergy also may occur from environmental allergens, such as wandering jew, jasmine, and various weeds.

D. Immune-mediated skin diseases
   1. Pemphigus foliaceus, Pemphigus erythematosus, discoid lupus erythematosus, systemic lupus erythematosus, Pemphigus vulgaris, bullous pemphigoid, and drug eruptions (both systemic and topical) may all develop otitis as part of their clinical manifestation.
   2. The pinnae are affected in addition to other parts of the body.

E. Disorders of keratinization
   1. They may cause severe ceruminous otitis.
   2. Idiopathic seborrhea and hypothyroidism are the most commonly diagnosed diseases.
   3. Other endocrinopathies or sex-hormone diseases (e.g., male feminizing syndrome, Sertoli or interstitial cell tumors, ovarian imbalance) may be associated with a ceruminous otitis externa, but are rarely diagnosed.

F. Neoplasia and polyps
   1. Intraluminal tumors usually cause unilateral otitis and are more common in older animals.
   2. Intraluminal neoplasia causes canal stenosis and direct inflammation via tumor ulceration and necrosis.
   3. Inflammatory polyps are a cause of recurrent unilateral otitis in cats, particularly those <2 years of age, and have also been identified in the dog,
   4. Neoplasms include sebaceous gland, basal cell, mast cell, and ceruminous gland tumors, as well as fibroma, fibrosarcoma, chondroma, chondrosarcoma, squamous cell carcinoma, and trichoepithelioma.

G. Miscellaneous diseases
   1. Juvenile cellulitis
   2. Zinc-responsive dermatosis
   3. Lethal acrodermatitis of bull terriers
   4. Papillomas

IV. Perpetuating factors prevent the resolution of otitis or worsen an already existing otitis externa.
   A. Bacteria
      1. Low numbers of commensal and potentially pathogenic bacteria are found in normal ears.
      2. The most common bacteria associated with otitis externa are *Staphylococcus intermedius, Pseudomonas* spp., *Enterococcus* spp., *Corynebacterium* spp., *Streptococcus* spp., *Proteus* spp., and *Escherichia coli*.
      3. Once alterations in the ear canal's microenvironment occur, the bacteria are able to proliferate unchecked and perpetuate the inflammatory reaction in the ear.
   B. Fungi
      1. *Malassezia* spp. are the most common fungal organisms found in both normal and inflamed ears.
         a. *Malassezia* spp. are extremely opportunistic and colonize the ear canal even if inflammation and maceration are mild.
         b. Yeast overgrowth produces ceruminous otitis more often than purulent otitis.
         c. Recurrent yeast otitis is often associated with underlying allergic disease (atopic dermatitis, food allergy).
      2. Other fungi and yeast that cause ear disease include *Candida* spp., *Aspergillus* spp., *Trichophyton* spp., and *Microsporum* spp.
   C. Otitis media: usually secondary to chronic otitis externa
   D. Chronic pathologic changes: proliferative changes important in the perpetuation of chronic otitis externa

Pathophysiology

I. A common pathway exists for the development of chronic otitis externa.
II. In the acute stage, the canal becomes erythematous and swollen; histologically there is hyperkeratosis and acanthosis of the epidermis, dermal vasodilatation and edema, and an increase in migration of inflammatory cells into the dermis and epidermis.
III. As inflammation continues, the apocrine glands hypertrophy and dilate, which leads to an increase in the production of cerumen and changes in its composition.
IV. If inflammation is left unchecked, the epidermis begins to fold and normal epidermal migration is inhibited and potentially reversed.
V. Increased epidermal thickness, increased glandular activity, and decreased epithelial migration lead to excessive wax production, keratinaceous debris buildup, and microbial overgrowth.
VI. Continued inflammation can result in calcification and/or ossification of the auricular cartilages, dermal fibrosis, and permanent stenosis of the ear canal lumen.

Clinical Signs

I. The most common signs of otitis externa are pruritus, pain, erythema, and swelling of the ears.

II. Common signs are head shaking or rubbing, periauricular excoriations and alopecia, or a head tilt toward the affected side (indicative of pain).
III. A discharge or foul odor is often present.
IV. Erythema of the pinna and vertical canal with an essentially normal horizontal canal is most commonly associated with uncomplicated allergic otitis externa.
V. Erosions and ulcerations of the ear canal may occur with gram-negative bacterial infections or contact dermatitis.
VI. Canal stenosis, palpable auricular calcification/ossification, and decreased hearing are common sequelae of chronic otitis.

Diagnosis

I. A complete dermatological and/or otic history and dermatological examination are essential.
II. Gross and microscopic otic examinations are performed.
  A. The presence of masses and the degree of erythema, erosion/ulceration, tissue hyperplasia, and exudation (color and odor) are noted.
  B. Cytological examination of the otic exudate is performed.
    1. Stains used include Gram stain, Wright-Giemsa stain, modified Wright-Giemsa stain (Diff-Quik), and new methylene blue.
    2. Cytological slides are examined for the presence of bacteria, yeast, fungal hyphae, parasites, white blood cells, cerumen, and neoplastic cells.
    3. The abundance and morphology of bacteria and yeast are evaluated, because normal ears contain a few yeast and a few gram-positive cocci.
  C. If the otitis externa is chronic or recurrent, if gram-negative rods are noted on cytology, or if otitis media/interna is suspected, a bacterial culture is submitted.
  D. Otoscopic examination is performed after the cytological examinations and cultures have been done.
    1. The animal may need to be sedated or anesthetized to accurately assess the horizontal canal and tympanic membrane (TM).
      a. Active or previous middle ear disease is suspected if the TM is ruptured or is discolored, thickened, or bulging (see Chapter 108).
      b. The presence of an intact TM does not rule out middle ear disease.
    2. In severe cases of otitis externa, 2 to 3 weeks of topical or systemic antiinflammatory medications (glucocorticoids), or both, may be required to reduce the inflammation before performing a proper otoscopic examination.
III. A definitive diagnosis may require further diagnostic tests or therapeutic trials.
  A. Fungal culture
  B. Skin scraping for parasitic diseases and trial scabicidal therapy
  C. Examination of skin scrapings or preparations for *Malassezia* spp.
  D. Allergy work-up: food elimination trial, intradermal skin testing, or in vitro blood testing
  E. Discontinuation of topical and/or systemic medications for suspected drug reactions
  F. Biopsy of ear masses or skin if neoplasia or immune-mediated disease is suspected
  G. Surgical intervention for suspected sex-hormone diseases
  H. Thyroid evaluation
  I. Ruling out any systemic disease that may manifest with ear involvement

Differential Diagnosis

I. Otitis externa is a condition and does not imply a specific disease; therefore multiple causes may be involved.
II. A differential diagnosis list is based on history and physical and cytological examinations.
III. A concurrent otitis media must be ruled out in chronic and recurrent otitis externa.

Treatment and Monitoring

I. In-hospital ear cleaning
  A. General concepts
    1. Essential for successful medical management of otitis externa
    2. Performed after cytological examination and culture of otic exudate
    3. Sedation or anesthesia needed in severe cases
    4. Topical or systemic antiinflammatory treatment (glucocorticoids) 7 to 14 days before cleaning severely inflamed ears
    5. Excessive hair clipped from the pinnae or the external ear canal initially
  B. Flushing solution
    1. The type depends on the degree of inflammation, characteristics of discharge, and status of the TM.
    2. After flushing with a potent solution, rinse out the canal well with saline or water, especially if the TM is absent.
  C. Equipment used
    1. Bulb syringes
    2. Red rubber feeding tubes (3 to 12 French) or 8 French polypropylene urinary catheters, open-ended male cat urinary catheters
    3. Straight and curved Buck curettes
    4. Surgical suction unit
  D. Assessment of TM
    1. Visual assessment
      a. It may not be possible in many cases of chronic otitis externa.
      b. Video otoscopes usually give a more complete view than standard hand-held otoscopes.
    2. Blind assessment of ruptured TM
      a. Buck curette catches on bony prominence on the ventral lip of the external auditory meatus
      b. Red rubber feeding tube tip disappears from view
      c. Excessive fluid use
      d. Animal swallows when fluid is instilled in ear
    3. Indications for myringotomy

a. In most cases of chronic otitis
b. Evidence of fluid or debris behind the TM
c. Abnormal TM

E. Hazards of deep ear cleaning
1. Ruptured TM
a. In many chronic cases, the TM is weak and ruptures easily during the flushing procedure.
b. This is not necessarily an unwanted side effect and often indicates an abnormal TM is present, requiring a myringotomy
2. Facial nerve paralysis, Horner's syndrome
3. Vestibular dysfunction, auditory dysfunction
4. Induction of contact irritant/allergy
5. Introduction of new pathogens

II. At-home flushing
A. Vital for the successful medical management of otitis externa
B. Flushing frequency
1. Depends on the harshness of the solution used
2. Severe bacterial otitis: TID initially
3. Yeast otitis: one to three times weekly
4. Decreases over several weeks to a maintenance level

III. Topical therapy
A. The number of applications per day (SID to QID) depends on the type of infection, severity of infection, and chronicity of the disease.
B. Commercially available veterinary otic medications are usually combination products containing glucocorticoids, antibiotics, and antifungal agents in either an ointment (oil) or solution/lotion (aqueous) base.
C. Use the lowest potency glucocorticoid that decreases the clinical signs of inflammation.
D. Antibacterial agents are selected based on cytological evaluation of otic exudate, and culture and susceptibility testing.
E. Antifungal agents are needed when significant numbers of yeast are seen cytologically.

IV. Systemic therapy
A. Systemic therapy is necessary in cases of recurrent or chronic (>3 months duration) otitis externa.
B. Systemic antibiotic therapy is based on bacterial culture and susceptibility testing.
C. Systemic glucocorticoid therapy is needed to decrease tissue inflammation and edema in severe or chronic cases.
1. Start with prednisone 0.5 to 2.2 mg/kg/day PO, and then reduce over 7 to 21 days.
2. How quickly the dose is reduced depends on the severity of inflammation, the chronicity of the otitis, the microbes present, and the underlying causes of the otitis.
D. Use antifungal agents such as ketoconazole 5 to 10 mg/kg PO SID or itraconazole 5 mg/kg PO SID for *Malassezia* spp. infections that do not resolve with topical therapy.

V. Surgical therapy
A. Lateral ear canal resection
1. Indications
a. Animals with otitis externa that relapse despite appropriate diagnostics and medical therapy
b. Animals with vertical ear canal stenosis (e.g., Chinese shar-pei)
c. To facilitate biopsy of small masses within the ear canal or removal of tumors of the lateral wall of the canal
d. As a temporary technique to aid surgical margin assessment for vertical canal resections done for neoplastic excision
e. Irreparable trauma to the lateral aspect of the vertical ear canal
2. Surgical technique
a. A perioperative antimicrobial, such as a first-generation cephalosporin, is used because aseptic surgical preparation of the ear is usually incomplete.
b. The skin incisions (parallel and beginning at the intertragic and tragohelicine incisures) are extended $1^1/_2$ times the length of the vertical portion of the ear canal below the base of the horizontal canal.
c. Connecting the incisions at their ventral-most margin allows elevation of a long rectangular skin flap attached to the top of the vertical ear canal.
d. Soft tissues are sharply dissected cranial and caudal to the vertical ear canal, staying very close to the cartilage to lessen hemorrhage.
e. The parotid salivary gland is separated from the vertical ear canal cartilage ventrally.
f. Parallel incisions are made in the cranial and caudal edges of the vertical ear canal, extending from each incisure ventrally to the level of the horizontal ear canal, so that the flap extends to the level of the ventral aspect of the horizontal ear canal.
g. Once the cartilage flap is incised, minor incision adjustments may be needed so the baffle plate will hinge completely ventrally, and create a smooth flat surface.
h. The cartilage flap is trimmed such that a "drain board" or "baffle plate" of about 1 to 1.5 cm is created.
i. Absorbable sutures are placed through the platysma muscle fascia near the ventral aspect of the skin incision to the underside of the cartilage flap (baffle plate) to help secure it in the ventral position.
j. The remainder of the incision is closed with monofilament nonabsorbable suture.
3. Postoperative care
a. Bandage the pinna over the head or use an Elizabethan collar to protect the incisions from self-inflicted trauma.
b. Opioid analgesia is required for at least 24 hours after surgery; nonsteroidal antiinflammatory drugs (NSAIDS), tramadol, and extended-release

morphine tablets can be prescribed for use at home for several days.
c. Tranquilization is helpful in some dogs to facilitate rest but is not a substitute for analgesia.
d. Prednisone 0.25 mg/kg PO BID, then tapered over 2 weeks, is beneficial in some dogs to lessen head shaking and pawing at the ears, but cannot be combined with NSAIDs.
e. Ear canal cleansing and topical medication is continued.
f. Antimicrobial therapy is continued and adjusted based on results of culture and susceptibility results.

B. Vertical canal resection
1. Indications
a. Aural tumors of the vertical ear canal
b. Irreparable traumatic injuries localized to the vertical canal
c. Dogs with otitis externa secondary to allergic skin disease (atopy) with severe proliferative changes that partially or totally occlude the vertical canal, yet spare the horizontal canal
d. Relapsing otitis externa: lateral ear resection simpler but some dogs with severe, proliferative vertical canal disease may benefit
2. Surgical technique
a. The surgical approach is by a T-shaped incision that extends approximately 1 cm below the horizontal ear canal.
b. Preserve as much skin as possible near the ear canal opening.
c. The incision encircles the top of the vertical ear canal at a level sufficient to remove the proliferative tissue or tumor within the vertical ear canal.
d. The perichondrium is identified and soft tissue dissection is continued around the vertical canal, releasing the proximal portion of the canal from the pinna while using care not to disrupt the auricular blood supply.
e. The facial nerve is not commonly encountered unless the dissection is deep, with resection of a portion of the horizontal canal, but it is important to understand facial nerve anatomy.
f. Transection of the vertical ear canal cartilage near the horizontal canal, or at the level of the annular ligament distally, releases the vertical canal.
g. Sufficient horizontal canal must remain for apposition of skin to close the surgical wound.
h. When aural tumors are resected, the level of the canal resection is determined by the margin of normal canal deep to the tumor.
i. When resection of the vertical ear canal is for benign proliferative disease, sufficient vertical canal is left to allow creation of medial (dorsal) and lateral (ventral) baffle plates to help prevent stenosis of the canal opening.
j. Apposition of soft tissues around the remaining horizontal canal is done by subcutaneous sutures where necessary to alleviate dead space, followed by simple interrupted sutures of monofilament, nonabsorbable suture to appose skin margins.
3. Postoperative care: identical to lateral ear resection

C. Total ear canal ablation and lateral bulla osteotomy (TECA-LBO)
1. Indications
a. End-stage otitis externa in which hyperplastic and inflammatory changes have obstructed the horizontal ear canal
b. Failed lateral or vertical ear canal resection
c. Neoplastic disease of the horizontal canal or the periphery of the ear canal
d. Congenital stenosis of the horizontal canal
e. Traumatic avulsion (with stricture) of the horizontal ear
f. Used in cats for the removal of neoplastic tissue or for infection secondary to inflammatory polyps
2. Surgical technique
a. Make a curvilinear incision (an upside-down L) starting at the anterior margin of the vertical ear canal, rather than the standard T-shaped incision, and extend caudally following the undulations near the incisures and curve ventrally and parallel over the caudal aspect of the vertical ear canal.
b. Extend the dissection to the perichondrium and retract the parotid salivary gland ventrally.
c. The vertical and horizontal ear canals are isolated by blunt and sharp dissection, staying close to the perichondrium.
d. The vertical canal is transected from the auricular cartilage close to the perichondrium to avoid the great auricular vessels that extend dorsally toward the tip of the pinna, and high enough to remove all proliferative tissue within the canal.
e. Dissection and excision of the entire ear canal is carried to the level of the external acoustic meatus, where it is released.
f. Palpate the mastoid process located caudal to the horizontal canal.
g. The facial nerve exits the skull at the stylomastoid foramen and turns ventrally and rostrally toward the auricular muscles, and the muscles of the eyelids and lip.
h. It is not necessary to isolate the facial nerve, but dissect carefully and avoid excessive pressure or too much traction on the nerve.
i. A lateral bulla osteotomy is created to aid removal of debris and exudate from the middle ear using an air drill or Leksell rongeur.
j. The bulla is curetted carefully to avoid damaging the bony labyrinth of the inner ear (vestibular and cochlear windows) located dorsally and medially.
k. Avoid the external carotid artery and the hypoglossal nerve traversing in the soft tissues ventral to the bulla.
l. Drains are not required for most TECA-LBO procedures, but Penrose or small closed-suction

drains may be used, depending on the surgeon's preference.

m. Wound closure is in three layers.
   (1) Absorbable suture is used to appose the attachments of the auricular muscles and subcutaneous tissues to close "dead space."
   (2) A continuous subcuticular pattern is used to appose the margins of the wound, taking care to avoid exposure of cartilage.
   (3) Nonabsorbable, monofilament suture is used to appose the skin.

3. Postoperative care
   a. The ear may be bandaged up over the dog's head or an Elizabethan collar used to prevent self-inflicted trauma.
   b. If drains are used, keep the animal in the hospital until they are removed.
   c. Give morphine 0.1 to 0.5 mg/kg SC every 3 to 4 hours, or as a continuous rate infusion at 1.5 mg/kg/24 hr, instilled in a 250-mL bag of normal saline and administered at a rate of 10 mL/hr IV for analgesia.
   d. Transdermal fentanyl patches, oxymorphone, and hydromorphone are alternatives.
   e. NSAIDs, tramadol, or extended-release morphine may be used or prescribed for home use.
4. Effect on hearing function
   a. Total ear canal ablation does not appear to cause complete deafness.
   b. After TECA-LBO, dogs can still hear, as measured by osseous conduction and air conduction to a level equal to preoperative levels.
   c. Total ear canal ablation performed for resection of neoplastic disease will impact hearing function, if the eardrum was intact before surgery, in the affected ear.

D. Ventral bulla osteotomy
1. Indications
   a. Debride inflamed, infected, or foreign debris from the tympanic bulla
   b. Removal of tumors, including inflammatory polyps in cats, or obtain tissue for culture and susceptibility testing or histopathologic evaluation
   c. Provide a route to achieve improved ventral drainage of exudate
   d. Treatment of otitis media with or without otitis externa
   e. Resolution of cholesteatomas (if ear canal is to be preserved)
2. Surgical procedure in the dog
   a. Surgery in large brachycephalic breeds such as the boxer or English bulldog can be difficult, because the thickness of the neck results in a deep surgical field.
   b. A paramedian incision is made between the angular process of the mandible extending caudally to the wings of the atlas.
   c. The tympanic bulla may be palpable between the angle of the mandible and the jugular process of the skull.
   d. Once the bulla is identified, the small overlying muscles are bluntly separated and the exposure is widened using a small Freer elevator.
   e. The tympanic bulla is penetrated using a Steinmann pin or a pneumatic drill, using care not to damage the dorsal aspect of the tympanic cavity.
   f. As the exposure is increased, remember that the oral cavity and pharynx are millimeters away and careless probing may penetrate the pharyngeal mucous membrane, resulting in contamination from oral flora.
   g. Epithelial lining is removed from the inner surfaces of the bulla with a small curette, taking care not to curette or damage structures of the dorsal wall of the tympanic cavity and in the region of the promontory.
   h. Drains may not be required; however, a simple Penrose drain may be used to allow dependent drainage from the tympanic cavity, or ingress–egress drains may be placed if deemed necessary.
3. Surgical procedure in the cat
   a. When the ventral portion of the bulla is removed, the partitioning septum within the feline osseous bulla is exposed.
   b. The polyp is removed by traction and gentle curettage to remove the polyp base.
   c. Portions of the polyps that extend on a stalk through the eardrum into the ear canal may be removed by pulling the polyp into the middle ear, or by avulsing the polyp from the ear canal before ventral bulla osteotomy.
   d. Remember that small, sympathetic branches cross the promontory, and damage to them frequently (nearly 50%) results in postoperative Horner's syndrome.
   e. The dorsal and medial aspects of the middle ear are not aggressively curetted, because the auditory ossicles, cochlear window, and vestibular window are contained within the mesotympanum and epitympanic recess.
   f. Care is also taken not to remove too much of the vertical walls of the osseous bulla, as ingrowth of fibrous scar within the tympanic cavity can disrupt ossicle function and affect hearing.
4. Postoperative care
   a. A nonadherent, absorptive bandage is applied to protect the incision and the drain (if used).
   b. Antimicrobial therapy (based on culture and susceptibility) is used for 2 to 4 weeks, especially if there is associated otitis externa.
   c. Drains are usually removed in 3 to 5 days.
   d. Analgesic therapy, as for other ear surgeries, can be tailored based on the invasiveness of surgery.

DISEASES OF THE PINNA

Pinnal Dermatoses

Dawn E. Logas

See Table 107-1.

Aural Hematoma

Jamie R. Bellah

Definition and Causes

I. An aural hematoma is the accumulation of serosanguineous fluid or blood within the pinna.
II. Trauma to the pinna from scratching or shaking the head is the primary cause.
III. Aural hematomas may be associated with otitis externa, or the ear canal may be completely normal.
IV. A primary or secondary, immune-mediated component has been suggested but remains controversial.

Clinical Signs

I. A firm or fluctuant swelling involves small regions to nearly the entire pinna.
II. There may be concurrent otitis externa.
III. It may be painful when acute.
IV. The pinna becomes firm and scarred, with a cauliflower appearance, if the hematoma is left untreated.

Diagnosis

I. History and clinical signs usually diagnostic
II. Aspiration of serosanguineous fluid
III. No fluid if the hematoma is chronic, organized

Differential Diagnosis

I. Neoplasia
II. Abscessation
III. Generalized pinnal edema

Treatment

I. Simple aspiration is the most conservative treatment and relieves acute pain, but recurrence is common.
II. Surgical drainage decreases pain and reduces likelihood of recurrence; several methods are available.
   A. Silastic drain placement
      1. Use heavy sedation (narcoleptic) or general anesthesia.
      2. Infiltrate lidocaine at the dorsal-most and ventral-most boundaries of the swelling.
      3. A stab incision is made at both locations and the fluid is drained.
      4. Using a straight mosquito hemostat, a small-diameter (3 to 4 mm) Silastic drain is pulled through the cavity and sutured at each opening.
      5. The ear may be bandaged over the head.
   B. Teat cannula placement
      1. Make a stab incision at the most dependent aspect of the hematoma (relative to the ear being in a normal position), and on the concave or inner surface of the ear.
      2. Remove the screw cap from a teat cannula and make two holes in the collar of the cannula using a 19-gauge needle.
      3. Introduce the cannula into the hematoma through the stab incision.
      4. Secure the cannula with a suture placed through the skin and the collar.
      5. A second suture may be placed through the skin around the end of the tube.
   C. Closed suction catheter system
      1. Make a stab incision in the most dependent region.
      2. Cut the luer-lock tip off a butterfly catheter and fenestrate 1 to 2 cm near the end of the tube.
      3. Insert the fenestrated end into the cavity and affix the catheter to the ear by a finger-snare suture.
      4. Insert the needle of the butterfly catheter into a red-top Vacutainer; change as needed.
   D. Incisional drainage
      1. Usually reserved for more chronic or organized hematomas.
      2. General anesthesia is required.
      3. An incision (straight or S-shaped) is made into the hematoma on the concave side of the ear.
      4. Organized blood clots and fluid are removed.
      5. Full-thickness mattress sutures are placed parallel to the vasculature of the pinna (parallel to the long axis of the pinna), so blood supply is not compromised.
   E. Carbon dioxide (CO_2) laser procedure
      1. The laser is used to make three or four circular skin incisions of 3 to 7 mm in diameter.
      2. The hematoma is drained and lavaged.
      3. Nonabsorbable sutures are placed through small stents (i.e., cut segments of IV tubing or other suitable material), and through the cartilage while avoiding penetration of the haired surface of the pinna (convex surface).
      4. Alternatively the ear is not sutured.
      5. Home care consists of application of warm compresses to the ear for 5 to 10 minutes BID and removal of soft scabs as they form, to encourage drainage.
      6. If sutures are used, they are removed in 7 days; weekly examination is recommended.
III. Treat any underlying causes with proper medical therapy.
   A. Antimicrobial therapy is based on concurrent diseases and culture and susceptibility test results.
   B. Prednisone 0.25 mg/kg PO BID and tapering over 3 weeks helps relieve pruritus, head shaking, and self trauma.

Monitoring of Animal

I. Silastic drain or cannula techniques
   A. Instruct owners to keep the opening of the drain or cannula free of debris or clots and to milk out fluid as it accumulates.

TABLE 107-1

Dermatoses of the Pinna

DISEASE	AREAS AFFECTED	CLINICAL SIGNS	DIAGNOSIS	TREATMENT
Actinic (solar) dermatitis	1	A,B,C,D	Biopsy	Limit sun exposure, sunscreen
Alopecia areata	2	B	Biopsy	No treatment
Atopy	2	A	Skin test, blood test	Desensitization vaccine, topical glucocorticoids, cyclosporine
Bullous pemphigoid/pemphigus vulgaris	3	E	Biopsy	Immunosuppressive drug therapy
Cold agglutinin disease	2	D,E	Biopsy, positive 4° C Coombs' test	Systemic glucocorticoids, surgery
Congenital alopecia	2	B	Other disorders excluded	No treatment
Contact dermatitis	1	A,B,C,D,E	Provocative exposure	Avoidance of cause, pentoxifylline
Cutaneous lupus erythematosus	3	B,D,E	Biopsy	Topical and systemic glucocorticoids, tetracycline and niacinamide, tacrolimus
Deep/subcutaneous mycotic disease	3	E,F	Biopsy, culture	Systemic antifungal therapy
Demodicosis	2	A,B,C,D	Skin scrape	Local—no treatment Generalized—amitraz, ivermectin, milbemycin
Dermatomyositis	2	A,B,D,E	Muscle, skin biopsy; EMG	None, pentoxifylline
Dermatophytosis	2	A,B,C,D	Culture	Topical antifungal agents and systemic griseofulvin, ketoconazole, terbinafine, or itraconazole orally
Ear margin dermatosis	1	A,B,D,E	Other disorders excluded	Topical antiseborrheic therapy
Fly strike	1	A,C,D	Clinical signs	Fly control, topical glucocorticoids
Food allergy	2	A	Food trials	Avoidance of allergen
Frostbite	2	D,E	Clinical signs	Warm area, surgery
Hypothyroidism	3	B,D	T_4, free T_4, and TSH	T_4 supplementation
Insect-induced granuloma	3	A,B,D,F	Biopsy	Avoidance of insect repellants
Juvenile cellulitis	3	A,B,D,E	Biopsy	Glucocorticoids ± antibiotics
Keratinization disorder	2	B,D	Other disorders excluded, biopsy	Topical antiseborrheic therapy, vitamin A, glucocorticoids
Lichenoid-psoriasiform dermatitis of springer spaniels	1	A,C,D	Biopsy	None, ± antibiotics
Linear granuloma	3	E,F	Biopsy	Systemic glucocorticoids
Neoplasia	2	F	Biopsy	Surgery, chemotherapy
Pattern baldness	2	B	Biopsy, other disorders excluded	Melatonin
Pemphigus foliaceus, erythematosus	3	C,D	Biopsy	Immunosuppressive drug, topical glucocorticoids
Periodic alopecia	1	B	Other disorders excluded	No treatment
Pinnal alopecia	1	B	Other disorders excluded	No treatment
Proliferative thrombovascular necrosis	1	E	Biopsy	Surgery, ± pentoxifylline
Sarcoptiform mange	2	A,B,D	Skin scrape, response to therapy	Lime sulfur, ivermectin, selamectin
Sebaceous adenitis	3	A,B,C,D	Biopsy	Topical baby oil/propylene glycol soaks; systemic fatty acids, retinoids, cyclosporine
Squamous cell carcinoma	1	A,B,D,E	Biopsy	Surgery

1, Pinna affected only; *2,* pinna and sometimes other body areas affected; *3,* pinna and other body areas affected; *A,* erythema; *B,* alopecia; *C,* pustule/papules; *D,* scale/crust; *E,* ulcer/scar; *F,* nodule; *T4,* thyroxine; *TSH,* thyroid-stimulating hormone; *EMG,* electromyogram.

TABLE 107-1

Dermatoses of the Pinna—*cont'd*

DISEASE	AREAS AFFECTED	CLINICAL SIGNS	DIAGNOSIS	TREATMENT
Staphylococcal folliculitis	3	C,D	Biopsy, response to therapy	Antibiotics
Sterile eosinophilic pinnal folliculitis	1	C,D	Biopsy	Topical and systemic glucocorticoids
Subcorneal pustular dermatosis	3	C,D	Biopsy	Dapsone
Systemic lupus erythematosus	3	B,D,E	Biopsy, work-up for systemic disease	Immunosuppressive drug therapy
T-cell lymphoma	3	A,E,F	Biopsy	Chemotherapy
Vasculitis	2	D,E	Biopsy, work-up for underlying disease	Immune-modulating drugs, pentoxifylline
Zinc-responsive dermatosis	3	A,D	Biopsy	Zinc supplementation

   B. Drains or cannulas are removed in 3 weeks and the wounds heal by second intention.
   C. Antimicrobials are not used routinely.

II. Incisional technique
   A. Sutures are removed in 10 to 14 days.
   B. Antimicrobials are not used routinely.
   C. Disfigurement of the pinna may occur.

III. Complications of aural hematoma treatment
   A. Pinnal contracture caused by organized hematomas or sutures placed with excessive tension
   B. Disfigurement of the pinna
   C. Hematoma recurrence
   D. Pinnal necrosis secondary to improper suturing or tight bandaging

CHAPTER 108

Diseases of the Middle and Inner Ear

Lynette K. Cole | Michael Podell

OTITIS MEDIA

Definition

I. Otitis media is defined as inflammation of the middle ear.
II. Otitis media is an important cause of recurrent otitis externa.

Causes

I. Infectious causes
  A. The most frequent cause is a bacterial infection (Cole et al., 1998).
    1. Most common bacterial isolates: *Staphylococcus intermedius, Pseudomonas aeruginosa*
    2. Other less common isolates: *Corynebacterium* spp., *Enterococcus* spp., *Proteus* spp., β-hemolytic streptococcus, *Citrobacter* spp., non–group D streptococcus, *Escherichia coli, Lactobacillus* spp., anaerobes
  B. Yeast may be a significant pathogen (isolated alone in 23.7% of ears in dogs with otitis media) (Cole et al., 1998).
  C. Otitis media appears to be uncommon in the cat.
II. Noninfectious causes
  A. Congenital diseases (Gregory, 2000): palatine defects (secondary cleft palate)
  B. Trauma
  C. Neoplasia, polyps
    1. Tumors are usually malignant when found in both the ear canal and tympanic bulla.
    2. If the tumor is present only in the tympanic bulla, 33% are malignant in dogs and up to 50% are malignant in cats (London et al., 1996).
    3. Inflammatory polyps are common in the cat, but are relatively uncommon in the dog.
  D. Foreign bodies
  E. Primary secretory otitis media
    1. It is reported in the Cavalier King Charles spaniel (Stern-Bertholtz et al., 2003).
    2. Principal signs are moderate to severe pain in the head or cervical region, neurological signs (ataxia, facial paralysis, nystagmus, head tilt), otic pruritus, otitis externa, and fatigue.
    3. In most cases, a bulging but intact tympanic membrane (TM) was observed.
    4. After myringotomy, a highly viscous mucus plug may be removed with ear forceps or a suction catheter.
    5. Removal of the mucus plug and flushing the middle ear may need to be repeated up to six times for resolution.
  F. Otoliths (mineral opacities within the tympanic bullae)
    1. Rarely reported in dogs as an incidental finding radiographically or with signs of vestibular disease (Ziemer et al., 2003)
    2. Significance unknown

Pathophysiology

I. Route of inflammation and infection
  A. Otitis media occurs as a direct extension from an existing otitis externa through a ruptured TM.
    1. The presence of an intact TM does not rule out otitis media, because the defect in the membrane may have healed.
    2. In dogs with infectious otitis media, 71.1% have an intact TM (Cole et al., 1998).
  B. Less common routes include extension through the eustachian tube or hematogenous dissemination.
II. Potential factors involved in the pathogenesis of otitis media
  A. The mucociliary system in the eustachian tube drains the middle ear of mucus, debris, and bacteria (Edwards et al., 1992).
  B. Blockage of the eustachian tube may result in the inability to clear these secretions and produce a sterile otitis media.
  C. A surface tension–lowering substance has been found in the canine eustachian tube (Birken and Brookler, 1972).
    1. Infection diminishes production of the surface tension–lowering substance.
    2. The eustachian tube is then more resistant to opening, resulting in a serous otitis media.

Clinical Signs

I. Signs of otitis externa may be seen, including discharge from the external ear canal, pawing or rubbing the affected ear, head shaking, and pain.
II. Facial nerve paralysis or paresis is possible.
  A. It is characterized by drooping of or inability to move the ear or lip, drooling of saliva, and decreased or absent palpebral reflex.

B. Facial neuropathy secondary to otitis media has been reported in 21.5% of dogs and 18.8% of affected cats (Kern and Erb, 1987).
C. Cocker spaniels with facial neuropathy are more likely to have otitis media as the underlying cause, as compared to other breeds (Kern and Erb, 1987).

III. Injury to the facial nerve may result in ipsilateral keratoconjunctivitis sicca (KCS).
IV. Horner's syndrome results from injury to the sympathetic nerve as it courses through the middle ear.
A. Horner's syndrome is characterized by ptosis, miosis, enophthalmos, and protrusion of the third eyelid.
B. Horner's syndrome secondary to otitis media occurs in 26.9% of cats and 2.7% of affected dogs (Kern et al., 1989).
V. Otitis media may lead to otitis interna.
A. Clinical signs of otitis interna include horizontal nystagmus, asymmetrical ataxia, head tilt, circling, falling, or rolling toward the affected side.
B. In dogs with peripheral vestibular disease, as many as 49% have concurrent otitis media/interna (Schunk and Averill, 1983).

Diagnosis

I. Examinations to perform
A. Complete physical examination of lymph nodes, oral cavity, and nasopharyngeal region
B. Dermatological examination to evaluate for underlying diseases (e.g., parasites, allergy, keratinization disorders, autoimmune disease)
C. Neurological examination to evaluate for signs suggestive of facial nerve paralysis/paresis, nystagmus, KCS, and vestibular disease
D. Otoscopic and video otoscopic examination of the external ear canal and TM
1. Otoscopic examination is performed using a hand-held otoscope.
2. Video otoscopy using an otoendoscope, camera, light source, and monitor may also be performed.
3. If the ears are ulcerated, hyperplastic, or stenotic, 2 to 3 weeks of topical or systemic glucocorticoids, or both, are often necessary before the otic examination.
4. The normal TM is translucent and concave.
5. Otitis media is suspected if the TM is ruptured, bulging, opaque, or cloudy.

II. Specific diagnostic tests: see Table 108-1
III. Laboratory tests
A. Cytological examination, as well as culture and sensitivity testing, is useful.
1. It is uncommon to find identical organisms or isolates when concurrent otitis externa and otitis media are diagnosed (Cole et al., 1998).
2. Obtain samples from both the horizontal ear canal and middle ear.
B. Biopsy any mass found in the vertical ear canal, horizontal ear canal, or middle ear, and submit tissue for histopathologic evaluation.

Differential Diagnosis

I. The early stages of otitis media may be overlooked, and it is important to recognize that otitis media is present in 50% to 82.6% of dogs with chronic otitis externa (Spreull, 1964; Cole et al., 1998).
II. Rule out other causes of Horner's syndrome, facial nerve paralysis/paresis, and peripheral vestibular disease.

Treatment

I. Goals of treatment
A. It is important to clean the ear for evaluation of the TM.
B. If the TM is ruptured, obtain samples for cytology and culture from the middle ear cavity.
1. When using the hand-held otoscope, pass a small sterile culture swab (Calgiswab Type 1; Hardwood Products, Guilford, Me.) through a sterile otoscopic cone attached to a hand-held otoscope into the middle ear cavity to obtain samples.
2. If the video otoscope is used, an open-ended Tom cat urinary catheter attached to a 12-mL syringe is passed through the port on the otoendoscope into the middle ear cavity to obtain samples.
3. Once the samples have been obtained, flush the middle ear repeatedly with sterile saline to remove any exudate and any residual ceruminolytic agent.
C. If the TM is intact but abnormal, a myringotomy is required (see later).
D. Once the ear is clean, treat infections systemically, topically, or both, based on results from cytology and culture and susceptibility testing.

II. Ear flushing
A. Deep ear flushing is best performed under general anesthesia.
B. Soak the ear canal for 10 minutes with a ceruminolytic cleaner, then flush with sterile isotonic saline, first with a bulb syringe and then with an 8 French polypropylene urinary catheter attached to a 12-mL syringe passed through an otoscopic cone.
C. Once the exudate and debris are removed from the ear canal, evaluate the TM with an otoscope or video otoscope.
D. Some ceruminolytic agents may be ototoxic (Mansfield et al., 1997) and are avoided or thoroughly flushed out with sterile saline if the TM is ruptured.

III. Myringotomy
A. It is indicated if the TM is intact but abnormal, in order to obtain samples for cytological examination and culture, to flush the middle ear, and allow the middle ear to drain.
B. Make an incision into the caudoventral quadrant of the TM.
1. This procedure can be performed with a small, sterile culture swab (Calgiswab Type 1, Hardwood Products, Guilford, Me.) passed through a sterile otoscopic cone attached to a hand-held otoscope.
a. Submit the first swab for culture; insert a second swab to obtain material for cytological evaluation.

TABLE 108-1

Diagnostic Techniques Available for Otitis Media

DIAGNOSTIC TEST	PURPOSE	TECHNIQUE PERFORMED	ABNORMAL FINDINGS
Plain radiographs	Visualize changes in tympanic bulla, external ear canal, middle and inner ear	Views performed include dorsoventral, right and left lateral obliques, open-mouth rostral-caudal (best view for evaluation of tympanic bullae)	Suggestive findings include thickening or lysis of bulla, sclerosis and proliferation, or lysis of petrous temporal bone Abnormal radiographs suggest otitis media Normal radiographs do not rule out otitis media
CT	Same as radiographs	Serial radiographic images obtained with CT scanner	Abnormallities are same as with radiographs; however, CT appears to be a more sensitive indicator of otitis media compared to plain radiographs (Love et al., 1995)
MRI	Same as radiographs	Uses radio waves in combination with a strong magnetic field to create concise images of internal organs and tissues	Fluid in the tympanic bulla appears hyperintense on T2-weighted images and is isointense with brain tissue on T1-weighted images T1 and T2 are intrinsic tissue characteristics and are representative of the relative content of water molecules moving throughout the intracellular and extracellular structures Its limitation compared to CT is that it is poor for evaluation of osseous changes
Ultrasonography	Detection of fluid in the tympanic bulla	Ultrasound probe is placed on the skin overlying the tympanic bulla	To date, this procedure has been performed only in cadavers (with water introduced via myringotomy into the tympanic bulla) and in live dogs with no evidence of otitis; the presence of fluid in the tympanic bulla could be differentiated from gas with the ultrasound The fluid-filled tympanic bulla was visible as an oval-shaped, anechoic region while the gas-filled tympanic bulla created a reverberation artifact, causing an acoustic shadow obscuring deeper areas (Dickie et al., 2003)
Pneumotoscopy	Used to judge the mobility (compliance) of the tympanic membrane and determine presence or absence of fluid in the middle ear	A hand-held, diagnostic-head otoscope with a pneumatic bulb attachment is inserted into the horizontal ear canal The tympanic membrane is visualized, and air is blown against the membrane with the pneumatic bulb in a pulsatile fashion while observing the motion of the tympanic membrane	Lack of movement (compliance) of the tympanic membrane indicates possible fluid in the middle ear or thickened tympanic membrane, suggestive of otitis media Normal compliance does not rule out otitis media
Impedance audiometry			
Tympanometry	Used to indirectly measure air pressure in the middle ear and compliance of the tympanic membrane, and estimate external ear canal volume	Requires a middle ear analyzer	A flat tympanogram suggests middle ear effusion, a severely scarred tympanic membrane, or, if associated with increased ear canal volume, a perforated tympanic membrane An abnormal tympanogram suggests otitis media; however, a normal tympanogram does not rule out otitis media

CT, Computed tomography; *MRI*, magnetic resonance imaging.

Continued

TABLE 108-1

Diagnostic Techniques Available for Otitis Media—*cont'd*

DIAGNOSTIC TEST	PURPOSE	TECHNIQUE PERFORMED	ABNORMAL FINDINGS
Acoustic reflex	This reflex protects the inner ear from damaging levels of noise A normal acoustic reflex results in a change in compliance of 0.02 mL or greater as the stimulus intensity is increased	A middle ear analyzer is used to measure the decrease in compliance of the tympanic membrane when a loud noise is introduced to the ear	An acoustic reflex less than the normal range in conjunction with an abnormal tympanogram is suggestive of otitis media A normal acoustic reflex does not rule out otitis media
Positive contrast canalography	Evaluates the patency of the tympanic membrane by infusing positive contrast medium into the ear canal of anesthetized dogs (Trower et al., 1998)	Precontrast and postcontrast bulla radiographs are performed	Contrast material in the bulla indicates tympanic membrane rupture Lack of contrast material in the bulla does not rule out a ruptured tympanic membrane

b. Flush the middle ear repeatedly with sterile saline using an open-ended Tom cat urinary catheter passed through the sterile otoscopic cone.

2. If using a video otoscope, pass an open-ended Tom cat urinary catheter attached to a 12-mL syringe through the port on the otoendoscope and use it to make the myringotomy incision.
   a. Flush saline into the middle ear cavity, aspirate it back, and culture the fluid.
   b. Then flush the middle ear repeatedly with saline through the open-ended Tom cat urinary catheter.

IV. Systemic antimicrobial, antifungal agents
   A. The choice of antibiotic is based on cytology and culture and susceptibility results.
   B. Certain systemic antibiotics (primarily aminoglycosides) can be ototoxic and must be used cautiously.
   C. If yeast otitis media is present, consider an antifungal agent, such as ketoconazole or itraconazole at 5 mg/kg PO SID.
   D. Administer antibiotics or antifungal agents for at least 3 to 6 weeks, or until the infection resolves.

V. Topical antibacterial, antifungal agents
   A. With topical medications, concentrations are achieved in the ear 100 to 1000 times higher than when the drug is given systemically.
   B. An antibiotic considered resistant on culture and susceptibility may be efficacious if administered topically, but use caution when administering topical otic preparations in an ear with a ruptured TM.

VI. Systemic prednisone
   A. Dose: 0.5 to 1 mg/kg PO SID, then tapered
   B. To reduce hyperplasia and stenosis of the ear canal

VII. Topical glucocorticoids
   A. They are available in combination products or as the sole agent in otic preparations.
   B. They are indicated for hyperplasia and stenosis of the external ear canals.

VIII. Topical cleaning and drying agents
   A. These are used to keep the external ear clean by removing exudate, and numerous products are available.
   B. Most products contain some type of acid, sometimes in combination with isopropyl alcohol, to dry the ear canal.
   C. Even though chlorhexidine (0.2%) is not considered ototoxic (Merchant et al., 1993), these products must be used with great caution in ears with a ruptured TM.

IX. Surgical management
   A. Surgical intervention is required in unresponsive or recurrent cases of otitis media.
   B. Surgery is indicated if middle ear polyps, neoplasia, foreign bodies, or osteomyelitis of the tympanic bulla are present.
   C. The surgical techniques used depend on which specific condition is present (see Chapter 107).

Monitoring of Animal

I. Otoscopic examination
   A. Perform with a hand-held otoscope or video otoscope at each reevaluation.
   B. Monitor healing of the TM.
   C. Reevaluate every 2 weeks until infection has resolved.
   D. Repeat ear flushing under general anesthesia as needed to keep the ear canal clean of otic exudate.

II. Cytology and culture

A. Perform a cytological examination of exudate from the external ear canal at each reevaluation to monitor response to treatment.
B. Also, submit a culture of external ear canal exudate if the infection worsens or is nonresponsive to treatment.

III. Neurological signs
A. Horner's syndrome and facial nerve paralysis/paresis may persist even after the infection has cleared.
B. Treat exposure keratitis from facial nerve paralysis or KCS with artificial tears, lubricating eye ointments, or topical cyclosporine (see Chapter 97).

IV. Complications and sequelae
A. Chronic otitis media
1. Occurs if infection does not completely resolve
2. Associated with persistent otic discharge and pain on palpation of the bulla

B Aural cholesteatoma or epidermal cyst
1. Epidermal-lined cavity containing keratinous debris
2. May develop in the middle ear of dogs secondary to chronic otitis media

C. Osteomyelitis of the petrous temporal bone
1. Signs of peripheral vestibular disease may develop.
2. Sensorineural hearing loss is common.

D. Meningitis, intracranial abscess, or meningoencephalitis (Spangler and Dewey, 2000)
E. Possible complications of the ear flushing or myringotomy procedure
1. Horner's syndrome
2. Facial nerve paralysis/paresis
3. Vestibular disturbances, deafness

OTITIS INTERNA

Michael Podell

Definition

I. Otitis interna is an inflammatory condition of the structures of the inner ear.
II. Clinical signs arise with disruption of the peripheral vestibulocochlear nerve (cranial nerve VIII) input to the central nervous system.
III. Labyrinthitis is inflammation of the membranous labyrinth housing the vestibular receptors of the inner ear.

Causes

I. Infectious causes
A. Bacteria
1. Extension from the middle ear
a. *Staphylococcus* spp.
b. *Streptococcus* spp.
c. *Proteus* spp.
d. *Pseudomonas* spp.
e. *E. coli*
f. *Enterococcus* spp.
2. Hematogenous infection: less common

B. Fungal agents
1. Extension from the middle ear
a. *Malassezia* spp.
b. *Candida* spp.
c. *Aspergillus* spp.
2. Hematogenous infection
a. *Aspergillus* spp.
b. *Blastomyces* spp.
c. Other systemic mycoses

C. Rickettsial diseases: *Ehrlichia canis,* causing vasculitis in the dog

II. Noninfectious causes
A. Idiopathic, congenital disease
1. Signs from birth
2. Most common in purebred dogs: Doberman pinscher, German shepherd dog, English cocker spaniel, beagle
3. Cats: Burmese, Siamese

B. Idiopathic, acquired diseases
1. "Old dog" vestibulitis
2. Feline vestibulitis

C. Metabolic disorders
1. Hypothyroidism
2. Hypercortisolism

D. Traumatic and compressive events
1. Foreign body penetration
2. Blunt trauma
3. Polyp formation

E. Toxicity
1. Mitotane *(Lysodren)*
2. Aminoglycosides

Pathophysiology

I. Infectious diseases
A. Direct extension of infection from the middle ear is the most common mechanism for the development of otitis interna.
1. Invasion through the round window
2. Secondary to osteomyelitis of the petrous temporal bone

B. A hematogenous source is most likely with rickettsial and systemic fungal organisms.

II. Noninfectious diseases
A. Idiopathic vestibular disease has no identified etiology; pathologic changes include abnormalities in endolymphatic fluid absorption, production, or circulation, as well as inflammatory neuritis.
B. Inflammatory polyps in cats originate within the middle ear or auditory (eustachian) tube and are secondary to chronic inflammation.

Clinical Signs

I. Goals in evaluation of clinical signs
A. Determine whether the vestibular disease is peripheral or central (Schunk, 1988).
B. Determine whether the peripheral disease is unilateral or bilateral.
C. Determine whether another systemic illness is present

TABLE 108-2

Differentiation of Normal versus Pathologic Nystagmus

NYSTAGMUS	FUNCTION	TEST	DESCRIPTION
Normal			
Oculovestibular reflex (doll's eye reflex)	To maintain visual fixation on stationary points as the body rotates	Horizontal movement of head and/or body with a rigid neck to elicit quick and slow eye movements	Tonic phase = slow deviation of eyes away from the turn Saccadic phase = quick deviation of eyes toward the turn
Postrotatory nystagmus		Initiate rapid rotation of animal (acceleration)	Quick phase is in the direction of rotation
		Maintain constant velocity of rotation	No nystagmus
		Stop rotation of animal rapidly (deceleration)	Quick phase is opposite the direction of rotation
Pathologic	Arises from an imbalance in resting extraocular muscle tone owing to asymmetrical input from the vestibular nuclei	Direct observation and placing head in different positions	Temporal phase *Spontaneous:* sustained (constant) *Positional* Direction phase *Horizontal*: side-to-side eye movements *Vertical*: perpendicular eye movements relative to head position Direction changing Fatigability *Nonfatigable*: no decrease in velocity *Fatigable*: decreases in velocity with time or position

II. Essential signs of peripheral vestibular disease caused by otitis interna
  A. Changes in head posture
  B. Gait changes
  C. Nystagmus
    1. Nystagmus is an involuntary rhythmic oscillation of the eyes, with either pendular movements or quick (i.e., jerk) and slow phases that occur in any plane.
    2. The direction of the jerk nystagmus is described according to the quick phase.
    3. Determine if abnormal vestibular nystagmus is present (Table 108-2).
  D. Associated with other neurological deficits
III. Unilateral peripheral vestibular disease
  A. Typically acute onset of dramatic signs
  B. Presence of many of the described clinical signs (Table 108-3)
  C. May be confused with an epileptic seizure if thrashing or struggling noted during the acute episode
  D. Often misdiagnosed as a stroke
IV. Bilateral peripheral vestibular disease
  A. Acute to subacute onset
  B. No normal or pathologic nystagmus: loss of oculovestibular reflex pathognomonic
  C. No head tilt
  D. Symmetrical ataxia
  E. Wide head excursions to both sides
V. Central vestibular disease (see Table 108-3)
  A. Subacute to chronic onset
  B. Paradoxical central vestibular disease
    1. Head tilt is opposite the side of the lesion owing to injury of the caudal cerebellar peduncle.
    2. Remaining clinical signs are all ipsilateral to the lesion.
VI. Signs of infections
  A. Infections occur most commonly in the dog.
  B. Any age, gender, or breed may be affected, although cocker spaniels and long-eared dogs are more commonly affected.
  C. Extension of disease into the inner ear is most commonly seen in cases of recurrent otitis externa and media.
  D. Signs of unilateral peripheral disease are typical.
  E. Signs of central vestibular disease may occur from focal extension into the central nervous system (Sturges et al., 2006).
    1. Often associated with cranial nerves V (trigeminal), VII (facial), and VIII (vestibulocochlear) deficits
    2. Focal lesion situated at the cerebellopontine angle
VII. Signs of congenital disease
  A. Unilateral peripheral vestibular signs from birth

TABLE 108-3

Signs Associated with Peripheral versus Central Unilateral Vestibular Disease

CLINICAL ABNORMALITY	PERIPHERAL SIGNS	CENTRAL SIGNS
Head position	Head tilt toward lesion	Head tilt toward lesion Exception: central paradoxical vestibular disease with head tilt away from lesion
Nystagmus	Sustained Most common = horizontal to rotatory Fast phase away from lesion Does not change direction Positional Usually seen with recovery Rotary to upbeat Delayed onset Short duration Fatigable (see Table 108-2) Abnormal postrotatory nystagmus Rotation in the direction *opposite* the side of the lesion results in depression of postrotatory nystagmus	Sustained Pure vertical, horizontal, or rotary Fast phase to or away from lesion Direction changing Positional Most common Pure vertical or horizontal Rapid onset Persistent duration Nonfatigable
Gait	Asymmetrical ataxia Circling, falling toward lesion No paresis No proprioceptive deficits	Asymmetrical ataxia Circling, falling toward lesion Ipsilateral hemiparesis Ipsilateral proprioceptive deficits
Strabismus	Positional, ventral	Positional, ventral
Cranial nerve involvement	VII ipsilateral to lesion	Cerbellopontine angle = V, VII, VIII Others possible: VI, IX, X, XII
Pupillary changes	Horner's syndrome ipsilateral to lesion	Changes present with rostral brain stem lesions
Mental status	Alert but disoriented	Changes in arousability Disorientation

B. Also smaller stature, failure to thrive
C. Multiple littermates possibly affected

VIII. Signs of idiopathic canine ("old dog") vestibulitis (Schunk and Averill, 1983)
A. Median age of onset 12.5 years and typically >10 years
B. No breed predisposition
C. Peracute onset of clinical signs
D. No history of trauma or recent otitis externa
E. Typically "pure" unilateral peripheral vestibular signs
1. No other cranial nerve deficits
2. No paresis or proprioceptive deficits
3. Consistent sustained, horizontal to rotatory nystagmus with the fast phase opposite the head tilt
F. Bilateral vestibular disease less common

IX. Signs of idiopathic feline vestibulitis (Burke et al., 1985)
A. Median age of onset 4 years and typically <7 years
B. Peracute onset of clinical signs
C. Possibly more common in summer months
D. Unilateral or bilateral disease

Diagnosis

I. Infectious diseases
A. History is often suggestive.
1. Prior history of chronic otitis externa and/or media
2. Acute (days) to subacute (weeks) onset of unilateral peripheral vestibular signs
3. Failure to improve with current medical treatment
B. Initial diagnostic procedures are similar to those described for otitis media and include the following:
1. Otoscopy or video otoscopy
2. Cytological examination of exudate and middle ear fluid
3. Culture of exudate and middle ear fluid
4. Schirmer tear test
C. Imaging is a very important tool.
1. Tympanic bullae radiography
a. Specific test but not very sensitive, and may miss subtle and early lesions
b. Insensitive method in detecting extent of disease process
c. Requires general anesthesia
d. The least expensive diagnostic tool
2. Computed tomography (CT)
a. Highly sensitive and specific test that detects bone and soft tissue changes associated with otitis media extending to otitis interna

b. Less sensitive test to detect extension of disease into the brainstem
c. Requires general anesthesia

3. Magnetic resonance imaging (MRI) (Garosi et al., 2001)
a. Highly sensitive and specific test that detects soft tissue changes associated with otitis media extending to otitis interna
b. Diagnostic test of choice for detecting extension into the brainstem and to rule out other causes of vestibular disease
c. Requires general anesthesia and is the most expensive modality

D. Cerebrospinal fluid analysis is indicated in certain circumstances.
1. Indications
a. Presence of brain involvement on imaging studies
b. Presence of central vestibular disease in the face of otitis media or interna
c. Presence of multifocal central nervous system disease
2. Potential contraindications
a. Coagulopathies
b. Potential brainstem herniation if mass detected with imaging

E. Ventral bulla osteotomy with debridement, culture and sensitivity, and biopsy may be both therapeutic and diagnostic.

F. Serological testing is indicated if rickettsial or fungal agents are suspected.

II. Noninfectious diseases
A. History
1. Determine whether any trauma has occurred.
2. Determine prior signs of upper respiratory disease, especially if inflammatory polyps are suspected in cats.
3. Onset is most often acute.

B. Diagnostic procedures
1. Congenital, nontraumatic peripheral vestibular disease: otoscopic exam
2. Idiopathic vestibular disease
a. It is important to rule out underlying causes of infectious disease, as described previously.
b. Hypothyroidism is always ruled out in older dogs (Jaggy et al., 1994).
3. Trauma: radiographic or CT imaging
4. Polyp formation
a. Examine ear and oropharynx under sedation.
b. Evaluate behind the soft palate.
c. CT or MRI is helpful.

Differential Diagnosis

I. Other causes of peripheral vestibular disease
A. Neoplasia
1. Peripheral nerve sheath tumors
2. Meningioma
3. Lymphosarcoma
4. Bone-related tumors
5. Carcinomas

B. Polyneuropathy
1. Endocrine disease: hypothyroidism
2. Toxicities
3. Degenerative forms

C. Vestibulotoxic agents
1. Aminoglycoside antibiotics
2. Mitotane *(Lysodren)*
3. Diuretics
4. Heavy metals
5. Antineoplastic agents (cisplatin)

II. Causes of central vestibular disease
A. Neoplasia
1. Cerebellopontine angle tumors
a. Involve cranial nerves V (trigeminal), VII (facial), and VIII (vestibulocochlear) on the same side, along with central vestibular signs
b. May cause paradoxical central vestibular disease
2. Meningioma
3. Choroid plexus tumors: papilloma or carcinoma
4. Ependymoma
5. Invasive peripheral nerve sheath tumor
6. Pituitary-dependent hyperadrenocorticism with macroadenoma

B. Inflammatory disorders
1. Infectious diseases
a. Canine distemper virus
b. Feline infectious peritonitis
c. Rocky Mountain spotted fever
d. Fungal diseases
e. Protozoal infections: *Neospora caninum* (dogs), *Toxoplasma gondii* (cats)
2. Immune-mediated diseases
a. Granulomatous meningoencephalitis
b. Steroid-responsive meningoencephalitis
c. Vasculitis

C. Metabolic diseases
1. Hypothyroidism
2. Pituitary-dependent hyperadrenocortisolism

D. Drug toxicity: metronidazole

III. Other causes of cranial nerve disease
A. Facial nerve disorders
1. Idiopathic facial neuritis: loss of blink reflex, unilateral or bilateral
2. Hemifacial spasm: facial nerve irritation from inflammation or physical trauma (e.g., postsurgical)
3. Peripheral nerve sheath tumor
4. Myasthenia gravis
a. Bilateral decrease in blink reflex
b. May worsen with repetitive testing of the blink reflex
5. Otitis media without interna

B. Trigeminal nerve disorders
1. Idiopathic neuritis
a. Acute onset of dropped jaw and pain around the zygomatic arch
b. May be associated with Horner's syndrome

2. Peripheral nerve sheath tumor: asymmetrical temporalis muscle atrophy

C. Horner's syndrome
1. Idiopathic form: Horner's syndrome without any other neurological deficits
2. Otitis media without interna
3. Cranial mediastinal neoplasia

Treatment

I. Infectious diseases
A. Appropriate antimicrobial drug therapy
1. Optimal selection of antibiotic is based on culture and susceptibility testing.
2. Long-term treatment of 3 to 6 weeks is recommended for bacterial otitis interna.
3. Systemic antifungal therapy is based on cytological examination, culture, or positive serology testing.
4. Topical therapy alone is inadequate.

B. Debridement of mass or fluid removal via ventral bulla osteotomy
1. Indicated for recurrent otitis interna with otitis media, or if there is significant inflammatory tissue accumulation
2. Helps to improve healing

C. Corticosteroid therapy: contraindicated

II. Noninfectious diseases
A. Congenital form
1. Supportive care to maintain normal growth is most important.
2. No known therapy alters the clinical outcome.

B. Acquired disorders
1. Supportive care is critical during the acute phases of vestibular disease.
a. Provide adequate hydration.
b. Provide adequate nutritional support.
c. Provide appropriate environment to prevent decubital ulcers and recumbency-induced pneumonia.
2. Corticosteroid therapy is contraindicated for any of the idiopathic vestibular syndromes.
3. Treat any endocrine imbalance appropriately.
4. Bulla osteotomy is indicated for polyp resection and traumatic injury associated with middle ear hemorrhage (see Chapter 107).

III. Antivertiginous therapy
A. Anecdotally, certain drugs reduce the effect of vertigo or dizziness.
1. Meclizine *(Antivert)* 0.5 mg/kg PO BID
2. Diazepam *(Valium)* 0.1 to 0.2 mg/kg PO SID to BID
3. Acepromazine 1 mg/kg PO SID for possible nausea control

B. A dark, quiet room with minimal visual stimulation also helps minimize vertigo.
C. Over time, gradual institution of exercise on flat surfaces allows the vestibular system to start to compensate.
D. Caution must be used around stairs until a full recovery is present.

Monitoring of Animal

I. Immediate hospital or home care
A. Hydration status and nutritional intake are carefully monitored to prevent dehydration and malnutrition, especially in the older animal.
B. Prevent self-injury from excessive rolling or falling.
C. Monitor for gastric dilatation–volvulus in dogs with excessive rolling.

II. Recovery period
A. Improvement of clinical signs is usually seen during the first week after treatment of bacterial otitis interna.
B. Improvement of clinical signs is usually seen during the first 2 weeks after the onset of idiopathic vestibular disease, but may take several weeks to stabilize.
C. Rapid recovery from clinical signs occurs with appropriate treatment of hypothyroidism.

III. Residual signs
A. Mild to moderate head tilt may persist indefinitely.
B. Positional, direction-changing nystagmus may be present during the recovery period from unilateral vestibular disease.
C. Decreased oculovestibular eye movements are also possible.
D. Permanent facial nerve paresis or paralysis may occur with concurrent otitis media.

IV. Recurrence
A. Recurrent episodes of infectious otitis interna are most common with chronic bacterial otitis media.
B. Recurrent episodes of idiopathic vestibular disease are uncommon.

V. Prognosis
A. Infectious otitis interna
1. Fair to excellent with appropriate antimicrobial therapy
2. Worse for fungal infections

B. Noninfectious otitis interna
1. Excellent for acquired idiopathic vestibular disease
2. Fair for congenital idiopathic vestibular disease
3. Excellent for polyp- or trauma-induced disease, with adequate surgical correction

CHAPTER 109

Deafness

Michael Podell

Definition

I. Deafness is the loss of normal hearing function.
II. Deafness can be classified as follows:
  A. Conductive hearing loss is the result of failure of sound energy to be transmitted to mechanical energy in the outer and middle ear structures.
  B. Sensorineural hearing loss is the result of loss of electrical energy transfer from the cochlear sensory receptors or cochlear nerve.
  C. Central-mediated hearing loss is the failure to process auditory information at the level of the brain.
  D. Presbycusis is an age-related hearing loss that is not associated with a specific pathologic process.

Causes

I. Conductive hearing loss
  A. Outer ear diseases
    1. Otitis externa with reduction in ear canal volume
      a. Acute: fluid, debris, medication accumulation
      b. Chronic: stenosis
    2. Ear wax impaction
    3. Foreign body
    4. Neoplasia
    5. Trauma: iatrogenic (ear canal ablation) or blunt
    6. Tympanic membrane (TM) perforation
  B. Middle ear diseases
    1. Aural atresia
    2. Ossicular chain dysfunction: disarticulation, fusion
    3. Otitis media
    4. Otosclerosis
    5. Foreign body
    6. Inflammatory polyp, neoplasia
II. Sensorineural hearing loss
  A. Congenital, hereditary deafness is seen most commonly in dog and cat breeds with white pigmentation or blue eyes (Strain, 2004).
    1. It is the most common cause of deafness in dogs.
    2. It is typically present at birth, but may be progressive as the animal matures.
    3. Numerous purebred dogs are affected, including the Dalmatian, Australian blue heeler, English setter, Argentine dogo, bull terrier, Australian shepherd dog, Jack Russell terrier, and Cavalier King Charles spaniel (Hayes et al., 1981; Strain, 1999).
    4. White-coated, blue-iris cats and dogs may be also affected.
    5. Female Dalmatians may be predisposed (Wood and Lakhani, 1998).
  B. Acquired or age-related forms also occur.
    1. Ototoxicity from chemical or noise-induced toxic changes to the inner or outer hair cells (Mansfield, 1990)
      a. Approximately 200 ototoxic drugs and chemicals have been identified.
      b. In most cases, the hearing loss is irreversible and often progressive, even after cessation of exposure to the toxic agent.
      c. Common ototoxic agents include the following:
        (1) Aminoglycoside antibiotics, polymyxin B, erythromycin
        (2) Loop diuretic agents
        (3) Cisplatin, salicylates
        (4) Topical antiseptics: chlorhexidine, iodine
        (5) Heavy metals
        (6) Otic ceruminolytic agents
    2. Otitis interna
    3. Trauma: petrous temporal bone fractures, hemorrhage
    4. Neoplasia
    5. Presbycusis: individual or combined degeneration of cochlear, sensory, neural, strial structures

Pathophysiology

I. Normal hearing function (Hall, 1997)
  A. Sound waves travel to the outer ear, are transmitted through the external ear canal to the external auditory meatus, and are received by the TM.
    1. The TM resonates to convert the sound waves into mechanical energy.
    2. Vibrations of the TM set the bones of the middle ear (malleus, incus, and stapes) into motion.
  B. The mechanical energy is amplified over 20 times in the bony ossicles of the middle ear by the time the energy is transmitted to the oval window, just before entering the inner ear.
    1. Movements of the oval window initiate pressure waves in the perilymph within a structure of the cochlea called the *scala vestibuli*.

2. The fluid wave energy is then transferred into the scala tympani, where the basilar membrane of the scala tympani begins to vibrate as a result of this fluid wave energy transfer.
3. Sitting firmly attached to the basilar membrane is the organ of Corti, a specialized receptor organ.
   a. The organ of Corti is composed of neuroepithelial hair cells and several types of supporting cells.
   b. The rocking motion of the basilar membrane moves the organ of Corti, causing a shearing motion of the small stereocilia sitting on top of the hair cells.

C. When the shearing force produces a deflection of stereocilia toward the taller stereocilia, the cell becomes depolarized, generating an electrical impulse that is synaptically transmitted to the auditory nerve fibers.

D. As the basilar membrane becomes shorter with each turn of the cochlea, it vibrates at a different frequency relative to its width.
1. Low-frequency sound is detected near the base, and high-frequency sound near the apex of the cochlea.
2. Dogs can hear sounds from a low frequency of 2 Hz to a high frequency of 47 kHz.

II. Conductive hearing loss

A. Failure to transform sound waves to mechanical energy

B. Diseases that create an obstruction of air (sound waves)
1. Fluid accumulation
2. Tissue proliferation from chronic inflammation
3. Mass effect

C. Diseases that prevent mechanical energy from forming
1. Loss of compliance of the TM
2. Loss of mobility of the ossicular chain
3. Loss of connection of the ossicular chain onto the oval window

D. Presbycusis: age-related event where conduction no longer occurs

III. Sensorineural hearing loss

A. In dogs carrying the merle or piebald gene, the deafness arises from loss of hair cells secondary to degeneration of the cochlear blood supply (stria vascularis)
1. Hearing loss is permanent and usually complete by 3 weeks of age, but may progress later in life.
2. Unilateral deafness is twice as prevalent as bilateral deafness (Wood and Lakhani, 1998).

B. Deafness in breeds carrying the piebald gene is neither a dominant nor a recessive trait (Strain, 1999).
1. Deaf dogs can produce normal offspring and normal-hearing dogs can produce deaf offspring.
2. Blue eyes, white coat color, or a deaf parent are phenotypic risk factors (Strain, 2004).
3. Evidence exists that congenital, hereditary deafness is a polygenic trait with incomplete penetrance or expression (Cargill et al., 2004).

Clinical Signs

I. History with congenital, hereditary forms

A. Signs are present soon after birth.

B. Puppy does not respond to environmental noises.
1. Failure to wake up with rest of litter
2. Failure to respond to noises from people, toys, and so forth
3. Startles easily

C. Unilaterally deaf dogs often go undetected or may exhibit difficulty localizing sound.

D. Progressive hearing loss may occur in certain breeds as they mature over several years, such as the Cavalier King Charles spaniel (Podell, 1999).

II. History with acquired forms

A. Acute-onset deafness
1. May be the result of a chronic, progressive disease pattern that goes unnoticed
   a. Otitis externa, media, interna
   b. Presbycusis
   c. Procedure or manipulation of the ear canal in older animals that raises the hearing threshold to a level of noticeable hearing loss (e.g., dental, ear cleaning procedures)
2. Association with aminoglycoside antibiotic treatment
3. Known trauma
4. Postoperative total ear canal ablation

B. Chronic-onset deafness
1. Preceding history of recurrent otitis externa, media, interna
2. Progressive pattern of altered behavior: not following commands or responding to auditory cues
3. Failure to be aroused from sleep

III. Physical examination findings with congenital, hereditary forms

A. Usually the physical examination is normal.

B. Animals with a developmental anomaly of the brain may have neurological deficits and changes in cranial structure (e.g., domed skull with hydrocephalus).

C. Certain purebreed dogs may have multiple congenital anomalies that are detected at the time of the examination.
1. An example is Alport syndrome in Dalmatians and bull terriers (Hood et al., 2002).
2. Alport syndrome is an inherited disease characterized by hematuria, renal failure, and deafness.
3. The cause is a genetic mutation that alters type IV collagen that translates into a lamellated glomerular basement membrane.
4. The disease is progressive over the first 2 years of life in dogs.

D. Concurrent congenital peripheral vestibular disease may be associated with deafness and is reported in Doberman pinschers (Wilkes and Palmer, 1992).

IV. Physical findings with acquired forms

A. Concurrent signs of ear disease may be present.

B. Physical examination findings may be normal with age-related changes.

C. Concurrent peripheral vestibular disease may be present.

V. Caveats

A. The accuracy of the historical information for the onset and progression of acquired hearing loss is often poor owing to the wide frequency range detected by dogs, and their ability to compensate with other sensory modalities.
B. Unilateral deafness is very difficult to detect accurately with historical or physical examination findings.
C. The most accurate method of confirming hearing loss is with specific diagnostic testing.

Diagnosis

I. Rule out causes of otitis externa and media (see Chapters 107 and 108).
II. Behavioral audiometry requires active participation from the animal.
  A. Both conscious and reflexive responses can be monitored with this sensitive, but less specific, test of hearing loss.
    1. Conscious responses are obtained in conditioned dogs to determine the tonal range of hearing; however, this type of testing is unrealistic in a clinical setting.
    2. Reflexive testing is used to try to determine an "absolute" positive response.
      a. Caution must be used in the interpretation of reflexive responses because many dogs are attuned to vibratory motions that occur with most startle reaction tests.
      b. Significant hearing loss may be present even in the face of a positive response.
  B. Unilateral deafness is difficult to detect with this method.
III. Impedance audiometry is a noninvasive, objective means of evaluating the integrity of the middle ear utilizing tympanometry and acoustic reflex testing.
  A. Tympanometry is the measurement of changes in eardrum compliance (mobility) as pressure in the external ear is changed.
  B. Tympanometry provides an indirect measurement of the air pressure in the middle ear and the degree of compliance of the TM, and an estimate of the external ear canal volume.
  C. The acoustic reflex is the involuntary action of the middle ear in response to a sound stimulus (Sims, 1988).
    1. When a loud noise is introduced into a normal ear, the muscles in the middle ear contract reflexively, thus decreasing the compliance of the ear.
    2. The purpose of this reflex is protection of the inner ear from damaging levels of noise through attenuation of high-intensity sounds.
    3. All measurements are tested at the pressure at which maximum compliance occurs.
    4. The reflexes are elicited by pure tones presented at frequencies of 2000 to 4000 Hz and intensities ranging from 70 to 110 dB in 5- to 10-dB increments delivered through the probe for ipsilateral reflexes and through an earphone for contralateral reflexes.
    5. An acoustic reflex less than the normal range, in conjunction with an abnormal or normal tympanogram, indicates otitis media or retrocochlear pathology, respectively.
IV. Evoked potential audiometry measures the electrical manifestation of the brain's reception of, and response to, an external stimulus (Sims, 1988).
  A. Auditory evoked responses (AERs) are signal-averaged recordings of brain activity in response to acoustic stimuli.
  B. AERs have the advantage of providing objective, quantifiable data that do not require the animal's cooperation and are highly resistant to the effects of sedatives and anesthetic agents.
  C. Evoked potential audiometry measures very specific components of the auditory pathway.
    1. Several types of AER can be recorded, depending on the time over which the response to the stimulus is averaged.
    2. Early-latency (0 to 10 msec) components are the result of activation of peripheral receptor, nerve, and brainstem structures, and thus are often referred to as a brainstem auditory evoked response (BAER) (Figure 109-1).
  D. The BAER test can be used to characterize both conductive and sensorineural deafness.
    1. Changes in latency onset, amplitude, and interval between waveforms can be analyzed to evaluate for site-specific pathology of the auditory pathway.
    2. Either clicks (2 to 4 kHz) or frequency-specific tones can be introduced as acoustic stimuli.
    3. Exposure to specific tones at varying intensities (tone burst BAER) provides the ability to distinguish hearing loss at specific frequencies.
    4. Requirements for the tests differ.
      a. Click BAER testing often can be done in awake, lightly restrained dogs.

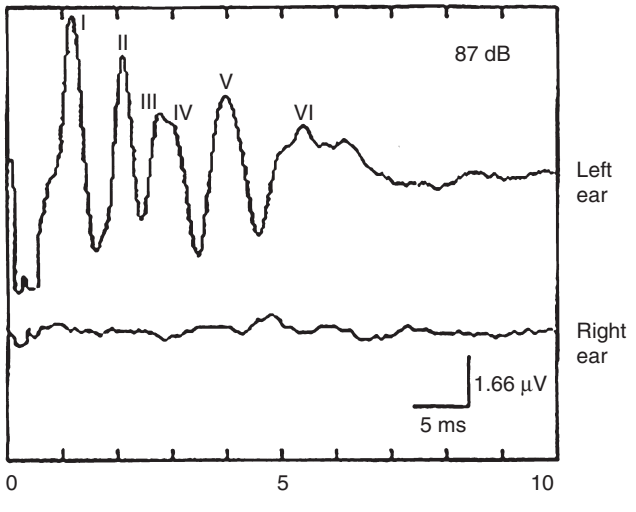

FIGURE 109-1 Early-latency brainstem auditory evoked response testing in a unilaterally (right ear) deaf 8-week-old male Jack Russell terrier. This recording is an example of congenital/hereditary sensorineural deafness from birth.

b. Tone-burst BAER testing requires sedation and a sound-attenuated room.

5. The BAER test is the preferred test for congenital deafness screening in animals, owing to its high sensitivity and ease of administration.

V. Otoacoustic emissions (OAEs) are spontaneous or acoustic-stimulated sounds generated within the normal cochlea (Lonsbury-Martin et al., 1997).
   A. These sounds can be measured when the middle ear and cochlea are functioning normally.
   B. The reemitted sounds of OAEs are thought to originate from active feedback of sound energy into the cochlea, a function attributed to outer hair cells.
   C. A decrease in amplitude of OAEs is found in pathologic conditions that result in loss of outer hair cells, such as noise exposure, anoxia, and aminoglycoside intoxication.
   D. Measurement of OAEs provides increased sensitivity and specificity in establishing the degree and type of hearing loss.
   E. Two types of otoacoustic emissions are commonly evaluated.
      1. Transient evoked OAEs are produced by presenting a broad-band "click" to the ear and measuring the magnitude of the emissions.
      2. In distortion product OAEs, two tones of overlapping frequencies are used to stimulate the basilar membrane.
   F. Measurement of OAEs requires sedation and a sound-attenuated room, which are only available in audiology laboratories at this time.

Differential Diagnosis

I. In young dogs, developmental diseases of the brain with abnormal behavior or failure to respond appropriately to auditory stimuli must be considered.
   A. Hydrocephalus
   B. Lissencephaly
   C. Storage disorders
II. Age-related behavior changes may occur in older pets who no longer respond to normal owner commands or interactions; although these animals may appear deaf, they no longer are processing the hearing information.
III. Forebrain neoplasia with behavioral disturbances in older animals may be mistaken for age-related deafness.

Treatment

I. Treatment of reversible conditions
   A. Appropriate antimicrobial agents for infectious otitis externa, media, interna
   B. Removal of accumulated ear wax or other debris
   C. Removal of inflammatory tissue from ear canal
II. Improving hearing with hearing aids
   A. Bone-anchored hearing aids may be useful in restoring hearing function in dogs with bilateral total ear canal ablation and lateral bulla osteotomy (Sommerlad et al., 1999).
   B. Hearing aids that are seated in the ear canal to amplify sound for partial sensorineural deafness are not well tolerated in the dog or cat.
III. Conditions with no available treatment
   A. Congenital, hereditary deafness
   B. Presbycusis
IV. Animal–owner behavioral modifications (Becker, 1998)
   A. Owners can develop hand signals to train their dogs.
   B. Identify the dog as being deaf, via either collar or tags.
   C. Bright, reflective markings may be used when the dog is outside, to alert others (i.e., cars) to the dog.

Monitoring of Animal

I. A return of hearing function is most likely to be seen with resolution of inflammatory or infectious diseases.
II. Preventive measures include the following:
   A. Congenital, hereditary forms
      1. Stop the breeding of lines that produce deaf offspring.
      2. Early screening of breeds with a predisposition for hereditary deafness is strongly recommended.
      3. Auditory evoked response (BAER) screening of sire, dam, and all puppies after 7 weeks of age is recommended.
   B. Acquired forms
      1. Systemic aminoglycoside dosages must be adjusted according to renal function to reduce the total time of peak serum concentration that may cause ototoxicity.
      2. Do not use topical agents with the potential for ototoxicity.
III. Repeated auditory screening is performed in any dog thought to have hearing loss, but is not completely deaf.
IV. Normal auditory screening with an evoked potential test may warrant further diagnostic testing to evaluate for central-mediated disease, especially in older dogs.

CHAPTER 110

Introduction

Lynn Guptill

GENERAL CONSIDERATIONS

I. Infectious diseases remain an important component of daily veterinary practice.
   A. Recognized diseases such as leptospirosis and ehrlichiosis are reemerging and being redefined.
   B. Pathogens "new" to companion animals in the United States are being recognized, such as leishmaniasis in foxhounds and other dogs.
   C. For pathogens previously considered "minor," a broader understanding is developing.
      1. Bartonellosis is increasingly recognized in cats and dogs.
      2. Increased recognition of methicillin-resistant *Staphylococcus aureus* (MRSA) infections is occurring in cats and dogs.
   D. "Traditional" pathogens persist (e.g., rabies virus, parvovirus, canine distemper, feline leukemia, feline immunodeficiency, and feline infectious peritonitis viruses).
II. Concepts of antibiotic use are being reexamined.
   A. Increased awareness and concerns about multiple antibiotic-resistant strains of bacterial pathogens
   B. Increased awareness and analysis of antimicrobial use in large veterinary hospitals
   C. American Veterinary Medical Association (AVMA) guidelines for antibiotic use (www.avma.org/scienact/jtua)
III. Vaccination protocols and concepts are continually revised.
   A. "Core" and "noncore" vaccine protocols and exposure risks are being redefined for individual animals.
   B. Reexmaination of the duration of vaccine-induced immunity is causing vaccination frequency to be reconsidered.
   C. Vaccines are changing, with new recombinant vaccines and DNA vaccines either in use or being developed.
   D. Vaccine-associated adverse event characterization has improved.

Changes in Exposure

I. Cats and dogs are exposed to an increasingly diverse set of infectious diseases.
   A. Increased proximity of homes and recreational areas to wildlife reservoirs
   B. Introduction of organisms and vectors through travel of people, pets, and livestock
II. Immunocompromised owners and their pets require special consideration.
   A. Pets are an important source of comfort and should be retained by immunocompromised individuals.
   B. Although uncommon, it is possible for pets to transmit zoonotic and opportunistic pathogens to immunocompromised people.
   C. Veterinarians, clients, and physicians are working together to address the following:
      1. Understanding the true potential for transmission of zoonotic and opportunistic pathogens
      2. Developing plans for choice of and care of pets by immunocompromised clients

NEW DIAGNOSTIC TECHNIQUES

I. Polymerase chain reaction (PCR) tests are available commercially and other molecular diagnostic tools are increasingly available.
II. Veterinarians must realize both the advantages and shortcomings of these tests.
   A. Difficult-to-culture pathogens (e.g., *Bartonella* spp. in endocarditis lesions) are detected.
   B. Species and strains are identified and reclassified.
      1. Better characterization of *Ehrlichia* spp., *Anaplasma* spp., and *Neorickettsia* spp.
      2. Better characterization of the hemoplasma and *Babesia* spp.

C. Nucleic acid detected and/or amplified by PCR does not necessarily indicate the organism is viable or responsible for the disease state.
D. False-positive results occur from contamination.
E. False-negative results can occur from degradation of nucleic acids in tissue specimens.

SUMMARY

I. Infectious diseases remain an important component of veterinary practice, and the understanding of infectious agents, pathogenesis, and epidemiology continues to develop.
II. The chapters in this section have been updated to address what the authors consider the most important infectious diseases encountered in dogs and cats in the United States.

CHAPTER 111

Systemic Mycoses

Joseph Taboada

BLASTOMYCOSIS

Definition

I. Blastomycosis is a systemic, fungal infection that usually originates in the lungs and then disseminates to the lymphatics, skin, eyes, bones, and other organs.
II. Young, male, large-breed dogs (especially sporting breeds and hounds) living near water are at increased risk; most affected animals live within one-quarter mile of water.
III. Dogs have been used as a sentinel animal for human disease, because the incidence in dogs is approximately 10 times higher.
IV. Cats are rarely infected.

Cause

I. Blastomycosis is caused by the dimorphic fungus *Blastomyces dermatitidis*.
II. *Blastomyces dermatitidis* characteristics are as follows:
    A. In tissue or when cultured at 37° C, the organism is a thick-walled yeast (5 to 20 μm) that usually has a single bud attached to the mother cell by a broad base.
    B. When cultured at 25° C, the organism grows as a white, cottony mold that may become tan as it ages.
    C. Colonies grow slowly and contain branching septate (1 to 2 μm) mycelia that form round to pyriform-shaped (2 to10 μm) conidia, resembling the microconidia of *Histoplasma capsulatum.*
III. *Blastomyces dermatitidis* is probably a soil saprophyte, but the natural reservoir remains unidentified.
    A. It is often grown from wet, acidic, or sandy soil containing decaying wood, animal feces, or other organic enrichment.
    B. Moisture is important for growth and transmission; therefore the organism is primarily endemic along the Mississippi, Ohio, Missouri, Tennessee, and St. Lawrence rivers; in the southern Great Lakes; and in the southern mid-Atlantic states.

Pathophysiology

I. Infection occurs most commonly via inhalation of infective conidia from the environment, but direct inoculation may rarely result in localized cutaneous disease.
II. Blastomycosis is not a contagious disease; however, it is an occupational hazard to laboratory workers and veterinary personnel when handling infective materials or cultures.
    A. Activities that disrupt the soil, such as digging or construction, may also play a role in the aerosolization of spores.
    B. Point sources of exposure within enzootic areas are important in establishing infections.
III. After inhalation, conidia are phagocytized by alveolar macrophages and transformed from the mycelial phase to the yeast phase, which induces a marked suppurative to pyogranulomatous response.
    A. Phagocytized yeast are then transported into the pulmonary interstitium, where access is gained to the lymphatic and vascular systems.
    B. Hematogenous and lymphatic dissemination results in multisystemic disease.
    C. Although dissemination may affect any organ system, the lymph nodes, eyes, skin, bones, subcutaneous tissue, and prostate gland are commonly affected in dogs.
    D. The skin, subcutaneous tissue, eyes, central nervous system (CNS), and lymph nodes are often affected in cats.
IV. Incubation period varies in dogs from 5 to 12 weeks.
V. Immune response determines the severity of clinical disease.
    A. Antibody production occurs in most cases, with higher serological titers found in severe disseminated disease (Klein et al., 2000).
    B. Recovery is probably dependent on cell-mediated immune responses.
        1. Adequate immune response may result in mild respiratory disease that resolves spontaneously or may result in disease in other organ systems without apparent pulmonary involvement.
        2. A poor or weak immune response results in severe pulmonary and disseminated disease.

Clinical Signs

I. High-risk breeds include the blue tick coonhound, pointer, and Weimaraner (Rudmann et al., 1992).
    A. Male dogs are affected more than females.
    B. Large-breed dogs are affected more than small breeds.
    C. Any age dog can be affected, with the highest incidence occurring at 1 to 5 years.
II. Clinical findings are variable.
    A. Nonspecific signs such as anorexia, depression, weight loss, cachexia, and fever (about 40%) are common.

B. The lungs are the portal of entry for organisms; thus pulmonary signs are seen in up to 85% of dogs (Arceneaux et al., 1998).
   1. Signs range from cough and mild respiratory distress to severe dyspnea.
   2. Hypoxemia results in cyanosis in the most severely affected cases.
C. A dry, hacking cough is common with compression of primary bronchi from enlargement of perihilar lymph nodes, and from bronchointerstitial and alveolar disease.
D. Rapid, shallow respiratory efforts are occasionally caused by pleural effusion and pleuritic pain.
E. Chylothorax and solid pulmonary masses are uncommon.
F. Cranial vena caval syndrome may result from anterior mediastinal disease (Howard et al., 2000).

III. Diffuse lymphadenopathy occurs in up to 60% of dogs (Arceneaux et al., 1998).

IV. Cutaneous signs occur in 30% to 50% of dogs and are commonly noted in cats (Arceneaux et al., 1998).
   A. Skin lesions are usually single or multiple papules, nodules, or plaques that may ulcerate and drain a serosanguineous to purulent exudate.
   B. Large abscesses occasionally occur, especially in cats.
   C. Paronychia is common in dogs, so the feet and nail beds should be examined closely.

V. Ocular involvement is noted in 20% to 50% of the cases, with approximately 50% of affected dogs having bilateral involvement (Brooks et al., 1991; Arceneaux et al., 1998).
   A. Posterior segment disease usually occurs first and may progress to endophthalmitis, panophthalmitis, or secondary glaucoma.
   B. Posterior segment disease includes chorioretinitis, retinal detachment, subretinal granulomas, or vitreitis.
   C. Optic neuritis is occasionally seen.
   D. Anterior segment disease is usually secondary to posterior segment disease.
      1. It includes anterior uveitis, conjunctivitis, keratitis, and episcleritis.
      2. Secondary glaucoma is common in dogs with anterior segment disease.
   E. Long-term effects on vision can be severe.
      1. Dogs with only focal chorioretinitis have a better prognosis for vision than those with anterior segment disease or endophthalmitis (Brooks et al., 1991).
      2. It is unlikely that dogs with severe visual impairment will regain vision even after appropriate therapy.

VI. Lameness is noted in up to 25% of dogs (Arceneaux et al., 1998).
   A. Osteomyelitis is noted in 10% to 15% of dogs, usually involving the epiphyseal regions below the elbow or stifle (as a single lesion).
   B. Paronychia may cause pain and lameness.
   C. Monoarthritis or polyarthritis is a rare cause of lameness.

VII. Reproductive system is affected in approximately 10% of dogs (Arceneaux et al., 1998).
   A. Orchitis is seen in 16% of intact male dogs (Arceneaux et al., 1998).
   B. Prostatitis or mastitis is seen in <5% of dogs.

VIII. The CNS is affected in <5% of dogs; a higher percentage of cats have CNS involvement.
   A. CNS signs are dependent on the location of lesions.
   B. CNS involvement may occur without obvious clinical signs.

IX. Other potential sites of infection include liver, spleen, kidneys, bladder, and nasal cavity; the gastrointestinal (GI) tract is rarely affected.

X. Feline blastomycosis is uncommon.
   A. Most clinical signs seen in dogs may also occur in cats.
   B. Large abscesses are more common.
   C. Neurological signs are more common.
   D. CNS involvement is an important risk factor for recurrence in cats.

Diagnosis

I. Hematological and serum biochemistry findings
   A. Results of hematological examination are often normal, but mild nonregenerative anemia and mature neutrophilia or neutrophilia with a mild left shift may be seen.
   B. Hypoalbuminemia and hyperglobulinemia are the most consistent biochemical abnormalities.
   C. Mild to moderate hypercalcemia is noted in <10% of cases.

II. Radiographic findings (Arceneaux et al., 1998).
   A. Interstitial patterns are observed in about 70% of dogs, and include nodular interstitial (41%), diffuse interstitial (24%), and bronchointerstitial (5%) forms.
   B. Alveolar or mixed interstitial/alveolar patterns can occur (20%).
   C. Tracheobronchial lymphadenopathy may be noted (30%).
   D. Mediastinal (8%) or solitary pulmonary masses (8%) are uncommon.
   E. Pleural effusion (7%) may obscure the pulmonary parenchyma.
   F. Pneumothorax (1%) is rare.
   G. Bone lesions occur in about 12% of cases (Arceneaux et al., 1998).
      1. Most bony lesions (66%) are solitary osteomyelitis lesions.
      2. Most lesions (75%) occur in the extremities.
         a. Lesions are osteolytic and typically at the ends of the long bones.
         b. The forelimbs are affected more than the hind limbs.
         c. Most extremity lesions are below the elbow or stifle.
      3. Periosteal proliferation and soft tissue swelling is noted in about 50% of lesions.

III. Organism identification

A. Cytological findings from tissue are as follows:
   1. Suppurative or pyogranulomatous inflammation is present, often with thick-walled yeast (5 to 20 μm in diameter, 0.5 to 0.75 μm wall) that bud to form daughter cells from a broad base.
   2. The yeast cells lack a capsule, helping to differentiate them from *Cryptococcus* spp.
   3. Infected skin yields organisms in about 80% of impression smears, skin scrapings, or fine-needle aspirates (FNA) of nodular lesions.
   4. Vitreal aspirates yield organisms from most affected, blind eyes.
   5. Lymph node aspirates yield organisms approximately 60% of the time.
   6. Bone and lung aspirates, transtracheal washes, and bronchoalveolar lavage yield organisms <50% of the time.
   7. FNAs of focal parenchymal lesions of the lungs yield organisms more often than transtracheal washes or bronchoalveolar lavage.
   8. Urine sediment, prostatic washes, or peritoneal lavage rarely reveal organisms.
   9. Organisms are occasionally identified in the stool of dogs with pulmonary disease (Baumgardner and Paretsky, 1997).

B. Histopathological findings are as follows:
   1. Purulent to pyogranulomatous lesions with broad-based organisms are usually apparent.
   2. Special stains (periodic acid–Schiff [PAS], Gridley's fungal, Gomori methenamine silver) demonstrate the organisms best in tissue.

C. Fungal culture and identification are as follows:
   1. They are not needed for definitive identification in clinical cases.
   2. Mycelial growth on Sabouraud's dextrose agar may require 1 to 4 weeks at 37° C, whereas growth occurs on blood or brain-heart infusion agar in 1 to 2 weeks at 25° C.
   3. Culturing the organisms from the environment is rarely achieved (Baumgardner and Paretsky, 1999).

IV. Serology

A. Antibody response
   1. It is used primarily when a high degree of probability exists or repeated attempts fail to demonstrate the organisms.
   2. Agar-gel immunodiffusion (AGID) test is most commonly used.
      a. It detects antibodies directed against the fungal organism (sensitivity 41% to 90%, specificity 90%).
      b. It may be negative in early disease, and some dogs fail to develop a serologic titer.
      c. It is not useful in following response to therapy.
      d. There is a low prevalence of antibodies in unaffected dogs living in endemic areas.

B. Antigen detection
   1. A highly sensitive, competitive, enzyme-linked immunosorbent assay (ELISA) has been developed to detect *B. dermatitidis* antigen in urine (Shurley et al., 2005).
   2. Specificity has not been critically evaluated.

Differential Diagnosis

I. Other multisystemic granulomatous, neoplastic, and immune-mediated diseases

II. Skin involvement
   A. Bacterial diseases: actinomycosis, mycobacteriosis, botryomycosis, brucellosis, or *Rhodococcus equi* infection
   B. Mycotic and related diseases: cryptococcosis, coccidioidomycosis, sporotrichosis, basidiobolomycosis, phaeohyphomycosis, hyalohyphomycosis, eumycotic mycetoma, dermatophytic mycetoma, protothecosis, pythiosis, lagenidiosis, nodular leishmaniasis
   C. Noninfectious pyogranulomatous diseases: foreign body reaction, idiopathic nodular panniculitis, sebaceous nodular adenitis, and canine cutaneous sterile pyogranuloma/granuloma syndrome
   D. Neoplasia: squamous cell carcinoma, cutaneous T-cell lymphoma, cutaneous histiocytosis
   E. Miscellaneous diseases: systemic lupus erythematosus, systemic vasculitis, cutaneous embolic disease

III. Ocular involvement
   A. Fungal disease: cryptococcosis, coccidioidomycosis, geotrichosis, histoplasmosis, aspergillosis
   B. Neoplasia: lymphosarcoma, metastatic tumors
   C. Other diseases: protothecosis, brucellosis, toxoplasmosis, neosporosis, leishmaniasis

IV. Lymph node involvement
   A. Lymphosarcoma
   B. Other fungal infections, rickettsial diseases, brucellosis
   C. Mycobacteriosis, protothecosis, leishmaniasis

V. Bony involvement
   A. Primary or metastatic neoplasia
   B. Other fungal or bacterial osteomyelitis

Treatment

I. Spontaneous recovery from systemic blastomycosis rarely occurs in dogs, so symptomatic animals are always treated.

II. Itraconazole is the preferred treatment (Legendre et al., 1996).
   A. Give dogs 5 mg/kg PO BID for the first 3 to 5 days, then 5 mg/kg PO SID for 2 to 3 months or until active disease has subsided.
   B. Cats may require 5 mg/kg PO BID or 10 mg/kg PO SID.
   C. Itraconazole oral solution has more consistent bioavailability in cats.
   D. Response may be minimal in the initial 1 to 2 weeks of treatment.
   E. Drug-induced side effects include the following:
      1. Increased liver enzymes may indicate hepatocellular damage or only enzyme induction.
         a. Mild to moderate increases in serum alanine transaminase (ALT), aspartate transaminase (AST), and alkaline phosphatase (ALP) activities

occur in about 50% of treated animals, especially at a dose of 10 mg/kg.
b. Therapy is discontinued if liver enzyme elevations are marked or if they are accompanied by anorexia, vomiting, or abdominal pain.
c. Therapy can be reinstituted at a lower dose following a return to normal liver enzyme levels.
2. Anorexia is the most common side effect.
a. It is dose-related and more common in cats.
b. Cyproheptadine 2 mg PO SID to BID or oxazepam 2 to 3 mg PO SID to BID may be used as appetite stimulants in cats.
3. A dose-dependent cutaneous vasculitis (ulcerative skin lesions with appearance similar to a recurrence of blastomycosis) is seen in about 7% of dogs receiving 10 mg/kg.
4. Fearful behaviors (e.g., hiding, submission) are rare complications in dogs.

F. Itraconazole does not cross the blood–brain, blood–ocular, or blood–prostatic barriers well, but it is still effective in some CNS, ocular, and prostatic infections.
G. It concentrates well in the skin, making it highly effective in treating cutaneous infections.
H. Severely ill or hypoxemic dogs may have a better outcome if they are treated initially with itraconazole and amphotericin B in combination, or with IV fluconazole or itraconazole.
1. Worsening respiratory signs may occur in the first few days after beginning treatment.
2. Dexamethasone (0.25 to 0.5 mg/kg IV SID for 2 to 3 days) may improve prognosis for dogs with severe respiratory disease whose hypoxemia worsens after starting treatment.

III. Fluconazole is less expensive, but typically not as effective as itraconazole.
A. Give dogs or cats 2.5 to 5 mg/kg PO, IV SID for one month beyond complete clinical remission.
B. It does not require a low gastric pH for maximal bioavailability and is not affected by the presence or absence of food.
C. Fluconazole is excreted in the urine; crosses the blood–brain, blood–ocular, and blood–prostatic barriers well; and may be the preferred treatment for urinary tract, prostatic, and CNS infections.
D. Side effects are similar to those of itraconazole.

IV. Ketoconazole is another choice.
A. Give dogs or cats 5 to 15 mg/kg PO BID for a minimum of 3 months (with food, not concurrently with antacids).
B. Response rates are much lower and relapses are higher, and dogs generally must be treated for a longer periods.
C. Anorexia, vomiting, hepatotoxicity, and adrenal insufficiency are more likely.

V. Amphotericin B is used in selected cases.
A. It has good efficacy against blastomycosis, but nephrotoxicity is the primary limiting side effect.
B. Amphotericin B lipid complex *(Albecet)* is recommended in combination with itraconazole or fluconazole for severely affected or hypoxemic cases.
1. It allows higher total doses to be used and reduces nephrotoxicity compared to the less expensive deoxycholate salt of amphotericin B.
2. Recommended dose in dogs is 1 to 2 mg/kg IV QOD to a total dose of 12 to 24 mg/kg (Krawiec et al., 1996).
C. Deoxycholate salt of amphotericin is less expensive but more toxic.
1. Nephrotoxicity is the primary limiting factor.
2. Fever is another major side effect and is usually ameliorated by pretreatment with nonsteroidal anti-inflammatory drugs.
3. Other side effects include thrombophlebitis, hypokalemia, distal renal tubular acidosis, hypomagnesemia, cardiac arrhythmias, and nonregenerative anemia.
4. Reconstitute with 5% dextrose in water and infuse IV over 10 to 15 minutes or over 1 to 6 hours.
5. The longer infusion rates or pretreatment saline diuresis reduce the likelihood of nephrotoxicity.
6. Dosage is 0.5 mg/kg (dog) or 0.25 mg/kg (cat) IV QOD to a total dose of 4 mg/kg (total dose of 8 mg/kg if amphotericin B is the sole treatment).
7. Renal function is monitored before each treatment, and therapy is discontinued if azotemia (blood urea nitrogen >50 mg/dL, creatinine >3 mg/dL) develops.
8. Calcinosis cutis is occasionally noted (Gortel et al., 1999).
D. Efficacy of amphotericin B when combined with itraconazole is equal to that of itraconazole alone in most dogs.

Monitoring of Animal

I. Initial in-hospital monitoring includes daily vital signs, body weight measurements, and physical and/or ocular examinations.
II. Monthly examinations during therapy also include a serum biochemistry profile.
III. After 2 months of itraconazole therapy, consider whether to discontinue the drug.
A. Discontinue therapy if the animal is outwardly normal, there is no evidence of active ocular disease, and thoracic radiographs have improved substantially.
B. Thoracic radiographs often continue to improve after discontinuing therapy.
C. If doubt exists concerning the presence or absence of active disease, the animal is treated for an additional month.
IV. If fluconazole is used, treatment is continued at least 1 month beyond complete clinical remission.
V. After discontinuing therapy animals are reevaluated at 3 and 6 months for evidence of relapses.
VI. Prognosis for dogs and cats with blastomycosis is good.

A. Approximately 50% to 75% of dogs treated with either itraconazole or a ketoconazole–amphotericin B combination respond completely to therapy.
B. Dogs most often die of severe respiratory disease and hypoxemia; however, dogs that survive the first 10 days of therapy usually do well.
C. Hypoxemia and involvement of three or more body systems warrant a poor prognosis.
D. Relapse occurs in 15% to 20% of treated dogs, usually in the first 6 months.
E. CNS signs on relapse are common in cats.
F. Relapses are treated similarly to any new infection.

HISTOPLASMOSIS

Definition

I. Histoplasmosis is a systemic, fungal infection that usually originates in the lungs or GI tract and then disseminates to the lymphatics, liver, spleen, bone marrow, eyes, and other organs.
II. Cats are more susceptible than dogs.
III. Dogs and cats <4 years old are at an increased risk, but any age can be affected.
IV. No apparent sex predilection exists in dogs.
V. Pointers, Brittany spaniels, and Weimaraners are overrepresented.

Cause

I. It is caused by the dimorphic fungus *Histoplasma capsulatum*.
II. *H. capsulatum* characteristics are as follows:
A. In tissue or when cultured at 30° to 37° C, the organism is a yeast and is usually found intracellularly.
B. When cultured at 25° C, the organism grows as a white cottony or buff-brown mold that requires 7 to 10 days for growth.
III. *H. capsulatum* is a soil saprophyte that survives in a wide range of moistures and temperatures.
IV. Nitrogen-rich soil (containing bird or bat guano) appears ideal for its growth.
V. *H. capsulatum* is endemic to most temperate and subtropical regions of the world and mostly occurs in the central United States along the Mississippi, Ohio, and Missouri rivers.

Pathophysiology

I. Infection occurs most commonly via inhalation or ingestion of infective conidia from the environment.
A. Inhalation is probably the primary route of infection.
B. Ingestion of conidia may occur in dogs.
II. After inhalation or ingestion, conidia transform from the mycelial phase to the yeast phase and are phagocytized by cells of the macrophage-monocyte system, where they grow as facultative intracellular organisms.
A. Hematogenous and lymphatic dissemination results in multisystemic disease.
B. Although dissemination may affect any organ system, the lungs, GI tract, lymph nodes, liver, spleen, bone marrow, eyes, and adrenal glands are commonly affected in dogs.
C. Lungs, liver, lymph nodes, eyes, and bone marrow are most commonly affected in cats.
III. Incubation period is 12 to 16 days in dogs.
IV. The immune response determines the severity of clinical disease.
V. Subclinical infection is probably common.
VI. Point-source outbreaks of disease are usually associated with exposure to areas heavily contaminated with *Histoplasma* spp. (e.g., chicken coops, bat habitats, starling roosts).

Clinical Signs

I. Feline histoplasmosis
A. Signs are usually insidious in onset and nonspecific (e.g., depression, anorexia, fever, pale mucous membranes, weight loss).
B. Pulmonary signs (e.g., dyspnea, tachypnea, abnormal lung sounds) are seen in about 50% of animals, but coughing is uncommon.
C. Hepatomegaly, splenomegaly, or lymphadenopathy is seen in about one third of animals.
D. Ocular signs include eyelid granulomas, retinal pigment proliferation, retinal edema, granulomatous chorioretinitis, anterior uveitis, panophthalmitis, and optic neuritis; retinal detachments and secondary glaucoma are uncommon.
E. Lameness in one or more limbs may occur from lytic bone lesions and soft tissue swelling.
F. Cutaneous lesions consisting of multiple small nodules that either ulcerate, drain, or crust over are uncommon.
G. Oral and lingual ulcerations are atypical manifestations; icterus is occasionally seen with hepatic involvement.
II. Canine histoplasmosis
A. Subclinical infection is probably common following inhalation of organisms.
B. GI signs occur most commonly.
1. Large intestinal diarrhea with tenesmus and passage of mucus and fresh blood is common in early stages of the disease.
2. Small intestinal diarrhea, possibly voluminous and associated with malabsorption or protein-losing enteropathy, may be apparent with progressive disease.
C. Elaboration of inflammatory mediators may cause nonspecific signs of fever, anorexia, depression, and severe weight loss.
D. Abnormal lung sounds with or without coughing, tachypnea, or dyspnea are seen in <50% of dogs.
E. Splenomegaly, hepatomegaly, and lymphadenopathy occur occasionally.
F. Oral ulceration, lameness from bony involvement, neurological signs, nodular skin disease, ocular involvement, and adrenal insufficiency are less common.

Diagnosis

I. Hematological and serum biochemistry findings
   A. Normocytic normochromic nonregenerative anemia is the most common change and results from chronic inflammation, GI blood loss, or bone marrow infection.
   B. Neutrophilia and monocytosis are often seen, but total leukocyte counts are variable.
      1. Neutropenia or pancytopenia are unusual occurrences, especially in cats.
      2. Organisms are rarely seen within monocytes, neutrophils, or eosinophils.
   C. Thrombocytopenia caused by increased platelet utilization or destruction is common.
   D. Hypoalbuminemia is the most consistent biochemical abnormality, especially in cats.
   E. Increased serum ALT, AST, ASP, and total bilirubin concentrations indicate hepatic involvement.
   F. Hypercalcemia may occur, especially in cats.

II. Radiographic findings
   A. Thoracic radiography often shows a diffuse interstitial or linear interstitial pattern that may coalesce into a nodular interstitial pattern, although alveolar infiltrates are rare.
   B. Hilar lymphadenopathy is common in dogs but unusual in cats.
   C. Calcified pulmonary infiltrates or hilar lymph nodes usually indicate inactive disease.
   D. Bony lesions of the distal appendicular skeleton, especially carpal and tarsal bones, are rarely seen.
   E. Pleural or abdominal effusions are occasionally seen.

III. Organism identification
   A. Cytological examination may reveal organisms in mononuclear phagocytic cells.
      1. Some organisms are released from infected cells during slide preparation and are seen as free organisms on slides stained with a Wright-Giemsa stain.
      2. Evidence of pyogranulomatous inflammation may exist with numerous intracellular small, round to oval yeast cells (2 to 4 μm in diameter, basophilic center) with a light halo caused by shrinkage of its cell wall during fixation.
      3. In cats, aspirates from bone marrow and lymph nodes, or cells from tracheal washes or bronchoalveolar lavage, are most likely to yield organisms.
      4. In dogs, cells from rectal scrapings or biopsies; aspirates from bone marrow, liver, lymph nodes, or spleen; or cells from tracheal washes or bronchoalveolar lavage are most likely to yield organisms.
      5. Buffy coat smears, cerebrospinal fluid (CSF), aspirates of lytic bone lesions, or aspirates and impression smears of nodular skin lesions may also yield organisms.
   B. Histopathologic findings are as follows:
      1. Pyogranulomatous lesions with multiple intracellular organisms are usually seen.
      2. Special stains (PAS, Gridley's fungal, Gomori methenamine silver) best demonstrate organisms in tissue.
   C. Fungal culture and identification are as follows:
      1. It is not needed for definitive identification.
      2. Buff-brown mycelial growth on Sabouraud's dextrose agar usually takes 7 to 10 days at room temperature, whereas yeast produces white, moist colonies on blood agar at 30° to 37° C.
      3. Attempts at culture are not advised because of the potential public health risk.

IV. Other tests
   A. Serology is presently an ineffective method of diagnosis; both false-positive and false-negative results occur commonly.
   B. Cats with histoplasmosis are typically negative for feline leukemia virus (FeLV) and feline immunodeficiency virus (FIV).

Differential Diagnosis

I. Blastomycosis or other systemic fungal diseases
II. Other GI diseases
   A. Large intestinal disease: see Chapter 34
   B. Small intestinal disease: see Chapter 33

Treatment

I. Treatment is similar to that described for blastomycosis, although azole antifungal usage is not as well-studied.
II. Longer treatment times are probably needed with the azole antifungals, but such treatment times are variable depending on the severity of the infection and the response of the animal.
III. Pulmonary disease may be self-limiting, but antifungal treatment is recommended because of the potential for chronic dissemination.
IV. Feline histoplasmosis is treated as follows:
   A. Itraconazole 5 mg/kg PO BID for at least 2 to 4 months is the treatment of choice (Hodges et al., 1994).
      1. Bioavailability of capsules is variable, and doses up to 10 mg/kg PO BID may be required in some cats.
      2. Bioavailability of the oral solution is better, and 10 mg/kg/day is adequate.
   B. Ketoconazole is effective in about one third of cats.
   C. Fluconazole may be effective, but it has not been studied well.
   D. Amphotericin B may be added to the treatment protocol in severely affected cats.
V. Canine histoplasmosis requires the following:
   A. Itraconazole 10 mg/kg PO SID is the preferred treatment.
   B. Ketoconazole is effective, but amphotericin B is added in fulminant cases.
   C. Amphotericin B may also be added to itraconazole in dogs with severe, disseminated disease.
   D. Fluconazole has not been well studied but may be effective.
   E. Corticosteroids may be indicated in dogs with airway obstruction secondary to hilar lymph node enlargement (Schulman et al., 1999).

Monitoring of Animal

I. Resolution of clinical signs is the best means of monitoring therapy.
II. Initially, in-hospital monitoring includes daily vital signs, body weight measurements, and physical and/or ocular examinations.
III. Monthly examinations also include a serum biochemistry profile.
IV. Treatment is continued for 1 month beyond complete resolution of clinical signs.
V. Animals are reevaluated 3 and 6 months after discontinuing therapy to assess for relapses.
VI. Serological evaluation is not useful in monitoring response to therapy or evaluating for relapse.
VII. Prognosis is variable.
  A. Prognosis is good for dogs with only pulmonary signs.
  B. Dogs with GI or severe disseminated signs have a guarded prognosis.
  C. The prognosis is fair to good for cats treated with itraconazole, although long-term therapy may be required.
  D. Severely debilitated cats have a guarded prognosis.

COCCIDIOIDOMYCOSIS

Definition

I. Coccidioidomycosis (Valley fever, San Joaquin Valley fever) is a systemic fungal infection that typically originates in the lungs and may disseminate to the lymphatics, bones, and other organs.
II. Dogs are affected more often than cats.
III. Young, large- and medium-sized male dogs kept outdoors are most commonly affected, with the likelihood of infection decreasing with advancing age.
IV. Boxers, pointers, Australian shepherds, beagles, Scottish terriers, Doberman pinschers, and cocker spaniels may be at an increased risk (Davidson, 1995).
V. No breed or sex predilection occurs in domestic cats (Greene and Troy, 1995).
VI. Epizootics occur in endemic areas when drought conditions are followed by periods of rain, dust storms, earthquakes, or other conditions that spread soil-derived arthrospores into the air.

Cause

I. It is caused by the geophilic, dimorphic fungus *Coccidioides immitis*.
II. *C. immitis* characteristics are as follows:
  A. In tissue or when cultured at 37° C, the organism grows as large spherules that gradually enlarge to 20 to 200 μm.
  B. Endospores are produced by cleavage from the wall of the spherule.
  C. In the environment or when cultured at 25° C, the organism grows as a mycelium that forms square to rectangular (2 to 4 μm by 3 to 10 μm) multinucleate arthrospores.
III. *C. immitis* is a soil saprophyte that is restricted to the lower Sonoran life zone.
  A. It grows only in areas with sandy alkaline soils, semiarid conditions, high summer and moderate winter temperatures, and low geographic elevations (sea level to a few hundred feet).
  B. It is endemic to the desert southwest (parts of California, Arizona, Texas, New Mexico, Nevada, Utah) and to Mexico, Central America, and parts of South America.

Pathophysiology

I. Infection is usually via inhalation of infective arthrospores from the environment or direct inoculation of arthrospores into the skin.
  A. During periods of high temperatures and low rainfall, the mycelia lie dormant below the soil surface.
  B. Following periods of rain, the organism then returns to the surface, sporulates, and releases large numbers of arthrospores that are disseminated by the wind.
  C. After drought periods, large numbers of arthrospores may be released, resulting in disease epidemics.
  D. Dust storms or earthquakes may cause aerosolization of arthrospores and disease epidemics.
  E. Coccidioidomycosis is not a contagious disease.
II. Inhalation of <10 arthrospores produces clinical disease.
  A. After inhalation, arthrospores move from peribronchial tissues to the subpleural area; spherules then form and produce endospores, which become more spherules.
  B. Respiratory signs result from the endospore formation and subsequent inflammation.
  C. Hematogenous and lymphatic dissemination is uncommon and results in multisystemic disease.
  D. Although dissemination may occur to any organ system, areas most commonly affected are the bones, joints, spleen, liver, kidneys, heart, reproductive organs, eyes, brain, and spinal cord.
  E. In cats, the skin is often affected.
  F. Rarely, primary cutaneous infections occur after a penetrating injury (Plotnick et al., 1997).
III. The incubation period varies from 1 to 3 weeks in dogs.
IV. The immune response determines the severity of clinical disease.
  A. Recovery is dependent on cell-mediated immunity, but a humoral response is present in most dogs living in endemic areas.
    1. An adequate immune response results in subclinical or mild respiratory disease that resolves spontaneously; most cases in dogs and cats are probably subclinical.
    2. A poor immune response allows severe pulmonary and disseminated disease to develop.
  B. It is unknown whether recovered dogs and cats are immune.

Clinical Signs

I. Most affected dogs and cats probably show no or only mild respiratory signs before mounting an effective immune response.

II. Disseminated feline coccidioidomycosis is uncommon (Greene and Troy, 1995).
  A. Cats are more resistant to infection when compared with dogs.
  B. No age, sex, or breed predisposition exists.
  C. Clinical findings are variable because of the multisystemic nature of the disease, and signs of disease are often present for <1 month before diagnosis.
  D. Nonspecific signs of depression, anorexia, fever, and weight loss are common.
  E. Pulmonary signs (e.g., dyspnea, tachypnea, abnormal lung sounds) occur in about 25% of cats.
  F. Skin lesions (e.g., draining lesions, subcutaneous masses, abscesses) are seen in >50% of cats, and localized lymphadenopathy is noted in one third of these cats.
  G. Lameness develops in approximately 20% of cats.
  H. Ocular involvement (e.g., granulomatous chorioretinitis with retinal detachment, uveitis, panophthalmitis) occurs in approximately 10% of cats.
  I. CNS involvement is uncommon.
III. Disseminated canine coccidioidomycosis often occurs in dogs <4 years of age (Green and Troy, 1995).
  A. Males are affected twice as often as females.
  B. The clinical findings are related to the severity of pulmonary involvement and the extent of systemic dissemination.
    1. Clinically inapparent infection is common following inhalation of organisms.
    2. When clinical signs develop, they are often present for 1 to 6 months before the initial diagnosis.
  C. The most common presenting complaint is a chronic cough.
  D. Prolonged intermittent fever, anorexia, depression, and weight loss are also common.
  E. Lameness associated with osteomyelitis and painful periarticular swelling is common.
    1. The appendicular skeleton is affected about 3 times more often than the axial skeleton.
    2. Multiple osseous lesions may be seen in many dogs.
    3. The distal portion of long bones is affected most commonly.
  F. Approximately 20% of dogs have cutaneous lesions characterized by nodules, abscesses, ulcers, and draining tracts.
    1. Skin lesions usually occur as an extension from an infected osseous lesion.
    2. Primary skin and subcutaneous infections following direct cutaneous inoculation in dogs are rare.
    3. Regional lymphadenopathy associated with cutaneous or osseous lesions is common, but generalized peripheral lymphadenopathy is unusual.
  G. Rarely visceral organ involvement may result in icterus, renal failure with renomegaly, or GI signs.
  H. Cardiac involvement may result in right- or left-sided heart failure, pericardial effusion, arrhythmias, and syncope.
  I. Seizures, ataxia, behavioral changes, and coma have been associated with CNS involvement.
  J. Ocular lesions often involve both the posterior and anterior segments, but they are not as common as with other systemic fungal infections.
    1. Anterior segment disease (iritis, granulomatous uveitis) is usually an extension of posterior segment disease.
    2. Glaucoma occurs in almost half of affected eyes.
    3. Granulomatous chorioretinitis, with or without retinal detachment, is common but may not be apparent because of the severity of the anterior segment disease.
    4. Lesions are usually unilateral, but bilateral disease may develop.

Diagnosis

I. Hematological and serum biochemistry findings
  A. A mild normocytic, normochromic nonregenerative anemia is common.
  B. Moderate neutrophilia, usually with a left shift, and monocytosis are often seen.
  C. Hypoalbuminemia and hyperglobulinemia are consistent abnormalities.
  D. Increased serum ALT, AST, ALP, and total bilirubin concentrations indicate hepatic involvement.
  E. Azotemia and hyperphosphatemia may indicate renal involvement.
  F. Hypercalcemia may occur.
II. Radiographic findings
  A. Numerous abnormalities may be found on thoracic radiographs.
    1. Hilar and central lung regions often reveal an ill-defined, diffuse, interstitial, or peribronchiolar pattern.
    2. Involvement of peripheral regions and alveolar infiltrates are uncommon.
    3. Hilar lymphadenopathy is seen in approximately 80% of dogs.
    4. Mediastinal widening as a result of mediastinal lymph node enlargement is less common.
    5. Pleural involvement (pleural thickening, effusion) is seen in almost 65% of dogs.
  B. Osseous lesions consisting of periosteal and endosteal new bone formation and osteolysis are noted in approximately 20% of dogs.
    1. Bones of the distal appendicular skeleton are affected about 3 times more frequently than bones of the axial skeleton.
    2. The distal diaphysis, metaphysis, and epiphysis are affected most often.
    3. Multiple osseous lesions are usually evident.
    4. Hypertrophic osteopathy may occur secondary to pulmonary or hilar lymph node involvement.
III. Cytological findings
  A. Fewer spherules make cytological demonstration difficult.
  B. Exudates from draining skin lesions and pleural fluid are the most likely to yield organisms.
  C. Tracheal washes or bronchoalveolar lavage samples, lymph node aspirates, or aspirates from affected tissue may also yield organisms.

D. Bone aspirates do not usually yield organisms.
E. Spherules appear as large (20 to 200 μm), round, double-walled structures with endospores.
1. The walls appear refractile, on wet preparations or potassium hydroxide (KOH) preparations.
2. They stain blue when hematoxylin and eosin (H&E) stain is used.
3. They stain deep red to purple with PAS, whereas the endospores stain bright red.
4. They stain purple-black with Papanicolaou stain, whereas the cytoplasm stains yellow and the endospores stain red-brown.

IV. Histopathological findings
A. A biopsy is more likely than cytological examination to demonstrate organisms.
B. Multiple samples are taken when biopsying bone to increase the likelihood of finding organisms.
C. Special stains (PAS, Gridley's fungal, or Gomori methenamine silver) best demonstrate the organisms.

V. Fungal culture and identification
A. *C. immitis* grows readily on a wide variety of agars at room temperature as a white, cotton-like mold that changes to tan or brown with age.
B. Arthrospores from cultures are highly infectious.

VI. Serological evaluation
A. It is used in dogs and cats from endemic areas to make a presumptive diagnosis when clinical signs are suggestive but organisms cannot be demonstrated.
B. Precipitin antibodies are thought to represent immunoglobulin (Ig) M and are detectable 2 to 4 weeks after initial infection.
1. The precipitin test may become negative after 4 to 5 weeks and then positive again in those animals in which dissemination has occurred.
2. False-negative results may occur in early infections, fulminant disease, chronic infections, and immunosuppressed animals.
C. Complement-fixing (CF) antibodies are thought to represent IgG and are detectable shortly after precipitin antibodies.
1. An AGID test is used as a screening test for CF antibodies.
2. The CF titer generally increases with the severity of disease.
3. Low titers (<1:16) may indicate early, very chronic, localized or past infections.
4. Titers >1:32 are suggestive of active, disseminated disease.
5. Higher titers are generally seen in more severe disease.

Differential Diagnosis

Rule out blastomycosis or other systemic fungal diseases.

Treatment

I. Ketoconazole 5 to 15 mg/kg PO BID or itraconazole 5 to 10 mg/kg PO SID is the preferred treatment.
A. Fluconazole or ketoconazole are generally used, because they are less expensive than itraconazole.
B. Treatment is continued for at least 2 months beyond clinical remission, often for at least 6 to 12 months.
C. Itraconazole treatment may allow for a shorter course of treatment, but limited studies exist in dogs.
D. Chronic low-dose therapy beyond the initial treatment period may be necessary to keep some animals in remission.

II. Coccidioidomycosis is less responsive to amphotericin B than the other systemic fungal infections.

Monitoring of Animal

I. Resolution of clinical signs is the best means of monitoring response to therapy.
II. Initial in-hospital monitoring include daily vital signs, body weight, and physical and/or ocular examinations.
III. Monthly examinations also include a serum biochemistry profile to evaluate liver enzyme activities for animals receiving azole antifungals.
IV. Cataracts may occur in dogs on long-term (>12 months) ketoconazole.
V. Animals are reevaluated 3 and 6 months after discontinuing therapy to assess for relapse.
VI. Serological evaluation has been used to monitor response to therapy and to evaluate for relapses.
A. CF titers may stay elevated for >1 year following therapy.
B. CF titers should be <1:16 when therapy is discontinued.
C. CF titers often increase with relapses.

VII. Prognosis is variable.
A. The prognosis is good for animals with only pulmonary signs.
B. The prognosis is guarded with disseminated disease; although most animals respond well initially, relapse is common when treatment is discontinued.
C. The prognosis is poor with CNS involvement or involvement of multiple bones.
D. If untreated, disseminated disease is usually fatal.

CRYPTOCOCCOSIS

Definition

I. Cryptococcosis is an opportunistic, systemic, fungal infection of worldwide significance that usually originates in the nasal cavity, paranasal tissues, or lungs and is then disseminated to the skin, eyes, or CNS.
II. Cats are most commonly affected.
III. Unlike the other systemic mycoses, it does not follow any specific geographic boundaries.

Causes

I. It is caused most commonly by *Cryptococcus neoformans* and *Cryptococcus gattii.*
II. *C. neoformans* is the species that most commonly causes clinical disease in cats and is usually associated with pigeon droppings or other avian habitats.
A. *C. gattii* is geographically more restricted and is associated with bark and leaf litter of certain Eucalyptus trees in tropical and subtropical environments.

B. In tissues and cultures, the organism is a variably sized yeast (3.5 to 7 μm), with a large heteropolysaccharide capsule (1 to 30 μm thick).
C. Temperature-sensitive strains may produce hyphae within nasal tissues.
D. The organism primarily reproduces by budding from a narrow base.
E. Under controlled laboratory conditions, the organism undergoes sexual reproduction, but most infections are thought to be caused by environmental exposure to the yeastlike phase.

III. Pigeons are thought to be the most important vector of *C. neoformans.*
A. *C. neoformans* can be found in high numbers in pigeon roosts, barn lofts, hay mows, and along cupolas and cornices where pigeons often sit.
B. In the desiccated state, the organism may be ≤1 μm in size and may survive up to 2 years.
C. Direct exposure to sunlight or soil quickly kills the organism.

IV. *C. neoformans* may be found in nasal washings from dogs and cats as an incidental finding but may also progress to clinical disease.

Pathophysiology

I. Infection is most commonly via inhalation of yeast organisms from the environment.
A. Most yeast are probably too large to be inhaled directly into the lungs but tend to settle in the nasal passages.
B. Small, desiccated forms of the yeast are infective and can be inhaled directly into the small airways and alveoli.

II. After inhalation, nasal, paranasal sinus, or pulmonary granulomas form.
A. Dissemination may occur by direct extension or by hematogenous spread.
1. Direct extension through the cribriform plate to the CNS or to the paranasal soft tissues or skin is common.
2. Although dissemination to any organ can occur, the skin, eyes, and CNS are most commonly affected.
B. Lesions often exist as either granulomatous inflammation with few organisms or as gelatinous masses of organisms with little inflammation.
C. The capsule surrounding the cryptococcal organism contributes to its pathogenicity by inhibiting phagocytosis, plasma cell function, and leukocyte migration.

III. The immune response determines the severity of clinical disease.
A. Antibodies are not protective.
B. Recovery is dependent on cell-mediated immunity.
1. Immunosuppression has not been an apparent problem in infected cats and dogs.
2. An association with FeLV and FIV infections in cats appears unlikely (Flatland et al., 1996).
3. Prolonged glucocorticoid use may be a predisposing factor.

IV. Cryptococcosis is not a contagious disease.

Clinical Signs

I. Feline cryptococcosis
A. No apparent breed or sex predilection exists.
B. Clinical findings are usually related to upper respiratory, cutaneous, ocular, or CNS involvement.
C. Depression and anorexia are common in chronic cases, but fever is uncommon.
D. Upper respiratory signs related to nasal cavity involvement are seen in 50% to 80% of cats.
1. Sneezing and unilateral or bilateral mucopurulent nasal discharge, ± blood, are typically seen.
2. Proliferative soft tissue masses or ulcerative lesions within the nasal passage or on the bridge of the nose are seen in approximately 70% of cases with upper respiratory involvement (Malik et al., 1992).
3. Nasopharyngeal granulomas resulting in snoring, stertor, and inspiratory dyspnea are occasionally seen (Malik et al., 1997a).
E. The lungs are affected less often than in the other systemic mycoses.
F. Oral ulcerations are occasionally seen.
G. The skin and subcutaneous tissues are affected in approximately 30% to 50% of cats (Malik et al., 1992).
1. Papules or nodules are the primary lesions; multiple lesions are typical, and larger lesions are usually ulcerated.
2. Regional lymphadenopathy is common.
H. The eyes are affected in 20% to 25% of cats, especially those with CNS involvement.
1. Granulomatous chorioretinitis, with or without exudative retinal detachment, is the most common lesion and may lead to a panophthalmitis.
2. Optic neuritis may cause acute blindness.
3. Anterior uveitis is present in some cats.
I. CNS involvement is reported in approximately 25% of cats (Gerds-Grogan and Dayrell-Hart, 1997; O'Brien, et al, 2004).
1. Behavioral changes, seizures, circling, and ataxia occur.
2. Head pressing, cranial nerve (CN) deficits, and paresis may also occur.
J. Hematogenous spread from the respiratory tract may result in lameness (osteomyelitis), renal failure, and generalized lymphadenopathy.

II. Canine cryptococcosis
A. Large-breed dogs <4 years of age are most commonly affected.
B. The American cocker spaniel, Labrador retriever, Great Dane, border collie, boxer, Dalmatian, German shepherd dog, and Doberman pinscher are overrepresented.
C. Clinical findings are most often related to CNS, upper respiratory, ocular, or cutaneous involvement.
D. Depression and anorexia are common, but fever is uncommon.
E. CNS involvement occurs in approximately 50% to 80% of dogs (Berthelin et al., 1994a, 1994b).
1. The brain is most often affected, but involvement of the spinal cord may also occur.

2. Neurological signs include mental depression, vestibular syndrome, ataxia, CN deficits (especially CN V, VII, and VIII), seizures, paresis, blindness, hypermetria, and cervical pain.
3. Most dogs with CNS involvement have other affected organ systems.

F. Upper respiratory tract or perinasal tissues are affected in approximately 50% of dogs (Malik et al., 1995).
1. Caudal nasal passages and frontal sinuses are affected more commonly than are the rostral nasal passages.
2. Respiratory signs include upper airway stridor, nasal discharge and sneezing, epistaxis, and firm swellings on the bridge of the nose or periorbitally.

G. Eyes or periorbital tissue are affected in approximately 20% to 40% of dogs.
1. Granulomatous chorioretinitis, with or without exudative retinal detachment, is the most common lesion and can lead to panophthalmitis.
2. Retinal hemorrhage or retinal scarring may be seen.
3. Optic neuritis may cause acute blindness.
4. Anterior uveitis is less common than posterior segment disease.

H. The skin is affected in approximately 10% to 20% of dogs.
1. Subcutaneous nodules with ulcerative draining lesions are typical.
2. The head, footpads, nail beds, and oral mucous membranes are common sites.

I. Proliferative lesions in the external ear canals, and direct extension from the ear canals to the CNS may occur.

J. Multiorgan dissemination is common, may be subclinical, or may result in clinical signs.

Diagnosis

I. Hematological and serum biochemistry findings.
A. They are often normal, but mild nonregenerative anemia and mature neutrophilia, with a left shift, may be seen.
B. Serum biochemistry findings are usually normal.

II. CSF analysis
A. CSF pressure and protein levels are often increased, and a mixed mononuclear and neutrophilic pleocytosis is common.
B. Organisms are seen in approximately 90% of dogs with CNS involvement.

III. Radiographic findings
A. Thoracic radiographs are usually normal, but a nodular to interstitial lung pattern, pleural effusion, and tracheobronchial lymphadenopathy can occur.
B. Nasal radiographs may demonstrate increased soft tissue density and bony destruction in the nasal passages and frontal sinuses.

IV. Organism identification
A. Cytological testing is the quickest and easiest means of identifying cryptococcal organisms.
1. Nasal swabs, exudate from cutaneous lesions, or aspirates from soft-tissue masses, subretinal lesions, or vitreous often reveal organisms.
2. Organisms may not be apparent in approximately 25% of animals (Medleau and Barsanti, 1990).
3. The organism's thin wall and large capsule, as well as its budding from a narrow base, help differentiate it from *Blastomyces* spp.

B. Histopathological findings are as follows:
1. Nodular to diffuse granulomatous lesions or areas of degeneration with limited inflammation are seen in infected tissue, and yeastlike organisms are usually numerous.
2. Special stains (PAS, Gridley's fungal, and Gomori methenamine silver) best demonstrate the organisms.
3. Mucicarmine stains demonstrate the organism's capsule.

C. Fungal culture can also be used for identification.
1. The organism can be cultured from infected tissue, exudate, CSF, urine, joint fluid, and blood if sufficient samples are submitted.
2. Yeastlike growth occurs in 2 to 42 days on Sabouraud's dextrose agar.
3. Hyphae rarely grow, even at 37° C.

V. Serology
A. It is very useful when cytological testing fails to demonstrate organisms.
B. Latex agglutination (LA) detects cryptococcal capsular antigen and is the preferred test.
C. Commercially available LA tests can be used on serum, urine, or CSF.
1. CSF is the preferred sample in animals with neurological signs.
2. Serum is the preferred sample in animals with other signs.

D. False-negative LA antigen titers may occur with localized disease.
E. False-positive LA antigen titers are uncommon and are usually related to technique or interfering substances, such as rheumatoid factor.
F. LA antigen titer tends to correlate well with the extent of disease and may be used to evaluate the effectiveness of treatment (Malik et al., 1996b).
G. Sensitivity and specificity are both 90% to 100%.
H. Detection of serum or CSF antibodies is not a useful diagnostic tool.

Differential Diagnosis

I. Other upper respiratory diseases: primary nasal neoplasia, nasal aspergillosis, other nasal fungal infections, nasal foreign body, chronic viral sinusitis in cats, oronasal or oroantral fistula, tooth root abscess

II. CNS disease: toxoplasmosis (primary differential in cats)

III. Cutaneous disease: see differential diagnoses for Blastomycosis

IV. Ocular disease: see differential diagnoses for Blastomycosis

Treatment

I. Fluconazole 2.5 to 10 mg/kg PO BID is effective and may be the preferred treatment in cats, because it causes fewer side effects and is less expensive than amphotericin B. (O'Brien et al., 2006).

A. Fluconazole is the least expensive means of treatment and may require the fewest months of therapy.
B. Cats with CNS involvement are probably more effectively treated with protocols that contain amphotericin B.

II. Itraconazole 10 mg/kg PO SID or divided BID is also effective in cats and dogs, but treatment time is longer (mean >8 months) (Medleau et al., 1995; O'Brien et al., 2006).
III. Amphotericin B is the most effective drug in vitro against the various cryptococcal isolates.
A. Amphotericin B lipid complex (2 mg/kg IV 3 times per week for 12 treatments) is recommended as the form of the drug that will reduce toxicity and allow for the highest cumulative amounts to be administered (see under Blastomycosis).
B. Amphotericin B is synergistic with flucytosine 25 to 50 mg/kg PO QID, and the combination is useful in CNS infections.
1. CSF concentrations of flucytosine approach those of serum.
2. Cryptococcal organisms may rapidly develop resistance to flucytosine, so it has limited efficacy as a single treatment agent.
3. Toxicity to flucytosine includes ulcerative drug eruptions of the skin (especially of the face and mucocutaneous junctions), enterocolitis, leukopenia, and thrombocytopenia.
4. The dose of flucytosine is decreased in animals with advancing renal failure.
C. Amphotericin B in combination with azole antifungals or flucytosine has been used to successfully treat feline and canine cryptococcosis.
D. Amphotericin B (deoxycholate formulation) can be used SC in a protocol that has been shown to reduce toxicity and costs associated with administration.
1. When given SC, amphotericin (0.5 to 0.8 mg/kg) is diluted in 0.45% saline/2.5% dextrose solution (400 mL for cats, 500 mL for dogs <20 kg; 1000 mL for dogs >20 kg) and administered 2 to 3 times per week.
2. This protocol may allow for larger cumulative doses of amphotericin because of reduced toxicity.
3. Amphotericin B has been used SC to reduce nephrotoxicity; concentrations >20 mg/L cause local irritation.

IV. Ketoconazole (10 to 30 mg/kg PO BID) is slightly less effective.
V. Large lesions, especially those affecting the bridge of the nose, often require surgical reduction before medical therapy.

Monitoring of Animal

I. Resolution of clinical signs is the best means of monitoring response to therapy.
II. In-hospital monitoring includes daily vital signs, body weight, and physical and/or ocular examinations.
III. Monthly examinations include a serum biochemistry profile to evaluate liver enzyme activities for animals receiving azole antifungals and LA antigen titer.
IV. Treatment is continued until clinical signs have resolved and LA antigen titers are negative or have been low and stable for several months.
A. LA antigen titers that drop after treatment indicate that the treatment is having an effect.
1. A tenfold drop at the end of 2 months indicates a favorable prognosis.
2. No change in titer after 2 months may indicate the need for a change in treatment.
B. LA antigen titer is also monitored after discontinuing treatment.
1. An increasing titer indicates that clinical relapse is likely.
2. A low-positive titer that does not increase is seen in some cats that are clinically cured.

V. Animals are reevaluated 3 and 6 months after discontinuing therapy to assess for relapses.
VI. The prognosis is good for cats with extraneural disease; however, cats with FeLV or FIV may require longer therapy.
VII. The prognosis is guarded for dogs with any form of the disease and for cats with CNS involvement.

PYTHIOSIS AND LAGENIDIOSIS (OOMYCOSIS)

Definition

I. Pythiosis is an uncommon infectious disease in dogs and cats.
II. Most infections occur in dogs; cats are only rarely infected.
III. It occurs mainly in tropical and subtropical areas of the world.
IV. In the United States, it occurs primarily along the Gulf of Mexico, mostly in southern Louisiana, Texas, Alabama, and Florida, but cases in the eastern, western, and midwestern states are being reported more frequently.

Causes

I. Pythiosis is caused by a protistan member of the Oomycetes class, *Pythium insidiosum,* which is evolutionarily more closely related to algae than to true fungi.
II. *P. insidiosum* grows in tissues and the environment as thick-walled, septate hyphae.
III. In an aquatic environment, it produces motile zoospores.
IV. *Lagenidium* spp. is the cause of a similar disease in dogs (Grooters, 2003).

Pathophysiology

I. The infective stage is thought to be the motile zoospore.
A. Zoospores are released into a warm water environment, where they are able to chemotactically orient themselves toward certain aquatic plants and animal hair.
B. They enter the host through damaged skin or mucous membranes.

II. *P. insidiosum* is considered to be a true pathogen rather than an opportunist because immune suppression is not a prerequisite for infection.

III. Three forms of pythiosis include cutaneous disease (most common in cats), GI disease (predominantly in dogs), and rare multisystemic disease.
IV. In the GI form of the disease, any part of the GI tract may be affected, but the stomach and proximal small intestine are affected most commonly.
  A. Occasionally only the mesenteric lymph nodes are affected.
  B. Diffuse to irregular transmural thickening of a segment (5 to 25 cm) of the GI tract, with variable irregular mucosal ulceration occurs.
V. Arterial thrombosis and arterial disruption from growing *Pythium* spp. and the inflammatory processes may occur, and probably account for rare cases of multisystemic involvement.

Clinical Signs

I. Canine GI pythiosis
  A. Male, large-breed (especially hunting breeds) dogs <3 years old are most likely to be infected.
  B. Vomiting, pronounced weight loss, and a palpable abdominal mass are typical clinical findings.
  C. Other signs may include regurgitation if the esophagus is involved, diarrhea if the distal small intestine is affected, or hematochezia if the colon is involved.
  D. Presentation is often late in the disease, because affected dogs usually remain bright and alert.
  E. Signs of systemic illness occur when intestinal obstruction, infarction, or perforation occur.
II. Canine cutaneous pythiosis
  A. Cutaneous disease is less common than the GI disease.
  B. The German shepherd dog may be predisposed.
  C. Cutaneous lesions may occur anywhere.
    1. Slightly pruritic, poorly defined nodules that soon become ulcerated are typical.
    2. Multiple tracts may drain a serosanguineous or purulent exudate.
    3. Rarely, they are complicated by GI involvement.
  D. Dogs with cutaneous pythiosis rarely have systemic involvement.
III. Canine lagenidiosis is characterized by cutaneous signs that are similar to pythiosis.
  A. Affected dogs usually have systemic involvement.
  B. Great vessels, sublumbar and inguinal lymph nodes, lungs, the cranial mediastinum, and the pulmonary hilus are often involved.
IV. Feline pythiosis is rare.
  A. Most cats have cutaneous disease.
  B. Nasal and retrobulbar disease may also be seen.

Diagnosis

I. Hematological and serum chemistry findings are usually normal.
II. Radiographic and ultrasonographic findings are variable.
  A. An abdominal mass with or without an obstructive pattern may be seen on abdominal radiographs.
  B. Esophagitis induced by *Pythium* spp. may result in megaesophagus.
  C. Ultrasonography may reveal markedly thickened intestinal or gastric walls with loss of the normal layered pattern.
III. Organism identification involves the following:
  A. Histologically, a presumptive diagnosis can be made based on the morphological examination of the hyphal organisms and the inflammatory response pattern.
    1. A pronounced granulomatous or eosinophilic inflammatory response is seen.
    2. *Pythium* spp. and *Lagenidium* spp. do not stain well on H&E–stained sections.
    3. Gridley-stained or Gomori methenamine silver–stained sections are best used to identify hyphae.
    4. An immunohistochemical staining technique is also useful in identifying hyphal organisms, such as *Pythium* spp., and for differentiating them from *Lagenidium* spp. or other Zygomycetes.
  B. Fungal culture and identification are as follows:
    1. *Pythium* spp. is relatively easy to culture on a variety of fungal culture media.
    2. Failure to grow the organism is usually related to sample handling.
    3. *Pythium* spp. are sensitive to temperature stress and dehydration.
      a. Freezing of samples results rapidly in organism death.
      b. Chilling samples for short periods does not seem to reduce the likelihood of successful culture.
IV. Serological findings
  A. Antibody titers via ELISA appear sensitive in diagnosing pythiosis and lagenidiosis.
  B. A polymerase chain reaction (PCR) assay has been developed for use on tissue and blood that is able to differentiate between *Pythium insidiosum* and *Lagenidium* spp.

Differential Diagnosis

I. With the GI form of disease, rule out neoplasia, such as lymphosarcoma or adenocarcinoma.
II. True Zygomycetes such as *Mucor* spp., *Absidia* spp., or *Rhizopus* spp. infections, as well as *Basidiobolus* spp. and *Conidiobolus* spp. infections, must be differentiated from pythiosis.
III. Differential considerations for the cutaneous form of disease are the same as for blastomycosis.

Treatment

I. Wide surgical excision is the preferred treatment.
II. Amphotericin B and ketoconazole have been unsuccessful in resolving the disease.
III. Itraconazole 10 mg/kg PO SID to BID and terbinafine 10 mg/kg PO SID are efficacious in approximately 10% to 20% of dogs
IV. Amphotericin B lipid complex 2 mg/kg IV QOD for 12 treatments has been successful in some cases.
V. The prognosis is generally poor if surgical resection is not possible.

Monitoring of Animal

I. Resolution of clinical signs and weight gain are the primary monitoring tools.
II. It may take a month or more before improvement occurs with itraconazole and terbinafine therapy.
III. Abdominal palpation or ultrasonography can be used to assess the size of the abdominal mass.
IV. Serological evaluation is an effective means of evaluating surgical success and for recurrence.

CHAPTER 112

Viral Infections

Leah A. Cohn | Paige Langdon

CANINE CORONAVIRUS

Definition

I. Canine coronavirus (CCV) causes contagious enteritis of variable severity (rarely fatal) in young dogs.
II. The true significance of this pathogen in juvenile diarrhea is not fully known, but it may contribute to the morbidity and mortality of other infectious enteropathies, such as canine parvovirus (CPV) (Pratelli et al., 2004).

Cause and Pathophysiology

I. CCV, a single-stranded (SS) ribonucleic acid (RNA) virus of the family Coronaviridae, is closely related to feline coronavirus and transmissible gastroenteritis virus of pigs.
II. CCV is highly contagious via fecal–oral transmission.
III. Fecal shedding results in environmental contamination, an important route of exposure.
IV. CCV infects any age group, but clinical disease is usually seen only in very young puppies.
V. After ingestion, the virus localizes in the villus tips of the small intestines, where it replicates and results in villous atrophy and crypt cell hyperplasia.

Clinical Signs

I. Adults
   A. Infected, seronegative adult dogs usually asymptomatic
   B. Possibly mild gastrointestinal (GI) signs
II. Puppies
   A. Acute onset of mild to severe, ± bloody diarrhea in neonatal and very young puppies
   B. Lethargy, anorexia, vomiting ± dehydration
   C. Typically self-limiting, but possibly life-threatening

Diagnosis

I. Suspicious signalment, history, and clinical presentation
II. Clinical pathology: findings nonspecific, leukopenia not recognized
III. CCV-specific testing
   A. Virus identification is rarely necessary or indicated.
   B. Fourfold rise in immunoglobulin (Ig) G titer on paired serum samples is supportive, but rarely performed.
   C. Direct viral detection may be performed on feces.
      1. Electron microscopy (EM)
      2. Enzyme-linked immunosorbent assay (ELISA)
      3. Intestinal tissue fluorescent antibody (FA) testing (Tuchiya et al., 1993)
   D. Viral detection may also be done with intestinal tissue immunohistochemistry (Evermann et al., 2005).
   E. CCV can also be detected in the feces of clinically healthy dogs (Tennant et al., 1993).

Differential Diagnosis

I. Canine parvovirus
II. Parasites, bacterial enteritis
III. Canine distemper virus (CDV), canine herpesvirus (CHV)
IV. Toxins, foreign bodies, intussusception, or metabolic diseases

Treatment

I. Supportive care may be instituted, although many dogs require no therapy.
II. See Box 112-1 for treatment of GI signs.

Monitoring and Prevention

I. The need for routine CCV vaccination is questionable, although inactivated and modified live virus (MLV) vaccines are available for at-risk populations.
II. Avoid exposure of young puppies to potentially contaminated environments.
III. CCV is inactivated by various disinfectants (Table 112-1).
IV. Viral shedding may occur for up to 6 months postinfection (Pratelli et al., 2004).

CANINE DISTEMPER VIRUS

Definition

I. CDV is a highly contagious virus with either focal or multisystemic manifestations, and variable morbidity and mortality.
II. Respiratory, GI, and neurological tissues are all targets.

Cause and Pathophysiology

I. CDV is a SS-RNA virus of the family Paramyxoviridae and is closely related to measles virus of primates and rinderpest in domestic livestock.
II. CDV is highly contagious.
   A. Large viral concentrations occur in respiratory secretions.
   B. It is commonly spread by aerosolization.

Box 112-1

Therapy for Gastrointestinal Manifestations of Viral Disease*

1. Animals with vomiting ± moderate to severe diarrhea are kept NPO.
2. Crystalloids (LRS, Plasmalyte, 0.9% NaCl) via parenteral routes (IV, intraosseous, SC) are indicated to rehydrate, replace ongoing losses, and maintain hydration.
   a. Maintenance: 55-66 mL/kg/day; rehydration and losses must be estimated and added to the maintenance fluid rate.
   b. SC fluids are not effective for moderate to severe dehydration.
   c. Potassium and dextrose supplementation are often required.
3. Colloid therapy is indicated for moderate to severe hypoalbuminemia and hypotension.
   a. Hydroxyethyl starch (Hetastarch): give 10 mL/kg in dogs, 5 mL/kg in cats IV bolus or 20-30 mL/kg/day CRI.
   b. Plasma provides minimal oncotic support.
4. Antiemetics may be useful if obstructive GI disease is ruled out, especially when risk of aspiration exists.
   a. Metoclopramide 0.2-0.4 mg/kg SC BID-TID or 1-2 mg/kg/day IV as CRI (dogs)
   b. Prochlorperazine 0.1-0.5 mg/kg IM, SC TID or chlorpromazine 0.2-0.4 mg/kg IM, SC TID (dogs)
      (1) Contraindicated in hypotensive or dehydrated animals
      (2) May cause sedation; contraindicated with seizure disorders
   c. Ondansetron 0.1-0.2 mg/kg SC, IV BID-QID for intractable vomiting
5. Antibiotics BID-QID are given for hemorrhagic diarrhea, neutropenia, or suspected bacterial infection.
   a. Ampicillin 10-20 mg/kg IV TID-QID; gram-negative coverage may be inadequate
   b. Enrofloxacin 2.5-5.0 mg/kg SC BID for dogs; relatively contraindicated in growing puppies and kittens owing to potential cartilage damage
   c. Gentamicin 6-6.6 mg/kg IV, IM, or SC SID or amikacin 15-30 mg/kg IV, IM, or SC SID
      (1) Contraindicated in dehydration, hypotension, or renal failure
      (2) May cause renal failure, ototoxicity
      (3) Covers gram-negative bacteria only
   d. Cefazolin 22 mg/kg IV TID with enrofloxacin or gentocin
   e. Cefoxitin 22 mg/kg IV TID
6. H_2-blocker therapy may decrease gastric acidity and its associated complications.
   a. Famotidine 0.5-1.0 mg/kg IV, SC, or IM SID-BID
   b. Cimetidine 5-10 mg/kg IV, SC, or IM TID
   c. Ranitidine 2 mg/kg IV BID
7. Adjunctive therapy includes the following:
   a. Animals on NPO restrictions for 3 days or longer require parenteral nutrition.
   b. Whole blood, packed RBCs, or blood substitute are indicated for anemia.
   c. Routine nursing care is critical to keep IV sites clean and prevent urine or fecal scald.
8. Recovery and realimentation are important.
   a. Small amounts of water are offered 12-24 hours after cessation of vomiting.
   b. If no vomiting occurs within 12-24 hours of water administration, small amounts of a bland diet are offered every 2-3 hours.
   c. Animals are gradually weaned onto maintenance requirements of a bland diet over 2-4 days.
   d. Bland diet is maintained for 1-3 weeks, followed by gradual reintroduction of a diet appropriate for age.

NPO, Nothing by mouth; *LRS*, lactated Ringer solution; *CRI*, constant rate infusion; *GI*, gastrointestinal; *H_2*, histamine$_2$; *RBCs*, red blood cells.
*Doses are recommended for both dogs and cats unless otherwise specified.

C. Infective virus is also present in urine and other bodily fluids.
D. Recovered dogs shed the virus for 60 to 90 days postinfection (Greene and Appel, 2006).

III. The virus is viable in cold and freezing environments, but susceptible to heat, drying, and ultraviolet light.
IV. Younger animals are most susceptible to infection.
V. Susceptibility is enhanced in older dogs not adequately vaccinated and with either concurrent stress or immunosuppressive conditions.
VI. During systemic infection, CDV contacts upper respiratory epithelium; replicates within respiratory lymphatics; eventually disseminates to other lymphatic tissues, intestines, and liver; and produces viremia.
   A. Host immunity may be suppressed by the virus.
   B. Several outcomes are possible, depending on immunity and antibody (Ab) response.
      1. Adequate immunity
         a. Virus cleared with no illness
         b. Central nervous system (CNS) invasion possible
      2. Partial immunity
         a. Virus spreads to epithelial tissues and CNS
         b. Mild or subclinical illness
         c. Virus partially cleared, CNS persistence possible
      3. No immunity
         a. Viremia, epithelial and CNS infection, and viral persistence
         b. Illness often severe and fatal
VII. CNS infection is common, but the exact mechanism of entry into the CNS is unknown.
   A. Direct viral injury in animals with poor immunity results in acute multifocal encephalitis of gray and white matter.
   B. White matter lesions of demyelination are possible, and this noncytolytic form does not induce inflammatory changes.
   C. Chronic CNS infection leads to progressive dysfunction or relapse months to years after subclinical

TABLE 112-1

Efficacy of Common Disinfectants against Viruses

DISINFECTANT CLASS	ENVELOPED VIRUS*	NONENVELOPED VIRUS†
Alcohols		
Ethyl alcohol	+	+
Isopropyl alcohol	+‡	–
Aldehydes (gluteraldehyde)	+	+
Bisguanide (chlorhexidine)	+‡	±
Halogens		
Hypochlorite (bleach)	+	+
Iodines (tinctures)	+	±
Iodophores (providone-iodine)	+	±
Peroxygens (hydrogen peroxide)	+	+
Phenolics *(Lysol)*	+	±
Quartenary ammonium	+	–

Data from Greene CE: Environmental factors in infectious disease. p. 673. In Greene CE (ed): Infectious Diseases of the Dog and Cat. 2nd Ed. WB Saunders, Philadelphia, 1998; Love BC, Hirsch DC: Disinfectant and antiseptic use in small animal practice. p. 258. In Bonagura JD (ed): Kirk's Current Veterinary Therapy XIII: Small Animal Practice. WB Saunders, Philadelphia, 2000.

+, Susceptible; ±, somewhat susceptible; –, not susceptible.

*Enveloped viruses include canine distemper, coronaviruses, herpesviruses, rabies virus, and feline leukemia and immunodeficiency viruses.

†Nonenveloped viruses include canine adenoviruses, parvoviruses, and feline calicivirus.

‡Rabies virus is not susceptible.

infection or apparent recovery (also called *old dog encephalitis*).

Clinical Signs

I. Mild or subclinical infection
   A. Mild lethargy, fever
   B. Cough, oculonasal discharge possible
   C. Often unnoticed
II. Systemic infection
   A. Most common in young puppies, unvaccinated adults, and immunosuppressed animals
   B. First clinical signs: fever and general malaise
   C. Respiratory signs common
      1. Serous or mucopurulent oculonasal discharge soon after onset of fever
      2. Dry cough that becomes productive, and/or dyspnea
   D. GI signs common
      1. Anorexia, vomiting, dehydration, diarrhea
      2. Shock from hypovolemia or secondary bacterial sepsis and/or endotoxemia
III. CNS infection
   A. Signs often occur 1 to 3 weeks after recovery from systemic signs, but may be delayed for months to years after infection (Greene and Appel, 2006).
   B. CNS manifestations may be the only signs of CDV infection.
   C. CNS signs vary from multifocal to localized, with variable progression.
   D. Neurological signs include seizures, vestibular disease, myoclonus, behavioral changes, hyperesthesia, tetraparesis, paraparesis, and cervical pain.
      1. Myoclonus (involuntary, repetitive muscle contraction of a specific area) is common, with or without other CNS signs.
      2. Classic focal facial seizures ("chewing gum seizures") may occur.
IV. Additional manifestations
   A. Dermatological: hard pad disease
   B. Ocular: keratoconjunctivitis sicca, chorioretinitis
   C. Dental enamel hypoplasia (pock marks)
   D. Transplacental infection possible

Diagnosis

I. Compatible signalment, history, and clinical presentation
II. General diagnostic tests
   A. Hematological evaluation: lymphopenia common with acute infections
   B. Rarely, pathognomonic cytoplasmic inclusions in blood cells or conjunctival scrapings
   C. Hyperglobulinemia and hypoalbuminemia, or hypoglobulinemia with transplacental or neonatal infection
   D. Cerebrospinal fluid (CSF) analysis
      1. Lymphocytic pleocytosis (>5 to 10 cells/μL) and increased protein (>25 mg/dL) common
      2. Inclusion bodies rare
      3. Possibly normal in noninflammatory demyelinating disease
   E. Radiography
      1. Thoracic radiographs normal, or possibly interstitial or alveolar patterns
      2. Intussusception ruled out with abdominal radiographs and/or ultrasonography
III. CDV-specific testing
   A. Elevated serum Ab titers as detected by virus neutralization or ELISA support the diagnosis.
      1. Increased IgG titer indicates vaccination or either prior or recent CDV infection.
      2. A fourfold rise in IgG titers from paired serum samples suggests recent infection.
      3. Increased IgM titers without recent vaccination suggest acute infection.
   B. CSF Ab titers, if uncontaminated by blood, provide direct evidence of CNS infection.
      1. Vaccination does not produce detectable antibodies within the CSF.
      2. To rule out the possibility that serum Ab has contaminated CSF, a ratio of serum to CSF titers is compared for CDV and another vaccine component, such as canine adenovirus-2.
   C. FA testing performed on conjunctival or other epithelial scrapings, CSF, buffy coat, or bone marrow often yields false-negative results.
   D. Histopathologic evaluation may demonstrate inclusion bodies.

Differential Diagnosis

I. Respiratory signs: infectious tracheobronchitis, aspiration, bacterial or parasitic pneumonia, rickettsial diseases, dysautonomia
II. GI signs: CPV or CCV, bacterial enteritis, toxin ingestion, foreign bodies, intussusception, metabolic disease
III. Neurological signs: hypoglycemia, toxins, hepatic encephalopathy, hypocalcemia, rabies, other causes of CNS disease (see Chapter 23).

Treatment

I. Maintain adequate hydration.
II. Administer antibiotics for secondary bacterial infections.
III. Provide good nursing care with physical therapy (chest coupage) as needed.
IV. Consider the use of bronchodilators.
V. CNS therapy may involve the following:
   A. Phenobarbital 2.5 mg/kg PO, IM, or IV BID to TID
   B. Diazepam 0.3 to 1.0 mg/kg IV to effect or 1 to 2 mg/kg per rectum during seizures
   C. Diazepam, pentobarbital, or propofol IV for refractory or recurrent seizures (see Chapter 22)
   D. Myoclonus often refractory to medication and usually persists for life
   E. Prednisone 0.5 to 1.0 mg/kg/day PO for 2 weeks, with gradual tapering, for progressive CNS signs, refractory seizures, and late-onset encephalitis

Monitoring and Prevention

I. Isolate sick dogs.
II. Maternal Ab is usually gone by 12 weeks of age, but may interfere with initial vaccination (Greene and Appel, 2006).
III. MLV vaccines are administered 3 to 4 weeks apart, with at least one vaccine given after maternal Ab has waned.
   A. Annual to triennial vaccines are currently recommended to booster protection (Table 112-2).
   B. Measles vaccine provides cross-protection against CDV and may be given as an initial puppy vaccination at 6 to 12 weeks, when maternal Ab interferes with CDV vaccine response.
   C. Inactivated (i.e., killed virus) vaccine is used in pregnant or immunosuppressed animals, but it confers a lower degree and duration of immunity than MLV vaccines.
   D. MLV vaccines are contraindicated in pregnant or immunosuppressed animals.
IV. Vaccination complications can occur.
   A. Encephalitis may develop in severely immunosuppressed puppies or in puppies whose dam received MLV vaccination while pregnant.
   B. CDV vaccine is inactivated by hyperthermia, and an attenuated response may occur with concurrent parvovirus infection or chemotherapy (Greene and Appel, 2006).
V. Recovery from natural infection provides prolonged immunity.
VI. CDV is inactivated by various disinfectants (see Table 112-1).

CANINE HERPESVIRUS

Definition and Cause

I. CHV is a relatively common infection, but an uncommon cause of disease.
II. When disease occurs, it causes abortions in pregnant bitches or a fatal hemorrhagic disease in puppies <3 weeks of age.
III. CHV, a double-stranded DNA virus of the family Herpesviridae, infects only Canidae.

TABLE 112-2

Viral Vaccination Recommendations for Adult Dogs*

VIRUS	ADMINISTRATION FREQUENCY	COMMENTS
Core vaccines†		
Canine distemper	1 year, then every 3 years for MLV or recombinant product	Annual booster vaccines are suggested by some manufacturers; distemper-measles vaccine should never be used in adult dogs
Canine adenovirus-2	1 year, then every 3 years	Parenteral MLV forms are generally preferred to killed or topical MLV vaccines
Canine parvovirus	1 year, then every 3 years for MLV vaccines	Efficacy may last >3 years
Rabies	1 year, then every 1 to 3 years	Local regulations impact frequency of booster vaccines
Noncore vaccines†		
Canine parainfluenza virus	1 year, then every 3 years	Intranasal or parenteral forms

Adapted from Canine Vaccine Task Force: 2006 AAHA canine vaccine guidelines. J Am Anim Hosp Assoc 42:80, 2006.

MLV, Modified live virus.

*Vaccination protocols must be tailored to the individual dog in a given environment. This table provides guidelines only and does not address vaccine recommendations for nonviral diseases (bordetellosis, leptospirosis, borreliosis).

†Core vaccines are recommended for all dogs; noncore vaccines are optional and recommended only in some dogs.

Pathophysiology

I. CHV requires close contact for transmission.
II. It spreads transplacentally at birth or through direct dog-to-dog contact (e.g., during breeding).
III. It is unstable in the environment, so it is rarely transmitted through fomites.

Clinical Signs

I. Consequences of rare, transplacental infection include abortions, stillbirths, weak puppies, and puppies that succumb to neonatal infection.
II. Neonatal infection occurs via exposure to the dam's vaginal secretions at birth or to infected littermates, and is most common during the first 3 weeks of life (Anvik, 1991).
III. Signs in puppies 3 to 5 weeks old may be less severe and include neurological signs, such as trigeminal neuropathy, ataxia, and blindness.
IV. Adults are usually asymptomatic.
    A. Females that appear healthy may experience infertility, abortion, or stillbirths.
    B. Genital lesions include papulovesicular lesions that regress and reappear in both males and females.
    C. CHV may play a minor role in canine respiratory infections.
    D. Latent infections recrudesce in some immunosuppressed dogs (Okuda et al., 1993).

Diagnosis

I. Clinical pathologic evaluation
    A. Limited usefulness in neonates because of sampling difficulty and lack of specificity
    B. Puppies: thrombocytopenia, evidence of disseminated intravascular coagulopathy and increased liver enzyme activity (particularly alanine aminotransferase)
II. CHV-specific testing
    A. Virus isolation from tissues of affected puppies is diagnostic.
    B. Serological testing indicates exposure, but does not diagnose active infection in adults.
    C. Multifocal hemorrhages and necrosis with inclusion bodies in epithelial tissues, or CHV identified in tissue via FA, EM, or polymerase chain reaction (PCR) assays are also conclusive.

Differential Diagnosis

I. Neonatal death
    A. Bacterial septicemia with *Salmonella* spp., *Streptococcus* spp.
    B. Other viral infections: CPV-1, CPV-2, CDV
    C. Protozoal diseases
II. Abortion and stillbirths: brucellosis, leptospirosis, bacterial metritis, CDV, protozoal diseases, endocrinopathies

Treatment

I. Supportive therapy is typically unsuccessful.
II. Provide parenteral fluids with oral or IV dextrose, nutritional support, nursing care, animal warming, and broad-spectrum antibiotics.
III. Hyperimmune serum from recovered dogs may protect other puppies (<5 weeks of age) in an affected litter; administer 1 to 2 mL intraperitoneally (Anvik, 1991; Greene and Carmichael, 2006).
IV. Rapid progression of neonatal disease makes the role of antiviral therapy questionable.
V. Infected adult dogs remain latently infected because there is no way to clear all virus from the body.

Monitoring and Prevention

I. Puppies that are kept warm (37° to 38° C [99° to 100° F]) have lower morbidity and mortality.
II. Although bitches that have recovered from infection usually raise subsequent litters without problems, it is recommended they not be bred again.
III. Isolate young puppies from dogs that might shed viral particles.
IV. A preventative vaccine is available only in Europe.
V. CHV is easily inactivated by most disinfectants (see Table 112-1).

CANINE PARVOVIRUS

Definition

I. CPV causes acute contagious enteritis with a high morbidity and mortality in immunologically naive dogs.
II. Rarely, myocardial disease results from perinatal infection.

Cause

I. Canine parvovirus-2
II. SS-DNA virus of the family Parvoviridae
III. CPV-2b: most common disease-causing strain in the United States
IV. CPV-2: distinct from CPV-1 (including disease manifestations)

Pathophysiology

I. Epidemiological findings
    A. This highly contagious virus is shed primarily in the feces of infected and recovering animals.
    B. Fomites are a more common source of exposure than direct contact with feces, and CPV-2 persists in the environment.
    C. Incidence is higher in summer and late fall (Houston et al., 1996).
    D. Immunologically naive animals (young puppies) are the most susceptible to CPV-2 infection; however, older, immunocompromised animals are also at risk.
    E. Reported breed predispositions include the rottweiler, American pit bull terrier, Doberman pinscher, and German shepherd dog (Houston et al., 1996).
II. Pathogenesis
    A. After oronasal exposure (primary route) initial replication occurs in local lymphoid tissues, with subsequent viremia in 2 to 5 days.
    B. Rapidly dividing tissues (e.g., intestinal crypt cells, bone marrow leukocyte precursors) are preferentially infected; dissemination to the lungs, kidneys, and myocardium is possible.

C. Infection of intestinal crypt cells and leukocyte precursors leads to classic manifestations of the disease.
   1. Crypt necrosis and villous blunting with secondary diarrhea
   2. Neutropenia with increased susceptibility to secondary bacterial infections and sepsis
D. In utero or perinatal infections cause myocardial disease (rare) if insufficient maternal antibody is present.

Clinical Signs

I. Enteritis
   A. Initially anorexia, depression, vomiting, ± fever (Cohn et al., 1999)
   B. Diarrhea, often hemorrhagic
   C. Dehydration with inadequate fluid intake and losses via the GI tract
   D. Hypovolemic or endotoxic shock in severely affected dogs or progressive disease
II. Myocarditis
   A. Entire litter affected (rare)
   B. Sudden death or congestive heart failure

Diagnosis

I. General diagnostic testing
   A. Hematological findings
      1. Neutropenia is a classic finding.
      2. Lymphopenia, anemia, and thrombocytopenia are also possible.
   B. Serum biochemistry: panhypoproteinemia and electrolyte imbalances possible
   C. Abdominal imaging
      1. Nonspecific findings suggestive of enteritis
      2. Used to rule out other intestinal diseases, especially intestinal intussusception
II. CPV-2–specific testing
   A. Fecal ELISA for viral antigen is the most commonly used test, but false positives (MLV vaccine 5 to 12 days previously) and false negatives (limited fecal shedding) occur (McCaw and Hoskins, 2006).
   B. Fecal or intestinal EM, fecal PCR, and virus isolation are rarely used clinically.
   C. Serological testing is rarely performed, but a fourfold rise in convalescent IgG titers is diagnostic.
   D. Histological findings include intestinal crypt necrosis or nonsuppurative myocarditis (rare).

Differential Diagnosis

I. GI signs: CCV, bacterial enteritis, parasites, CDV, CHV, toxins, foreign body, intussusception, metabolic diseases
II. Congestive heart failure: congenital heart disease, protozoal diseases, noncardiogenic pulmonary edema (e.g., electrocution, neurological disease, trauma)

Treatment

I. Antiviral therapy is not necessarily required.
   A. Interferon omega 2.5 million units/kg IV SID for 3 consecutive days (de Mari et al., 2003) may be tried.
   B. Oseltamivir phosphate *(Tamiflu)* is a neuraminidase inhibitor used for influenza virus, and may be given for parvoviral enteritis at 2 mg/kg PO BID for 5 days (anecdotal).
II. GI therapy is outlined in Box 112-1.
   A. Adjunctive therapy involves hyperimmune plasma transfusions (1.1 to 2.2 mL/kg IV) from recovered dogs (Cohn LA, unpublished data, 2006).
   B. Empirical deworming is used to eliminate concurrent intestinal parasites.
   C. Treatment with recombinant human granulocyte colony-stimulating factor (G-CSF) is not beneficial (Rewerts et al., 1998).
   D. CPV-2 infection may be fatal, but many animals fully recover.
III. Myocardial disease is extremely difficult to treat.
   A. Because the disease is rapidly progressive and fatal, therapeutic intervention is rarely attempted.
   B. Treat congestive heart failure in survivors.

Monitoring and Prevention

I. Quarantine unvaccinated animals.
II. Passive immunity is important in neonates.
   A. Maternal Ab titers >1:80 (hemagglutination-inhibition) are protective (McCaw et al., 1997).
   B. Maternal Ab typically protects for 6 to 12 weeks and may interfere with vaccination responses up to 18 weeks of age (Coyne, 2000).
III. Good acquired immunity is achieved through vaccination.
   A. High-titer potentiated MLV CPV-2 vaccines are preferred.
      1. They induce protective immunity in puppies when maternal Ab is present (Larson and Schultz, 1997).
      2. Annual (McCaw et al., 1997) to triennial booster vaccines (see Table 112-2) are recommended.
   B. Low-titer, MLV CPV-2 vaccines do not always protect puppies with high maternal Ab levels, even at 20 weeks of age, but the vaccines do provide adequate protection for older puppies and adults (Hoskins, 1998).
IV. Following natural infection, recovered animals have long-lasting immunity.
V. The virus is resistant to most disinfectants (see Table 112-1).

RABIES VIRUS

Definition and Cause

I. Rabies is an invariably fatal infection resulting in encephalitis in most mammals.
II. Although now rare in domestic animals, the zoonotic potential of this fatal disease makes it crucial that every veterinarian understand the disease.
III. Rabies virus (RV) is an SS-RNA virus if the family Rhabdoviridae.

Pathophysiology

I. Epidemiological findings
   A. RV is maintained in wildlife reservoirs worldwide (e.g., fox, skunk, bat, raccoon).

B. Different wildlife reservoirs predominate in certain geographic areas and carry different RV variants.
C. Cats have a higher incidence of RV infection than dogs in the United States.

II. Transmission
A. It occurs primarily through contact with infectious particles in saliva via bite wounds or contamination of mucous membranes or open wounds.
B. Other minor sources include other body fluids, particularly urine, airborne virus, or ingestion.
C. Rabies in dogs and cats is usually contagious only if a bite exposure occurs.

III. Pathogenesis
A. The virus replicates locally and then spreads along the peripheral nervous system axons to the CNS and back down the peripheral nervous system and cranial nerves to the salivary glands.
B. Inoculation at the head often leads to signs of encephalitis more rapidly than inoculation elsewhere on the body.
C. Viral shedding via saliva typically does not begin until 5 to 10 days before the onset of clinical signs.

Clinical Signs

I. The onset of CNS signs is usually with in 2 to 24 weeks, but depends on the viral load inoculated, the degree of innervation at the site, the proximity of the site to the CNS, and the strain of RV.
II. Classic clinical presentation is either "furious" or "paralytic," but not all cases fit these categories, and a combination of signs is possible.
III. With the furious form of rabies, the disease course lasts only days.
A. Behavioral changes, hyperexcitability, hyperesthesia, and aggression occur.
B. Ataxia and seizures develop and are followed by death.
IV. With the paralytic form, the disease course typically lasts about 1 week.
A. Progressive ascending lower motor neuron paralysis begins at the inoculation site and leads to dysphagia, masticatory muscle paralysis, and laryngeal and pharyngeal dysfunction, with classic signs of salivation.
B. Death is caused by respiratory paralysis.

Diagnosis

I. History of a recent bite wound and classic clinical presentation may be helpful.
II. Clinical pathologic findings are nonspecific.
III. Antemortem testing may confirm RV infection, but cannot adequately rule it out.
IV. Owing to the serious public health implications, euthanasia of animals suspected of RV infection is urgently recommended and often required by law.
V. Postmortem testing confirms or denies the diagnosis.
A. Submit the brain—chilled but not frozen—as soon as possible to a state diagnostic laboratory.
B. Direct FA testing of the brain is the diagnostic method of choice.
C. Additional tests on brain specimens include PCR for viral particles, histopathologic evaluation (intracellular inclusions or Negri bodies), and mouse inoculation (Kasempimolporn et al., 2000).
D. RV strains may be identified to help determine the source of exposure.

Differential Diagnosis

I. Dogs: CDV, acute polyradiculoneuritis, botulism, tick paralysis, pseudorabies, neoplasia, organophosphate intoxication, other intoxications, and other causes of meningitis and encephalitis
II. Cats: toxoplasmosis, feline infectious peritonitis (FIP), feline immunodeficiency virus (FIV), feline leukemia virus (FeLV), pseudorabies, thiamine deficiency, intoxications, and other causes of meningitis and encephalitis

Treatment

I. Treatment is unsuccessful and RV infection is invariably fatal.
II. Because of the public health risk, animals with suspected RV infection are euthanized.

Monitoring and Prevention

I. Vaccination provides excellent protection against the disease.
A. Vaccination in most states is initiated by a killed vaccine at 12 to 16 weeks of age, with a booster vaccination at 1 year of age followed by triennial boosters.
B. Some states require yearly vaccination; some vaccines are approved for yearly use only (e.g., canary pox-vectored vaccines).
C. The use of rabies vaccine has been associated with injection-site sarcomas in cats.
II. In most municipalities, rabies vaccination for dogs and cats is required by law.
III. Recommendations for preexposure vaccination and management and postexposure management are available yearly from the American Veterinary Medical Association (AVMA; www.avma.org/issues/policy/rabies_control.asp) and from the Centers for Disease Control and Prevention (CDC; www.cdc.gov/ncidod/dvrd/rabies; see Table 112-2).
IV. Use extreme care when handling an animal or its bodily fluids if RV infection is suspected.
V. RV is susceptible to most disinfectants and does not survive well in the environment (see Table 112-1).

FELINE CORONAVIRUS

Definition and Cause

I. Feline coronavirus (FCoV) causes either subclinical infection or mild, transient diarrhea in exposed cats.
II. Spontaneous mutation of enteric FCoV may lead to clinical FIP, which is associated with very high morbidity and mortality.
III. FCoV is an SS-RNA virus of the family Coronaviridae.

Pathophysiology

I. FCoV is highly contagious via fecal–oral transmission, but salivary, urinary, and transplacental sources of exposure are uncommon.
II. Most infected cats shed the virus intermittently and then stop shedding, although some shed persistently.
III. FCoV that has mutated to an FIP-causing form is seldom shed in feces, so epizootics are rare.
IV. Although inactivated by most disinfectants, FCoV may persist in the environment (see Table 112-1).
V. Enteric infection results in villous atrophy and mild, self-limiting diarrhea.
VI. With FIP, a history of recent stress or illness may precede the disease.
    A. Mutated FCoV invades intestinal epithelium and enters macrophages, resulting in disseminated spread of mutated viral particles.
    B. Immunological response is ineffective and pathologic changes occur.
    C. Two forms of FIP are recognized.
        1. Effusive (wet) form
            a. Immune complexes circulate and are deposited in endothelia.
            b. A vasculitis ensues with exudation of protein-rich fluid into body cavities.
            c. The wet form is usually more rapidly progressive than the dry form.
        2. Noneffusive (dry) form
            a. An ineffective cell-mediated immune response is mounted against the virus.
            b. Pyogranulomatous inflammation in a variety of tissues results in disease.
            c. The dry form may become effusive in its terminal stages.

Clinical Signs

I. Enteric FCoV: often subclinical or mild diarrhea
II. FIP
    A. Young (<2 years) and elderly cats more commonly affected
    B. Sexually intact and purebred cats more commonly affected
    C. Effusive FIP
        1. Common: fever, pale mucous membranes, dyspnea, abdominal distention
        2. Variable: abdominal masses, abdominal organomegaly, icterus
    D. Noneffusive FIP
        1. Development of clinical signs is often insidious.
        2. Signs reflect the body system affected.
            a. Hepatomegaly, icterus, abdominal masses, renomegaly
            b. Pathologic ocular findings: uveitis, chorioretinitis
            c. CNS signs, dyspnea
            d. Fever and weight loss common

Diagnosis

I. Enteric FCoV infection
    A. Definitive diagnosis is seldom necessary.
    B. Antibody titers suggest prior exposure, but do not reflect fecal shedding or active infection.
    C. Viral particles identified in fecal specimens by PCR or EM have few, if any, implications for the health of an individual cat.
II. FIP infection
    A. General diagnostics tests
        1. Hematological findings: nonregenerative anemia, neutrophilia ± left shift
        2. Supportive biochemical findings
            a. Hyperglobulinemia with a low albumin:globulin ratio
            b. Other potential findings: icterus, elevated liver enzymes, azotemia
        3. Serum electrophoresis: polyclonal gammopathy
        4. Fluid analysis
            a. Clear to straw-colored, viscous effusion with low to moderate cellularity, and high protein content
            b. Contains lymphocytes, macrophages, and non-degenerate neutrophils
        5. Radiography: body cavity effusions ± organomegaly, pulmonary infiltrates
        6. Ultrasonography: nodular lesions within organs, organomegaly, effusions (pleural, peritoneal, pericardial, retroperitoneal)
    B. Coronavirus-specific serological tests
        1. Detection of serum Ab identifies exposure to FCoV, but is not diagnostic of FIP.
        2. Titers cannot distinguish exposure to enteric FCoV from exposure to the mutated virus causing FIP.
        3. Titers cannot distinguish exposure to corona viruses of other species from exposure to FCoV.
        4. Most healthy cats with Abs to FCoV never develop FIP.
        5. Positive FCoV Ab titers do not suggest that the cat is shedding virus.
        6. Cats with FIP occasionally have negative titers, especially during terminal stages of disease.
        7. In cats with signs suggestive of FIP, high Ab titers support a diagnosis of FIP.
    C. PCR tests for coronavirus
        1. PCR may identify FCoV in cats with either FIP or enteric FCoV.
        2. It cannot distinguish between enteric FCoV and the FIP-causing mutated forms.
        3. The test result may be negative in a significant number of cats with confirmed FIP.
        4. Positive PCR results from body effusions support a diagnosis of FIP.
        5. A fecal PCR test identifies viral shedding; although persistent viral shedding does not increase the risk for development of FIP, it can be a source of exposure for other cats.
    D. Histopathologic findings
        1. Histopathologic evaluation remains the best method to diagnose FIP.
        2. Affected tissues exhibit pyogranulomatous inflammation with vasculitis and perivascular cuffing with

mononuclear cells, macrophages, lymphocytes, and neutrophils.
3. FA and immunohistochemical testing of tissue specimens from biopsy (ultrasound-guidance or surgically obtained hepatic or renal tissue) or necropsy may confirm FIP.

Differential Diagnosis

I. Enteric FCoV infection with diarrhea: feline panleukopenia, parasites, dietary indiscretion, protozoal infections, bacterial infections, foreign body, and inflammatory bowel disease
II. Effusive FIP: peritonitis, pyothorax, chylothorax, neoplasia, heart failure, cholangiohepatitis, and disseminated fungal or bacterial infections
III. Noneffusive FIP: toxoplasmosis, fungal infection, neoplasia, and cholangiohepatitis

Treatment

I. Enteric FCoV with diarrhea
   A. Because the disease is usually subclinical or self-limiting, specific therapy is not often necessary.
   B. No known therapy reduces the small chance that FCoV-infected cats will develop FIP.
II. Feline infectious peritonitis
   A. Treatment is unsuccessful because the disease is usually fatal.
   B. Spontaneous remissions occur rarely.
   C. Supportive care with nutritional supplementation, relief of effusions that impair respiration, blood transfusions, parenteral fluid therapy, and antibiotic therapy for secondary infections may help prolong life.
   D. Immunosuppressive or immunomodulatory therapy may benefit a small number of cats.
      1. Prednisone 2 to 4 mg/kg PO BID
      2. Cyclophosphamide 2.2 mg/kg PO 4 days/week or chlorambucil 20 mg/m^2 PO every 2 to 3 weeks
      3. Human-recombinant interferon-α 30 U PO SID on alternating weeks
      4. Pentoxifylline: suggested therapy but data insufficient
   E. Clinical studies of other proposed treatments (e.g., vitamins E, A, C) are not availble.

Monitoring and Prevention

I. Catteries and multicat households
   A. Control exposure to feces and disinfect fomites.
   B. Ab tests identify exposed cats but do not predict fecal shedding or propensity to develop FIP, so do not euthanize healthy cats based on positive Ab test results.
   C. Fecal PCR identifies chronic shedders; segregation may reduce exposures.
   D. Strategy to eradicate FCoV is as follows:
      1. Obtain negative (zero) titers on new cats.
      2. Segregate positive cats in the facility from negative cats.
      3. Keep all cats indoors.
      4. Remove kittens from seropositive queens at 5 to 6 weeks of age.
II. Vaccination
   A. The available intranasal vaccine appears safe when used as directed.
      1. Temperature-sensitive vaccine virus replicates only in respiratory epithelium, inducing mucosal immunity.
      2. Vaccine efficacy is 50% to 75% for previously unexposed cats (Pederson, 1995).
      3. It is not indicated in low-risk cats, such as adults or cats in single-cat households.
      4. At-risk kittens possibly benefit from vaccination, with two doses given 3 to 4 weeks apart and followed by yearly booster vaccinations.
      5. Currently, the vaccine is not recommended for routine use (Table 112-3).
   B. Vaccination does not prevent mutation of FCoV in an infected cat.

FELINE IMMUNODEFICIENCY VIRUS

Definition and Cause

I. FIV causes chronic infections with a long subclinical period, and eventual development of acquired immunodeficiency with associated clinical syndromes.
II. FIV, a lentivirus, is a SS-RNA virus of the family Retroviridae that only infects Felidae and is closely related to human immunodeficiency virus.

Pathophysiology

I. Epidemiological findings
   A. Horizontal and vertical transmission occur, but vertical spread is not epidemiologically important.
   B. Close contact is required for transmission, and fomites are involved only minimally.
   C. Horizontal transmission occurs primarily via bite wounds, and also occurs via blood transfusions, contaminated needles and instruments, or other contact with bodily fluids.
   D. Males, particularly intact, outdoor cats that fight, are more commonly infected than females.
   E. Adults (middle aged and older) are infected more often than kittens.
   F. A higher seroprevalence of FIV occurs in areas with large outdoor cat populations.
II. Pathogenesis
   A. FIV initially replicates in lymphoid (including thymic) and salivary tissue, with subsequent dissemination to many tissues.
   B. As the cat mounts a partially effective immune response, the number of circulating viral particles lessens and the cat appears healthy.
   C. During the subclinical period (possibly many years), gradual deterioration in immune function occurs (not a true latency).
   D. Secondary infections and associated illness eventually occur, resulting in the terminal phase of disease.

TABLE 112-3

Viral Vaccination Recommendations for Adult Cats*

VIRUS	ADMINISTRATION FREQUENCY	COMMENTS
Core vaccines†		
Panleukopenia	1 year, then every 3 years	Efficacy of MLV may last >3 years MLV should not be administered to pregnant queens
Herpesvirus-1	1 year, then every 3 years	Either parenteral or topical MLV product may be given Inactivated-virus vaccine with an adjuvant is an alternative
Calicivirus	1 year, then every 3 years	Either parenteral or topical MLV product may be given Inactivated-virus vaccine with an adjuvant is an alternative
Rabies	1 year, then every 1 to 3 years	Local regulations impact frequency of booster vaccines
Noncore vaccines†		
Feline leukemia virus	Annually	Test cats before vaccination Kittens and young cats are more susceptible to infection than adult cats Consider lifestyle risks
Feline immunodeficiency virus	Annually	Test cats before vaccination Vaccinated cats cannot be distinguished from infected cats Consider lifestyle risks
Feline infectious peritonitis	Annually	It is not recommended for most cats

Adapted from Richards JR, Elston TH, Ford RB et al: The 2006 American Association of Feline Practitioners Feline Vaccine Advisory Panel Report. J Am Vet Med Assoc 229:1405, 2006.

MLV, Modified live virus.

*Vaccination protocols must be tailored to the individual cat in a given environment. This table provides guidelines and does not address vaccine recommendations for nonviral diseases (chlamydophilosis, bordetellosis).

†Core vaccines are recommended for all cats; noncore vaccines are optional and recommended only in some cats.

Clinical Signs

I. Acute infection may be inapparent, but can cause self-limiting fever, neutropenia, and lymphadenopathy.
II. Lymphadenopathy is variably present during the subclinical period (months to years).
III. Clinical illness has a variety of manifestations.
  A. Recurrent fevers, anorexia, malaise, gingivitis, stomatitis (common)
  B. Secondary infections of the GI, respiratory, and urinary tracts
  C. Inflammatory diseases of the eye (Hartmann, 1998)
  D. A variety of malignancies (Hutson et al., 1991)
  E. Rare peripheral or central neurological dysfunction (Podell et al., 1993)
  F. Severe weight loss and cytopenia (terminally)

Diagnosis

I. Hematological findings
  A. Lymphopenia and neutropenia acutely, and during later stages of disease
  B. Anemia and thrombocytopenia
II. Serum biochemistry profile: hyperglobulinemia or findings related to secondary diseases
III. Cytological evaluation of fine-needle aspirates of enlarged lymph nodes: hyperplasia or mimic lymphoma
IV. FIV-specific diagnostic testing
  A. In-hospital ELISA tests identify Abs.
    1. FIV is not always detected during acute infection or during terminal stages.
    2. False positives can occur from maternal Ab, so retest positive kittens after 6 months of age (Sellon, 2006).
    3. False positives can occur in vaccinated cats.
  B. Although Western blot is used as a confirmatory test for a positive ELISA result, it cannot distinguish Ab formed in response to infection from maternal Ab or Ab formed in response to vaccination (Levy et al., 2004).
  C. PCR assays are available but vary greatly in reliability (Crawford et al., 2005).

Differential Diagnosis

I. Primary infections with any of the secondary pathogens
II. FeLV infection
III. Bone marrow infiltrative diseases
IV. Neoplasia
V. Chronic fungal infections

Treatment

I. Asymptomatic cats
  A. Keep the animal indoors and well vaccinated for other diseases to minimize risks of other infections.
  B. No specific treatment is available.
II. Symptomatic cats

A. Provide supportive care and prompt therapy for secondary infections.
B. Human recombinant G-CSF may be helpful for severe neutropenia (see Treatment under Feline Leukemia Virus).
C. The use of recombinant human granulocyte-macrophage colony stimulating factor may lead to increased FIV load (Arai et al., 2000).
D. Other immune modulators and antiviral therapy may be tried (see Treatment under Feline Leukemia Virus).

Monitoring and Prevention

I. A vaccine is available but does not confer perfect protection (Huang et al., 2004).
   A. Test cats for FIV before administering the vaccine.
   B. The vaccine is effective for at least 12 months.
   C. Vaccinated cats can test positive on ELISA and Western blot FIV Ab tests.
   D. Consider microchip identification for all vaccinated cats so that ownership and FIV vaccination status can be determined.
   E. Vaccine is not currently recommended for routine use (see Table 112-3).
II. Discourage fighting, and do not breed infected cats.
III. Ideally, separate FIV-positive cats from FIV-negative housemates; however, unless they fight, the risk of transmission with normal contact (e.g., sharing litter boxes, food bowls) is low.

FELINE LEUKEMIA VIRUS

Definition and Cause

I. FeLV causes a chronic infection that may induce neoplasia, immune deficiency, or bone marrow suppression.
II. FeLV is an SS-RNA virus of the family Retroviridae, subfamily Oncornavirinae.

Pathophysiology

I. Epidemiological findings
   A. Horizontal and vertical transmission occur.
   B. Close contact is required, and fomites are minimally involved.
   C. FeLV, though shed in all bodily secretions, is transmitted primarily via saliva (usually during grooming); bite wounds; and shared use of food bowls, water bowls, and litter boxes.
   D. Rarely, transmission occurs transplacentally via the milk during nursing and through blood transfusions, needles, or surgical instruments.
   E. Viral particles are shed from both ill and healthy infected cats.
   F. Kittens are far more susceptible to infection than adult cats.
II. Pathogenesis
   A. Many outcomes are possible after exposure, including recovery, latent infection, or persistent viremia.
   B. The outcome depends on the subgroup of FeLV, age of the cat, immune response, and other variables.
   C. If the initial immune response is ineffective, viremia occurs with replication in lymphoid tissue and bone marrow.
   D. With an effective immune response, viremia ceases, but virus may remain integrated in bone marrow cells.
      1. Latently infected cats are not viremic and not a source of exposure for other cats.
      2. Infections can remain latent for life or may reactivate during stress or immunosuppression.
   E. Many viremic cats remain persistently viremic, with viral particles in bone marrow, epithelial tissues, and salivary glands.
      1. Persistently viremic cats may be healthy for a period of time or develop one of several clinical diseases.
      2. Malignancy is thought to result from insertional mutagenesis during viral replication.
      3. Antibodies to feline oncornavirus cell-associated membrane antigen protect the cat from malignancy, but not from other disease manifestations.
      4. Direct viral invasion of stem cell precursors or stromal damage causes myelosuppression.
      5. Immunosuppression may arise from lymphopenia and alterations in lymphocyte function.
      6. Decreased T suppressor cells and antigen–Ab complexes contribute to immune-mediated disease.

Clinical Signs

I. Acute infection has a variety of manifestations.
   A. Often subclinical
   B. Fever, depression, diarrhea, lymphadenopathy, ± leukopenia
   C. Possible apparent recovery with no signs for months to years
II. Cats with latent infection may be asymptomatic.
III. Immunosuppression with secondary infections is the major cause of morbidity and mortality.
IV. Myelosuppression causes nonregenerative anemia, leukopenia, and thrombocytopenia.
V. Malignancy has several forms.
   A. Lymphoma is the most common neoplasia associated with FeLV infection.
   B. Clinical signs of lymphoma reflect the site involved, and include dyspnea (mediastinal); uremia (renal); and ataxia, paralysis, or seizures (CNS).
   C. Less commonly, hematopoietic malignancies (leukemias) develop and can involve any cell line, with clinical signs reflecting a reduction in normal hematopoietic cell numbers.
VI. Other signs include evidence of immune-mediated hemolytic anemia (IMHA), glomerulonephritis, infertility, abortion, and osteochondromatosis.

Diagnosis

I. Hematological findings
   A. Nonregenerative anemia, macrocytic anemia, nucleated red blood cells
   B. Possibly circulating blast cells, cytopenia, or leukemia

II. Serum biochemistries and urinalysis: nonspecific changes reflecting secondary conditions
III. Lymph node, bone marrow, or mass aspirates: confirm neoplasia or secondary infection
IV. Radiography and ultrasonography: useful to identify neoplasia
V. FeLV-specific diagnostic testing
   A. A very sensitive and specific ELISA test detects circulating FeLV p27 core antigen.
      1. No false positives occur with maternal Abs.
      2. In-hospital kits can be used on serum, plasma, whole blood, saliva, or tears; saliva and tears are less reliable than serum.
      3. ELISA tests are positive earlier in infection than FA tests.
      4. Test results may revert from positive to negative with latent or cleared infection, so confirm a positive ELISA result by FA testing or a second ELISA test in 1 to 3 months.
   B. FA tests are confirmatory.
      1. FA detects p27 core antigen in leukocytes and platelets from blood or bone marrow.
      2. Because a positive FA test means the virus has replicated in precursor cells in the bone marrow, positive cats are unlikely to revert to a negative status.
   C. Culture or FA of bone marrow samples can be done to diagnose latent FeLV infection.
   D. PCR has no advantage over ELISA on blood samples and is useful only to identify FeLV in preserved neoplastic tissues.
   E. Identification of FeLV does not confirm a particular illness is secondary to FeLV.

Differential Diagnosis

I. Acute illness: feline panleukopenia, FCoV, bacterial infections, FIP
II. Anemia: hemorrhage, hemotrophic *Mycoplasma* spp. (see Chapter 115), chronic disease, renal failure, IMHA, histoplasmosis, atypical tuberculosis, myelophthisis, toxin exposure, etc.
III. Neoplasia: non–viral-related leukemia and lymphoma, non-neoplastic causes of lymphadenopathy, pleural effusion, renomegaly, etc.

Treatment

I. No specific treatment is necessary in asymptomatic cats.
II. FeLV-induced neoplasia is treated similarly to non-FeLV neoplasia.
III. Myelosuppression is addressed as follows:
   A. Anemia
      1. Blood transfusion may be life saving.
      2. Although erythropoietin levels in anemic FeLV-positive cats are elevated, short-term use of exogenous erythropoietin is potentially beneficial at 100 U/kg SC 3 times per week (Arai et al., 2000).
      3. Address other causes of anemia, such as hemotrophic *Mycoplasma* spp. infection and IMHA.
   B. Neutropenia
      1. The use of human recombinant G-CSF (5 μg/kg/day SC for ≤2 weeks) in severe neutropenia is controversial (Obradovich et al., 1993; Hartmann, 2006; Arai et al., 2000), because at higher doses or for longer periods it may cause production of antibodies to feline colony stimulating factors.
      2. Consider prophylactic antibiotics.
IV. Secondary bacterial infections require prompt therapy with appropriate antibiotics.
V. Immune modulator and antiviral therapy may be tried, but evidence of efficacy is slim (McCaw et al., 2001).
   A. *Staphylococcus aureus* protein A 10 μg/kg IP twice weekly
   B. Human recombinant interferon-α 30 U PO SID on alternating weeks
   C. Feline recombinant interferon omega 1×10^6 U/kg/day SC for 5 consecutive days in 3 series, beginning on days 0, 14, and 60 (de Mari et al., 2004).

Monitoring and Prevention

I. Isolate cats with FeLV from noninfected cats; keep infected cats indoors, vaccinate them for other infectious diseases, and do not breed them.
II. Vaccination involves the following (see Table 112-3).
   A. Test before FeLV vaccination, because vaccination of positive cats provides no benefits.
   B. Vaccination is not indicated for low-risk cats (e.g., indoor cats, single-cat households, or households in which all cats test negative).
   C. Killed and subunit vaccines are equally efficacious.
   D. Vaccine efficacy is <100%, and estimates of true efficacy vary (Legendre et al., 1991; Jarret and Ganiere, 1996).
   E. Initially give two vaccines 3 to 4 weeks apart, with annual booster vaccinations.
   F. Use of FeLV vaccine has been associated with injection-site sarcomas in cats.

FELINE PARVOVIRUS

Definition and Cause

I. Feline panleukopenia is a highly contagious, acute enteric disease of young cats, typically accompanied by severe leukopenia and high morbidity and mortality.
II. In utero or early neonatal infection may cause cerebellar disease.
III. Feline parvovirus (FPV), an SS-DNA virus of the family Parvoviridae, is related to CPV-2, which is rarely isolated from cats with panleukopenia.

Pathophysiology

I. Epidemiology
   A. FPV is highly contagious to all domestic and wild members of the family Felidae.
   B. Virus is shed in all body secretions, with fecal shedding being the primary source of infection.
   C. Transmission is from contact with infected animals, contaminated environment, or fomites.

D. FPV is seldom encountered in vaccinated domestic cats, but is problematic in feral, shelter, and stray cats.
E. Disease is most common in 3- to 5-month-old kittens, because most cats >1 year old are immune from subclinical infection and younger kittens are protected by maternal Abs.

II. Pathogenesis
A. After oronasal exposure, the virus replicates in regional lymph nodes and causes viremia.
B. FPV preferentially infects rapidly dividing cells (e.g., intestinal epithelial cells, lymph tissue, hematopoietic cells of bone marrow).
C. Secondary GI bacterial infection, translocation of gut bacteria, and increased susceptibility to bacterial infection and sepsis all contribute to the clinical signs produced.

Clinical Signs

I. Adult cats: usually asymptomatic
II. Kittens
A. Initial signs: fever, lethargy, complete anorexia, vomiting, diarrhea (sometimes hemorrhagic), severe dehydration
B. Outcome: peracute death or spontaneous recovery, with milder disease in older kittens
III. Transplacental and early neonatal infection
A. Early gestational infection: fetal resorption, infertility in apparently healthy queens
B. Late gestational or neonatal infection
1. Abortion of mummified fetuses, stillbirths
2. CNS abnormalities: cerebellar hypoplasia with hypermetria and intention tremors
C. Other signs of in utero infection: hydrocephalus, hydranencephaly, retinal dysplasia

Diagnosis

I. Hematological findings
A. Severe leukopenia, neutropenia, variable lymphopenia (early)
B. Rebound leukocytosis (often pronounced) during the recovery phase
C. Anemia: rarely severe with intestinal blood loss
D. Thrombocytopenia
II. Serum biochemistry profile
A. Increased hepatic enzyme activity
B. Azotemia, electrolyte imbalances
III. Specific diagnostic testing
A. Canine parvoviral fecal ELISA kits can detect FPV antigen (imperfect sensitivity).
B. Virus isolation (fecal material and/or urine) is not routinely used.
C. A fourfold increase in paired serum Ab titers is diagnostic, but the test is not commercially available.
IV. Histopathologic findings are similar to those with CPV.

Differential Diagnosis

I. Bacterial enteric infection
II. Septicemia
III. Parasitism
IV. FeLV, FCoV
V. GI obstruction

Treatment

I. Provide supportive care as for CPV (see Box 112-1).
II. CNS signs are not treatable but are nonprogressive, and many affected kittens can be functional pets.

Monitoring and Prevention

I. Passive immunity
A. Colostral Ab prevents infection and interferes with vaccination up to 12 weeks of age.
B. Plasma provides passive immunity (up to 4 weeks) if the kitten is colostrum-deprived.
II. Active immunity
A. Inactive (killed virus) vaccine
1. Requires at least two administrations to be effective
2. Safe in pregnant queens or young kittens (<4 weeks of age)
B. MLV vaccines
1. They provide long-lasting immunity, although yearly booster vaccinations are still recommended by manufacturers.
2. They are not safe in pregnant queens and potentially cause neurological dysfunction in kittens.
3. Give kittens at least two vaccines, with at least 1 dose occurring after 12 weeks of age.
4. For current recommendations, see Table 112-3.
III. Natural infection produces lifelong immunity.
IV. FPV is resistant to environmental degradation and to many disinfectants (see Table 112-1).

MISCELLANEOUS VIRAL INFECTIONS

See Table 112-4.

TABLE 112-4

Other Viruses Affecting Dogs and Cats

VIRUS	SPECIES	PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PREVENTION
Feline sarcoma virus	Cat	Requires FeLV to replicate Induces multicentric fibrosarcoma in young cats Unrelated to injection-site sarcomas	Solitary or multiple cutaneous masses ± visceral metastases	FeLV positive with fibrosarcoma	Wide surgical excision
Feline syncytium-forming virus	Cat	Highly prevalent, but rarely produces disease Coinfection with FeLV results in immune complex deposition in joints	Most infections are asymptomatic Severe progressive polyarthritis may occur	Inflammatory joint tap, FA serology Diseased cats are FeLV positive	Treatment unrewarding Immunosuppressive therapy with prednisone or cyclophosphamide may provide some relief
Astrovirus	Cat	Unknown clinical significance Experimentally, fecal–oral transmission occurs	Diarrhea, anorexia ± vomiting, fever, dehydration	EM of feces	Supportive care Routine disinfection No vaccine is available
Poxvirus	Cat	Found in Europe and Asia Oronasal or skin inoculation Spreads via blood stream to distant skin	Single or multiple skin lesions with scabs ± draining cellulitis	Virus culture, EM of scab, FA test for serum Ab	Supportive care Vaccine not available Zoonotic potential
Borna disease virus	Cat	Found in Europe Believed to cause acute progressive nonsuppurative gray matter encephalomyelitis	Fever and anorexia followed by behavioral change, stiff legs, ataxia, ± seizures, salivation, constipation, altered vision	Histopathology, IHC	Supportive care Vaccine not available
Papillomavirus	Dog, cat	Species-specific virus infects basal cells Young and/or immunodeficient animals affected	Single or multiple oral, ocular, or cutaneous proliferative "wart-like" lesions Lesions often more plague-like in cats	Visual diagnosis ± histopathology and virus identification	Spontaneous regression typical May be excised if interfere with function
Pseudorabies virus	Dog, cat	Pigs are common reservoir, with virus ingested in raw pork Virus travels through nerves to brain, often to brainstem	Peracute illness Behavioral changes, GI signs, dyspnea, intense pruritus Cranial nerve deficits are common	Direct FA, PCR, VI, rabbit inoculation	Typically fatal despite supportive care Prevent exposure to pigs, raw pork No commercial vaccine available

FeLV, Feline leukemia virus; *FA*, fluorescent antibody; *EM*, electron microscopy; *Ab*, antibody; *IHC*, immunohistochemistry; *GI*, gastrointestinal; *PCR*, polymerase chain reaction; *VI*, virus isolation.

TABLE 112-4

Other Viruses Affecting Dogs and Cats—*cont'd*

VIRUS	SPECIES	PATHOPHYSIOLOGY	CLINICAL SIGNS	DIAGNOSIS	TREATMENT/PREVENTION
Rotavirus	Dog, cat	Infects epithelial cells of intestinal villi in dogs and cats Clinically affected dogs are usually young puppies High rate of infection but rare disease in cats	No signs or mild diarrhea for several days Severe, fatal diarrhea can occur in young puppies	ELISA, EM of feces, FA of tissue	Supportive care Vaccine not available
Canine adenovirus-1 (CAV-1; infectious canine hepatitis)	Dog	Highly contagious, shed in secretions Young, unvaccinated dogs most commonly affected Viremia leads to hepatocyte and endothelial damage causing hepatic necrosis, disseminated intravascular coagulation, ± neurological signs	Signs may be peracute, acute, or mild/subclinical Fever, abdominal pain, vomiting, diarrhea, icterus, lymphadenopathy may occur Milder signs with possible corneal edema and anterior uveitis may be noted	Paired Ab titers, virus culture, histopathology (inclusion bodies), FA testing of tissues	Passive (up to 7 wk of age) or acquired immunity is protective Modified live canine adenovirus-2 vaccine provides protection CAV-1 vaccines are avoided owing to risk of secondary corneal edema
Canine parvovirus-1	Dog	Affects puppies <3 wk; may cross placenta Infects lymphoid tissue and rapidly dividing cells	Sudden death or GI signs, dyspnea, crying ("fading puppy syndrome") ± Abortions	EM of feces, hemagglutination inhibition	Supportive care typically unrewarding Vaccine not available
Canine influenza virus	Dog	Highly contagious respiratory virus of high morbidity but low mortality Hemorrhagic pneumonia is rare but life-threatening. Secondary bacterial infections account for most mortality	Cough (often soft), fever, and nasal discharge are common	Paired antibody titers, PCR assay, viral isolation	No vaccine yet available Treatment is largely supportive and includes antibiotics for secondary bacterial infections

ELISA, Enzyme-linked immunosorbent assay.

CHAPTER 113

Bacterial Infections

Craig E. Greene | Janet Calpin | Lynn Guptill

SALMONELLOSIS

Definition

I. Salmonellosis is a bacterial disease of the gastrointestinal (GI) tract of dogs and cats, as well as many other mammals, birds, reptiles, and insects.
II. Under certain circumstances, the disease can become systemic.
III. Subclinical infections can also occur.

Causes

I. *Salmonella enterica* are motile, non–spore-forming, gram-negative bacilli, the majority of which show little or no specific host adaptation.
II. Serovariety *Salmonella typhimurium* is most commonly isolated from dogs and cats.

Pathophysiology

I. Organisms enter the body through the GI tract from contaminated food, water, and fomites.
II. Salmonellae attach preferentially to tips of intestinal mucosal villi, where they invade and multiply.
III. Localization and persistence in intestinal epithelium and lymph nodes account for shedding of organisms for 3 to 6 weeks, or intermittently, and for longer periods.
IV. Once infected, stress (e.g., overcrowding, hospitalization) increases the risk of clinical disease.

Clinical Signs

I. Clinical signs may vary with the number of infecting organisms, host immune status, complicating factors, and concurrent diseases.
II. Clinical syndromes are referable to the organ system affected (most likely in tissues damaged or devitalized by a previous disease), and include gastroenteritis, bacteremia, and endotoxemia.
III. Within 3 to 5 days of exposure, signs may include fever, malaise, anorexia, vomiting, abdominal pain, pale mucous membranes, diarrhea (from watery to mucoid with fresh blood present in severe cases), weight loss, dehydration, epistaxis, or coughing and dyspnea from pneumonia.
IV. Central nervous system (CNS) signs include hyperexcitability, incoordination, posterior paresis, blindness, and seizures.
V. Cardiovascular collapse, shock, disseminated intravascular coagulopathy, and icterus may precede death.
VI. Rarely, chronic or intermittent diarrhea of up to 8 weeks duration may occur.
VII. An asymptomatic carrier state may also develop.

Diagnosis

I. Hematological and serum biochemical findings are nonspecific and typical for infectious diarrhea or septicemia.
II. Isolation of the organism is most definitive.
  A. Isolation is especially significant if it is from normally sterile body fluids or tissues (e.g., blood, urine, synovial fluid, transtracheal washings, cerebrospinal fluid, bone marrow).
  B. Isolation rates are improved by use of selective media.
  C. Isolation only from the GI tract or its secretions does not confirm *Salmonella*-induced disease.
III. Histopathologic evaluation may show hemorrhagic ulcerative enteritis and suppurative lesions in lungs, liver, and brain (with disseminated infection).

Differential Diagnosis

I. Canine and feline enteric viral infections
II. Canine distemper
III. Feline panleukopenia
IV. Campylobacteriosis
V. Helicobacteriosis
VI. Giardiasis, coccidiosis, cryptosporidiosis

Treatment

I. Treatment varies with the type and severity of clinical illness.
II. For acute gastroenteritis without systemic signs, give parenteral isotonic fluids to replace losses.
III. Antibiotics are used only in animals with immunosuppression or signs of systemic illness and are chosen based on susceptibility testing.

Monitoring and Prevention

I. Surviving animals usually recover within 3 to 4 weeks of infection.
II. Surviving animals may shed organisms for ≥6 weeks.
III. Zoonotic potential exists, so isolate affected animals from other animals and people.

IV. Practice proper hygiene if contact is made with affected animals or their feces.
V. People may transmit infection as a reverse zoonosis.
VI. Organisms are susceptible to disinfection with phenolic compounds or household bleach (5.25% sodium hypochlorite diluted 1:32), but the presence of organic material interferes with disinfection.
VII. Handle food properly to avoid contamination.
VIII. Feed only fully cooked foods and treats.

CAMPYLOBACTERIOSIS

Definition and Causes

I. Campylobacteriosis is an enteric bacterial disease associated with diarrhea in dogs and cats that are housed in densely populated or unsanitary environments.
II. *Campylobacter jejuni* is a gram-negative, slender, curved or spiral-shaped rod associated with diarrhea in animals and people.
III. *Campylobacter upsaliensis* and *Campylobacter lari* are isolated from diarrheic and asymptomatic dogs and asymptomatic cats (Hald and Madsen, 1997; Koene et al., 2004).

Pathophysiology

I. Transmission is by the fecal–oral route, usually via contaminated food, such as poultry and milk, or from water supplies.
II. Most infected dogs and cats are asymptomatic carriers and may shed organisms for prolonged periods (Hald and Madsen, 1997).
III. Clinical disease usually occurs in animals <6 months old, and has a duration of 5 to 15 days.
IV. Severity is dependent on prior exposure, number and virulence of organisms ingested, development of protective antibodies, and presence of other enteric pathogens.
V. Disease severity is exacerbated by environmental and physiological stresses.

Clinical Signs

I. Acute diarrhea: soft feces to watery, bloody, or mucoid stool, possibly bile-streaked
II. Rare signs: partial anorexia, occasional vomiting, fever

Diagnosis

I. Microscopic examination of feces with darkfield or phase-contrast microscopy may reveal organisms.
II. Definitive diagnosis is by culture.
   A. Fresh feces or rectal swabs are streaked onto specific isolation media maintained in a reduced-oxygen atmosphere at 42° C for up to 96 hours.
   B. Multiple colonies must be evaluated, because coinfection with multiple *Campylobacter* spp. occurs (Koene et al., 2004.)
III. Gram stain of feces may show gram-negative "gull wing"–shaped organisms.

Differential Diagnosis

I. Canine and feline enteric viral infections
II. Canine distemper
III. Feline panleukopenia
IV. Salmonellosis, helicobacteriosis
V. Giardiasis, coccidiosis, cryptosporidiosis

Treatment

I. Efficacy of antibiotic treatment in animals is unknown; however, treatment may be instituted in animals with clinical signs to minimize exposure of other pets and people.
II. Erythromycin, chloramphenicol, and second generation cephalosporins may be effective.
III. Avoid routine use of enrofloxacin to limit development of resistant bacterial strains.
   A. Enrofloxacin is contraindicated in young animals.
   B. The dose in cats is restricted to 5 mg/kg/day to avoid retinal toxicity.

Monitoring and Prevention

I. Fecal culture should be repeated 1 to 4 weeks after therapy to confirm efficacy.
   A. Clinical improvement may occur despite continued fecal shedding.
   B. Antibiotic therapy has been associated with protracted shedding and antibiotic resistance, particularly to fluoroquinolones (Fox, 2006a).
II. Campylobacteriosis causes enteric disease in people, and pets may be a source of exposure.
III. Strict sanitation and hygiene are essential for control of this disease.
IV. Organisms are viable at room temperature for at least 3 days and for at least 1 week at refrigerated temperatures.

HELICOBACTERIOSIS

Definition and Causes

I. Several *Helicobacter* spp. are associated with gastritis in dogs, cats, and people, and prevalence of infection is high (Fox, 2006b).
II. Other *Helicobacter* spp. are associated with proctitis, colitis, and hepatitis, especially in immunocompromised hosts.
III. *Helicobacter* spp. are gram-negative microaerophilic bacteria similar to *Campylobacter* spp.

Pathophysiology

I. Transmission is via the direct fecal–oral or oral–oral route through contact with infected animals or from fomites.
II. Bacterial proliferation likely causes gastric inflammation and lymphoid proliferation.
III. The pathogenic nature of nongastric *Helicobacter* spp. is poorly defined.
IV. Many infected animals remain asymptomatic.

Clinical Signs

I. Gastric and intestinal infections: vomiting, weight loss, diarrhea

II. Hepatic infections: signs of hepatitis, generally in immunocompromised hosts

Diagnosis

I. *Helicobacter*-positive cultures are not always associated with clinical disease, so histological confirmation is needed.
II. Tests to detect urease activity in biopsy specimens help confirm the diagnosis.
III. Culture is difficult; therefore notify commercial laboratories in advance and use special transport broth to send the specimens.

Differential Diagnosis

I. Gastric infection: campylobacteriosis and other causes of gastritis (see Chapter 31)
II. Intestinal and hepatic infection: other causes of enteritis or hepatitis (see Chapters 33 and 37)

Treatment

I. Antibiotic therapy for gastric infection has not been thoroughly evaluated, and there is no clearly superior treatment (Simpson, 2005).
II. Treatment usually involves a regimen of three oral drugs given for 14 to 28 days:
    A. Gastrointestinal protectant
        1. Dogs: bismuth subsalicylate 0.5 to 2 mL/kg PO TID to QID
        2. Dogs or cats: famotidine 0.5 mg/kg PO SID to BID
    B. Metronidazole
        1. Dogs: 15 mg/kg PO SID to BID
        2. Cats: 62.5 mg PO SID
    C. Amoxicillin 22 mg/kg PO TID: dogs and cats
III. Treatment of nongastric infections is also poorly defined.

Monitoring and Prevention

I. Animals can asymptomatically harbor the infection.
II. Transmission to people is possible through oral contact.

MYCOBACTERIOSIS

Definition and Causes

I. Three forms are recognized, and involve tuberculous, lepromatous, and opportunistic organisms.
II. Tuberculosis is caused by *Mycobacterium tuberculosis, Mycobacterium bovis,* and *Mycobacterium avium*.
III. Feline leprosy is caused by *Mycobacterium lepraemurium*.
IV. *Mycobacterium fortuitum, Mycobacterium chelonei, Mycobacterium smegmatis,* and *Mycobacterium plei* are the most common causes of opportunistic infections in dogs and cats.
V. *Mycobacterium* spp. are environmentally resistant, non–spore-forming, acid-fast bacteria.

Pathophysiology

I. *Mycobacterium* spp. are ubiquitous in nature and not highly pathogenic under normal circumstances.
II. Tuberculous mycobacteria enter the body via the lungs, GI tract, or the skin.
    A. They induce granuloma formation at the site of entry.
    B. They sometimes disseminate systemically.
III. Lepromatous *Mycobacterium* spp. are transmitted from bites or contact with infected rats, and cause primarily cutaneous disease in cats.
IV. Opportunistic mycobacterial infections follow penetrating skin or soft-tissue injuries and cause pyogranulomas.

Clinical Signs

I. Infections are frequently subclinical in dogs and cats.
II. When clinical signs occur, they reflect the sites of granuloma formation.
    A. Bronchopneumonia, pulmonary nodule formation, and hilar lymphadenopathy are common in dogs and cause fever, weight loss, anorexia, and harsh nonproductive coughing.
    B. Cats with intestinal lesions have weight loss, anemia, vomiting, and diarrhea.
III. Feline leprosy manifests as soft, fleshy nodules in the skin and subcutis.
IV. Opportunistic mycobacterial infections occur as multiple, fistulous, draining tracts with purulent drainage into subcutaneous tissues.

Diagnosis

I. Tuberculosis
    A. Cytological evaluation of exudates with acid-fast staining allows a rapid, presumptive diagnosis.
    B. Intradermal skin testing of the inner side of the pinna with tuberculin may induce a delayed-type hypersensitivity reaction in dogs.
    C. Polymerase chain reaction (PCR) assays are available for some species.
    D. Definitive diagnosis requires demonstration of organisms within lesions.
II. Feline leprosy
    A. Large numbers of organisms in histological sections
    B. Identification of organisms in impression smears of affected tissues
III. Opportunistic infections
    A. Difficult to diagnose
    B. Require finding extensive granulomatous to pyogranulomatous inflammation of the dermis and panniculitis
    C. PCR assays at certified laboratories helpful

Differential Diagnosis

I. Consider other causes of respiratory problems, such as canine distemper, feline respiratory viruses, chlamydial and mycoplasmal infections (see Chapters 18 and 114).
II. Rule out feline lymphosarcoma (LSA), bacterial L-form infections, feline abscesses, and dermatophilosis.

Treatment

I. Tuberculous mycobacterial infections
    A. Treatment is not recommended for confirmed infections.
    B. Consider euthanasia, because of public health concerns, particularly for infections with *M. tuberculosis* and *M. bovis*.

C. For treating possible infections, use combination antibiotic therapy for ≥6 months (Greene and Gunn-Moore, 2006).

II. Feline leprosy is treated with aggressive surgical excision of all nodules and medical therapy for at least 2 months.
   A. Clofazimine 25 mg PO SID or 50 mg PO QOD
   B. Combined with clarithromycin 62.5 mg PO BID or rifampin 10 to 15 mg/kg PO SID (Malik et al., 2006).

III. Opportunistic mycobacterial infections are treated as follows:
   A. Administer antibiotics in accordance with susceptibility testing.
      1. While awaiting results, treat empirically with fluoroquinolones or clarithromycin.
      2. Treatment may be necessary for 6 to 12 months (Malik et al., 2006).
   B. Surgical resection of large granulomas may be more successful in dogs than in cats.

Monitoring and Prevention

I. If treatment is pursued, monitor tuberculous mycobacterial infections closely because of the zoonotic potential.
II. Lepromatous infections may be minimized by preventing contact with rodents.
III. Opportunistic mycobacteriosis has a guarded prognosis because lesions frequently recur and can spread.
IV. *Mycobacteria* spp. are killed by heat, phenolic compounds, and direct sunlight.

BRUCELLOSIS

Definition and Cause

I. Brucellosis is a zoonotic disease affecting reproductive organs and is associated with a persistent, insidious bacteremia.
II. *Brucella canis* is a small, gram-negative coccobacillary organism with a rough colonial morphology that distinguishes it from other *Brucella* spp.

Pathophysiology

I. Transmission usually occurs during breeding or birth, possibly via inhalation of aerosols associated with abortion or vaginal discharges.
II. Organisms penetrate mucous membranes, enter lymphatic and genital tissues, and persist intracellularly or spread to intervertebral disks, eyes, and kidneys.
III. Infected adult dogs are rarely seriously ill.

Clinical Signs

I. Reproductive problems
   A. Late gestational abortion of dead (partially autolyzed) puppies
   B. Stillborn or weak puppies
   C. Conception failures
   D. Epididymitis, scrotal enlargement, scrotal dermatitis
II. Nonreproductive abnormalities
   A. Spinal hyperesthesia, paresis, or paralysis with discospondylitis
   B. Anterior uveitis

Diagnosis

I. Hematological and serum biochemical tests results are usually normal or have nonspecific changes.
II. Hyperglobulinemia, ± concomitant hypoalbuminemia, occurs in chronic infections.
III. Semen abnormalities are seen and include immature sperm, deformed acrosomes, swollen midpieces, detached tails, and head-to-head agglutination.
IV. Serological testing is the primary method of diagnosis.
   A. Mercaptoethanol rapid slide agglutination test (ME-RSAT) is the preferred in-office screening test.
      1. It is quick and highly sensitive.
      2. False-positive results are common.
      3. Results are confirmed by additional tests.
   B. Tube agglutination test is used by some laboratories to confirm ME-RSAT and quantitate titers, but it lacks specificity.
   C. Agar-gel immunodiffusion test is the most sensitive test and is used by commercial laboratories to confirm infection.
V. Bacterial culture, especially of the blood, is valuable.
   A. It is the only definitive way to resolve serological differences.
   B. Negative results may occur owing to intermittent bacteremia.
VI. Histopathologic findings may show diffuse lymphoreticular hyperplasia or necrotizing vasculitis of reproductive tissue.

Differential Diagnosis

I. Infectious diseases: canine herpesvirus and canine parvovirus-1 infections, ehrlichiosis, anaplasmosis, Rocky Mountain spotted fever (RMSF), neonatal streptococcal infections, neosporosis
II. Other diseases with similar clinical signs: intervertebral disk disease, LSA, testicular inflammation or tumors, any cause of recurrent uveitis

Treatment

I. Treatment may not be advisable.
   A. Uncertain eradication from tissues
   B. Zoonotic potential
II. Neutering of all infected animals is highly recommended.
III. Combination therapy with a tetracycline and an aminoglycoside may be tried (Mateu de Antonio and Martin, 1995).
   A. Resolving the infection is difficult because *B. canis* is intracellular.
   B. Relapses are common once therapy is stopped.
IV. Multiple courses of therapy, separated by 1 to 2 months, may be necessary.
   A. Doxycycline or minocycline 12.5 mg/kg PO BID for 4 weeks *with*
   B. Gentamicin 5 mg/kg IM, SC SID during weeks 1 and 4
   C. Rifampin 10 mg/kg PO BID to TID in combination with doxycycline 5 mg/kg PO SID for 4 weeks
V. Male dogs may be sterile if they recover, and recovery with return to successful breeding is rare in bitches.

Monitoring and Prevention

I. Measure serological titers every 3 to 6 months to monitor treatment efficacy.
II. Test all breeding animals before breeding.
III. Test blood donors.
IV. Because people are susceptible, consider euthanasia of infected dogs, although neutering and treatment are possibly an option.

ACTINOMYCOSIS AND NOCARDIOSIS

Definition

I. Actinomycosis is a pyogranulomatous disease that produces abscesses, chronic draining fistulas, or infections of bones or body cavities.
II. Nocardiosis causes similar lesions; however, a disseminated form originating in the respiratory tract also occurs.

Causes

I. *Actinomyces* spp. are branching, filamentous, gram-positive, fastidious, microaerophilic bacteria of the family Actinomycetaceae.
II. *Nocardia* spp. are acid-fast staining, aerobic members of the family Nocardiaceae.

Pathophysiology

I. Epidemiological findings and transmission
  A. *Actinomyces* spp.
    1. Commensal organisms, found in oral cavities of animals and people
    2. Inoculation via bite, puncture wounds, or tissue trauma
    3. More commonly infects outdoor dogs and cats
  B. *Nocardia* spp.: inoculation of soil saprophytes via wound contamination or inhalation
  C. Entry and spread influenced by host immunocompetence
II. Actinomycosis
  A. Usually involves the cervicofacial region, thorax, abdomen, retroperitoneal space, bone, and subcutaneous tissues
  B. Spreads to adjacent tissues by direct extension via normal tissue planes
III. Nocardiosis
  A. Usually develops in alveolar spaces
  B. Erodes blood vessels and spreads systemically (e.g., thoracic cavity, CNS, retroperitoneal space)
  C. Cutaneous-subcutaneous disease in cats (Malik et al., 2006)

Clinical Signs

I. Actinomycosis
  A. Localized swellings or fluid accumulation in body cavities with serosanguineous drainage often containing small yellow granules
  B. Persistently draining, fistulous tracts
II. Nocardiosis
  A. Localized lesions similar to actinomycosis
  B. Chronic respiratory signs
    1. Mucopurulent oculonasal discharge
    2. Anorexia, weight loss
    3. Cough, dyspnea
    4. Diarrhea, hyperthermia
  C. Disseminated nocardiosis
    1. Rare without obvious pulmonary disease
    2. Signs referable to organ systems involved

Diagnosis

I. Hematological and serum biochemistry changes are nonspecific and typical of any pyogenic inflammation.
II. Cytological examination of lesion exudates is most specific when granules are present.
  A. Gram-positive branching filamentous rods and cocci
  B. Acid-fast staining for *Nocardia* spp. identification
III. Histopathologic examination of tissue with Gram stain and acid-fast stains may reveal organisms.
IV. Definitive diagnosis is via bacterial culture.
  A. Notify the laboratory that these organisms are suspected.
  B. Obtain samples anaerobically to aid the isolation of *Actinomyces* spp.

Differential Diagnosis

I. Other causes of draining skin lesions
II. Other causes of pyothorax (see Chapter 19)
III. Systemic fungal diseases

Treatment and Monitoring

I. For both disorders, surgical drainage and debridement of focal affected areas is undertaken.
II. Antibiotic therapy is administered for several weeks to months.
  A. Actinomycosis: penicillin V or G 40 mg/kg PO TID
  B. Nocardiosis: trimethoprim/sulfonamide (TMS) 15 to 30 mg/kg PO BID
    1. Some *Nocardia* spp. require alternative therapies.
    2. *Nocardia farcinia* may respond to amikacin or imipenem in addition to TMS.
    3. *Nocardia farci* may respond to TMS followed by amoxicillin (20 mg/kg PO BID) plus clarithromycin (62.5 to 125 mg PO BID) or doxycycline (5 mg/kg PO BID) (Malik et al., 2006).
III. Monitor closely for potential relapse, especially following completion of antibiotic therapy.

BORRELIOSIS

Definition and Cause

I. Borreliosis is one of a large group of tick-borne diseases caused by spirochetes that affect people and animals worldwide.
II. These diseases are divided into the Lyme disease group (transmitted by ixodid ticks) and the relapsing fever group (transmitted by soft ticks).

III. Lyme borreliosis is caused by *Borrelia burgdorferi sensu lato,* which is transmitted by nymph or adult *Ixodes ricinus* ticks.

Pathophysiology

I. Following tick attachment, organisms enter the host and spread to connective tissues, joints, and other tissues.
II. Clinical syndromes are produced by the host's inflammatory reaction to the organism (documented in naturally infected dogs but not in cats).

Clinical Signs

I. Fever, inappetence, lethargy, lymphadenomegaly, and episodic, shifting lameness develop 60 to 90 days after infection.
II. Skin lesions (expanding erythema around tick bite) and neurological signs (meningitis or encephalitis) are not well documented in dogs.

Diagnosis

I. Diagnosis is based on clinical signs, a history of recent tick exposure, serological testing, and response to treatment.
II. No specific hematological or serum biochemical changes occur.
   A. Dogs with renal involvement may be azotemic.
   B. Proteinuria, hematuria, pyuria, and tubular casts can be found on urinalysis.
III. Serological testing is used as a screening tool.
   A. A fourfold rise in titer over 2 to 4 weeks is significant.
   B. Rule out nonspecific or vaccine-induced positive titers with use of a quantitative antibody assay (e.g., C6 enzyme-linked immunosorbent assay [ELISA]) or immunoblotting procedures.
IV. Bacterial isolation is the most definitive means of confirmation of disease, but is difficult owing to low numbers of organisms.
V. PCR assays of infected skin or connective tissue biopsies offer a specific means of confirmation.

Differential Diagnosis

I. Consider other tick-borne diseases (e.g. ehrlichiosis, anaplasmosis, RMSF).
II. Geographic location and regional tick populations are also important considerations.

Treatment

I. Antibiotic treatment is usually begun before infection is confirmed.
   A. Doxycycline is the drug of choice (10 mg/kg PO BID for 30 days).
   B. Amoxicillin 20 mg/kg PO TID for 30 days is used.
II. Nonsteroidal antiinflammatory drugs (NSAIDs) can relieve pain during episodes of recurrent synovitis.

Monitoring and Prevention

I. Relapse and recrudescence of infection is possible even if treatment is continued for months.
II. Vaccines available in the United States must be given before exposure to ticks.
III. Tick control in endemic areas requires use of residual acaricides and environmental management (Stafford, 2004).

LEPTOSPIROSIS

Definition and Causes

I. Leptospirosis is a multisystemic disease in dogs, livestock, people, and many other animals, with worldwide significance; it is rare in cats.
II. Serovars of the spirochete *Leptospira interrogans sensu lato* are the causative agents.
   A. Serovars *grippotyphosa, pomona, bratislava,* and *autumnalis* are currently the most common serovars detected in clinically ill dogs.
   B. *Leptospira icterohemorrhagiae* and *Leptospira canicola* are now less commonly associated with clinical illness.

Pathophysiology

I. Epidemiological findings
   A. Leptospires persist in stagnant or slow-moving water.
   B. Various mammals serve as reservoirs (e.g., fox, mouse, rat, raccoon, opossum, deer).
II. Pathogenesis
   A. Leptospires are shed in the urine of infected animals.
   B. They penetrate mucous membranes or abraded skin and enter blood vascular spaces, where they replicate and produce inflammation.
   C. Damage to kidneys, liver, and other tissues ensues.

Clinical Signs

I. Mild or inapparent in cats
II. Signs in dogs
   A. Dependent on age, immunity, environment, and virulence factors of the serovar
   B. Chronic or subclinical infections common
   C. Peracute infections: massive leptospiremia, shock, death
   D. Other infections: fever, anorexia, vomiting, dehydration, increased thirst, reluctance to move
   E. Progressive deterioration in renal and hepatic function: oliguria or anuria, icterus possible

Diagnosis

I. Hematological findings: leukocytosis, thrombocytopenia
II. Serum biochemistry and urine tests
   A. Increased serum urea nitrogen and creatinine concentrations with isosthenuria reflect renal involvement.
   B. Electrolyte alterations parallel the degree of renal and GI tract dysfunction.
   C. High serum hepatic transaminase activity and bilirubinemia indicate liver damage.
III. Serological testing
   A. Microscopic agglutination test is the standard serological test.
   B. A fourfold rise in titer over 2 to 4 weeks is required to confirm infection.

C. Single high (>800) titers are often indicative of recent or active infection or prior vaccination.

IV. PCR assays and culture of urine for leptospires may also be used.

Differential Diagnosis

Rule out other causes of kidney and liver disease (see Chapters 37 and 48).

Treatment

I. Penicillins for 2 weeks are the drug of choice for initial treatment of leptospiremia.
   A. Ampicillin 22 mg/kg PO, SC, IV TID
   B. Amoxicillin 22 mg/kg PO BID
   C. Penicillin G 25,000 to 40,000 U/kg IM, SC, IV BID

II. Use doxycycline to minimize or eradicate the carrier state.
   A. Started after penicillin treatment is completed
   B. Dosage: 5 mg/kg PO, IV BID for 2 weeks

Monitoring and Prevention

I. Vaccination is available for serovars canicola, icterohaemorrhagiae, pomona and grippotyphosa.

II. Leptospires are killed by heat and most disinfectants; removal of organic debris before disinfection is essential.

TETANUS

Definition and Cause

I. Tetanus is a disease of warm-blooded animals that results from a potent bacterial neurotoxin formed in the host by *Clostridium tetani*.

II. Spores of *C. tetani*—a motile, gram-positive anaerobic bacillus—are introduced into wounds, vegetate, and then produce tetanospasmin.

Pathophysiology

I. Dogs and cats are relatively resistant to the effects of the toxin.

II. Toxin produces either a localized progressive illness or a generalized syndrome, depending on how it is spread throughout the body.

III. Visceral and motor neuron disturbances also occur.

Clinical Signs

I. Usually occur within 5 to 21 days of exposure

II. Localized signs common
   A. Increased stiffness in a muscle or an entire limb (Malik et al., 1989)
   B. Gradual progression to involve the entire nervous system

III. Generalized signs
   A. Facial muscle spasms (risus sardonicus)
   B. Protrusion of the third eyelid
   C. Trismus (lockjaw)
   D. Increased salivation
   E. Laryngeal spasms, dysphagia
   F. Extreme muscle rigidity
   G. Elevated body temperature from excessive muscular activity
   H. Altered heart and respiratory rates

Diagnosis

I. Usually based on the clinical signs and history.

II. History of a bite wound or surgical wound is variable.

III. Isolation of the organism is very difficult.

Differential Diagnosis

I. Strychnine intoxication

II. Meningitis

III. Other causes of seizures or muscle rigidity (see Chapters 22 and 82)

Treatment

I. Mildly affected animals may recover with wound management only.

II. Severely affected animals require labor-intensive supportive therapy and prolonged hospitalization; complications are possible.

III. Supportive care may include the following (Bandt et al., 2007):
   A. Intravenous fluids
   B. Tracheostomy with assisted ventilation
   C. Indwelling feeding tube, partial or total parenteral nutrition

IV. Antitoxin is used to neutralize toxin that is unbound or as yet unformed.
   A. Initial dose is 0.1 to 0.2 mL SC, ID; observe for 30 minutes for signs of anaphylaxis.
   B. Equine antitoxin (100 to 1000 U/kg) may be administered once IV, IM, SC near or proximal to the wound site for localized tetanus (Bandt et al., 2007).

V. Metronidazole (15 mg/kg PO, IV BID) or penicillin G (20,000 U/kg IV QID or 20,000 to 100,000 U/kg IV, SC, IM BID to TID) for 10 days is used to kill vegetative organisms.

Monitoring and Prevention

I. Supportive care is essential to maximize recovery of animals with severe clinical signs.

II. Avoid exposure to the bacteria by thorough cleansing and treatment of wounds.

BOTULISM

Definition and Cause

I. Botulism is a bacterial disease that produces neuromuscular paralysis.

II. *Clostridium botulinum* is a gram-positive, anaerobic, spore-forming soil saprophyte that produces neurotoxins.

Pathophysiology

I. Botulism is usually caused by ingestion of a preformed toxin in food.

II. Toxin absorbed from the stomach and upper small intestine circulates to neuromuscular junctions or cholinergic nerves.

III. Toxin prevents presynaptic release of acetylcholine, resulting in generalized lower motor neuron disease and parasympathetic dysfunction.

Clinical Signs

I. Symmetrical ascending weakness from rear to forelimbs
II. Depressed limb reflexes
III. Mydriasis and other signs (see Chapter 25)
IV. Decreased jaw tone, gag reflexes, and excessive salivation

Diagnosis

I. Electromyography shows conduction defects at the neuromuscular junction.
II. Finding toxin in the serum, feces, vomitus, or food sample by using specific assays for the most common toxin (type C) confirms the diagnosis, but assays are not always readily available.

Differential Diagnosis

I. Polyradiculoneuritis
II. Myasthenia gravis
III. Tick paralysis
IV. Organophosphate toxicity (nicotinic receptor paralysis)

Treatment

I. Supportive treatment (see Chapter 25) is most important; spontaneous recovery can occur in moderately affected animals.
II. Metronidazole or penicillins have been used to reduce potential intestinal growth of the clostridial agents, but are not recommended because they may not alter the course of disease and may cause further toxin release upon death of the bacteria (Barsanti, 2006).

Monitoring and Prevention

I. Monitor for aspiration pneumonia and urinary tract infections in recumbent, paralyzed animals.
II. Preventing access to carrion and thorough cooking of food reduces the prevalence of the disease.
III. Toxin is destroyed by heating to 100° C for 10 minutes.

BARTONELLOSIS

Definition and Causes

I. Bartonellosis is a group of arthropod-borne bacterial diseases of people and animals caused by members of the genus *Bartonella*.
II. *Bartonella* spp. are fastidious gram-negative bacteria.
III. Multiple *Bartonella* spp. infect cats and dogs.
   A. Cats: *B. henselae, B. clarridgeiae, B. koehlerae, B. bovis, B. quintana*
   B. Dogs: *B. vinsonii* subsp. *berkhoffii, B. henselae*, *B. clarridgeiae, B. elizabethae, B. quintana*

Pathophysiology

I. *B. henselae* is transmitted to cats by fleas (Chomel et al., 1996).
II. Cats are reservoirs and vectors for human *B. henselae* infections.
III. *B. vinsonii* subsp. *berkhoffii* and other species are probably transmitted among dogs by ticks.
IV. Coyotes are likely reservoirs for canine and human *B. vinsonii* subsp. *berkhoffii* infections (Chang and Kasten, 2000).
V. Cats develop relapsing *B. henselae* bacteremia that persists for months to years.
VI. *Bartonella* spp. are presumed to be intracellular bacteria.

Clinical Signs

I. Cats infected with *B. henselae* may have a self-limiting, febrile illness for days to weeks; most infections appear to be subclinical.
II. Transient fever, lymphadenomegaly, CNS signs, and reproductive failure are reported in experimentally infected cats, especially with more virulent strains (Guptill, 2003).
III. Evidence is lacking to confirm a causal association between natural *Bartonella* spp. infection and stomatitis, uveitis, and CNS signs in cats (Brunt et al., 2006).
IV. Dogs infected with *B. vinsonii* subsp. *berkhoffii* may have inapparent signs or severe signs from endocarditis and bacteremia.
V. It was recently proposed that *B. henselae* and other *Bartonella* spp. may cause multiple clinical syndromes in dogs alone (opportunistic pathogens) or in combination with other vector-transmitted pathogens (Breitschwerdt et al., 2004; Goodman and Breitschwerdt, 2005).

Diagnosis

I. Cultivation and identification of the organism is as follows:
   A. Blood culture: negative results possible from relapsing bacteremia in cats; rarely useful for dogs
   B. Identification in tissues via PCR
II. Positive serological tests (immunofluorescent assay, ELISA) indicate exposure, and are not indicative of active infection (approximately 50% positive predictive value for cats).

Differential Diagnosis

I. Other causes of fever
II. Other causes of endocarditis
III. Other causes of lymphadenomegaly

Treatment

I. Antibiotic treatment is not proven to be effective at clearing infections in cats or dogs.
II. Doxycycline, enrofloxacin, or azithromycin treatment (2 to 6 weeks) may decrease bacteremia in cats.
   A. Whether any treatment eradicates infection is not known (Brunt et al., 2006).
   B. Use caution when administering doxycycline tablets to cats; to avoid esophagitis and subsequent strictures, follow tablets with water and do not crush or use partial tablets.
III. Bacteremia in cats may recur after treatment is discontinued (Greene et al., 1996).

Monitoring and Prevention

I. Bacteremia relapses, so follow-up cultures may not reveal the true efficacy of treatment.
II. *Bartonella henselae* is transmitted from cats to people by scratches and possibly bites; the role of fleas in this transmission has not been determined.
III. *Bartonella vinsonii* subsp. *berkhoffii* is possibly transmitted from dogs to people by bites (Chang and Kasten, 2000).
IV. Vector control is essential to decrease transmission among cats and dogs, and possibly from animals to people.
V. Cats may be reinfected or coinfected with multiple *Bartonella* spp. or subtypes (Guptill, 2003).

OTHER BACTERIAL INFECTIONS

See Table 113-1.

TABLE 113-1

Other Bacterial Diseases in Dogs and Cats

DISEASE	ORGANISM	SPECIES	CLINICAL SIGNIFICANCE	DIAGNOSIS	TREATMENT
Shigellosis	*Shigella* spp.	Dogs, cats	Asymptomatic to diarrhea	Culture	Ampicillin, sulfonamides, tetracycline
Yersiniosis	*Yersinia enterolytica*	Dogs, cats	Asymptomatic to diarrhea, increased stool frequency, tenesmus	Culture	Chloramphenicol, gentamicin Avoid raw foods
Clostridium perfringens infection	*Clostridium perfringens*	Dogs, cats	Diarrhea, tenesmus, inflamed anal tissues	Clinical signs plus culture	Metronidazole
Staphylococcal infections	*Staphylococcus* spp.	Dogs	Opportunistic pathogens Abscesses of the skin, eyes, ears, respiratory and urinary tracts, skeleton, and joints	Culture, Gram stain of clinical specimens	β-Lactamase–resistant penicillins, first-generation cephalosporins
	MRSA	Dogs, cats	Same as for other *Staphylococcus* spp. Possible zoonosis or reverse zoonosis	Oxacillin resistance is a marker PCR test required to confirm	Based on susceptibility tests, but multiple drug resistance possible Avoid clindamycin, as resistance may develop quickly
Melioidosis	*Burkholderia (Pseudomonas) pseudomallei*	Dogs, cats	Chronic nodular or purulent inflammatory disease of the skin	Isolation and identification from blood or lesion	Surgical drainage Antimicrobial therapy for months
Glanders	*Pseudomonas mallei*	Dogs, cats	Wound contamination with bacteremia Nodular lesions resembling tuberculosis	Culture and identification	Sulfonamides, tetracycline
Plague	*Yersinia pestis*	Dogs, cats Fleas involved in transmission	Buboes, pneumonia, septicemia Zoonosis	Epidemiological evidence, clinical signs, isolate from clinical samples Contact state veterinarian or public health officials	Gentamicin and streptomycin are drugs of choice Exercise caution and use appropriate PPE Flea control
Tularemia	*Francisella tularensis*	Dogs, cats Rabbits and ticks involved in transmission	Fever, anorexia, listlessness Zoonosis	Serological testing	Gentamicin may be best choice Possibly doxycycline or chloramphicol, but relapse possible Use appropriate PPE

MRSA, Methicillin-resistant *Staphylococcus aureus; PCR,* polymerase chain reaction; *PPE,* personal protective equipment.

TABLE 113-1

Other Bacterial Diseases in Dogs and Cats—*cont'd*

DISEASE	ORGANISM	SPECIES	CLINICAL SIGNIFICANCE	DIAGNOSIS	TREATMENT
Dermatophilosis	*Dermatophilus congolensis*	Dogs, cats	Dermatological lesions in dogs; deeper abscesses in cats	Culture, cytological examination	Wound management Penicillins most practical
Rhodococcosis	*Rhodococcus equi*	Dogs, cats	Abscess, pyogranuloma Possible zoonosis	Culture	Wound management, surgical drainage Lincomycin and gentamicin most effective
Feline abscesses	Bacterial flora of the oral cavity and claws	Cats	Abscess	Culture, physical examination	Wound management, surgical drainage Penicillin derivatives
L-form infections	Cell wall–deficient bacteria	Cats	Fever; lymphadenomegaly; persistently draining, spreading cellulitis and synovitis often involving the extremities	History, clinical signs Culture rarely positive	Tetracyclines
Tyzzer's disease	*Clostridium piliforme*	Dogs, cats	Multifocal hepatic necrosis, rapid-onset lethargy, anorexia, abdominal discomfort, hepatomegaly Affected animals often stressed or immunosuppressed	Rapidly fatal (with 24-48 hours) Usually diagnosed at necropsy	Unsuccessful Prevented by avoiding contact with infected rodent urine
Streptococcosis	*Streptococcus* spp.	Dogs, cats	Depends on affected tissue or organ: skin lesions, metritis, pyelonephritis, necrotizing fasciitis, toxic shock–line syndrome	Culture	Based on susceptibility testing

CHAPTER 114

Mixed Respiratory Infections

Leah A. Cohn | Paige Langdon

CANINE INFECTIOUS TRACHEOBRONCHITIS

Definition

I. Canine infectious tracheobronchitis (ITB) is a highly contagious syndrome resulting from acute respiratory infections caused by viral and/or bacterial pathogens.
II. The term *kennel cough* is often used synonymously with ITB.

Causes

I. Multiple pathogens have been incriminated in the ITB disease complex (Box 114-1).
II. ITB may be caused by a single pathogen or mixed infections including secondary bacterial pathogens.
III. ITB is most commonly encountered when dogs are housed close together.
IV. Viral pathogens and *Bordetella bronchiseptica* spread quickly by aerosolization.
V. Dogs of any age, sex, or breed are susceptible.

Pathophysiology

I. The common viral pathogens replicate in the respiratory epithelium, where damage facilitates secondary infection.
II. Most viruses are cleared in 1 to 2 weeks, but clinical signs may persist longer.
III. *Bordetella bronchiseptica* elaborates toxic substances that inhibit ciliary movement and impair phagocytic function, thereby facilitating primary infection.
IV. *Mycoplasma* spp. colonize the upper airways; although they seldom cause disease, they may worsen clinical signs of other respiratory infections.
V. Secondary infections with opportunistic pathogens worsen clinical signs.

Clinical Signs

I. Signs depend on the type of pathogens, host immunity, and presence of opportunistic infection.
II. Paroxysmal coughing is the most consistent clinical sign.
  A. The cough may be dry, hacking, or productive.
  B. Owners may mistake productive coughing for retching or vomiting.
III. Uncomplicated cases are not associated with systemic illness.
IV. Secondary infection, or infection in young or unvaccinated dogs, produces more severe disease.
  A. Productive cough, mucopurulent nasal discharge
  B. Fever, anorexia, depression
  C. Less common: dyspnea, pneumonia, respiratory failure, or sepsis
  D. Canine influenza
    1. It is often associated with fever and mild systemic illness (Joly, 2005; Crawford et al., 2005).
    2. Mortality ranges from 1% to 8%.
    3. Mortality may be associated with hemorrhagic viral pneumonia or secondary bacterial pneumonia.
V. Prior vaccination alleviates the severity of signs.

Box 114-1

Pathogens Incriminated in the Canine Infectious Tracheobronchitis Disease Complex

Viruses	
Canine parainfluenza virus (CPiV)	Most common isolate from dogs with ITB
Canine adenovirus-2 (CAV-2)	Frequent isolate; related CAV-1 causes infectious canine hepatitis and may be isolated during ITB
Other viruses	
Canine reoviruses and herpesvirus	May contribute to ITB
Canine distemper virus	*Not* considered agent of ITB despite frequent respiratory signs
Canine influenza virus	Associated with cough, fever, and nasal discharge
Bacteria	
Bordetella bronchiseptica	Most common bacterial isolate in ITB; may be a primary or secondary pathogen
Streptococcus spp., *Pasteurella* spp., *Pseudomonas* spp., coliforms	May be isolated; often opportunistic; cause morbidity and mortality
Mycoplasma spp.	Fastidious microbes lacking cell wall; may be a primary or secondary pathogen

ITB, Infections tracheobronchitis; *CAV-1,* canine adenovirus-1.

Diagnosis

I. History and clinical presentation
  A. Recent exposure to other dogs
  B. Acute onset of cough several days after exposure
II. Routine laboratory tests
  A. No abnormalities or nonspecific changes
  B. Neutrophilia ± left shift with some complicated infections or pneumonia
III. Thoracic radiography
  A. Indication depends on severity of clinical signs
  B. Moderate to severe disease
    1. Possibly abnormal lung patterns: interstitial, bronchointerstitial, or alveolar infiltrates
    2. Lung consolidation (rare)
  C. Helps rule out other causes of cough and dyspnea
IV. Other diagnostic aids
  A. In complicated cases, transtracheal wash or bronchoalveolar lavage may show neutrophilic exudate.
  B. Culture and sensitivity testing helps with choosing antibiotic therapy.
  C. Viral isolation and antibody titers are rarely indicated for mildly affected dogs.
  D. Acute phase and convalescent titers can distinguish canine influenza from other causes of infectious tracheobronchitis.
    1. Titers may be useful as an epidemiological tool.
    2. Paired titers are generally preferred over polymerase chain reaction (PCR) assays for influenza.

Differential Diagnosis

I. Other infections causing a cough: canine distemper; rickettsial, fungal, bacterial, or parasitic infections
II. Aspiration pneumonia
III. Collapsing trachea or bronchi
IV. Airway foreign body
V. Allergic tracheobronchitis
VI. Pulmonary edema: cardiogenic, noncardiogenic
VII. Pulmonary hemorrhage: trauma, coagulopathy

Treatment

I. Uncomplicated ITB
  A. Although it is typically a self-limiting disease, owners often request therapy.
  B. Paroxysmal coughing is treated with cough suppressants.
    1. Hydrocodone 0.25 mg/kg PO BID to QID
    2. Butorphanol 0.5 to 1.0 mg/kg PO BID to QID
    3. Contraindicated if pneumonia present
  C. Antibiotics, although not necessary, possibly prevent opportunistic infection.
    1. Doxycycline 10 mg/kg PO SID
    2. Chloramphenicol 40 to 50 mg/kg PO TID
    3. Amoxicillin/clavulanic acid 13.75 mg/kg PO BID
    4. Trimethoprim/sulfonamide 15 mg/kg PO BID
  D. Nebulized antibiotics (gentamicin 6 to 8 mg/kg diluted 1:5 to 1:10 in 0.9% saline) delivered by face mask SID may be useful for *B. bronchiseptica* infection.
  E. Rest the animal and isolate it from other dogs for at least 2 to 3 weeks.
II. Complicated ITB
  A. Intensive care may be required in an isolation ward.
  B. Antibiotic therapy, with bactericidal antibiotics, is started based on culture and sensitivity testing.
    1. Trimethoprim/sulfonamide 15 to 30 mg/kg IV/PO BID
    2. Amoxicillin/clavulanic acid 13.75 mg/kg PO BID
    3. Cefoxitin 22 mg/kg IV TID
    4. Ampicillin 10 to 20 mg/kg IV TID to QID or amoxicillin 20 mg/kg SC, PO plus enrofloxacin 2.5 to 10 mg/kg IM, PO BID
  C. Hydration with parenteral crystalloid solutions facilitates loosening of respiratory secretions.
  D. Consider inhalation therapy with saline, bronchodilator, and/or antibiotic nebulization.
  E. Supplemental oxygen may be indicated.

Monitoring and Prevention

I. Isolate animals until all clinical signs resolve.
II. Thoroughly clean and disinfect kennel facilities with dilute (1:32) bleach solution.
III. Adequate immunity prevents or lessens severity of the disease.
  A. Passive immunity
    1. Currently, all dogs are considered susceptible to canine influenza virus.
    2. Maternal immunity to other pathogens is variable.
    3. Unvaccinated puppies are at high risk for severe infections.
  B. Acquired immunity from natural infection
    1. Duration of immunity to viruses after exposure is unknown.
    2. At least 6 months of immunity occurs after *B. bronchiseptica* exposure (Bemis, 1992).
  C. Acquired immunity from vaccination
    1. Vaccination is available and suggested for canine parainfluenza virus (CPiV) and canine adenovirus-2 (CAV-2).
      a. They provide protection from clinical disease, although infection is still possible.
      b. Administer routine parenteral combination canine vaccines (CPiV and CAV-2) 2 to 3 times to puppies (3 weeks apart).
      c. CPiV and CAV-2 vaccines are administered again at 1 year and every 3 years thereafter.
    2. Vaccine is not yet available for canine influenza virus infection.
    3. Vaccination for *B. bronchiseptica* is considered optional.
      a. Many boarding facilities and canine competitions require current *B. bronchiseptica* vaccination.
      b. Both parenteral and intranasal vaccines can be effective.
      c. Duration of immunity is generally ≤1 year.
    4. Intranasal vaccines for CPiV and *B. bronchiseptica* are available.
      a. Quicker onset of local and systemic immunity with intranasal forms

b. No maternal antibody interference with intranasal vaccination
c. Mild upper respiratory signs possible after intranasal vaccination

IV. *B. bronchiseptica* is potentially a zoonotic risk for immunocompromised people.
V. There is no evidence of zoonosis associated with canine influenza virus infection.

FELINE UPPER RESPIRATORY INFECTION COMPLEX

Definition

I. Feline upper respiratory infection (URI) complex results from infection with one or more of a number of viral and bacterial pathogens.
II. URI is highly contagious and results in high morbidity and low mortality in infected cats.
III. A virulent variant of one cause of feline URI, feline calicivirus (FCV), results in systemic illness with high mortality (Hurley et al., 2004).

Causes

I. Multiple pathogens have been incriminated in the URI complex (Box 114-2).
II. URI develops from any of several single agents or may be a mixed infection, with most cases arising from feline herpesvirus 1 (FHV-1; feline rhinotracheitis) or FCV infection.
III. URI is most prevalent in group-housed or outdoor cats.
IV. Viral pathogens and *B. bronchiseptica* are spread by aerosolization, close contact, and/or fomites.
A. *Chlamydophila felis* is rarely spread by aerosolization.
B. Direct contact with infected secretions is most important for spread of all URI pathogens.
C. Virulent FCV is readily transmitted via fomites.
V. Many URI pathogens cause acute disease followed by latency with occasional recrudescence.
VI. Kittens and young cats are more often affected, but cats of any age are susceptible.
A. Respiratory disease severity is worse in kittens.
B. Systemic illness from virulent FCV is worse in adult cats.
C. Except for virulent FCV, vaccinations limit severity of signs.

Pathophysiology

I. Viral replication occurs primarily in oral, respiratory, and ocular epithelial tissues, causing direct damage and providing opportunity for secondary pathogens to colonize.
II. Each pathogen has particular propensities for certain tissue damage, thereby producing certain clinical signs (Gaskell et al., 2006).
III. Secondary infection with bacterial pathogens, including *Mycoplasma* spp., worsens tissue damage.
IV. Carrier states are common in cats infected with FHV-1, FCV, *B. bronchiseptica*, and *C. felis* (Helps et al., 2005).
A. The majority of cats infected with FHV-1 maintain latent infections.
1. Active infection may recrudesce years after initial infection.
2. Damage or inflammation in intranasal tissues may predispose to chronic rhinosinusitis.
3. Viral shedding of FHV-1 is intermittent in carrier cats.
B. Cats with FCV may either remain carriers or clear the infection after weeks to months
1. As many as 24% of healthy cats may be FCV carriers (Wardley et al., 1974).
2. Viral shedding of FCV is nearly continuous in carrier cats.

Box 114-2

Pathogens Incriminated in the Feline Upper Respiratory Infection Complex

Viruses	
Feline herpesvirus (FHV-1)	Causes inapparent carrier state with intermittent shedding; kittens typically infected by asymptomatic carrier queen
Feline calicivirus (FCV; formerly feline picornavirus)	Causes inapparent carrier state with continual shedding
Other Viruses	
Feline reoviruses	May contribute in some cases
Poxviruses	May cause mild upper respiratory signs in cats; rare virulent form possibly fatal
Bacteria	
Bordetella bronchiseptica	May be a primary or secondary pathogen; can be found in normal cats
Chlamydophila felis (formerly *Chlamydia psittaci* var. *felis)*	Obligate intracellular bacteria, associated with more ocular than respiratory symptoms
Staphylococcus spp., *Streptococcus* spp., *Pasteurella* spp., *Escherichia coli*	May be isolated primary cause but are most likely secondary, opportunistic pathogens
Mycoplasma spp.	Fastidious microbes lacking cell wall; a primary or secondary pathogen; can be found in normal cats

Clinical Signs

I. Signs depend on the pathogens involved, host immunity, and any opportunistic infections present.
II. The most common signs of uncomplicated URI are oculonasal discharge, conjunctivitis, lethargy, and anorexia with variable sneezing and fever.

A. FHV-1 infection is more likely to cause salivation and corneal disease (see Chapter 98).
B. FCV infection is most likely to cause oral ulcers; sneezing is a less prominent feature.
C. *Chlamydophila felis* infection is likely to cause severe conjunctivitis, sometimes as the only clinical sign.
D. *B. bronchiseptica* infection is more likely to cause coughing.

III. Complicated infections lead to pneumonia and other systemic signs.
A. Young cats and unvaccinated cats are particularly susceptible to complications of URI.
B. Secondary bacterial infections worsen disease severity.
C. *B. bronchiseptica* or secondary bacterial infections may lead to bronchopneumonia.
D. Infection with *Mycoplasma* spp. and FCV is sometimes associated with lameness.
E. Virulent FCV is rare, but it causes systemic and respiratory signs.
1. Clinical signs include the following:
a. Fever
b. Facial, limb, and ventral edema
c. Ulcers, sores, and crusting of the skin and mucus membranes
2. Mortality associated with virulent FCV is approximately 50% (Hurley and Sykes, 2003).
3. Mortality from virulent FCV is higher in adult cats than kittens.

Diagnosis

I. History and clinical signs are usually highly suggestive of URI.
A. Cats often have a history of recent exposure to other cats, recent stress, or concurrent immunosuppressive therapy or disease.
B. Clinical signs may suggest the specific agents involved.

II. Routine laboratory tests are generally inconclusive; however, a neutrophilia ± a left shift occurs with complicated infections and pneumonia.

III. Thoracic radiography is not indicated unless clinical signs of pneumonia are present.

IV. Pathogen-specific diagnostic tools are employed on occasion, particularly in cattery situations.
A. Conjunctival scrapings, oropharyngeal swabs, and transtracheal washes provide diagnostic specimens, with separate swabs and different transport media required for viral versus bacterial culture.
B. Various tests exist for FHV-1 and FCV.
1. The viruses may be isolated in cell culture or detected by fluorescent antibody techniques; however, false negatives occur, especially with chronic FHV-1 infection.
2. PCR assay is a more sensitive way to detect infection, but test results may be positive in healthy cats.
3. Serological testing is generally not useful because of the presence of antibody owing to vaccination or natural exposure.
4. Virulent FCV infection is confirmed by genetic sequencing from multiple infected cats.
C. *B. bronchiseptica* and *Mycoplasma* spp. may be cultured from both infected and healthy cats.
D. *C. felis* is identified by enzyme-linked immunosorbent assay (ELISA), cell culture isolation, or intracellular inclusion bodies identified on cytological examination.

Differential Diagnosis

I. Uncomplicated disease
A. Exposure to irritant or caustic substances
B. Allergic bronchitis
C. Nasopharyngeal, tracheal foreign body
D. Cryptococcal infection

II. Complicated disease
A. Other infectious pneumonias: hematogenous bacterial, fungal, protozoal, parasitic
B. Aspiration pneumonia
C. Heartworm disease
D. Neoplasia
E. Systemic vasculitis

Treatment

I. Uncomplicated URI
A. Mainly supportive with routine nursing care
1. Isolate symptomatic cats and disinfect food bowls and all potential fomites.
2. Ensure adequate water and food intake.
a. Entice cats to eat by heating food or offering pungent foods like tuna.
b. Force-feed or tube feed if necessary.
3. Provide adequate airway hydration to facilitate loosening of respiratory secretions.
a. Parenteral fluids are sometimes required—usually subcutaneously.
b. Environmental humidification eases breathing and loosens secretions.
B. Antibiotics to prevent or treat secondary infections
1. Amoxicillin 10 to 20 mg/kg PO TID or amoxicillin/clavulanic acid 13.75 mg/kg PO BID
2. Doxycycline 5 mg/kg PO BID
a. Treatment of choice for *C. felis* and *Mycoplasma* spp.
b. Followed with water to avoid esophageal erosions and stricture
C. Ocular therapy (see Chapter 98)
1. Clean away eye secretions TID to QID.
2. Consider idoxuridine (1 drop OU 4 to 6 times daily) for severe or chronic FHV-1 corneal disease.
3. Oxytetracycline ointment is applied TID for conjunctivitis associated with *C. felis* or *Mycoplasma* spp.
D. Adjunctive therapy for chronic FHV-1
1. L-Lysine 250 mg PO BID
2. Human interferon-α 30 U PO SID on alternative weeks

II. Complicated URI

A. Cats with pneumonia may require intensive care, isolation, intravenous crystalloid fluid therapy, and supplemental oxygen.
B. Bacteriocidal antibiotics are chosen based on culture and sensitivity testing.
   1. Trimethoprim/sulfonamide 15 to 30 mg/kg IV, PO BID
   2. Amoxicillin/clavulanic acid 13.75 mg/kg PO BID
   3. Cefoxitin 22 mg/kg IV TID
   4. Ampicillin 10 to 20 mg/kg IV TID to QID or amoxicillin 20 mg/kg SC, PO BID plus enrofloxacin 2.5 mg/kg PO SID to BID
C. Consider doxycycline 5 mg/kg PO, IV BID for *Mycoplasma* spp.
D. Consider inhalation therapy with saline, a bronchodilator, or antibiotic nebulization.
   1. Plain saline nebulization TID to QID may loosen secretions.
   2. Gentamicin (diluted 1:5 to 1:10 in 0.9% saline) can be nebulized by face mask at 6 to 8 mg/kg SID.
   3. Albuterol may be given SID to QID by metered dose inhaler (90 μg/actuation at 1 to 2 actuations) or by nebulization through a face mask (0.5 mL of a 2.5-mg/3-mL solution in 3.5 mL saline).

Monitoring and Prevention

I. Husbandry is important in preventing the spread of URI.
   A. Isolate cats with URI while they are clinically ill, but realize that shedding may persist or recur intermittently.
   B. Isolate recovered cats from unvaccinated or immunocompromised cats and kittens.
   C. If virulent FCV is suspected, facilities must be closed to unexposed cats.
      1. Virulent FCV is readily transmitted by fomites; therefore the feline pets of exposed clinic personnel are at risk.
      2. Isolation of cats and disinfection of premises must be stringent.
   D. Thoroughly clean and disinfect cattery facilities.
      1. Most agents, including virulent FCV, are effectively inactivated by dilute (1:32) bleach solutions.
      2. *C. felis* is inactivated by quaternary ammonium compounds.
II. Adequate immunity may prevent disease or reduce its severity.
III. Passive immunity with maternal antibodies has a variable duration (Wills et al., 1988; Jacobs et al., 1993; Coutts et al., 1996).
   A. FHV: 2 to 10 weeks
   B. FCV: 10 to 14 weeks
   C. *C. felis:* 9 to 12 weeks
   D. *B. bronchiseptica:* 2 to 6 weeks
   E. Protection unpredictable: unvaccinated kittens probably at risk
IV. Acquired immunity is achieved following natural infection or vaccination.
   A. Natural infection
      1. FHV-1 and FCV result in carrier states with possible periods of disease recrudescence; immunity after natural infection is not considered protective.
      2. Some short-term immunity to *C. felis* infection exists, but it is unknown whether effective immunity develops to *B. bronchiseptica* and *Mycoplasma* spp.
   B. Vaccination
      1. Vaccines are available for FHV-1, FCV, *C. felis*, and *B. bronchiseptica*.
      2. FHV and FCV vaccines are available as a modified live virus (MLV) form for parenteral use, intranasal use, or as killed vaccines for parenteral use (see Table 112-3).
         a. Initially 2 to 3 vaccinations are given 2 to 3 weeks apart in kittens, repeated at 1 year of age, and then given every 3 years.
         b. Vaccines are better suited to limiting disease than preventing all infections.
         c. Parenteral MLV vaccines may produce a brief period of mild respiratory signs.
         d. Intranasal MLV vaccines induce rapid immunity and often induce mild clinical signs.
         e. Killed vaccines are used in pregnant queens or retrovirus-positive cats.
         f. Current FCV vaccines do not offer protection from virulent FCV.
      3. Vaccination for *C. felis* protects against disease for 1 year, but vaccination is not routinely recommended or necessary.
      4. Intranasal vaccination for *B. bronchiseptica* is available, but not routinely recommended or necessary.
V. The zoonotic potential exists for development of *C. felis* and *B. bronchiseptica* in immunocompromised people.

CHAPTER 115

Rickettsial Infections

Laia Solano-Gallego | Nolie K. Parnell | Michael Lappin

EHRLICHIOSIS, ANAPLASMOSIS AND NEORICKETTSIOSIS

Feline Ehrlichiosis

Laia Solano-Gallego

Definition and Causes

Ehrlichiosis, anaplasmosis and neorickettsiosis are clinical syndromes induced by *Ehrlichia canis*, *Anaplasma phagocytophilum,* and *Neorickettsia risticii*, respectively.

Pathophysiology

I. Epidemiology
   A. Most affected cats are >2 years of age and are domestic shorthair cats.
   B. Intracytoplasmic morulae in leukocytes are detected in cats in multiple countries.
   C. DNA consistent with *E. canis* and *A. phagocytophilum* has been sequenced or amplified from tissues of naturally infected cats.
   D. Antibodies (Ab) against *N. risticii, E. canis* and *A. phagocytophilum* occur in sera of healthy and ill cats in multiple countries.

II. Transmission
   A. The method of transmission is currently unknown.
   B. *Haemophysalis leachi* and *Ixodes ricinus* ticks are identified on some infected cats.

III. Pathogenesis
   A. The pathogenesis is currently unknown.
   B. Owing to clinical similarities in cats and dogs with ehrlichiosis, anaplasmosis, and neorickettsiosis, the pathogenesis is likely similar.
   C. Experimental infections have certain characteristics:
      1. Morulae of *N. risticii* develop in mononuclear cells (Dawson et al., 1988).
      2. Morulae of *A. phagocytophilum* develop in neutrophils and eosinophils (Lewis et al., 1975).
      3. No *E. canis* DNA or Abs have been detected in experimentally inoculated cats (Lappin and Breitschwerdt, 2006).

Clinical Signs

I. Common signs include fever, inappetence, lethargy, weight loss, hyperesthesia, joint pain and/or polyarthritis, pale mucous membranes, splenomegaly, dyspnea, and lymphadenomegaly.

II. Concurrent diseases may include *Mycoplasma haemofelis, Candidatus* Mycoplasma haemominutum, *Cryptococcus neoformans*, feline leukemia virus (FeLV), feline immunodeficiency virus (FIV), and lymphosarcoma.

III. An epidemiological comparison of cats that are seropositive and seronegative for *Ehrlichia* spp. (Stubbs et al., 2000) revealed the following:
   A. Cats with *E. canis* Abs were more likely to have ocular discharge, monoclonal gammopathy, or polyarthritis.
   B. Cats with *N. risticii* Abs had more vomiting than seronegative cats.
   C. Cats with *N. risticii* and/or *E. canis* Abs were more likely to have ocular discharge with uveitis than seronegative cats.

IV. Cats experimentally infected with *N. risticii* occasionally developed fever, lethargy, lymphadenopathy, anorexia, and diarrhea (Dawson et al., 1988).

Diagnosis

I. Clinical pathologic abnormalities vary.
   A. Regenerative or nonregenerative anemia
   B. Leukocytosis (neutrophilia, lymphocytosis, monocytosis) or leukopenia
   C. Intermittent thrombocytopenia, hyperglobulinemia
   D. Rarely, polyclonal or monoclonal gammopathy (Stubbs et al., 2000)

II. Antibodies may be detected, but do not necessarily correlate to presence of clinical disease.

III. Some cats with positive polymerase chain reaction (PCR) assays are seronegative.

IV. Tentative diagnosis is based on a combination of serological results, compatible clinical signs, exclusion of other causes of the clinical signs, and response to treatment.

V. Definitive diagnosis is based on culture of the agent from blood or positive PCR assay.

Differential Diagnosis

I. Other infectious causes of fever, anemia, or splenomegaly
   A. FeLV-associated diseases
   B. Mycoplasmosis, bartonellosis
   C. Babesiosis, hepatozoonosis
   D. Plague, tularemia

II. Other causes of polyarthritis (see Chapter 80)

A. Feline calicivirus
B. Septic arthritis
C. Immune-mediated arthritis
D. L-form disease

III. Neoplasia, especially lymphosarcoma

Treatment

I. Doxycycline 5 to 10 mg/kg PO SID to BID is given as liquid or intact tablet for ≥28 days, with tablets followed by water to avoid esophagitis.
II. Tetracycline 15 mg/kg PO TID is given for 21 days, with monitoring for fever and anorexia.

Monitoring and Prevention

I. A positive therapeutic response is usually noted within 3 days.
II. Although it is unknown whether infection of cats is arthropod-borne, vector control is highly recommended.
III. Cats may be potential reservoirs for infection of vectors, but direct zoonotic transfer is unlikely.

Canine Ehrlichiosis

Laia Solano-Gallego

Definition and Causes

I. Ehrlichiosis, anaplasmosis and neorickettsiosis are clinical syndromes induced by *Ehrlichia* spp., *Anaplasma* spp., and *Neorickettsia* spp., respectively.
II. Geographical distribution and vector transmission are summarized in Table 115-1.

Pathophysiology

I. These species are obligate intracellular parasites that replicate in host cells, forming clusters of organisms called *morulae.*
II. They induce leukocyte and platelet abnormalities, plasma cell infiltration of parenchymal organs, and antigen–Ab complex formation.
III. Clinical course is variable, depending on the infecting species.
  A. In acute *E. canis* infection, clinical signs are possible, but asymptomatic infections also occur.
  B. Because of serological cross-reactivity (see Table 115-1), it is difficult to determine whether clinical conditions previously attributed to *E. canis* were actually *E. canis, E. ewingii*, or *E. chaffeensis* infections.
  C. Clinical signs attributed to *A. phagocytophilum* occur with acute or chronic infections.
  D. It is not known whether signs attributed to *N. risticii* occur during acute or chronic infection.
  E. Spontaneous resolution, resolution with treatment, or persistent subclinical infection may occur.
  F. Subclinical infections have a variable duration and may last for years.
    1. Organisms persist (primarily in spleen) and Abs are produced.
    2. Spontaneous clearance of organisms is possible.
IV. *Anaplasma platys* infection has a more predictable course.
  A. Initial thrombocytopenia occurs from platelet injury by replicating organisms.
  B. Platelet counts return to normal within 3 to 4 days after parasitemia resolves.
  C. Cyclic thrombocytopenia can occur every 1 to 2 weeks and immune-mediated mechanisms may cause subsequent thrombocytopenic episodes.
  D. Infection often resolves spontaneously.
  E. More virulent forms reportedly occur outside of the United States, causing clinical signs similar to those from the other species.
  F. Coinfection with other vector-transmitted diseases may result in more severe clinical signs.

Clinical Signs

I. *E. canis* infections (not *A. platys* infections)
  A. Coinfection with other tick-borne agents may alter the clinical presentation.
  B. Signs vary with the phase of disease.
    1. Fever, lethargy, anorexia, weight loss
    2. Lymphadenomegaly, splenomegaly, peripheral edema
    3. Petechiae, ecchymoses, epistaxis
    4. Ocular signs: anterior uveitis, chorioretinitis, retinal hemorrhages, papilledema, bullous retinal detachments, possible acute blindness
    5. Neurological signs from inflammation or bleeding: seizures, ataxia, paresis, vestibular disease, anisocoria, intention tremors, hyperesthesia
    6. Musculoskeletal signs: lameness, myalgia, muscle atrophy, joint swelling, myositis
II. Factors affecting severity
  A. Host age, breed (German shepherd dogs predisposed), immune status (Shaw et al., 2001)
  B. *Ehrlichia* spp., *Anaplasma* spp., and *Neorickettsia* spp. and strain involved
  C. Coinfection with other pathogens
III. Classification
  A. Originally divided into monocytic and granulocytic forms, the diseases are now classified by genogroup (see Table 115-1).
  B. It is difficult to attribute one set of clinical signs to any genogroup or forms.
  C. Natural *E. canis* and *E. chaffeensis* infections may cause more severe disease than other species.
  D. Experimental *E. chaffeensis* infections produce only mild clinical signs (Dawson and Ewing, 1992; Breitschwerdt et al., 1998b).
  E. *E. ewingii* and *A. phagocytophilum* may be more likely to cause mild clinical signs.
  F. *E. ewingii* and *A. phagocytophilum* may be more likely to cause polyarthritis (Goodman et al., 2003).
  G. *N. risticii* var. *atypicalis* may cause severe disease (Kakoma et al., 1994).
  H. Coinfection occurs and may result in more severe clinical signs.

TABLE 115-1

Classification of *Ehrlichia* spp., *Anaplasma* spp., and *Neorickettsia* spp. by Genogroup

ORGANISM	GEOGRAPHIC DISTRIBUTION	VECTORS	CELLS INFECTED	HOSTS	CROSS-REACTIVITY WITH *EHRLICHIA CANIS*
Monocytotropic, Genogroup/Serogroup I					
Ehrlichia canis	Worldwide	*Rhipicephalus sanguineus, Dermacentor variabilis*	Mononuclear cells	Dogs, wild canids, cats, humans (Venezuela)	NA
Ehrlichia chaffeensis	United States, Asia	*Amblyomma americanum, Amblyomma testudinarium, Dermacentor variabilis, Ixodes ovatus, Haemophysalis* spp.	Mononuclear cells, neutrophils	Dogs, humans, goats	3
Ehrlichia ruminatum	Sub-Saharan Africa	*Amblyomma hebraeum*	Mononuclear cells, endothelial cells, neutrophils	Cattle, sheep, goats, dogs	2
Monocytotropic, Genogroup/Serogroup III					
Neorickettsia risticii	United States, Canada	Trematode larvae	Mononuclear cells, enterocytes, mast cells	Snails (reservoir), dogs (subsp. *atypicalis*), horses, cats	0 to 1
Neorickettsia helminthoeca	Northwestern United States, southwestern Canada	Trematode	Mononuclear cells	Fish (reservoir), dogs	2
Granulocytotropic, Genogroup/Serogroup I					
Ehrlichia ewingii	United States, Africa	*Amblyomma americanum,* possibly *Dermacentor variabilis, Rhipicephalus sanguineus*	Neutrophils, eosinophils deer	Dogs, humans, white-tailed	3
Granulocytotropic, Genogroup/Serogroup II					
Anaplasma phagocytophilum	United States, Europe, Africa, Asia	*Ixodes scapularis, Ixodes ricinus, Ixodes pacificus, Ixodes persulcatus, Rhipicephalus sanguineus*	Neutrophils, eosinophils	Humans, dogs, cats, horses, sheep, goats	0 to 1
Thrombocytotropic, Genogroup/Serogroup II					
Anaplasma platys	Unites States, Australia, southern Europe, South America, Asia, Middle East, Africa	Possibly *Rhipicephalus sanguineus*	Platelets	Dogs	0

NA, Not applicable; *0,* no cross-reactivity; *1,* weak cross-reactivity; *2,* low cross-reactivity; *3,* high cross-reactivity.

Diagnosis

I. Hematological and coagulation abnormalities
  A. Thrombocytopenia common
  B. Nonregenerative (most common) or regenerative anemia
  C. Leukopenia, especially neutropenia
  D. Pancytopenia: usually in severe disease
  E. Possible large granular lymphocytosis
  F. Prolonged activated clotted time
  G. Prolonged bleeding time, especially with platelet dysfunction
  H. Prolonged prothrombin and partial thromboplastin times uncommon
II. Serum biochemistry changes
  A. Hyperproteinemia: monoclonal or polyclonal gammopathy with hypoalbuminemia, hyperviscosity
  B. Increased alanine transaminase, alkaline phosphatase (ALP) activities
  C. Possible azotemia
III. Urinalysis results
  A. Proteinuria
  B. Decreased urine specific gravity
  C. Possible bacteriuria: secondary infections in immunocompromised dogs
IV. Cerebrospinal fluid (CSF) analysis: increased protein; mononuclear, lymphocytic, neutrophilic pleocytosis
V. Bone marrow cytological findings: hyperplastic or hypoplastic cell lines, plasma cell infiltration
VI. Arthrocentesis: neutrophilic inflammation
VII. Organism identification
  A. Blood buffy coat and bone marrow smears or tissue aspirates (e.g., lymph node, spleen)
    1. Morulae are occasionally seen in monocytes, neutrophils, eosinophils, and platelets (see Table 115-1).
    2. False-negatives occur owing to a low number of organisms.
  B. Morulae rarely seen in joint fluid, CSF
  C. PCR assays using genus- or species-specific primers: spleen more sensitive than blood with *E. canis*
VIII. Serological testing
  A. Indirect immunofluorescent antibody (IFA) testing is the most common and best assay.
  B. Other techniques exist, including enzyme-linked immunosorbent assay (ELISA) and Western immunoblotting.
  C. Antibodies are detected 2 to 7 days postinfection, peak at 2 to 5 months, and may persist for long periods.
  D. No serological test exists for *E. ewingii,* but infected animals show cross-reactivity with *E. canis* antigens.
  E. Positive titers occur in some clinically healthy dogs in endemic areas.
  F. Serological cross-reactivity among different *Ehrlichia* spp., *Anaplasma* spp., and *Neorickettsia* spp. pose problems in interpretation (see Table 115-1).
  G. Perform acute and convalescent tests (2 to 4 weeks after initial presentation); a fourfold increase in titers indicates acute infection.

Differential Diagnosis

I. Rocky mountain spotted fever (RMSF)
II. *Leishmania infantum*
III. *Bartonella* spp.
IV. Other causes of thrombocytopenia (see Chapter 67) and pancytopenia
V. Other causes of lymphadenopathy and splenomegaly (see Chapters 69 and 70)

Treatment

I. Standard treatment: doxycycline 10 mg/kg PO, IV SID to BID for 4 to 6 weeks
  A. Shorter treatment with doxycycline or tetracycline (10 to 21 days) may be used for *E. ewingii* and *A. phagocytophilum* infections.
  B. If not certain of infecting species, treat for 4 to 6 weeks
II. Tetracycline 22 mg/kg PO TID for 28 days
III. Oxytetracycline 25 mg/kg PO, IV TID for 28 days
IV. Minocycline 10 mg/kg PO, IV BID for 28 days
V. Chloramphenicol 15 to 25 mg/kg PO, SC, IV TID for 28 days
VI. Imidocarb dipropionate 5 mg/kg IM once; repeat in 2 to 3 weeks, with cholinergic side effects treated with atropine
VII. Supportive care: IV fluids, blood transfusions

Monitoring and Prevention

I. Dogs treated in the acute phase usually respond within 72 hours.
II. Resolution of thrombocytopenia usually indicates a good response to therapy.
III. Platelet counts begin to increase within 48 hours and are commonly normal within 14 days.
IV. Chronically infected dogs often need long-term therapy and their response may be poor or incomplete.
V. Complete immunity does not occur in recovered animals and cross-protection probably does not occur.
VI. Titers often decline after treatment.
VII. Vector control is very important.
VIII. Prophylactic treatment with doxycycline at 3 mg/kg PO SID may reduce infections but can also result in antimicrobial resistance (Davoust et al., 2005).

ROCKY MOUNTAIN SPOTTED FEVER

Nolie K. Parnell

Definition and Cause

I. RMSF is a tick-borne disease of dogs that occurs throughout the United States.
II. The etiologic agent is *Rickettsia rickettsi,* an obligate intracellular organism in the family Rickettsiaceae.

Pathophysiology

I. Epidemiological findings
  A. Reported in all lower continental states except Maine

B. Predominantly seen in the southeastern states
C. Also reported in Canada, Mexico, Central America, and South America

II. Transmission
A. Ticks are the natural hosts, reservoirs, and vectors, and are infected by horizontal transmission either transtadially or transovarially.
B. *Dermacentor variabilis* (American dog tick) is the primary vector in the eastern United States, and *Dermacentor andersoni* (wood tick) is important in the western United States.
C. *Rhipicephalus sanguineus* (brown dog tick) was recently implicated as a vector for *R. rickettsii* (Demma et al., 2005).

III. Pathogenesis
A. *R. rickettsii* replicates in endothelial cells of small vessels, causing vasculitis and activation of the complement and coagulation systems.
B. Increased vascular permeability ensues, with plasma loss; hypotension; and subcutaneous, pulmonary, and sometimes cerebral edema.
C. Shock, multiple organ failure, and disseminated intravascular coagulopathy occur in the terminal stages.

Clinical Signs

I. Subclinical infections can occur.
II. Common signs include fever, lethargy, and anorexia.
III. Cutaneous edema, vesicles, macules, dermal necrosis, petechiae, and ecchymoses may occur.
IV. Neurological signs include central vestibular deficits (most common), seizures, and spinal hyperesthesia.
V. Other signs include the following:
A. Arthralgia
B. Ocular and nasal discharge: serous to serosanguineous
C. Retinal hemorrhages
D. Cough, dyspnea
E. Orchitis (Ober et al., 2004)

Diagnosis

I. Early diagnosis is important to reduce mortality.
II. Known tick exposure can be as low as 17% (Gasser et al., 2001).
III. Occurrence is highest from April through September.
IV. Hematological and clotting abnormalities are common.
A. Thrombocytopenia, anemia
B. Leukopenia early: predominately neutropenia
C. Leukocytosis as illness progresses: neutrophilia with a left shift
D. Prolonged clotting times, increased fibrin degradation products
V. Serum biochemistry findings are nonspecific.
A. Possibly no abnormalities
B. Increased liver and muscle enzyme activities
C. Electrolyte abnormalities
D. Hypoalbuminemia, hypercholesterolemia
E. Possibly azotemia
VI. Urinalysis may show proteinuria, hematuria, and bilirubinuria.
VII. CSF analysis may show normal to slightly increased protein, and neutrophilic pleocytosis.
VIII. Synovial fluid analysis often shows an increased leukocyte count (nondegenerate neutrophils).
IX. A mild interstitial pattern is common on thoracic radiographs.
X. Several diagnostic tests are available.
A. Indirect IFA, microimmunofluorescence, latex agglutination, ELISA tests
1. Immunoglobulin (Ig) M is detectable in the first 2 weeks, diminishes after 1 month, and becomes undetectable after 80 days.
2. IgG is detectable in 2 to 3 weeks, peaks at 1 to 2 months, and usually decreases by 4 to 5 months.
a. A single, very high IgG titer (>1:1024) supports the diagnosis.
b. Measurement of acute and convalescent IgG titers with a fourfold increase is diagnostic.
3. Cross-reaction with other nonpathogenic spotted fever group rickettsiae can occur.
B. Direct fluorescent antibody testing of biopsies of mucosal or skin lesions
C. Possible increased antiplatelet antibody titers
D. PCR of blood or tissues

Differential Diagnosis

I. Ehrlichiosis, anaplasmosis, borreliosis
II. Other causes of vasculitis and fever
III. Other causes of anterior and posterior uveitis (see Chapters 99 and 102)
IV. Other causes of seizures and neurologic signs (see Chapters 22 and 23)

Treatment

I. Antibiotics are given for 10 to 14 days.
A. Doxycycline 5 to 10 mg/kg PO, IV BID
B. Tetracycline 22 to 30 mg/kg PO, IV TID
C. Chloramphenicol 25 to 30 mg/kg PO, SC, IM, IV TID
D. Enrofloxacin 3 mg/kg PO, IM BID
II. Supportive care is also provided.
A. Intravenous colloid or cautious use of crystalloid solutions as needed
B. Transfusions as indicated
C. Judicious use of prednisone for immune-mediated complications (Breitschwerdt et al., 1997)

Monitoring and Prevention

I. A rapid response (24 to 48 hours) to therapy is common.
II. Delayed diagnosis and presence of severe disease delays the response.
III. Delayed recovery is more common with organ failure or central nervous system damage.
IV. Immunity to RMSF probably occurs for at least 3 years after recovery.
V. Tick control is important.

HEMOTROPIC MYCOPLASMOSIS

Laia Solano-Gallego

Feline Hemoplasmosis

Definition and Causes

I. The disease is caused by three variants of gram-negative, epicellular parasites of feline erythrocytes (red blood cell [RBC]).
   A. *Mycoplasma haemofelis (Mhf):* previously *Haemobartonella felis* large variant (Ohio strain)
   B. *Candidatus* Mycoplasma haemominutum *(Mhm):* previously *H. felis* small variant (California strain)
   C. *Candidatus* Mycoplasma turicensis *(Mht):* novel hemoplasma recently discovered in Swiss cats

II. All organisms are considered species-specific, do not survive outside the host, and culture attempts have been unsuccessful.

Pathophysiology

I. Epidemiology
   A. *Mhf* and *Mhm* are reported in clinically healthy and ill cats in North America, Europe, Japan, and Australia.
   B. A higher prevalence of *Mhf* infection occurs in anemic cats from North America and Spain, whereas prevalence of *Mhm* infection is similar between anemic and nonanemic cats (Jensen et al., 2000; Criado-Fornelio et al., 2003).
   C. Prevalence of coinfection with *Mhf* and *Mhm* is low.
   D. *Mht* has been detected by PCR in 1% of ill cats, and healthy cats have been PCR-negative in Switzerland (Willi et al., 2005, 2006).
   E. Natural hemoplasma infections are more likely in male, outdoor, older, and mixed-breed cats (Tasker et al., 2003, 2004; Willi et al., 2006).

II. Transmission
   A. *Mhf* is experimentally transmitted by IV, intraperitoneal, and oral inoculation of blood.
   B. *Mhm* and *Mht* are experimentally transmitted by IV inoculation of blood.
   C. *Ctenocephalides felis* transmission of *Mhf,* but not *Mhm,* via hematophagous activity is documented.
   D. Cat-to-cat transmission may occur by biting.
   E. Transmission from clinically ill queens to kittens may occur in utero, during parturition, or via nursing.

III. Pathogenesis
   A. RBC destruction via immune-mediated extravascular erythrophagocytosis
   B. Minimal direct RBC injury
   C. *Mhf* more pathogenic than *Mhm* or *Mht*
      1. One third of *Mhf*-infected cats die if not treated.
      2. Cats that recover from acute illness remain infected for months to years, if not for life.

Clinical Signs

I. Subclinical infection, mild anemia, or severe hemolytic anemia may occur (Messick, 2004).

II. Concomitant diseases or infections (e.g., neoplasia, FeLV) that modify the immune system, and stressful conditions can activate subclinical hemoplasma, resulting in clinical disease.

III. With *Mhf,* clinical disease occurs in immunocompetent and immunosuppressed naturally-infected cats.
   A. Hemolytic anemia: pale mucous membranes, tachypnea, lethargy, inappetence, weakness, icterus, dehydration, occasional splenomegaly
   B. Weight loss
   C. Intermittent fever: chronically infected cats

IV. With *Mhm,* subclinical infections or mild clinical signs occur in experimentally infected cats (Foley and Pedersen, 2000).
   A. Mild fever may occur.
   B. It is more often common in sick cats, but it is unclear whether signs are related to *Mhm* infection or to concomitant diseases.

V. With *Mht,* mild to severe hemolytic anemia occurs in ill or immunosuppressed cats (Willi et al., 2005, 2006).

Diagnosis

I. Hematological findings
   A. Regenerative anemia (normochromic or hypochromic) with polychromasia, macrocytosis, aggregate reticulocytosis
   B. Nonregenerative anemia: unusual
   C. Positive Coombs' test: common
   D. Possible neutrophilia or monocytosis

II. Serum biochemistry: possible hyperbilirubinemia, increased alanine aminotransferase (ALT) or ALP activity

III. Urinalysis: possible bilirubinuria

IV. Demonstration of organisms on RBCs
   A. Blood film examination result is falsely negative about half the time, especially with chronic infections.
   B. If the cat is cytologically negative, make a blood smear without ethylenediamine tetraacetic acid (EDTA) anticoagulant and consider PCR testing.
   C. Acridine orange labeling is more sensitive, but requires a fluorescence microscope.

V. PCR assay
   A. Test of choice because of its higher sensitivity
   B. Able to determine the infecting species

VI. Interpretation of test results
   A. Positive test results document infection, not clinical illness.
   B. Demonstration of organisms or a positive PCR test in a clinically ill cat indicate the need for treatment.

Differential Diagnosis

I. Other causes of hemolytic anemia
   A. *Cytauxzoon felis, Babesia* spp., bacterial septicemia
   B. Primary immune-mediated hemolytic anemia (IMHA)
   C. Secondary IMHA

II. Other infectious, neoplastic, and immune-mediated causes of fever and icterus

III. FeLV, FIV infections

Treatment

I. Because mycoplasmosis and primary IMHA are difficult to differentiate, treat cats with severe, regenerative anemia with antibiotics followed by glucocorticoids.
   A. Oxytetracycline 22 mg/kg PO TID for 21 days
   B. Doxycycline 2.5 to 5 mg/kg PO BID to SID for 14 to 21 days
      1. Preferred, fewer side effects
      2. Given as liquid or pills, followed with water to avoid esophagitis
   C. Enrofloxacin 5 mg/kg PO SID for 14 days; efficacy equals doxycycline, but blindness possible (Dowers et al., 2002)
II. Treatment does not eliminate *Mhf* or *Mhm* infections, but doxycycline may eliminate *Mht* infection.
III. If autoagglutination is evident, cautiously use prednisolone 1 to 2 mg/kg PO BID for the first 7 days or until autoagglutination is no longer evident.
IV. Administer supportive care, including IV fluids and blood transfusions as indicated.
V. Treatment of healthy cats infected with *Mhf* and *Mhm* may not be indicated as no drug has been shown to clear the organisms.
VI. Consider treating healthy *Mht* infected cats because clearance of the organism is reported after therapy, and immunosuppression or stress in infected cats may lead to severe, acute hemolysis.

Monitoring and Prevention

I. Monitor blood count SID to QOD until microagglutination resolves and hematocrit is normal.
II. Warn the owner that the disease can recur from recrudescence or reinfection.
III. The prognosis is generally good for immunocompetent cats.
IV. Control potential arthropod vectors such as fleas.
V. Keep cats indoors to avoid vectors and fighting.
VI. Use PCR assays to screen cats used as blood donors.

Canine Hemoplasmosis

Laia Solano-Gallego

Definition and Causes

I. *Mycoplasma haemocanis (Mhc)* is a rare cause of anemia in dogs.
II. Clinical relevance of a novel hemotropic *Mycoplasma (Candidatus* M. haemoparvum *[Mhp]),* recently detected in dogs and molecularly similar to *Mhm* is not known (Sykes et al., 2005; Kenny et al., 2004).

Pathophysiology

I. Epidemiological findings
   A. Dogs worldwide are likely infected.
   B. *Mhp* and/or *Mhc* have been detected in dogs in France.
   C. *Mhc, Mhp,* and *Mhm* have been detected by PCR in dogs in the United States (Sykes et al., 2006).
II. Transmission of *Mhc*
   A. *Rhipicephalus sanguineus*
   B. Blood transfusion, contaminated equipment
   C. Ingestion of infected blood
III. Pathogenesis of *Mhc*
   A. Organism attaches to RBC surface, distorting its shape.
   B. Lysis of the RBC may result.

Clinical Signs

I. Splenectomized or immunocompromised dogs are more likely to develop clinical signs of *Mhc.*
II. Possible signs include the following:
   A. Pale mucous membranes
   B. Lethargy, anorexia, icterus
   C. Death in severe infections

Diagnosis

I. Hematological findings with *Mhc* infection
   A. A regenerative anemia occurs within 1 to 2 days with constant parasitemia.
   B. A slow onset (2 to 3 weeks) regenerative anemia occurs with relapsing parasitemia.
   C. Severity of the anemia varies.
II. Urinalysis: possible bilirubinuria
III. Organism identification
   A. Chains of organisms on RBC surfaces
   B. PCR assay

Treatment

I. Antiparasiticidal treatment (when necessary) includes the following:
   A. Doxycycline 5 mg/kg PO BID for 21 days
   B. Tetracycline 20 mg/kg PO TID for 21 days
   C. Oxytetracycline 20 mg/kg PO TID for 21 days
II. Blood transfusions and other supportive care are administered as needed.

Monitoring and Prevention

I. Dogs that have recovered from clinical disease are persistently infected.
II. Clinical signs may recur with subsequent stress or other illnesses.
III. Tick control is important.
IV. Screen dogs used as blood donors via PCR assays.

SALMON POISONING DISEASE

Nolie K. Parnell

Definition and Cause

I. Salmon poisoning is a mild to severe (fatal) gastrointestinal (GI) or systemic disease of wild (e.g., coyote, fox) and domestic canids.
II. Elokomin fluke fever is nearly identical but associated with less mortality.
III. The etiologic agent is *Neorickettsia helminthoeca.*

Pathophysiology

I. Epidemiological findings
  A. It occurs primarily from northern California to central Washington and is also reported in British Columbia (Vancouver Island).
  B. The trematode vector *Nanophyetus salmincola* harbors the rickettsia throughout its life cycle and infects salmonid fish.
II. Life cycle
  A. Dogs ingest *N. helminthoeca*–infected metacercariae in raw fish, and the metacercariae mature in 5 to 6 days.
  B. The adult stage attaches to intestinal mucosa, and *N. helminthoeca* are released via unknown mechanisms.
  C. The agent enters monocytes and macrophages; migrates to the lymph nodes, spleen, brain, liver, and lungs; and causes severe inflammation and edema of the intestines.
  D. Although mild intestinal epithelial inflammation is possible without systemic signs, severe signs and death may occur.

Clinical Signs

I. Acute, transient fever (40° to 42° C) followed by hypothermia within 1 week
II. Moderate to marked anorexia, lethargy, vomiting, diarrhea (watery, yellowish, blood tinged), weight loss
III. Serous ocular and nasal discharge
IV. Lymphadenomegaly

Diagnosis

I. Exposure to endemic area
II. Hematological findings: thrombocytopenia, lymphopenia, eosinophilia, leukopenia followed by leukocytosis
III. Serum biochemistry results: increased ALP activity, hypoalbuminemia
IV. Lymph node aspirate cytology: organisms seen with Romanowsky or Giemsa stains
V. Discovery of trematode eggs in feces supportive but not definitive
VI. Serological testing with IFA and Western immunoblot analysis
  A. Antibodies are not detected until 2 weeks after infection.
  B. Do not delay treatment while waiting for serological test results.

Differential Diagnosis

I. Canine distemper
II. Parvovirus
III. Other causes of hemorrhagic diarrhea

Treatment and Monitoring

I. Parenteral antibiotic administration is preferred because of the severe GI involvement.
  A. Doxycycline 10 mg/kg PO, IV BID for 7 days
  B. Oxytetracycline 7 mg/kg PO, IV TID for 3 to 5 days
  C. Tetracycline 22 mg/kg PO, IV TID for 3 to 5 days
  D. Chloramphenicol 30 mg/kg PO, SC, IM, IV TID for 7 days
  E. Praziquantel 10 to 30 mg/kg PO, SC once to eradicate the fluke infestation
II. Supportive care includes IV fluids and maintaining body temperature.
III. Early treatment minimizes morbidity and helps prevent mortality.
IV. Prevent dogs from eating raw salmonid fish.
V. Freeze (–20° C for at least 24 hours) or cook fish completely to destroy organisms.
VI. Protective immunity occurs with recovery; however, immunity is not cross-protective for Elokomin fluke fever.

Q FEVER

Michael Lappin

Definition and Cause

Q fever is a systemic disease caused by *Coxiella burnetii,* a rickettsial agent found throughout the world, including North America.

Pathophysiology

I. Epidemiological findings
  A. Multiple arthropods, including *R. sanguineus*, are naturally infected with *C. burnetii*.
  B. Cats, dogs, cattle, sheep, and goats are subclinically infected and pass the organism into the environment in urine, feces, milk, and parturient discharges.
  C. The precise incidence of disease in cats and dogs has not been determined, but serological tests suggest exposure is common (Higgins and Marrie, 1988; Boni et al, 1998; Komiya et al, 2003a).
  D. The organism has been grown from vaginal cultures of normal cats in Japan (Nagoaka et al., 1998).
II. Transmission
  A. Infection may follow tick exposure, ingestion of contaminated carcasses, or aerosolization from a contaminated environment.
  B. Infection of people by exposure to cats or dogs most commonly occurs by inhalation of the organism in secretions from parturient or aborting animals.

Clinical Signs

I. Fever, anorexia, and lethargy develop in experimentally infected cats.
II. Natural infection is associated with abortion, but the role the organism plays in other clinical syndromes is unknown.

Diagnosis

I. Definitive diagnosis is based on culture or PCR (Greene and Breitschwerdt, 2006).
II. Positive serological tests confirm exposure to *C. burnetii.*

Differential Diagnosis

I. Other causes of abortion or fever must be ruled out.
II. Most cats and dogs are subclinically infected.

Treatment and Monitoring

I. Because infection is difficult to confirm and most cats and dogs are subclinically infected, successful treatment has not often been reported.
II. Minocycline 5 mg/kg PO SID for 4 weeks has converted a few dogs and cats from PCR-positive to PCR-negative status (Komiya et al., 2003b).
III. Because Q fever is an occupational hazard for veterinary health care providers, gloves and masks should be worn when attending to parturient or aborting cats and dogs.
IV. Medical attention is recommended for people with signs of severe respiratory disease who have recently been exposed to cats or dogs.

CHAPTER 116

Protozoal Infections

Nolie K. Parnell | Lynn Guptill | Laia Solano-Gallego

ENTERIC INFECTIONS

Nolie K. Parnell

Giardiasis

Definition and Cause

I. Giardiasis is an acute or chronic gastrointestinal (GI) tract disease characterized by diarrhea and weight loss in both cats and dogs.
II. *Giardia duodenalis,* a flagellate protozoan, has many morphologically identical isolates.
III. There are at least seven described genetic groups; four (Groups A, B, C, D) infect dogs, and two (Groups A and F) infect cats.

Pathophysiology

I. Epidemiological findings
  A. Worldwide distribution
  B. Prevalence
    1. Dogs: 4.7% to 10%, up to 50% in puppies and 100% in kennels (Barr et al., 1994; Nolan and Smith, 1995)
    2. Cats
      a. 1.3% to 13.64% in general population (Vasilopulos et al., 2006)
      b. 3.9% to 35% in cats with diarrhea, from shelters, or from catteries (Hill et al., 2000; Gookin et al., 2004)
      c. Possibly higher in general population (McGlade et al., 2003)
  C. Risk factors
    1. High housing density, presence of nonfeline species (Gookin et al., 2004)
    2. Coinfection with *Cryptosporidium* spp. (Vasilopulos et al., 2006)
II. Transmission: direct fecal–oral
III. Life cycle
  A. Cysts are ingested from contaminated water, feces, or other items.
  B. Trophozoites exist in the small intestines, and then mature and attach to the enterocyte brush border.
  C. Cysts and trophozoites are passed in feces and are infective for the next host.
IV. Pathogenesis
  A. Attachment to epithelium may cause villous atrophy, malabsorption, and increased enterocyte turnover.
  B. Host immune responses (humoral and cellular) are important in clearing infection.
  C. Host immune response, nutritional status, concurrent GI disease, coinfection with multiple enteric protozoa, and virulence of *Giardia* strain all affect severity of clinical disease (Gookin et al., 2004; Lappin, 2005).

Clinical Signs

I. Most infections asymptomatic
II. Common: acute, often self-limiting small-bowel diarrhea
III. Less common: intermittent or chronic diarrhea, weight loss, inappetence, vomiting in cats
IV. Rare: acute or chronic large-bowel diarrhea

Diagnosis

I. Clinical pathological tests: nonspecific results
II. Parasite identification in feces
  A. Direct smear of fresh feces
    1. Some infected dogs (40%) are identified by direct fecal smears done on 3 separate days (Leib et al., 1999).
    2. Trophozoites have a "smiling face" appearance owing to two nuclei, erratic tumbling motion, and a concave ventral disk.
    3. Identification is made easier with one drop of Lugol's iodine.
  B. Zinc sulfate concentration technique (specific gravity 1.18)
    1. Approximately 70% of infected dogs are identified with a single assay, and up to 93% with three examinations on 3 consecutive days (Leib et al., 1999).
    2. Cysts are distorted by sucrose and other fecal analysis solutions.
  C. Enzyme-linked immunosorbent assay (ELISA) for fecal antigens: false-positives and false-negatives possible
  D. Polymerase chain reaction (PCR) assays: more sensitive (McGlade et al., 2003)
  E. Immunofluorescent antibody (IFA) (Lappin, 2005)
    1. Assays for human isolates, so false-negatives possible
    2. Can be performed on refrigerated or frozen stored samples
III. Parasite identification in duodenal aspirates possible

Differential Diagnosis

I. Rule out other causes of small-bowel diarrhea.
   A. Dietary indiscretion
   B. Viral enteritis
   C. Other intestinal parasites
   D. Drug reactions, toxicosis
   E. Food allergy
   F. Pancreatic exocrine insufficiency
   G. Inflammatory bowel disease, small intestinal bacterial overgrowth
   H. Feline hyperthyroidism
   I. Neoplasia
II. Rule out other causes of large-bowel diarrhea.
   A. Other intestinal parasites
   B. Bacterial or fungal enterocolitis
   C. Dietary indiscretion
   D. Inflammatory bowel disease
   E. Neoplasia

Treatment

I. Metronidazole 15 to 25 mg/kg PO BID for 5 to 7 days
   A. Used in dogs and cats
   B. Neurological side effects possible with prolonged treatment or higher dosages
II. Fenbendazole 50 mg/kg PO SID for 5 days in dogs and cats
III. Albendazole 25 mg/kg PO BID for 2 days in dogs
   A. Use it with caution, because it can cause bone marrow suppression.
   B. Do not use it in cats.
IV. Praziquantel, pyrantel pamoate, febantel combination *(Drontal-Plus)* at recommended label dose PO for 3 to 5 days

Monitoring and Prevention

I. Bathing animals during treatment is essential to remove parasites from the hair coat.
II. Treatment failures and relapses are possible, because drug-resistant *Giardia* spp. exist and reexposure occurs in contaminated environments.
III. Environmental management is essential and involves removal of feces and all organic material followed by disinfection with 1 part household bleach (5.25% sodium hypochlorite) in 32 parts water.
IV. A killed vaccine for dogs and cats is sometimes used in conjunction with other methods for high-risk populations or resistant infections, but efficacy is uncertain (Stein et al., 2003; Olson et al., 2001; Anderson et al., 2004).
V. Some *Giardia* spp. genogroups are known to infect dogs (A1 and B) and humans or cats (A1); therefore some forms of giardiasis are likely zoonotic.

Trichomoniasis

Definition and Cause

I. *Tritrichomonas foetus* is a single-celled, flagellated protozoa that causes diarrhea in cats (Gookin et al., 2004).
II. Trichomonad infections are documented in dogs with diarrhea, but their pathogenicity is unproven.

Pathophysiology

I. Epidemiological findings
   A. Young cats and cats from multiple-cat environments more susceptible
   B. Some breeds possibly more susceptible: Pixie-Bob cat, Abyssinian, Bengal (Romatowski, 2000)
II. Transmission: fecal–oral
III. Pathogenicity
   A. Debated and not completely understood
   B. Concurrent mild-to-moderate lymphoplasmacytic and neutrophilic colitis with crypt epithelial cell hypertrophy, hyperplasia, loss of goblet cells, and microabscesses (Yaeger and Gookin, 2005)

Clinical Signs

I. Asymptomatic infections occur.
II. Chronic large-bowel diarrhea is the primary clinical sign.
III. Diarrhea waxes and wanes and is not associated with systemic illness (Gookin et al., 2004)

Diagnosis

I. Diagnosis is by identification of the organism.
II. Test feces within 1 hour of defecation; do not refrigerate the sample.
   A. Direct smear to identify motile trophozoites
   B. Protozoal culture with modified Diamond medium or commercially available system (In Pouch) (Gookin et al., 2003)
   C. PCR more sensitive than culture (Gookin et al., 2002; Houser et al., 2006)
III. *T. foetus* is easily confused with *Giardia* spp. and *Pentatrichomonas* spp. on fecal examination.

Differential Diagnosis

I. Bacterial enterocolitis
II. Giardiasis
III. Inflammatory bowel disease
IV. Large-bowel neoplasia

Treatment

I. Ronidazole may be given at 30 to 50 mg/kg PO BID for 14 days (Gookin et al., 2006).
   A. Only used in a small number of animals to date
   B. May be difficult to acquire in the United States
   C. Neurological side effects possible
II. Metronidazole at 25 mg/kg PO BID for 5 to 7 days may improve clinical signs, but relapses are common and organisms may persist.

Monitoring and Prevention

I. Many cats have spontaneous resolution of clinical signs within 2 years (Foster et al., 2004).
II. Some cats remain infected for life.
III. Relapses occur following treatment.

IV. Zoonotic potential is unproven, but immunocompromised people should avoid contact with infected cats.

Cryptosporidiosis

Definition and Causes

I. *Cryptosporidium parvum,* a ubiquitous protozoan, has a wide mammalian host range and causes diarrhea in dogs and cats.
II. Other species may infect animals and are morphologically identical to *C. parvum* (Sargent et al., 1998).
  A. *Cryptosporidium felis* is primarily found in cats.
  B. *Cryptosporidium canis* is primarily found in dogs.

Pathophysiology

I. Transmission occurs via the fecal–oral route.
II. All stages of the life cycle take place in one host.
  A. Sporulated oocysts are ingested, and sporozoites infect enterocytes.
  B. Trophozoites form in parasitophorous vacuoles.
  C. Thick-walled oocysts are released into feces.
  D. Thin-walled oocysts may reinfect the host.
III. Pathogenesis is uncertain.
  A. It may cause morphological and functional changes in enterocytes.
  B. Host immune response influences pathogenesis.
  C. Clinical disease is more common in young or immunocompromised animals.

Clinical Signs

I. Asymptomatic infections possible
II. Common: small-bowel diarrhea
III. Less common
  A. Dogs and cats: large-bowel diarrhea (chronic)
  B. Cats: anorexia, weight loss

Diagnosis

I. Parasite identification
  A. Feces
    1. Direct smear using crystal violet or acid-fast stain: false-negatives possible
    2. Sugar solution centrifugation and zinc sulfate concentrations combined with staining
    3. Formalin–ether or formalin–ethyl acetate fecal sedimentation
    4. IFA assay
  B. Intestinal biopsy
    1. Giemsa stain is best; hematoxylin/eosin is acceptable.
    2. False-negatives occur.
    3. Organisms are most easily found in the ileum.
II. Ancillary testing
  A. IFA labeling of tissues is available.
  B. ELISA test for serum antibodies indicates exposure, but does not predict oocyst shedding.
  C. ELISAs to detect antigen in feces are being evaluated.
    1. Greater sensitivity in kitten feces than IFA (Marks et al., 2004)
    2. Not yet evaluated in dogs
  D. PCR is more sensitive than IFA (Scorza et al., 2003).

Differential Diagnosis

I. Other endoparasites
II. Inflammatory bowel disease
III. Viral and bacterial enteritis
IV. Dietary indiscretion
V. Neoplasia

Treatment

I. Treatment may not be necessary in immunocompetent animals because infections are often self-limiting.
II. Azithromycin 5 to 10 mg/kg (dogs) or 7 to 15 mg/kg (cats) PO BID may be given for 5 to 7 days (Barr, 2006b).
III. Tylosin 11 mg/kg PO BID in food for 28 days may improve diarrhea in cats (Lappin et al., 1997).
IV. Paromomycin 150 mg/kg PO SID to BID for 5 days must be used with extreme caution because it is nephrotoxic.
V. Supportive care with IV fluids and nutritional support as needed.

Monitoring and Prevention

I. Treatment failure is common and necessitates evaluation for concurrent immunosuppressive conditions or environmental contamination.
II. Clean the environment, then disinfect with steam followed by thorough drying, or apply 50% ammonia solution for 30 minutes using appropriate protective equipment.
III. Cryptosporidiosis can be zoonotic.
  A. Immunocompromised people should avoid infected animals.
  B. Use caution when handling feces and tissues to prevent accidental infection.

Enteric Coccidiosis

Definition and Causes

I. Coccidia cause GI disease that is characterized by diarrhea, weight loss, and possibly vomiting.
II. Multiple genera infect dogs and cats, including *Isospora (Cystoisospora), Hammondia*, *Besnoitia, Sarcocystis, Toxoplasma, Neospora*, and *Cryptosporidium*.
III. *Isospora (Cystoisospora)* is the most common genus, and multiple species are incriminated.
  A. Dogs: *I. canis, I. ohioensis, I. burrowsi, I. neorivolta*
  B. Cats: *I. felis, I. rivolta*
IV. *Eimeria* spp. oocysts appear in the feces of cats and dogs that ingest *Eimeria*-infected prey or feces, but are not considered pathogenic.

Pathophysiology

I. Oocysts in feces sporulate in 6 hours to 3 days.
  A. Sporozoites excyst from ingested oocysts and invade intestinal mucosa.
  B. Asexual reproduction produces meronts and schizonts with multiple cycles of merogony.

C. Sexual cycle (microgamonts and macrogamonts) produces oocysts.
II. Prepatent period is 5 to 11 days.
III. Transmission also occurs via ingestion of infected paratenic hosts (e.g., mice, insects).
IV. Sporozoites may invade extraintestinal tissues (e.g., mesenteric lymph nodes), form monozoic cysts, and persist for life.
V. Pathogenicity is possibly linked to oocyst dose, age of animal, and host immune status.

Clinical Signs

I. Animals <6 months of age or immunocompromised animals are more likely to develop clinical signs.
II. Subclinical carriers are common.
III. Small- and large-bowel diarrhea of varying severity is the major clinical abnormality.
IV. Rarely, abdominal pain, vomiting, dehydration, anorexia, anemia, and death occur.

Diagnosis

I. Diagnosis is easier when diarrheic feces are used for testing.
II. Diagnosis is by demonstration of oocysts in feces, preferably using Sheather's sugar centrifugation method.
III. Oocyst size aids in determining the genus and species.

Differential Diagnosis

I. Viral enteritis
II. Dietary indiscretion
III. Other endoparasites

Treatment

I. Sulfonamides
  A. Dogs and cats: trimethoprim-sulfonamide 15 mg/kg PO SID to BID for 5 days
  B. Dogs and cats: sulfadimethoxine 50 mg/kg PO SID for 10 days
  C. Dogs: ormetoprim-sulfadimethoxine 66 mg/kg PO (55 mg/kg sulfadimethoxine and 11 mg/kg ormetoprim) SID for 7 to 23 days
II. Amprolium 60 to 100 mg (total) PO SID for 5 days (Lappin, 2005)
III. Nitrofurazone 8 to 20 mg/kg PO SID to BID for 5 days in dogs and cats; decrease dose by 50% when used with sulfonamides.
IV. Supportive care as needed

Monitoring and Prevention

I. Most infections are self-limiting, but it is important to eliminate any underlying predisposing condition.
II. Bathe animals during treatment to remove fecal material and oocysts.
III. Environmental sanitation is important to prevent infection and facilitate treatment.
  A. Avoid contamination of food and water bowls by infected feces.
  B. Remove feces daily, wash and treat premises with 10% ammonia solutions, or use steam.
  C. Control insects (paratenic host) in the environment (e.g., flies).

GENERALIZED INFECTIONS

Babesiosis

Laia Solano-Gallego

Definition and Causes

I. Babesiosis is a worldwide, tick-borne disease caused by hemoprotozoa of the genus *Babesia.*
II. It is characterized by erythrocyte (red blood cell [RBC]) destruction and mild to severe systemic signs.
III. Canine babesiosis is usually caused by *B. canis* or *B. gibsoni* (Table 116-1).
IV. Two newly described species are associated with hemolytic anemia in dogs in the United States.
V. Feline babesiosis is not reported in the United States.

Pathophysiology

I. Epidemiology, transmission, life cycle
  A. For the geographic distribution, see Table 116-1.
  B. Transmission is mainly by ticks, but is also possible via blood transfusion, contaminated equipment, and transplacentally (Fukumoto et al., 2005).
  C. *Babesia gibsoni* is possibly transmitted via bite wounds, saliva, and ingested blood.
  D. *Babesia canis* sporozoites are transferred to the dog as ticks feed (over 48 to 72 hours), then they invade RBCs, reproduce by binary fission, and form merozoites.
II. Pathogenesis
  A. As parasites replicate in RBCs, osmotic fragility increases, hemolysis occurs, and results in anemia.
  B. Severe hypoxia and the inflammatory response from hemolysis lead to tissue damage, multiple organ dysfunction, and potentially death.

Clinical Signs

I. Canine babesiosis: severity varies with species and host
  A. Hyperacute infection with *B. canis rossi*: hypothermia, shock, coma, disseminated intravascular coagulopathy (DIC), metabolic acidosis, death
  B. Acute infections with *B. canis rossi*, *B. canis canis*, *B. gibsoni, B. conradae, B. microti-like*:
    1. Fever, anorexia, lethargy, weakness, icterus, pale or congested mucous membranes, vomiting, splenomegaly, lymphadenopathy
    2. Atypical signs mainly from *B. canis rossi*: rhabdomyolysis, myalgia, vomiting, diarrhea, ascites, edema, upper respiratory signs, pancreatitis, acute renal failure, neurological signs
  C. Chronic and subclinical infections with *B. canis vogeli, B. gibsoni*

TABLE 116-1

Distribution, Vectors, and Cytological Characteristics of Selected *Babesia* spp.

SPECIES APPEARANCE*	GEOGRAPHIC DISTRIBUTION	HOST	VECTORS	SIZE (μm)	CYTOLOGICAL CHARACTERISTICS
B. canis rossi	South Africa	Dog	*Haemaphysalis leachi*	2 × 5	Usually paired
B. canis canis	Europe, Asia	Dog	*Dermacentor reticulatus*	2 × 5	Usually paired
B. canis vogeli	Africa, Asia, Europe, North America, Central America, South America, Australia	Dog	*Rhipicephalus sanguineus*	2.5 × 4.5	Single or paired
B. gibsoni	Asia, United States,† Australia, Europe?	Dog	*Haemaphysalis bispinous?* *Rhipicephalus sanguineus?*	1 × 3	Usually singular
B. conradae	California	Dog	*Rhipicephalus sanguineus?*	0.3 to 3	Ring, tetrad, ameboid
B. microti-like (Theileria annae)	Spain (Galicia)	Dog	*Ixodes hexagonus?*	1 × 2.5	Usually singular
B. felis	Africa, Europe?, Asia?	Cat	Unknown	0.9 × 0.7	Single or in pairs
B. canis presentii	Israel	Cat	Unknown	2.5 × 1.5	Round to oval

?,Distribution suggested but unproven.

*Organisms possibly more concentrated in capillary blood (e.g. ear tip).

†Sporadic infections, mostly in American Staffordshire and pit bull terriers.

1. *B. gibsoni:* intermittent pyrexia, decreased appetite, weight loss, lymphadenopathy, splenomegaly, hepatomegaly
2. *B. canis vogeli*
   a. Usually subclinical
   b. Possible severe to fatal hemolytic anemia in puppies
   c. Clinically healthy seroreactive greyhounds in the United States

II. Feline babesiosis (chronic): lethargy, anorexia, weakness, pale mucous membranes, diarrhea

Diagnosis

I. Hematological findings
   A. Variable anemia: normocytic normochromic to macrocytic, hypochromic, or regenerative
   B. Thrombocytopenia: common in dogs, inconsistent in cats
   C. Variable leukocyte changes: neutropenia, neutrophilia, lymphocytosis

II. Serum biochemistry tests
   A. May be normal
   B. Azotemia, metabolic acidosis
   C. Elevated liver enzymes, hyperbilirubinemia
   D. Increased positive acute phase proteins: α_1-glycoprotein, C-reactive protein, ceruloplasmin (Ulutas et al., 2005)

III. Variable urinalysis results
   A. Bilirubinuria, hemoglobinuria
   B. Proteinuria casts

IV. Organism identification
   A. Wright's, Giemsa, or Diff-Quik stain of blood smears (see Table 116-1)
   B. PCR assay of blood: sensitive, determines infecting species

V. Serologic testing
   A. IFA is more specific.
   B. ELISA is more sensitive, but cross-reactions occur.
   C. False-negative results are possible in peracute or acute infection, so use convalescent titers.

Differential Diagnosis

I. Septicemia
II. Ehrlichiosis, anaplasmosis, rickettsiosis, hemoplasmosis
III. Other causes of hemolytic anemia: immune-mediated diseases, drug, zinc, onion toxicity
IV. Other causes of thrombocytopenia (see Chapters 67 and 68)

Treatment

I. Repeated therapy possibly needed

II. *B. canis*
   A. Imidocarb dipropionate 5 to 6.6 mg/kg IM once; may repeat in 14 days
   B. Diminazene aceturate 3.5 to 5 mg/kg IM once; not available in United States
   C. Phenamidine isethionate 15 to 20 mg/kg SC SID for 2 days; not available in United States
   D. Trypan blue (1% solution) 10 mg/kg IV once
      1. Does not eliminate infection
      2. For severe cases or relapses
      3. Followed by imidocarb if possible
      4. Induces blue discoloration of mucosae and urine

III. *B. gibson*
   A. Azithromycin 10 mg/kg PO SID for 10 days
   B. Atovaquone 13.3 mg/Kg PO TID for 10 days (Birkenheuer et al., 2004)

IV. *B. felis*
   A. Primaquine phosphate 0.5 mg/kg PO SID for 3 days or 1 mg per cat IM every 36 hours for 6 days
   B. NOTE: 1 mg/kg lethal to cats

V. Supportive care
   A. Blood and plasma transfusions, IV fluids
   B. Glucocorticoids controversial

Monitoring and Prevention

I. Institute tick control.
II. Species-specific immunity only lasts a few months.
III. Transmission to people may occur from laceration with blood-contaminated sharp equipment.
IV. Screen animals used as blood donors via PCR.
V. A vaccine for *B. canis* is available in some European countries and appears to limit clinical signs (Schetters et al., 2005).

Toxoplasmosis

Lynn Guptill

Definition and Cause

I. *Toxoplasma gondii*, an obligate intracellular protozoan with worldwide distribution, causes many clinical syndromes.
II. Enteroepithelial infection occurs only in the cat (definitive host).
III. Systemic infection develops in cats and many other intermediate hosts.

Pathophysiology

I. Life cycle
   A. Cats ingest tissue cysts, which undergo enteroepithelial replication.
   B. Oocysts are shed in feces for 1 to 3 weeks.
   C. Oocysts sporulate in the environment (>24 hours outside of body).
   D. Cats or other intermediate hosts ingest sporulated oocysts, then the sporozoites penetrate intestinal cells and divide into tachyzoites.
   E. Tachyzoites multiply intracellularly and are disseminated when cells rupture.
   F. Tissue cysts (bradyzoites) form and persist indefinitely.
II. Transmission in cats and dogs
   A. Common: ingestion of tissue cysts in small rodents, uncooked beef or pork, other sources
   B. Less common: ingestion of sporulated oocysts
   C. Transplacental or transmammary transmission
   D. Tissue cysts possibly reactivated, followed by dissemination of zoites
      1. It may occur during another illness or with immunosuppression.
      2. Cyclosporine therapy may reactivate or increase the susceptibility to disseminated toxoplasmosis in both dogs and cats (Barrs et al., 2006; Webb et al., 2005).
III. Pathogenesis
   A. Extent of replication and tissue damage vary with host age and immunity, number of parasites ingested, and strain of *T. gondii.*
   B. For example, cats with feline immunodeficiency virus (FIV) may have more severe disease.
   C. All tissues are susceptible, and the type of illness depends on tissues affected.

Clinical Signs

I. Signs are not observed in all infected animals.
II. Signs develop most commonly in animals that are young, immunosuppressed, or coinfected with another pathogen.
   A. Enteroepithelial infection: rare, self-limiting diarrhea
   B. Neurological signs: ataxia, weakness, cranial nerve deficits, abnormal mentation
   C. Respiratory signs: dyspnea, tachypnea, cough (see Chapter 18)
   D. Ocular signs (more common in cats): optic neuritis, chorioretinitis, anterior uveitis
   E. Liver disease and pancreatitis: fever, anorexia, vomiting, weight loss, icterus
   F. Disseminated disease: multisystemic signs
   G. Canine toxoplasmosis: similar signs to neosporosis

Diagnosis

I. Tentative diagnosis of clinical toxoplasmosis is based on a combination of the following (Lappin, 2000):
   A. Serum antibodies: high immunoglobulin (Ig) M titer, ≥fourfold increase in IgG titer
   B. Clinical signs consistent with *T. gondii* infection
   C. Exclusion of other common causes of clinical signs
   D. Positive response to treatment for *T. gondii*
II. Hematological and serum biochemistry results reflect the organ systems affected.
III. Cerebrospinal fluid (CSF) analysis often shows increased protein levels, and mixed pleocytosis.
   A. Organisms rarely seen
   B. May be submitted for immunological testing and PCR
IV. Diagnostic imaging results are variable and depend on the organ systems affected.
V. Immunological testing via IFA and ELISA for IgM and IgG antibodies (Abs) can be performed on serum, CSF, or aqueous humor.
   A. Serum Abs document exposure to *T. gondii,* but do not diagnose disease because clinically normal animals may have positive Ab titers.
   B. IgM Abs correlate best with clinical disease, but failure to detect IgM does not exclude toxoplasmosis.
   C. IgG Abs persist for years, because the host rarely clears the infection completely.
      1. A fourfold rise in titer suggests recent infection (Lappin, 2000).
      2. Failure to detect a fourfold rise does not exclude toxoplasmosis.
   D. Testing of CSF or aqueous humor complements serum testing.
      1. Compare *T. gondii*–specific IgM or IgG in these fluids to serum *T. gondii*–specific IgM or IgG to try to determine whether local antibody formation may reflect active disease.
      2. *T. gondii*–specific IgM plus detection of *T. gondii* DNA by PCR in CSF or aqueous humor correlates well with clinical disease (Lappin, 2000).

3. Circulating antigens of *T. gondii* may be detected in CSF and aqueous humor via ELISA tests.

VI. Fecal flotation with Sheather's sugar solution occasionally detects oocysts, but cats usually shed oocysts only in the first 2 weeks after infection.

VII. Organism identification in tissues or fluid helps confirm the diagnosis.
   A. Perform cytological examinations on tissue aspirates, CSF, tracheal wash or bronchoalveolar lavage fluid, and aqueous humor.
   B. Immunohistochemistry is required to differentiate *T. gondii* from *Neospora caninum* and other related protozoa.
   C. PCR can be performed on tissues, CSF, and aqueous humor.

Differential Diagnosis

I. Cats
   A. Other causes of anterior uveitis, chorioretinitis (see Chapters 99 and 102)
   B. Other infectious causes of systemic disease
      1. Feline infectious peritonitis, feline leukemia virus, FIV
      2. Systemic mycoses
      3. Neoplasia

II. Dogs
   A. Neosporosis
   B. Other causes of central nervous system (CNS) and ocular disease
      1. Canine distemper
      2. Systemic mycoses
      3. Protothecosis
      4. Lymphosarcoma
   C. Other causes of myositis (see Chapter 82)

Treatment

I. No drug clears all *T. gondii* from the body.

II. Choices of available drugs include the following:
   A. Best: clindamycin 12.5 mg/kg PO BID for 4 weeks
   B. Cats: trimethoprim/sulfonamide 15 mg/kg PO BID for 4 weeks
   C. Dogs: pyrimethamine 0.25 to 0.5 mg/kg PO SID for 4 weeks with sulfonamides at 30 mg/kg PO SID

III. Institute additional supportive care as needed.

Monitoring and Prevention

I. Prognosis for animals with disseminated disease is guarded to poor.

II. Ocular and CNS signs are slow to respond to treatment.

III. Vision is often diminished or lost with severe uveitis.

IV. Prevent exposure to oocysts and tissue cysts.
   A. Feed only fully cooked foods.
   B. Prevent hunting and coprophagy.

V. Toxoplasmosis is a zoonotic disease.
   A. Usually transmitted by ingestion of undercooked meat, contaminated water
   B. Rarely transmitted by direct contact with cats
   C. Possible exposure by contact with sporulated oocysts from litter boxes, or while gardening
   D. Prevention of exposure to people
      1. Practice good hygiene in food preparation, and cook meats thoroughly.
      2. Clean litter boxes daily so oocysts do not sporulate; do not aerosolize contents while cleaning litterbox.
      3. Wear gloves when gardening and cleaning the litter box, and cover children's sandboxes.

Neosporosis

Lynn Guptill

Definition and Cause

I. *Neospora caninum* causes multifocal neurological disease, myositis, and reproductive failure in dogs.

II. It has a worldwide distribution in dogs and many other species (Dubey, 1999).

Pathophysiology

I. Life cycle
   A. Dogs (definitive host) ingest tissue cysts, which undergo enteroepithelial replication.
   B. Cats have been infected experimentally, but clinical disease in naturally infected cats is not documented.
   C. Some cats are serologically positive, suggesting exposure to *N. caninum* (Ferroglio et al., 2005).
   D. Oocysts are shed in dog feces for 1 to 3 weeks, possibly more than once, and puppies may shed more oocysts than adult dogs (McGarry et al., 2003; Gondim et al., 2005).
   E. Oocysts sporulate in the environment (24 to 72 hours outside of body).
   F. Dogs or other intermediate hosts ingest sporulated oocysts; sporozoites penetrate intestinal cells and divide into tachyzoites.
   G. Tachyzoites multiply intracellularly and are disseminated when cells rupture.

II. Transmission
   A. Dogs and coyotes are definitive and intermediate hosts.
   B. Cattle, deer, and other herbivores are intermediate hosts.
   C. Congenital infection can occur (Barber and Trees, 1998).

III. Pathogenesis
   A. Tachyzoites proliferate in muscle (including myocardium) and neural tissue.
   B. The cells are destroyed, and an inflammatory response ensues with mononuclear cell infiltrates, central areas of necrosis, and granuloma formation.
   C. Other affected tissues include skin, eyes, liver, lungs, spleen, heart, lymph nodes, and adrenal glands.
   D. Tissue cysts containing bradyzoites induce minimal or no host reaction.
   E. Immunosuppression probably induces activation of tissue cysts and clinical neosporosis (La Perle et al., 2001).

Clinical Signs

I. Young dogs
  A. Congenital infection usually fatal
    1. Ascending paralysis, hyperextension and ataxia; pelvic limbs most severely affected
    2. Polymyositis: multiple affected areas
  B. Other possible clinical signs
    1. Multifocal CNS signs, cervical weakness, head tilt
    2. Dysphagia, muscle atrophy
  C. Rarely, myocarditis and sudden death (Odin and Dubey, 1993)
II. Adult dogs
  A. Possibly same signs as for young dogs
  B. Also ulcerative dermatitis, pneumonia

Diagnosis

I. Compatible signalment, history, clinical signs
II. Rare hematological abnormalities
III. Possible elevated liver and muscle enzymes
IV. CSF analysis
  A. Possible increased protein and mixed pleocytosis (non-suppurative meningoencephalitis)
  B. Abs to *N. caninum* in CSF supportive of diagnosis
V. Electromyographic findings consistent with lower motor neuron disease
VI. Organism identification
  A. Tachyzoites in CSF, tracheal wash or bronchoalveolar lavage fluid, lung aspirates, tissue biopsies, or impressions of dermal lesions are indistinguishable from *T. gondii* on light microscopy.
  B. Immunocytochemistry or electron microscopy is needed for definitive diagnosis.
  C. PCR is useful to distinguish *N. caninum* from other species.
VII. IFA test on CSF or serum not definitive
  A. Titers as high as 1:12,800 reportedly persist at least 4 years in clinically normal dogs (Barber and Trees, 1998).
  B. Histologically confirmed neosporosis is reported with titers <1:50 (Dubey and Lappin, 2006).

Differential Diagnosis

I. *Toxoplasma gondii* infection
II. Other causes of polymyositis (see Chapter 82), multifocal CNS disorders (see Chapters 23 and 24), necrotizing dermatitis, or pneumonia

Treatment

I. Early diagnosis and treatment may improve survival.
II. Potential effective treatments are as follows:
  A. Trimethoprim/sulfonamide 15 to 20 mg/kg PO BID *or*
  B. Sulfonamide 15 to 20 mg/kg PO BID with pyrimethamine 1 mg/kg PO SID for 2 to 4 weeks (Dubey and Lappin, 2006)
  C. Clindamycin 7.5 to 15 mg/kg PO TID for 4 to 8 weeks

Monitoring and Prevention

I. Pay particular attention to progression of neurological signs, and the animal's ability to prehend food, swallow, and breathe.
II. Pelvic limb rigidity may persist in treated dogs (Barber and Trees, 1996).
III. Gait abnormalities may require physical therapy.
IV. Puppies do not usually respond, particularly if diagnosis and treatment are delayed.
V. No treatment inhibits transplacental transmission, so do not breed animals with previously affected litters.
VI. The zoonotic potential of *N. caninum* is unknown.
VII. Avoid feeding uncooked meat or offal.

Hepatozoonosis

Lynn Guptill

Definition and Causes

I. Hepatozoonosis is a multisystemic disease of dogs, and occurs rarely in cats.
II. *Hepatozoon americanum* is the primary agent in North America.
III. *Hepatozoon canis* occurs in Japan, Africa, the Middle East, southern Europe, Asia, South America and other regions.

Pathophysiology

I. Infected ticks are ingested.
  A. *Rhipicephalus sanguineus* for *H. canis*
  B. *Amblyomma maculatum* for *H. americanum*
II. Vertical transmission of *H. canis* has been reported (Murata et al., 1993).
III. Life cycle is as follows:
  A. Ticks ingest gametocytes from leukocytes in dog peripheral blood.
  B. Oocysts with multiple sporozoites form within ticks and dogs ingest the ticks.
  C. Sporozoites penetrate intestines, with eventual formation of schizonts, cysts, and gametocytes in dogs.
IV. *Hepatozoon americanum* forms tissue cysts in striated muscle, and rarely other tissues (Panciera et al., 1998).
  A. Muscle cysts form by 5 weeks (Panciera et al., 1998).
  B. Intact cysts produce no inflammation.
  C. Ruptured cysts induce pyogranulomatous myositis (Vincent-Johnson et al., 1997).
  D. Marked periosteal proliferation occurs primarily in long bone diaphyses (Panciera et al., 2000).
  E. The disease is usually severe and often fatal without treatment.
V. *H. canis* localizes in liver, spleen, lymph nodes, lungs, kidneys, and bone marrow (Baneth et al., 1998b).
  A. Infection is often subclinical.
  B. Organisms occur in multiple tissues.
  C. Cysts resembling those of *H. americanum* are uncommon.
  D. Heavy parasite burdens can be life-threatening (Baneth and Weigler, 1997).

Clinical Signs

I. *Hepatozoon americanum*
  A. Subclinical infections rare
  B. Natural infections (Macintire et al., 2001)
    1. Fever, muscle pain, stiffness, gait abnormalities

2. Lethargy, mucopurulent ocular discharge
3. Possible glossitis, pharyngitis
4. Pelvic limb paresis and ataxia, with upper motor neuron signs
5. Generalized lymphadenopathy
6. Cachexia, vasculitis, and renal failure in late stages

II. *Hepatozoon canis*
   A. Subclinical infections common
   B. Dogs, often with severe parasitemia: lethargy, fever, weight loss, other signs (Baneth and Weigler, 1997)

III. Cats
   A. *H. canis* infection is possible.
   B. Other *Hepatozoon* spp. infections of cats are reported.
   C. Clinical signs may vary (Baneth, 2006).

Diagnosis

I. History of tick infestation with compatible clinical signs
II. Clinical pathologic findings
   A. Leukocytosis (commonly marked with *H. americanum*), nonregenerative anemia
   B. Increased serum alkaline phosphatase activity
   C. Hypoalbuminemia common with *H. americanum*
III. Radiological findings: periosteal reaction, especially long bones (*H. americanum*)
IV. Test of choice for identifying the organism
   A. *H. canis:* gametocytes in peripheral leukocytes
   B. *H. americanum:* schizonts or merozoites in tissues, histopathology of muscle biopsy
V. Serological testing with IFA and ELISA (Baneth et al., 1998b; Mathew et al., 2001)

Differential Diagnosis

I. Rule out other causes of fever, neutrophilia, myositis, and periosteal bone reaction.
II. Rule out other infectious, immune-mediated or metabolic diseases, and neoplasia with similar clinical signs.

Treatment

I. Dogs with advanced disease respond poorly.
II. No treatment eliminates tissue cysts.
III. *H. canis* is treated with imidocarb dipropionate 5 mg/kg IM in 2 doses, 14 days apart.
   A. Consider repeating treatment every 14 days until no gametocytes are seen on blood smears.
   B. Cholinergic signs are possible side effects; treat with atropine as necessary.
   C. Doxycycline 10 mg/kg PO SID for 14 days may be added to imidocarb.
IV. *H. americanum* is treated with a combination of four drugs for 14 days.
   A. Trimethoprim/sulfa 15 mg/kg PO BID
   B. Clindamycin 10 mg/kg PO TID
   C. Pyrimethamine 0.25 mg/kg PO SID
   D. These drugs followed with decoquinate *(Deccox)* 10 to 20 mg/kg PO BID in food indefinitely or at least for 2 years (Macintire et al., 2001)

Monitoring and Prevention

I. Monitor animals closely; relapses are common.
II. Prolonged treatment (years) tends to decrease relapses.
III. Tick control is the most important preventative measure.
IV. Test and/or monitor for co-infection with other tick-transmitted pathogens.
V. Zoonotic potential is unknown, but is thought to be low (Baneth, 2006; Macintire et al., 2006).

Leishmaniasis

Laia Solano-Gallego

Definition and Causes

I. Leishmaniasis is a group of infectious diseases affecting humans, and domestic and wild animals worldwide.
II. Canine visceral leishmaniasis (CVL) is caused by *Leishmania infantum.*
III. Dogs are also infected with *Leishmania mexicana* and *Leishmania braziliensis* (cutaneous leishmaniasis).
IV. Feline leishmaniasis is rare.
   A. It is usually caused by *L. infantum*, and has subclinical, cutaneous or visceral (immunosuppressed cats) manifestations.
   B. Cats may also be infected with *L. mexicana* or *L. braziliensis* (cutaneous form).

Pathophysiology

I. Epidemiology and transmission
   A. Dogs are a reservoir host for *L. infantum*.
   B. CVL is endemic in the Mediterranean basin and South America and is reported in foxhounds in North America.
   C. Female sand flies (*Phlebotomus* spp., *Lutzomyia* spp.) are the principal agents of transmission to dogs.
   D. Unusual routes of transmission (congenital, blood transfusion, direct contact, ingestion, laboratory inoculation) are also reported in dogs.
II. Life cycle
   A. Sandflies regurgitate promastigotes into skin where they become coated by complement and are phagocytized by macrophages.
   B. A parasitophorous vacuole develops and promastigotes become amastigotes that are resistant to enzymes and low pH.
   C. Amastigotes multiply until host cells burst and then enter other phagocytes to continue the cycle.
III. Host immune response
   A. Protective immunity is mediated by T-helper cells.
   B. Dogs that develop specific cell-mediated immunity restrict the infection and have no clinicopathological abnormalities.
   C. Susceptible or sick dogs develop an exaggerated, humoral immune response with a reduced or absent cell-mediated response, and progressive immunosuppression.
   D. In these dogs circulating immune complexes may cause uveitis, glomerulonephritis, meningitis, polyarthritis and vasculitis.

E. CVL is a chronic disease and clinical signs may develop up to 7 years after infection.

Clinical Signs

I. Clinical features vary widely (subclinical to fatal).
II. The main clinical findings (listed from most to least frequent) in dogs are skin lesions, local or generalized lymphadenopathy, weight loss, apathy, lameness, diarrhea, ocular lesions, vomiting, pale mucous membranes, fever and epistaxis.
   A. Cutaneous lesions: symmetrical dry, exfoliative; ulcerative; or nodular, proliferative, papular dermatitis
   B. Ocular signs: anterior uveitis, keratoconjunctivitis, blepharitis
III. Other signs: splenomegaly, hepatomegaly, polyuria, polydipsia

Diagnosis

I. Laboratory findings
   A. Complete blood count: nonregenerative anemia, thrombocytopenia, leukocytosis or leukopenia
   B. Serum biochemistry tests: increased total protein (hyperglobulinemia [polyclonal gammopathy]), hypoalbuminemia, renal azotemia, elevated liver enzymes
   C. Urinalysis: mild to severe proteinuria
II. Specific diagnostic tests
   A. Organism identification
      1. Parasite recovery methods (not routinely used)
         a. Culture: Novy-MacNeal-Nicolle or Schneider's *Drosophila* medium
         b. Hamsters inoculated with suspect tissue
      2. Direct visualization of amastigotes (2.5 to 5 μm 1.5 to 2 μm)
         a. Cytological or histological evaluation of cutaneous lesions, lymph nodes, bone marrow, etc.
         b. Improved detection with immunoperoxidase labeling
      3. Molecular testing: specific and sensitive
         a. PCR: conventional (qualitative) or real-time (quantitative)
         b. Tissue selection: lymph node, bone marrow, skin, blood
   B. Serological testing
      1. IFA, ELISA, direct agglutination (Dog-DAT), and Western blot assay have high sensitivity and specificity.
      2. Antibody quantification (IFA or ELISA) is recommended.
      3. Cross reaction can occur with *Trypanosoma* spp. and *Babesia* spp.
      4. Some clinically healthy, infected dogs are seropositive.
      5. Interpret test results in light of clinical signs, laboratory abnormalities, and test results.
III. Positive diagnosis: suspicious laboratory abnormalities and at least two positive specific tests (e.g., serology, organism identification)

Differential Diagnosis

I. Ehrlichiosis caused by *Ehrlichia canis*
II. Systemic lupus erythematosus
III. Neoplasia: lymphoma, multiple myeloma, leukemia

Treatment

I. Relapses are common and long-term therapy is necessary.
II. Preferred treatment is a combination of antimonials and allopurinol.
   A. Antimonials
      1. Meglumine antimonate *(Glucantime)* 75 mg/kg SC BID for 30 to 40 days
      2. Sodium stibogluconate *(Pentostam)* 30 to 50 mg/kg SC SID for 3 to 4 weeks
   B. Allopurinol 10 to 20 mg/kg PO BID for ≥6 months (duration depending on individual)

Monitoring and Prevention

I. Monitor for improvement of clinicopathological abnormalities.
II. Monitor for decrease in antibody levels and parasite load (via real-time PCR).
III. Stop treatment when serological evaluation is almost negative.
IV. Monitor dogs after treatment termination at least every 6 months, with routine laboratory tests, serological evaluation ± PCR.
V. Use insecticidal collars, and confine animals indoors during dawn and dusk to prevent infection.
VI. A new vaccine for CVL may reduce clinical disease and *L. infantum* infection in dogs.
VII. Most *Leishmania* spp. infecting humans are zoonotic.

OTHER PROTOZOAL INFECTIONS

See Table 116-2.

TABLE 116-2

Other Protozoal Infections

DISORDER	AGENT	AFFECTED SPECIES	TRANSMISSION	CLINICAL SIGNS	DIAGNOSIS	TREATMENT	PUBLIC HEALTH CONSIDERATIONS
Acanthamebiasis	*Acanthamoeba castellani* *A. culbertsoni*	Dog	Unknown	Fever, oculonasal discharge, anorexia, lethargy Later: respiratory distress, neurologic signs	Rarely diagnosed antemortem Clinical pathologic data usually nonspecific: leukopenia (marked lymphopenia), possibly pancytopenia Culture, histopathology	Poor efficacy of drugs attempted in dogs TMS 30 mg/kg PO BID attempted Sulfonamides effective in mice	No known zoonotic potential Dogs possibly sentinels
Cytauxzoonosis	*Cytauxzoon felis*	Cat	Ticks *(Dermacentor variabilis)*	Fulminating systemic disease (fever, disease anorexia, lethargy, dyspnea, dehydration) leads to death (probably more virulent strains) Recovery possible	Parasite identification in erythrocytes (possibly also in phagocytes) on blood smears or in aspirates of spleen, bone marrow, lymph nodes, liver, lungs	Imidocarb dipropionate 2-5 mg/kg IM once or repeated in 14 days Diminazene aceturate 2 mg/kg IM once Treatment may not affect course of disease	None known
Cyclosporiasis	*Cyclospora cayetanensis*	Possible in Brazilian dogs	Ingestion of contaminated water or food	Possibly causes small-bowel diarrhea, weight loss, vomiting	Direct fecal examination with Ziehl-Neelsen staining (8- to 10-μm oocysts) Do not confuse with smaller *Cryptosporidium* spp.	TMS 15 mg/kg PO BID for 7 days	Dogs possibly carry the organism and contaminate the environment
Encephalitozoonosis	*Encephalitozoon cuniculi*	Dog, cat	Ingestion or transplacental	Fulminating in puppies Renal failure, CNS signs Adults possibly same or asymptomatic	Identifing organism in urine or tissues Serological testing not commercially available	No successful treatment reported Provide supportive care	Possible zoonosis via contact with infected tissues or urine Immunocompromised people should use caution

TMS, Trimethoprim–sulfonamide; *CNS*, central nervous system.

TABLE 116-2

Other Protozoal Infections—*cont'd*

DISORDER	AGENT	AFFECTED SPECIES	TRANSMISSION	CLINICAL SIGNS	DIAGNOSIS	TREATMENT	PUBLIC HEALTH CONSIDERATIONS
Pneumocystosis	*Pneumocystis carinii*	Dog, cat	Aerosol	Rare Usually subclinical unless immunosuppressed Signs: weight loss, cough, dyspnea, possible vomiting, diarrhea	No commercial serological tests for dog and cat Thoracic radiographs: diffuse interstitial to aveolar pattern Detection of organism in TTW fluid, other secretions, and aspirates; biopsy specimens: PCR, immunofluorescence	TMS 15 mg/kg PO BID for 2 weeks Other agents less effective Supportive care: oxygen therapy, nebulization, coupage Glucocorticoids possibly improve survival in people	Minor zoonotic potential Caution if immuno-compromised
Trypanosomiasis	*Trypanosoma cruzi*	Dog, people	*Triatoma* spp. (reduviid bug), blood transfusion, across mucous membrane or open wounds	*Acute*: splenomegaly, lymphadenomegaly *Subclinical* (latent): no signs *Chronic*: signs of progressive right heart failure with multiple arrhythmias	Serological testing: IFA Organism identification: blood smears, aspirates, histopathology, PCR	No readily available effective drugs Provide supportive care	Transmission via exposure to infected reduviid bugs and contact with infected blood (mucous, membranes, open wounds, contaminated sharp instruments) Dogs possibly sentinels

TTW, Transtracheal wash; *PCR*, polymerase chain reaction; *IFA*, indirect fluorescent antibody.

CHAPTER 117

Introduction to Behavioral Diagnosis and Treatment

Sharon L. Crowell-Davis

BEHAVIORAL HISTORY

I. Chief complaint
   A. Obtain detailed descriptions of the actual behaviors that are considered unacceptable.
   B. Words such as *jealous, hates,* and *spiteful* are used by owners to refer to a great variety of behaviors and do not provide useful information about the problem behavior or its motivation.
II. Physical environment
   A. Detailed descriptions of the animal's physical environment
   B. Size of house or apartment, access to fenced-in yard, type of fencing, size of fenced area, map of house, location of litterboxes
III. Social environment
   A. Obtain information on all the people and other animals who frequently interact with the animal and how the animal interacts with them.
   B. In cases of suspected separation anxiety, determine the schedule of all caregivers.
IV. Learning and exercise
   A. Obtain detailed information on the training techniques used, commands taught, and the type and duration of exercise.
   B. Many trainers who use aversive training techniques that produce fear and anxiety incorrectly call themselves "positive trainers."
   C. Discern the specific techniques used, not just the general type of training.
V. Early history
   A. Learn as much about the early history as possible.
   B. In cases of adopted animals, little to no information may be available.
VI. Medical history
   A. Medical problems can incite learned behavior problems (e.g., cats with urinary tract infections may learn to eliminate outside the litterbox and continue to do so even when the infection is resolved).
   B. Medical problems that cause pain and discomfort can be the direct cause of behavior problems.

PSYCHOPHARMACOLOGY

I. Ethical and legal issues
   A. Use of most psychoactive medications in small animals is extra-label.
   B. The Animal Medicinal Drug Use Clarification Act of 1994 requires a valid veterinarian-client-animal relationship to prescribe extra-label medications.
   C. In the case of behavior problems, the veterinarian must conduct a complete behavioral and physical examination.
   D. Recommendations by a trainer or nonveterinary behaviorist are not sufficient for prescribing any medication.
II. Benzodiazepines (Crowell-Davis and Murray, 2006)
   A. Benzodiazepines bind to gamma amino butyric acid (GABA) receptors, thereby facilitating the action of GABA in the central nervous system (CNS).
   B. They reduce anxiety and increase affiliative behavior.
   C. Their use in aggression is controversial; although they reduce the fear that motivates much aggression, they may also cause loss of learned inhibitions.
   D. Treatment of an overdose is primarily supportive.
   E. Flumazenil is a benzodiazepine receptor antagonist.
   F. Side effects include sedation, ataxia, and increased appetite.
   G. Liver failure is a rare complication in cats (Levy et al., 1994; Hughes et al., 1996).
   H. They have a rapid onset of action and can be given as needed.
   I. When prescribing benzodiazepines, use the lowest dose and frequency that adequately addresses the problem (Table 117-1).

TABLE 117-1

Doses for Psychoactive Medications

MEDICATIONS	DOSE FOR DOGS	DOSE FOR CATS
Benzodiazepines		
Alprazolam	0.02 mg/kg PO every 4 hours	0.2-1.0 mg/kg PO BID
Chlordiazepoxide	2.0-6.5 mg/kg PO TID	0.2-1.0 mg/kg PO BID
Clonazepam	0.1-0.5 mg/kg PO TID	0.015-0.2 mg/kg PO TID
Clorazepate	0.5-2.0 mg/kg PO QID	0.5-2.0 mg/kg PO BID
Diazepam	0.5-2.0 mg/kg PO every 4 hours	0.1-1.0 mg/kg PO every 4 hours
Flurazepam	0.1-0.5 mg/kg PO BID	0.1-1.0 mg/kg PO BID
Lorazepam	0.02-0.5 mg/kg PO TID	0.03-0.08 mg/kg PO BID
Oxazepam	0.04-0.5 mg/kg PO QID	0.2-1.0 mg/kg PO BID
Selective Serotonin Reuptake Inhibitors		
Fluoxetine	1.0-2.0 mg/kg PO SID	0.5-1.5 mg/kg PO SID
Fluvoxamine	1.0-2.0 mg/kg PO SID	0.5-1.5 mg/kg PO SID
Paroxetine	1.0-1.5 mg/kg PO SID	0.5-1.5 mg/kg PO SID
Sertraline	0.5-4.0 mg/kg PO SID	0.5-1.5 mg/kg PO SID
Tricyclic Antidepressants		
Amitriptyline	1.0-6.0 mg/kg PO BID	0.5-2.0 mg/kg PO SID-BID
Clomipramine	1.0-3.0 mg/kg PO BID	0.25-1.3 mg/kg PO SID
Doxepin	3.0-5.0 mg/kg PO BID-TID	0.5-1.0 mg/kg PO BID
Imipramine	0.5-2.0 mg/kg PO BID-TID	0.5-2.0 mg/kg PO BID-TID
Azapirones		
Buspirone	0.5-2.0 mg/kg PO BID-TID	0.5-1.0 mg/kg PO BID
Monoamine Oxidase Inhibitors		
Selegiline	0.5-1.0 mg/kg PO SID	0.5-1.0 mg/kg PO SID
Central Nervous System Stimulants		
Dextroamphetamine	0.2-1.3 mg/kg PO BID-TID	Not recommended
Methylphenidate	2.0-4.0 mg/kg PO BID-TID	Not recommended

III. Selective serotonin reuptake inhibitors (SSRIs) (Crowell-Davis and Murray, 2006)
   A. They inhibit the reuptake of serotonin, resulting in down-regulation of the postsynaptic serotonin receptors and increased activity of serotonin in the CNS.
   B. They have antidepressant, anxiolytic, anticompulsive, and antiaggression effects (Charney et al., 1990; Dodman et al., 1996; Larson and Summers, 2001; Olivier and Mos, 1992; Reist et al., 2003).
   C. Side effects include mild sedation and changes in appetite or gastrointestinal (GI) function (constipation or diarrhea).
   D. Overdoses can result in serotonin syndrome, which has a variety of signs (e.g., mental changes, neuromuscular and autonomic changes) (Brown et al,. 1996; Martin, 1996).
   E. Treatment of serotonin syndrome includes discontinuation of all SSRIs, decontamination with activated charcoal, anticonvulsants, thermoregulation, and fluid therapy.
   F. SSRIs should not be given with monoamine oxidase inhibitors (MAOIs).
   G. SSRIs are generally given SID and may take 2 to 6 weeks to produce an effect (see Table 117-1).
   H. Their efficacy is difficult to determine with less than 1 month of therapy.
   I. They must be given per os; no transdermal medication provides comparable blood levels (Ciribassi et al., 2003).

IV. Tricyclic antidepressants (TCAs) (Crowell-Davis and Murray, 2006)
   A. They inhibit the reuptake of both serotonin and norepinephrine, resulting in down-regulation of serotonin and norepinephrine receptors, and increased activity of serotonin and norepinephrine in the CNS.
   B. They also have antihistaminic, anticholinergic effects, and are α-adrenergic antagonists.
   C. They have antidepressant, anxiolytic, antiaggressive, and anticompulsive effects (King et al., 2000; King et al., 2004).

D. Side effects vary widely.
   1. Sedation, vomiting, diarrhea, constipation
   2. Urinary retention, appetite changes, ataxia
   3. Decreased tear production
   4. Rarely, arrhythmias

E. Amitriptyline has been used most often because of its low cost; however, it has a higher incidence of side effects (antihistaminic, antimuscarinic) and is no longer considered the first drug of choice.

F. Clomipramine is the most serotonin-specific of the TCAs.

G. Commonly used TCAs are presented in Table 117-1.

V. Azapirones (Crowell-Davis and Murray, 2006)

A. Azapirones are serotonin 1A agonists and are anxioselective.

B. Although a rapid response can occur, response may require 1 to 4 weeks.

C. Azapirones should not be given in combination with MAOIs.

D. Side effects are rare but include mild sedation and increased anxiety.

E. Buspirone is the only commercially available azapirone (see Table 117-1).

F. Transdermal absorption of buspirone is poor compared with oral absorption (Mealy et al., 2004).

VI. MAOIs

A. They prevent the action of MAO-A, MAO-B, or both.

B. Selegiline hydrochloride slows the progression and reverses some of the symptoms of canine cognitive dysfunction, may increase lifespan, and is sometimes used as an anxiolytic (see Table 117-1) (Milgram et al., 1993; Milgram et al.,1995; Ruehl et al., 1994; Ruehl et al., 1997; Mills and Ledger, 2001).

C. MAOIs should not be given with SSRIs, TCAs, or azapirones, as serious and sometimes life-threatening side effects can occur.

D. When changing from an MAOI to any of these other medications, wait a minimum of 2 weeks.

E. Side effects include agitation, vomiting, disorientation, diarrhea, and diminished hearing.

F. Treat for a minimum of 1 to 2 months.

VII. CNS stimulants

A. CNS stimulants increase synaptic dopamine and norepinephrine.

B. In dogs, CNS stimulants are used to treat attention deficit disorder, which is commonly called *hyperkinesis*.
   1. True canine hyperkinesis is very rare.
   2. Most "hyperactive" dogs are young, inappropriately trained, or inadequately exercised.

C. They should not be given concurrently with an MAOI.

D. They cause increased arousal and activity, and possibly stereotypic behavior in normal dogs and cats.

E. Commonly used CNS stimulants include dextroamphetamine and methylphenidate (see Table 117-1).

VIII. Other drugs

A. It may be necessary to try several different medications or combinations of medications before identifying an effective treatment for any given animal.

B. Acepromazine has sedative properties but is not a true anxiolytic.
   1. It is not used in the treatment of anxiety disorders, except as a supplement to true anxiolytics.
   2. It may be tried in animals in which the behavior is so violent that it risks harm to itself or its environment.

C. Hormones have serious and sometimes life-threatening side effects and are used only as a last resort.

LEARNING

I. Habituation (Domjan, 2003): a natural (not learned) behavior that decreases in intensity and eventually discontinues after repeated exposure to the natural stimulus for the behavior

II. Classic conditioning (Domjan, 2003)

A. A stimulus that does not naturally elicit a response does so through pairing with a stimulus that naturally causes the response.
   1. An unconditioned stimulus causes a natural or unconditioned response.
   2. An example would be the fear that occurs when a dog is hit by a human.
   3. The sight of the human initially does not cause fear (human is a neutral stimulus).
   4. After the human has hit the dog several times, the dog becomes afraid when it sees the human.
   5. The human has now become a conditioned stimulus and the fear that occurs at the sight of the human is a conditioned response.

B. Classic conditioning affects physiological and emotional responses, not voluntary behavior.

C. Stimulus discrimination is the phenomenon in which only a specific, discrete stimulus becomes the conditioned stimulus for the response (e.g., short, blonde humans wearing glasses).

D. Stimulus generalization is the phenomenon in which a broad category of stimuli become the conditioned stimuli for the response (e.g., all humans).

III. Operant conditioning (Domjan, 2003)

A. The probability that a behavior will recur given a specific stimulus is increased or decreased by the consequences of the behavior.

B. An eliciting stimulus informs the animal that if it does not give a particular response, a particular controlling stimulus will not follow the response.

C. Operant conditioning changes voluntary behavior.

D. With positive conditioning, the controlling stimulus occurs after the response.

E. With negative conditioning, the controlling stimulus does not occur or is removed after the response.

F. Reinforcement increases the probability that the behavior will recur given a specific eliciting stimulus; to be effective, reinforcers must occur as the behavior is happening or immediately after the behavior occurs.

G. Punishment decreases the probability that the behavior will recur given a specific eliciting stimulus.

H. Positive reinforcement increases the probability that the behavior will recur, depending on the presence of the controlling stimulus subsequent to the behavior.
   1. Schedules of reinforcement vary and affect both the speed with which the animal learns and resistance to extinction of the behavior.
   2. In continuous reinforcement, the animal's behavior is reinforced every time it engages in the desired behavior.
   3. In variable ratio reinforcement, the animal's behavior is reinforced after a variable number of repetitions.

I. Negative reinforcement increases the probability that the behavior will recur, dependent on the removal or absence of the controlling stimulus subsequent to the behavior.

J. Positive punishment decreases the probability that the behavior will recur, depending on the presence of the controlling stimulus subsequent to the behavior.

K. For punishment to be effective, the following criteria must be met:
   1. It must be *immediate* (occurs as the animal is engaging in the undesired behavior or within 1 second of discontinuation of the behavior).
   2. It must be *consistent* (occurs every time the undesired behavior occurs).
   3. It must be *appropriate* (a type and intensity of behavior that disrupts the undesired behavior, but does not cause a fear response).

L. Negative punishment decreases the probability that the behavior will recur, dependent on the removal or absence of the controlling stimulus subsequent to the behavior.

M. Prompting and fading are learning processes where the animal is prompted (induced to engage in the desired behavior by a strong stimulus), then reinforced, and the intensity of the prompt is progressively decreased as it is repeated.

N. Shaping is a learning process where a behavior that approximates the final desired behavior is reinforced.
   1. Progressively, the animal must engage in a behavior that is more and more like the final, desired behavior to obtain the reinforcer.
   2. An example would be teaching the dog to assume the down position by only giving it a reinforcer when it is sitting and lowers its head a little, then requiring more and more, until it finally lies down.

IV. With desensitization, the animal is exposed to a stimulus that causes an undesired behavior (usually behaviors resulting from fear), but at such a low level that the undesired behaviors do not occur (Crowell-Davis and Murray, 2006).
   A. Over time and with multiple repetitions, the intensity of the stimulus is gradually increased.
   B. Ideally the undesired response is not provoked.

V. Counter-conditioning occurs when a behavior is induced that is both behaviorally and physiologically incompatible with the undesired response (Crowell-Davis and Murray, 2006).

VI. Extinction is the loss of a learned behavior (Domjan, 2003).
   A. Extinction of classic conditioning occurs when the animal is repeatedly exposed to the conditioned stimulus without pairing it with the unconditioned stimulus, and the association between the two is lost.
   B. Extinction of reinforced operant conditioning occurs when the consequences of the response change.
      1. For example, the reinforcer is no longer given or the aversive stimulus is no longer removed.
      2. Eventually the response wanes and discontinues.

CONDITIONS OF BOTH CATS AND DOGS

Dominance

Definition

I. There are various definitions of dominance.

II. A dominance relationship exists between two animals if one animal consistently submits to another in antagonistic interactions at a rate greater than would be predicted by chance (Bernstein, 1981).

III. This definition does not require that the subordinate animal always submit to the dominant animal, only that it submits more than would be predicted if there was no dominant-subordinate relationship between the two animals.

IV. This definition does not require that the dominant animal be aggressive or even exhibit dominance signals to the subordinate, only that the subordinate give submissive signals to the dominant animal.

V. In most interactions, the dominant animal exhibits ritualized dominance behaviors.

VI. This definition does not make any assumptions about the function of dominant-subordinate relationships.

Anxieties and Phobias

Definition

I. Fear is an emotional state that is normal under certain conditions and motivates survival behavior ("fight or flight" response).

II. Animals are assumed to be fearful if they avoid, scream, cry, or engage in other signaling behaviors that are typically associated with fear.
   A. Dogs indicate fear by turning their ears back or down, lowering their tail between their hind limbs, crouching, turning their head or body away from the cause of the fear, whimpering, whining, lip-licking, yawning, retracting the commissure of their lips, salivating profusely, pacing, panting, urinating, defecating, and damaging objects with their teeth or claws.
   B. Cats indicate fear by turning their ears back or down, lowering their tail lateral to one of their hind limbs, crouching, turning their head or body away from the cause of the fear, gaping (opening the mouth wide and

holding it open), hissing, profuse salivation, urination, and defecation.
   C. Some of these behaviors may also occur for other reasons.
III. Fear is identified as being a behavior problem by the context in which it occurs.
   A. A phobia is present if the animal exhibits a consistent, strong behavior indicative of fear to one or more stimuli over multiple exposures to those stimuli, and the fear is not rational or adaptive.
   B. An anxiety disorder is milder than a phobia in terms of intensity of the behavior, but the animal exhibits the behavior over multiple exposures to given stimuli or, in the case of generalized anxiety disorder, to no particular stimulus.

Causes

I. Some strains of dogs and cats appear to be more susceptible to developing fear responses than others, so genetics may contribute (Angel et al., 1982).
II. Early experience in both dogs and cats, such as specific exposure to a variety of nonharmful stimuli, helps make the animal less likely to develop fear-related problems.
III. Learning, particularly classic conditioning, is the main cause of many anxiety disorders and phobias.

Clinical Signs and Diagnosis

I. The animal repeatedly exhibits behaviors indicative of fear to the same stimuli.
II. The animal may be afraid of more than one stimulus.
III. If the animal almost constantly exhibits at least low levels of anxiety, it has generalized anxiety disorder (GAD) (Reisner, 2003).
   A. Animals with GAD may exhibit intense fear responses to certain stimuli because they have become particularly sensitized to those stimuli.
   B. Some animals have multiple phobias (e.g., storms, being alone, meeting strange people), but are calm when none of those stimuli are present, so they do not have GAD.

Treatment and Monitoring

I. Except in mild cases, anxiolytic medications are necessary to significantly improve the signs.
II. Use of antipsychotics (acepromazine) is contraindicated, except when the behaviors are likely to result in bodily harm.
III. Early in treatment, avoid exposing the animal to the fear-inducing conditions.
IV. Desensitize and counter-condition the animal to the stimuli that cause fear responses.
   A. For dogs or cats with separation anxiety, fear of being alone or fear of separation from particular attachment figures, desensitize the animal by a series of short, then progressively longer departures.
   B. Counter-conditioning is generally not possible in these cases, as there is no way to induce competing behaviors in the owner's absence.
   C. For dogs or cats with storm phobia, desensitize and counter-condition the animal to sounds of storms.
   D. For dogs or cats that are afraid of people, desensitize and counter-condition to the approach and physical contact with people.
V. Flooding (i.e., exposure to the fear-inducing stimulus until the animal ceases exhibiting a fear response) is generally an undesirable treatment because the animal may harm itself or the environment before a flooding session has ended.
   A. There are rare exceptions in which flooding can be useful, practical, and not harmful.
   B. Placing a negative ion generator or an artificial waterfall in the house of an animal that is storm-phobic floods the animal to the presence of negative ions, and in the case of the waterfall, the sound of falling water.
VI. Cases of anxieties and phobias vary substantially in their severity, and results of treatment must be monitored closely.

Fear Aggression

Definition

I. Fear-motivated aggression is a very common behavior problem in both dogs and cats.
II. Aggression includes, but is not limited to, growling, snarling, snapping, and biting (dogs), or snarling, biting, scratching, and hissing (cats), which are motivated by anxiety and fear.

Causes

I. Poor socialization as a puppy or kitten to the feared species, usually dogs or humans, is a common cause.
II. Frightening experiences have occurred with the feared species or individuals (e.g., being abused by humans, attacked by other dogs or cats).
   A. Stimulus discrimination may occur in which the dog or cat is afraid only of the individual that caused harm or of individuals that are very similar in appearance, sound, or odor.
   B. Stimulus generalization may occur in which the dog or cat is afraid of a broad spectrum of individuals (all dogs or all humans).
III. Genetics or a lack of early exposure to a variety of stimuli may make the animal more sensitive to fear-inducing stimuli.
IV. Fear is one of the most common reasons for dogs and cats to exhibit human-directed aggression, and use of aversive training techniques is a contributing factor, especially in dogs.

Clinical Signs and Diagnosis

I. Fear is indicated by one or more of the following and is combined with aggressive behavior:
   A. Lowered tail, ears, and head
   B. Crouch or semicrouch, moving away
   C. Avoidance of eye contact
   D. Whining (dogs), gaping (cats), hissing (cats)

II. Some dogs or cats that begin as fear-aggressors subsequently develop body language that includes approaching or even chasing the victim with the tail up (dogs), ears up, and eyes staring.
III. In human-directed fear aggression, the dog or cat may attack when the person has turned around and is walking away.
IV. The underlying emotion motivating the behavior is still fear, even though the overtly visible behaviors have evolved from learning.

Treatment

I. Avoid the aggression by not placing the dog or cat in situations in which fear is likely to be triggered.
   A. Try not to approach, stare at, or reach toward the animal.
   B. In some cases, placing a basket muzzle on a dog while it is in fear-inducing situations may be useful.
   C. With cats, wear protective clothing (pants made of strong cloth, close-toed shoes).
II. Administration of an SSRI or TCA may be helpful (see Table 117-1).
   A. In general, avoid use of benzodiazepines, as they may cause loss of inhibition.
   B. In some cases benzodiazepines can be useful, but they must be used with caution and careful supervision.
III. Institute systematic desensitization and counter-conditioning, beginning with the dogs, cats, or humans to whom the animal exhibits minimal fear.
IV. Do not use aversive training techniques (punishment or negative reinforcement), as these techniques exacerbate the fear that is the underlying cause of the aggression.

Monitoring of Animal

I. Do not place the animal in situations that are likely to trigger incidents of aggression.
II. Communicate with the owner regarding progress every 1 to 2 weeks initially.
III. Communication intervals can be gradually increased if the owner clearly understands the treatment protocol and if the animal is making progress.
IV. Depending on the severity of the problem, it may resolve in a few weeks or a few months.
V. Some cases, especially dogs and cats that have been subjected to abuse by humans, may never resolve, although improvement can usually be achieved with appropriate treatment.

Compulsive Disorder

Definition

I. A stereotypic behavior is a repetitive behavior that is constant in form, serves no obvious goal or function, and occurs in a predictable sequence.
II. A compulsive behavior is a stereotypic behavior that is exhibited regardless of context.
III. Compulsive behaviors are derived from natural behaviors and are typically excessive, intense, performed out of context, or directed toward unnatural stimuli.
IV. Common compulsive behaviors vary from species to species.
   A. In dogs, tail chasing, hunting "invisible game," and excessive self-grooming are common.
   B. In cats, excessive self-grooming, licking, and sucking or chewing on household objects are common.

Causes

I. Stress, including an understimulating or overstimulating environment, can initiate a compulsive disorder.
II. Genetic predispositions make certain individuals more or less susceptible in response to stress.
III. Animals with compulsive disorder undergo neurochemical and even neuroanatomical changes.

Clinical Signs and Diagnosis

I. The animal engages in a stereotypic behavior.
II. Although certain stereotypic behaviors are most common in certain species, any behavior can develop into a compulsive disorder.
III. The behavior is exhibited in a variety of contexts.
IV. The animal spends excessive and increasing amounts of time engaging in the behavior.
V. As the disorder progresses, it may interfere with normal and even essential behaviors, such as play, social interactions, eating, and drinking.
VI. In cases of excessive grooming, the animal eventually harms itself, causing abrasions, lacerations, and in extreme cases, removal of body parts (e.g., toe, end of the tail).

Treatment and Monitoring

I. Do not use any aversive training techniques (punishment, shock, reprimanding).
   A. The disorder is caused by stress and the use of aversive training techniques only increases the stress.
   B. This principle applies to all species.
II. If the problem is mild or just beginning, resolution may be accomplished without medication.
   A. Identify stressors in the environment and remove, decrease, or modify them.
      1. A common stressor is excessive confinement in insufficient space, with too little to do.
      2. Provide the animal with increased time in larger spaces, appropriate toys, and activities.
   B. Using positive reinforcement, teach the animal a variety of commands, so the owner can distract and redirect the animal by giving the command and subsequently redirecting it to another activity.
III. Most cases require medication, such as fluoxetine, clomipramine, other SSRIs, or TCAs (see Table 117-1).
IV. If the animal is very anxious, supplementation with a benzodiazepine may be beneficial.
V. Owners are often very frustrated with this problem, and regular monitoring is necessary to provide appropriate guidance.

Maternal Aggression

Definition and Causes

I. Aggression is exhibited by a female in the context of defending her young.
II. This is a natural behavior that facilitates survival of the offspring.
III. In the domestic dog and cat, both genetics and experience can cause a female to be aggressive to the point where it is problematic.

Clinical Signs and Diagnosis

I. Aggression is exhibited by a female that is otherwise not aggressive when a person or another animal approaches or attempts to handle the young.
II. When the individual approaches, threat behavior, such as growling (dog and cat) or hissing (cat), occurs.
III. If the individual initiates direct interaction with the young, biting or scratching may ensue.

Treatment and Monitoring

I. Prevention is of primary importance.
  A. Ensure that the pregnant female is very familiar and comfortable with everyone involved with her postpartum care.
  B. Provide a suitable and secure nesting area.
  C. Keep animals that are unfamiliar or may present a risk to the young away from the nest.
II. Some females may have such severe aggression that they are not suitable for breeding.
  A. If the female exhibits severe aggression upon her first parturition, she may have a genetic predisposition for strong defense of young.
  B. If the mother undergoes an extremely frightening experience (e.g., someone harms her offspring in her presence), she may become classically conditioned to severe aggression in this context.
III. Most cases of mild to moderate maternal aggression naturally improve over a period of days as the offspring mature.
IV. Supervise the animal closely for the first several days postpartum, without disturbing the puppies or kittens more than is absolutely necessary.

Redirected Aggression

Definition and Causes

I. Aggression is redirected to a secondary target because the primary target cannot be reached.
II. The initial motivators of the aggression are numerous and varied.
III. Humans can become the object of aggression when they get close to or interfere in the actions of a cat or dog that is already motivated to be aggressive toward another subject.

Clinical Signs and Diagnosis

I. Aggression occurs when the animal is already motivated to be aggressive to another animal or person.
II. Examples include but are not limited to the following:
  A. Picking up a cat when it is fighting with a dog or another cat
  B. Taking hold of a dog's collar when it is fighting with another dog or cat, or when it is behaving aggressively toward another person

Treatment and Monitoring

I. Identify the primary cause of the aggression and treat it.
II. Educate owners on prevention of aggressive conditions.
III. The need for monitoring varies substantially, depending on the cause of the primary aggression.

Predatory Aggression

Definition and Causes

I. It is aggression by a dog or cat where specific behaviors preceding the aggression are consistent with normal predatory behavior in these species.
II. Dogs and cats are both predators, and predatory aggression is a natural behavior.
III. For cats, whether the predatory aggression is a behavior problem depends on the context in which the cat is kept.
  A. For example, if the cat is kept on a dairy farm with expectations that it controls the rodent population, the predatory aggression is desirable.
  B. If the cat is allowed to run loose in a wild bird sanctuary or in other habitats where there are small animal populations that can be seriously harmed by predation, its behavior is highly undesirable.
IV. This same general rule also applies to dogs.
  A. If a dog is trained to assist in hunting, its behavior is not considered a problem.
  B. However, dogs may direct their predatory behavior to livestock, pet cats, small dogs, children, and even adult humans.
  C. In these cases the behavior is considered highly undesirable.
V. Genetics contributes to a dog's tendency to engage in particular predatory behaviors.
  A. Herding dogs have a low threshold for stalking and chasing behavior, but a high threshold for biting.
  B. Some breeds have little innate predatory behavior and require a strong stimulus to trigger such behavior.

Clinical Signs and Diagnosis

I. Cats stalk, chase, and pounce on small game and kill it, usually with a fatal bite to the neck.
II. Dogs stalk, chase, and bite the victim of the predatory attack.
III. Dogs often hunt in packs and bring down their prey by multiple bites or by the weight of multiple dogs holding onto the victim.
IV. In the case of predatory dog attacks on babies, small toddlers, small dogs, pet cats, and other small animals, the dog often grabs the victim and violently shakes it.

Treatment and Monitoring

I. Pet cats that live in or near areas where it is undesirable for them to kill small animals must be kept entirely indoors.
II. Although desensitization and counter-conditioning may increase a dog's threshold to engage in predatory attacks, they cannot be entirely relied upon.
III. Because predatory attacks often lead to serious maiming and even death, dogs with a history of independent predatory behavior must always be leashed or restrained in an enclosure from which they cannot escape.
IV. Dogs running loose in packs present a high risk of mass predatory attacks.

Pain-Induced Aggression

Definition and Causes

I. Aggression occurs as a consequence of pain.
II. The existence of this phenomenon is one reason that it is critical for all pets exhibiting aggressive behavior to be thoroughly evaluated by a veterinarian.
III. The cause of the pain may not be obvious to the lay person or even upon a basic physical examination.
IV. Any painful condition, including illness or injury that may or may not be obvious, is a potential cause.

Clinical Signs

I. Onset of aggression is often sudden and severe but may be gradual.
II. Pain-induced aggression is suspected anytime the aggression only occurs when a specific part of the body is reached for or touched (e.g., ears with ear infections, hindquarters with hip dysplasia).

Diagnosis

I. Identify the underlying illness or injury.
II. The cause may not be obvious, or the animal may hide an injury (e.g., a cat may walk without lameness on a limb with a greenstick fracture, but be aggressive to anyone who attempts to touch it).

Treatment and Monitoring

I. Treat the primary problem.
II. Use protective gear (muzzles, leather gloves) to handle the animal, and only use as much restraint as is absolutely necessary.
III. Fear aggression or other fear-based problems may develop secondary to an episode of pain-induced aggression (see Fear Aggression).
IV. Development of fear-related behavior problems secondary to pain-induced aggression is common; therefore monitor behavioral improvement independent of the physical improvement.

Cognitive Dysfunction

Definition and Causes

I. Changes in cognitive function occur as a pathologic process in some aged animals and may involve loss of memory, learning ability, awareness, and perception.
II. Although cognitive dysfunction is a process of aging, not all dogs and cats exhibit this phenomenon.
III. Genetics and environmental factors, including diet, probably affect the likelihood of the animal developing cognitive dysfunction.

Clinical Signs and Diagnosis

I. Multiple changes in behavior occur that are consistent with cognitive decline and cannot be explained by other medical conditions.
   A. Loss of prior learning, such as housetraining, litterbox training, and basic obedience (sit, come)
      1. Dogs may signal to go outside less or even discontinue this behavior.
      2. Dogs may eliminate inside right after they have been outside and may eliminate in front of the owner.
      3. Cats may become erratic in their litterbox usage.
   B. Changes in sleep patterns, increased sleeping
   C. Changes in social interactions
      1. The animal may not recognize family members or may exhibit decreased social interactions with both human family members and other pets.
      2. Dogs that have historically been aggressive to strangers may begin exhibiting aggression to family members.
      3. Cats that have historically hidden when strangers visit may begin hiding whenever anyone, including family members, is home.
   D. Disorientation
      1. The animal may walk behind doors instead of through them, or wander around the house appearing to look for something.
      2. Some animals stand and stare into space for long periods.
      3. Some animals exhibit decreased or no response to auditory stimuli (e.g., doorbell ringing, humans talking).
   E. Possible appetite changes
   F. Changes in type and frequency of activity
      1. Pacing or vocalizing at night
      2. Overall decrease in total activity per 24 hours
   G. Anxious, even with no history of an anxiety problem
II. The diagnosis is based primarily upon owner observations.
III. A comprehensive geriatric medical work-up is indicated to identify or rule out other causes or contributing factors.

Pathophysiology

I. The pathophysiology of canine cognitive dysfunction is very similar to human Alzheimer's disease (Shimada et al., 1992; Uchida et al., 1992; Cummings et al., 1996).
   A. Decreased total brain size and mass
   B. Dilation of the ventricles
   C. Decreased cerebral blood flow
   D. Meningeal fibrosis
   E. Decreased number of cells in the brain
   F. Degeneration of the white matter

II. Neurotransmitter changes include decreased levels, function, and activity of norepinephrine, serotonin, dopamine, and acetylcholine.
III. β-Amyloid plaques develop in the cerebral cortex and hippocampus.

Treatment

I. Selegiline is administered to both dogs and cats at 0.5 to 1.0 mg/kg PO SID (Head et al., 1996; Ruehl et al., 1996; Landsberg, 1999).
   A. It may require 30 to 60 days for improvement to be observed.
   B. Selegiline does not cure the disease.
   C. It only slows the progress and ameliorates many of the signs.
II. Increase the level of antioxidants in the diet.
III. Educate the owner about the disease and the pet's special needs.
IV. For dogs that have lost their house-training, take them outside frequently and reward them for eliminating outside, as for a 6-week-old puppy.
V. For cats that have become inconsistent in litter box usage, add additional litterboxes and place the cat in them several times a day.
VI. Avoid major changes in the environment, if possible.
VII. Provide mental and tactile stimulation (walks), regular training using positive reinforcement, and massage treatments.
VIII. Do *not* ever use aversive stimuli, including punishment, for any reason.

Monitoring of Animal

I. Improvement is gradual, occurring over many weeks.
II. Some animals exhibit little to no improvement, even with aggressive treatment.

CHAPTER 118

Canine Behavioral Disorders

Sharon L. Crowell-Davis

AGGRESSION

General Considerations

I. With all cases of canine aggression, it is important to inform the owners of the potential risk their dog presents if it is not euthanized.
II. The exact degree of risk varies with the size of the dog, type and severity of the aggression, ability of the owners to adequately restrain the dog, and use of special equipment such as muzzles and head collars.
III. Risk is also affected by the presence or absence of especially vulnerable individuals (children, elderly), or pets that are substantially smaller than the aggressor.

Dominance Aggression Syndrome

Definition

I. A dog behaves as if it were dominant to another dog, human, or other animal (Crowell-Davis, 1991).
II. It is accompanied by actual aggression, including (but not limited) to snarling, snapping, and biting.
III. The term *syndrome* is used because there is no single diagnostic criterion; it is identified by a collection of signs.
IV. True dominance aggression is rare in dogs and is only diagnosed after a thorough behavioral evaluation excludes other possible diagnoses and confirms a consistent pattern of dominant behavior.

Causes

I. The causes are not fully understood.
II. Genetics, early experience, inadequate early socialization, and persistent behavior by owners that the dog interprets as submissive are probably contributing factors.

Clinical Signs

I. The dog frequently exhibits ritualized dominance signals to the target individual, such as staring, directing the ears toward the individual, holding the tail up while staring, and approaching the individual.
II. The dog either does not or rarely exhibits fear, anxiety, or submission toward the individual (i.e., does not turn the head away, avoid eye contact, move away, lower the tail or crouch).
III. Signs occur most commonly in 1- to 3-year-old, intact males.
IV. Signs can occur at any age, in any gender (neutered or intact), and in any breed.

Diagnosis

I. Dominance aggression is a problem based on relationships.
   A. Aggression is usually directed toward family members, people, or dogs the aggressor knows well, rather than toward strangers.
   B. In severe cases, the dog may exhibit intense aggression to both family members and strangers, attempting to establish dominance with any human it meets.
   C. The latter condition is rare and may be secondary to underlying pathologic central nervous system (CNS) findings, such as low serotonin levels (Reisner et al., 1996).
II. Aggression occurs in conjunction with ritualized signals of dominance, including staring, tilting or pulling the ears forward, upright stance, and approaching with the tail up.
   A. The tail may be wagging.
   B. Tail wagging is from arousal, not friendliness.
III. Actual bites are often unpredictable.
   A. The owner may reach to pet the dog and the dog suddenly bites.
   B. This behavior can also occur with fear aggression, and information on the dog's current and historical signaling (behaviors) is important to differentiate.
IV. Spontaneous or unpredictable growling may be reported.
V. Affected dogs are often resistant to learning the "down" command, especially if it is taught with prompting and fading, and may have bitten when attempts were made to force them to lie down in a submissive posture.
VI. Affected dogs commonly jump into their owner's laps and stare at the owner.
   A. This must be differentiated from dogs that have been taught to jump in the owner's lap because the owner pets them when they do so.
   B. The owner may also call the dog to their lap.
VII. Dogs commonly demand to be let out or in, and demand to be petted, and their attention-seeking behavior escalates to aggression if the owner does not perform acts when

the dogs signal that they want such actions from the owner.

VIII. Dogs may physically block the owner's movements in the home, and may attack if the owner attempts to get past them.

IX. Any punishment, verbal or physical, is likely to trigger aggression.

X. Dogs may mount the owner's legs, which must be distinguished from abnormal sexual imprinting and attention-seeking behavior.

XI. Affected dogs may or may not guard food or a sleeping area.

XII. In cases of interdog dominance, establishment of a hierarchy is normal.
   A. Ritualized dominance and submissive signaling that does not include aggression should be allowed.
   B. Dominant and subordinate interactions can escalate to fighting under a variety of circumstances, including but not limited to the following:
      1. Poor early socialization resulting in a dog being unable to recognize and respond appropriately to signals of submission from other dogs.
      2. Poor early socialization resulting in a dog not recognizing ritualized signals of dominance from another dog or not responding with a ritualized submissive behavior.
      3. Two dogs that are evenly matched in size, strength, and motivation may both try to be the dominant dog; these cases are often the most severe and resistant to resolve.
      4. Owner interference in the natural order may contribute to fighting (e.g., owner acts supportive of and gives special attention to a geriatric or sick dog while trying to get a healthy, young adult dog to act deferential to the old dog).

Treatment

I. Human-directed dominance aggression
   A. Open confrontation is likely to lead to human injury and is not recommended.
   B. Castrate intact males.
   C. Instruct the owner to avoid situations in which the dog is likely to behave aggressively.
   D. The owner should frequently give low intensity, ritualized dominance signals that the dog will tolerate (e.g., touching the top of the dog's head).
   E. Teach the dog the "down" command using shaping, not prompting and fading.
   F. Require the dog to obey a command (preferably "down") to get anything it wants (e.g., petting).
   G. Reward ritualized submission (e.g., if the dog looks away from the owner when the owner looks at it), and reinforce that behavior.
   H. Do not allow the dog on furniture, and if it currently defends furniture, call it off for a reward.
   I. Selective serotonin reuptake inhibitors (SSRIs) or tricyclic antidepressants (TCAs) may be helpful (see Table 117-1).
   J. Hormonal treatments (megestrol acetate, medroxyprogesterone acetate) may be considered in dogs that have not responded to more conservative therapy, but are only considered as a last resort.

II. Interdog dominance aggression
   A. Educate owners about normal dog communication and social organization.
   B. Dogs that exhibit dominance aggression to other dogs owing to poor early socialization, as well as failure to recognize submission and inhibit their own aggression, may require muzzling, confinement, or both on an indoor leash with a head collar.
      1. Teach the dog a variety of commands and use these to redirect its behavior whenever it exhibits the intention of being dominant or aggressive to other dogs.
      2. Always supervise the dog when it is in the presence of other dogs.
   C. For dogs that fail to exhibit submissive responses to ritualized dominance signals by other dogs, teach them the "down" command and tell them to go down anytime another dog approaches in a dominant fashion.
   D. When a young, healthy dog attacks a geriatric dog in response to the owner's preferential treatment of the older dog, the owner must give preferential treatment (feed first, pet first, let in and out first) to the young dog.
   E. If owner compliance is a problem, special treatment can be given to the older dog when the young dog is not around.

Monitoring of Animal

I. Dogs with dominance aggression can be very dangerous, especially if they are large.

II. Frequent contact must be made with the family regarding treatment progress.

Possessive Aggression

Definition and Causes

I. It is aggression that occurs while defending an object (e.g., toy, bone, bowl of food).

II. Attempts to control important resources are somewhat normal behaviors for dogs.

III. Extreme manifestations (dog becomes highly aggressive if a person or another dog gets near or enters the same room) develop in part because of learning.
   A. Dogs that have lived on the street may developed aggression to survive.
   B. If a puppy's first attempt to defend a desired object results in a person or another dog backing away, they will learn that aggression is an effective tool.

Clinical Signs and Diagnosis

I. Aggression occurs only in the specific context of defending a certain object or objects.

II. If dogs that defend certain objects exhibit no other signs of aggression or dominance toward the owner or other dogs, they do not have dominance aggression syndrome.

Treatment and Monitoring

I. If the item is discrete and nonessential, removing all examples of the item from the dog's environment can eliminate the problem.
II. If the item cannot be eliminated from the environment, use desensitization and counter-conditioning to alter the dog's response to people and other dogs approaching the item.
III. Owners that use desensitization and counter-conditioning may need daily guidance during the first several days of treatment.

Territorial Aggression

Definition and Causes

I. It is defined as defense of a specific geographical area, which may be as small as a room or as large as a farm.
II. As with possessive aggression, some degree of territorial defense (e.g., brief barking at strangers) is normal.
III. In cases that represent a potential public health problem, the dog barks persistently and loudly, and the behavior may escalate to growling, snapping, and biting.
IV. A combination of genetics and learning contribute to this problem.

Clinical Signs and Diagnosis

I. The aggression is usually directed toward non-family members, humans, or other dogs that enter the dog's perceived territory.
II. When off of its territory, the dog is not aggressive.
III. Occasionally the aggression is directed toward human or canine family members that enter certain areas of the house.

Treatment and Monitoring

I. Do not leave the dog outside unsupervised.
II. If necessary, keep the dog muzzled or on a leash when visitors arrive.
III. Conduct basic obedience training using only positive reinforcement methods.
IV. Desensitize and counter-condition the dog to strangers approaching and entering its territory.
V. Check in with the owner every 2 to 4 weeks, depending on the severity of the case.

Protective Aggression

Definition and Causes

I. Aggression is exhibited in the context of defending a person or another animal.
II. Genetics is a contributing factor, as some breeds have a low threshold for protective behavior.
III. Learning is a significant contributing factor.
   A. Although some owners deliberately train their dogs in protective behavior, others inadvertently encourage it.
   B. Especially in the latter case, the dog may present a significant risk of harm to anyone approaching the owner or handler, because the dog has learned to engage in aggressive behavior toward non-family members, and control of the dog's behavior may not be maintained.

Clinical Signs and Diagnosis

I. Aggression is exhibited anytime someone approaches the person or animal being protected.
II. In some cases, the owner can disrupt the dog's aggression by a command that indicates the individual approaching is welcome.
III. In other cases, the owner has no control over the dog's behavior.

Treatment and Monitoring

I. If necessary, muzzle the dog anytime it is exposed to people against whom it might be aggressive.
II. Head collars are especially useful as they improve the owner's ability to control the dog's head and mouth.
III. Teach the dog basic obedience commands using positive reinforcement training techniques, shifting from continuous reinforcement to variable ratio reinforcement to generate a high level of motivation.
IV. Desensitize and counter-condition the dog to people approaching the owner or to any individual being protected.
V. Training with multiple stimuli is necessary to produce stimulus generalization.
VI. This problem, if severe, typically takes weeks or months to resolve, and the dog may never be truly trustworthy around some people.

ATTENTION DEFICIT DISORDER/ HYPERKINESIS

Definition and Causes

I. A phenomenon similar to human attention deficit disorder is often referred to as *hyperkinesis* in dogs (Corson et al., 1976; Luescher, 1993).
II. It is a rare phenomenon in dogs.
   A. Most dogs that are hyperactive as young, healthy dogs are exhibiting normal behavior for their species and age.
   B. In some cases, the dog is underexercised, and inadequately or inappropriately trained for their environment.
III. The dog is consistently and easily distracted and is usually hyperactive.
IV. Learning is poor, even with a good trainer using appropriate techniques.
V. Cause is unknown, although one group of related dogs with this problem had low levels of norepinephrine, dopamine, and homovanillic acid in the brain (Bareggi et al., 1979).

Clinical Signs and Diagnosis

I. The dog usually performs poorly in any kind of training.
II. Most of these dogs are hyperactive, constantly in motion, or getting into things.
III. The dog may rest only at night.

IV. In the examination room, the dog does not sit or rest.
V. In the examination room, attempts at basic training are likely to be unsuccessful because the dog is constantly in motion.

Treatment

I. Treatment with CNS stimulants, such as methylphenidate or amphetamine, results in less activity and more attentiveness.
II. Because the dog has historically been unable to learn any basic training and has multiple experiences with undesirable behaviors, it does not immediately exhibit good learning and appropriate behavior.
III. If the owners attempt basic training (as if they were just starting with a young puppy), the dog should respond as long as it is on medication.

Monitoring of Animal

I. Owners are often very frustrated with their dog by the time the problem is diagnosed.
II. Frequent communication with the owners and the trainer involved in case management is essential during the first few weeks of treatment.

ELIMINATION PROBLEMS

Definition and Causes

I. These problems consist of urination, defecation, or both in the house or another undesired location.
II. Urine and occasionally feces are used to mark territory.
III. Urination in the house may occur because of an anxiety disorder, such as separation anxiety or storm phobia (see Anxieties and Phobias in Chapter 117).
IV. Dogs urinate as a demonstration of submission to dogs or humans they perceive as being dominant to them.
V. Dogs that are very excited may lose control of their urinary sphincter and urinate while running or jumping.
VI. Dogs may eliminate in the house because they have not been appropriately housetrained or because they have unlearned their housetraining.
VII. See Section 7 for the medical causes of inappropriate urination.

Clinical Signs and Diagnosis

I. Marking is identified by elimination of small volumes of urine or (rarely) feces, on vertical surfaces.
II. Urination associated with anxiety or fear only occurs when the dog is afraid and is typically combined with other indicators of fear.
III. Submissive urination is accompanied by other submissive signals, such as lowering the head, lying down, and rolling over when a person approaches.
IV. Dogs with excitement-induced urination only urinate when exhibiting other signs of excitement, such as barking, jumping, or running.
V. A review of housetraining techniques reveals that appropriate housetraining was not conducted or maintained (e.g., the dog may be kept inside for longer periods than it can reasonably hold its urine).

Treatment

I. Castrate intact male dogs that exhibit territorial marking.
II. Dogs with anxiety disorders or phobias are treated as discussed under Anxieties and Phobias in Chapter 117.
III. Avoid triggering urination in submissive dogs through the following:
   A. Do not reach over the dog's head, approach it quickly, vocalize loudly, stare into the dog's eyes, or pet it on top of the head.
   B. Squat to interact with the dog, but avoid eye contact.
      1. Speak in a gentle, quiet voice and pet the dog under the chin.
      2. If this behavior triggers submissive urination, do not approach the dog, and keep interactions to a minimum.
   C. Dogs with severe submissive urination may require an anxiolytic medication (see Table 117-1) (Creed and Tulloch, 1982).
IV. Avoid reinforcing behaviors of excitement in dogs with excitement-induced urination.
   A. Ignore the dog whenever it is running around, spinning, barking, jumping, etc.
   B. Only give the dog attention when it is calm.
   C. Imipramine or phenylpropanolamine may be useful.
V. Basic housetraining considerations include the following:
   A. Take the dog out frequently to an area where it is acceptable for the dog to eliminate.
   B. Praise the dog every time it eliminates in an acceptable area.
   C. Puppies are taken out after they eat, play, or wake up from a nap.
   D. Do not punish the dog after the fact.
      1. If you find urine or feces in an unacceptable location, do not take the dog back to the location and administer aversive stimuli.
      2. These methods do not help stop the elimination problem.
   E. If the puppy or dog is seen in the act of eliminating in an unacceptable area, disrupt the behavior by calling its name, taking it immediately outside, and praising it when it finishes eliminating outside.
   F. Confine puppies to a small area in the house when not supervised.
   G. Older dogs that have unlearned their housetraining may be kept on a leash attached to the owner for several days so that the owner can continuously monitor them.

Monitoring of Animal

I. The frequency with which cases of inappropriate elimination must be monitored varies with the type of problem.
II. If a relapse of a previously resolved behavioral elimination problem occurs, examine the dog for medical problems.

JUMPING

Definition and Causes

I. The dog repeatedly jumps on people.
II. Jumping can be play- or attention-seeking behavior that is often on a variable ratio reinforcement schedule.
III. The dog is not trying to be dominant to the person.

Clinical Signs and Diagnosis

I. Persistent jumping on people occurs in spite of various attempts by the owner to get the dog to stop.
II. This occurs most commonly in healthy, young dogs.

Treatment and Monitoring

I. Teaching the dog an alternative behavior is critical and more effective than simply attempting to punish the behavior.
II. Teach the dog to "sit-stay" or "down-stay" for a treat, and ask all visitors to do this when they first encounter the dog.
III. If a dog jumps on someone after this training has occurred, turn around and ignore the dog (i.e., do not talk to it, look at it, or touch it).
IV. It is critical that all people who interact with the dog be consistent in reinforcing the appropriate behavior.

CHAPTER 119

Feline Behavioral Disorders

Sharon L. Crowell-Davis

AGGRESSION

Introduction of a New Cat

Definition and Causes

I. It is aggression by a new cat to cats already living in the household or by the household cats toward a new cat.
II. Cats are highly social and form discrete social groups called *colonies* (Crowell-Davis, 2005).
III. Members of the colony recognize other members and nonmembers, and they reject attempts by nonmembers to interact with the colony.
IV. Cats that have lived in isolation from their own species since youth or for several years may have poor social skills.
V. All introductions of a new cat to a household have the potential to lead to aggression, especially if one or more cats have poor social skills.

Treatment

I. Introduction should always be gradual.
II. Place the new cat in its own room with its own food, water, bed, and litterbox.
III. If glass or screened doors are not available within the house, a solid door can be propped open by about one-inch, which allows the cats to hear, see, and smell each other without being able to interact aggressively.
IV. Rotate bedding among the cats.
V. Gently and playfully rub a small cloth on each cat's perioral area to facilitate familiarizing the cats with each other's scent.
VI. In some cases, systematic desensitization and counterconditioning may be useful.
   A. Place one or more cats in a harness or in cages.
   B. It is critical that fear not be induced (e.g., placing cat in a cage of which it is already frightened).
VII. In refractory cases, tricyclic antidepressants (TCAs) or selective serotonin reuptake inhibitors (SSRIs) may be useful (see Table 117-1).

Monitoring

I. Advise owners that introductions should be done gradually to prevent a serious incident that makes it difficult for the cats to adapt to each other.
II. Well-socialized and friendly cats may become comfortable with each other in a matter of minutes or hours.
III. Poorly socialized cats may require weeks or months to be comfortable with another cat.

Dominance Aggression

Definition and Causes

I. Aggression, combined with multiple dominance signals, is directed toward a cat or a human with whom the cat is familiar (Crowell-Davis et al., 1997).
II. Cats that are not well socialized as kittens are particularly prone to being the aggressor or the victim in this problem.
III. Genetics contribute to the ease with which a cat is socialized.
IV. A variety of changes in the cat's environment or traumatic events may trigger dominance conflicts.
   A. If a high-ranking cat is removed from the household for a period (e.g., because of illness), its status in the household may not be acknowledged upon its return.
   B. The addition of a new cat may disrupt the existing hierarchy and coalitions.
   C. If a major fight is triggered by a disruptive event that causes displaced or arousal-related aggression (e.g., new cat growls at the household cats through a screened door), a previously stable hierarchy may be disrupted.

Clinical Signs and Diagnosis

I. Cats that previously got along well begin exhibiting aggression involving intense signaling of dominance or submission.
II. The aggressor approaches the victim with a stiff-legged walk.
III. The base of the tail is elevated, with the remainder drooping.
IV. The cat stares at the victim or may exhibit a slow, side-to-side head wag.
V. Subordinate cats may trigger attacks by otherwise nonaggressive dominant cats by exhibiting intense displays of running away when they see the dominant cat.
VI. Human-directed dominance aggression is extremely rare in the cat.

Treatment

I. Separate the cats that are in conflict when they are not being supervised.

II. Make sure that all cats have access to essential resources without having to encounter cats with whom they are in conflict.
III. Cats that get along are rotated among the cats that are in conflict so that their stable, amicable relationships are not disrupted.
IV. Conduct desensitization and counter-conditioning in neutral areas; do not conduct treatment sessions in any of the cats' favorite or core areas.
V. Medication with SSRIs or TCAs may be useful in some cases (see Table 117-1).

Monitoring of Animal

I. These cases often require weeks or months of consistent treatment.
II. Resolution is possible but does not always occur.

Play Aggression

Definition and Causes

I. Biting and scratching occurs in the context of play.
II. Inadequate or inappropriate socialization to humans or cats when they are kittens is a cause.
III. Inappropriate play by one or more humans (using the hands or feet as a toy) teaches the kitten that it is acceptable to bite or claw at hands or feet.
IV. Genetics and other factors that contribute to a cat's general level of arousal may contribute to the problem.
V. Some cats appear to become overly aroused in the context of play.

Clinical Signs and Diagnosis

I. The cat approaches, stalks, and chases the owner, leaps on to them, and may bite or claw (usually deeply).
II. Postures characteristic of predatory cats may be observed before attacks, especially tail twitching and focused stares.
III. The cat is more likely to attack moving targets rather than stationary targets.
IV. In the case of intercat play aggression, normal play may escalate into fighting.

Treatment

I. This problem can usually be prevented by providing kittens and adult cats with adequate opportunities for acceptable play and vigorous exercise.
II. Never encourage a cat to bat at or otherwise play with hands or feet.
III. If a cat has significant human-directed play aggression, it is important that all the people being attacked wear sturdy, protective clothing when around the cat until the problem is resolved.
IV. Jumping, running, and vocalizations made by people can stimulate the cat to further attack as part of the "game."
V. Provide the cat with multiple toys and opportunities for interactive play, either alone or with the owner.
VI. For cats whose bouts of normal wrestling escalate into actual fights, disrupt the play when escalation first begins.
VII. For cats that become highly aroused, treatment with SSRIs or TCAs may be useful (see Table 117-1).

Monitoring of Animal

I. Although the cat's biting and scratching are a form of inappropriate play, this form of human-directed aggression is the one that most often leads to serious injury.
II. Some owners become afraid of their cat even when they wish to pursue treatment.
III. Regular contact with the owner during early phases of treatment is important.

Petting Intolerance

Definition

I. The cat begins growling, biting, and scratching when petted.
II. Some cats only exhibit this problem if petting is initiated by the human, during a certain type of petting, or after a certain amount of petting.

Causes

I. The cause of petting intolerance is not fully understood.
II. With intercat interactions, grooming (licking) is typically directed to the head and neck of the cat being groomed, so humans who pet other areas of the cat's body may trigger a defensive response.
III. Genetics is probably a contributing factor, with some strains of cats being more or less likely to develop this problem.
IV. Early experience and habituation to human handling makes this problem less likely to develop.
V. Owner-initiated interaction with the cat has a significant effect on this problem.
   A. At one extreme, some owners have minimal physical interaction with their cat.
   B. At the other extreme, some owners want to carry their cat around, hold it in their lap, and pet it for long periods.

Clinical Signs and Diagnosis

I. The cat becomes aggressive only when handled and petted.
II. Although some owner's may initially claim that the cat gives them no warning of its intention to bite or scratch, careful observation invariably reveals that the cat is giving signals that the owner is missing (e.g., twitching tail, twitching ears, rippling skin, low volume growling).

Treatment

I. It is important to recognize that some cats have thresholds for tactile contact and handling beyond which they are not comfortable.
   A. If a cat only becomes aggressive when petted a certain way, avoid petting it that way.
   B. If a cat only becomes aggressive when a human (rather than the cat) initiates petting, then pet the cat only when it initiates or seeks petting.

C. If the cat becomes aggressive after a certain amount of petting, only pet it for brief periods.

II. Sometimes an owner and cat are not a good match, so adoption of another cat that has a preference for or high tolerance of petting may be desirable.

III. Progressive desensitization and counter-conditioning may increase the cat's tolerance of petting.

IV. Treatment with an SSRIs or TCAs may be helpful (see Table 117-1).

Monitoring of Animal

I. Clarifying goals about this problem at the first visit is critical.

II. The problem may be resolved almost immediately if the owner understands the cat's needs and interacts with it appropriately.

III. Owners who do not fully understand the situation may continue to engage in behaviors that stimulate aggression.

ELIMINATION PROBLEMS

Definition

I. Failure to use the litterbox includes defecating or urinating large volumes of urine on a horizontal surface.

II. Urine marking primarily occurs when the cat backs up to a vertical object and ejects a small amount of urine onto the object.

III. With urine marking, the tail is held straight up with the tip twitching, or it may be held aside in a J shape.

IV. Sometimes urine-marking cats partially squat and spray the lower part of vertical surfaces, such as baseboards or the bottom of curtains.

V. A small number of urine-marking cats pass large volumes of urine in a single marking episode, whereas others assume the position of marking but do not pass any urine.

VI. Medical problems are common causes of elimination behavior problems, so a thorough medical evaluation must be conducted before pursuing behavioral issues (see Section 7).

VII. In some cats, a medical problem initiates a behavioral elimination problem through learning.

Causes

I. Failure to use the litterbox is generally caused by aversion to some aspect of the litter, the litterbox, the location of the box, or by preference for some other substrate or location.

II. Multiple causes may be present and may change over time.

III. There is no single cause of urine marking.

A. Urine marking is not used to mark territory or territorial boundaries.

B. Because there is a higher rate of urine marking among estrous females and intact males, it is probable that urine marking gives information about sexual status.

C. Feral cats may use urine marking to give information to other colony members about their location.

D. Urine marking in household cats is often associated with environmental stress, such as overcrowding and major changes in the household.

E. Not all cats subjected to stress develop urine marking.

Clinical Signs

I. Urine and feces are found outside the litterbox.

II. Failure to use the litterbox is discriminated from urine spraying by location (horizontal versus vertical surface) and the volume of urine.

Diagnosis and Treatment

I. Diagnosis is determined by evaluating potential problems, correcting them, and evaluating whether the cat responds in a desired fashion.

II. Litterboxes are checked and cleaned at least BID.

A. If this resolves the problem, the diagnosis is aversion to soiled litterbox.

B. A small number of cats will not use litterboxes that have any soiled material in them.

III. If nonclumping litter is used, completely change it every 2 to 3 days.

IV. If clumping litter is used, completely change it every 1 to 4 weeks.

V. If the cat spends little time digging (0 to 8 seconds), litter aversion is a possibility (Horwitz, 1997; Sung and Crowell-Davis, 2006).

A. Cats with litter aversion may stand with one or more paws on the rim of the litterbox, or they may vigorously shake their paws upon exiting.

B. Offer cats multiple litterboxes of the same type and in the same location with several different kinds of litter.

C. Some cats prefer one type of litter for urination and another litter for defecation.

D. In general, most cats prefer unscented, fine-grained, clumping litter.

E. Certain cats reject this kind of litter and prefer something unusual (e.g., potting soil, cloth); for cloth preference, using cloth baby diapers in the litterbox may be the best solution.

VI. Litterbox aversion can occur in a variety of ways.

A. If a cat has an unpleasant experience at the litterbox (e.g., painful defecation), it may become conditioned to fear the litterbox, so a new type and location of the box may help.

B. Litterboxes themselves may be undesirable for a variety of reasons.

1. The box may be too small.
   a. The box should be at least 1.5 times the length of the cat.
   b. Plastic storage boxes may be preferable.
2. Cats do not normally enter small caves to eliminate and many cats find hooded boxes aversive.
3. The box may be located in an inappropriate place, where high traffic, loud noises, drafts, or other unpleasant conditions make the cat avoid the area.
4. Kittens and geriatric cats may not be able to enter high-sided litterboxes.

VII. Cats sometimes have a location preference for elimination where there is no litterbox.
  A. They may prefer to eliminate in a location close to where they spend most of their time.
  B. Cats sometimes develop a location preference because of inappropriate litterbox management.
  C. Confirm appropriate management, then make the preferred area inaccessible (closed doors, stacked baby gates or furniture, food bowls over the area) or undesirable (placing a citrus room deodorizer nearby).

VIII. Cats may prefer to eliminate on a substrate the owner does not want them to use, such as carpet or linoleum.
  A. These problems often begin with inappropriate litterbox management, so appropriate management must be verified before other treatment is initiated.
  B. If the cat prefers carpet (one of the most common problems), there are two main approaches to retraining.
    1. Isolate the cat from carpeting except under supervision.
      a. It is essential that the cat have supervised time on carpet every day for this technique to work.
      b. Several weeks may be required.
    2. Place carpet squares in the litterbox regularly and discard them as they become soiled, or place a carpet frame around the box so that the cat can have tactile contact with carpet while eliminating in the box.
  C. If the cat prefers smooth surfaces (linoleum, vinyl), try multiple boxes that have no litter in them or that contain pieces of linoleum or vinyl.

IX. Overcrowding can contribute to elimination behavior problems.
  A. Social conflict may result in one or more cats keeping a cat away from the litterbox.
  B. In multicat households, have as many boxes as there are cats plus one more, and place the litterboxes in multiple locations.
  C. Make sure timid and low-ranking cats can reach a box without having to encounter other cats.
  D. Litterbox cleanliness is a special challenge in households with several cats, so it is imperative that owners check and clean the boxes several times a day.

X. A coprophagic dog in the household may disturb the cat while it is attempting to defecate.
  A. In this case, a covered litterbox may be useful.
  B. The litterbox can be kept in a room to which the dog does not have access.

XI. Long-haired cats with elimination problems sometimes show substantial improvement if the hair between their toes and around their perineum is clipped.

XII. Stressors, including owner absence, can sometimes cause elimination behavior problems.
  A. Identify and attempt to remove the stressor or desensitize and counter-condition the cat to the stressor.
  B. Medications with anxiolytic activity may be necessary.

XIII. Placing the litterbox in an extremely dark location can sometimes cause elimination behavior problems, so try adding a night light or some other light source to the area.

XIV. Some cats respond well to toilet training.
  A. Place a frame that holds litter over a toilet.
  B. The cat is encouraged to use it by such means as burying catnip in the litter and playing with the cat at the location.
  C. Cats that are generally attracted to the toilet are the easiest to toilet train.
  D. Once the cat is using the litter frame over the toilet, gradually decrease the amount of litter and eventually remove the frame.
  E. Do not train the cat to flush the toilet, as some cats will do this dozens of times a day.

XV. Spraying is significantly enhanced by environmental stressors.
  A. If the cat is an intact male, castrate it (Hart and Barrett, 1973).
  B. If possible, identify, decrease, or eliminate stressors, or desensitize and counter-condition the cat to the stressor.
  C. Anxiolytic medications (buspirone, clomipramine, fluoxetine, paroxetine,) are often helpful, particularly in cases of spraying (Hart et al., 1993; Pryor et al., 2001; King et al., 2004)
  D. They may also be helpful for nonspraying problems when the anxiety of the cat is obviously high.

XI. Since learning is involved in many elimination behavior problems, several days are allowed between changes in management to identify whether the cat is responding.

SCRATCHING OBJECTS

Definition and Causes

I. Even though it is a common complaint among cat owners, scratching is a normal behavior.

II. Scratching is part of normal grooming and serves to remove the outer layer of the claw.

III. Scratching leaves a visual and an olfactory marker from scent deposited from the interdigital glands.

Treatment and Monitoring

I. A common error in managing this problem is for the owner to select a commercially available scratching post and, if the cat does not scratch it, assume a designated scratching post is not an option.

II. It is important to realize that each cat is unique in terms of its preferences, and the scratching post must fit its preferences.

III. The following must be taken into consideration:
  A. Identify if the cat prefers to scratch in a particular location and make the scratching post available in that location.
  B. Identify if the cat prefers to scratch on vertical, horizontal, or sloping surfaces, or some mixture of these.
  C. Identify the textures the cat prefers to scratch.

D. While carpet-covered scratching posts are probably the most available type, various other textures may be tried, including natural wood with bark, cardboard and rope.
E. Some cats have a specific texture preference that is not available commercially.
   1. Identify the cat's preference by examining the objects in the house that are being scratched.
   2. Try to make a post with a texture that matches those surfaces.
F. To help train a cat to use a scratching post, play with the cat in the vicinity of the post, or rub catnip on the post.

IV. It is important to contact owners regularly during the early training period so that they do not become frustrated after trying one or two options.

CHAPTER 120

Introduction

Joseph W. Bartges | Susan D. Lauten | Claudia A. Kirk

Animal Factors

I. Dogs and cats eat to meet energy requirements and maintain body mass based on the following:
   A. Signalment: species, breed, age, gender
   B. Life stage: growth, adult, pregnancy, lactation
   C. Individual variation
   D. Environmental factors: temperature, housing, presence of other animals
II. Perform a good physical examination at every appointment.
   A. Record body weight at every examination.
   B. Body condition score is an important measurement.
      1. Provides assessment of overall nutritional status
      2. Either a 5- or 9-point scale for dogs and cats (see Chapter 1; Table 120-1)

Dietary Factors

I. Acquire a good dietary history including type and amount of food consumed, frequency of feeding, exposure to other foods or foreign matter, and administration of supplements.
II. An adequate diet is complete, balanced, and of sufficient palatability so that the animal eats an appropriate amount.
III. Inspect the food when possible and any time a concern exists about the food.
   A. Physically inspect the food for appearance, presence of foreign material, and odor.
   B. Pet foods are available in different forms.
      1. Dry diets are produced from dry ingredients (e.g., grains, meals) that are mixed to a doughy consistency, cooked, and extruded.
         a. Antioxidants and low moisture content preserve food and prevent fat oxidation.
         b. Digest is sprayed on the extruded food to increase palatability and to provide acidification for cat foods.
         c. Dry diets are the most economical and convenient to feed.
      2. Semimoist and semidry diets are more calorically dense, palatable, and expensive to feed than dry diets and require chemical preservation.
      3. Canned diets often contain whole ingredients, are highly digestible and palatable, require chemical preservation, and are more expensive to feed than other forms.
      4. Frozen diets are often composed of whole ingredients, but do not typically contain preservatives.
      5. Liquid diets are used to provide nutrition for critically ill animals and as milk replacement for neonates.
IV. Inspect the pet food label for information on the diet.
   A. The product display panel contains the product identity, information on whether the food is for dogs or cats, the net weight of the product, and marketing vignettes.
   B. The information panel contains the ingredient list, guaranteed analysis, nutritional adequacy statement, feeding guidelines, and manufacturer or distributor information.
      1. Ingredients are listed in descending order according to preprocessed weight.
         a. Ingredient names are set by the American Association of Feed Control Officials (AAFCO).
            (1) Information panel does not give information as to quality of ingredients.
            (2) Panel does not give information as to exact amount of ingredient present.
         b. A specific component of the diet may come from two different sources, which appears further down the list.
         c. Ingredients with chemical-like names are vitamins, minerals, and preservatives, and must be recognized by AAFCO as being "generally regarded as safe."
      2. The guaranteed analysis lists major dietary components as percentages (as fed).

TABLE 120-1

Semiquantitative Body Condition Scoring System

DESCRIPTOR	FINDINGS	POINT SCALE (1-5)	POINT SCALE (1-9)
Cachectic	Ribs are easily palpated, with no fat cover Bony structures are prominent and easy to identify Muscle tone and mass often decreased Little to no subcutaneous fat Hair coat often poor Pronounced abdominal tuck	1	1
Underweight	Ribs are easily palpated, with little fat cover Bony structures are palpable but not prominent Muscle tone and mass may be good or slightly decreased Hair coat may be poor Abdominal tuck is present	2	3
Ideal	Ribs are easily palpated, but fat cover is present Bony prominences are palpable but not visible Some subcutaneous fat present, but no large accumulations Good muscle tone and mass Hair coat quality is good Hourglass shape and abdominal tuck are present, but not pronounced	3	5
Overweight	Ribs are difficult to palpate owing to overlying fat accumulation Cannot identify bony prominences Subcutaneous fat obvious, with some areas of accumulation Good muscle tone and mass Hair coat quality may be decreased Hourglass shape is not prominent and abdominal tuck is absent	4	7
Obese	Ribs are impossible to palpate owing to overlying fat Subcutaneous fat is obvious and accumulations are present in the neck, tail-base, and abdominal regions Muscle tone and mass may be decreased Hair coat quality may be decreased Hourglass shape is absent and animal may have a round appearance	5	9

a. Pet food content must guarantee the following:
   (1) Minimum amount of crude protein
   (2) Minimum amount of crude fat
   (3) Maximum amount of crude fiber
   (4) Maximum amount of moisture
b. Values are based on "crude" analytical procedures and do not refer to the quality of the ingredient.
c. Compare different forms of food by converting nutrients to a "dry matter" basis:

% nutrient as fed ÷ (100 – % moisture) = % nutrient dry matter (DM)

d. Another and perhaps better way to compare information is based on the food's caloric density:

amount of nutrient as fed (e.g., grams) ÷ energy density of diet (kilocalories) = amount of nutrient per kilocalorie of energy

3. The nutritional adequacy statement ensures that if the diet is fed as the sole source of nutrition, it will adequately sustain an animal during certain life stages.
   a. It includes wording such as "complete and balanced," the life stage for which the food is intended (adult, pregnancy, lactation, growth), and how the product was found to be adequate.
   b. The two methods used to determine adequacy are calculation of nutrient profile by chemical analysis or feeding trials.
   c. Therapeutic diets do not often have a nutritional adequacy statement.
   d. Supplements and treats are not designed to be fed as the sole source of nutrition.
4. Feeding guidelines must be included to provide a general recommendation as to the amount of food that should be fed to a dog or cat.
5. Name and address of manufacturer or distributor are provided for contact purposes.
6. The Universal Product Code is present on the label.

Feeding Factors

I. How the nutrition is provided is as important as what is fed.

II. The appropriate diet must be provided in the appropriate amount.

Formulate a Feeding Plan

I. Once assessments are made, a nutritional plan is formulated that includes the food and feeding method.
II. Monitor the animal and reformulate the nutritional plan as needed, especially when the margin of safety for nutrition is narrow and nutrient demands are high.

CHAPTER 121

Nutrition in Health

Susan D. Lauten | Joseph W. Bartges | Claudia A. Kirk

ADULT DOGS

Animal Factors

I. A wide margin of safety exists for nutritional requirements in healthy adult dogs; however, the margin becomes narrower with stressful physiological or pathologic states.
II. The American Association of Feed Control Officials (AAFCO) mandates adequate nutrition for all life stages (AAFCO, 2006), whereas the National Research Council (NRC) provides recommended allowances for all life stages (NRC, 2006).

Dietary Factors

I. Energy requirement is based on energy expenditure (e.g., physiological status and activity) (Table 121-1).
   A. It can be estimated using one of the following formulas:
      1. Linear: 1.1 to 2.0 × (30 × body weight in kilograms [BW_{kg}] + 70) (Hand et al., 2000)
      2. Exponential: 80 to 200 × $BW_{kg}^{0.75}$ (NRC, 2006)
      3. Lower estimated values used for less-active and neutered dogs, and dogs prone to obesity
      4. Higher estimated values used for more active and reproductively intact dogs
   B. These formulas are estimates; only 60% of dogs need the calculated energy requirements.
II. Protein requirement is 18% to 25% of the diet (dry matter [DM] basis); 25% to 50% of the maintenance energy requirement (MER); or 4.0 to 6.5 g of digestible protein per 100 kcal of metabolizable energy (ME).
III. Fat requirement is 8% to 12% (DM) or 20% to 50% of MER.
   A. Linoleic acid is an essential fatty acid.
   B. NRC recommends inclusion of α-linolenic, docosahexaenoic (DHA), and eicosapentaenoic (EPA) acid in diets (NRC, 2006).
IV. There is no carbohydrate requirement for dogs.
V. Average dietary characteristics are as follows:
   A. Energy: 3.5 to 4.5 kcal ME/g
   B. Crude protein: 18% to 30% DM
   C. Crude fat: 10% to 20% DM
   D. Crude fiber: 5% DM
   E. Calcium: 0.5% to 1.0 % DM
   F. Calcium-to-phosphorous ratio: 1:1 to 2:1

Feeding Factors

I. May be dictated by lifestyle of owner or dog (Hand et al., 2000)
   A. Feed one to two meals per day.
   B. Cost of food may influence feeding choices.
   C. Dry food can be fed ad libitum, whereas moist and canned foods are fed as meals.
II. Monitor body condition and body weight (BW), and adjust intake to maintain ideal body condition.

TABLE 121-1

Comparison of Typical Nutrient Content in Dog Diets

NUTRIENT	SENIOR DIET	ADULT MAINTENANCE DIET	DIFFERENCE
Energy (kcal/g of DM)	3.7 to 4.7	4.1 to 4.5	−0.4 to 0.2
Protein			
(g/100 kcal)	4.6 to 7.1	5.3 to 6.8	−0.7 to 0.3
(% kcal)	16 to 29	18 to 26	−2 to 3
Fat			
(g/100 kcal)	2.4 to 4.4	2.8 to 4.3	−0.4 to 0.1
(% kcal)	19 to 42	23 to 38	−4 to 4
Carbohydrate			
(g/100 kcal)	11.8 to 17.6	10 to 13.4	1.8 to 4.2
(% kcal)	29 to 62	37 to 53	−8 to 9
Fiber (% DM)	0.2 to 2.4	0.2 to 0.7	0 to 1.7

DM, Dry matter.

ADULT CATS

Animal Factors

I. Cats are true carnivores.
II. They are more suited to animal protein-based diets because they cannot down-regulate hepatic enzymes involved in protein metabolism.

Dietary Factors

I. Cats require less energy per kg BW for maintenance than dogs, but resting energy requirements are similar (NRC, 2006).

A. Cats derive part of their energy from dietary protein.
B. Energy requirements can be estimated using one of the following formulae:
   1. Linear: 0.8 to 1.5 × (30 × BW_{kg} + 70) (Hand et al., 2000)
   2. Exponential: 70 to 199 × $BW_{kg}^{0.75}$ (NRC, 2006)

II. Adult cats require 26% to 30% protein (DM) or 6.0 to 8.0 g/100 kcal ME.
   A. Protein increases palatability of foods for cats.
   B. Requirements include certain amounts of specific amino acids.
      1. Taurine is a sulfur-containing amino acid, and diets should contain 0.1% DM (extruded diets) or 0.2% DM (canned diets).
      2. Arginine requirements are higher in cats than in dogs (Hand et al., 2000).

III. Dietary fat requirements are 10% to 20% DM.
   A. Linoleic and arachidonic acids are essential fatty acids.
   B. Cats cannot convert linoleic to arachidonic acid (Case et al., 2000).
   C. Arachidonic acid is found primarily in animal tissues.
   D. NRC recommends inclusion of EPA and DHA in diets (NRC, 2006).

IV. Cats cannot convert beta-carotene to vitamin A; therefore, it must be supplied in the diet.

V. Cats cannot convert tryptophan to niacin, so it must also be supplied in the diet.

VI. Cats require more pyridoxine (vitamin B_6) than dogs.

VII. No calcium-to-phosphorus ratio has been established by AAFCO for cat diets.

VIII. Average dietary characteristics include the following:
   A. Energy: 4.0 to 5.0 kcal ME/g
   B. Crude protein: 30% to 45% DM
   C. Crude fat: 10% to 30% DM
   D. Crude fiber: <5% DM
   E. Calcium: 0.5% to 1.0 % DM
   F. Calcium-to-phosphorous ratio: 0.9 to 1.5:1.0 considered safe (Hand et al., 2000)

Feeding Factors

I. Ad libitum feeding helps to maintain an acidic urinary pH in cats.

II. Feeding meals is associated with a postprandial alkaline tide and alkaluria.

III. Cats generally consume many small meals throughout the day (Case et al., 2000).
   A. Dry food is more appropriate for this feeding behavior.
   B. Dry foods are generally carbohydrate-based, not animal protein–based.
   C. Canned and semimoist foods are appropriate for meal feeding.

GERIATRIC DOGS AND CATS

Animal Factors

I. Defining *geriatric* is difficult in dogs and cats.
   A. Cats may be considered geriatric at 7 years.
   B. Small-breed dogs can be considered geriatric at 9 years, medium- and large-breed dogs at 7 years, and giant-breed dogs at 5 years.

II. Older dogs have decreased metabolic rates, glucose tolerance, and renal function, as well as increased protein requirements.

III. Body condition and physical activity determine the nutritional needs of geriatric animals.

Dietary Factors

I. Types of diets that can be fed include the following:
   A. Adult maintenance diet
   B. Senior diet (lower in energy, protein, and fat, higher in fiber and carbohydrate) compared with an adult maintenance diet
   C. Calorically (energy) dense diet: growth diet
   D. Therapeutic diets: depending on diseases present

II. Type of appropriate diet is determined by physiological, metabolic, and clinical characteristics of the individual animal.
   A. Physiologically young, efficient metabolism, clinically healthy: adult diet
   B. Physiologically old, efficient metabolism, gains weight easily, clinically healthy: calorie-restricted diet
   C. Physiologically old, inefficient metabolism, loses weight easily, clinically healthy: calorie-dense diet
   D. Physiologically old, inefficient metabolism, clinically unhealthy: disease-specific diet

Feeding Factors

I. Older animals may not eat as well as younger dogs; therefore, it may be necessary to offer food free choice or feed several meals daily.

II. Changes in body condition can occur quickly in geriatric animals, which make frequent follow-up evaluations essential.

WORKING ADULT DOGS

Animal Factors

I. Dogs may be required to perform work at a wide range of activity levels.

II. Maintain body condition and BW to achieve these desired activity levels.

Dietary Factors

I. Feed seasonal working dogs (e.g., hunting dogs) a maintenance diet during the off season.

II. Transition to a calorie-dense diet before training and conditioning, and continue to feed this diet during heavy activity.

III. Additional protein intake is not advantageous but is not harmful.

IV. Average dietary characteristics include the following:
   A. Energy: >3.8 kcal/g
   B. Crude protein: >26% DM
   C. Crude fat: 17% DM
   D. Crude fiber: <2% DM

Feeding Factors

I. Maintain an ideal body condition during the off season (NRC, 2006).
II. Extended periods of exercise deplete glycogen stores rapidly.
  A. Energy requirements are met by utilization of fat.
  B. If fat is not available, the body catabolizes protein to provide energy.
III. Feeding high fat diets are appropriate.
IV. Carbohydrate loading is not effective for intermediate or endurance exercise but helps to restore glycogen levels for sprint-type exercise (Reynolds et al., 1997).
V. An additional, small meal can be given the night before heavy exercise.
VI. Consider feeding a meal several hours before heavy exercise, but realize it may predispose to fatigue and bloat.
VII. Give treats during rest periods or breaks.
VIII. Maintain hydration.

PREGNANT DOGS

Animal Factors

I. Before breeding, the dam should be in good physical condition and at ideal BW.
II. For the first 4 to 5 weeks of pregnancy there is no increase in energy or nutritional needs.
III. Fetuses do not grow in size until the last 3 to 4 weeks of gestation.
IV. By the end of gestation, the dam should be eating 60% >MER on average (Meyer et al., 1985).

Dietary Factors

I. Feed a diet suitable for gestation through peak lactation.
  A. Average dietary characteristics are as follows:
    1. Energy: >3.8 kcal/g
    2. Crude protein: >26% DM
    3. Crude fat: >17% DM
    4. Crude fiber: <2% DM
    5. Calcium: 1.0% to 1.5% DM
    6. Calcium-to-phosphorous ratio: 1.1 to 1.5:1.0
  B. Majority of ingredients should be of animal origin.
    1. Plant-based protein diets tend to have lower digestibility, nutrients of less bioavailability, and inadequate zinc levels.
    2. High-carbohydrate diets may not contain enough protein and energy for pregnancy and lactation.
II. Dietary supplementation is not recommended and may be detrimental.
III. Vitamin D and calcium supplementation may result in eclampsia.
IV. Some dogs experience anorexia briefly during week 4 or 5 of pregnancy, with a 2- to 3-day duration being normal; longer durations may indicate fetal loss.

Feeding Factors

I. Dry foods are fine, but higher water intake is needed to promote milk production.
II. During the last trimester of pregnancy, dam may be fed free choice (if dry food) or given multiple small meals because the enlarging uterus decreases space for gastric expansion at feeding (Case et al., 2000).
III. Transition the food to a growth/pregnancy/lactation diet at midpregnancy.
  A. Increase food volume by approximately 15% per week from weeks 5 to 9.
  B. Dam should be consuming about 60% >MER by end of pregnancy, with a gain in BW of 5% to 10% (excluding weight of fetuses).
IV. Free choice feeding may be necessary to maintain proper body condition.
V. During the 12 to 24 hours before whelping, food intake decreases.

PREGNANT CATS

Animal Factors

I. They are similar to dogs but with some exceptions.
II. Cats gain weight throughout gestation.
  A. Kittens grow primarily during the last 3 weeks of gestation.
  B. Early pregnancy weight gain is body fat.
  C. Weight gain is proportional to the number of kittens.

Dietary Factors

I. Pregnancy is accompanied by an increased demand for protein, fat, vitamins, minerals, and caloric density of food.
II. Average dietary characteristics include the following:
  A. Energy: 4.0 to 5.0 kcal/g
  B. Crude protein: 35% to 50% DM
  C. Crude fat: 18% to 35% DM
  D. Crude fiber: <5% DM
  E. Taurine: 1000 ppm (dry diet) or 2500 ppm (canned diet)

Feeding Factors

I. A canned product may be more palatable and calorically dense, and provides moisture for lactation.
II. As pregnancy progresses, feed as free choice or multiple, small meals.
III. At parturition, queen should be consuming 1.25 to 1.5 × MER.
IV. Appetite decreases within 24 to 48 hours of parturition.

LACTATION IN DOGS

Animal Factors

I. The dam quits eating 12 to 24 hours before whelping.
  A. At whelping, dam should weigh >5% to 10% prebreeding weight.
  B. Dam should be consuming 1.6 × MER.
II. Lactation represents the greatest nutrient demand (Hand et al., 2000)
  A. Dam must eat, digest, absorb, and use large amounts of nutrients to produce milk and maintain milk production.

B. Most dams require 2 to 4 × MER.
C. Other nutrient requirements are also increased.

Dietary Factors

I. Protein content is a major determinant of milk production (Kronfeld, 1975).
II. Average diet characteristics include the following:
  A. Energy: >3.8 kcal/g
  B. Crude protein: >26% DM
  C. Crude fat: >17% DM
  D. Crude fiber: <2% DM
  E. Calcium: 1.0% to 1.5% DM
  F. Calcium-to-phosphorous ratio: 1.1 to 1.5:1.0
III. The first two or three ingredients listed should be of animal origin, because they are of higher digestibility and nutrient bioavailability.
IV. Feed canned food or moistened dry foods and have clean, fresh water available at all times.

Feeding Factors

I. Dam needs to eat free choice or have multiple, small meals.
II. At peak lactation, energy intake can be as high as 4 × MER.
III. If moistened dry or canned growth diet is available, puppies can be weaned to this diet.
  A. Weaning occurs around 5 to 6 weeks after birth.
  B. On first day of weaning, remove food, but not water, from dam and do not allow puppies access to the dam, to reduce milk production.
    1. The following day, give 25% to 35% of daily food volume to dam.
    2. On the third day, give 50% to 65% of daily food volume to dam.
  C. Feed full ration to the dam thereafter.
    1. If body condition is good, switch to adult maintenance diet gradually over the next few days.
    2. If body condition is reduced, continue with growth diet and then gradually switch to adult maintenance diet when BW and condition have improved.

LACTATION IN CATS

Animal Factors

I. Peak lactation occurs around 2 weeks after parturition.
II. Nutrient demands at peak lactation are often 2 × MER.

Dietary Factors

I. Growth/gestation/lactation diet is started after breeding.
II. Average dietary characteristics are as follows:
  A. Energy: 4.0 to 5.0 kcal/g
  B. Crude protein: 35% to 50% DM
  C. Crude fat: 18% to 35% DM
  D. Crude fiber: <5% DM
  E. Taurine: 1000 ppm (dry diet) or 2500 ppm (canned diet)
III. This diet is suitable for kittens to consume before and after weaning.

Feeding Factors

I. Maintain body condition during lactation.
II. Free-choice feeding or providing small meals is needed.
III. Kittens begin eating solid food around 21 to 28 days after birth.
IV. Weaning begins at about 6 weeks of age and may take up to 9 weeks to accomplish (NRC, 2006).
V. Weaning is done in a manner similar to dogs.
  A. If body condition is good, switch to adult maintenance diet gradually over the next few days.
  B. If body condition is reduced, continue with growth diet and then gradually switch to adult maintenance diet when BW and condition have improved.

GROWTH IN DOGS

Animal Factors

I. The growth period involves the time from birth to adulthood.
II. Between birth and weaning, nutrition is obtained from dam's milk.
  A. In the first 1 to 2 days of life, puppies must nurse to receive antibody-rich colostrum.
  B. Serum may be given orally if neonates are unable to obtain colostrum from the dam.
III. Neonates are unable to regulate body temperature and must be kept in a warm, draft-free environment.
IV. They have little fat and glycogen stores and must nurse periodically throughout the day.
V. Birth weight doubles within the first 7 to 10 days and increases 6 to 10 times by weaning.
  A. Puppies should gain 2 to 5 g/day/kg of anticipated adult weight.
  B. Energy requirements are approximately 4 × MER at birth and decrease to approximately 2 × MER by weaning.
  C. Weight gain occurs in a stepped fashion, not continuously.
  D. As puppies grow, they will eat available solid food and nurse less often.
  E. Weaning is initiated around 6 weeks of age.
VI. Following weaning, puppies are fed three to four times a day.
  A. Rate of growth depends on the breed, but approximately 50% of adult weight and size is reached by 5 to 6 months of age.
  B. Energy requirements decrease from weaning to adulthood, when requirements are MER.
  C. Other nutrient requirements are higher than in adults in order to promote growth.

Dietary Factors

I. Average diet characteristics include the following:
  A. Energy: >3.8 kcal/g
  B. Crude protein: >26% DM
  C. Crude fat: >17% DM
  D. Crude fiber: <2% DM
  E. Calcium: 1.0% to 1.5% DM
  F. Calcium-to-phosphorous ratio: 1.1 to 1.5:1.0

II. Make clean water available at all times.
III. Additional nutrient supplementation is unnecessary and can be detrimental.

Feeding Factors

I. During weaning, the diet consumed is typically what the dam is eating.
II. Following weaning, a dry food or canned growth diet are fed.
III. Meal feeding is preferred over free-choice feeding.
IV. Monitor body condition frequently and adjust dietary intake as needed.
V. Food can be changed to an adult diet after 50% of adult weight is reached.

GROWTH IN LARGE- AND GIANT-BREED DOGS

Animal Factors

I. Large-breed puppies are at risk for developmental orthopedic diseases (DOD), such as hip dysplasia, osteochondrosis desiccans, joint laxity, ligament laxity, and hyperextended joints.
II. Rate of growth, specific nutrients, food consumption, and feeding methods affect the onset of DOD.

Dietary Factors

I. Excess energy intake results in rapid growth and obesity, which are associated with DOD; therefore, maintain optimal body condition during growth.
II. Excess dietary protein (>27% DM) does not contribute to DOD.
III. Calcium directly influences DOD.
   A. Calcium intake of >3% DM is associated with DOD.
   B. For example, supplementation with 2 level teaspoons of calcium carbonate to a 15-week-old, large-breed puppy eating a growth diet more than doubles the calcium intake.
IV. Vitamin C is necessary for hydroxylation of proline and lysine during biosynthesis of collagen (Geesin and Berg, 2001).
   A. No known dietary vitamin C requirement exists for dogs.
   B. Supplementation to puppies for 147 to 154 days did not affect growth and development (Dzanis, 1995).
V. Vitamin D excess and deficiency affects DOD.
   A. Deficiency results in disturbance of calcium metabolism; however, it is difficult to induce when feeding commercial diets.
   B. Excess may occur with vitamin-mineral supplementation (Richardson and Toll, 1997).
VI. Copper and zinc deficiency also impair normal development.
VII. Average diet characteristics are as follows:
   A. Energy: 3.2 to 3.8 kcal/g
   B. Crude protein: >26% DM
   C. Crude fat: 9% to 12% DM
   D. Crude fiber: <2% DM
   E. Calcium: 0.7% to 1.2% DM
   F. Calcium-to-phosphorous ratio: 1.1:1.0 to 1.5:1.0

Feeding Factors

I. Free-choice feeding increases risk of DOD when compared with meal feeding.
II. Rapid growth rate increases risk of DOD.
III. Feed large-breed growth diet as meals to decrease risk of DOD.
IV. Adult food can be fed after 6 months of age, but it may limit protein, vitamin, and mineral intake, which may be detrimental.

GROWTH IN CATS

Animal Factors

I. Growing cats have higher nutrient requirements than adults.
II. Cats have higher protein and energy requirements than dogs.
III. Adult weight is reached around 6 to 8 months of age.

Diet Factors

I. Growth diet is fed before and after weaning.
II. Average dietary characteristics include the following:
   A. Energy: 4.0 to 5.0 kcal/g
   B. Crude protein: 35% to 50% DM
   C. Crude fat: 18% to 35% DM
   D. Crude fiber: <5% DM
   E. Taurine: 1000 ppm (dry diet) or 2500 ppm (canned diet)

Feeding Factors

I. During weaning, the diet consumed is typically what the dam is eating.
II. After weaning, a dry food or canned growth diet are fed.
III. Meal feeding is preferred over free-choice feeding.
IV. Monitor body condition frequently and adjust dietary intake as needed.
V. Diet can be changed to an adult diet after 50% of adult weight is reached.

CHAPTER 122

Nutrition in Disease

Joseph W. Bartges | Claudia A. Kirk | Susan D. Lauten

ADVERSE REACTIONS TO FOOD

Animal Factors

I. Although providing nutrition to companion animals is relatively easy and safe, situations arise where an adverse reaction to a diet or nutrient, or exposure to a food hazard, occurs.
II. Reactions may occur to components that are present normally but are unbalanced, or they may occur to components that are not present normally.

Dietary Factors

I. Nutrient imbalances may occur with problems in the formulation or manufacture of a diet, or if the owner supplements a complete and balanced diet with an incomplete and unbalanced food or supplement (Tables 122-1 and 122-2).
II. Certain food components are toxic.
    A. Onion poisoning causes a Heinz body hemolytic anemia in cats.
    B. Chocolate toxicity causes vomiting, diarrhea, and seizures from the effects of theobromine.
    C. Raisins and grapes have been associated with acute renal failure in dogs.
III. Certain food additives may cause problems.
    A. Ethoxyquin is an antioxidant that may cause reproductive disorders, dermatological problems, and immune-mediated diseases.
    B. Most pet food manufacturers no longer use ethoxyquin.
    C. Other synthetic or so-called natural antioxidants are usually mixed with tocopherols, ascorbic acid, or both.
IV. Contamination may occur from contaminated foodstuffs or the food may become contaminated after production.
    A. Mycotoxins occur sporadically in dry foods and cause hepatic failure and death.
    B. Pet foods may become contaminated if mold is allowed to grow, especially if the food becomes moist or if the fat becomes rancid.
    C. Bacterial contamination may occur with *Salmonella* spp., *Campylobacter* spp., and *Clostridium* spp.
    D. Ingestion of animal tissues containing residues of toxic substances (e.g., warfarin) may result in disease.
V. An *adverse reaction to food* is defined as a clinically abnormal response attributed to an ingested food substance, and it may be categorized as immunological or non-immunological.
    A. Food hypersensitivity is an immune-mediated reaction to ingested food.
        1. A particular foodstuff activates one or more immunological pathways.

TABLE 122-1

Nutrient Excesses

NUTRIENT CLASS/ELEMENTS	ASSOCIATED DISEASES/CONDITIONS
Energy	
	Obesity Increased risk for other diseases Developmental orthopedic diseases in growing large- and giant-breed dogs
Protein	
	May result in imbalanced or deficient diet
Carbohydrate	
	Lactose intolerance Diarrhea, bloating
Minerals	
Calcium, phosphorous	Developmental orthopedic diseases in growing large- and giant-breed dogs
Magnesium	Struvite-related urolithiasis and urethral plugs
Sodium	Hypertension, congestive heart failure, fluid retention
Vitamins	
Vitamin A	Cervical osteocartilaginous hyperplasia in cats
Vitamin D	Soft tissue calcification
Trace Elements	
Iron	Vomiting, diarrhea, neurological signs
Copper	Chronic active hepatitis
Zinc	Hemolytic anemia
Iodine	Hyperthyroidism

TABLE 122-2

Nutrient Deficiencies

NUTRIENT CLASS/ELEMENTS	ASSOCIATED DISEASES/CONDITIONS
Energy	
	Malnutrition Poor growth and body condition
Protein	
Total protein	Poor hair coat, hypoproteinemia, edema/ascites, vacuolar hepatopathy
Taurine (cats)	Dilated cardiomyopathy, retinal degeneration, poor reproductive performance
Fat	
Linoleic, arachidonic (cats)	Poor hair coat, vitamin deficiencies
Minerals	
Calcium, phosphorous	Nutritional secondary hyperparathyroidism
Magnesium	Calcium oxalate urolithiasis, cardiac dysfunction
Sodium	Poor appetite
Potassium	Polymyopathy
Vitamins	
Vitamin A	Dermatological and ophthalmologic disease
Vitamin D	Rickets
Thiamine	Seizures
Niacin	Pellagra/black tongue
Biotin	Poor hair coat
Vitamin E	Cats: steatitis Dogs: muscle disease, decreased immunocompetence
Trace Elements	
Iron	Anemia
Copper	Anemia, depigmentation of skin
Zinc	Parakeratosis, poor hair coat
Iodine	Goiter, alopecia
Selenium	Muscular weakness

2. After development of this response, subsequent ingestion of the foodstuff causes clinical signs.
3. Factors that lead to hypersensitivity are speculative.
   a. Heat- and acid-stable glycoproteins with molecular weights (MW) of 18,000 to 30,000 Daltons (D) are most frequently implicated.
   b. Most basic food ingredients can potentially induce an allergic response, although proteins are thought to cause most of the reactions.
   c. Causative dietary components include cow's milk, beef, mutton, pork, chicken, rabbit, horse meat, fish, eggs, oatmeal, wheat, corn, soy, rice flour, potatoes, kidney beans, canned foods, cod liver oil, dry food, pet treats, and food additives.
4. Clinical signs include pruritus, skin erythema, otitis externa, pyoderma, and inflammatory bowel disease.

B. Food intolerance is a nonimmunological, abnormal response to a food item.
   1. The reactions may be toxic, pharmacological, metabolic, or idiosyncratic (i.e., the animal is unable to digest or process a dietary component).
   2. Lactose intolerance, gluten intolerance, reactions to dietary vasoactive amines, and reactions to histamine-containing foods or foods that stimulate histamine release are examples.

C. Food hypersensitivity can be treated in several ways.
   1. Elimination diets are the most useful and reliable way to diagnosis dietary sensitivity and involve the feeding of a restricted diet, followed by dietary challenge with a test meal.
      a. The diets are individualized based on previous dietary exposure.
      b. Identify foods that have not been fed before and use them to formulate a nutritionally balanced diet that is hypoallergenic.
      c. Clinical signs may subside in 3 to 5 days, but may it take 4 to 6 weeks.
   2. A restricted antigen diet may be used that contains only one or two potential allergens, preferably ones that the animal has not eaten in the preceding month.
      a. Many homemade diets are incomplete and unbalanced (e.g., cottage cheese and rice, chicken and rice).
      b. Supplementation with vitamins and minerals is encouraged, but avoid use of supplements that contain potentially offending foodstuffs (e.g., beef, pork).
      c. Commercially prepared, hypoallergenic diets are complete and balanced and may be used for convenience.
         (1) Many diets are available that contain novel protein and carbohydrate sources (e.g., duck, potato)
         (2) Because proteins >18,000 D are incriminated as antigens, modification of proteins to compounds with lower MW may be beneficial.
         (3) Protein modification is a process that alters the physical characteristics of protein molecules, presumably reducing the antigenicity and rendering them less able to elicit an immune response.
         (4) To be effective, protein hydrolysates are <18,000 D.

D. Introducing the presumed offending antigen may be done to confirm a dietary allergy.

E. Long-term management of food hypersensitivities may involve the following:
   1. It is preferable to change from a home-prepared elimination diet to a commercially prepared diet of a selected protein to provide a nutritionally balanced and complete diet.
   2. There are many single-protein diets available, including diets that contain duck, venison, lamb, rabbit, and kangaroo.
   3. A homemade diet may be continued, but must be formulated to be complete and balanced.
   4. A protein hydrolysate diet may be fed.
   5. If the animal does well, emphasize that the owner must not give table scraps or treats, or change the diet even if clinical signs do not recur.

VI. Other adverse food problems include the following:
   A. Mechanical injuries: ingestion of bones
   B. Poisonous plants and chemical toxins
   C. Metals and minerals: lead, zinc, salt

Feeding Factors

I. Management of adverse reactions to food involves changing the diet.
II. It may also involve changing feeding patterns to more or less frequent feedings.

NUTRITION AND CANCER

Animal Factors

I. Four stages of metabolic alterations may occur with cancer.
   A. Phase 1 is a preclinical phase with no obvious clinical signs; metabolic changes include hyperlactatemia, hyperinsulinemia, and altered amino acid profiles.
   B. Phase 2 is associated with early clinical signs, such as anorexia, lethargy, and weight loss; metabolic changes are similar to phase 1.
   C. Phase 3 is associated with advanced clinical signs, such as cachexia, anorexia, lethargy, and increased morbidity associated with cancer treatment; metabolic changes are more profound than in phases 1 and 2.
   D. Phase 4 is recovery and remission; metabolic changes usually persist.
II. Cancer causes many alterations in metabolism.
   A. Abnormalities in carbohydrate metabolism include glucose intolerance, insulin resistance, delayed glucose clearance, abnormal insulin secretion, increased glucose turnover, increased gluconeogenesis, hyperlactatemia, and increased Cori cycle activity.
   B. Abnormalities of fat metabolism include excess depletion of body fat relative to protein loss, decreased total body lipid content, increased lipolysis, decreased lipogenesis, hyperlipidemia, increased free fatty acid and glycerol turnover rates, failure of glucose to suppress free fatty acid oxidation, and decreased serum lipoprotein lipase activity.
   C. Abnormalities in protein metabolism include increased whole-body protein turnover, increased liver protein fractional synthetic rates, reduced muscle fractional synthetic rates, decreased incorporation of amino acids into muscle, increased hepatic protein synthesis, muscle breakdown, and decreased plasma branched-chain amino acids.
   D. Depending on the location and distribution of the cancer, malnutrition may occur from interference with eating and digestion.
III. Treatment of cancer also induces problems.
   A. Surgery increases nutritional requirements, especially for energy and protein, and may impair food intake or result in malassimilation.
   B. Chemotherapy may induce anorexia, vomiting, mucositis, infections, and organ injury.
   C. Radiation therapy may cause mucositis or dermatitis.
   D. Complications may increase if multimodality therapy is used.
IV. Immunosuppression occurs with malnutrition, which promotes tumor growth, infections, and impaired wound healing.
V. Cachexia and malnutrition can occur with any type of cancer.
   A. Hormones, cytokines, and neurotransmitters associated with cancer can affect food intake.
   B. Tumor necrosis factor produced by monocytes causes anorexia.

Dietary Factors

I. Animals with lymphoma may not utilize carbohydrates efficiently; therefore, a low carbohydrate diet (<20% dry matter [DM]) may be beneficial.
II. Animals with lymphoma may preferentially utilize fat, so fat content should be 25% to 50%.
III. Greater protein intake may help maintain protein balance; therefore, protein content should be 25% to 40% DM for dogs and 40% to 50% DM for cats.
IV. Other nutrients may be of benefit in animals with cancer.
   A. Fish oils containing omega-3 fatty acids are anti-inflammatory.
   B. Glutamine is an amino acid that is an energy source for enterocytes.
   C. Antioxidants, such as retinoids, vitamin C, and vitamin E, may improve immune function and help in treating cancer.
V. Preventing obesity decreases the risk of cancer in general and of certain types of cancer (e.g., mammary cancer).

Feeding Factors

I. Because many animals have decreased appetite or anorexia, take a good dietary history.
II. Getting an animal to eat may involve changing food type, texture, or feeding patterns, or may involve stimulating appetite.
III. Nutritional support is individualized.
   A. If possible, feed enterally; however, parenteral nutrition may be required.
   B. Goals of nutrition include maintaining body condition and lean muscle mass, and minimizing nutritional support of the actual cancer.

IV. Select a food.
  A. The diet should contain more fat and protein, and fewer carbohydrates.
  B. It should contain omega-3 fatty acids (>5% DM) and have an omega-6:omega-3 ratio of <3:1.
V. Most importantly, the animal should eat the diet.
VI. The goal is to maintain body condition and weight and to provide a good quality of life.

NUTRITION AND CARDIOVASCULAR DISEASE

Animal Factors

I. Obesity results in blood volume expansion with elevated cardiac output, increased plasma and extracellular fluid volume, increased neurohumoral activation, reduced urinary sodium and water excretion, tachycardia, abnormal systolic and diastolic ventricular function, exercise intolerance, and systemic arterial hypertension.
II. Cachexia associated with heart disease or failure results in negative nitrogen and energy balance.
III. Cats have a dietary requirement for taurine because they have limited ability to synthesize it, and because it is used exclusively for bile acid conjugation.
IV. L-Carnitine is a conditionally essential nutrient involved with transport of long chain fatty acids from the cytosol into the mitochondria where they undergo beta-oxidation for energy production.
V. Hypokalemia and hypomagnesemia are associated with arrhythmias, decreased myocardial contractility, and muscle weakness.

Dietary Factors

I. Average dietary recommendations are as follows:
  A. Restrict calories if obese; however, increase caloric intake if cachectic.
  B. Protein content must be adequate or greater than normal.
  C. Omega-3 fatty acids may be beneficial in an omega-6: omega-3 ratio of 5:1.
  D. Sodium restriction (<0.05% to 0.3% DM) is indicated with congestive heart failure.
  E. Adequate potassium, phosphorous, magnesium are important.
  F. Taurine can be supplemented to cats at 250 to 500 mg PO SID to BID and to dogs at 500 to 1000 mg PO TID.
  G. For L-carnitine deficiency, supplement dogs with 50 to 100 mg/kg PO TID.
II. Commercial diets formulated for dogs and cats with cardiovascular disease are available.

Feeding Factors

I. Some animals require feeding of frequent small meals.
II. Additional nutrients that may be beneficial include the following:
  A. Coenzyme Q10 is required for energy reactions and is an antioxidant.
  B. Antioxidants may decrease oxidative stress in dogs with dilated cardiomyopathy.

NUTRITION AND COGNITIVE DYSFUNCTION

Animal Factors

I. Dogs can develop cognitive dysfunction from certain brain pathologies.
II. Oxidative stress with aging results in brain pathology.
III. Animals with cognitive dysfunction have increased sleep time; decreased activity; loss of learned behaviors (e.g., house training); and decreased recognition of familiar people, things, and places.

Dietary Factors

I. Provide balanced antioxidants.
  A. Vitamin E: membrane radical scavenger, decreases lipid peroxidation
  B. Vitamin C: protects against radical-mediated effects
  C. Flavonoids
  D. Minerals: cofactors for antioxidant enzymes
  E. Coenzyme Q: regenerates vitamin E
  F. Enzymes: catalase, superoxide dismutase, glutathione peroxidase
  G. Nonenzymatic scavengers: uric acid, glutathione, coenzyme Q, transport protein (transferrin, ferritin, lactoferrin, ceruloplasmin)
II. Diets designed for dogs with cognitive dysfunction are available and contain increased levels of vitamins C and E, lipoic acid (an antioxidant), L-carnitine, selenium, and omega-3 fatty acids.

NUTRITION AND CRITICAL CARE

Animal Factors

I. Critical illnesses may be caused by factors such as trauma and acute or chronic disease.
II. Nutritional support is indicated in animals that have not eaten for 3 to 5 days, have poor body condition, or have increased needs for nutrition.

Dietary Factors

I. Provide a complete and balanced diet, if possible.
II. Provide specific nutrients for specific diseases.

Feeding Factors

I. Provide nutrition enterally when possible, because it is the most physiological, easiest, and safest route.
II. Nutrition may be provided orally using one of several techniques.
  A. Try a different flavor or texture of diet.
  B. Add water and warm to near body temperature (especially cats).
  C. Consider forced oral feeding.
  D. Syringe feeding may be tried.
    1. Use food gruel and inject it into oral cavity.

2. Risk of aspiration pneumonia is high and it is difficult to meet requirements with this method.

E. Orogastric feeding tubes are usually used for neonates.

III. Appetite may be stimulated pharmacologically.

A. Benzodiazepines are used cautiously in animals with liver disease and may cause sedation.
1. Diazepam is given at 0.05 to 0.15 mg/kg IV, IM, PO as needed, or at 1 mg PO SID.
2. Oxazepam works better in dogs than cats, and the dosages are 0.2 to 1 mg/kg PO SID to BID in dogs and 2 mg PO SID to BID in cats.
3. Alprazolam is used for behavioral disorders but may stimulate appetite.
   a. Dogs: 0.01 to 0.1 mg/kg PO as needed; maximum 4 mg/day
   b. Cats: 0.05 to 0.2 mg/kg PO SID to BID
4. Flurazepam dosage is 0.2 to 0.4 mg/kg PO every 4 to 7 days in both dogs and cats.

B. Anabolic steroids are not as effective as benzodiazepines and may cause hepatopathy.
1. These testosterone derivatives are given IM and have a delay between initiation of treatment and effect.
2. Nandrolone decanoate dose in dogs is 5 mg/kg IM every 7 days, with a maximum of 200 mg per dose.
3. Stanozolol dose in dogs is 1 to 4 mg PO BID or 25 to 50 mg IM every 7 days, and in cats the dose is 1 to 2 mg PO BID or 25 mg IM every 7 days.

C. Glucocorticoids are catabolic and mobilize muscle (resulting in atrophy), redistribute adipose tissue, and induce insulin resistance.
1. Prednisone 0.2 to 0.5 mg/kg PO SID to QOD
2. Triamcinolone
   a. Initial dosage is 0.11 mg/kg PO SID and may be increased to 0.22 mg/kg PO SID if initial response is unsatisfactory.
   b. Quickly taper to 0.028 to 0.055 mg/kg PO SID.

D. Megestrol acetate has been associated with insulin-resistant diabetes mellitus.
1. It is rarely used for appetite stimulation.
2. Dose in dogs is 0.5 to 1.0 mg/kg PO SID.
3. Dose in cats is 0.25 to 0.5 mg/kg PO SID for 3 to 5 days, then every 48 to 72 hours.

E. Cyproheptadine is a serotonin antagonist that works in cats, but not in dogs.
1. It may cause sedation and liver disease.
2. Dosage is 1 to 4 mg PO SID to BID.

F. B-vitamin deficiency is associated with anorexia and is often supplemented at a dosage of 1 to 2 mL/L of IV fluids; however, no proof of its efficacy exists.

G. Interferon α-2b is used in cats at 30 units PO SID.

IV. Several choices of feeding tubes are available.

A. Nasogastric feeding tubes are inserted through the nasal cavity into the esophagus and stomach.
1. They are placed using topical anesthesia.
2. A 3.5 to 5 French tube is used in small cats and dogs and a 5 to 8 French tube is used in average-size cats and larger dogs.
3. Liquid diets or very watery gruels are fed.
4. Do not use if the animal is comatose, lacks a gag reflex, or has esophageal motility problems because of the increased risk of aspiration pneumonia.
5. Complications include rhinitis, dacryocystitis, esophageal reflux, vomiting, aspiration, pneumonia, inadvertent tube removal, and tube obstruction.

B. Esophagostomy feeding tubes are inserted directly into the cervical esophagus.
1. Use size 12 French tubes or larger.
2. They do not interfere with voluntary consumption of food.
3. Gruels may be used because of the size of the tube used.
4. Insert surgically or by blind percutaneous techniques, with the animal under heavy sedation or anesthesia.
5. Esophagitis usually does not occur unless the distal tip passes through the lower esophageal sphincter.

C. Gastrostomy feeding tubes are inserted directly into the stomach and exit through the lateral abdominal wall.
1. They may be placed surgically through a small laparotomy incision; at the time of abdominal surgery; endoscopically or via nonendoscopic techniques.
2. Gastrostomy tubes can be used in animals with esophageal or oral disease, are usually large-bore tubes (16 to 24 French) through which gruels of canned foods can be administered, are usually well tolerated, and can be left in place for months to years.
3. Disadvantages and complications include vomiting, aspiration pneumonia (often associated with rapid administration of cold foods), peritonitis from dislodgement of the tube, and difficulty in maintaining the tube and associated bandages.

D. Low-profile gastrostomy tubes can be left in place for years and have the advantage of not requiring bandage material; however, they are expensive and must be inserted surgically or percutaneously, after another gastrostomy tube has been in place for at least a month.

E. Enterostomy feeding tubes are inserted surgically into the small intestine.
1. A 5 French tube is inserted into the small intestine for $\geq$ 20 cm.
2. Because they by-pass the stomach, they can be used in animals that are vomiting, have had gastric surgery, or have pancreatitis.
3. They require use of a liquid diet.

V. Parenteral nutrition may be used for short-term nutritional support, if enteral nutrition cannot be used or to supplement enteral food intake.

A. Total parenteral nutrition (TPN) provides protein (amino acids), carbohydrate (dextrose), fat (lipids), vitamins, minerals, and electrolytes to meet daily nutritional requirements.
1. Nonprotein calories are divided between carbohydrate and fat.

2. Solutions are hypertonic and must be administered through a central venous catheter.
3. Formulations depend on the animal's underlying disease.

B. Partial parenteral nutrition is administered through a peripheral venous catheter.
1. A TPN formulation may be diluted until it is isotonic or only certain components may be administered.
2. The solution must be isotonic.
3. It meets only part of the daily nutritional requirements.

NUTRITION AND DERMATOLOGICAL CONDITIONS

Animal Factors

I. Nutritional factors affect the skin and coat.
II. Clinical signs associated with nutritional abnormalities include a sparse, dry, dull, and brittle hair coat that epilates easily, slow hair growth, abnormal scale accumulation, alopecia, erythema, crusting, decubital ulcers, and slow wound healing.

Dietary Factors

I. Inadequate energy intake is associated with keratinization abnormalities, depigmentation, changes in epidermal and sebaceous glands, and increased susceptibility to trauma.
II. Protein deficiency is associated with similar clinical signs.
III. Essential omega-6 fatty acids include linoleic acid (>1% DM dogs, >0.5% DM cats) and arachidonic acid for cats (>0.02% DM).
A. Omega-3 fatty acids can supply part of the omega-6 fatty acid component.
B. Clinical signs of essential fatty acid deficiency include scaling, matting of hair, loss of skin elasticity, dry and dull haircoat, erythema, epidermal peeling, otitis externa, and slow hair growth.
IV. Certain mineral deficiencies may affect the skin (see Table 122-2).
A. Copper deficiency is associated with loss of normal hair coloration, decreased density or lack of hair, and rough or dull haircoat.
B. Many dermatological conditions may occur with zinc deficiency and respond to zinc supplementation.
1. Dietary phytate binds zinc, resulting in clinical signs of deficiency.
2. Clinical signs of zinc deficiency include erythema, alopecia, and hyperkeratosis.
V. Certain vitamins may affect the skin.
A. Vitamin A deficiency is associated with skin lesions and focal sloughing of skin.
B. Vitamin E deficiency occurs in cats in association with steatitis.
1. Clinical signs include erythema and keratinization defects.
2. Vitamin E–responsive dermatoses include discoid lupus erythematosus, systemic lupus erythematosus, pemphigus erythematosus, sterile panniculitis, acanthosis nigricans, dermatomyositis, and ear margin vasculitis.
VI. Dermatological conditions also arise from food allergies (see Adverse Food Reactions).

Feeding Factors

I. Evaluate the quality and amount of diet fed.
II. Consider a dietary change (see Adverse Food Reactions).
III. Feed a better quality diet if a nutritional deficiency is suspected.
IV. Supplement specific nutrients for dietary deficiencies.
A. Dogs with seborrhea may respond to essential fatty acid supplementation even if they are consuming an adequate diet.
B. Omega-3 fatty acid supplementation may decrease inflammation.
C. Give zinc supplementation for zinc-responsive dermatoses.
1. Zinc sulfate 10 to 15 mg/kg/day PO
2. Zinc methionine 2 mg/kg/day PO
3. Not given with food
D. Supplement vitamin A for vitamin A–responsive dermatoses.
1. Tretinoin topically SID to BID
2. Isotretinoin 1 to 3 mg/kg/day PO
3. Etretinate 0.75 to 1 mg/kg/day PO
E. Vitamin E is given to dogs at 200 to 800 IU PO BID.

NUTRITION AND DIABETES MELLITUS

Animal Factors

I. Metabolic pathways (protein, lipid, carbohydrate, energy) are disrupted with diabetes mellitus.
II. Animals with insulin-dependent diabetes mellitus (IDDM) have a ravenous appetite, lose weight, are polyuric and polydipsic (PU/PD), and develop ketoacidosis.
III. Animals with non–insulin-dependent diabetes mellitus (NIDDM) have insulin resistance, are obese, and do not commonly develop ketoacidosis.

Dietary Factors

I. Dehydration may occur from PU/PD and from vomiting with ketoacidosis.
II. Obesity and hyperlipidemia may induce insulin resistance.
III. Protein catabolism results in loss of muscle mass.
IV. In cats, avoid fructose and simple sugars, which are found in semimoist diets.
V. Moderate to high intake of fiber decreases obesity and increases insulin responsiveness.
VI. Omega-3 fatty acids may be beneficial in dogs and cats.
VII. Hypokalemia may occur from PU/PD, decreased food intake, and vomiting with ketoacidosis.
VIII. Hypophosphatemia may occur when treating ketoacidosis.

IX. Chromium, manganese, iron, and zinc may be important in the management of diabetes mellitus; however, their role is unclear.

Feeding Factors

I. Nutritional modification complements the treatment of IDDM.
   A. The goal is to achieve optimal body condition and weight.
   B. Different diets have been recommended.
      1. High-fiber diets may help decrease obesity but are less calorically dense.
      2. Moderate-fiber diets may be as effective as high-fiber diets in dogs.
      3. High-fat, low-carbohydrate diets are beneficial in some cats.
   C. Match dietary intake with insulin administration.
      1. Most animals require insulin BID.
      2. Feed two to four meals a day, if possible.
II. Weight reduction is important with NIDDM.
   A. Nutrient requirements are similar to IDDM.
   B. Reduce weight carefully in obese cats because of the risk of hepatic lipidosis.
III. Diabetic ketoacidosis requires intensive hospital care.
   A. Parenteral nutrition may be required.
   B. Regular feedings are usually begun once vomiting stops, and then intensive insulin therapy is switched to maintenance insulin.

NUTRITION AND GASTROINTESTINAL DISEASES

See Section 5 and Table 122-3.

NUTRITION AND HEPATIC DISEASE

Animal Factors

I. Liver failure is associated with disruption of several metabolic processes.
II. Hepatoencephalopathy is a neurological manifestation of liver failure.

Dietary Factors

I. Maintain adequate caloric intake to reverse fat mobilization.
II. Restrict dietary protein if hepatoencephalopathy is present.
III. Decrease copper intake for copper-associated hepatopathy.
   A. Chelating agents may be required.
   B. Zinc decreases hepatic copper levels.
IV. Omega-3 fatty acids may be helpful for inflammatory hepatic disease.
V. Taurine may be administered to induce choleresis.

Feeding Factors

I. Consider changing the diet or supplementing the current diet.
II. Feed small meals frequently or use a feeding tube.

NUTRITION AND MUSCULOSKELETAL DISEASES

Developmental Orthopedic Diseases

See Chapter 121.

Osteoarthritis

Animal Factors

I. Degenerative joint disease (DJD) or osteoarthritis has multiple etiologies and is characterized by pathologic changes of synovial or diarthrodial joints that are accompanied by pain and disability.
II. Although an association exists between obesity and DJD, cause and effect are unproven.
   A. Obesity may cause excessive forces on joints and articular cartilage, which result in inactivity and further weight gain.
   B. Abnormal forces are placed on joints.
   C. A vicious cycle ensues.

Dietary Factors

I. Manage obesity if present.
II. Consider supplementing specific nutrients.
   A. Omega-3 fatty acids alter inflammation associated with DJD.
      1. Arachidonic acid is metabolized to prostaglandins, leukotrienes, and thromboxanes, which are pro-inflammatory, vasoactive substances.
      2. Substituting an omega-3 fatty acid for arachidonic acid results in production of cytokines that have less proinflammatory and vasoactive effects.
      3. Omega-3 fatty acids derived from fish oil have been shown to be of benefit for DJD.
   B. Antioxidants scavenge free radicals that are increased with DJD, and may also be beneficial.
   C. Cartilage-modulating agents, such as chondroitin sulfate and glucosamine, may slow progression or alter processes involved with DJD.
      1. They stimulate cartilage matrix synthesis and hyaluronate by synovial membranes, and inhibit catabolic enzymes.
      2. Some commercial diets contain chondro-modulating agents.

Feeding Factors

I. Manage obesity, if present.
II. Consider changing from ad libitum to meal feeding.

NUTRITION AND OBESITY

Animal Factors

I. Obesity is defined as body weight ≥15% over ideal weight that is associated with fat deposition.
II. It is the most common nutritional disease, with 25% to 50% of dogs and cats being obese.

TABLE 122-3

Dietary Recommendations for Gastrointestinal Diseases

DISEASE	DIETARY RECOMMENDATIONS
Dental	
	Feed a dry diet with fiber-like texture to promote mechanical cleaning. Consider a diet with microcleansing crystals.
Pharyngeal, Esophageal	
	Feed a diet of high calorie, fat, and protein content. Feed small volumes of food frequently in an upright position.
Gastric, Small Intestinal	
Gastritis, gastric motility problems	Use a low fat diet. Feed small volumes of food frequently.
Gastric dilatation-volvulus	Feed an adult dry food. Feed several meals a day. Avoid rapid consumption of food and large amounts of water.
Acute gastroenteritis	Withhold food for 1-2 days. Feed a highly digestible diet with moderate fat content.
Inflammatory bowel disease	Feed a novel protein diet or protein hydrolysate diet.
Protein-losing enteropathy	Feed a high-protein, low-fat, calorically dense diet. Consider feeding small meals frequently.
Small intestinal bacterial overgrowth, exocrine pancreatic insufficiency	Feed a highly digestible, moderate-fat-content diet. Dietary fructooligosaccharides may be beneficial. Incubate food with pancreatic digestive enzymes for pancreatic exocrine insufficiency.
Large Intestinal	
Inflammatory colitis	Feed a hypoallergenic diet or a high-fiber diet.
Constipation, megacolon	Some animals respond to a high-fiber diet. A low-fiber diet may be beneficial for megacolon.
Flatulence	Feed a highly digestible diet containing alpha-galactosidase. Do not feed diets containing fermentable fiber. Do not feed sulfur-containing vegetables.
Pancreatitis	
Acute	After vomiting subsides, begin small amounts of fluids. Then start small meals. Feed a highly digestible diet containing moderate fat, and moderate protein diet during recovery.
Chronic, hyperlipidemia	Feed a low-fat, high-fiber diet.

III. Associated health risks include musculoskeletal and cardiovascular disease; hypertension; diabetes mellitus; hyperlipidemia; hepatic lipidosis in cats; higher incidence of transitional cell carcinoma and mammary cancer in dogs; possible anesthetic and surgical complications; decreased heat tolerance and stamina; and reproductive problems.

IV. Assessment of body composition is important.
   A. Compare current weight to ideal body weight in early adulthood.
   B. Body condition scoring (BCS) incorporates body weight and overall condition (see Chapter 1).
      1. It may be based on a 9- or 5-point scale.
      2. The middle of the scale (5/9 or 3/5) is ideal.
         a. Lower numbers: underconditioned
         b. Higher numbers: overconditioned
      3. Optimal body condition (5/9 or 3/5) is equivalent to 15% to 20% body fat.
         a. BCS of 3/9 or 2/5 = 7% to 15% body fat
         b. BCS of 1/9 or 1/5 = 1% to 6% body fat
         c. BCS of 7/9 or 4/5 = 20% to 30% body fat
         d. BCS of 9/9 or 5/5 > 30% body fat and possibly >50% body fat

V. Obesity occurs when energy intake exceeds energy expenditure and other risk factors are present.
   A. Certain breeds (e.g., Labrador retriever, Cairn terrier, American cocker spaniel, dachshund, basset hound, beagle) have increased incidence.

B. Females have higher incidence.
C. Gonadectomy increases risk of obesity in dogs and cats because metabolic rates are 20% to 25% below those of reproductively-intact animals.
D. Obesity occurs commonly in middle-aged animals because of decreased activity.
E. Feeding calorically dense, highly palatable foods increases risk of obesity.
F. Free choice feeding increases risk of obesity.
G. Obese pets are more likely to be owned by middle-aged or older humans who are also obese.
H. Hypothyroidism and hyperadrenocorticism are associated with obesity.

Dietary Factors

I. Body weight and condition are determined by the nutrient composition of the diet, amount of diet eaten, and activity level.
II. Obesity develops when daily intake of energy exceeds daily energy expenditure over a period.
  A. Obesity occurs in a stair-step fashion.
  B. Often animals require fewer calories than estimated to maintain the obese state.
III. Take a good dietary history to determine how much food the animal is eating.
  A. From the amount of food eaten and from the package information, estimate the caloric content of the diet.
  B. Also include calories from treats and table scraps.
IV. Change the diet and feeding method to induce weight loss.
  A. Feeding less of the same food is usually unsuccessful.
    1. Calorically dense foods contain more fat than weight-reduction diets.
    2. Digestibility of food is inversely proportional to total amount eaten.
    3. When less of a calorically dense food is fed, the proportion digested increases.
  B. Low-carbohydrate, high-fat diets are recommended in some cats because peripheral fat is mobilized.
  C. Less calorically dense diets are preferred.
    1. Diets formulated for weight reduction contain <3.4 kcal/g (DM) for dogs and <3.6 kcal/g (DM) for cats.
    2. They contain reduced fat and increased fiber, as well as air or moisture that induces a feeling of satiety.

Feeding Factors

I. Weight loss is better achieved with meal feeding than free-choice feeding.
II. Limit access to other food, table scraps, and treats.
III. Weight-reduction programs involve a multistep approach that involves good owner commitment, a feeding plan, an exercise plan, and repeated communication and montoring.
  A. Owners must recognize that their pet is obese and understand the health risks.
    1. Use BCS charts or posters as a visual aid.
    2. Use other tests (e.g., radiographs, hyperlipidemic serum) to demonstrate associated abnormalities.
    3. Educate owners as to the costs of cruciate repair or management of diabetes mellitus.
  B. Institute a feeding plan.
    1. Detailed history of food and caloric intake is essential.
    2. Set the amount of calories to be fed.
      a. Use optimal body weight.
        (1) Estimate maintenance energy requirement (MER) at optimal body weight.
        (2) Feed 50% to 75% of this MER.
        (3) Compare the estimated MER with current caloric intake, because many animals require less than the estimated MER and caloric intake may need further restriction.
      b. Determine how much to feed to induce a 1% to 4% loss of body weight per week.
    3. Select the diet and feed as meals.
    4. Eliminate or account for treats, snacks, and table scraps.
    5. In multianimal households, feed the obese animal away from other animals or have the animal work for its meal.
    6. Increase exercise.
  C. Communication is extremely important.
    1. Obesity is a disease and requires periodic reassessment.
    2. Weigh the animal every other week.
    3. The goal is for 1% to 2% loss of body weight per week on average.
    4. Use positive reinforcement.
    5. Reward animals and owners as milestones are reached.
    6. Graph weight reduction as a visual reinforcement.
    7. Take photographs before and after initiating the weight loss program.
IV. Prevention of obesity is critical.
  A. Prevent obesity from occurring in growing animals.
  B. When adult animals successfully finish a weight reduction program, make a weight maintenance program available.
    1. It may include feeding a maintenance diet that is less calorically dense and higher in fiber.
    2. Certain diets labeled as *light* can be used, but are not as effective.
  C. Treats, snacks, and table scraps should be <5% of total caloric intake.

NUTRITION AND UROLOGICAL DISEASES

Chronic Renal Failure

Animal Factors

I. Appetite may be decreased.
II. Evidence of chronic disease includes decreased body weight, loss of muscle mass, poor haircoat, and pale mucous membranes.
III. Signs of uremia include oral ulcers, dehydration, hematochezia, and melena.

Dietary Factors

I. Water requirements are increased; therefore, feed a canned food, add water to dry food, or supplement with PO or SC fluids.
II. Increase caloric density of the diet to compensate for anorexia.
III. Decrease protein fed to 1.25 to 1.75 g/kg body weight/day or 15% to 20% DM for dogs and to 3.8 to 4.4 g/kg/day or 28% to 32% DM for cats.
IV. Hypokalemia may occur, especially in cats; therefore, feed a diet replete in potassium (0.3% to 0.5% DM for dogs and 0.8% to 1.2% DM for cats) or provide supplementation.
V. Decrease sodium content if the animal is hypertensive (<0.25% DM for dogs and <0.35% DM for cats).
VI. Feed an alkalinizing diet to offset metabolic acidosis or supplement with an alkalinizing agent (e.g., potassium citrate).
VII. Decrease phosphorous to 0.15% to 0.3% DM for dogs and 0.4% to 0.6% DM for cats.
VIII. Omega-3 fatty acids may be beneficial in dogs when fed at an omega-6:omega-3 ratio of 5:1.

Feeding Factors

I. Anorexia is often present from uremic gastroenteritis; therefore administer histamine-2 receptor antagonists or antacids.
II. Feed small meals frequently.
III. Feeding tubes may be required.

Urolithiasis

Animal Factors

I. Uroliths may be composed of several different types of minerals (see Section 7).
   A. In pediatric dogs and cats, infection-induced struvite and urate uroliths occur most commonly.
   B. In young adults, infection-induced struvite (dogs), sterile struvite (cats), urate, and cystine are the most common types.
   C. In geriatric adults, infection-induced struvite and calcium oxalate occur most commonly.
II. Urolith formation is associated with varying underlying causes.
   A. Infection-induced struvite uroliths are associated with systemic or local diseases that result in a bacterial urinary tract infection with urease-producing microbe.
   B. Sterile struvite uroliths are associated with the feeding of meals and dry foods, and alkaluria.
   C. Calcium oxalate uroliths are associated with hypercalcemia (idiopathic hypercalcemia in cats) or hypercalciuria (e.g., hyperadrenocorticism).
   D. Urate uroliths are associated with liver disease or an underlying defect in uric acid metabolism.
   E. Cystine uroliths are associated with an inborn error of cystine reabsorption in the renal proximal tubule.

Dietary Factors

I. Struvite, urate, and cystine uroliths can be dissolved medically.
   A. For dissolution of struvite uroliths, feed a low-magnesium, low-phosphorous, low-protein, acidifying, and diuretic diet, and administer antibiotics if the uroliths are associated with infection.
   B. For dissolution of urate uroliths, feed a low-protein, alkalinizing, and diuretic diet, and administer allopurinol.
   C. For dissolution of cystine uroliths, feed a low-protein, alkalinizing, and diuretic diet, and administer 2-mercaptopropionyl glycine.
II. Prevention of uroliths may involve dietary changes.
   A. For infection-induced struvite uroliths, no dietary change is required.
   B. For sterile struvite uroliths, feed a diet that is low in protein, magnesium, and phosphorous, and that induces aciduria.
   C. Dietary management of calcium oxalate uroliths is dependent on whether the animal is normocalcemic or hypercalcemic.
      1. In animals that are normocalcemic, feed an oxalate-preventative diet that is low in calcium, replete in magnesium, and induces a neutral to alkaline urine pH.
      2. In cats with idiopathic hypercalcemia and in dogs that are intolerant of higher fat intake, feed a higher fiber diet and supplement with potassium citrate.
   D. For urate uroliths, feed a low-protein, alkalinizing, and diuretic diet, with or without administration of allopurinol.
   E. For cystine uroliths, feed a low-protein, alkalinizing, and diuretic diet, with or without administration of 2-mercaptopropionyl glycine.

Feeding Factors

I. Feeding a canned diet may decrease risk of recurrence of sterile struvite, calcium oxalate, urate, and cystine uroliths by decreasing concentrations of calculogenic compounds in the urine.
II. Monitor response to diet using urine specific gravity, urine pH, and absence of crystalluria.

Feline Idiopathic Cystitis

Animal Factors

I. Idiopathic cystitis usually occurs in young adult cats (see Chapter 50).
II. Males may obstruct from matrix-crystalline urethral plugs that are often composed of struvite.

Dietary Factors

I. Dry diets may result in concentrated urine and increased concentration of crystallogenic compounds.
II. Canned diets increase water intake and urine volume, and decrease urine specific gravity, which may be beneficial.

Feeding Factors

I. Free-choice feeding is associated with persistent aciduria.
II. Feeding a canned diet increases volume and frequency of urination.

CHAPTER 123

Introduction

Petra A. Volmer

DECONTAMINATION

Definition

I. Decontamination is the removal or neutralization of poisonous or otherwise harmful substances in the body and enhancement of their elimination.
II. There is no one correct approach to decontamination; the process must be adapted to address the needs of the individual animal.

Gastrointestinal Decontamination

Emesis

I. Emesis is one of the most rapid, safe, and easiest methods for removing substances from the gut.
II. Effectiveness of emesis is dependent on the physical properties of the toxin ingested, time from ingestion to emesis, the volume of gastric contents, and the emetic agent used.
III. Recovery of gastric contents varies widely (from 9% to 75%) (Peterson, 2006).
IV. Contraindications to emesis include the following:
    A. Clinical signs of central nervous system (CNS) stimulation or depression
        1. Induction of emesis in the stimulated animal can induce a seizure and cause aspiration.
        2. This is also true for rapidly acting agents that may produce CNS stimulation before the emetic action takes effect.
        3. Animals with CNS depression may have a compromised gag reflex, thereby risking aspiration.
    B. Ingestion of a volatile hydrocarbon
        1. Volatile hydrocarbons readily evaporate at ambient temperatures and pressures.
        2. Volatile hydrocarbons enter the pulmonary tree and can cause fairly rapid changes, such as inflammation, edema, and hemorrhage (chemical pneumonitis).
    C. Ingestion of a corrosive or caustic substance
        1. Corrosives (acids) or caustics (alkalis) can cause coagulative and liquefactive necrosis of mucosa and submucosa.
        2. Cationic detergents are strong surfactants that disrupt cell walls.
        3. Oral and esophageal burns are possible, with subsequent stricture formation.
    D. Species that cannot vomit are rabbits and rodents.
V. Emesis is not recommended or is of questionable benefit under the following circumstances:
    A. If the animal has already vomited
    B. If the animal has a preexisting medical condition that may make vomiting hazardous
    C. If the exposure was via inhalation or intravenously
    D. If the exposure occurred more than 2 hours previously
        1. Exceptions include extended-release medications or some plant materials that digest slowly.
        2. In these cases emesis may be rewarding for up to 4 hours, if no clinical signs are present.
VI. Emetics work best with food in the stomach; if possible, feed a small, moist meal prior to inducing emesis.
    A. Hydrogen peroxide (3%)
        1. Hydrogen peroxide is thought to act by causing gastric irritation, and can be administered by the veterinarian or the owner.
        2. The recommended dose is 1 to 2 mL/kg PO for dogs and cats; the dose can be repeated one time if emesis does not occur within 20 minutes.
        3. Gentle agitation, such as walking, may promote emesis.
    B. Apomorphine hydrochloride
        1. Apomorphine acts directly on the chemoreceptor trigger zone.
        2. Apomorphine is usually used in the dog.

3. Although a safe and effective dose has not been established in the cat, it has been used successfully in this species by some clinicians.
4. Administration is by instillation in conjunctival sac.
   a. Tablet or a portion of the tablet is placed in the inferior conjunctival sac.
   b. Apomorphine can also be dissolved in water and instilled in the eye.
   c. After emesis, the tablet or residue is removed and the conjunctiva is rinsed.
5. Apomorphine can also be injected at 0.03 to 0.04 mg/kg IV, 0.04 to 0.08 mg/kg IM, or 0.08 mg/kg SC (Plumb, 2005).
6. CNS depression is possible and can be reversed with naloxone 0.04 mg/kg IV, IM, or SC in dogs and 0.05 to 0.1 mg/kg IV in cats (Plumb, 2005).

C. Xylazine *(Rompun)*
1. Xylazine is a centrally acting α-2 adrenergic agonist.
2. It has been recommended as an emetic in cats at 0.44 mg/kg IM, but is not a reliable emetic in dogs.
3. Sedation can be reversed with an α-2 adrenergic antagonist (e.g., yohimbine 0.1 mg/kg IV).

D. Syrup of Ipecac
1. It is no longer routinely recommended, because it is not as reliable as other emetics.
2. It causes emesis by gastric irritation; however when absorbed, emesis also occurs from stimulation of the chemoreceptor trigger zone.
3. Overdoses can cause cardiotoxicity.
4. Because of its unpleasant taste, it usually requires administration via a stomach tube.
5. Dose in the dog is 1 to 2.5 mL/kg PO and in cats is 3.3 mL/kg PO, diluted 50:50 with water.

VII. The following methods of emesis are not recommended because they are ineffective, dangerous, and waste valuable time.
A. Sodium chloride (table salt): inconsistent emesis, sodium ion toxicosis possible
B. Liquid dishwashing detergent: emesis inconsistent
C. Placing fingers or other objects in the back of the throat: risk of injury to the human or animal, inconsistent results

VIII. Emetics may not remove all material from the stomach and may propel some ingesta into the duodenum.

IX. Other measures to evacuate the gut or prevent absorption are gastric lavage, enterogastric lavage, and the use of activated charcoal and cathartics.

Gastric Lavage

I. Gastric lavage: evacuation of stomach contents by gastric intubation and irrigation

II. Indications
A. Emetics have failed.
B. Animal is exhibiting clinical signs.
C. Other conditions prevent the safe use of emetics.

III. Contraindications
A. If caustic or corrosive substances have been ingested
B. If volatile hydrocarbons have been ingested
C. Large chunky material in stomach

IV. Procedure
A. Animal may be anesthetized or unconscious, with a cuffed endotracheal tube inflated in the airway.
B. Pass a large bore stomach tube, keeping the head lower than animal's chest.
C. Gently force warm water into the stomach tube using a stomach or bilge pump.
1. Approximately 5 to 10 mL/kg of fluid is used per rinse.
2. Allow water to mix with stomach contents.
D. Using gravity, allow fluid to drain from tube, retrieving the approximate amount that was administered, and repeat until the water comes out clear.
E. Administer activated charcoal prior to removal of tube, then occlude the end of tube and withdraw it.
F. Retrieved fluid is saved for future toxicological testing.
G. The procedure may result in esophageal perforation or accidental tracheal intubation.

Enterogastric Lavage

I. This procedure is an extension of gastric lavage, with additional decontamination of the intestines.

II. Perform gastric lavage as described above, leaving the lavage tube in place.

III. Perform tepid water enema.

IV. Attach enema tube to faucet with an adapter.
A. At low pressure, continuously run water into the colon while applying mild digital pressure around anus (to prevent leakage).
B. Intestines will fill with water.
C. Atropine 0.02 mg/kg IV may be required to relax the smooth muscle of gut.

V. Monitor for intestinal distension using abdominal palpation.

VI. Observe for fluid draining from the gastric tube and continue infusion until this fluid runs clear.

VII. Contraindications are similar to those for gastric lavage.

Activated Charcoal

I. Activated charcoal is a highly porous material capable of trapping a wide range of organic substances.

II. Powdered and liquid activated charcoal products have surface-binding areas of 900 to 1500 m^2/g.

III. Tablet and capsule formulations are unsuitable for the treatment of poisoning, because they have surface-binding areas of only 2 to 4 m^2/g (Rosendale, 2002).

IV. Burnt toast, charcoal briquettes, or wood ashes are inert and are *not* substitutes for activated charcoal.

V. Not all toxic substances bind equally to activated charcoal; alcohols, hydrocarbons, metals, inorganic minerals, and corrosive/caustic agents do not adsorb well.

VI. Contraindications to the use of activated charcoal are as follows:
A. The substance ingested poses a significant danger of aspiration (volatile hydrocarbons).
B. Esophageal or gastrointestinal perforation is suspected.

C. The animal is experiencing severe vomiting.

VII. Administration is as follows:
- A. Powdered activated charcoal is given at 1 to 2 g/kg PO, mixed with 50 to 200 mL of water to make a slurry.
  1. Liquid preparations are also available and may contain sorbitol.
  2. *ToxiBan Suspension* (Lloyd, Inc., Shenandoah, Iowa) has a recommended label dose of 10-20 mL/kg PO.
- B. Charcoal stains clothing and other surfaces, so consider administration in a bathtub or other easily cleanable area.
- C. Administration is repeated every 6 to 12 hours at half the original dose for delayed release substances or for those suspected of undergoing extensive enterohepatic recirculation.
- D. If the animal is exhibiting signs, administer charcoal with a stomach tube under sedation, with a cuffed endotracheal tube in place.
- E. Activated charcoal may also be administered with a syringe or turkey baster to the unanesthetized animal, although this increases the risk of aspiration.
- F. Some animals may ingest the charcoal if it is mixed with a small amount of food.

VIII. Several precautions exist.
- A. Aspiration of activated charcoal can lead to pulmonary complications.
- B. Administration has been associated with electrolyte disturbances (hypernatremia).

Gastrotomy

I. Gastrotomy or physical removal is indicated for some toxins.

II. Examples include polyurethane glues (e.g., *Gorilla glue*) in which other methods of decontamination are inadequate.

Cathartics

I. Cathartics: hasten passage of material through the gastrointestinal tract

II. Contraindications
- A. The animal has diarrhea.
- B. The animal is dehydrated.
- C. Gastrointestinal ileus or obstruction is present.

III. Osmotic cathartics
- A. Magnesium sulfate (Epsom salts) and sodium sulfate (Glauber's salts)
  1. Saline cathartics
  2. Dose: 250 mg/kg PO added to charcoal slurry
  3. Magnesium sulfate
     a. It is used with caution in animals with slowed gastrointestinal transit time or those with renal insufficiency.
     b. Excess magnesium may be absorbed.
- B. Sorbitol
  1. It is a nonabsorbable sugar.
  2. Some activated charcoal slurries contain sorbitol as a cathartic.
  3. Dose is 1 to 2 mL/kg of a 70% solution added to a charcoal solution.

IV. Bulk cathartics
- A. They add bulk to the ingesta.
- B. They are particularly useful for encouraging passage of physical objects.
- C. Psyllium *(Metamucil)* is given at 3 to 10 g in dogs and 3 g in cats, and mixed with food SID to BID.
- D. Canned pumpkin (unspiced) added to food or a high-fiber pet food can also be tried.

Dermal Decontamination and Bathing

I. Stabilize animals before initiating bathing.

II. Liquid dish detergents are recommended over shampoos or hand soaps.

III. Do not use insecticidal shampoos, detergents designed for automatic dishwashers, or citrus-based cleaners.

IV. Repeated bathing is required in some instances, followed by thorough rinsing and drying.

V. Bathing alone may not be sufficient for some sticky or viscous substances.

VI. Hand cleaners such as *Goop* (Critzas Industries, St. Louis, Mo.) may work well to remove some thick, petroleum-based products, followed by thorough bathing with a detergent.

VII. In some cases, clipping or shaving the hair coat may be required to remove the offending substance.

Ocular Decontamination

I. Clinical effects may range from mild irritation to severe damage of the cornea or conjunctiva.

II. Immediate irrigation can be initiated by the owner, followed by more extensive irrigation by the veterinarian.

III. Rinse with copious amounts of appropriate fluid for 20 to 30 minutes.
- A. Tap water, lactated Ringer's solution, or normal saline at body temperature are used for irrigation.
- B. Rinse from the medial aspect of the eye to the lateral aspect, to avoid contamination of the opposite eye.
- C. For severe exposures, sedation may be required.

PRACTICAL CONVERSIONS

I. Perform calculations to determine exposure based on the amount of toxic agent per unit of body weight.

II. Most toxicities are reported in milligrams of toxic substance per kilogram of body weight (mg/kg).

III. Table 123-1 provides useful conversions to use in estimating exposure.

DIAGNOSTIC TOXICOLOGY

I. Arriving at a toxicological diagnosis requires cooperation among the owner, veterinarian, and diagnostic toxicologist.

II. Communicating with the diagnostic laboratory is one of the most important steps that can be taken prior to collecting and submitting samples.

III. The most common reason for an inadequate analytical result is the lack of an appropriate sample or insufficient sample quantity.

TABLE 123-1

Useful Conversions for Calculating Exposures to Toxicants

AMOUNT	APPROXIMATE EQUIVALENT
1 teaspoon (tsp)	5 g dry or 5 mL wet
1 tablespoon (Tbsp)	15 g dry or 15 mL wet
2.2 lb	1 kg dry or 1 L wet
1 lb	454 g
1 g	15.4 grains
1 grain	65 mg
1 oz	28 g dry, 29.6 mL wet
1 cup	237 mL
1 gal	3.785 L
1 qt	0.946 L
1 mg/kg	1 ppm
1 µg/kg	1 part per billion (ppb)
1 part per million (ppm)	0.0001%

IV. Provide a thorough and complete history.
   A. A comprehensive, yet succinct, history helps narrow down and prioritize the possible list of toxic agents.
   B. Include information on the recent circumstances surrounding the illness in question.
      1. Breed, sex, age, weight and relevant medical history and current medications
      2. Total number of animals in environment and number affected
      3. If known, substance ingested, time ingested, signs noted, and response to treatment
      4. Results of any clinical pathologic tests
      5. Environmental factors, such as sources of food and water, and possible access to hazardous sub stances
      6. Relationship of owners with others, such as neighbors
      7. Recent visitors to home who may have misplaced medications
      8. Supervision of animal while outdoors
      9. Vaccination status of animal
      10. Children in home who may have innocently fed the animal inappropriate substances
   V. Be as specific as possible regarding requested analyses; there is no such thing as a "poison screen."
   VI. Submit appropriate specimens.
      A. Considering the toxicokinetics of the agent helps to determine the most appropriate tissue to submit.
      B. Submit a large quantity of the specimen to allow for repeated analyses or searching for other toxicants.
      C. Submit specimens refrigerated or frozen.
      D. Package, store, and label each tissue individually.
   VII. Triple-bag specimens and ship as quickly as possible on ice or dry ice.
   VIII. Avoid shipping on weekends or holidays, as specimens may sit for days in hot conditions.

CHAPTER 124

Rodenticides

Donna Mensching | Petra A. Volmer

ANTICOAGULANT RODENTICIDES

Sources

I. First-generation anticoagulant agents
   A. Hydroxycoumarin agents
      1. They include short-acting compounds (warfarin and dicoumarol) and long-acting compound (coumafuryl and fumarin).
      2. Duration of vitamin K_1 epoxide reductase inhibition is 4 to 6 days (half-life, 14.5 hours in the dog).
      3. Brand names include *D-Con, Mouse Prufe II, Havoc, Jaguar, Talon-G, Final Blox, Enforcer, Contrac,* and *Just One Bite.*
      4. Warfarin-containing products are generally 0.025%.
      5. Toxicosis typically requires repeated ingestion.
   B. Indandione agents
      1. They include long-acting pindone, valone, and chlorphacinone.
      2. Trade names include *Pival Parakake, Eaton's A-C Formula 50, Purina Rat Kill, Contrax P, Enforcer,* and *Tri-Ban.*
      3. Formulations are typically 0.025%, but the previously listed products range from 0.011% to 0.14%.

II. Second-generation anticoagulant agents were formulated as a result of resistance against the first-generation anticoagulant agents.
   A. Formulations
      1. Second-generation anticoagulant agents are usually 0.005%, but exceptions do occur.
      2. Toxicosis can occur with one dose.
      3. Relay toxicosis—clinical effects that occur in a predator that has consumed prey that succumbed to the anticoagulant—is more likely as a result.
   B. Hydroxycoumarin agents
      1. They include brodifacoum and bromadiolone.
      2. Duration of vitamin K_1 epoxide reductase inhibition is 30 days for brodifacoum and 21 days for bromadiolone.
      3. Half-lives are 4 to 6 days in the dog.
   C. Indandione agents
      1. They include diphacinone and difethialone.
      2. Agents are derivatives of indane-1,3-dione.
      3. Duration of vitamin K_1 epoxide reductase inhibition is 1 to 4 weeks.
      4. Brand names include *Assassin, Gold Crest, Diphacine, Contrax-D, Rozol, Ditrac, Kill-Ko, D-Cease, Mouse and Rat Bait,* and *Tomcat*.
      5. Difethialone-containing products are generally 0.0025%.

Action

I. Inhibition of vitamin K_1 epoxide reductase prevents formation of vitamin KH_2 (hydroquinone), a necessary cofactor of the enzyme vitamin K_1 carboxylase, which activates clotting factors II, VII, IX, and X via carboxylation.
II. Upon consumption of the liver's store of vitamin K_1, clotting factors can no longer be carboxylated and remain inactive in the prozymogen state.
III. Spontaneous and fatal hemorrhage can then occur.

Clinical Signs

I. Signs of toxicosis depend on the location of the hemorrhage and are often nonspecific.
II. Signs may include lethargy, dyspnea, acute collapse, pale mucous membranes, lameness, paralysis, petechiae, ecchymoses, hematomas, hematuria, hemoptysis, epistaxis, hematochezia, weakness, or sudden death.

Diagnosis

I. Evidence of hemorrhage, significant prolongation of the prothrombin time (PT), and historical evidence of exposure within the preceding 3 to 7 days are diagnostic of anticoagulant rodenticide toxicosis.
II. In the postmortem specimen, evidence of massive internal hemorrhage is consistent with anticoagulant rodenticide ingestion, and the diagnosis can be confirmed by detecting anticoagulant rodenticide residues in the liver.

Differential Diagnosis

I. Any disease that results in a coagulopathy, bleeding diathesis (see Chapters 67 and 68), or severe anemia is considered.
II. Examples include von Willebrand disease, immune-mediated thrombocytopenia, immune-mediated hemolytic anemia, disseminated intravascular coagulation (DIC), hemangiosarcoma, inherited platelet disorders, trauma, rickettsial diseases, and severe liver disease.

Treatment

I. Asymptomatic animal
   A. Decontamination with emesis and one dose of activated charcoal (6.6 to 11 mL/kg PO with sorbitol) is indicated if the toxicant was ingested within 2 to 3 hours of presentation.
   B. Initiate additional treatment if the calculated dosage is >0.02 mg/kg and decontamination does not decrease the dosage below this level, based on one tenth of the lowest reported LD_{50} dose ranges in dogs and cats (ASPCA, 2006).
   C. Vitamin K_1 is given at 1 to 1.5 mg/kg PO TID (or daily equivalent) for the duration of effect of the ingested anticoagulant.
      1. Two weeks of therapy are recommended for first-generation anticoagulant ingestions (ASPCA, 2006), 3 weeks for bromadiolone, and 1 month for other second-generation anticoagulants.
      2. If in doubt as to the identity of the anticoagulant, then treat for 30 days.
      3. Vitamin K_1 is well absorbed orally, particularly if given with a fatty food, so giving injectable vitamin K_1 to an asymptomatic animal is not necessary.
      4. Subcutaneous and IV administration has been associated with anaphylactic reactions; the IV route is not recommended.
      5. When the weight of the animal is so small that available capsule sizes are too large, the injectable product can be given orally.
II. Symptomatic animal
   A. Vitamin K_1 administration is given as for the asymptomatic animal.
      1. Subcutaneous vitamin K_1 is given if the animal is vomiting or otherwise unable to take oral medications.
      2. Once able to take oral medications, oral vitamin K_1 is supplemented for the duration of action of the anticoagulant.
   B. Whole blood transfusion is indicated for active bleeding.
   C. Plasma transfusion may serve as a source of clotting factors if whole blood is not available (see Chapter 71).
   D. Oxygen supplementation is indicated for the dyspneic or severely anemic animal.
   E. Strict rest and gentle handling are instituted until the PT has normalized.

Monitoring of Animal

I. Measurement of PT 48 and 72 hours after ingestion can determine if vitamin K_1 therapy is indicated.
   A. If PT is normal at 48 hours, then repeat the measurement at 72 hours to be sure that clotting factors have not become depleted in the intervening 24 hours.
   B. Administration of vitamin K_1 before drawing blood for PT can result in falsely normal values.
II. Monitor packed cell volume (PCV) and clotting times in symptomatic animals.
III. For animals treated with vitamin K_1, perform a PT test 48 and 72 hours after cessation of therapy.
IV. Closer monitoring is warranted in more susceptible animals, such as young and hypothyroid animals, as well as those with underlying coagulopathies or liver disease, because prolonged therapy and adjustment of vitamin K_1 dosages may be required.
V. Closer monitoring is also warranted for animals on drugs that have potential metabolic interactions with anticoagulant rodenticides, such as metronidazole, cimetidine, chloramphenicol, sulfonamides, allopurinol, and anabolic steroids.
VI. Drugs that are highly protein-bound (e.g., aspirin, phenylbutazone, erythromycin, ketoconazole, propranolol, diazoxide) can displace anticoagulant rodenticides and increase the amount of free anticoagulant available.

BROMETHALIN

Sources

I. Formulations are typically 0.01% bromethalin in pellets or blocks.
II. Brand names include *Assault, Trounce, Real-Kill, Hot Shot, Top Gun, Fastrac, Rampage,* and *Vengeance.*
III. Talpirid is more concentrated (0.025%) and marketed to kill moles.

Action

I. Bromethalin is a secondary amine that exerts its neurotoxic effects via uncoupling of oxidative phosphorylation in mitochondria.
II. Spongy degeneration and edema of the white matter of the brain, spinal cord, and optic nerves occur as a result of separation and fluid accumulation within the myelin lamellae.
III. Lesions are irreversible.
IV. Bromethalin's active metabolite, desmethyl bromethalin, is the compound responsible for the toxicosis.
V. Because guinea pigs are deficient in N-demethylate, they are relatively resistant to bromethalin toxicosis.

Clinical Signs

I. Ingestion of dosages at or near the LD_{50} (0.40 to 0.71 mg/kg in cats; 2.38 to 5.6 mg/kg in dogs; ASPCA, 2006) can result in clinical signs within 2 to 4 hours, but more commonly by 8 to 12 hours.
II. Acute signs include hyperexcitation, tremors, seizures, paralysis, and death.
III. At lower dosages (about 0.30 to 0.45 mg/kg in cats; 1.67 mg/kg in dogs; ASPCA, 2006), the onset of signs may develop gradually over several days and can include ataxia, pelvic limb paresis, decreased sensory response, labored respiration, depression, coma, seizures (generalized or focal motor), and death.
IV. Sublethal clinical effects may be slowly reversible or permanent.

Diagnosis

I. History of exposure
II. Consistent clinical signs
III. Positive analysis of bromethalin in gastric contents
IV. Postmortem detection of the active metabolite in gastrointestinal contents, liver, brain, or adipose tissue
V. Histopathologic findings: severe spongiosis of the white matter of the central nervous system (CNS)

Differential Diagnosis

I. Seizure-inducing agents: lead, metaldehyde, strychnine, tremorogenic mycotoxins, methylxanthines, organophosphates, carbamates, methamphetamine, pseudoephedrine, phenylpropanolamine
II. Other CNS disorders: intracranial neoplasia, infectious meningitis

Treatment

I. Asymptomatic animal
  A. Induce emesis and administer multiple doses of activated charcoal.
    1. Activated charcoal is beneficial because bromethalin undergoes enterohepatic recirculation.
    2. If >0.1 mg/kg of bromethalin has been ingested (ASPCA, 2006), then emesis (if <4 hours postexposure) and activated charcoal are recommended.
    3. Give activated charcoal 6 to 11 mL/kg PO TID for 48 hours with large exposures.
  B. Further treatment guidelines are presented in Tables 124-1 and 124-2.
II. Symptomatic animal
  A. Attempt to manage seizure activity caused by cerebral edema.
    1. Osmotic agents (mannitol), corticosteroids, and furosemide have not been very effective.
    2. Administration of diazepam, barbiturates, inhalant anesthetics, and propofol can be tried.
  B. An extract of *Gingko biloba* (100 mg/kg PO) has experimentally reduced cerebral edema and lipid peroxidation of the brain when given to rats immediately after a lethal dose of bromethalin, but its efficacy in dogs and cats has not been proven.
  C. Supportive care includes IV fluids and regulation of seizure-induced hyperthermia.

TABLE 124-1

Treatment Guidelines for Bromethalin Exposure in Dogs

TIME SINCE INGESTION	AMOUNT INGESTED	TREATMENT RECOMMENDATIONS
<4 hours	0.1-0.49 mg/kg	Emesis or one dose of activated charcoal
>4 hours	0.1-0.49 mg/kg	One dose of activated charcoal
<4 hours	0.5-0.75 mg/kg	Emesis and three doses of activated charcoal
>4 hours	0.5-0.75 mg/kg	Three doses of activated charcoal
<4 hours	>0.75 mg/kg	Emesis and three doses of activated charcoal
>4 hours	>0.75 mg/kg	Three doses of activated charcoal for 48 hours

TABLE 124-2

Treatment Guidelines for Bromethalin Exposure in Cats

TIME SINCE INGESTION	AMOUNT INGESTED	TREATMENT RECOMMENDATIONS
<4 hours	0.05-0.1 mg/kg	Emesis or one dose of activated charcoal
>4 hours	0.05-0.1 mg/kg	One dose of activated charcoal
<4 hours	0.1-0.3 mg/kg	Emesis and three doses of activated charcoal
>4 hours	0.1-0.3 mg/kg	Three doses of activated charcoal
<4 hours	>0.3 mg/kg	Emesis and three doses of activated charcoal
>4 hours	>0.3 mg/kg	Three doses of activated charcoal for 48 hours

CHOLECALCIFEROL

Sources

I. Cholecalciferol is vitamin D_3 marketed commercially as a rodenticide and dietary supplement.
II. Brand names include *Quintox, Rampage, Ceva True Grit, Ortho Mouse-Be-Gon* and *Rat-B-Gon.*
III. Formulations are typically pelleted, but may also be sold as seed mixtures or bait chunks.
IV. Products are generally 0.075% cholecalciferol.

Action

I. Cholecalciferol is metabolized in the liver to 25-hydroxycholecalciferol (calcifediol or 25-(OH) vitamin D_3), which is then metabolized by the kidney to the actively toxic compound 1,25-dihydroxycholecalciferol (calcitriol or 1,25-$(OH)_2$ vitamin D_3).
II. Calcitriol increases intestinal absorption and renal tubule reabsorption of calcium, and stimulates bone resorption, resulting in hypercalcemia and hyperphosphatemia.
III. When serum calcium × phosphorus calculations are ≥60, soft tissue mineralization may occur.
  A. Because the kidneys are uniquely susceptible to dystrophic mineralization, renal failure ensues.

B. Other soft tissues, such as the cardiovascular and gastrointestinal systems, may also undergo mineralization.

Clinical Signs

I. Initial signs of exposure may appear as early as 12 hours (typically in 36 to 48 hours), and include lethargy and vomiting.
II. As the kidneys fail, the animal may become anorexic, polydipsic, and polyuric.
III. In end-stage kidney failure, anuria may occur.
IV. Significant signs may be seen at oral doses of 0.5 mg cholecalciferol/kg in the dog.
V. Sudden death may occur after initial exposure from mineralization of soft tissues (e.g., rupture of a mineralized aorta).

Diagnosis

I. History of exposure
II. Consistent clinical signs
III. Laboratory findings: elevated calcium, phosphorus, blood urea nitrogen (BUN); creatinine, dilute urine
IV. Abnormal endocrine assays
  A. Suppressed serum parathyroid hormone (PTH) level (normal values: dog, 2 to 13 pmol/L; cat, 0 to 4 pmol/L) in conjunction *with*
  B. Markedly elevated serum 25-$(OH)_2$ vitamin D_3 (normal values: dog, 60 to 215 nmol/L; cat, 65 to 170 nmol/L)
V. Analysis of bile or kidney 25-$(OH)_2$ vitamin D_3 levels on necropsy

Differential Diagnosis

I. *Dovonex* ingestion containing calcipotriene, a synthetic analogue of calcitriol
II. *Cestrum diurnum* (day jessamine, China berry, inkberry) ingestion
III. Hypercalcemia of malignancy (see Chapter 73)
IV. Other causes of renal failure (see Chapter 48)
V. Renal secondary hyperparathyroidism, primary hyperparathyroidism
VI. Blastomycosis: hypercalcemia
VII. Hypoadrenocorticism

Treatment and Monitoring

I. Fluid diuresis is done with 0.9% sodium chloride (NaCl) IV for 4 days postingestion or until resolution of hypercalcemia and azotemia.
  A. Treatment may be required for several weeks.
  B. Avoid fluids containing calcium (lactated Ringer's solution).
II. Furosemide is started at 2.5 to 4.5 mg/kg IV TID to QID or as a 5 mg/kg/hr IV constant rate infusion (CRI), after an initial 5 mg/kg IV dose.
  A. Diuretic therapy is continued until hypercalcemia resolves.
  B. Thiazide diuretics are contraindicated because they are calcium-sparing.
III. Prednisolone is also given (1 to 3 mg/kg PO BID), until hypercalcemia abates, and is then tapered over several weeks, as long as calcium levels remain normal.
IV. Salmon calcitonin or pamidronate may be tried for persistent hypercalcemia.
  A. Salmon calcitonin is given at 4 to 6 IU/kg SC or IM BID to TID.
  B. Pamidronate is given as a slow IV infusion of 1.3 to 2.0 mg/kg over 2 hours and may be repeated in 5 to 7 days.
V. Oral phosphate binders (e.g., *Amphojel* 10 to 30 mg/kg PO TID) are indicated to bind dietary phosphorus.
VI. Gastrointestinal protectants may be needed for uremic gastritis.
  A. Sucralfate 0.5 to 1 g PO TID in dogs and 0.25 to 0.5 g PO BID to TID in cats
  B. Famotidine 0.5 mg/kg PO, SC, IM, IV SID to BID
VII. See Chapter 48 for additional therapy of renal failure.
VIII. BUN, serum creatinine, calcium, phosphorus, urine output, and hydration status are monitored SID for 4 days in the asymptomatic animal.
IX. In the hypercalcemic and/or azotemic animal, these parameters are monitored frequently until they normalize, then intermittently throughout the tapering of corticosteroid therapy.

ZINC PHOSPHIDE

Sources

I. Zinc phosphide (Zn_3P_2) is a metallophosphide rodenticide used predominantly to kill moles and gophers.
II. Formulations are almost exclusively 2% but can be as high as 10%.
III. Brand names include *Sweeney's Poison Peanuts, Prozap, Forces, Bonide, Gopha-Rid, Revenge, Black Leaf, True Grit,* and *Tomcat.*
IV. Relay toxicosis is possible if enough of the bait is present in the gut of the consumed prey.

Action

I. Zinc phosphide is converted to phosphine gas (PH_3) in the acidic environment of the stomach.
II. Phosphine gas is an irritant to the stomach and lungs.
III. Intracellularly, phosphine is thought to block cytochrome oxidase, thereby inhibiting mitochondrial oxidative phosphorylation and causing cell necrosis, particularly in organs with high oxygen demand (heart, brain, kidneys, and liver).
IV. Formation of free radicals contributes to the oxidative damage.
V. Metabolic acidosis is a common finding.
VI. Residual zinc phosphide can be absorbed, resulting in delayed hepatic and renal failure (5 to 14 days postexposure).

Clinical Signs

I. Within 4 hours of ingestion, clinical signs of vomiting (frank blood or "coffee grounds" appearance if digested), lethargy, tachypnea and dyspnea (pulmonary edema), abdominal pain, ataxia, weakness, recumbency, tremors, hypersalivation, seizures, shock, and death may be seen.

II. Garlic or rotten fish odor on the breath is characteristic of the formation of phosphine gas.
III. LD_{50} in various mammals ranges from 20 to 50 mg of zinc phosphide/kg.
IV. Signs may be seen at one-tenth LD_{50} in the sensitive individual.

Diagnosis

I. Definitive diagnosis relies on a history of exposure, consistent clinical signs, the characteristic smell of the phosphine gas on the breath, and possible confirmation of the gas in the vomitus or gastric contents.
II. Samples for analysis must be placed in an airtight container and frozen before shipping.
III. Presumptive diagnosis can be made based on elevated zinc levels in the serum (royal blue blood tubes used), liver, and kidneys.

Differential Diagnosis

I. Aluminum phosphide
II. Metaldehyde

Treatment and Monitoring

I. Asymptomatic animal
   A. Administration of aluminum and magnesium hydroxide–containing products (*Maalox* 90 to 180 mg/kg PO TID) increases the gastric pH and slows the conversion of zinc phosphide to phosphine gas.
      1. A mixture of the two hydroxides is recommended because magnesium hydroxide raises the gastric pH higher and faster than aluminum hydroxide, which has a longer duration of action.
      2. If a large volume has been ingested, then gastric lavage with *Maalox* may be an option (ASPCA, 2006).
   B. Induction of emesis with apomorphine is recommended.
   C. Providing adequate ventilation upon induction of emesis or upon passing a lavage tube is critical, because phosphine gas is toxic to attending personnel even at levels below which it can be smelled.
   D. Obtain baseline laboratory tests to monitor for the possible development of delayed renal or hepatic damage.
II. Symptomatic animal
   A. Respiratory support with supplemental oxygen and ventilation is indicated in the severely affected animal.
   B. Institute treatment for shock (IV crystalloids or colloids, see Chapter 132).
   C. Fluids containing magnesium *(Normosol-R*, *Plasma-Lyte)* may correct mild hypomagnesemia.
   D. Metabolic acidosis is treated with addition of sodium bicarbonate to IV fluids as indicated by the degree of base deficit.
   E. Control seizures with diazepam, barbiturates, or inhalant anesthetics (see Chapter 22).
   F. Administer aluminum and magnesium hydroxide as for the asymptomatic animal.
   G. Gastrointestinal protectants are indicated for hemorrhagic gastroenteritis.
      1. Sucralfate 0.5 to 1 g PO TID in dogs and 0.25 to 0.5 g PO TID in cats
      2. Famotidine 0.5 mg/kg PO, SC, IM, IV SID to BID
      3. Misoprostol 1 to 3 μg/kg PO TID
   H. Hepatoprotective therapies may be used to minimize damage from reactive oxygen species.
      1. S-Adenosyl-methionine (SAMe) 17 to 20 mg/kg PO SID in dogs and 200 mg/day PO in cats
      2. Milk thistle (silymarin) 20 to 50 mg/kg/day PO
      3. N-Acetylcysteine as a loading dose of 140 mg/kg PO, IV followed by 70 mg/kg PO, IV QID
   I. Regulation of seizure-induced hyperthermia may be warranted.
   J. Monitor acid-base status and electrolytes, and reevaluate renal and hepatic values 1 week after recovery from the initial crisis.

STRYCHNINE

Sources

I. Strychnine is a bitter alkaloid extracted from the seeds of *Strychnos nux vomica* trees.
II. Strychnine use is restricted to burrowing rodents, such as moles and gophers.
III. Brand names include *Monterey Go Die Gopher, Force's Poison Peanuts, Sweeney's Poison Peanuts,* and *Wilco Gopher Getter.*
IV. Formulations typically range from 0.3% to 0.5%.
V. Baits are often dyed red, green, or blue, and combined with grain.
VI. Mammalian median lethal dosages range from 0.5 to 3 mg/kg.
VII. Over-the-counter availability varies across the United States.
VIII. *Nux vomica* is a homeopathic formulation of *Strychnos nux vomica* that is used as an appetite stimulant and for indigestion caused by atonic dyspepsia.

Action

I. Strychnine competitively and reversibly binds to postsynaptic glycine receptors in the Renshaw cells of the spinal cord and medulla.
II. Antagonizing the action of this inhibitory neurotransmitter results in continuous muscle and CNS stimulation that progresses to violent seizures and death owing to exhaustion or anoxia (inability to relax muscles of respiration).
III. Margin of safety is narrow with 3.5 g (<1 teaspoon) of a 0.3% bait considered to be a lethal dosage for a 15-kg dog.

Clinical Signs

I. Anxiety, stiff muscles (especially extensor muscles of limbs), sawhorse stance, tremors, tetanic seizures
II. Tachypnea, apnea, dyspnea
III. Myoglobinuria

IV. Strained expression from facial muscle contracture
V. Death 10 to 120 minutes postingestion

Diagnosis

I. Diagnosis is based on a history of exposure, consistent clinical signs, and positive analysis of strychnine in bait and gastric contents or lavage washings.
II. If the animal does not die peracutely, strychnine may be detected in the urine.
III. The liver, bile, and kidneys may be analyzed for strychnine at necropsy, but peracute death may preclude sufficient amounts in the tissues for confirmation of the toxicosis.

Differential Diagnosis

I. Certain toxicoses: metaldehyde, zinc phosphide, tremorgenic mycotoxins, organophosphate compounds, 1080 (fluoroacetate), fluorouracil *(Efudex),* nicotine
II. Tetanus
III. Liver disease
IV. Other causes of seizures: idiopathic epilepsy, congenital brain anomalies, intracranial neoplasia, etc. (see Chapter 22)

Treatment

I. Asymptomatic animal
   A. Because clinical signs may begin as early as 10 minutes after ingestion, the opportunity to induce emesis is often lost.
      1. If the exposure is witnessed and emesis can be induced immediately, then it may be efficacious.
      2. Emesis is contraindicated once signs are present because of the risk of inducing a seizure.
   B. Administer activated charcoal with a cathartic agent (e.g., sorbitol) at 6.6 to 11 mL/kg PO.
   C. Enterogastric lavage, although an extreme measure, may be lifesaving following a known lethal ingestion.
II. Symptomatic animal
   A. Manage seizures with diazepam (rarely efficacious alone), barbiturates, or inhalant anesthetic agents (see Chapter 22).
   B. Methocarbamol 55 to 220 mg/kg IV to effect (maximum of 330 mg/kg/day) can be given for muscle relaxation not controlled by barbiturate administration.
   C. IV fluid support is indicated to prevent renal injury from myoglobinuria.
      1. Forced diuresis with IV fluids at twice the maintenance rate may also be helpful.
      2. Acidification of the urine with ammonium chloride 50 mg/kg PO QID can maximize the excretion of strychnine but is contraindicated with myoglobinuria or lactic acidosis.
      3. Consider IV administration of bicarbonate for severe lactic acidosis (based on evaluation of pH and base deficit).
   D. Manage hyperthermia induced by muscle rigidity and/or seizure activity with cooled IV fluid therapy.
   E. Minimize stimulation because of the hyperesthetic state.
   F. Provide ventilatory support if the animal is not adequately oxygenated.
   G. Hypertension and tachycardia may be seen, especially with sublethal exposures.
   H. Monitor acid-base status and for the onset of severe lactic acidosis.

CHAPTER 125

Insecticides and Molluscicides

Donna Mensching | Petra A. Volmer

METALDEHYDE

Sources

I. Metaldehyde is a tetramer of acetaldehyde and is used primarily to kill snails and slugs.
II. Brand names include *Deadline, Prozap, Snarol, Turf King, Eliminator, Terminide, Ortho Bug-Geta,* and *Soilserv Sevin* (in combination with carbaryl, an organophosphorus compound).
III. Formulations are commonly 2% to 3% active ingredient but may be as high as 7.5%.

Action

I. Exact mechanism is unclear; however, decreased gamma-aminobutyric acid (GABA), serotonin, and norepinephrine may be involved in the toxic mechanism of metaldehyde.
II. Alterations in monoamine oxidases and 5-hydroxytryptamine may also be involved.
III. Metabolic acidosis results from the metabolism of metaldehyde to acetaldehyde.
IV. As little as 1 teaspoon of bait can be lethal to a 2.5-kg dog.

Clinical Signs

I. Tremors, seizures, hypersalivation, hyperesthesia
II. Tachycardia, hyperpnea, cyanosis, acidosis
III. Ataxia, nystagmus, anxiety, mydriasis
IV. Hyperthermia, diarrhea
V. Depression and death
VI. Signs as early as 1 hour postingestion, typically within 4 hours
VII. Liver failure possible 2 to 3 days postexposure

Diagnosis

I. History of exposure, consistent clinical signs, and analysis of gastric contents for acetaldehyde help to confirm metaldehyde toxicosis.
II. Metaldehyde can also be confirmed in a bait sample or detected in liver, urine, and plasma.

Differential Diagnosis

I. Any toxicant that causes seizures including strychnine: organophosphate and carbamate compounds, tremorgenic mycotoxins, 1080 (fluoroacetate), zinc phosphide, bromethalin, organochlorine insecticides, 5-fluorouracil *(Efudex)*
II. Other causes of seizures: see Chapter 22

Treatment and Monitoring

I. Asymptomatic animal
  A. Decontamination with induction of emesis is warranted if the ingestion was within 1 hour.
  B. Activated charcoal with a cathartic is recommended thereafter.
  C. Monitor the animal closely for a minimum of 4 hours.
  D. Gastric lavage is an alternative to inducing emesis, particularly if a large volume of metaldehyde has been ingested.
II. Symptomatic animal
  A. Manage muscle tremors with methocarbamol 55 to 220 mg/kg IV to effect (maximum of 330 mg/kg/day).
  B. Control seizures with diazepam, barbiturates, or inhalant anesthetics (see Chapter 22).
    1. Diazepam may be preferred because barbiturates compete with an enzyme that metabolizes acetaldehyde.
    2. Acepromazine (to effect) can also be helpful with managing central nervous system (CNS) excitation (APSCA, 2006).
  C. Perform baseline laboratory tests to evaluate liver function, electrolytes, and acid-base status.
  D. Institute IV fluid therapy to combat dehydration and acidosis.
  E. Sodium bicarbonate can be added to the IV fluids as needed for severe acidosis.
  F. Oxygen and ventilation may be needed if respiration is significantly depressed.

ORGANOPHOSPHORUS INSECTICIDES

Sources

I. Organophosphorus (organophosphate) insecticides (OPs) are a class of insectiides that inhibit acetylcholinesterase (AChE) activity by irreversibly phosphorylating the enzyme.
II. OPs are widely available commercially.

III. Some representative brand names include *Bonide/Ortho Systemic Rose and Flower Care* (disulfoton), *Dursban* and *Lorsban* (chlorpyrifos), *Wellmark's Paramite* (phosmet), *Maltox* (malathion), *Hartz 2-in-1 Collar* for dogs (tetrachlorvinphos), and *Orthene* (acephate).
IV. Use of many OPs, such as diazinon, is restricted.
V. Exposure to older OP formulations continue, however, because of prolonged storage of the chemical in areas such as garages, sheds, and barns.
VI. Formulations vary widely in concentration, carrier, and form; they include sprays, dips, powders, food mixtures for ant and roach baits, and impregnated collars.

Action

I. OPs irreversibly inhibit AChE, the enzyme that normally hydrolyzes the neurotransmitter acetylcholine to acetic acid and choline.
   A. This results in an excess of the neurotransmitter at the neuromuscular junction and at synapses of the parasympathetic and sympathetic nervous system.
   B. Overstimulation of postsynaptic muscarinic and nicotinic cholinergic receptors results in clinical signs.
II. If a covalent bond forms between the OP and the enzyme, a process termed *aging*, then the bond becomes irreversible.
   A. Not all OPs "age," and the rate at which those that age differs with different OPs.
   B. For example, the warfare agents sarin and VX age within seconds.
   C. Abatement of signs then relies on the body's synthesis of new AChE.

Clinical Signs

I. Muscarinic signs include salivation, lacrimation, increased urination, diarrhea, dyspnea, and emesis, as well as bradycardia, miosis, and bronchoconstriction.
II. Nicotinic signs include muscle tremors, seizures, and weakness.
III. Catecholamine-induced tachycardia may override muscarinic-induced bradycardia.
IV. Onset of clinical signs varies widely with the type of OP and the amount ingested; a potent OP (e.g., disulfoton) may cause clinical signs within minutes, whereas chlorpyrifos may take days.
V. Organophosphate-induced delayed neuropathy syndrome occurs 1 to 4 weeks after exposure.
   A. It is an axonal dying-back neuropathy that results in irreversible paralysis.
   B. An intermediate syndrome occurs in cats exposed to chlorpyrifos in which weakness, anorexia, and depression are exhibited for several days after exposure and are thought to be related to subnormal cholinesterase (ChE) levels.

Diagnosis

I. Inhibition of ChE is detectable in the live animal by determination of ChE activity in whole blood (ethylenediamine tetraacetic acid [EDTA] tube).
   A. Markedly decreased ChE activity (<25% of normal) is diagnostic for OP intoxication.
   B. Normal canine ChE activity in whole blood is 1.46 ± 0.33 μm/mL/min, and normal feline ChE activity in whole blood is 1.37 ± 0.42 μm/mL/min (University of Illinois, 2006).
II. In the postmortem specimen, ChE activity can be determined in the retina or the brain, and OP compounds can be detected in the liver, skin, or stomach contents.
III. Administration of a test dose of atropine (0.02 mg/kg IV) can be given to determine if the muscarinic signs are from a source other than intoxication with an OP or carbamate insecticide.
   A. If the heart rate increases and the other signs abate with this small dose of atropine, then the signs are *not* likely to be the result of an OP or carbamate.
   B. Ten times the preanesthetic dose of atropine is required to appreciably change the clinical signs associated with OP or carbamate intoxication because atropine acts by competitively inhibiting excess acetylcholine at the muscarinic receptor.

Differential Diagnosis

I. Carbamate toxicosis must be ruled out.
II. Anatoxin-a(s), produced by cyanobacteria, inhibits AChE in the peripheral nervous system but does not cross the blood-brain barrier.

Treatment and Monitoring

I. Asymptomatic animal
   A. Decontamination via induction of emesis and administration of activated charcoal with a cathartic agent is done for oral exposures.
   B. For dermal exposures, remove the treated collar and/or bathe with a liquid dishwashing detergent.
   C. Monitor the animal for development of clinical signs.
II. Symptomatic animal
   A. Institute oxygen therapy for dyspnea.
   B. Atropine 0.05 to 0.5 mg/kg IV and 0.15 to 1.5 mg/kg SC, IM is indicated for life-threatening muscarinic signs.
      1. These include severe bradycardia and/or dyspnea from excessive bronchial secretions.
      2. Give atropine to effect, but use with caution because atropine toxicosis can occur with excessive administration.
   C. Pralidoxime (2-PAM; *Protopam chloride*) 10 to 15 mg/kg IM, SC is an AChE reactivator that binds to the OP after it binds with AChE.
      1. 2-PAM and the OP complex is excreted, thereby freeing the enzyme.
      2. 2-PAM is indicated for predominantly nicotinic signs and is ineffective after aging occurs.
      3. Because the aging process varies with the particular OP, administration of 2-PAM may be beneficial days after the initial exposure.
      4. 2-PAM administration is discontinued after three doses if steady improvement is not seen.

5. The drug has the ability to inhibit AChE itself at high doses (LD_{50}, 190 mg/kg).

D. Diazepam is given for seizures (5 mg increments IV to effect) and may be protective against additional CNS effects and bradycardia.

E. The most critical parameters to monitor are heart rate, oxygenation status, and CNS status.

CARBAMATES

Sources

I. Carbamates are carbamic acid–derivative insecticides that inhibit AChE.

II. Brand names include *Sevin* (carbaryl), *Temik* (aldicarb), *Golden Malrin* (methomyl), *Furadan* (carbofuran), and *Baygon* (propoxur).

Action

I. Carbamate insecticides inhibit AChE in a reversible fashion by carbamylating the enzyme.

II. Clinical signs with aldicarb intoxication, for example, appear within minutes to hours and may spontaneously resolve within 4 to 12 hours as AChE is freed from the carbamate.

Clinical Signs

I. Signs are identical to those of the OP insecticides.

II. Because of the reversible nature of carbamate's action, spontaneous recovery is possible.

III. Clinical signs of acute toxicosis may be severe enough to be life-threatening.

Diagnosis

I. Decreased whole blood ChE activity (<25% normal) is diagnostic for both OPs and carbamates.

A. Distinguishing between the two is possible if the analysis is repeated 1 hour later.

B. If ChE activity has increased, then decarbamylation has occurred, freeing the enzyme from the carbamate, whereas activity after OP exposure is not expected to increase.

C. Because of the rapid reversibility of carbamates, the timing of analysis is critical.

II. A negative atropine response test is indicative of either OP or carbamate intoxication (see previous discussion).

Differential Diagnosis

I. OP toxicosis

II. Anatoxin-a(s) toxicosis

Treatment and Monitoring

I. The main difference between treatment of a carbamate versus an OP intoxication is the lack of efficacy of 2-PAM with carbamates; reactivation of the enzyme is not necessary because decarbamylation occurs readily with time.

II. All other treatment and monitoring recommendations are identical to OP intoxication (see previous discussion).

ORGANOCHLORINE INSECTICIDES

Sources

I. This class of insecticides is also known as *chlorinated hydrocarbons* or *organochlorines* (OCs).

II. OCs can be divided into three main categories: diphenyl aliphatics (dichlorophenylethanes), aryl hydrocarbons (chlorinated benzenes and cyclohexanes), and cyclodiene insecticides.

III. Examples of diphenyl aliphatics include dichlorodiphenyltrichloroethane (DDT), DDD, dicofol, ethylan, chlorobenzilate, and methoxychlor.

IV. Examples of aryl hydrocarbons include hexachlorobenzene (paradichlorobenzene) and lindane.

V. Examples of the cyclodiene insecticides include chlordane, heptachlor, aldrin, and dieldrin.

VI. Lindane is the active ingredient in *Kwell,* a human ectoparasiticide product.

VII. Mitotane (o,p'-DDD), a metabolite of DDT, is approved for the treatment of pituitary-dependent hyperadrenocorticism in dogs.

Action

I. The mechanism of action of OCs involves slowing of sodium (Na^+) influx and inhibiting potassium (K^+) efflux from neurons.

II. This results in a decreased threshold for the next action potential and sustained neurotransmission.

III. Cyclodienes also inhibit postsynaptic binding of GABA, adding to the neuronal stimulation.

Clinical Signs

I. Acute toxicoses from OCs are rare today.

II. Although all species can be affected, the cat is the most sensitive species.

III. Clinical signs can include hypersalivation and vomiting followed by behavioral changes, such as agitation, apprehension, aggression, and/or hyperexcitability.

IV. Incoordination, tremors, tonic-clonic seizures, hyperthermia, respiratory depression, coma, and death may then occur.

V. Signs may last for days owing to enterohepatic recirculation and the lipophilicity of the OCs, which allows them to accumulate in adipose tissue.

VI. Acute toxicosis may occur, with rapid weight loss as lipid stores are liberated.

VII. Chronic effects are more common as a result of the bioaccumulative potential of OCs.

A. Accumulation in body fat is particularly an issue for predators at the top of the food chain.

B. Dichlordiphenylethane (DDE), a long-lived metabolite of DDT, has been implicated in the thinning of eggshells and decline of many birds of prey, including the bald eagle.

Diagnosis

I. Diagnosis relies on a history of exposure, consistent clinical signs, and confirmation of the OC or metabolite in blood, brain, liver, or fat (including milk fat).
II. Samples are collected in glass containers because plastics may interfere with the analysis.

Differential Diagnosis

I. Any toxicant causing seizures (see previous discussion of OP toxicity)
II. Any disease process causing seizures (see Chapter 22)

Treatment and Monitoring

I. Asymptomatic animal
   A. Decontamination with activated charcoal and a cathartic is indicated for oral exposures, and repeated doses may be needed because of enterohepatic recirculation.
   B. Dermal exposures require bathing with a liquid dishwashing detergent.
II. Symptomatic animal
   A. No specific antidote exists for OC intoxication, so treatment is largely supportive and symptomatic.
   B. Seizures are treated with diazepam, barbiturates, inhalant anesthetics, or propofol (see Chapter 22).
   C. Muscle tremors are treated with methocarbamol 55 to 220 mg/kg IV to effect (maximum of 330 mg/kg/day).
   D. Supplemental oxygenation or intubation may be necessary for the severely depressed animal.
   E. Other supportive measures, such as managing hyperthermia, nutritional support and IV fluids, may be indicated.
   F. CNS status, peripheral oxygenation, body temperature, electrolytes, and acid-base status are closely monitored.

AMITRAZ

Sources

I. Amitraz is a formamidine antiparasitic agent commonly used in small animals to treat demodicosis and ascarids.
II. It is also used as an agricultural pest control agent.
III. *Mitaban* (19.9% amitraz) is approved for use in dogs and for treatment of demodicosis.
IV. *Preventic* collars (9% amitraz) are approved for dogs >12 weeks old (2500 mg of amitraz in each collar, 25 inches in length).
V. Products labeled for use in large animals such as *Taktic* (12.5% amitraz) and *Point-Guard* (2% amitraz) may be diluted and used in dogs.

Action

I. Amitraz possesses α_2-adrenergic activity, and its clinical effects may be mediated via α_2 receptors.
II. Its exact mechanism of action is not completely understood.
III. Amitraz is thought to inhibit monoamine oxidase and to possess weak serotonin antagonist properties.
IV. The potential for inducing ileus is caused by inhibition of smooth muscle contractility.
V. Hyperglycemia may be mediated by suppression of insulin release.

Clinical Signs

I. Clinical signs may occur with appropriate use of amitraz products and include sedation, ataxia, bradycardia, vomiting, diarrhea, hypothermia, and transient hyperglycemia.
II. Toy and small breeds are more susceptible to adverse effects with appropriate use.
III. Clinical signs may also be more likely if the animal has a deep pyoderma with cutaneous ulceration.
IV. Use of amitraz must be done cautiously in a diabetic animal, given the risk of hyperglycemia.
V. In addition to the previously mentioned signs, an overdose may also cause disorientation, ileus, hypertension or hypotension, coma, respiratory depression, seizures, and death.

Diagnosis

I. Diagnosis of amitraz toxicosis relies on a history of exposure and presence of consistent clinical signs.
II. Analysis for amitraz may be performed in urine, plasma, skin, blood, or gastric contents.

Differential Diagnosis

I. Any toxicant causing CNS depression: alcohol, ethylene glycol, avermectins, marijuana, benzodiazepines, barbiturates, phenothiazines
II. Other causes of bradycardia: hyperkalemia, hypoadrenocorticism, β-adrenergic blocking agents, urethral obstruction, bladder rupture, calcium channel blocker toxicosis, primary cardiac diseases

Treatment and Monitoring

I. Asymptomatic animal
   A. Decontamination via emesis followed by administration of a cathartic agent is indicated; although activated charcoal can be helpful, its use must be weighed against the potential development of ileus.
   B. For dermal exposures, bathe the animal with warm water and a liquid dishwashing detergent.
   C. If an ingested collar containing amitraz is not recovered with emesis, then endoscopic retrieval is warranted before the development of severe clinical signs.
II. Symptomatic animal
   A. Yohimbine *(Yobine)* and atipamezole *(Antisedan)* are α_2-adrenergic antagonists that can be used to specifically reverse the life-threatening clinical effects of amitraz toxicosis.
      1. Yohimbine is given at 0.11 to 0.2 mg/kg IV slowly; because of its short half-life (1.5 to 2 hours in dogs), it may need to be repeated.
      2. Atipamezole is given at a dosage of 50 μg/kg IM, and its longer half-life (2 to 3 hours in the dog) allows less frequent administration than yohimbine.
   B. Supportive care such as IV fluid therapy and management of hypothermia are important.

C. Endoscopic or surgical removal of an amitraz-containing collar may be necessary, given the potential for severe ileus and prolonged duration of signs from continued release of the drug from the collar.
D. Activated charcoal adsorbs amitraz, yet its use must be weighed against the potential for ileus and anticipation of a possible gastrotomy or enterotomy to remove an ingested collar.
E. Seizures may be treated with diazepam (5-mg increments IV to effect).
F. Atropine is *not* recommended for bradycardia.
G. Monitoring of heart rate, rhythm, and blood pressure is critical.
H. CNS status is also closely monitored, especially for the onset of extreme depression and seizures.
I. Blood glucose is monitored because of the potential for hyperglycemia.

PYRETHRINS AND PYRETHROIDS

Sources

I. Pyrethrins are a group of six insecticides that are derived from pyrethrum, a natural insecticide from the flowers of *Chrysanthemum cinerariaefolium* and *Chrysanthemum cineum*.
II. Natural pyrethrins include pyrethrin I and II, cinerin I and II, and jasmolin I and II.
III. Pyrethroids are synthetic analogues of pyrethrins, with a longer duration of action, higher toxicity, and greater stability than their natural counterparts.
  A. Type II pyrethroids are distinguished from type I by the presence of a cyano group at the alpha position, which further increases their potency.
  B. Type I pyrethroids include allethrin, bifenthrin, permethrin, phenothin, resmethrin, sumithrin, tefluthrin, and tetramethrin.
  C. Type II pyrethroids include cyfluthrin, cyhalothrin, cypermethrin, deltamethrin, fenvalerate, flumethrin, fluvalinate, and tralomethrin.
IV. Pyrethrins and pyrethroids are readily marketed as flea treatments for dogs and cats and commonly available for insecticidal use in homes.
V. Formulations vary widely in concentration and include sprays, liquids, spot-ons, foggers, and gels.

Action

I. Pyrethrins and pyrethroids exert their insecticidal properties by binding to the membrane of neurons near sodium channels to slow their opening and closing.
II. Type I pyrethroids result in repetitive discharging of the neuron while type II pyrethroids cause membrane depolarization.
III. Neurological signs can be seen with <1% of sodium channels affected.
IV. Paresthesia can occur and is thought to be a direct action of pyrethroids on sensory nerve endings.

Clinical Signs

I. Cats
  A. Exposure of cats to flea treatments containing low concentrations (<2%) of pyrethrin and pyrethroid insecticides is not expected to cause severe clinical signs.
  B. Dermal application may result in a local reaction such as erythema and paresthesia ("pins and needles" tingling sensation), as a result of stimulation of local nerve endings within minutes to a few hours after application.
    1. Cats may react to this feeling by flicking the tail, twitching the ears and skin, shaking the paws, walking abnormally, or exhibiting other behavioral aberrations.
    2. Signs typically resolve within 24 to 48 hours.
  C. Spot-on flea treatments labeled for dogs contain higher concentrations of permethrin (45% to 65%) in particular and may induce severe systemic signs in cats.
    1. Signs include hyperesthesia, tremors, and seizures.
    2. Signs are expected within 12 to 18 hours after exposure.
    3. Secondary effects include possible hypoglycemia, myoglobinuric renal failure, and hyperthermia.
    4. Death is possible if appropriate treatment is not administered.
    5. Cats are often exposed by rubbing against or grooming a recently treated dog or by intentional treatment with a product when the labeled instructions are not followed.
  D. Oral exposures to any pyrethroid may result in hypersalivation from a taste reaction and gastrointestinal irritation, often from the product carriers.
II. Dogs
  A. Exposure to pyrethroids in dogs is not expected to cause severe signs unless the exposure is massive or the dog is otherwise predisposed (e.g., a young age, underlying liver disease, debilitated as with a severe flea infestation).
  B. Local dermal reactions identical to those described for cats are possible in dogs.
  C. Oral ingestion is expected to cause mild to moderate gastroenteritis; however, with appropriate care, signs usually resolve within 24 hours.

Diagnosis

I. History of exposure and consistent clinical signs are sufficient in most cases to make a diagnosis of pyrethrin or pyrethroid intoxication.
II. A "greasy" spot on the back or detection of the odor of the product on the coat is evidence of exposure.
III. Fur may be tested to confirm exposure.
IV. Postmortem, the compounds may also be detected in the liver.

Differential Diagnosis

I. Consider any neurotoxicant that results in CNS stimulation.

II. Clinical signs of intoxication with strychnine, metaldehyde, 1080 (fluoroacetate), 5-fluorouracil *(Efudex),* 4-aminopyridine, caffeine, theobromine, amphetamine, cocaine, OPs, carbamates, OCs, cationic surfactants, and tremorgenic mycotoxins resemble those of pyrethroid intoxication.

Treatment and Monitoring

I. Asymptomatic animal
   A. With dermal exposure, bathe the animal with a liquid dishwashing detergent to remove the residue.
   B. Monitor for gastrointestinal upset and signs consistent with paresthesia within a few hours of exposure, for tremors and seizure activity within 12 to 18 hours postexposure, and for local skin irritation in the first 24 hours.

II. Symptomatic animal
   A. Treat tremors, hyperesthesia, or seizures with a slow injection of methocarbamol 55 to 220 mg/kg IV (maximum of 330 mg/kg/day) to effect, and repeat as needed as long as CNS depression is not present.
   B. Seizures refractory to methocarbamol may be controlled by barbiturates, inhalant anesthetics, or propofol (see Chapter 22).
   C. Once the animal is stable, treat any dermal exposure with thorough bathing in warm water using a liquid dishwashing detergent.
   D. Tremors and seizures may cause significant hyperthermia, yet the bathing process may result in hypothermia, which can enhance the toxicosis.
   E. Supportive care including IV fluids and IV dextrose supplementation may be indicated.
   F. Canned food or a tasty treat may be given to the hypersalivating animal suspected of reacting to the adverse taste of the dermal products.
   G. For animals exhibiting paresthesia and local dermal irritation, liquid vitamin E may be applied to the affected skin after adequate bathing to remove the product residue.
   H. Gastrointestinal irritation is treated symptomatically and supportively (see Chapter 31).

AVERMECTINS

Sources

I. Avermectins are macrolide parasiticides commonly used as a heartworm *(Dirofilaria immitis)* preventative and as a treatment for mite infestations such as scabies (*Sarcoptes* spp.), demodicosis (*Demodex* spp.), and ear mites (*Otodectes* spp.).
II. Certain members of the class are also used in ant and roach baits.
III. Macrolide parasiticides are fermentation products of *Streptomyces* spp. fungi.
IV. Brand names include *Heartgard, Ivomec, Tri-Heart* (ivermectin); *Revolution* (selamectin); *Proheart* (moxidectin); *Interceptor* (milbemycin); and *Avomec, Raid,* and *Hot Shot MaxAttrax* (abamectin).

Action

I. Macrolides cause death of their target species by binding to GABA-containing neurons in the parasite's neuromuscular junction and to glutamate-gated chloride channels in the CNS.
II. This binding causes an influx of chloride ions into the postsynaptic neuron, hyperpolarization that prevents subsequent action potential initiation or propagation, and ultimately flaccid paralysis.
III. The normal mammalian blood–brain barrier prevents high concentrations of macrolides from accumulating in the brain by using the P-glycoprotein efflux pump.
IV. Mammals also do not have glutamate-gated chloride channels, so a wide margin of safety of macrolide parasiticides exists in host animals relative to the target.
V. Dogs deficient in P-glycoprotein (from MDR1 mutation, classically in herding breeds) are uniquely susceptible to macrolide toxicosis because of the inability to pump these drugs out of the brain.
VI. Once in the brain, macrolides potentiate the release of GABA and bind to its receptors.

Clinical Signs

I. Signs occur within several hours of ingestion and include depression, mydriasis, blindness (often reversible with time), tremors, ataxia, respiratory depression, hypothermia, bradycardia, coma, and death.
II. Severe CNS depression and seizures may also occur.
III. Depending on the degree of toxicosis, signs may persist for weeks because of enterohepatic recirculation.

Diagnosis

I. History of exposure, consistent clinical signs, and breed predisposition help make the diagnosis.
II. Drug levels may be determined in serum, liver, adipose tissue, and the brain for confirmation of the toxicosis.
III. Blood levels do not correlate well with clinical toxicosis because the level of the drug in the brain is what determines the extent of the clinical reaction.
IV. A genetic test for the MDR1 gene mutation can be performed on a cheek swab of a suspected P-glycoprotein–deficient dog.
V. Although the genetic test is not diagnostic of an avermectin toxicosis, it provides evidence of the susceptibility of the individual.

Differential Diagnosis

I. Any agent that causes CNS depression: alcohol, ethylene glycol, amitraz, marijuana, benzodiazepines, barbiturates, opiates, phenothiazines
II. Any condition that results in obtundation or severe lethargy: diabetic ketoacidosis, intracranial neoplasia, hypoadrenocorticism, renal failure

Treatment and Monitoring

I. Asymptomatic animal
   A. Decontamination with emesis, followed by activated charcoal with a cathartic is indicated.

TABLE 125-1

Miscellaneous Insecticides and Molluscicides

TOXICANT	SOURCES	ACTION	CLINICAL SIGNS	TREATMENT
Naphthalene	Mothballs: *Miracle, Enoz, Curran Home Guard, Excell* Pesticides: *Bonide Mosquito Beater, Shot Gun, Dr. T's Bat Scat, Detour* Herbicides: *Prestige, Vantage*	Oxidizes hemoglobin to methemoglobin via a 1,2-oxide metabolite that forms epoxides or quinones Results in Heinz body formation and erythrolysis Also directly irritating to GI mucosa	PO: vomiting, diarrhea, abdominal pain, anorexia, pale mucous membranes, tachypnea, dyspnea, tachycardia, exercise intolerance, hemoglobinuria, fever, hepatomegaly, icterus, acute renal failure Inhalation: pulmonary edema, respiratory distress	Asymptomatic animal: decontamination with induction of emesis and administration of activated charcoal Symptomatic animal: antiemetic agents, sucralfate, famotidine; NPO for GI signs; whole blood transfusion, N-acetylcysteine, methylene blue, or ascorbic acid for methemoglobinemia; fluid therapy to protect kidneys; oxygen for inhalation exposure; bicarbonate to alkalinize urine to enhance excretion
Borate	*Borax, Timbor*	Unknown: thought to be secondary to cytotoxic properties	Vomiting most commonly, hypersalivation, retching, depression, abdominal pain, anorexia, diarrhea Less commonly weakness, ataxia, tremors, seizures, renal tubular nephrosis, hepatotoxicosis, metabolic acidosis, coma, death Dermal exposures may result in erythema, desquamation, exfoliation	Asymptomatic animal: decontamination with induction of emesis with large ingestions (>6.51 g/kg PO); activated charcoal no benefit; bathe areas in contact with liquid dishwashing detergent Symptomatic animal: IV fluids, antiemetic agents, GI protectants, electrolyte and glucose supplementation as needed, sodium bicarbonate as needed for acidosis, forced diuresis for 48 hours if kidney function may be compromised, diazepam for seizures
Rotenone	*Derris* and *Lonchocarpus* spp., *Bonide Garden Dust, Hilo Flea Dip, Goodwinol* ointment, *Durakyl Pet Dip, Flys Off Insect Repellant for Dogs, Noxfish, Green Light Rotenone Dust, Otocide, Durvet Earmite Lotion*	Inhibitor of complex I of mitochondrial electron transport in the respiratory chain	Vomiting, tachypnea, muscle tremors, respiratory and CNS depression, seizures, hypoglycemia, respiratory failure, death	Asymptomatic animal: decontamination with induction of of emesis and administration of activated charcoal for oral exposure; bathe with a liquid dishwashing detergent for dermal exposure Symptomatic animal: supportive care including antiemetic agents and GI protectants, IV fluids, diazepam or barbiturates for seizures, supplemental oxygen, endotracheal intubation, dextrose as needed
DEET	*Cutters, Deep Woods Off, 3M Ultrathon, Autan*	Unknown	Dogs and cats: tremors, hyperactivity, hypersalivation, vomiting, ataxia, seizures, death Rabbits and rats: depression, excitation, ataxia, tremors, seizures, coma, death	Asymptomatic animal: decontamination with induction of emesis for a recent and significant oral ingestion if risk of aspiration is outweighed; activated charcoal Symptomatic animal: supportive care including IV fluids to maintain hydration and promote excretion, diazepam or barbiturates for seizures

PO, Per os exposure; *NPO,* nothing by mouth; *CNS,* central nervous system; *GI,* gastrointestinal; *IV,* intravenous; *DEET,* N,N-diethyl-m-toluamide.

B. Because of enterohepatic recirculation, repeated doses of activated charcoal are given (6.6 to 11 mL/kg PO initially, followed by 3.3 to 5.5 mL/kg PO TID for 1 to 2 days).
C. Use caution with cathartic agents because the potential exists for diarrhea and hypernatremia to develop.

II. Symptomatic animal
A. Endotracheal intubation and assisted ventilation may be required in the animal with severe respiratory depression.
B. IV fluid therapy, parenteral nutrition, management of hypothermia, and prevention of decubital ulcers are important supportive measures.
C. If activated charcoal can be safely administered, repeated doses of it are helpful because of the agent's ability to undergo enterohepatic recirculation.
D. Atropine can be used for severe bradycardia.
E. CNS status, cardiovascular status, arterial blood gases, body temperature, and ophthalmic changes are important parameters to continually assess.
F. Signs may persist for weeks; however, with aggressive supportive care, recovery is expected.

MISCELLANEOUS INSECTICIDES AND MOLLUSCICIDES

CHAPTER 126

Household Hazards

Eric K. Dunayer

ZINC

Sources

I. U.S. pennies minted after 1982 (zinc core with copper cladding)
II. Zinc, brass, or galvanized steel metal hardware
III. Zinc oxide topical ointments

Action

I. Zinc oxide is directly irritating to the gastric mucosa and generally causes mild, self-limiting vomiting.
II. Elemental zinc is released from metallic objects by the action of stomach acid.
III. Zinc causes hemolysis in dogs and cats; the exact mechanism is unknown.

Clinical Signs

I. Vomiting, lethargy, weakness, diarrhea, and abdominal pain are common.
II. Hemoglobinuria, oliguria, anemia, and icterus develop several days after metal ingestion.

Diagnosis

I. Evidence of recent ingestion of pennies or metallic objects
II. Presence of hemolytic anemia or hemoglobinuria
III. Presence of metallic objects in the gastrointestinal (GI) tract on radiographs
IV. Serum zinc levels >10 ppm
    A. Collect in royal blue top tubes.
    B. Rubber stoppers in syringes may falsely elevate zinc levels.

Treatment

I. Blood transfusions for severe anemia
II. IV fluid therapy to protect the kidneys
III. Alkalization of the urine to reduce risk of precipitation of hemoglobin in the renal tubules
IV. Endoscopic or surgical removal of GI metallic objects
V. Chelation therapy not required once objects removed
VI. Symptomatic control of vomiting, especially from zinc oxide ointments

LEAD

Sources

I. Lead paints such as exterior or artist paints
    A. Lead levels in interior paint have been strictly regulated since 1977.
    B. Older homes may still contain lead paint.
II. Lead weights such as fishing sinkers or curtain weights
III. Lead hunting shot
IV. Environmental contamination from lead smelters or discarded auto and marine batteries

Action

I. Lead binds to sulfhydryl groups on proteins and can inhibit numerous enzymes and other cellular functions.
II. Lead inhibits heme synthesis and red blood cell production.
III. Lead competes with calcium and may alter nerve transmission.

Clinical Signs

I. GI signs
    A. Vomiting, diarrhea
    B. Abdominal pain
    C. Anorexia
    D. Weight loss with chronic toxicosis
II. Neurological signs
    A. Ataxia
    B. Tremors, seizures
    C. Behavioral changes

Diagnosis

I. History
    A. Ingestion of paint containing lead or lead paint chips, typically found in old dwellings
    B. Recent or ongoing lead removal projects in the house
    C. Ingestion of lead weights
II. Radiography
    A. Dense metallic objects or radiopaque chips in GI tract
    B. Lead shot in tissues

1. Pellets in tissue are stable.
2. Pellets in acidic environments (joints, abscesses) can release lead.

C. Possible lead lines (dense opacification of the metaphyseal region of long bones) in young, growing animals

III. Clinical laboratory tests
A. Hematological findings
1. Anemia
2. Basophilic stippling
3. Increased number of nucleated red blood cells
B. Blood lead levels
1. Assays are run on whole blood samples.
2. Blood lead levels >0.15 to 0.3 ppm (>15 to 30 μg/dL) indicate significant exposure.
3. Blood lead levels >0.35 ppm (>35 μg/dL) are diagnostic for lead poisoning.
4. Animals with compatible clinical signs and blood lead levels of >0.15 ppm (>15 μg/dL) should be treated.

Treatment and Monitoring

I. Prevent further absorption from GI tract.
A. Emesis if ingestion recent
B. Activated charcoal not effective
C. Enemas
D. High fiber or increased dietary bulk to decrease transit time
E. Surgical or endoscopic removal of GI or selected soft tissue metallic objects

II. Control seizures and neurological signs (see Chapter 22).

III. Chelation therapy binds lead for renal excretion.
A. Chelators can be nephrotoxic.
1. Ensure adequate hydration.
2. Monitor renal parameters during treatment.
B. Most should not be used until the GI tract is free of lead (succimer is an exception).
C. They may also bind essential minerals.
D. Calcium disodium ethylenediamine tetraacetic acid (EDTA) is effective in most cases.
1. Dosage is 100 mg/kg/day for 2 to 5 days SC divided into four treatments per day and given in a 10 mg/mL solution of 5% dextrose in water (D5W).
2. Do not exceed 2 g/day in dogs.
3. Dogs with initial blood lead levels >100 μg/dL may require two courses of therapy, separated by 7 to 10 days.
4. Cats have an increased risk of nephrotoxicity.
5. Side effects and disadvantages are as follows:
a. Painful injections
b. Removes lead from bones, so treatment may initially increase blood lead levels and worsen clinical signs
c. Cannot be administered until the GI tract is free of lead materials; requires hospitalization because of QID treatments
6. Do not use sodium EDTA because it may cause hypocalcemia.
E. D-Penicillamine *(Cuprimine)* may be used in animals that are not vomiting.
1. Dosage in dogs is 30 to 50 mg/kg/day PO divided QID for 7 days on, 7 days off, 7 days on.
2. Dosage in cats is 125 mg PO BID for 5 days.
3. Vomiting is common, so consider diphenhydramine 2 mg/kg PO or dramamine 2 to 4 mg/kg PO 30 minutes before penicillamine.
F. Succimer *(Chemet)* may be used in most animals.
1. Dosage in dogs: 10 mg/kg PO TID for 10 days
2. Dosage in cats: 10 mg/kg PO TID for 5 days followed by 10 mg/kg PO or rectally BID for 10 days
3. Given rectally if animal is seizuring or unable to swallow
4. Advantages over other chelators
a. Low nephrotoxicity
b. Does not chelate essential minerals such as zinc, copper, or iron
c. Reduced incidence of vomiting
d. Can be used if lead is still present in the GI tract

IV. Additional care may be needed for the animal and the environment.
A. Identify and remove lead source to prevent further exposure.
B. Recheck blood lead levels 2 weeks after treatment and repeat chelation if needed (blood lead values ≥40 μg/dL).
C. People in the house, especially children, may need to be tested for lead exposure.

CORROSIVES

Sources

I. Acids
A. Toilet bowl cleaners
B. Antirust compounds
C. Metal-etching chemicals

II. Alkalis
A. Drain openers: potassium or sodium hydroxide, lye
B. Automatic dishwasher detergents
C. Alkaline batteries
D. Chlorine bleaches

III. Cationic detergents
A. Germicidal detergents such as quaternary ammonium compounds
B. Fabric softeners
C. Liquid simmering potpourri

Action

I. Acids
A. They produce localized coagulation necrosis of tissues.
B. Immediate pain on contact may limit further exposure.

II. Alkalis
A. They penetrate tissues and produce localized liquefactive necrosis.
B. Little pain on contact may lead to greater exposure.

III. Cationic detergents
A. They may produce both local and systemic effects.

B. Concentrations of 1% to 7.5% may be irritating; concentrations >7.5% are corrosive.
C. Cats may show significant tissue injury with concentrations <2%.
D. Systemically, cationic detergents appear to block ganglionic function and can cause muscular paralysis.

Clinical Signs

I. Local ulcerative and/or necrotic injury: mouth, esophagus, stomach, cornea, and/or skin
II. Vomiting, drooling, anorexia, depression, vocalization
III. Central nervous system (CNS) depression with cationic detergents

Diagnosis

I. Evidence of recent ingestion or exposure to agent
II. Presence of typical burnlike injuries

Treatment and Monitoring

I. Decontamination is essential.
A. Emesis, gastric lavage, and activated charcoal are contraindicated.
B. Do not attempt to neutralize acids or alkalis because of potential generation of heat from the neutralization process.
C. Dilution with milk and/or water may be done for recent oral exposure.
D. Copious flushing of eyes or skin with water or saline is indicated for ocular or dermal exposure.
II. Monitor tissues for signs of irritation or necrosis.
III. The following may help oral exposures:
A. Sucralfate 25 to 40 mg/kg PO BID to TID (liquid or slurried tablets) to coat and protect GI tract injuries
B. Pain control with injectable opioids
1. Butorphanol 0.2 mg/kg IV, IM, SC TID to QID
2. Buprenorphine 0.01 mg/kg IV, IM, SC BID to QID
C. Broad-spectrum antibiotic agents for secondary oral infection
1. Amoxicillin 10 mg/kg IM, SC, PO BID
2. Cefadroxil 20 mg/kg PO BID
3. Metronidazole 25 mg/kg BID PO or 10 to 15 mg/kg IV BID
D. Fluid support with balanced electrolyte solutions (*Normosol-R*, lactated Ringer solution)
E. Feeding tube insertion (gastrotomy tube) for nutritional support
F. Monitoring for esophageal stricture
1. Signs may not appear for several weeks.
2. Use of short-acting corticosteroid medications to prevent esophageal scarring is controversial.

METHYLXANTHINES

Sources

I. Caffeine
A. Coffee
1. Coffee beans contain about 1% to 2% w/w dry weight caffeine.
2. Brewed coffee may contain 8 to 30 mg/oz caffeine.
B. Tea
1. Dry tea contains 3% to 4% w/w dry weight caffeine.
2. Brewed tea contains 1.8 to 10 mg/oz caffeine.
II. Chocolate
A. Derived from the cocoa bean
B. Contains combination of caffeine and theobromine (Table 126-1)
C. Found in candies, baked goods, cocoa, baker's chocolate, and cocoa bean mulch

TABLE 126-1

Methylxanthine Content of Various Chocolates

COMPOUND	THEOBROMINE (mg/oz)	CAFFEINE (mg/oz)
White chocolate	0.25	0.85
Milk chocolate	58.0	6.0
Semisweet chocolate chips	138.0	22.0
Baker's chocolate (unsweetened)	393.0	47.0
Dry cocoa powder	737.0	70.0

Action

I. Methylxanthine agents antagonize adenosine receptors.
II. Calculate methylxanthine dose based on combined caffeine and theobromine in products; see Table 126-1 for typical amounts in chocolates.
III. GI upset occurs with ingestion of 20 mg/kg of methylxanthines PO.
IV. Cardiac stimulation occurs with ingestion of 40 to 50 mg/kg PO.
V. CNS stimulation occurs with ingestion of 60 mg/kg PO.
VI. Minimum lethal dose is 100 mg/kg PO.

Clinical Signs

I. Polydipsia
II. Vomiting, diarrhea
III. Tachycardia
IV. CNS stimulation: agitation, tremors, seizures

Diagnosis

I. Evidence of recent ingestion of agent
II. Presence of agent in vomitus
III. Appropriate clinical signs

Treatment and Monitoring

I. Decontamination is indicated.
A. Emesis
1. Chocolate may form a large ball in the stomach.
2. Emesis may be useful even 6 to 8 hours after ingestion if animal is still asymptomatic.
B. Activated charcoal
1. Theobromine has a longer half-life in dogs (17.5 hours) than caffeine (4.5 hours) because of enterohepatic recirculation.

2. Multiple doses of activated charcoal (every 3 to 4 hours) may disrupt this recirculation.

II. Manage vomiting with antiemetic agents.
   A. Metoclopramide 0.2 to 0.4 mg/kg SC, IM TID to QID or 1 to 2 mg/kg/day IV as constant rate infusion (CRI)
   B. Chlorpromazine 0.5 mg/kg IV, IM, SC TID to QID

III. Control cardiac signs.
   A. Tachycardia can be controlled with propranolol 0.02 to 0.06 mg/kg IV.
   B. Ventricular tachycardia in dogs may be controlled with lidocaine 1 to 2 mg/kg IV bolus, followed by 60 to 90 μg/kg/min CRI.

IV. Control agitation, tremors, and/or seizures.
   A. Diazepam 0.5 to 2.0 mg/kg IV
   B. Methocarbamol 50 to 220 mg IV slowly
   C. Phenobarbital 2 to 6 mg/kg IV

V. Fluid diuresis promotes excretion.

VI. Caffeine can be reabsorbed through the bladder wall.
   A. Encourage frequent voiding.
   B. Insert urinary catheter to keep the bladder empty.

VII. Because of the high fat content of many chocolate products, monitor for pancreatitis.

GRAPES AND RAISINS

Sources

I. Commercially sold grapes and raisins
II. Pulp from wine pressings
III. Backyard vines

Action

I. Grapes and raisin ingestion can cause acute tubular necrosis with acute renal failure in dogs and possibly cats.
II. Toxic mechanism is unknown.

Clinical Signs

I. Vomiting (usually within 6 hours of ingestion)
II. Diarrhea
III. Lethargy
IV. Polydipsia, polyuria
V. Oliguria or anuria (may develop in 48 to 72 hours)

Diagnosis

I. Evidence of recent ingestion of grapes or raisins
II. Presence of grapes or raisins in vomitus or stool
III. Elevated blood urea nitrogen (BUN), creatinine, phosphorus
   A. Values may start to increase 24 to 36 hours postingestion.
   B. Creatinine level may be disproportionately elevated compared with BUN.
IV. Renal tubular casts in urine sediment

Treatment

I. Emesis and activated charcoal are indicated within 4 hours of ingestion if spontaneous vomiting is not present.
II. Fluid diuresis (IV administration of balanced electrolyte fluids at twice maintenance) is done for at least 48 hours.
III. Prognosis varies.
   A. Good with early intervention in asymptomatic animals
   B. Guarded if oliguria and anuria occurs
      1. Renal function may return to normal in days to weeks.
      2. Chronic renal failure may be a sequela.
      3. Peritoneal dialysis or hemodialysis may be useful until renal function improves.

ADHESIVES

Sources

I. Commercially available glues
II. Cyanoacrylate-based "super" glues
III. Isocyanate-based polyurethane glues
   A. *Gorilla Glue*
   B. *Elmer's Probond Polyurethane Ultimate Glue*

Action

I. Super glues can instantly glue skin, eyelids, and lips together.
   A. They may cause local tissue burns from release of heat during the polymerization process.
   B. These glues polymerize rapidly, so systemic toxicity from ingredients is unlikely.
II. Polyurethane glues contain isocyanate monomers that polymerize to polyurethane, forming a large gastric foreign body.

Clinical Signs

I. Super glues
   A. Inability to open mouth or eyelids
   B. Localized irritation
II. Polyurethane glues
   A. Vomiting
   B. Anorexia
   C. ± Firm abdominal mass

Diagnosis

I. Evidence of recent ingestion of product
II. Polyurethane glues
   A. Radiographic presence of large, granular gastric foreign body
   B. Full stomach in a chronically vomiting animal

Treatment

I. Super glues
   A. Do not force glued skin or eyelids apart.
   B. Allow glue around gums and teeth to wear away from abrasion.
   C. Allow eyelids and skin to separate on their own.
II. Polyurethane glues
   A. Do not induce emesis, as it may result in an expanding esophageal mass.

B. Activated charcoal, food, and other diluents are contraindicated because they may accelerate the polymerization process.
C. Gastrotomy may be needed to remove the foreign body.
D. GI protectants such as sucralfate (0.5 to 1 g PO TID in dogs) may be helpful.

MACADAMIA NUTS

Sources

I. Macadamia nuts are harvested from the *Macadamia integrifolia* tree.
II. They are sold as nuts or in baked goods.

Action

I. Mechanism of action has not been determined.
II. Doses >2.4 g/kg PO may cause symptoms in dogs.

Clinical Signs

I. Vomiting, anorexia
II. Weakness, pelvic limb ataxia
III. Tremors
IV. Mild hyperthermia

Diagnosis

I. Evidence of recent ingestion of the nuts
II. Presence of macadamia nuts in vomitus or stool

Treatment

I. Emesis is induced within 4 hours of ingestion if animal is not already spontaneously vomiting.
II. Give repeated doses of activated charcoal (1 g/kg PO followed by 0.5 g/kg TID).
III. Most cases recover without specific treatment.
IV. Signs usually appear within 12 hours of ingestion.
V. Signs may take 12 to 48 hours to resolve.
VI. Severe cases may require the following:
A. Control tremors with methocarbamol 50 to 200 mg/kg IV slowly.
B. Cold-water enemas may help recovery by decreasing transit time.
C. Prognosis is usually excellent.
VII. Because of the high fat content of macadamia nuts, monitor for pancreatitis.

HOPS

Sources

I. Derived from the *Humulus lupulus* plant
II. Used for brewing beer

Action

I. Ingestion of hops by dogs can lead to a malignant hyperthermia-like syndrome.
II. No toxicity has been reported in cats.
III. Mechanism of action is unknown.

Clinical Signs

I. Vomiting
II. Restlessness
III. Abdominal pain
IV. Panting
V. Hyperthermia: may exceed 41.7° C (107° F)
VI. Rapid onset and progression of signs: usually within 3 to 6 hours of ingestion

Diagnosis

I. Evidence of recent ingestion of hops
II. Presence of hyperthermia without other obvious causes (e.g., heatstroke)

Treatment

I. Emesis and activated charcoal are indicated early.
II. Fluid therapy may be needed for cardiovascular support.
III. Manage hyperthermia.
A. External cooling with cold-water baths
B. Dantrolene sodium
1. Skeletal muscle relaxant
2. Dosage: 2 to 3 mg/kg IV or 3.5 mg/kg PO, followed by 3.5 mg/kg PO BID for 3 days
IV. Prognosis is guarded with severe, prolonged hyperthermia.

BREAD DOUGH

Sources

I. Raw yeast dough
II. Examples: bread or pizza dough
III. Usually occurs in dogs

Action

I. Dough expands from carbon dioxide accumulation and causes gastric distension.
A. Pressure necrosis of gastric mucosa
B. Compromise of caudal venous return to heart
II. Yeast releases ethanol during fermentation.
A. CNS depression
B. Acidosis from ethanol breakdown products

Clinical Signs

I. Nonproductive vomiting, retching
II. Gastric distention
III. Ataxia
IV. CNS depression, collapse, coma

Diagnosis

I. Evidence of recent ingestion of uncooked dough
II. Abdominal distention
III. Radiographic evidence of soft tissue density (foreign body) in the stomach

Treatment

I. Emesis early
A. Consider if ingestion was within 1 to 2 hours.
B. Do not induce emesis if CNS signs are present.

II. Intravenous fluid therapy for cardiovascular support and acidosis
III. Cold-water lavage
  A. To remove dough
  B. To inhibit ethanol production
IV. Correction of any acid-base imbalances
V. Possible gastrotomy to remove mass of dough

GLOW JEWELRY

Sources

I. Glow-in-the-dark necklaces, bracelets, and light sticks
II. Common around holidays such as Halloween and Independence Day
III. Often sold at fairs and carnivals

Action

I. Products contain dibutyl phthalate.
II. Dibutyl phthalate has a wide margin of safety (rat oral LD_{50} >8 g/kg).
III. Signs arise from the extremely unpleasant taste of dibutyl phthalate, which causes a repugnant reaction in the animal.

Clinical Signs

I. Profuse salivation
II. Vomiting
III. Agitation or aggression
IV. Cats more likely to show signs than dogs
V. Generally occur immediately after exposure

Diagnosis

I. Evidence of ingestion of the agent
II. Liquid on fur that glows in the dark

Treatment

I. Gently rinse the mouth or offer the animal an oral treat, such as milk, tuna juice, or canned cat food.
II. Remove any agent from the fur to prevent reexposure; placing the animal in a darkened room aids with identification and removal of the agent.
III. Signs may resolve quickly even without treatment.

XYLITOL

Sources

I. A five-carbon sugar alcohol used as a sugar substitute
II. Sugar-free gums, candies, or mints
III. Low-carbohydrate baked goods
IV. Toothpastes, mouthwashes
V. Granular powder used for sweetening baked goods, drinks, cereals

Action

I. In dogs, xylitol causes release of large amounts of insulin with resultant hypoglycemia.
II. Hepatic metabolism of xylitol may cause depletion of adenosine triphosphate (ATP) and hepatic necrosis.
III. As little as 0.15 g/kg PO of xylitol may cause hypoglycemia.

Clinical Signs

I. Vomiting
II. Weakness progressing to ataxia, collapse, and seizures
III. Hypoglycemia
  A. May develop in <30 minutes.
  B. With some gums, onset of hypoglycemia may be delayed up to 12 hours.
  C. Hypoglycemia may persist for 24 to 36 hours.
  D. Some dogs may become hyperglycemic secondary to glycogenolysis by the liver (which develops to compensate for hypoglycemia).
IV. Hypokalemia
V. Possible acute hepatic failure and necrosis in 24 to 72 hours
  A. Elevated alanine aminotransferase, aspartate aminotransferase, serum alkaline phosphatase
  B. Hyperbilirubinemia
  C. Coagulopathy
  D. May occur without initial signs of hypoglycemia

Diagnosis

I. Evidence of recent ingestion of agent
II. Progressive weakness, ataxia, seizures
III. Hypoglycemia
IV. Hypokalemia
V. Elevated liver enzymes

Treatment and Monitoring

I. Emesis is indicated in asymptomatic animals with recent ingestion.
II. Activated charcoal is of limited use.
III. Monitor blood glucose levels.
IV. Supplemental IV dextrose (bolus of 25% dextrose at 2 mL/kg IV, followed by D5W 1 to 2 mL/kg/hr IV) is often required.
V. Supplement with potassium if hypokalemia is severe (<2.5 mmol/L).
VI. Hepatic failure is treated similarly to other causes (see Chapter 37).
  A. Liver protectants such as S-adenosylmethionine *(Denosyl)* 20 mg/kg PO SID may be helpful.
  B. Plasma may be given for a coagulopathy (see Chapters 68 and 71).
VII. Prognosis is variable.
  A. Good for hypoglycemia
  B. Guarded if liver failure develops

PAINTBALLS

Sources

I. Marble-sized paint-filled balls used for warlike games
II. Labeled as nontoxic

Action

I. They contain osmotically active agents such as sorbitol, polyethylene glycol (PEG), and glycerol that can draw water into the GI tract and cause a relative hypernatremia.
II. Low-molecular weight PEGs can be absorbed and cause direct CNS depression and acidosis.

Clinical Signs

I. Vomiting
II. Ataxia
III. Tremors, seizures
IV. Hypernatremia

Diagnosis

I. Evidence of recent ingestion of paintballs
II. Paint in vomitus or on fur
III. Hypernatremia

Treatment and Monitoring

I. Emesis may be induced in asymptomatic animals.
II. Consider gastric lavage for large ingestions, especially if CNS depression is present.
III. Do not give activated charcoal because it can exacerbate the hypernatremia.
IV. Institute low-sodium IV fluid diuresis (D5W, 0.45% sodium chloride and 2.5% dextrose) to lower blood sodium levels.
V. Plain-water enemas (3 to 5 mL/kg) are given to provide free water to lower blood sodium levels and are repeated as needed.
VI. Monitor serum sodium levels.
VII. Prognosis is good with prompt control of clinical signs.

CHAPTER 127

Human Medications

Charlotte Means

IRON

Sources

I. Iron is an essential mineral.
II. Iron is found in vitamin supplements, generally as a ferric (Fe^{3+}) or ferrous (Fe^{2+}) salt.
III. Children's vitamins are frequently flavored and palatable.
IV. Other sources include the following:
  A. Injectable iron (iron dextran)
  B. Fertilizers
  C. Snail and slug bait
  D. Instant hand warmers
  E. Birth control pills

Action

I. Iron has a direct corrosive effect on the gastrointestinal (GI) tract.
II. It is metabolized in the stomach and mucosal cells to the Fe^{3+} form and transported to the blood where iron binds to transferrin.
III. When transferrin is saturated, free iron (serum iron) is released in the circulation.
IV. Free iron increases lipid peroxidation, which damages mitochondria, microsomes, and organelles in the brain, heart, and liver.
V. Vitamin C enhances the absorption of iron.
VI. In dogs, oral doses of elemental iron <20 mg/kg are nontoxic, 20 to 60 mg/kg are mild to moderately toxic, >60 mg/kg are seriously toxic, and 100 to 200 mg/kg are potentially lethal.

Clinical Signs

I. Iron toxicosis occurs in four stages.
II. Stage 1 occurs within the first 6 hours.
  A. During this stage the direct corrosive effect on the gut causes vomiting and diarrhea, possibly hemorrhagic.
  B. In mild to moderate cases, clinical signs may not progress beyond stage 1.
III. In stage 2 the animal appears to stabilize while the reticuloendothelial system takes up iron.
IV. In stage 3 (12 to 96 hours after the overdose) severe to life-threatening signs develop.
  A. Recurrence of GI signs: frequently hemorrhagic
  B. Metabolic acidosis
  C. Hepatic necrosis, hypoglycemia
  D. Coagulopathies
  E. Hypotension, shock
  F. Cardiovascular collapse, death
V. Stage 4 develops 2 to 6 weeks postingestion when healing GI ulcers cause scarring and stricture formation.

Diagnosis

I. Iron is absorbed erratically.
II. Submit samples to measure serum iron (SI) and total iron-binding capacity (TIBC) at 3 to 4 and 8 to 10 hours postingestion to human hospital laboratories.
III. If SI > TIBC, then the animal is at risk for toxicity.
IV. Radiographs of the abdomen may be helpful to verify ingestion.
  A. Negative findings on radiographs are meaningless.
  B. If iron tablets are present, then radiodense outlines of the tablets may be seen.

Differential Diagnosis

I. Other causes of hemorrhagic gastroenteritis or hepatic necrosis
II. Other toxicities
  A. Sago palm
  B. Castor beans
  C. Mushrooms
  D. Arsenic
  E. Bacterial, viral gastroenteritis

Treatment and Monitoring

I. Decontamination
  A. Induce emesis within 2 hours of ingestion in asymptomatic animals.
  B. Gastric lavage is indicated for massive ingestions.
  C. Magnesium hydroxide 30 to 90 mg/kg PO, repeated in 6 hours may complex with iron, resulting in decreased absorption.
  D. Activated charcoal does not adsorb iron well.
II. Symptomatic care
  A. IV fluids: rate and type dependent on maintenance and replacement needs
  B. GI protectants: sucralfate 0.5 to 1.0 g/25 kg PO TID in dogs and 0.25 g PO TID in cats
  C. Monitoring of electrolytes and serum biochemistries
III. Chelation therapy

A. Give deferoxamine *(Desferal)* at 40 mg/kg IM TID to QID.
B. Deferoxamine turns the urine a salmon-pink color.
C. Continue until the urine is normal in color.

ACETAMINOPHEN

Sources

I. Acetaminophen is a synthetic, nonopiate derivative of p-aminophenol.
II. It is also known as APAP, paracetamol *(Panadol),* and nonaspirin pain reliever.
III. More than 200 prescription and nonprescription formulations exist, and it may be found in combination with antihistamines, decongestants, opiates, or other agents.
IV. It is used to treat mild to moderate pain and fever.

Action

I. It is rapidly absorbed from the GI tract, but absorption can be delayed by other drugs and high carbohydrate foods that prolong gastric emptying.
II. It is metabolized in the liver by glucuronidation, glutathione conjugation, or sulfation.
A. Cats are deficient in glucuronyl transferase.
B. The metabolite N-acetyl-p-benzoquinone (NAPQI) is toxic because it damages hepatic cells and red blood cells.
III. Depletion of glutathione stores allows NAPQI to bind to hepatic cell membranes.
IV. NAPQI binds to sulfhydryl groups on cell membranes causing hepatic cell necrosis.
V. If glutathione is present, then NAPQI can be neutralized.
VI. NAPQI also oxidizes Fe^{2+} to Fe^{3+}, resulting in methemoglobinemia.
VII. Oxidation of hemoglobin forms disulfide bonds that precipitate hemoglobin and form Heinz bodies.
VIII. Toxic doses are as follows:
A. Dogs
1. Hepatoxicity: 100 mg/kg
2. Potential for methemoglobinemia: 200 mg/kg
3. Potential for keratoconjuctivitis sicca (KCS): therapeutic doses
4. Therapeutic dose in dogs: 10 mg/kg PO BID
5. Trigger dose for decontamination: 50 mg/kg PO
B. Cats
1. Never use in cats.
2. Cats may develop toxicity with doses of 10 mg/kg (Aaronson and Drobatz, 1996).

Clinical Signs

I. Methemoglobinemia 2 to 4 hours postexposure in cats
II. Heinz bodies and anemia
III. Hypersalivation, edema of face and feet (more common in cats)
IV. Vomiting
V. Icterus
VI. Tachycardia, tachypnea
VII. Cyanosis, purplish-brown color to mucous membranes
VIII. Hematuria, hemoglobinuria
IX. Acute hepatic necrosis (more common in dogs)
X. KCS (more common in toy breed dogs)
XI. Acute renal failure

Diagnosis

I. History of exposure to agent
II. Measurement of acetaminophen plasma levels 4 hours postexposure
A. Most human hospitals can run this assay.
B. If acetaminophen is present in the plasma, then exposure is confirmed.
III. Elevated liver enzymes
IV. Methemoglobinemia
V. Heinz bodies on peripheral blood smears
VI. Central lobular necrosis of the liver on histopathology

Differential Diagnosis

I. Methemoglobinemia: naphthalene, local anesthetic agents, oxidant drugs (phenazopyridine [*Pyridium*]), chlorates, phenols, onions or garlic (*Allium* spp.)
II. Hepatotoxicity: iron, mycotoxins, mushrooms, phosphorus (P), carbon tetrachloride, phenolics, nitrosamines, thiacetarsamide, pyrrolizidine alkaloid plants, blue-green algae

Treatment and Monitoring

I. Decontamination
A. Emesis within 1 hour of exposure
B. Activated charcoal 1 to 2 g/kg PO; repeated in 6 to 8 hours
II. Oxygen therapy for dyspnea or cyanosis
III. Whole-blood transfusion for significant anemia
IV. N-acetylcysteine (*Mucomyst* PO, *Acetadote* IV) to supplement glutathione
A. Loading dose is 140 to 280 mg/kg PO, IV.
B. Then give 70 mg/kg PO, IV QID for 7 to 17 treatments.
V. S-adenosyl-methionine (SAMe) 18 mg/kg PO for 1 to 3 months to increase hepatic glutathione levels
VI. Ascorbic acid 30 mg/kg PO BID to QID to reduce methemoglobin to hemoglobin
VII. Cimetidine 5 to 10 mg/kg PO TID to QID to reduce metabolism of acetaminophen
VIII. IV fluid therapy
IX. Contraindicated drugs: corticosteroids, antihistamines
X. Monitoring
A. Methemoglobinemia: drop blood on white filter paper and compare color to normal animal's blood
B. Heinz bodies on peripheral blood smears
C. Packed cell volume
1. Ingestion of 60 mg/kg PO in cats can produce 21.7% methemoglobinemia within 4 hours.
2. If anemia has not developed by 72 hours, then it is unlikely.
D. Liver and renal function tests
E. Schirmer tear test: baseline and 72 hours later
XI. Prognosis
A. Prognosis is guarded to poor if severe methemoglobinemia, anemia, or hepatic damage occur.

B. In most other cases, prognosis is good with prompt treatment.

ASPIRIN AND OTHER SALICYLATES

Sources

I. Salicylates are analgesics with antipyretic and antiinflammatory actions.
II. Aspirin (acetylsalicylic acid [ASA]) is the salicylate ester of acetic acid.
III. Many brands and generic forms are available, some in combination with other products.
IV. Bismuth salicylate is found in several brands of antidiarrheals *(Pepto-Bismol, Kaopectate)*.
V. Salicylates are found in liniments, creams, and lotions (e.g., sunblock).
VI. Methyl salicylate is found in many plants and some foods (e.g., apples, blackberries).

Action

I. Salicylates decrease prostaglandin and thromboxane synthesis by inhibiting cyclooxygenase (COX).
II. They also inhibit platelet function.
III. Mitochondrial oxidative phosphorylation is uncoupled, resulting in hyperglycemia and hyperthermia.
IV. Salicylates stimulate the central nervous system (CNS) respiratory center in the medulla.
V. Metabolic acidosis occurs from increased production of organic acids.
VI. Gastric ulceration is a common side effect.
VII. Toxic doses are as follows:
  A. Dogs
    1. With doses <150 mg/kg, signs are generally mild and can be managed by the owner at home.
    2. Ingestion of 150 to 300 mg/kg requires decontamination and medical management.
    3. Doses >300 mg/kg generally require hospitalization.
    4. Therapeutic dose is 10 to 20 mg/kg PO BID.
  B. Cats
    1. Clinical signs are possible at doses above the therapeutic range.
    2. Therapeutic dose is 6 to 10 mg/kg PO QOD.

Clinical Signs

I. Hyperthermia (body temperature >39° C [102.5° F])
II. Tachypnea initially, respiratory depression as signs progress
III. Vomiting ± blood
IV. GI ulceration
V. Metabolic acidosis
VI. Prolonged bleeding times
VII. Hepatic necrosis
VIII. Seizures, coma

Diagnosis

I. History of exposure to salicylate-containing products
II. Compatible clinical signs
III. Metabolic acidosis and increased anion gap (see Chapter 2)
IV. Serum or urine salicylate levels to confirm exposure

Differential Diagnosis

I. Acetaminophen or other nonsteroidal antiinflammatory drugs (NSAIDs)
II. Toxic mushroom ingestion: *Agaricus* spp., *Albatrellus* spp., *Boletus* spp., *Laetiporus* spp.
III. Blue-green algae ingestion
IV. Iron toxicity
V. Hepatotoxic mushroom ingestion: *Amanita* spp., *Galerina* spp., *Lepiota* spp.
VI. Other causes of acute gastritis or hemorrhagic gastritis (see Chapter 31)
VII. Other causes of metabolic acidosis

Treatment and Monitoring

I. Decontamination
  A. Induce emesis in asymptomatic animals, within 2 hours of exposure.
  B. Give activated charcoal 1 to 2 g/kg PO, repeat in 6 to 8 hours.
  C. Peritoneal dialysis can be considered for massive (>300 mg/kg) doses.
II. GI protectants
  A. Dogs: misoprostol 1 to 3 µg/kg PO TID to QID
  B. Sucralfate
    1. Dog: 0.5 to 1 g/25 kg PO BID to TID
    2. Cat: 250 to 500 mg PO BID to TID
  C. Famotidine
    1. Dog: 0.5 to 1 mg/kg PO SID to BID
    2. Cat: 0.5 mg/kg PO SID to BID
III. Urine alkalinization
  A. Give sodium bicarbonate at 10 to 90 g/day PO.
  B. The goal is a urine pH of 7.0.
  C. Do not attempt if acid-base status cannot be monitored.
IV. IV fluid for maintenance and replacement needs
V. Assisted ventilation if comatose
VI. Management of seizures: see Chapter 22
VII. Whole-blood transfusions for severe bleeding
VIII. Cool-water baths or enemas for severe hyperthermia: see Chapter 135
IX. Monitoring
  A. Liver enzymes
  B. Acid-base status: blood gases
  C. Electrolytes: during severe vomiting or diarrhea
  D. Urine pH
  E. Coagulation profile: platelet count, prothrombin time

NONSTEROIDAL ANTIINFLAMMATORY DRUGS

Sources

I. NSAIDs are analgesic, antipyretic, and antiinflammatory drugs.

II. They comprise both over-the-counter and prescription drugs.
III. In general, NSAIDs have a narrow margin of safety in dogs and cats.
IV. Approved NSAIDs in dogs include the following:
  A. Carprofen *(Rimadyl)* 2.2 mg/kg PO BID
  B. Meloxicam *(Metacam)* 0.2 mg/kg PO, SC loading dose, then 0.1 mg/kg PO SID for maintenance
  C. Deracoxib *(Deramaxx)* 1 to 2 mg/kg PO SID
  D. Tepoxalin *(Zubrin)* 10 to 20 mg/kg PO loading dose, then 10 mg/kg PO SID for maintenance
  E. Etodolac *(EtoGesic)* 10 to 15 mg/kg PO SID
  F. Ketoprofen *(Anafen)* 2 mg/kg PO loading dose, then 1 mg/kg PO SID for 4 days
V. Piroxicam 0.3 mg/kg PO SID is not approved but is frequently used in dogs.
VI. A limited number of NSAIDs are approved for cats in United States.
  A. Meloxicam *(Metacam)* 0.3 mg/kg SC once
  B. No approved oral NSAIDs

Action

I. NSAIDs reduce prostaglandin synthesis by inhibiting cyclooxygenase (COX-1, COX-2).
II. NSAIDs cause a decrease in GI cytoprotective effects that allows gastric ulcers to form (with potential for hemorrhage or perforation), which is predominately a COX-1 effect.
III. Renal blood flow is decreased; mechanisms regulating filtration and urine output are altered (predominately COX-1 effects).
IV. Idiopathic hepatopathy may occur from interaction of reactive glucuronide metabolites with plasma and hepatocellular proteins, as well as from an immune-mediated attack on the proteins.
V. Toxic oral doses are as follows:
  A. Ibuprofen in dogs
    1. Gastric ulcers: 50 mg/kg
    2. Acute renal failure (ARF) and gastric ulcers: 125 mg/kg
    3. Seizures, ataxia, ARF, GI ulcers: 400 mg/kg
    4. Potentially lethal: 600 mg/kg
  B. Naproxen in dogs
    1. Ulcerative gastritis: 5 mg/kg for 7 days
    2. ARF: 25 mg/kg
  C. Piroxicam in dogs: GI ulcers and ARF with 1 mg/kg
  D. Indomethacin in dogs: gastric ulcers at 2 mg/kg
  E. Carprofen
    1. Dogs: GI ulcers with 20 mg/kg, ARF with 40 mg/kg
    2. Cats: GI ulcers with 4 mg/kg, ARF with 8 mg/kg
  F. Minimum toxic doses not established in small animals for most NSAIDs
  G. Hepatopathy: idiosyncratic, not dose-related

Clinical Signs

I. GI signs
  A. Lethargy, anorexia
  B. Vomiting ± blood, diarrhea, abdominal pain, melena
  C. Acute collapse and sudden death with perforating GI ulcers
II. Renal signs
  A. Polyuria, polydipsia
  B. Isosthenuria, oliguria, anuria
III. CNS signs: ataxia, seizures, coma
IV. Hepatobiliary signs: lethargy, anorexia, vomiting, diarrhea, icterus
V. Death

Diagnosis

I. History of exposure to agent
II. Abnormalities in total protein, liver enzymes, renal function tests
III. Urinalysis: hematuria, pyuria, proteinuria, isosthenuria
IV. Endoscopy to verify GI ulcers
V. Histopathology
  A. GI tract: ulcers, inflammation, hemorrhage
  B. Kidneys: renal tubular or papillary necrosis, interstitial nephritis
  C. Liver
    1. Multifocal to bridging hepatocellular degeneration and necrosis
    2. Periportal inflammation, bridging fibrosis, biliary hyperplasia, bile retention

Differential Diagnosis

I. Acetaminophen or salicylates
II. Ingestion of toxic (GI, hepatic) mushrooms
III. Iron toxicity
IV. Other causes of acute gastritis or hemorrhagic gastroenteritis (see Chapter 31)
V. Ingestion of lilies
VI. Ingestion of grapes or raisins
VII. Ingestion of arsenic
VIII. Other causes of acute renal failure

Treatment and Monitoring

I. Decontamination
  A. Induce emesis for recent ingestions in asymptomatic animals.
  B. Give activated charcoal 1 to 2 g/kg PO, and repeat in 6 to 8 hours.
II. GI protectants
  A. Dogs: misoprostol 1 to 3 µg/kg PO TID to QID
  B. Sucralfate
    1. Dogs: 0.5 to 1.0 g/25 kg PO BID to TID
    2. Cats: 250 to 500 mg PO BID to TID
  C. Famotidine
    1. Dogs: 0.5 to 1.0 mg/kg PO SID to BID
    2. Cats: 0.5 mg/kg PO SID to BID
  D. Omeprazole
    1. Dogs: 0.5 to 1.0 mg/kg PO SID
    2. Cats: 0.7 mg/kg PO SID
III. Fluid therapy
  A. Institute diuresis for a minimum of 48 hours.
  B. Fluid choice depends on the timing of treatment and electrolyte status (see ARF in Chapter 48).

IV. Monitoring
  A. Complete blood count (CBC): baseline, repeated if melena and hematochezia present
  B. Biochemistry panel: baseline, repeated at 48 and 72 hours
  C. Urinalysis: baseline, repeated in 72 hours after fluids stopped

HYPOGLYCEMIC AGENTS

Sources

I. Three major classes of hypoglycemic agents exist.
  A. Sulfonylurea agents
    1. Acetohexamide *(Dimelor)*
    2. Chlorpropamide *(Diabinase)*
    3. Glimepiride *(Amaryl, Avandaryl)*
    4. Glipizide *(Glucotrol)*
    5. Glyburide *(Diabeta)*
    6. Glibenclamide *(Glyben);* also called *glibenzyclamide*
    7. Tolazamide *(Ronase)*
    8. Tolbutamide *(Orinase, Mobenol)*
  B. Thiazolidinedione agents
    1. Troglitazone *(Rezulin)*
    2. Pioglitazone *(Actos, Actoplus Met)*
    3. Rosiglitazone *(Avandia, Avandamet)*
  C. Biguanide hypoglycemic agents: metformin *(Glucophage, Glucovance, Actoplus, Avandamet)*
II. These products are used therapeutically to control hyperglycemia in noninsulin-dependent human diabetics patients.

Action

I. Sulfonylurea agents stimulate insulin production by the beta cells of the pancreas.
II. Thiazolidinedione agents increase sensitivity to insulin as peroxisome proliferator-activated receptor (PPAR)-gamma agonists.
  A. These drugs only work in the presence of insulin.
  B. Activation of PPAR receptors increases the movement of glucose into tissues and decreases hepatic glucose output.
III. Biguanide increases metabolism of glucose to lactate in the intestines and reduces hepatic gluconeogenesis.
IV. Sulfonylurea agents have a narrow margin of safety.
  A. Hypoglycemia can be seen even with therapeutic doses.
  B. Therapeutic doses are as follows:
    1. Glipizide in cats: 0.25 to 0.5 mg/kg PO BID
    2. Glyburide in cats: 0.625 mg/day PO
    3. Chlorpropamide in cats and dogs: 10 to 40 mg/kg/day PO
  C. Glipizide 0.1 mg/kg PO has caused hypoglycemia in dogs.
V. Thiazolidinedione agents have a fairly wide margin of safety, and no minimum toxic doses have been established in dogs and cats.
VI. With biguanide agents, GI signs can be seen with doses as low as 33 mg/kg PO in dogs, and metabolic acidosis may occur with large ingestions.

Clinical Signs

I. Sulfonylurea and thiazolidinedione agents
  A. Depression, weakness
  B. Anorexia
  C. Behavioral changes: confusion, disorientation
  D. Tremors and seizures from hypoglycemia
II. Biguanide agents
  A. Vomiting, diarrhea
  B. Lactic acidosis: weakness, abdominal pain, Kussmaul breathing
  C. Hypoglycemia: rare finding

Diagnosis

I. History of exposure to agents
II. Suspicious clinical signs
III. Sulfonylurea agents detected in plasma or urine

Differential Diagnosis

I. Sulfonylurea and thiazolidinedione agents: insulin overdose, insulinoma, hunting dog (exercise-related) hypoglycemia, primary hypoglycemia
II. Biguanide agents: GI irritants; diabetic ketoacidosis; uremic acidosis; toxicity associated with ingestion of aspirin, methanol, ethanol, ethylene glycol, isoniazid

Treatment and Monitoring

I. Sulfonylurea and thiazolidinedione agents
  A. Induce emesis in asymptomatic animals if ingestion occurred <30 minutes ago.
  B. Give activated charcoal 1 to 2 g/kg PO if <2 hours after exposure.
  C. Monitor blood glucose every 3 hours for 24 hours, then periodically for 72 hours, especially if chlorpropamide was ingested.
  D. Obtain baseline electrolytes.
    1. Chlorpropamide can cause hyponatremia.
    2. Repeat electrolytes in symptomatic animals.
  E. Feed frequent small meals.
  F. If hypoglycemia develops, then give 1 to 2 mL/kg of 25% dextrose IV and continue a 2.5% to 5% dextrose infusion IV until glucose returns to normal.
  G. Control tremors and seizures (see Chapter 22).
  H. Signs generally resolve within 48 hours.
II. Biguanide agents
  A. Induce vomiting if within 3 hours of exposure.
  B. Give activated charcoal 1 to 2 g/kg PO if within 6 hours of exposure.
  C. Food in the stomach decreases absorption of biguanide agents, so feed the animal.
  D. Control vomiting (as needed) in dogs with metoclopramide 0.2 to 0.4 mg/kg SC, IM TID or chlorpromazine 0.25 to 0.5 mg/kg SC, IM BID to TID.
  E. Begin IV therapy.
  F. Monitor blood gases for 48 hours if severe vomiting, diarrhea, or other clinical signs are present.
  G. Monitor electrolytes as needed.
  H. Continue treatment until clinical signs resolve, which is usually within 48 hours.

CALCIPOTRIENE

Sources

I. Synthetic Vitamin D_3 derivatives contain calcipotriene *(Dovonex),* calcipotriol *(Calcijex),* or calcitriol *(Rocaltrol).*
II. Topical agents (e.g., calcipotriene, calcipotriol) are used to treat psoriasis in humans.
III. Calcitriol is an adjunctive treatment for chronic renal disease and hypoparathyroidism in dogs and cats.
IV. Calcipotriene ointments are formulated in μg/g of product.
  A. Calcipotriene: 0.005% cream, ointment or scalp solution (50 μg/g)
  B. Tacalcitol: 0.0002% to 0.0004% ointment (2 to 4 μg/g)
V. Calcitriol is dosed in nanograms (2.5 to 3.5 ng/kg PO SID in dogs and cats).
  A. *Rocaltrol:* 0.25 and 0.5 μg capsules; 1 μg/mL in 15 mL bottles
  B. *Calcijex:* 1 μg/mL, 2 μg/mL in 1-mL ampules (injectable)

Action

I. Parathyroid hormone synthesis and secretion are suppressed.
II. Osteocalcin secretion in bone cells is stimulated.
III. Calcium (Ca) absorption is enhanced from the gut, and resorption of Ca from bones and kidneys is increased.
IV. Net result is a hypercalcemia and hyperphosphatemia.
V. ARF and soft tissue mineralization account for the clinical signs.
VI. Margin of safety is very narrow, and therapeutic doses of calcitriol have caused hypercalcemia.
VII. Any ingestion of calcipotriene or calcitriol warrants decontamination and monitoring.
VIII. Clinical signs have occurred with ingestion of calcipotriene at 10 μg/kg, and doses of 36 μg/kg have caused death.

Clinical Signs

I. Vomiting, anorexia, lethargy, depression
II. Polyuria, oliguria, anuria
III. Cardiac arrhythmias or sudden death from mineralization cardiac tissue

Diagnosis

I. History of exposure to agent
II. Compatible clinical signs
III. Supportive laboratory findings
  A. Hypercalcemia, hyperphosphatemia
  B. Elevated blood urea nitrogen (BUN), creatinine
  C. Hyposthenuria
IV. Radiography or ultrasonography: soft tissue mineralization in the kidneys and heart
V. Assays for vitamin D_3 (test for cholecalciferol rodenticides): do not detect calcipotriene in blood or tissues

Differential Diagnosis

I. Cholecalciferol rodenticide toxicity: see Chapter 124
II. Vitamin-D toxicosis
III. Hyperparathyroidism: see Chapter 43
IV. Hypercalcemia of malignancy: see Chapter 73

Treatment and Monitoring

I. Decontamination
  A. Induce emesis if <4 hours postingestion.
  B. Repeated doses of activated charcoal 1 to 2 g/kg PO TID are given for 24 hours.
II. Initial monitoring
  A. Obtain a biochemistry profile.
    1. If Ca, P, BUN, and creatinine are initially normal, then repeat the profile SID for 4 days.
    2. P tends to increase before Ca.
  B. If Ca, P, BUN, and creatinine are elevated, then begin therapy for hypercalcemia.
  C. Monitor Ca × P product; with values >60, potential exists for soft tissue mineralization.
III. Management of hypercalcemia
  A. Fluid diuresis at twice the maintenance rate using 0.9% saline IV
  B. Furosemide 2.5 to 4.5 mg/kg PO, SC, IM TID to QID
  C. Dexamethasone or prednisone 0.25 mg/kg PO, SC QID
IV. Specific antidotes
  A. Pamidronate *(Aredia)* 1.3 to 2.0 mg/kg is diluted in 0.9% saline and administered IV over a 2-hour period; this drug is preferred over salmon calcitonin.
  B. Calcitonin *(Calcimar)* 4 to 7 IU/kg SC TID may be tried.
  C. Pamidronate and calcitonin cannot be used concurrently because of the increased risk of soft tissue mineralization.
V. Aluminum hydroxide *(Amphojel)* 60 mg/kg PO TID for hyperphosphatemia
VI. After stabilization of Ca levels
  A. Wean off IV fluids while monitoring Ca, P, BUN, and creatinine SID.
  B. If BUN and creatinine remain elevated, then continue diuresis.
  C. If Ca starts to rise, then continue IV fluids and consider a second dose of pamidronate (usually within 5 to 7 days of the first dose).
  D. Gradually decrease furosemide and dexamethasone as long as animal remains asymptomatic.
  E. Monitor appetite.
  F. Monitor Ca and P SID for 5 to 7 days after values return to normal, then two to three times weekly for 2 weeks, then at 1 month postexposure.

5-FLUOROURACIL

Sources

I. Antimetabolite used to treat solar keratitis, skin cancers, and plantar warts in humans
II. Available as a cream, topical solution, or injectable
III. The most common brands
  A. *Efudex:* 5% cream or 2% solution
  B. *Fluoroplex:* 1% cream or solution

Action

I. 5-Fluorouracil destroys rapidly dividing cells.
II. It is converted to fluorocitrate, which inhibits the Krebs cycle, resulting in seizures.
III. Bone marrow stem cells can be destroyed, most likely by the metabolite FdUMP.
IV. It has a narrow margin of safety, so treat all ingestions seriously.
  A. Minimum lethal dose in dogs is 20 mg/kg PO.
  B. Trigger dose for decontamination and treatment is 8.6 mg/kg PO.

Clinical Signs

I. Dogs and cats appear to be more sensitive to the development of CNS signs (seizures, tremors) than humans.
II. Other signs listed in decreasing frequency include the following:
  A. Vomiting ± blood
  B. Lethargy
  C. Death
  D. Cardiac arrhythmias
  E. Respiratory distress
  F. Hypersalivation
  G. Cardiac arrhythmias
  H. Ataxia
  I. Disorientation
  J. Diarrhea ± blood
  K. Bone marrow suppression: if survives acute stages

Diagnosis

I. History of exposure to the agent
II. Suspicious clinical signs
III. No specific lesions or laboratory abnormalities
IV. Definitive diagnosis: difficult without history of ingestion

Differential Diagnosis

I. Other causes of hemorrhagic vomiting or seizures
II. Other toxicoses
  A. Metaldehyde
  B. Fluoroacetate
  C. Zinc phosphide
  D. Other antimetabolite agents: methotrexate, hydroxyurea, 6-mercaptopurine

Treatment and Monitoring

I. Induce emesis and give activated charcoal in asymptomatic animals, if the ingestion was within 1 hour.
II. Start GI protectants.
  A. Sucralfate
    1. Dogs: 0.5 to 1.0 g/25 kg PO BID to TID
    2. Cats: 250 to 500 mg PO BID to TID
  B. Dogs: misoprostol 1 to 3 µg/kg PO TID
  C. Dogs: metoclopramide 0.1 to 0.3 mg/kg IV for severe vomiting, but controversial because can cause additional neurologic signs
  D. Dogs: ondansetron 0.11 mg/kg IV slowly BID to QID for severe vomiting
III. Control seizures and tremors.
  A. Diazepam rarely effective
  B. Phenobarbital 3 to 30 mg/kg IV slowly
  C. Propofol 4 to 6 mg/kg IV or as continuous rate infusion at 0.1 to 0.6 mg/kg/min IV
  D. Inhalant anesthetic agents
IV. Supportive care
  A. IV fluid crystalloid therapy
  B. Thermoregulation for hyperthermia from prolonged seizures
  C. Butorphanol 0.2 to 0.4 mg/kg every 2 to 5 hours SC, IM, IV for pain
  D. Antibiotics for secondary infections
V. Filgrastim *(Neupogen)* 4 to 6 µg/kg SC SID for ≤5 days for bone marrow suppression
VI. Monitoring
  A. Obtain a baseline CBC and biochemistry profile.
  B. Repeat biochemistries SID until clinical signs resolve.
  C. Repeat CBC every 24 to 72 hours for 2 weeks.
VII. Prognosis guarded to poor if clinical signs develop

SKELETAL MUSCLE RELAXANTS

Sources

I. Numerous skeletal muscle relaxants exist, with a variety of actions and range of toxicities.
II. Baclofen *(Lioresal)* is one of the most common muscle relaxants encountered.
III. Baclofen is prescribed for the treatment of spasticity in humans with multiple sclerosis, spinal disorders, Huntington's chorea, and Parkinson's disease.

Action

I. Baclofen mimics gamma-aminobutyric acid (GABA) within the spinal cord and blocks excitatory responses to sensory input.
II. Overall effect is a flaccid paralysis of skeletal muscles.
III. It has a narrow margin of safety in most species.
  A. Clinical signs occur with ingestions as low as 1.3 mg/kg PO in dogs.
  B. Death may occur with ingestions of 8 to 16 mg/kg PO in dogs.

Clinical Signs

I. Vomiting, hypersalivation
II. Vocalizing, seizures, ataxia
III. Coma, depression
IV. Hypothermia
V. Cardiac arrhythmias
VI. Respiratory depression, apnea

Diagnosis

I. History of exposure to agent
II. Suspicious clinical signs
III. Baclofen detected in urine and serum

Differential Diagnosis

I. Barbiturates
II. Other skeletal muscle relaxants

III. Opioids
IV. Benzodiazepines
V. Botulism
VI. Ivermectin toxicosis
VII. Ionophores: monensin, lasalocid, salinomycin, narasin
VIII. Tick paralysis

Treatment and Monitoring

I. Decontamination is performed under veterinary supervision because of the potential for rapid onset of signs.
   A. Onset of action is possible 30 minutes postingestion or may be delayed for several hours.
   B. Induce emesis only with very recent ingestions in asymptomatic animals.
   C. Give activated charcoal 1 to 2 g/kg PO once; repeated doses are not beneficial.
II. Control seizures with diazepam 0.5 to 1.0 mg/kg IV slowly (see Chapter 22).
III. Maintain respiration; positive-pressure ventilation may be needed for several days in severe cases.
IV. Institute supportive care.
   A. Comatose or recumbent animals can become hypothermic.
   B. IV fluid diuresis enhances excretion of baclofen and helps maintain blood pressure.
   C. Cyproheptadine 1.1 mg/kg PO or rectally TID can be used in vocalizing dogs.
V. Clinical signs may require 3 to 4 days of treatment.
VI. Monitor serum glucose, liver enzymes, and electrolytes SID in animals with significant clinical signs.
VII. Monitor electrocardiograms and respirations until clinical signs resolve.
VIII. Prognosis is generally good if adequate ventilatory support is provided.
IX. Prognosis is guarded for animals with seizures.

CHAPTER 128

Outdoor Hazards

Sharon M. Gwaltney-Brant

ANTIFREEZE

Sources

I. Antifreeze is most commonly formulated from ethylene glycol (EG), propylene glycol (PG), or methanol.
   A. EG is also present in brake fluid, photographic developing fluid, windshield deicer, ink, paint, industrial solvent and wood stains.
   B. PG is also found in a variety of food and pharmaceutical preparations, hydraulic fluid, cosmetics, and industrial solvents.
   C. Methanol is present in windshield washer fluid, as well as gasoline antifreezes.
II. Other ingredients that may be found in antifreezes include diethylene glycol, dipotassium phosphate, corrosion inhibitors, silicates, antifoaming agents, surfactants, dyes, and fragrances, but these compounds are generally present in low concentrations, are of relatively low toxicity, and are not clinically significant.

Action

I. EG, methanol, and PG produce inebriation and narcosis from the alcohol parent compound and aldehyde metabolic products.
II. EG, methanol, and PG are further metabolized to glycolic acid, formic acid, and lactic acid, respectively, which contribute to metabolic acidosis.
III. EG is further metabolized to oxalic acid, which binds with serum calcium to form calcium oxalate crystals in the kidney.
   A. Hypocalcemia and renal insufficiency result from the formation of calcium oxalate crystals.
   B. Rarely, calcium oxalate crystals may precipitate within the meningeal vessels of the central nervous system (CNS), resulting in profound and permanent CNS derangement.
IV. In cats, PG induces Heinz-body anemia by an unknown mechanism.

Clinical Signs

I. Signs from ingestion of EG, methanol, and PG occur within 40 to 60 minutes of exposure and include CNS depression, ataxia, vomiting, polyuria, and behavior changes (inebriation).
II. Ingestion of large amounts may cause severe CNS depression, coma, seizures, hypothermia, and severe acidosis.
III. Death is possible from hypoglycemia, respiratory depression, or aspiration.
IV. Signs generally improve over approximately 12 hours.
   A. With methanol and PG exposure, full recovery occurs in most cases.
   B. With EG, dogs may appear to have recovered for a short while.
   C. With EG, cats usually remain depressed.
V. With EG, severe acidosis occurs 4 to 6 hours after ingestion and results in tachypnea, vomiting, hypothermia, miosis, and profound depression.
   A. Cardiac arrhythmias, muscle fasciculations, and coma may develop.
   B. With EG, oliguric renal failure develops 12 to 36 hours after ingestion.
   C. Anorexia, vomiting, hypersalivation, lethargy, oral ulceration, oliguria, and anuria may occur.

Diagnosis

I. History of exposure to product
II. Consistent clinical signs
III. Ethylene glycol
   A. Ethylene glycol test
      1. Commercial kits detect levels ≥50 mg/dL and are reliable for dogs.
         a. Cats can develop toxicosis at <50 mg/dL, so false negatives are possible.
         b. False positives can occur if formaldehyde, metaldehyde, propylene glycol, glycerol, or diethylene glycol are present in the blood.
         c. Some commercial activated charcoal preparations contain PG or glycerol and cause false-positive results.
         d. Some injectable drugs (diazepam) contain PG.
         e. Methanol, ethanol, isopropanol, and fomepizole do not cause false positives.
      2. Laboratories in human hospitals can often run quantitative tests for EG on an urgent basis.
         a. These tests are specific for EG and there are no false positives if PG, metaldehyde, etc. are present.
         b. For dogs, levels >50 mg/dL are significant.
         c. For cats, any detectable level is significant.

B. Clinical laboratory results
   1. Early (within 12 hours) in clinical course
      a. Increased serum osmolality, metabolic acidosis, and decreased plasma bicarbonate may be found.
      b. Anion gap is high by 3 hours after ingestion, peaks at 6 hours, and remains increased for up to 48 hours.
      c. Hyperkalemia may be associated with acidosis.
      d. Hypocalcemia may be detected.
      e. Urine is usually isosthenuric.
      f. Calcium oxalate crystalluria occurs within 3 hours in cats and 4 to 6 hours in dogs.
      g. Absence of crystalluria does not rule out EG exposure.
   2. Late (24 to 72 hours) in clinical course
      a. Increased serum blood urea nitrogen (BUN) and serum creatinine occur.
      b. In cats, BUN and creatinine become elevated as early as 12 hours.
      c. Hyperkalemia may be associated with renal insufficiency.

C. Fluorescence testing
   1. Some antifreezes contain sodium fluorescein, which fluoresces if EG is present in vomitus or urine.
   2. Absence of fluorescence in urine or vomitus does not rule out the possibility of exposure.

D. Ultrasonography of the kidneys
   1. A "halo sign," an increase in cortical and medullar echogenicity with hypoechoic corticomedullary and central medullary regions, is highly suggestive of EG toxicosis.
   2. The presence of a halo sign indicates the presence of calcium oxalate crystals and warrants a grave prognosis.

E. Histopathology of kidneys
   1. Renal tubular degeneration and necrosis associated with calcium oxalate crystals
   2. Possible identification of calcium oxalate crystals under polarized light

IV. Propylene glycol
   A. Increased serum osmolality can occur with intravenously administered PG.
   B. No specific confirmatory tests are available that will provide timely results.

V. Methanol: serum methanol levels measured by some human hospitals

Differential Diagnosis

I. CNS effects of early methanol, PG, EG
   A. Other alcohol ingestion: ethanol, dipropylene glycol
   B. Marijuana toxicosis
   C. Ivermectin toxicosis
   D. Psychogenic drugs: tranquilizers, sedatives, antidepressants, etc.

II. Increased anion gap in EG: diabetic ketoacidosis, lactic acidosis (PG toxicosis)

III. Increased osmolality in EG: alcohol toxicosis

IV. Acute renal failure in EG
   A. Leptospirosis
   B. Nonsteroidal antiinflammatory drug toxicosis
   C. Grape or raisin toxicosis
   D. Lily toxicosis (cats)
   E. Cholecalciferol toxicosis
   F. Aminoglycoside toxicosis
   G. Hemolytic uremic syndrome

Treatment and Monitoring

I. Prevention of absorption
   A. Because of the rapid absorption and onset of signs following methanol, EG, and PG ingestion, oral decontamination must be done soon after exposure (within 20 to 40 minutes).
   B. Emesis may be induced in animals without severe neurologic signs.
   C. Apomorphine must be used with care as it may enhance CNS depression.
   D. Activated charcoal binds poorly with EG, methanol, and PG, and the risks of aspiration of charcoal may outweigh its benefits in this instance.

II. Management of alcohol toxicosis (inebriation, acidosis)
   A. Fluid diuresis with IV crystalloid solutions at two to three times maintenance promotes excretion of the parent alcohol.
   B. Acid-base and electrolyte abnormalities are corrected as needed.
      1. Sodium bicarbonate is administered according to the base deficit of the animal.
      2. For EG, correction of hypocalcemia with calcium gluconate or calcium chloride is indicated.
   C. Hypothermia or hyperthermia is managed as needed.
   D. For profoundly comatose animals, yohimbine 0.1 mg/kg IV has been successfully used as a general CNS stimulant.
   E. Monitor respiration, body temperature, heart rate and rhythm, hydration, and urine production carefully.
   F. For PG and methanol, general supportive care usually results in full recovery, with no residual adverse effects.

III. Prevention of calcium oxalate formation and renal failure in EG intoxication.
   A. Goal is to inhibit the metabolism of EG to its toxic metabolites, allowing excretion of the parent compound in urine via fluid diuresis.
   B. Dogs may be given fomepizole *(Antizol-Vet)* 20 mg/kg IV as a loading dose, followed by 15 mg/kg IV 12 and 24 hours later, and 5 mg/kg IV at 36 hours.
      1. Fomepizole inhibits alcohol dehydrogenase, reducing the amount of EG that is metabolized.
      2. Fomepizole is the treatment of choice for EG toxicosis in dogs.
   C. If fomepizole is unavailable, ethanol may be given to dogs, as described for the cat.
   D. Experimental studies have indicated there is a narrow window of opportunity (3 to 4 hours after ingestion) to successfully treat cats that have been exposed to EG.
      1. Ethanol (grade alcohol)

a. Constant rate infusion (CRI) is preferred over IV boluses to avoid fluctuations in CNS depression and acidosis.
b. Give 30% ethanol 1.3 mL/kg IV as a loading dose, followed by 0.42 mL/kg/hr IV as a CRI for 48 hours.
c. Boluses of 20% ethanol 5.5 mL/kg IV every 4 hours for five treatments, then QID for 4 treatments may also be used.
d. Ethanol contributes to acidosis, so monitor blood gases closely and use bicarbonate to manage any base deficits.
e. Ethanol competes with EG as a substrate for alcohol dehydrogenase, so it slows the metabolism of EG.

2. Fomepizole
a. Fomepizole is not approved for use in cats.
b. Give a loading dose of 125 mg/kg IV, followed by 31.25 mg/kg IV at 12, 24, and 36 hours.
c. All cats given lethal doses of EG and treated with fomepizole survived, compared with one third of cats treated with boluses of ethanol (Thrall et al., 2006).
d. One fomepizole-treated cat developed acute renal failure that was successfully treated with prolonged IV therapy (Thrall et al., 2006).

IV. Management of acute renal failure (see also Chapter 48)
A. Start IV fluid diuresis with crystalloid solutions at two times maintenance, or as needed to maintain hydration.
B. Antiemetics such as metoclopramide may be helpful.
1. Dogs: 0.1 to 0.4 mg/kg PO, SC, IM QID or 1 to 2 mg/kg/day IV as a CRI
2. Cats: 0.2 to 0.4 mg/kg PO, SC TID to QID or 1 to 2 mg/kg/day IV as a CRI
C. Consider diuresis with mannitol 0.25 to 0.5 g/kg IV over 15 to 20 minutes every 4 to 6 hours.
D. Peritoneal dialysis or hemodialysis has been used successfully in EG-intoxicated cats and dogs.
E. Renal transplantation may be considered in severe cases of chronic renal failure in stabilized animals.

HERBICIDES

Sources

I. Herbicides are commonly used for lawn care and agricultural purposes.
A. Agricultural formulations are more concentrated than residential products.
B. Table 128-1 summarizes several of the most commonly used herbicides in the United States.
II. With many of the modern herbicides, the solvents and surfactants in the products may account for most of their toxicity when compared with the active ingredients.

Action

I. Mechanisms vary with the specific herbicides (see Table 128-1).
II. The majority of the signs are secondary to the gastrointestinal (GI) irritation caused by the inert ingredients ("carriers").
III. Once liquid herbicides have dried on the plant, the likelihood of significant exposure to the animal is minimized, as most modern herbicides are internalized and translocated to plant roots.
IV. Paraquat is a vesicant that causes corrosive injury to alimentary tissues, skin, and corneas.
A. GI hemorrhage and perforation are possible.
B. Paraquat is readily absorbed, distributes widely in the body, and concentrates in the lung.
C. Paraquat undergoes cyclic oxidation-reduction reactions, resulting in the formation of oxygen-derived free radicals.
1. The high oxygen content of the lung provides ample substrate for free radical production.
2. Lipid peroxidation, inactivation of enzymes, DNA injury and damage to cell membranes result in cell necrosis, inflammation, and eventual fibrosis.
3. Regeneration of paraquat during the oxidation-reduction cycles results in further free-radical production.
4. Treatment with pure oxygen provides more fuel for the development of free radicals and accelerates the process.
D. Renal and hepatic injury develops from free-radical production in these tissues.

Clinical Signs

I. Expected clinical signs after exposure to major herbicides are summarized in Table 128-1.
II. Most signs are mild and self-limiting, and systemic toxicosis is not usually expected.
III. Paraquat may cause oral, esophageal, GI, dermal, or ocular irritation or ulceration.
A. Vomiting, diarrhea, abdominal pain
B. Polyuria, dehydration, azotemia in 48 to 72 hours as renal failure develops
C. Dyspnea from pulmonary edema (early) and pulmonary fibrosis (late), possibly leading to death
D. More insidious onset of pulmonary dysfunction with low levels of exposure

Diagnosis

I. History of exposure
II. Clinical signs, especially progressive pulmonary dysfunction
III. Measurement of plasma paraquat concentrations
IV. Measurement of urine paraquat levels up to 48 hours after ingestion
V. Necropsy samples
A. Histopathologic examination of the lungs reveals necrosis and fibrosis.
B. Lung, liver, and kidney can be analyzed for the presence of paraquat.

TABLE 128-1

Toxicological Features of Commonly Used Herbicides

HERBICIDE	USAGE	TOXICITY	MECHANISM OF ACTION	CLINICAL EFFECTS
2,4-D (2-chloro-4-phenoxyacetic acid) MCPA (4-chloro-2-methylphenoxyacetic acid) MCPP (2-methyl-4-chlorophenoxypropanoic acid)	Broadleaf herbicides Used on lawns and commercial properties 2,4-D is the most commonly used herbicide in United States Residues on treated grass: 25-75 ppm; rapidly dissipate after several days MCPA and MCPP are rarely used alone and are often combined with 2,4-D.	Severe toxicosis is unlikely from dilute products applied for residential use Rare systemic toxicities are related to ingestion of concentrates by dogs Dogs are more susceptible owing to poor excretion of organic acids No observable effects occurred from 2,4-D at oral doses of 1-20 mg/kg in dogs or from MCPA 1 mg/kg, and 6 ppm in diet for 1 year	Direct GI irritation Decreased chloride conductance in myocytes	Small exposures: vomiting Larger exposures: vomiting, diarrhea Massive exposures (rare): depression, ataxia, skeletal muscle rigidity (myotonia), mild tremors, spasticity, opisthotonos, anorexia, alimentary tract ulcers (may be related to carriers) CNS depression and coma in lethal exposures (very rare)
Glyphosate (N-[phosphonomethyl] glycine)	Nonselective herbicide Second most widely used herbicide in the United States Residues on grass following application = 1-100 ppm	Very wide margin of safety in animals Toxicity is related to surfactant carriers that can comprise up to 15% of formulated products.	Direct GI irritation from surfactants	Hypersalivation, vomiting, diarrhea, anorexia, lethargy Fluid and electrolyte abnormalities with protracted vomiting and/or diarrhea
Diquat (1,1′-ethylene-4,4′bipyridylium dibromide)	Dipyridyl herbicide related to paraquat Nonselective desiccant herbicide	Poor absorption No sequestration in lungs (unlike paraquat) Low concentrations in formulated products Systemic toxicosis unlikely	Can form free radicals and cause tissue necrosis Target organs are GI tract, liver, kidneys. GI irritation from carriers possible	Hypersalivation, vomiting, diarrhea, anorexia, lethargy Fluid and electrolyte abnormalities with protracted vomiting and/or diarrhea Massive exposures (very rare): corrosive oral injury, myocardial necrosis, seizures, coma, renal injury, hepatic injury
Dicamba (3,6-dichloro-2-methoxybenzoic acid)	Post-emergent broadleaf herbicide Often used in combination with other herbicides, such as 2,4-D and MCPP	Very low toxicity in mammals No observable effects at 50 ppm in daily diet for 2 years (dogs)	GI irritation from surfactant carriers	Hypersalivation, vomiting, diarrhea, anorexia, lethargy Fluid and electrolyte abnormalities with protracted vomiting and/or diarrhea
Pendimethalin (N-[1-ethylpropyl]-3,4-dimethyl-2,6-dinitrobenzeneamine) Prodiamine (2,6-dinitroaniline)	Most widely used pre-emergent herbicide in residential areas	Very low toxicity in mammals No observable effects at 2.5 mg/kg/day for 2 years (dogs)	GI irritation from surfactant carriers Pendimethalin: dye can stain hair coats	Hypersalivation, vomiting, diarrhea, anorexia, lethargy Fluid and electrolyte abnormalities with protracted vomiting and/or diarrhea Orange-yellow discoloration of haircoats Prodiamine: similar to pendimethalin but less likely to stain haircoats

GI, Gastrointestinal; *CNS*, central nervous system.

Differential Diagnosis

I. Paraquat
   A. Other causes of GI injury: other corrosives (alkalis, acids, etc.), uremic stomatitis, thallium toxicosis
   B. Other causes of renal failure
II. For 2,4-D in dogs, other causes of myositis, myopathy: myasthenia gravis, macadamia nut toxicosis, sewage-sludge fertilizer *(Milorganite)* exposure, etc.
III. Other herbicides: other causes of GI upset

Treatment and Monitoring

I. Paraquat
   A. Aggressive treatment is required as quickly as possible after exposure.
   B. Decontamination is undertaken.
      1. Because of its corrosive nature, induction of emesis is not recommended.
      2. Gastric lavage is performed under anesthesia, using a cuffed endotracheal tube.
      3. Activated charcoal is effective at adsorbing paraquat.
      4. Bathe off dermal exposures with liquid dishwashing detergent.
   C. IV fluids are used for general support, and forced diuresis with IV crystalloids and furosemide (2 mg/kg IV) may enhance elimination.
   D. Charcoal hemoperfusion using a Hemocol cartridge (113 to 156 mL/min IV) improves the chance of survival.
   E. GI protectants are indicated in most cases.
      1. Slurries of sucralfate 0.25 to 1 g PO TID (dogs)
      2. Famotidine 10 to 20 mg PO SID (or other acid reducers)
   F. Supportive care is required.
      1. Oxygen supplementation is contraindicated, as it hastens pulmonary injury.
      2. Pain medication may be required.
         a. Buprenorphine
            (1) Dogs: 0.005 to 0.02 mg/kg IM, IV, SC BID to QID
            (2) Cats: 0.005 to 0.01 mg/kg IM, IV, SC BID to QID
         b. Fentanyl patch
            (1) Dogs <10 kg, cats: 25 µg/hr
            (2) Dogs 10 to 20 kg: 50 µg/hr
            (3) Dogs 20 to 30 kg: 75 µg/hr
            (4) Dogs >30 kg: 100 µg/hr
      3. Manage renal insufficiency.
      4. Institute topical management of dermal or ocular injury.
   G. Monitor cardiovascular function, serum renal and hepatic values, hematologic parameters, and acid-base status.
II. Myotonia from 2,4-D
   A. Forced alkaline diuresis with sodium bicarbonate (1 to 2 mEq/kg) per liter of crystalloid solutions may enhance elimination (Osweiler, 1996).
   B. Most cases resolve within 24 hours with no residual effects.
III. GI upset from most herbicides
   A. Most cases are self-limiting and resolve without specific treatment.
   B. Withholding food and water for a few hours is often helpful.
   C. For protracted vomiting, antiemetics (chlorpromazine 0.5 mg/kg IV, IM, SC TID to QID) may be used.
IV. Dermal decontamination
   A. Wash with liquid dishwashing detergent.
   B. For haircoats stained from pendimethalin, use waterless hand cleaners (e.g., *GOJO*) on affected area, followed by shampoo and rinse.

HYDROCARBONS

Sources

I. Hydrocarbons encompass a huge array of vastly different products, ranging from those of high volatility (gasoline) to those of very low volatility (waxes).
II. The relative toxicity of hydrocarbons is related to their volatility, with toxicity increasing as the agent becomes more volatile.
   A. Low-volatility hydrocarbons (waxes, petroleum jelly, mineral oil, etc.) are of very low toxicity.
   B. High-volatility hydrocarbons (e.g., propane, gasoline, kerosene, diesel oil) have more potential to cause toxicity.
   C. Recently, some shoe and boot waterproofing sprays containing a variety of hydrocarbons, including hexane, have caused acute respiratory distress syndrome in pets.
III. Hydrocarbon products are found in motor vehicle fuels, as lubricants, and as solvents for paints, pesticides, and medications.
IV. Exposure of pets to hydrocarbons frequently occurs in or around the garage area.

Action

I. Hydrocarbons are irritants, and the primary toxic effect is irritation.
II. Contact of highly volatile hydrocarbons with the skin of dogs and cats may result in dissolution of dermal lipids, localized dermatitis, and chemical burns.
III. Ingestion of highly volatile hydrocarbons frequently results in immediate vomiting.
IV. The primary life-threatening effect from hydrocarbons is aspiration pneumonia, particularly with hydrocarbons of high volatility (gasoline, kerosene, lighter fluid).
V. Inhalation of highly volatile hydrocarbon fumes can result in CNS depression from a direct physicochemical interaction with neuronal membranes.
VI. Renal and hepatic injury after hydrocarbon exposure is rare and may arise from formation of toxic metabolites.
VII. Some hydrocarbons can sensitize the myocardium to endogenous catecholamines, resulting in arrhythmias.

Clinical Signs

I. Signs of oral irritation: hypersalivation, pawing at muzzle
II. Vomiting, retching

III. Gagging, coughing, dyspnea, and cyanosis if aspiration has occurred
IV. Acute respiratory distress within minutes after exposure to aerosolized waterproofing sprays for boots and shoes
V. Abdominal pain, diarrhea
   A. Ingestion of heavier oils (e.g., lamp oil, motor oil) may be followed by oily diarrhea within a few hours and is often associated with fecal incontinence.
   B. Cramping from rapid movement of oily compounds through the GI tract may manifest as abdominal pain.
VI. CNS depression, ataxia, behavioral changes after exposure to high concentrations of highly volatile hydrocarbon fumes
   A. Signs occur within minutes of exposure and resemble ethanol intoxication.
   B. Cardiac arrhythmias may also occur.
VII. Local erythema, irritation or ulceration at the site of dermal exposure

Diagnosis

I. History of exposure
II. Characteristic hydrocarbon odor to vomitus, breath, skin
III. Mixing vomitus with water: hydrocarbons floating to the surface
IV. Radiography of lungs
   A. May reveal fine perihilar densities and extensive infiltrates in ventral lung fields
   B. May have delayed onset up to 12 hours
   C. Progression of radiographic abnormalities during first 3 to 4 days, then gradual clearing

Differential Diagnosis

I. Respiratory signs: other causes of pneumonia and pneumonitis (e.g., infectious, toxic)
II. GI signs: other causes of GI irritation (e.g., infectious, dietary indiscretion)
III. Dermal signs: other chemical burns, dermatitis, demodicosis, etc.

Treatment

I. Therapy for aspiration
   A. Supplemental oxygen, mechanical ventilation
      1. Positive-pressure ventilation must be used with care because of the potential for pneumomediastinum and pneumothorax.
      2. Closed ventilation systems must be purged frequently, as the lungs are a primary route of hydrocarbon elimination.
   B. Cage rest
   C. Prophylactic antibiotics controversial
   D. Corticosteroids contraindicated
II. Decontamination
   A. Because of the risk of aspiration, decontamination of oral hydrocarbon exposure by induction of emesis is contraindicated.
   B. If gastric decontamination is necessary, gastric lavage may be performed.
   C. Bathing with warm water and a liquid dishwashing detergent are helpful for dermal exposures.
   D. Institute topical treatment of chemical burns (see Chapter 134).

TREMOROGENIC MYCOTOXINS

Sources

I. Several hundred toxins produced by several *Penicillium* spp. have been identified.
II. Penitrem A and roquefortine are the mycotoxins most commonly associated with toxicosis in pets (notably dogs).
III. Ingestion of moldy foods, compost, carcasses, and other decaying organic material is the most common source of exposure.

Action

I. The exact mechanism is unknown.
II. It is thought to involve inhibition of inhibitory CNS neurotransmitters, particularly glycine.

Clinical Signs

I. Signs begin within 30 minutes to several hours of ingestion.
II. Early signs include restlessness, hypersalivation, panting, and mild to moderate muscle tremors.
III. Later signs include severe tremors, hyperesthesia, seizures, hyperthermia, dehydration, metabolic acidosis, rhabdomyolysis, coma, and death.

Diagnosis

I. History of potential exposure is helpful.
II. Compatible clinical signs are supportive.
III. Analysis of suspect feed, gastric contents, and vomitus can confirm presence of penitrem A or roquefortine.
IV. Turnaround time limits usefulness of these analyses in acute situations.

Differential Diagnosis

I. Strychnine
II. Metaldehyde
III. Methylxanthines
IV. Anticholinesterase insecticides
V. Pyrethroids
VI. Organochlorine insecticides
VII. Nicotine
VIII. *Brunsfelsia* spp.: yesterday-today-tomorrow plant, lady of the night plant, kiss-me-quick plant

Treatment

I. Control tremor and seizures.
   A. Diazepam 0.5 to 2 mg/kg IV to effect for seizures and hyperesthesia
   B. Methocarbamol 50 to 220 mg/kg IV slowly (maximum 330 mg/kg/day) for tremors
   C. Phenobarbital 3 mg/kg IV to effect, if unresponsive to diazepam and methocarbamol
II. Minimize intake.
   A. Emesis in asymptomatic animals

B. Sedation/anesthesia and gastric lavage in symptomatic animals
C. Activated charcoal with a cathartic

III. Provide supportive care.
A. Intravenous fluid therapy with crystalloids
B. Management of hyperthermia as needed
C. Correction of electrolyte and acid-base disorders, as needed

CHAPTER 129

Illicit Human Drugs

Camilla Lieske | Petra A. Volmer

DEPRESSANTS

Barbiturates

Sources

I. Sources include the following:
   A. Amobarbital *(Amytal),* aprobarbital *(Alurate)*
   B. Butabarbital *(Busodium, Butalan, Butisol)*
   C. Mephobarbital *(Mebaral)*
   D. Pentobarbital *(Nembutal),* phenobarbital *(Solfoton, Luminal, Barbita)*
   E. Secobarbital *(Seconal)*
II. They are classified by their onset and duration of action.
   A. Short-acting drugs (pentobarbital, secobarbital) have an onset of 10 to 15 minutes and a duration of 3 to 4 hours.
   B. Intermediate-acting drugs (amobarbital, aprobarbital, butabarbital) have an onset of 45 to 60 minutes and a duration of 6 to 8 hours.
   C. Long-acting drugs (mephobarbital, phenobarbital) have an onset of 1 hour and a duration of 10 to 12 hours.
III. Forms include capsules, tablets, liquid, and suppositories.
IV. Street names are barbs, downers, red devils, goof balls, yellow jackets, block busters, pinks, reds and blues, and Christmas trees.
V. Secondary toxicosis can occur via ingestion of the carcass of an animal euthanized with pentobarbital.

Action

I. The principal effect of barbiturates is depression of the central nervous system (CNS) through interference with impulses to the cerebral cortex.
   A. Activation of inhibitory gamma-aminobutyric acid (GABA) receptors
   B. Inhibition of the excitatory glutamate receptors
II. The oral median lethal dose (LD_{50}) for phenobarbital in dogs is 150 mg/kg.
III. The minimum oral lethal dose of phenobarbital in cats is 125 mg/kg.
IV. Coma can occur with doses of 50 to 100 mg/kg PO (long-acting barbiturates).
V. These drugs may interact with other drugs.
   A. Accelerate clearance of certain drugs by increasing cytochrome p450 levels
   B. Additive effect with other compounds causing sedation
   C. Potentiate respiratory depression from tricyclic antidepressants
   D. Prolong effects of monoamine oxidase (MAO) inhibitors

Clinical Signs

I. Common signs: CNS depression, ataxia, incoordination, weakness, disorientation, dilated pupils
II. Possible signs with severe intoxication: respiratory depression, recumbency, coma, hypothermia, death
III. Excitement in some animals
IV. Tachycardia or bradycardia
V. Possible hepatotoxicity with chronic ingestion

Diagnosis

I. History of exposure and compatible clinical signs
II. Barbiturates detected in stomach contents, blood, urine, or feces

Differential Diagnosis

I. Other CNS depressants: alcohols (ethanol, methanol), opioids, benzodiazepines, phenothiazines, marijuana, ethylene glycol, muscle relaxants (baclofen), avermectins (especially ivermectin), amitraz
II. Other systemic conditions: hypoglycemia, hypotension

Treatment and Monitoring

I. Induce emesis if exposure was recent and the animal is asymptomatic.
II. Gastric lavage can be considered if emesis is contraindicated and the dose is >50 mg/kg.
III. Activated charcoal can decrease the duration of clinical effects.
   A. Repeated doses of activated charcoal (1 to 2 g/kg PO BID to TID) with a cathartic must be administered carefully to prevent aspiration.
   B. Magnesium-containing cathartics are avoided because excess magnesium may be absorbed.
IV. IV fluids are given for hypotension, and positive-pressure ventilation or oxygen supplementation may be need for respiratory abnormalities.
V. Alkaline diuresis may promote elimination in the urine (only recommended for long-acting barbiturates).

VI. Monitor liver enzymes with chronic ingestions or in animals with pre-existing hepatic dysfunction.
VII. Prognosis is good in acute ingestions if adequate cardiovascular and ventilatory support is provided.

Benzodiazepines

Sources

I. Benzodiazepines are prescription antianxiety, anticonvulsant, sedative drugs that are Schedule IV controlled substances.
II. Most have an "-azepam" or "-zolam" suffix.
   A. Examples: lorazepam *(Ativan),* clorazepate *(Tranxene),* prazepam *(Centrax),* clonazepam *(Klonopin),* flurazepam *(Dalmane),* triazolam *(Halcion),* chlordiazepoxide *(Librium),* halazepam *(Paxipam),* temazepam *(Restoril),* oxazepam *(Serax),* diazepam *(Valium),* alprazolam *(Xanax)*
   B. Flunitrazepam *(Rohypnol):* frequently used as a "date-rape" drug; not legal in the United States
III. Street names include downers, V *(Valium),* rophies, roofies, roach, and rope *(Rohypnol).*

Action

I. They bind to benzodiazepine receptors in the CNS, kidneys, liver, heart, and lungs, with potentiation of the GABA response.
II. They are rapidly and well absorbed orally.
III. These drugs are metabolized in the liver, conjugated with glucuronide, and eliminated in urine.
   A. In dogs, diazepam has a half-life of 2.4 hours, and its active metabolite (nordiazepam) has a half-life of 2.85 hours.
   B. In cats, the half-life of diazepam is 5.46 hours and of nordiazepam it is 21.3 hours.
IV. A wide margin of safety exists between symptomatic and lethal doses.

Clinical Signs

I. Low doses: ataxia, CNS depression
II. High doses: tremors, seizures
III. Possible hypothermia
IV. Vocalization, anxiety, excitation possible at therapeutic dosages

Diagnosis

I. Suspicious history and clinical signs
II. Benzodiazepines (or metabolites) identified in urine or blood

Differential Diagnosis

I. Other CNS depressants: alcohols (ethanol, methanol), opioids, barbiturates, phenothiazines, marijuana; ethylene glycol, muscle relaxants (e.g., baclofen), avermectins (especially ivermectin), amitraz
II. Other systemic conditions: hypoglycemia, hypotension

Treatment

I. Ingestion of low doses (<20 mg/kg diazepam PO in a healthy dog) requires monitoring and protection of the animal from injury (e.g., falling down stairs, off furniture).
II. Decontamination may be effective, especially with large exposures.
III. Low doses of acepromazine may effectively calm animals exhibiting excitation.
IV. Flumazenil *(Romazicon)* is an antidote (competitive blocker) that can be administered if signs are severe.
   A. Dose is 0.1 mg/kg IV in dogs and cats.
   B. Use with care in animals that are prone to seizures, because it may exacerbate seizures.
V. Institute symptomatic and supportive care for cardiovascular abnormalities, hypothermia, etc.

Gamma Hydroxybutyrate

Sources

I. Gamma hydroxybutyrate (GHB) is a naturally occurring CNS depressant that is structurally related to GABA and was developed as an anesthetic agent.
II. Sodium oxybate *(Xyrem)* has limited legal use in the United States as a sleep aid.
III. It is produced as clear liquid, white powder, tablet, and capsule.
IV. GHB may be illicitly manufactured from gamma-butyrolactone (GBL) and 1,4-butanediol (BD); the latter is found in acetone-free nail polish remover, paint strippers, and adhesives.
V. Street names include G, grievous bodily harm, Georgia home boy, liquid ecstasy, liquid x, scoop, and goop.

Action

I. Structurally related to GABA
   A. Acts as an inhibitory neurotransmitter on dopaminergic neurons
   B. Reduces dopaminergic activity
   C. Stimulates dopamine production
II. Rapidly absorbed
   A. Onset of signs is within 10 to 30 minutes.
   B. Signs may last 6 to 12 hours.
III. GBL and BD are both metabolized to GHB (in humans).
IV. Animal poisonings are not commonly reported.

Clinical Signs

I. Vomiting
II. Muscle weakness, depression
III. Bradycardia, respiratory depression

Diagnosis

History of exposure and compatible clinical signs

Differential Diagnosis

I. Other CNS depressants: see discussion under Barbiturates
II. Other systemic conditions: hypoglycemia, hypotension

Treatment

I. Emesis is not recommended owing to the rapid onset of signs and the risk of aspiration.
II. Activated charcoal (1 to 2 g/kg PO) may be beneficial.
III. Atropine (0.02 to 0.04 mg/kg IV, IM, SC) is indicated for bradycardia.
IV. Some animals may require ventilatory support.

Marijuana *(Cannabis sativa)*

Sources

I. The entire plant is toxic and generally available in three forms.
   A. Dried herb: composed of top leaves and buds
   B. Resin (hash or hashish): extracted from the buds and flower heads
   C. Sticky liquid (hash oil): prepared from the resin
II. Cannabinoids, such as dronabinol *(Marinol)* and nabilone *(Cesamet)* are prescribed in humans as antiemetics for chemotherapy patients and to decrease intraocular pressure with glaucoma.
III. Marijuana extract *(Sativex)* is used to treat multiple sclerosis in Europe and Canada.
IV. Street names include hemp, pot, grass, Mary Jane, sinsemilla, hash, hashish (may contain other drugs), Bhang, Ganja, charas, Thai stick, reefer, and wacky-backy.

Action

I. Δ-9-Tetrahydro-cannabinol (THC) is considered the primary toxic resin, although other compounds are present.
II. THC activates cannabinoid receptors in the cerebrum and causes the brain to misinterpret nerve impulses from the different sense organs.
III. THC interacts with neurotransmitters and neuromodulators to stimulate dopamine release and enhances GABA turnover.
IV. THC is metabolized by the liver, excreted in bile, and enterohepatic recirculation occurs.
V. Because it is lipid soluble, it has a long half-life.
VI. Behavioral effects are seen with THC doses of approximately 3 mg/kg PO in dogs.
VII. Lethal dose has not been established; dosages of 3 to 9 g/kg PO have not been lethal in dogs.

Clinical Signs

I. THC has biphasic clinical signs, with euphoria followed by depression.
II. Signs include nervousness and disorientation progressing to depression that may last for 18 to 72 hours.
III. Mydriasis, nystagmus, ataxia, and recumbency have been described.
IV. Vomiting, diarrhea, tremors, and respiratory difficulty can occur.
V. Usually bradycardia occurs, although occasionally tachycardia develops.
VI. Hypothermia may also occur.
VII. Exposure is rarely fatal, although death is possible in severe cases.

Diagnosis

I. History of exposure and compatible clinical signs are suggestive.
II. Marijuana may be identified in urine, but time from ingestion, concurrent water consumption, and the amount ingested can complicate the diagnosis.

Differential Diagnosis

I. Other CNS depressants: see discussion under Barbiturates
II. Other systemic conditions: hypoglycemia, hypotension

Treatment and Monitoring

I. Decontamination (emesis, activated charcoal) is indicated, especially with large exposures.
   A. Effectiveness of emesis may be limited owing to the antiemetic properties of cannabis.
   B. Repeated doses of activated charcoal (cathartic with first dose) can hasten recovery time.
      1. Give an initial loading dose of 1 to 2 g/kg followed by 0.5 to 1.0 g/kg PO TID for 24 hours in symptomatic animals.
      2. Use caution with administration to recumbent animals because of the risk of aspiration.
II. With ingestion of low doses, protect the animal from injury (e.g., falling down stairs, off furniture).
III. Diazepam may be effective in animals with excitation.
IV. In nearly all cases, effects wear off with little or no permanent damage.

OPIOIDS

Sources

I. Opioids are CNS drugs originally derived from the poppy plant *(Papaver somniferum)*.
II. They are classified by their activity at different opioid receptors.
   A. Agonists: apomorphine, hydromorphone, codeine, meperidine, fentanyl, methadone, morphine, oxycodone, hydrocodone, oxymorphone
   B. Partial agonists: buprenorphine, butorphanol
   C. Antagonists: naloxone, naltrexone
III. Street names include the following:
   A. Morphine: M, morph, Miss Emma
   B. Heroin: smack, skag, hammer, H, horse, rock, white, slow, Harry cone, China white
   C. Codeine: T-threes, schoolboy
   D. Methadone: dollies
   E. Hydromorphone: dillies

Action

I. Opioid receptors are present in the CNS, gastrointestinal (GI) tract, heart, kidneys, vas deferens, pancreas, fat cells, lymphocytes, and adrenal glands.
II. The mu receptor is the most important therapeutic opioid receptor.
   A. Mu_1 is associated with analgesia.
   B. Mu_2 is associated with respiratory depression.

III. Opioids are well absorbed from the GI tract.
IV. Peak plasma levels depend on the individual compound, but in general are as follows:
  A. When given IV: 5 minutes
  B. When given IM: 10 minutes
  C. When taken PO: 1 to 2 hours
V. They are metabolized in the liver, undergo enterohepatic recirculation, and are conjugated with glucuronic acid (which may account for the sensitivity of cats to them).
VI. Toxic doses are as follows:
  A. Morphine
    1. Minimum lethal doses: 210 mg/kg SC (dogs) and 40 mg/kg SC (cats)
    2. LD_{50} in dogs: 133 mg/kg IV
  B. Heroin minimum lethal doses: 25 mg/kg SC (dogs) and 20 mg/kg PO (cats)
  C. Codeine LD_{50} in dogs: 69 mg/kg IV

Clinical Signs

I. Common signs: vomiting, hypersalivation, ataxia, depression, miosis
II. Bradycardia or tachycardia
III. Severe cases: respiratory depression, hypothermia, tremors, seizures, coma
IV. Possible vocalizing
V. Excitation in some cats

Diagnosis

I. History of exposure and compatible clinical signs are suggestive.
II. If no improvement occurs after one or two doses of naloxone, reconsider the diagnosis.
III. Morphine can be detected in urine and serum.

Differential Diagnosis

I. Other CNS depressants: see section on Barbiturates
II. Other systemic conditions: hypoglycemia, hypotension

Treatment and Monitoring

I. Decontamination (emesis, activated charcoal) is indicated, especially with large exposures.
  A. Avoid apomorphine because it is an opioid.
  B. Give activated charcoal at 1 to 2 g/kg PO followed by repeated doses of activated charcoal at half the original dose BID to TID.
  C. Administer a cathartic with the first dose.
II. Antidote is naloxone 0.1 to 0.2 mg/kg IV, repeated as needed (short half-life).
III. Respiratory and cardiac function must be closely monitored.
  A. Assess blood gas status.
  B. Noncardiogenic pulmonary edema is possible.
  C. IV fluids are given for hypotension, and ventilatory support may be needed.
IV. Prognosis is good if respiratory and cardiovascular systems are adequately supported, but guarded in animals with seizures.

HALLUCINOGENS

Sources

I. Lysergic acid diethylamide (LSD)
  A. Forms include tablets, thin gelatin squares, impregnated paper, and sugar cubes.
  B. LSD is found naturally in morning glory seeds (e.g., *Ipomoea violacea*, *Rivea corymbosa*).
  C. Street names include acid, boomers, yellow sunshines, microdots, dots, cube, sugar cube, window pane (thin gelatin squares), and blotter acid.
  D. Toxicosis in animals is not commonly reported.
II. Psilocybin mushrooms
  A. They include mushrooms in the genera *Psilocybe*, *Panaeolus*, *Gymnopilus*, *Conocybe*, and some *Stropharia* spp.
  B. Hallucinogenic mushrooms can be found fresh, dried, brewed in tea, packaged in capsules, and added to cigarettes or marijuana.
  C. Frequently, they are covered in chocolate, and signs seen in animals are most likely from the mushrooms, not the chocolate.
  D. Street names include shrooms, magic mushrooms, and caps.
III. Phencyclidine (PCP)
  A. It is a dissociative anesthetic.
  B. Although it comes as a white crystalline powder (capsules, tablets), its most common form is a liquid.
  C. Cigarettes, marijuana joints, parsley, mint leaf, and basil are often dipped in liquid PCP.
  D. Street names include angel dust, boat, love boat, hog, embalming fluid (mixed with ether, formaldehyde, and methanol), rocket fuel, dummy dust, peace, supergrass, and zombie.
  E. Marijuana joints dipped in liquid PCP have been called wet-stick, amp, wet, sherm, and happy stick.
  F. Toxicosis in animals is not commonly reported.

Action

I. LSD affects multiple sites in the CNS, such as serotonin receptors (where it can be both stimulatory and inhibitory), and it is rapidly metabolized.
II. Psilocybin is the most common active agent in hallucinogenic mushrooms.
  A. Psilocybin is metabolized to psilocin, a hallucinogen that is structurally similar to serotonin.
  B. The hallucinogenic content of individual mushrooms varies widely; a dried mushroom contains about 0.2% to 0.4% psilocybin.
  C. Clinical signs are usually seen within 20 to 60 minutes after ingestion, although they can be delayed up to 3 hours.
  D. Effects usually last 2 to 4 hours, although there are reports of effects lasting 15 hours.
III. PCP is poorly absorbed from the stomach, but well absorbed in the relatively alkaline environment of the intestines.
  A. Absorbed PCP can be secreted into the stomach and reabsorbed in the intestines.

B. PCP has multiple effects on many neurotransmitters.
   1. GABA inhibition
   2. Anticholinergic and sympathomimetic effects
   3. Alpha-adrenergic stimulation
   4. Binds to opiate receptors

C. It is extensively metabolized in the liver in dogs, and doses of 2.5 to 10 mg/kg PO can result in clinical signs.

D. PCP is predominately excreted unchanged in the urine of cats, and clinical signs are seen at dosages of 1.2 to 12 mg/kg PO.

Clinical Signs

I. Signs vary greatly.
II. Disorientation, ataxia, tachycardia, apprehension, hyperesthesia, hypertension, and tremors are possible.
III. With psilocybin mushrooms, vomiting, vocalization, mydriasis, and hyperactivity have been reported in dogs.
IV. PCP exposure may also result in coma, seizures, hypotension or hypertension, and muscular rigidity.
V. Dogs may exhibit grimacing, jaw snapping, and blank stares with PCP.

Diagnosis

I. Known exposure with compatible clinical signs is suggestive.
II. Assays are difficult because of rapid metabolism of these agents.
   A. LSD may be detected in urine, serum, and feces.
   B. PCP may be detected in urine.

Differential Diagnosis

I. Other illicit substances: both stimulants and depressants
II. Other substances that increase serotonin: antidepressants, selective serotonin reuptake inhibitors, MAO inhibitors, 5-hydroxytryptophan, L-tryptophan, tricyclic antidepressants, avermectins, ketamine

Treatment

I. It depends on the clinical signs.
II. Decontamination (emesis, activated charcoal) is effective with psilocybin exposure, and activated charcoal may reduce GI recirculation of PCP.
III. LSD is rapidly metabolized, so most exposures are self-limiting and decontamination is not beneficial.
IV. Fluid therapy may enhance elimination of PCP in the cat.
V. Sensory stimulation should be minimized.
VI. Cyproheptadine (a serotonin blocker) at 1.1 mg/kg PO or rectally may be effective for psilocybin exposure.
VII. Diazepam has been recommended for signs of apprehension and aggression.
   A. Acepromazine is avoided with PCP exposures, as it may exacerbate anticholinergic effects and produce hypotension.
   B. Acepromazine may be used for treating psilocybin toxicosis.
VIII. In severely affected animals, barbiturates or general anesthesia may be needed.

STIMULANTS

Amphetamines

Sources

I. Methamphetamine or methylamphetamine *(Methedrine, Desoxyn)*
II. Dexamphetamine or dextroamphetamine *(Dexedrine)*
III. Amphetamine *(Benzedrine, Adderall)*
IV. 3,4-methylenedioxymethamphetamine (Ecstasy, MDMA): sometimes classified as a hallucinogen, although structurally related to amphetamine
V. Methylphenidate *(Ritalin),* ephedrine
VI. Street names: speed, bennies, meth, crank, crystal, chalk, snow seals (cocaine and amphetamine), b-bombs, aimies (amphetamine and amyl nitrite), ice

Action

I. Cause release of catecholamines from adrenergic nerve endings and act as dopamine excitatory receptor agonist
II. Potential for CNS stimulation: methamphetamine > dexamphetamine > amphetamine
III. Secondary effects on the serotonergic system: serotonin release with MDMA
IV. Inhibit MAO
V. Rapidly absorbed, onset delayed with sustained release preparations
VI. Highly lipophilic, cross the blood brain barrier
VII. Metabolized in the liver, excreted in urine
VIII. Half-life in dogs: 6.3 hours with urine pH of 7.5, 3.67 hours with urine pH of 5.96
IX. Oral LD_{50} in dogs
   A. Amphetamine sulfate: 20 to 27 mg/kg PO
   B. Methamphetamine hydrochloride: 9 to 11 mg/kg PO
X. Possible signs in dogs at therapeutic doses (unpublished ASPCA Poison Control Center data, 2006)
XI. Signs with doses of methylphenidate and *Adderall* <1 mg/kg PO
XII. Death with doses of approximately 3 mg/kg PO

Clinical Signs

I. Hyperexcitability and agitation occur within 1 to 2 hours of ingestion.
II. Dilated pupils, tachycardia, cardiac arrhythmias, hypertension, panting, or hyperpnea may be seen.
III. Tremors and shaking, hyperactive reflexes, and seizures (closely resembling tetanic seizures of strychnine poisoning) may occur.
IV. Hyperthermia can be a problem.

Diagnosis

I. History of exposure and clinical signs
II. Agents detected in urine, blood, or saliva

Differential Diagnosis

I. Cocaine, methylxanthines: theobromine, caffeine
II. Metaldehyde, tremorogenic mycotoxins, pseudoephedrine

III. Herbal preparations: ma huang, ephedra, guarana
IV. Strychnine, tricyclic antidepressants, 5-fluoruracil

Treatment and Monitoring

I. Decontamination (emesis, activated charcoal with cathartic) is indicated.
II. Sedate dogs with acepromazine 0.05 mg/kg IM, SC, IV (with caution) or chlorpromazine 0.10 to 0.18 mg/kg IV (Catravas et al., 1977).
   A. Phenobarbital, pentobarbital, or other barbiturates can also be used.
   B. Diazepam is not recommended, as it can cause excitation in some animals.
III. Cyproheptadine 1.1 mg/kg PO or rectally may be effective in dogs to control serotonin syndrome signs (e.g., hyperthermia) when other treatments are not effective.
IV. IV fluids promote elimination and maintain renal function.
V. Acidification of the urine with ammonium chloride or ascorbic acid (to pH of 4.5 to 5.5) can enhance urinary excretion, but it is contraindicated when renal function is compromised from severe myoglobinuria.
VI. Monitor for severe CNS effects, hyperthermia, and cardiac arrhythmias.
VII. Monitor acid/base status if acidification of urine is undertaken.
VIII. Monitor renal function, especially if myoglobinuria or acidosis is present.

Cocaine

Sources

I. Cocaine is a CNS stimulant derived from the coca plant (*Erythroxylum* spp.).
II. It is a Schedule II drug and is medically used as a topical, local anesthetic in people.
III. In general, it is found in two forms.
   A. Hydrochloride salt: powdered, soluble form
   B. "Free-base": not neutralized by an acid; often smoked
IV. Crack cocaine is made from cocaine powder and is 75% to 90% pure cocaine (1 g powder forms about 0.89 g crack cocaine)
V. Street names include all-American drug, beam, big C, blow, Carrie Nation, coke, girl, her, lady, leaf, nose candy, snow, snowbirds, stardust, white (generally for powder), basa, crack, electric kool-aid, flake, rock (crack cocaine), banano, bazooka, and tio (marijuana or tobacco cigarettes laced with cocaine).

Action

I. Cocaine blocks the reuptake of serotonin and norepinephrine at receptor sites.
II. Cocaine is well absorbed from all mucosal surfaces.
III. It is metabolized in the liver and excreted in the urine.
IV. The LD_{50} for pure cocaine in the dog is 13 mg/kg IV.
V. The lowest published subcutaneous lethal dose in the dog is 3.5 mg/kg SC and the cat is 16 mg/kg SC (Volmer, 2006).
VI. The lowest published lethal IV dose in the cat is 7.5 mg/kg.

Clinical Signs

I. Signs are similar to amphetamines but tend to be shorter acting.
II. The potential exists for significant cardiovascular (especially hypertension, arrhythmias) and CNS effects.
III. Aggression, excitation, hyperesthesia, and seizures have all been described.

Diagnosis

I. History of exposure
II. Cocaine detected in serum, stomach contents, or urine

Differential Diagnosis

I. Amphetamines, methylxanthines: chocolate, caffeine
II. Metaldehyde, tremorogenic mycotoxins, pseudoephedrine
III. Herbal preparations: ma huang, ephedra, guarana
IV. Strychnine, tricyclic antidepressants, 5-fluorouracil

Treatment

I. Because of rapid onset of signs, induce emesis cautiously.
II. Activated charcoal 1 to 2 g/kg PO may be beneficial.
III. Tremors and seizures are controlled with diazepam, chlorpromazine, or barbiturates, as needed.
IV. Severe tachyarrhythmias are treated with propranolol 0.02 mg/kg IV, slowly.
V. Institute IV fluid therapy to support cardiovascular function and promote excretion.
VI. Hyperthermia may be a problem and is treated appropriately (see Chapter 135).

CHAPTER 130

Herbal Toxicities

Charlotte Means

EPHEDRINE AND PSEUDOEPHEDRINE

Sources

I. *Ephedra sinica* (common names: ma huang, yellow horse, sea grape) contains sympathomimetic alkaloids, ephedrine, and pseudoephedrine.
II. *Sida cordifolia* (common name: Indian common mallow) contains sympathomimetic alkaloids, ephedrine, and pseudoephedrine.
III. *Citrus aurantium* (common name: bitter orange) contains synephrine.
IV. They are used as decongestants and for weight loss.
V. They are used illicitly as herbal ecstasy or as precursors for methamphetamine.

Action

I. They are rapidly absorbed.
II. α-Adrenergic and β-adrenergic receptors are stimulated, which release endogenous catecholamines that affect the brain and heart.
III. Catecholamines cause peripheral vasoconstriction and cardiac stimulation.
IV. Pseudoephedrine causes bronchodilation.
V. They are metabolized in the liver and excreted in the urine.
VI. Toxic doses are as follows:
    A. Clinical signs occur at 5 to 6 mg/kg.
    B. Death is possible with doses of 10 to 12 mg/kg.
    C. Toxicity increases with ingestion of other sympathomimetics (phenylpropanolamine) or methylxanthines.
    D. Drug interactions occur with nonsteroidal antiinflammatory drugs (NSAIDs), monoamine oxidase (MAO) inhibitors, digitalis, and tricyclic antidepressants.

Clinical Signs

I. Initial signs include agitation, restlessness, pacing, and vocalization.
II. Hallucinogenic behavior is possible.
III. Head bobbing has been associated with higher mortality.
IV. Tachycardia and hypertension are typical.
V. Bradycardia and hypertension are also possible.
VI. Tremors and seizures are frequent findings.
VII. Serotonin syndrome, which is characterized by hyperthermia, abdominal pain, vocalizing, and central nervous system (CNS) signs, may be seen.
    A. Serotonin syndrome is the overstimulation of serotonin receptors in the gastrointestinal tract, and CNS, cardiovascular, and respiratory systems.
    B. Sympathomimetics and amphetamines increase the release of stored serotonin.
VIII. Death generally results from cardiovascular collapse.

Diagnosis

I. History of exposure to agent
II. Compatible clinical signs
III. Laboratory tests: possible hypokalemia, hyperglycemia
IV. Pseudoephedrine detected in plasma and urine

Differential Diagnosis

I. Pharmaceuticals containing pseudoephedrine, phenylpropanolamine, or other sympathomimetics or amphetamines
II. Illicit drugs: cocaine, amphetamines
III. Methylxanthines: chocolate, tea, coffee, theophylline, aminophylline
IV. Tremorogenic mycotoxins
V. Insecticides: pyrethroids, organophosphorus and organochlorine agents
VI. Lead poisoning
VII. Other causes of seizure disorders: see Chapter 22

Treatment and Monitoring

I. Institute decontamination.
    A. Induce emesis with hydrogen peroxide (0.5 mL/kg PO; maximum 45 mL) or apomorphine (0.04 mg/kg SC or ocularly) for recent (<30 minutes) ingestions.
    B. Give activated charcoal 1 to 2 g/kg PO.
II. Administer a phenothiazine for agitation, restlessness.
    A. Acepromazine 0.05 to 1 mg/kg IV, IM, SC, as needed
    B. Chlorpromazine 0.5 to 1 mg/kg IV, IM, as needed
III. Cyproheptadine is used to treat serotonin syndrome.
    A. Dogs: 1.1 mg/kg PO QID, if needed
    B. Cats: 2 mg for cats PO QID, if needed
    C. Alternate route: tablets dissolved in saline and given rectally in symptomatic animals or with recent activated charcoal administration
IV. Propranolol (0.02 to 0.06 mg/kg IV slowly) is used to treat tachycardia, and it is also a serotonin antagonist.
V. Phenobarbital (3 mg/kg IV to effect) is used to control tremors and seizures.

VI. Urine acidification hastens elimination.
   A. Attempt only if blood gases can be monitored.
   B. Administer ammonium chloride 50 mg/kg PO QID.
   C. Alternatively, ascorbic acid 20 to 30 mg/kg PO, IM, IV TID can be tried.
VII. Fluid therapy is cautiously instituted to maintain renal function, and possibly increase elimination, but monitor closely for pulmonary edema or fluid overload.
VIII. Diazepam is contraindicated because of the possibility of paradoxical responses (e.g., increased vocalization, head bobbing, CNS excitation, death).
IX. Monitoring parameters include the following:
   A. Blood pressure
   B. Heart rate and rhythm
   C. Routine biochemistries, especially potassium and glucose
X. Signs generally resolve within 72 hours with appropriate treatment.

GUARANA

Sources

I. *Paullinia cupana* seeds contain 3% to 5% caffeine.
II. It is used for weight loss and as an herbal "no doze" stimulant.
III. It is also used as a caffeine source by the soft drink industry.

Action

I. It is well absorbed orally; the plasma half-life ($T_{1/2}$) is 4.5 hours in dogs.
II. Adenosine receptors are inhibited, which causes CNS excitation, vasoconstriction, and tachycardia.
III. Phosphodiesterase is inhibited, resulting in increased levels of cyclic adenosine monophosphate (AMP), which stimulates catecholamine release.
IV. Free calcium is released in muscle cells, which increases cardiac and skeletal muscle contractility.
V. It is metabolized in the liver and undergoes enterohepatic recirculation.
VI. It is excreted in urine.
VII. The LD_{50} of caffeine in dogs is 100 to 200 mg/kg PO, and 80 to 150 mg/kg PO in cats.
VIII. Mild signs occur with doses between 15 and 30 mg/kg PO, moderate signs with doses between 30 and 40 mg/kg PO, and serious signs with doses >40 mg/kg PO.
IX. Combination products containing ma huang increase the toxicity.
   A. Minimum toxic dose: 4.4 mg/kg guarana and 1.3 mg/kg ma huang.
   B. Minimum lethal dose: 19.1 mg/kg guarana and 5.8 mg/kg ma huang.

Clinical Signs

I. Initial signs: vomiting, polyuria, polydipsia, hyperactivity
II. Muscle tremors, ataxia
III. Cardiac arrhythmias
IV. Seizures
V. Death

Diagnosis

I. History of exposure to agent
II. Compatible clinical signs
III. Caffeine detected in stomach contents, serum, or urine

Differential Diagnosis

I. Methylxanthines: chocolate, coffee, tea, theophylline, aminophylline
II. Amphetamines, other pharmaceutical stimulants
III. Strychnine
IV. Insecticides: pyrethroids, organochlorines, carbamates, organophosphorous insecticides
V. Metaldehyde

Treatment and Monitoring

I. Decontamination
   A. Induce emesis in asymptomatic animals within 2 hours of exposure.
   B. Give activated charcoal 1 to 2 g/kg PO; repeat in 4 to 6 hours.
II. Treatment of muscle tremors and seizures (dogs and cats)
   A. Diazepam: 0.5 to 1.0 mg/kg IV
   B. Phenobarbital: 3 to 6 mg/kg IM, IV
III. Fluid diuresis until resolution of clinical signs
   A. Insert a urinary catheter in dogs or walk frequently.
   B. Methylxanthines can be reabsorbed through the bladder wall.
IV. Correction of cardiac arrhythmias
   A. Beta blockers are given for tachycardia.
      1. Metoprolol is preferred because it does not slow renal excretion of methylxanthines.
      2. Dose for metoprolol or propranolol is 0.02 to 0.06 mg/kg IV slowly in dogs and cats.
   B. Premature ventricular contractions are treated with lidocaine in dogs at 1 to 2 mg/kg IV bolus, followed by a constant rate infusion of 25 to 80 μg/kg/minute IV. (Avoid lidocaine in cats.)
   C. Bradycardia is treated with atropine at 0.02 mg/kg IV, IM, as needed.
V. Monitoring
   A. Monitor heart rate and rhythm.
   B. Obtain a baseline complete blood count (CBC) and electrolytes, and repeat electrolytes in 8 to 12 hours in animals with seizures or tremors.
   C. Clinical signs usually resolve within 48 hours with appropriate treatment.

SAINT JOHN'S WORT

Sources

I. *Hypericum perforatum* has the common names of St. John's Wort, rosin rose, and Klamath weed.
II. In the United States, it grows naturally in the Pacific Northwest and is considered a weed.

III. It contains the anthraquinone derivatives hypericin and pseudohypericin.
IV. It is commonly manufactured as a 300-mg standardized capsule.
V. It is used to treat depression.

Action

I. St. John's wort inhibits serotonin uptake and MAO activity.
II. It alters biogenic amine synthesis of neurotransmitters, including norepinephrine, histamine, and serotonin.
III. Toxicity is enhanced if other MAO inhibitors or other selective serotonin reuptake inhibitors (SSRIs) are ingested concurrently.
IV. A minimum toxic dose has not been established in small animals.

Clinical Signs

I. Depression
II. Vomiting, diarrhea
III. Serotonin syndrome with large ingestions: vocalizing, hyperthermia, tremors
IV. Seizures

Diagnosis

I. History of exposure to agent
II. Compatible clinical signs
III. Elevated liver enzymes

Differential Diagnosis

I. SSRI medications: fluoxetine, fluvoxamine, paroxetine, sertraline
II. MAO inhibitors: selegiline, phenelzine, nialamide

Treatment and Monitoring

I. Institute decontamination.
  A. Induce emesis in asymptomatic animals if a large or unknown amount of product was ingested.
  B. Give one dose of activated charcoal 1 to 2 g/kg PO to animals that have ingested large quantities.
II. Manage vomiting and diarrhea.
  A. Give nothing PO for 8 to 12 hours.
  B. Start sucralfate as a gastric protectant.
    1. Dog: 0.5 to 1 g/25 kg PO BID to TID
    2. Cat: 250 to 500 mg PO BID to TID
  C. Administer an antiemetic (metoclopramide, chlorpromazine) if necessary, but it is rarely needed.
  D. Once vomiting has stopped, start a bland diet.
III. Control tremors or seizures with diazepam 0.5 to 1 mg/kg IV.
IV. If serotonin syndrome is noted, give cyproheptadine 1.1 mg/kg for dogs or 2 to 4 mg for cats PO, or dissolve tablet in saline and give rectally.
V. Hepatic support is rarely needed.
  A. If liver disease is present, start S-adenosyl-L-methionine *(Denosyl)* at 18 mg/kg PO in dogs and cats.
  B. A low-protein diet and supplementation of B vitamins are beneficial for dogs.
VI. Monitoring is as follows:
  A. Mild gastrointestinal signs generally resolve within 24 hours.
  B. Baseline liver enzyme levels are obtained if the animal has ingested a large amount or has preexisting liver disease, and are repeated every few days if abnormal.

ECHINACEA

Sources

I. *Echinacea purpurea* is also known as *purple coneflower* and *scurvy root.*
II. The plant is native to the United States.
III. It contains essential oils and glycol-proteins, aklomide, and flavonoids.
IV. It is generally used as an immune stimulant and has a wide margin of safety.

Action

I. Immune function is enhanced by stimulation of phagocytosis, increased cellular respiration, and increased leucocyte mobility.
II. Cell-mediated immunity is enhanced with a single dose but suppressed with long-term usage.
III. Arabinogalactan, an active component of *E. purpurea*, has been given to mice at 4 g/kg in acute toxicity trials, without adverse effects.

Clinical Signs

I. Ingestion of a small amount does not usually produce clinical signs.
II. Vomiting and diarrhea are the most common signs.
III. Because the whole plant is used in commercial preparations, allergic or anaphylactic reactions are possible.

Diagnosis

I. History of exposure to agent
II. Compatible clinical signs

Differential Diagnosis

I. Other causes of mild gastroenteritis
II. Allergic reactions from other etiologies

Treatment

I. Ingestion of small amounts does not require medical intervention.
II. Induce emesis for a large ingestion.
III. Gastrointestinal signs are generally self-limiting.

VALERIAN

Sources

I. *Valerian officinalis* is also known as *all-heal, vandal root,* and *heliotrope.*
II. It contains volatile oils, alkaloids, and valepotriates.
III. The root is the only part of the plant used, and it is used as a sedative and sleeping aid.

Action

I. Some studies indicate that valerian inhibits gamma-aminobutyric acid (GABA) transaminase.
II. GABA-inhibitory effects are increased and lead to sedation.
III. Valerian has a wide margin of safety, with doses of >1 g/kg in mice producing only mild sedative effects.

Clinical Signs

I. Lethargy
II. Ataxia
III. CNS depression
IV. Respiratory depression

Diagnosis

I. History of exposure to agent
II. Compatible clinical signs

Differential Diagnosis

I. Benzodiazepine sedatives: diazepam, alprazolam, clonazepam, lorazepam
II. Nonbenzodiazepine hypnotics: zolpidem, zaleplon

Treatment and Monitoring

I. Small ingestions do not require treatment.
II. Sedative effects are short-lived.
    A. Confine the animal if it is ataxic to prevent injury.
    B. Monitor mental status and respirations.
III. Large, recent (within 2 hours) ingestions can be managed by induction of emesis and administration of activated charcoal.

CHAPTER 131

Toxic Plants

Valentina Merola

GASTROINTESTINAL IRRITANTS

Sources

I. Poinsettia (*Euphorbia* spp.)
II. Aloe *(Aloe vera)*
III. Crocus (*Crocus* spp.)
IV. Gladiola (*Gladiolus* spp.)
V. Hyacinth (*Hyacinthus* spp.)
VI. Iris (*Iris* spp.)
VII. Buttercup (*Ranunculus* spp.)
VIII. Insoluble oxalate containing plants
  A. Philodendron (*Philodendron* spp.)
  B. Caladium, elephant's ear (*Caladium* spp.)
  C. Jack in the pulpit *(Arisaema triphyllum)*
  D. Dumb cane (*Diffenbachia* spp.)
  E. Pothos (*Epipremnum* spp.)
  F. Peace lily (*Spathiphyllum* spp.)
  G. Calla lily (*Zantedeschia* spp.)

Action

I. Insoluble oxalate plants contain sharp crystals of calcium oxalate; during ingestion the crystals are expelled from the cell, penetrate tissues, and cause oral or gastrointestinal (GI) pain and inflammation.
II. Other plants contain a variety of toxic agents that cause GI irritation.

Clinical Signs

I. Vomiting, diarrhea, drooling, anorexia, and dehydration may all be seen.
II. Rarely, with calcium oxalate-containing plants, pharyngeal swelling and dyspnea may be seen.

Diagnosis

I. No specific laboratory findings are expected.
II. Diagnosis is based primarily on history and clinical signs.

Treatment

I. In recent exposures, emesis may be induced and activated charcoal administered at 1 to 2 g/kg PO.
II. Treatment is primarily symptomatic and supportive with fluid therapy, GI protectants, and antiemetics if needed.
III. With insoluble oxalate-containing plants, dairy products (yogurt or cottage cheese) may be given to help relieve discomfort caused by the crystals.
IV. Animals with severe pharyngeal swelling may require oxygen and close monitoring.

GASTROINTESTINAL SIGNS AND OTHER SERIOUS EFFECTS

Sources

I. Cyclamen (*Cyclamen* spp.)
II. Daffodil (*Narcissus* spp.)
III. Tulip (*Tulipa* spp.)
IV. Holly (*Ilex* spp.)
V. Ivy *(Hedera helix)*

Clinical Signs

I. In most exposures, signs are primarily GI (e.g., vomiting, diarrhea, drooling, anorexia).
II. In rare cases involving exposure to bulbs (for those plants that have bulbs) or with ingestion of large quantities, more serious and rarely fatal signs may occur.
  A. Cyclamen very rarely causes hemolysis, cardiac arrhythmias, and seizures (Burrows and Tyrl, 2001).
  B. Daffodils rarely cause central nervous system (CNS) depression, seizures, and cardiac dysfunction.
  C. Tulips can rarely increase the heart and respiratory rate.
  D. Holly and ivy can cause CNS depression.

Treatment

I. Induce emesis and give activated charcoal at 1 to 2 g/kg PO.
II. In general, further treatment is symptomatic and supportive.

CARDIOTOXIC PLANTS

Sources

I. Plants containing grayanotoxins
  A. Kalmia (*Kalmia* spp.)
  B. Rhododendron, azalea (*Rhododendron* spp.)
  C. Pieris (*Pieris* spp.)
II. Yew (*Taxus* spp.)
III. Plants containing cardiac glycosides
  A. Lily of the valley *(Convallaria majalis)*
  B. Foxglove *(Digitalis purpurea)*
  C. Oleander *(Nerium oleander)*

Action

I. Grayanotoxins bind to sodium channels and slow their opening and closing, leading to decreased cardiac conduction.
II. Yew contains taxine, which decreases cardiac conduction and contractility.
III. Cardiac glycosides inhibit the myocardial membrane sodium-potassium-ATPase pump, which leads to increased intracellular calcium and cardiac conduction deficits.

Clinical Signs

I. Vomiting and anorexia are common, and diarrhea is occasionally seen.
II. Weakness and ataxia may be noted.
III. Hypotension and many types of cardiac arrhythmias may occur.
IV. Dyspnea and pale mucous membranes are common findings.
V. In cases involving yew and oleander, sudden death often occurs.

Diagnosis

I. Diagnosis is based on history and clinical signs.
II. Animals exposed to cardiac glycosides may be hyperkalemic.
III. Urine and feces can be tested for grayanotoxins and for some of the cardiac glycosides.

Treatment and Monitoring

I. For recent exposures, induce emesis and administer activated charcoal at 1 to 2 g/kg PO.
II. Fluid therapy is started, and close monitoring of potassium and other electrolytes is performed.
III. Cardiac arrhythmias are treated as needed
IV. Digoxin immune Fab *(Digibind)* can bind to many of the cardiac glycosides and inactivate them, with 1 to 2 vials administered IV for most cardiac glycoside plant exposures.
V. Monitor heart rate, blood pressure, and electrocardiography.

ERYTHROCYTE TOXINS

Sources and Action

I. Onions, chives, and garlic (*Allium* spp.)
II. These plants contain a group of N-propyl disulfides that cause oxidative damage to red blood cells.

Clinical Signs

I. Initially, vomiting and diarrhea
II. Depression, anorexia, and weakness
III. Tachypnea, dyspnea, and tachycardia
IV. Heinz-body hemolytic anemia, hemoglobinemia, hemoglobinuria, and possibly methemoglobinemia

Diagnosis

I. History of ingestion or evidence of plant material in vomitus
II. Anemia and decreased numbers of red blood cells
III. Heinz bodies and evidence of regeneration on blood smears (reticulocytes, basophilic stippling, polychromasia)

Treatment and Monitoring

I. Induce emesis and administer activated charcoal at 1 to 2 g/kg PO for recent ingestions.
II. Monitor for red blood cell changes and clinical signs over the next few days.
III. Administer oxygen, whole blood, or purified hemoglobin as needed (see Chapter 71).
IV. Intravenous fluid therapy may be needed to maintain cardiovascular support and renal function.

NEPHROTOXIC PLANTS

Sources

I. Plants containing soluble salts of oxalic acid
  A. Rhubarb (*Rheum* spp.)
  B. Shamrock, wood sorrel (*Oxalis* spp.)
  C. Dock, sorrel (*Rumex* spp.)
II. Plants containing unknown toxic principles
  A. Grapes/raisins (*Vitus* spp.)
  B. Lilies (*Lilium* spp.)
  C. Day lilies (*Hemerocallis* spp.)

Action

I. Oxalic acid is absorbed systemically and chelates calcium.
II. In the renal tubules, calcium oxalate crystals can precipitate and cause tubular blockage and vascular stasis.
III. The mechanism of renal damage is not known with grape and lily intoxication.
IV. Lilies only appear to cause problems in cats.
V. Grapes only appear to cause problems in dogs.

Clinical Signs

I. Vomiting, diarrhea, and anorexia are commonly seen.
II. Acute renal failure with depression, dehydration, polydipsia, oliguria, polyuria, or anuria may be noted.

Diagnosis

I. Increased blood urea nitrogen (BUN), creatinine, and phosphorus are likely.
II. In cases involving oxalic acid–containing plants, hypocalcemia is expected.
III. In cases involving grapes, hypercalcemia is common, along with an elevation of the calcium × phosphorus product, so the potential for tissue mineralization exists.

Treatment and Monitoring

I. In recent exposures, induce emesis and administer activated charcoal at 1 to 2 g/kg PO.
II. Obtain baseline laboratory tests, and closely monitor chemistries and electrolytes.
III. Intravenous fluid diuresis is instituted for at least 48 hours to protect renal function and prevent tubular obstruction.
IV. Calcium supplementation may be needed in cases involving oxalate-containing plants.

V. Phosphorus binders (aluminum hydroxide) are given as needed (see Chapter 48).
VI. GI protectants and antiemetics are indicated if signs warrant them.
  A. Metoclopramide to control vomiting: 0.2 to 0.4 mg/kg TID, PO, or SC in dogs and cats
  B. Sucralfate for uremic gastritis: 0.5 to 1.0 g PO TID in dogs and 0.25 to 0.5 g PO TID in cats
  C. H_2 antagonist famotidine: 0.5 mg/kg PO SID to BID in dogs and cats
VII. Animals with renal damage may recover some function with aggressive therapy, but the potential exists for long-term, residual renal damage.

HEPATOTOXIC PLANTS

Sources and Action

I. Sago palm (*Cycas* spp.)
II. Contain at least two types of toxins in all parts of the plant, with highest concentrations in the nut
  A. Glycosides of methylazoxymethanol (cycasin and macrozamin)
    1. GI irritation
    2. Hepatic necrosis
    3. Alkylate deoxyribonucleic acid (DNA): mutagenic, teratogenic, and carcinogenic
  B. L-Beta-*N*-methylamino-L-alanine (L-BMAA): a neurotoxic amino acid

Clinical Signs

I. Moderate to severe GI signs: vomiting, diarrhea (often with blood), dehydration
II. CNS signs: depression, ataxia, seizures, coma
III. Hepatic necrosis: icterus, secondary coagulopathy
IV. Death

Diagnosis

I. Increased liver enzymes: alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, bilirubin
II. Possible increase in BUN
III. Increased activated partial thromboplastin time, partial thromboplastin time, activated clotting time

Treatment and Monitoring

I. Induce emesis and administer activated charcoal at 1 to 2 g/kg PO for recent exposure.
II. Institute supportive and symptomatic care.
  A. GI protectants
    1. Sucralfate for uremic gastritis: 0.5 to 1.0 g PO TID in dogs and 0.25 to 0.5 g PO TID in cats
    2. Famotidine: 0.5 mg/kg PO SID to BID in dogs and cats
    3. Metoclopramide to control vomiting: 0.2 to 0.4 mg/kg TID, PO, SC in dogs and cats
  B. SAMe as a hepatoprotectant at 20 mg/kg PO SID
  C. Whole blood transfusion as needed (see Chapter 71)
III. After recovery from acute signs, liver damage may be a lifelong complication.

INTERFERENCE WITH CELLULAR DIVISION

Sources

I. Castor bean, precatory bean *(Ricinus communis, Abrus precatorius)*
II. Autumn crocus *(Colchicum autumnale)*
III. Glory lily *(Gloriosa superba)*
IV. Mayapple *(Podophyllum peltatum)*

Action

I. Castor and precatory bean contain lectins that inhibit protein synthesis and cause cell death.
II. Autumn crocus, glory lily, and mayapple all contain toxic agents that disrupt normal microtubule function during cell division.

Clinical Signs

I. Severe GI irritation: vomiting and diarrhea that may be bloody
II. Dehydration
III. Possible bone marrow suppression
IV. Death
V. Castor bean: also renal and hepatic damage, ataxia, tremors, seizures

Diagnosis

I. Diagnosis is usually based on history and clinical signs.
II. Anemia and leukopenia may be seen after acute exposure.

Treatment and Monitoring

I. For recent exposures, induce emesis and administer activated charcoal at 1 to 2 g/kg PO.
II. Start aggressive IV fluid therapy.
III. Antiemetics and GI protectants are indicated (see under Gastrointestinal Irritants).
IV. Monitor complete blood counts.
  A. Myelosuppression can occur within a few weeks of exposure.
  B. Consider erythropoietin for anemia at 100 IU/kg SC three times weekly for dogs and cats.
  C. Consider filgrastim for leukopenia at 1 to 5 µg/kg SC SID for dogs and cats.

SOLANACEOUS PLANTS

Sources

I. Nightshades, potato (*Solanum* spp.)
II. Jimsonweed (*Datura* spp.)
III. Tomato *(Lycopersicon lycopersicum)*
IV. Belladonna *(Atropa belladonna)*

Action

I. These plants contain a mixture of tropane alkaloids and glycoalkaloids that have anticholinergic effects.
II. They also cause a variety of effects on the CNS and GI tract.

Clinical Signs

I. Signs variable and sometimes confusing
II. CNS signs: disorientation, hallucinations, sedation, weakness
III. GI signs
  A. Vomiting, drooling
  B. Diarrhea, cramping
  C. Possible dry mucous membranes or GI atony
IV. Cardiovascular abnormalities
  A. Bradycardia or tachycardia
  B. Hypotension or hypertension
V. Mydriasis possible

Diagnosis

I. A history of ingestion is often needed.
II. Diagnosis may be based on suspicious clinical signs because laboratory findings are nonspecific.

Treatment

I. Initially, decontamination is done by inducing emesis and administering activated charcoal at 1 to 2 g/kg PO.
II. Additional treatment is symptomatic and supportive.

CENTRAL NERVOUS SYSTEM TOXICANTS

See Table 131-1.

OTHER MISC PLANTS

See Table 131-2.

TABLE 131-1

Plants Affecting the Central Nervous System

PLANT	CLINICAL SIGNS	TREATMENT
Macadamia nuts *(Macadamia integrifolia)*	Weakness, depression, ataxia, tremors, hyperthermia Signs are generally self-limiting	Decontamination and supportive care
Yesterday, today, and tomorrow plant (*Brunfelsia* spp.)	Tremors, seizures, vomiting, diarrhea, death	Decontamination and supportive care Control seizures
Chinaberry *(Melia azedarach)*	Vomiting, drooling, diarrhea, ataxia, seizures, death	Decontamination and supportive care Control seizures
Bleeding-heart (*Dicentra* spp.)	Vomiting, ataxia, tremors, rarely seizures It is rare that enough is ingested to cause problems	Decontamination and supportive care

TABLE 131-2

Miscellaneous Toxic Plants

PLANT	CLINICAL SIGNS	TREATMENT
Avocado *(Persea americana)*	Noninfectious mastitis, agalactia in large animals and rabbits Cardiac arrhythmias, pulmonary edema, dyspnea, death in rabbits, birds, and goats Foreign body obstruction from the pit	Decontamination and supportive care
Hops *(Humulus lupulus)*	Malignant hyperthermia in dogs within 3 hours High body temperature, tachycardia, tachypnea, agitation	Decontamination and supportive care Dantrolene for malignant hyperthermia at 2 to 5 mg/kg IV once in dogs
Cyanogenic glycoside containing plants: plum, peach, cherry, apricot (*Prunus* spp.)	Whole pits are unlikely to be a problem Chewed pits can release cyanide Dyspnea, cyanosis, weakness, seizures, coma, death	Decontaminate if asymptomatic It is very rare to require or have the antidote available Sodium nitrite can be given at 16 mg/kg IV, followed by sodium thiosulfate 30 to 40 mg/kg IV The *treatment* can be life-threatening if animal has not been poisoned with cyanide

CHAPTER 132

Shock

Marie E. Kerl

Definition

Shock refers to the catastrophic failure of oxygen delivery to cells resulting in disordered cellular metabolism.

Causes

I. Classifications schemes are frequently applied to identify causes of shock; however, schemes vary, and an animal can have more than one cause simultaneously.
II. Hypovolemic shock occurs from low, ineffective circulating volume.
  A. Hemorrhage: external or internal
  B. Marked gastrointestinal (GI) losses from vomiting or diarrhea
  C. Renal losses from excessive diuresis
  D. Vascular losses from hypoalbuminemia and poor oncotic pressure
  E. Relative loss from sequestration of fluid volume (e.g., gastric torsion)
III. Cardiogenic shock occurs from inhibition of cardiac output.
  A. Impaired forward flow
    1. Dilated cardiomyopathy
    2. Valvular insufficiency
    3. Valvular stenosis
    4. Cardiac arrhythmias
    5. Myocardial depression from drugs or illness
  B. Impaired filling
    1. Hypertrophic cardiomyopathy
    2. Pericardial effusion/tamponade
    3. Severe pulmonary thromboembolism
IV. Distributive shock occurs from loss of vascular tone or peripheral resistance from anaphylaxis, septicemia, or heat stroke.

Pathophysiology

I. As shock ensues, compensatory mechanisms are triggered (early stage).
  A. Baroreceptors in carotid body and aortic arch are activated by actual (hypovolemic shock) or perceived (cardiogenic or distributive shock) loss of volume, with triggering of compensatory mechanisms, such as tachycardia, to improve cardiac output and peripheral vasoconstriction to normalize blood pressure.
  B. Declines in renal blood flow, glomerular filtration, and renal tubular flow cause activation of the renin-angiotensin-aldosterone system, which results in sodium retention.
  C. Hyperosmolarity and hypovolemia cause hypothalamic stimulation and release of antidiuretic hormone (ADH), resulting in free water uptake and vasoconstriction.
II. With no resolution of the inciting cause, these compensatory mechanisms fail to normalize heart rate, blood pressure, and cardiac output (middle stage).
III. With continued shock, compensatory mechanisms fail and the condition deteriorates (late stage).
IV. Upon decompensation, a systemic inflammatory response syndrome is triggered, and multiorgan dysfunction syndrome can occur.

Clinical Signs

I. Initiation of compensatory mechanisms coincides with early shock.
  A. Clinical signs are minimal.
  B. Mild tachycardia can occur.
II. Middle-stage shock is associated with tachycardia, prolonged capillary refill time, pallor, and weak pulses.
  A. Distributive shock in dogs can result in hyperemic mucous membranes.
  B. Cats commonly develop bradycardia and hypothermia with distributive shock.
III. Late-stage shock is associated with bradycardia, weakness, severe hypotension, marked pallor, hypothermia, and mental dullness or stupor.

Diagnosis

I. Historical findings
   A. Reduced fluid intake from lack of access or nausea
   B. Increased fluid loss from GI, urinary, dermal, or internal losses
   C. Evidence of infection, inflammation, trauma, cardiac disease
   D. Recent exposure to unusual environmental extremes
   E. Recent vaccinations or drugs

II. Physical examination findings
   A. Mental dullness
   B. Pallor or hyperemic mucous membranes
   C. Prolonged capillary refill time
   D. Poor pulse quality: dorsal pedal pulses lost at mean arterial pressure of 60 mm Hg
   E. Tachycardia or bradycardia
   F. Hypothermia or hyperthermia
   G. Evidence of hemorrhage, fluid loss, underlying disease

III. Clinicopathologic findings
   A. Hematocrit may be low with blood loss or elevated with hemoconcentration.
   B. Total protein is low with blood loss or proteinaceous fluid loss (GI), and high with dehydration or nonproteinaceous fluid loss.
   C. With acute blood loss, a decline in total protein precedes the decline in hematocrit.
   D. Leukocytosis or leukopenia can occur with septicemia.
   E. Mild to moderate thrombocytopenia can occur from hemorrhage or with disseminated intravascular coagulopathy (DIC).
   F. Prolonged coagulation times occur with DIC or indicate a cause of the hemorrhaging.
   G. In early septic shock, hypoglycemia is more common than hyperglycemia.
   H. Serum biochemistries may reveal increased alanine aminotransferase, alkaline phosphatase, total bilirubin, prerenal or renal azotemia.
   I. Blood gas analysis can indicate metabolic acidosis from poor tissue perfusion.
   J. Systemic blood pressure (BP) is frequently low (systolic BP <80 mm Hg).
   K. Serum lactate levels are elevated (>2.5 mmol/L) with poor tissue perfusion in shock, and failure of lactate to normalize (<2.5 mmol/L) with appropriate restoration of circulatory volume indicates ongoing anaerobic metabolism.

Differential Diagnosis

I. Tachycardia, bradycardia, pulse quality abnormalities
   A. Cardiac arrhythmias
   B. Myocardial failure

II. Pallor
   A. Anemia
   B. Peripheral vasoconstriction

III. Altered mentation, weakness
   A. Central or peripheral nervous system diseases
   B. Hypoglycemia
   C. Hepatic encephalopathy

Treatment

I. Supplemental oxygen therapy
   A. Provide emergency oxygen therapy on arrival to increase tissue oxygen delivery.
   B. With severe anemia, increasing the concentration of inspired oxygen does not significantly improve tissue oxygenation, as most of the oxygen delivery occurs from hemoglobin-bound oxygen.
   C. Deliver oxygen by mask or nasal cannulation.
   D. Recommended nasal cannula flow rates are 50 to 100 mL/kg/min (Dunphy et al., 2002).
   E. Oxygen cages are impractical for the animal in shock because they render the animal relatively inaccessible.

II. Fluid resuscitation
   A. Large-bore, peripheral catheters (cephalic, lateral, or medial saphenous) allow for rapid intravenous (IV) fluid administration to treat shock.
   B. With severe hypovolemia, peripheral vessel collapse may necessitate a vascular cutdown or fluid delivery via intraosseous catheterization or a central line.
   C. Administer a balanced, isotonic crystalloid solution, such as lactated Ringer or *Normosol-R* solution, for initial treatment of hypovolemic or distributive shock.
   D. Avoid rapid fluid administration with cardiogenic shock.
   E. Approximate starting doses for fluids are 60 to 90 mL/kg IV for dogs and 40 to 60 mL/kg IV for cats; however, each animal should be resuscitated with the fluid volume needed to normalize clinical parameters.
   F. Recommended fluid dosage ranges approximate one blood volume for dogs and cats, respectively.
   G. Initiate IV fluid therapy and monitor heart rate, blood pressure, peripheral pulse quality, mucous membrane color, and mental status approximately every 5 to 10 minutes.
      1. Mean arterial pressures >80 mm Hg or systolic pressures >100 to 120 mm Hg maximize tissue oxygen delivery.
      2. When clinical parameters improve, discontinue shock (high-volume) fluid resuscitation, and continue with calculated fluid needs for maintenance, dehydration, and ongoing loss.
   H. Colloid-containing fluids can be used with or instead of crystalloids.
      1. Colloids are indicated for animals with hypoproteinemia.
      2. Consider colloids in animals with normal hydration status before onset of shock, as colloids maintain vascular volume for a longer period than do isotonic crystalloids.
         a. Approximately 60% to 70% of isotonic crystalloids translocate to the interstitial space within an hour of administration.
         b. Half-life of the synthetic colloids commonly used (hetastarch, dextran-70) is 25 hours.
      3. Colloids can be used for shock refractory to isotonic crystalloid administration.

4. Approximate starting doses of hetastarch or dextran-containing fluid is 10 to 20 mL/kg IV in dogs and 5 to 10 mL/kg IV in cats, while concurrently monitoring the same resuscitative parameters mentioned above.

III. Sodium bicarbonate
   A. Administer bicarbonate following fluid resuscitation if metabolic acidosis persists (pH <7.1, base deficit >11).
   B. Bicarbonate deficit is calculated as (0.3) × (body weight in kg) × (base deficit).
   C. Administer half the deficit slowly IV over 4 to 6 hours and repeat blood gasses before further administration.

IV. Hemorrhage
   A. Apply pressure to external wounds or compression bandages to the abdomen on initial presentation.
   B. Monitor animal carefully for respiratory compromise if abdominal compression is instituted.
   C. Emergency surgery is indicated if hemorrhage does not respond to emergency control measures.
   D. Evaluation of coagulation status is imperative before surgical intervention.

V. Dilated cardiomyopathy
   A. Avoid resuscitative fluid administration.
   B. Administer positive inotropic support (Boag and Hughes, 2005).
      1. Dobutamine
         a. Dog: 5 to 10 µg/kg/min IV constant rate infusion (CRI)
         b. Cat: 1 to 2 µg/kg/min IV CRI
      2. Dopamine: 5 to 10 µg/kg/min IV CRI

VI. Pericardial effusion: immediate pericardiocentesis to resolve tamponade

VII. Septic shock
   A. Institute broad-spectrum antibiotics.
   B. Choose antibiotics that cover gram-positive and gram-negative bacteria.
   C. Coverage for anaerobic bacteria (metronidazole, ampicillin) may also be indicated.

VIII. Shock refractory to fluid resuscitation
   A. Consider administration of positive inotropes or vasopressors.
   B. Vasopressors include dopamine, norepinephrine, or aqueous vasopressin.
   C. Vasopressor therapy causes peripheral vasoconstriction, which diminishes peripheral tissue oxygen delivery.

Monitoring of Animal

I. Monitoring frequency is tailored to each animal according to the particular situation.

II. The following parameters can be evaluated every 2 to 12 hours:
   A. Blood pressure, pulse quality
   B. Mucous membrane color, capillary refill time
   C. Heart rate and rhythm, electrocardiography
   D. Urine output

III. Respiratory monitoring
   A. Respiratory rate and effort
   B. Arterial oxygen partial pressure (Pao_2) or saturation (SPo_2)
   C. Arterial or venous partial pressure carbon dioxide (Pco_2), end-tidal CO_2
   D. Pulmonary auscultation

IV. Body temperature
   A. Hypothermia indicates poor perfusion.
   B. Fever indicates infection or inflammation.

V. Hematocrit and total protein

VI. Blood glucose

CHAPTER 133

Electrical Cord and Smoke Inhalation Injuries

Jennifer E. Prittie

ELECTRICAL CORD INJURY

Definition and Causes

I. Electrical shock occurs most frequently when animals chew on live wires of household appliances, and most commonly affects puppies and kittens.
II. Both local and systemic injuries ensue after contact with alternating current.

Pathophysiology

I. Transformation of electrical energy into heat results in coagulation necrosis of tissue proteins at the point of contact, resulting in local thermal injury.
II. Systemic injury results from disruption of the electrophysiologic activity of excitable tissue, with muscle spasms, seizures, loss of consciousness, apnea, and life-threatening cardiac dysrhythmias as reported sequelae.
III. Injury is commonly associated with development of neurogenic (noncardiogenic) pulmonary edema, possibly from transient pulmonary hypertension after centrally mediated vasomotor changes and increased microvascular permeability.
IV. Injury severity is proportional to duration of exposure and intensity of current.

Clinical Signs

I. Local thermal injury
  A. The oral commissures and dorsolateral lingual surfaces are usually affected.
  B. Lesions are well circumscribed, pale, and yellow.
  C. Hypersalivation is common, and animals typically resist examination of the oral cavity because of associated pain.
  D. Oral discomfort may result in inappetence.
II. Systemic manifestations
  A. Neurogenic edema may result in respiratory distress.
    1. Signs include pallor or cyanosis, tachypnea, and dyspnea.
    2. Coughing of blood-tinged pulmonary edema fluid may be observed.
    3. Onset is typically rapid (<4.5 hours) but can be delayed 12 to 24 hours.
  B. Muscle stiffness or generalized seizures may occur during and immediately following electrocution.
  C. Abdominal pain and vomiting may develop.
  D. Cardiopulmonary arrest occurs from respiratory paralysis or ventricular fibrillation.

Diagnosis

I. History
  A. Owners may witness the electrocution or find the cord in the mouth.
  B. Animals may be found collapsed, stiff, seizuring, or dyspneic.
II. Compatible physical findings
  A. Characteristic oral lesions, oral pain, pallor, or cyanosis
  B. Tachypnea, dyspnea, moist cough, and auscultable harsh lung sounds and crackles from pulmonary edema
III. Thoracic radiography
  A. The cardiac silhouette and pulmonary vessels are normal to small.
  B. Neurogenic pulmonary edema is predominantly alveolar and located within the caudodorsal quadrants, but interstitial edema may also be observed.
  C. Distribution is typically bilateral and symmetrical.

Differential Diagnosis

I. Other causes of oral ulceration
  A. Viral infection
  B. Uremic ulcers
  C. Ingestion of a caustic substance
  D. Immune-mediated disease
II. Other causes of neurogenic pulmonary edema
  A. Head trauma
  B. Seizures
  C. Upper airway obstruction
III. Other causes of respiratory distress
  A. Congestive heart failure
  B. Pneumonia
  C. Pulmonary hemorrhage

Treatment

I. Disconnect the electricity and remove the pet from the source of current.
II. Clear the airway of edema, mucus, or vomitus with fingers or a suction catheter.
  A. Animals with altered mentation and diminished airway defenses (decreased gag reflex) require intubation and supplemental oxygen.

B. Mechanical ventilation is indicated for the following:
1. Hypoxemia that persists despite oxygen supplementation
2. Severe hypoventilation
3. Respiratory muscle fatigue

III. Consider oxygen therapy.
A. To ensure adequate tissue oxygenation, maintain arterial hemoglobin (Hb) oxygen saturation (SPo_2) >92%, which corresponds to a partial pressure of oxygen in arterial blood (Pao_2) > 75 mm Hg.
B. Oxygen can be supplied via mask, cage, tent, or nasal cannulation.

IV. Intravenous fluid therapy is based on maintaining adequate systemic perfusion and tissue oxygenation.
A. Crystalloids increase intravascular hydrostatic pressure and decrease intravascular oncotic pressure, possibly promoting pulmonary edema.
B. *Prudent* fluid restriction may be beneficial; however, restriction without maintaining cardiac output and tissue oxygenation should be avoided.
C. With sufficient increase in endothelial permeability, colloids pass through the pulmonary capillary endothelium and are osmotically active in the interstitium to exacerbate pulmonary edema.
D. A test infusion of IV fluids is advisable; if respiratory parameters worsen during administration, and if systemic perfusion is adequate, judicious fluid restriction is recommended.
E. Bolus administration of IV fluids acutely increases pulmonary hydrostatic pressure; constant-rate infusion is preferable.

V. Therapy for pulmonary edema may include the following:
A. Oxygen therapy as needed
B. Diuretic therapy
1. The goal is to decrease pulmonary hydrostatic pressure via reduction in plasma volume, thereby reducing edema formation.
2. Diuretics may be useful in the early stages of noncardiogenic edema formation, when pulmonary hydrostatic pressure may be elevated; however, the use of diuretics remains controversial.
3. Any reduction of cardiac output and tissue oxygenation is detrimental and is to be avoided.
4. Furosemide can be administered once at a dose of 2 to 4 mg/kg IV.
C. Bronchodilators
1. Terbutaline 0.01 mg/kg SC, IM BID to QID
2. Aminophylline
a. Dog: 6 to 10 mg/kg IM, PO TID
b. Cat: 4 to 8 mg/kg IM, PO BID to TID
D. Corticosteroids: no proven benefit, possibly harmful

VI. Oral burns are cleaned with an antiseptic solution BID to TID.
A. Most lesions heal satisfactorily by second intention.
B. Oronasal fistula formation may occur and may require surgical repair.
C. Systemic analgesics are administered as needed.
1. Torbugesic 0.2 to 0.4 mg/kg IV, SC, IM every 4 to 6 hours
2. Hydromorphone 0.05 to 0.1 mg/kg IV, SC, IM QID
3. Buprenorphine 0.01 to 0.02 mg/kg IV BID to QID

Monitoring of Animal

I. Animals are hospitalized for 24 to 48 hours and monitored for delayed-onset respiratory and cardiac symptoms.
II. Respiratory status is monitored by observation of respiratory rate and effort, lung auscultation, and thoracic radiographs.
A. Oxygenation is evaluated by pulse oximetry or arterial blood gas analysis.
B. Ventilatory ability can be monitored by evaluating arterial or venous carbon dioxide.
III. Continuous electrocardiography may be indicated for 24 to 48 hours after electrocution, as the development of ventricular arrhythmias can also be delayed.
IV. Survival rate for animals with neurogenic pulmonary edema secondary to electric shock is 39% to 85% (Drobatz et al., 1995).

SMOKE INHALATION

Definition and Causes

I. Smoke inhalation injury has been most commonly reported following exposure to smoke in residential fires.
II. Direct thermal injury, chemical irritants, and smoke particulates result in respiratory dysfunction and tissue hypoxia.
III. Carbon monoxide (CO) is a colorless, odorless, toxic gas that is a product of incomplete combustion; inhalation of CO exacerbates cellular hypoxia and results in neurologic dysfunction.

Pathophysiology

I. Damage to the respiratory system
A. Heat
1. Thermal injury affects primarily the upper airways (i.e., the supraglottic area and the larynx).
2. Partial or complete upper airway obstruction may occur subsequent to laryngeal inflammation and edema, within several hours of exposure.
B. Vapors
1. Respiratory irritants include sulfur dioxide, chlorine gas, and acrolein.
2. Chemical burns directly damage the respiratory mucosa, and chemicals may incite reflex bronchoconstriction and pulmonary inflammation.
3. Irritants inactivate surfactant, causing atelectasis and decreased compliance.
4. Particulates <5 μm deposit in large and small airways and alveoli, resulting in mucosal irritation and reflex bronchoconstriction.
5. Impaired mucociliary action impedes particulate clearance.

II. Complications
A. Early (0 to 36 hours): acute lung injury
B. Delayed complications

1. Bronchopneumonia (4 to 5 days)
2. Pulmonary fibrosis

C. Carbon monoxide toxicity
1. CO preferentially binds with Hb in place of O_2, forming carboxyhemoglobin (COHb) (Hb affinity for CO is 240 times greater than for O_2).
2. The resultant reduction in arterial O_2 content decreases O_2 delivery to the tissues.
3. Other mechanisms of CO toxicity include the following:
   a. Left shift of the oxyhemoglobin dissociation curve, impairing tissue O_2 release
   b. Decrease in cellular respiration through binding CO to cytochrome P450
   c. Binding to myoglobin with myocardial and skeletal muscle dysfunction

Clinical Signs

I. Manifestations of smoke toxicity include the following:
   A. Ocular abnormalities: corneal ulcers, blepharospasm, conjunctivitis
   B. Cutaneous burns on the face and footpads
   C. Smoky aroma to the animal
   D. Singed hair or soot on the haircoat
II. The major body systems affected include respiratory and central nervous system.
   A. Respiratory signs include nasal discharge, cough, gag, upper airway stridor, open-mouth breathing, tachypnea, and dyspnea.
   B. Neurologic signs include depression, ataxia, loss of consciousness, and coma.
   C. Hypovolemic shock results from respiratory and dermal fluid losses.

Diagnosis

I. History of exposure to household or other fire may be evident.
II. Evaluate for compatible clinical signs, as described above.
III. Additional physical examination findings may be seen.
   A. Cherry red mucous membranes consistent with CO toxicity
   B. Auscultation of harsh lung sounds, crackles or wheezes
IV. Radiographic abnormalities may not be evident for up to 48 hours after exposure.
   A. Alveolar and interstitial infiltrates predominate, with no consistent distribution.
   B. Collapse of the right middle lung lobe may be identified.
V. Documentation of hypoxemia is supportive.
   A. Pulse oximetry is inaccurate in the presence of COHb and overestimates Hb saturation with O_2.
   B. Cooximetry provides a direct measurement of oxy-, carboxy- and methemoglobin, but this technology is not readily available.
   C. Arterial blood gas analysis is unaffected by the presence of COHb.
VI. Measurement of COHb may be helpful.
   A. COHb >15% indicates toxicity.
   B. COHb level roughly correlates with the amount of CO inhaled and with the animal's clinical signs.
VII. Cytological examination of respiratory secretions may reveal the presence of soot, particulate matter, or secondary bacterial infection.
VIII. The results of hemogram and biochemical profile are unremarkable initially, but change with secondary complications.

Differential Diagnosis

I. Other causes of respiratory distress with pulmonary infiltrates: neurogenic edema (upper airway obstruction, electric cord injury, seizures), pneumonia
II. Other causes of oral and facial burns: electrical cord injury, exposure to caustic substances
III. Other causes of altered mentation: seizures (post-ictal), drug or toxin ingestion

Treatment

I. Airway and breathing
   A. Endotracheal intubation or tracheostomy may be indicated for upper airway edema or obstruction, or in cases with altered level of consciousness.
   B. Mechanical ventilation is indicated for respiratory failure.
II. Oxygen therapy
   A. Administer O_2 to any animals showing respiratory or neurologic signs.
   B. Administer high-flow O_2 therapy (80% to 100%) for several hours.
      1. Reduces the half-life of CO
      2. Increases the amount of unbound, dissolved O_2 in the blood
      3. Provided via tight-fitting mask, nasal cannulation, or mechanical ventilation
   C. After 1 to 4 hours of therapy, decrease the inspired concentration of O_2 to 40% to 60% to avoid O_2 toxicity, and attempt to maintain Pao_2 >75 mm Hg.
   D. Hyperbaric oxygen (HBO)
      1. Advocated for CO toxicity, but data are conflicting regarding its benefit
      2. Produces a rapid reduction in COHb levels, faster dissociation of CO from respiratory cytochromes, and decreases oxidative injury
III. Fluid therapy
   A. Intravenous fluids are administered to maintain adequate tissue perfusion and oxygenation, and to avoid drying and thickening of airway secretions.
   B. Overhydration with isotonic crystalloids may exacerbate pulmonary vascular leak and must be avoided.
   C. Burns affecting a large surface area can result in loss of a large quantity of protein-rich fluid; therefore aggressive IV fluid therapy, with the addition of a colloidal solution, may be necessary in burn victims.
IV. Bronchodilators
   A. Terbutaline 0.01 mg/kg SC, IM BID to QID
   B. Aminophylline

1. Dog: 6 to 10 mg/kg IM, PO TID
2. Cat: 4 to 8 mg/kg IM, PO BID to TID

V. Nebulization and coupage every 4 to 6 hours to clear airway secretions
VI. Analgesics
   A. Analgesics are administered if cutaneous burns exist.
   B. Appropriate agents include the following:
      1. Torbugesic 0.2 to 0.4 mg/kg IV, SC, IM every 4 to 6 hours
      2. Hydromorphone 0.05 to 0.1 mg/kg IV, SC, IM QID
      3. Buprenorphine 0.01 to 0.02 mg/kg IV BID to QID
VII. Corticosteroids
   A. Short-acting corticosteroids may be useful for treatment of upper airway edema.
   B. In general, corticosteroids are avoided because of the risk of respiratory and systemic infections.
VIII. Antibiotic therapy
   A. Prophylactic administration of antibiotics is not beneficial and can result in development of resistant infections.
   B. Broad-spectrum systemic antibiotic therapy is instituted after documentation of infection based on culture and sensitivity results.
IX. Monitor corneal ulceration with serial fluorescein staining; treat with topical broad-spectrum antibiotics, and topical atropine as indicated for ciliary spasm.

Monitoring of Animal

I. Respiratory signs may not develop until several hours or days after initial examination, necessitating hospitalization and monitoring for at least 24 to 48 hours.
II. Respiratory rate and effort, arterial blood gas analysis, and serial thoracic radiographs can be used to monitor for respiratory deterioration.
III. CO intoxication can result in a syndrome of delayed neurologic dysfunction, so serial monitoring of mentation, gait, and cranial nerve function is also indicated.
IV. Reported survival rate of dogs and cats following smoke inhalation (without accompanying burns) is 90% (Drobatz et al., 1999).
   A. Animals with concurrent dermal burns may have more severe pulmonary dysfunction.
   B. Respiratory deterioration after hospital admission is associated with a prolonged course of hospitalization and increased mortality in dogs.

CHAPTER 134

Burns

Rebecca J. Greer | F.A. Mann

Definition and Causes

I. There are three main types of burn injuries (Dhupa, 2002).
   A. With thermal burns, skin comes into contact with a source of heat of sufficient temperature to cause cell injury and death via protein coagulation
   B. With chemical burns, strong acids, bases, or other corrosive substances contact tissue and cause protein and collagen denaturation, generation of thermal energy, coagulation necrosis, and vascular thrombosis
   C. With electrical burns, electric current damages tissue by conversion of electrical energy into heat, and by causing depolarization of nerve/muscle cells (ventricular arrhythmia) (see also Chapter 133)

II. Various causes of burns are summarized in Table 134-1.

Classification

I. The severity of burn injury is determined by evaluating both the degree/depth of injury and the percentage of the total body surface area (TBSA) involved (Fox, 1985).

II. Depth of injury is divided into three categories (Table 134-2).
   A. Epidermal burns (first degree)
      1. Injury is to the outermost epidermis only.
      2. The epidermis is thickened, erythematous or desquamated.
   B. Dermal partial-thickness burns (second degree)
      1. Superficial partial-thickness burns
         a. Epidermis is destroyed but most of the dermis still present.
         b. The tissue has a moist surface, blanches with pressure, is erythematous, has large blebs or bullae, and intact hair follicles.
      2. Deep partial-thickness burns
         a. Dermal destruction occurs, with only the adnexal epithelium remaining in the upper layers of the subcutaneous fat.
         b. Tissue is dry, does not blanch, is dark or yellow-white in color, contains ruptured bullae, and has decreased sensation.
         c. The wound is subject to fluid loss, infection, pain, and can result in metabolic disturbances.
   C. Full-thickness burns (third degree)
      1. Destruction of all layers of skin occurs and may include fat, fascia, muscle and bone.

TABLE 134-1

Types of Burn Injuries

TYPE OF BURN	CLINICAL SIGNS	EXAMPLES
Direct Heat	Tissue damage by direct heat necrosis	*Dry:* heating pads, hot water bottles, heat lamps, radiators, stoves, hot packs, light bulbs, other hot surfaces *Wet:* steam, hot water, hot tar, hot cooking oils, potpourri oils
Flame	Tissue damage by direct heat necrosis	House or barn fires, camp fires, forest fires, malicious burnings
Chemical	Tissue damage via coagulation necrosis, liquefaction necrosis with denaturing of proteins and saponification of fats, and heat necrosis	*Acids:* toilet bowl cleaners, battery acid, metal cleaners, rust removers, concrete cleaners, sulfuric acid *Bases:* bleach, drain cleaners, oven cleaners, ammonias, toilet bowl cleaners, Lysol, potash, pool chlorinating solutions, lime *Oxidizing agents:* bleaches, peroxides, chromates, manganates *Solvents:* phenols, turpentine, paint thinners, gasoline, kerosene, creosols
Electrical	Tissue damage via electron flow depolarizing muscles/nerves, causing abnormal electrical rhythms in heart and brain, with heat and poration damage of cells	*High voltage:* lightning, high-tension power lines *Low voltage:* electrical cord exposure, electrosurgical burns (cautery and grounding plate burns)

TABLE 134-2

Burn Classifications Based on Depth

BURN CLASSIFICATION	USUAL CAUSE	GROSS PATHOLOGY	MICROPATHOLOGY	MAIN SEQUELAE	MEANS OF UNCOMPLICATED HEALING
Epidermal	Radiation (sunburn)	Erythema, small intradermal blebs, desquamation	Partial epithelial destruction	Pain	Spontaneous epithelial regeneration in 5 to 7 days
Partial thickness (dermal), superficial	Scalding, hair dryers, heating pads	Erythema, large blebs or bullae, hair follicles intact	Partial epidermal and dermal destruction	Fluid loss, infection, pain	Spontaneous epithelial regeneration in 7 to 21 days
Partial thickness (dermal), deep	Scalding, flame, heating pads	Dry, does not blanch, insensitive to pinprick, hair follicles intact	Total epidermal and partial dermal destruction	Fluid loss, infection, pain, metabolic disturbances	Spontaneous epithelial regeneration lengthy (≥ 30 days) with scarring
Full thickness	Flame	Charred, blanched, leather-like, hair follicles obliterated	All dermis and epidermis destroyed	Fluid loss, infection, difficult closure, metabolic disturbances	Grafting

Modified from Fox SM: Management of thermal burns—part I. Compend Contin Educ Pract Vet 7:631, 1985; with permission.

2. The tissue appears charred, blanched, and leather-like.
3. Increased permeability of intact deep vessels results in marked edema of the subcutis.
4. The wound is subject to fluid loss and infection, which can result in metabolic disturbances.
5. Skin grafts are required for closure of large wounds.
6. Closure is important and significant; life-threatening systemic effects can occur if large surface areas are involved.

III. No accurate method for estimating TBSA exists in small animals.
   A. The *Rule of Nines* is considered inaccurate in women, infants, and children, making it difficult to apply to animals (Sheridan, 2002).
      1. The head and neck = 9% of TBSA
      2. Each forelimb = 9% of TBSA
      3. Each hind limb = 18% of TBSA
      4. The thorax = 18% of TBSA
      5. The abdomen = 18% of TBSA
   B. Burns affecting >20% TBSA cause interstitial edema in organs as an indirect injury.
      1. The edema can cause significant physiologic abnormalities.
      2. The edema may impair cardiac, respiratory, and immune functions.
   C. Burns affecting >50% TBSA usually have a poor prognosis, but good outcomes were reported in two cases (Fox, 1986; Fox et al., 1988).

Pathophysiology

I. Physiological derangements can be severe in large thermal wounds (Dhupa, 2002; Fox, 1986; Sheridan, 2002).
   A. Degree of systemic involvement is related to both depth of injury and TBSA.
      1. Abnormalities can range from mild electrolyte disturbances to a systemic inflammatory response syndrome (SIRS) and multiple organ dysfunction syndrome (MODS).
      2. The systemic clinical course changes with time.
   B. Direct thermal injury results in coagulation necrosis of the tissue.

II. Systemic effects may occur in various organs.
   A. Cardiovascular effects
      1. Significant hypovolemia can arise from interstitial edema and evaporation if >20% TBSA is burned.
         a. Vascular leakage develops secondary to release of reactive oxygen species (hydrogen peroxide, hypochlorite ion, hydroxyl radical, superoxide anion) and vasoactive substances from the injured tissue, which results in fluid loss.
         b. The ability to medically manage vascular leakage is currently limited.
         c. Fluid loss is estimated at 1 to 4 mL/kg × %TBSA affected.
      2. Initially, a catecholamine surge results in tachycardia, peripheral vasoconstriction, and hypertension.
      3. Hypovolemia and the generation of myocardial depressant factors decrease cardiac output.
      4. Compensatory mechanisms are overwhelmed by fluid loss, resulting in hypovolemic shock.
      5. Low-voltage electrical injuries may cause fatal ventricular arrhythmias, noncardiogenic pulmonary edema, and death.
      6. The final consequences of cardiovascular failure are decreased tissue perfusion and hypoxemia.

B. Hematological effects
   1. Initial fluid losses can result in hemoconcentration.
   2. Hemolysis may occur as a result of direct thermal injury, passage through damaged vasculature, and disseminated intravascular coagulation (DIC).
   3. Hemolysis occurs even with less severe burns, resulting in hemoglobinuria and anemia.
   4. Platelet consumption contributes to DIC.
   5. Anemia is exacerbated by depressed hematopoiesis, hemolysis, cachexia, and blood loss from removal of eschar and graft harvesting.

C. Respiratory effects
   1. Hot-air inhalation results in mucosal damage, edema, and inactivation of cilia and surfactants.
   2. Inhaled particulate matter and toxins cause direct pulmonary injury, leading to acute lung injury or acute respiratory distress syndrome.
   3. Burns of the thoracic wall and eschar formation cause decreased thoracic compliance and may contribute to hypoventilation.
   4. Electrical injuries may result in noncardiogenic pulmonary edema.

D. Renal effects
   1. Hypovolemia causes decreased renal blood flow and direct renal damage.
   2. Hemoglobinuria and myoglobinuria contribute to acute renal failure.

E. Gastrointestinal effects
   1. Gastrointestinal tract edema results in increased mucosal permeability and compromise of the intestinal barrier, leading to bacterial translocation and endotoxemia.
   2. Gastrointestinal ulceration from compromise of the intestinal barrier may result in blood loss.
   3. Hepatic dysfunction causes hypoglycemia, immunosuppression, and septicemia.

F. Immunological effects
   1. Both the humoral and cell-mediated components of the immune system are affected.
   2. Immunosuppression may occur if >20% TBSA is burned (Sheridan, 2002).
   3. Loss of proteins, such as immunoglobulins, fibronectin, acute phase proteins, and albumin, alters the immune status.
   4. Increased plasma concentrations of cortisol and other "stress" hormones affect both humoral and cell-mediated immunity and may result in immunosuppression.
   5. Inflammatory mediators contribute to SIRS and MODS.

G. Electrolyte disturbances
   1. Hypernatremia or hyponatremia, hyperkalemia or hypokalemia, and acidosis (metabolic, respiratory, or both) can occur and change over time.
   2. Many topical medications placed on wounds draw electrolytes or fluid out of the tissues because of their osmotic effects.
   3. Impaired renal function contributes to altered electrolyte values.

H. Miscellaneous effects
   1. Thermoregulation is impaired by evaporative heat loss from the surface of large wounds.
      a. Initially, hypothermia results from overzealous wound cooling and evaporation of fluids.
      b. Over time, hyperthermia occurs secondary to a hypermetabolic state (Hart et al., 2000).
   2. Affected animals are at increased risk of infection because of gastrointestinal, renal, and hepatic dysfunction, protein catabolism, cytokine release, and immune system dysregulation.
   3. Hypermetabolic states can last for >6 months after injury.
   4. Daily protein loss may exceed 2 g/kg/day and may result in a negative energy balance.

Clinical Signs

I. Thermal burns
   A. Local damage (see Table 134-2)
   B. Systemic effects
      1. Organs other than the skin may manifest abnormalities following deep partial-thickness or full-thickness burns over >20% of TBSA.
      2. Systemic clinical course changes with time.
         a. Immediate effects include hypothermia, electrolyte disturbances, organ edema, cardiovascular compromise, immunosuppression, hemolysis, DIC, decreased urine output, and airway edema.
         b. In the first week, clinical signs can include anemia, DIC, SIRS, early wound infection, and small airway obstruction.
         c. From day 7 to wound closure, clinical signs include hyperthermia, a hypermetabolic state, sepsis, pneumonia, wound demarcation, and healing.

II. Electrical burns (see Chapter 133)

Diagnosis

I. History
   A. Elucidate the events surrounding the burn exposure.
   B. Determine the duration and type of exposure.

II. Physical examination of all body systems
   A. Neurological function
      1. Mentation deteriorates as the animal becomes moribund or receives pain medications, so knowledge of initial mental status is vital to assessment and prediction of return to normal mentation.
      2. Carbon monoxide (CO) intoxication and smoke inhalation causes neurologic signs, such as ataxia, mentation changes, and seizures.
      3. CO can result in neurologic signs days to weeks after discharge from the hospital (Mariani, 2003).
   B. Oropharyngeal structures
      1. Check for inhalation injuries; if noted, treat for smoke inhalation.

a. Look for burns around the mouth and nares or singed facial hair.
b. Look for soot particles in nostrils or pharynx.
2. Laryngeal swelling may necessitate intubation or placement of a tracheostomy tube.

C. Respiratory status
1. Ensure adequate ventilation.
a. Decreased thoracic wall compliance, bronchospasm, upper airway swelling, and lower airway edema may decrease oxygenation of blood, necessitating oxygen supplementation.
b. Assisted ventilation may be needed if hypoxia persists despite oxygen administration.
2. Thoracic radiography helps determine the presence of pulmonary edema and other thoracic trauma.

D. Cardiac changes
1. Monitor blood pressure to assess perfusion parameters.
2. Electrocardiography may be performed to characterize any arrhythmia that is present, especially if there is electrical injury or an auscultable arrhythmia.

E. Abdominal effects
1. Abdominal compliance may be decreased from eschar formation and may alter diaphragm movement and compromise respiration.
2. Gastric ulcers may develop secondary to decreased splanchnic blood flow and mucosal edema.

F. Urogenital changes
1. Swelling may cause a functional urethral obstruction.
2. Consider placement of an indwelling urinary catheter.

G. Changes in extremities
1. Assess large extremity wounds for vascular viability.
2. Evaluate vascular viability via Doppler blood flow, sensation, temperature, and voluntary motion.

III. Supplemental tests
A. Other tests are dependent on the condition of the animal but are recommended if >20% TBSA is affected.
B. Complete blood count (CBC), serum biochemistry profile, and urinalysis detect underlying conditions and provide baseline data.
C. Determine oxygenation and acid-base status via arterial blood gas analysis.

Treatment of Wounds

I. Biological closure of wounds is critical as soon as possible after the injury (Atiyeh et al., 2005; Fox, 1985; Fox,1989; Sheridan, 2002).
A. Wounds change over the first few days.
B. Remove all devitalized material, minimizing damage to viable tissue.

II. Small burns rarely lead to serious sepsis.
A. Allow time for wound evolution to reveal the depth and edges of the wound.
B. Use topical treatments at least once daily to prevent wound infection, decrease vapor loss, prevent desiccation, and control pain.
1. Silver sulfadiazine: painless, broad spectrum, poor eschar penetration, no metabolic effects
2. Silver nitrate: painless, broad spectrum, poor eschar penetration, leaches electrolytes
3. Mafenide acetate: painful, broad spectrum, excellent eschar penetration

III. Large wounds heal faster if surgically closed early (Sheridan, 2002).
A. Remove nonviable material, minimizing damage to viable tissue.
B. It can be difficult to determine margins of viable and nonviable tissue, particularly early in the wound course.
C. Use topical treatments, as described above, for small wounds.
D. Bleeding can be extensive with eschar removal and can be minimized by use of extremity tourniquets, dilute epinephrine injections, reduced operating time, and electrosurgery (Sheridan, 2002).
1. Sterile soaking of wounds helps with eschar removal.
2. Place gauze soaked in warm sterile saline over the wound for several minutes to help soften the eschar.
3. Hydrotherapy can be used to help soften and remove tissue.
4. Small animals can be placed in a clean, disinfected, and newly filled whirlpool tub to enhance softening of the eschar and improve skin circulation.
5. Perform manual removal of obviously devitalized tissue with forceps and scissors (lift and cut away dead tissue).
E. Debriding enzymes can be used to soften and remove eschar.
1. *Collagenase Santyl Ointment* (distributed under license from BioSpecifics by Ross Abbott) is a petroleum-based product for humans that can be placed directly on burns to help liquefy necrotic tissue.
2. G*ranulex V* by Pfizer is approved in animals for the treatment of rope burns.
3. *Debridase* (Mediwound LTD, Yavne, Israel) is a product for humans that has been used in animals (Hebda et al., 1998; Krieger et al., 2005; Rosenberg et al., 2004).
4. Reported use of topically applied enzymatic medications is limited in animals.

IV. Large areas of eschar are surgically removed, leaving viable tissue that bleeds, which is closed or grafted as soon as possible afterward.
A. Autografting is recommended; refer to surgery textbooks for techniques.
B. Use allograft or other temporary wound closure material (see following discussion) if autografting is not possible.
C. Primary grafting can prevent some wound contraction and loss of mobility.
D. Allografts or biological membranes may be used in several settings.

1. To provide temporary physiologic closure of burns while awaiting autografting
2. On donor sites to facilitate pain control and epithelialization from skin edges
3. As a dressing on clean superficial wounds
4. As a test graft over questionable wound beds

E. Multiple biological membranes and xenographs are commercially available.
1. Swine small intestinal submucosa (Cook Biotech Incorporated, West Lafayette, Ind.) is approved for use in animals and can aid wound healing.
2. *Integra* (Integra Life Science, Plainsboro, N.J.) is approved for humans and contains collagen isolated from bovine tissue that facilitates fibrovascular ingrowth from the host and then undergoes biodegradation.
3. *AlloDerm* (LifeCell Corporation, The Woodlands, Tex.) is approved for humans and is manufactured from split-thickness human cadaver skin.
4. Superiority of one xenograft versus another has not been established at this time.

V. Large wounds often become infected in the second week.
A. Systemic prophylactic antibiotics are not recommended because they can predispose the animal to resistant infections.
B. Systemic antibiotics are needed if sepsis or overwhelming wound infection occurs.
C. Obtain a bacterial culture of affected tissue before administering systemic antibiotics.
1. Choose antibiotics based on the culture or the probable agent while the culture is pending.
2. *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and β-hemolytic streptococci are common infectious organisms in burn wounds (Fox, 1985).
3. *Pseudomonas* spp. are the organisms of greatest concern.

VI. Wound protection is important.
A. If possible, bandage wounds with sterile dressings to prevent environmental contamination, desiccation, and to assist with thermoregulation.
B. Use an Elizabethan collar or other method to prevent self-inflicted trauma.

Treatment of Physiologic Abnormalities

I. Severe fluid loss
A. No formula perfectly predicts fluid losses, but the Parkland formula has historically been recommended (Fox, 1985; Sheridan, 2002).
1. Loss for the first 24 hours is body weight (kg) × %TBSA × 4 mL.
2. Replace 50% in the first 8 hours after injury.
3. Replace 25% in the second 8 hours after injury.
4. Replace 25% in the third 8 hours after injury.

B. Colloids improve cardiac output despite increased capillary permeability and may be used when indicated.
1. Administer hetastarch or dextrans at 20 mL/kg/day IV.
2. Concern that colloids add to oncotic leakage from tissues has been neither proven nor refuted.

C. Administer fluids until monitoring parameters are normal.
1. Maintain normal (0 to 5 cm H_2O) or slightly above normal central venous pressure (CVP).
2. Maintain normal urine output (1 to 2 mL/kg/hr).
3. Maintain normal blood pressure (mean arterial pressure of 70 to 110 mm Hg).
4. Normalize capillary refill time (1 to 2 seconds) and clinical assessments of hydration.

D. Blood products may be necessary when severe anemia, hypoproteinemia, or coagulation deficits are present (see Chapter 71).
E. Fluid losses should decrease over the first 48 hours and with wound closure.

II. Airway edema
A. Manually remove debris and dirt from nostrils and oropharynx.
B. Intubation or tracheotomy may be necessary.
C. Oxygenate or ventilate as needed.
D. Bronchodilator therapy may help maintain small airway patency.
E. If pneumonia is present, obtain cultures via transtracheal wash or bronchoalveolar lavage before antibiotic therapy.

III. Hypothermia
A. Evaporative losses from wounds contribute to heat loss.
B. Keep the animal in a warm environment; maintain cage temperature at 80° to 85° F (26.6° to 29.5° C).
C. Body temperature usually normalizes with time and especially after wound closure.
D. Watch for onset of hyperthermia by the second week.

IV. Pain control (Pascoe, 2000; Plumb, 2002)
A. Poor pain control contributes to slowed healing and immunosuppression.
B. Opioids are preferred but may cause respiratory depression.
1. Morphine 0.5 to 2.0 mg/kg IM, SC every 3 to 4 hours, or as a constant rate infusion (CRI) at 0.1 to 1.0 mg/kg/hr, with an IM or SC dose given before starting the infusion
2. Hydromorphone 0.1 to 0.2 mg/kg IM, IV, SC every 4 to 6 hours
3. Fentanyl 2 to 5 μg/kg IV, then as a CRI of 2 to 3 μg/kg/hr

V. Biochemical aberrations
A. Hyponatremia or hypernatremia, hypokalemia or hyperkalemia
1. Supplement as warranted.
2. Severe electrolyte aberrations can cause central nervous system alterations.

B. Hypoglycemia or hyperglycemia
1. Treat with insulin or dextrose as warranted.
2. Maintain normoglycemia to enhance wound healing and immune function.

C. Hemolysis (Norman et al., 2005)

1. Hemoglobinuria and myoglobinuria are often documented, so if present, administer IV fluids to reduce renal damage from these agents.
2. Renal damage can contribute to electrolyte abnormalities.
3. Blood transfusions may be needed to maintain the hematocrit in the low normal range.

D. Hypoproteinemia (Kern et al., 1992)
1. It is consistently documented in all severe burns.
2. Provide oncotic support, nutritional support, and plasma transfusions as warranted.
   a. For colloid oncotic pressures <12 mm Hg or total protein <4 g/dL, give the following:
      (1) Fresh or frozen plasma 10 mL/kg IV over 3 to 6 hours
      (2) Hetastarch or dextrans 20 mL/kg/day IV
      (3) Nutritional support (see below)
   b. For albumin values <1 g/dL and peripheral edema, consider 25% human albumin 2-5 mL/kg slow IV bolus, but be vigilant for signs of anaphylaxis (Mathews and Barry, 2005).
3. Protein loss is reduced once wounds are closed.

E. Other abnormalities
1. Acute renal failure can occur secondary to hypovolemia, shock, sepsis, hemoglobinuria and myoglobinuria (see Chapter 48).
2. Liver insufficiency may occur secondary to edema, splanchnic hypoperfusion, and congestion (see Chapter 37).

VI. Nutritional support

A. Hypermetabolic processes may persist for 6 to 12 months after the burn (Hart et al., 2000).
1. Doubling of cardiac output, doubling of resting metabolic rate, enhanced gluconeogenesis, insulin resistance, and increased protein catabolism are common.
2. A high-calorie, high-protein diet is recommended.

B. Enteric feeding methods are preferred.
1. Enteral feeding keeps enterocytes healthy, decreases bacterial translocation, and minimizes infection rates.
2. Enteral feeding methods include oral intake, as well as nasoesophageal, nasogastric, esophagostomy, gastrostomy, and jejunostomy tube feedings.

C. Vitamin and mineral supplementation is recommended.

D. Parenteral nutrition is required if the enteric route cannot be used.

E. Estimate basal metabolic rate in kilocalories at body weight (kg) × 30 + 70.

Monitoring of Animal

I. Level of monitoring is dependent on severity of the clinical signs.

A. Moribund, critical animals require intensive monitoring.
1. Hematocrit, total solids, blood glucose, CVP, blood pressure every 4 to 6 hours
2. Blood gases, serum electrolytes and biochemistry panel every 12 to 24 hours
3. Physical examination and wound care every 12 to 24 hours
4. CBC and coagulation profiles every 24 to 48 hours
5. Thoracic radiography or other imaging as indicated by clinical signs

B. Stable animals may only require initial diagnostic tests and continued wound care.
1. Initial CBC, serum biochemistry profile with electrolytes, and thoracic radiography
2. Physical examination and wound care every 12 to 24 hours

II. Wound healing can be prolonged (>6 months), and some animals require lengthy hospitalization (Probst et al., 1984).

A. Multiple surgeries may be required.

B. Emotional and financial dedication of the owner is necessary.

CHAPTER 135

Heat Prostration

Efrat Kelmer | Marie E. Kerl

Definition

I. Heat prostration is a multisystemic disorder that occurs with acute elevations of body temperature >40° to 41°C (104° to 106° F) (Morgan, 1985).
II. Classic or nonexertional heat stroke is exposure to high ambient temperatures that usually occurs in the summer and is precipitated by environmental or medical factors (e.g., confinement in an unventilated vehicle, laryngeal paralysis).
III. Exertional heat stroke occurs when the normal heat dissipation mechanisms cannot keep up with the amount of heat produced by the body, and it usually occurs in spring or early summer before acclimatization occurs.

Causes

I. Decreased ability to dissipate heat
  A. Exogenous factors
    1. Confinement in poorly ventilated space
    2. Lack of acclimatization to a warmer environment
    3. Increased humidity
    4. Water and shade deprivation
  B. Endogenous factors
    1. Obesity
    2. Cardiovascular diseases
    3. Central nervous system diseases
    4. Upper airway obstruction
      a. Laryngeal paralysis
      b. Brachycephalic airway syndrome
      c. Tracheal collapse
      d. Laryngeal or tracheal masses
    5. Previous episode of heat stroke
    6. Physical obstruction to heat exchange (e.g., thick haircoat)
II. Increased heat production
  A. Exogenous
    1. Drugs (data available primarily from humans)
      a. Phenothiazines: chlorpromazine, acepromazine
      b. Antihistamines
      c. Tricyclic antidepressants
      d. Anticholinergics
      e. Amphetamines
      f. Gas inhalants: halothane
    2. Macadamia nuts ingestion (Hansen et al., 2000)
    3. Hops ingestion (Duncan et al., 1997)
  B. Endogenous factors
    1. Prolonged seizure activity
    2. Hormonal hyperthermia: feline hyperthyroidism
    3. Malignant hyperthermia (rare)
    4. Exercise
    5. Eclampsia

Pathophysiology

I. The thermoregulation center, located in the preoptic region of the anterior hypothalamus, maintains the balance between heat production and loss.
  A. The range of temperatures ideal for metabolic activity is narrow.
  B. Body temperatures above this range trigger heat dissipation mechanisms.
  C. Nonpyrogenic hyperthermia (heat stroke) occurs when the body's natural mechanisms for heat dissipation are overwhelmed by elevated environmental temperatures.
II. Four mechanisms of heat exchange exist.
  A. Conduction
    1. Heat is conducted between the body and environmental objects, such as air, water, or a cold floor.
    2. Under normal conditions, conduction represents a small portion of an animal's heat loss.
    3. This mechanism is eliminated when the ambient temperature exceeds the body temperature.
  B. Convection
    1. It is the movement of air or water over the surface of the body.
    2. Under normal conditions, this is the second major source for heat loss.
  C. Radiation
    1. It involves electromagnetic exchange of heat between objects in the environment not in direct contact with the skin.
    2. Relative temperatures determine the direction of heat transfer.
    3. Under normal conditions radiant heat loss is the major source of heat loss.
  D. Evaporation
    1. Evaporation occurs when a liquid is converted to a gas.
    2. A considerable amount of heat is lost during humidification of inspired air with normal breathing.
    3. Panting enhances this mechanism as environmental temperatures increase.

III. Harmful effects of hyperthermia are related to direct thermal injury, high cellular metabolic activity and oxygen consumption, and may affect all body systems (Table 135-1).

Clinical Signs

I. History may include recent exercise, confinement to an unventilated area, prolonged exposure to sunshine without access to water or shade, exposure to certain drugs, as well as collapse or seizure activity.
II. In one study, Belgian malinois, retrievers, and brachycephalic dog breeds were overrepresented, and small dog breeds were underrepresented (Bruchim et al., 2006).
III. The severity of clinical signs is positively correlated to the maximal temperature and duration of exposure.
IV. Clinical signs may vary depending on the intensity and progression.
   A. Panting: most common clinical sign (Drobatz and Macintire, 1996)
   B. Hyperthermia (typical) or hypothermia (rare)
   C. Obtundation, dull mentation, stupor, coma
   D. Cranial nerve deficits, cortical blindness
   E. Ataxia
   F. Dehydration
   G. Tachypnea, respiratory distress
   H. Tachycardia, weak pulses
   I. Tacky, hyperemic, or pale mucous membranes
   J. Hematochezia, hematemesis
   K. Petechiation, ecchymosis
   L. Stridor or stertor with underlying upper airway obstruction
   M. Heart murmur with underlying cardiac disease
   N. Seizures from primary causes or secondary to prolonged hyperthermia

Diagnosis

I. Diagnosis is based on the presence or historical evidence of hyperthermia (body temperature >40° C (104° F), along with compatible history, clinical signs, and predisposing factors.
II. Initial diagnostic tests include the following:

TABLE 135-1

Systemic Effects of Hyperthermia on Various Body Systems

BODY SYSTEM	TIME OF OCCURRENCE	PHYSIOLOGICAL EFFECTS
Cardiovascular	Initial	Increased cardiac output and decreased systemic vascular resistance from peripheral vasodilation
	Late	Decreased cardiac output and circulatory collapse Thermal injury may cause myocardial ischemia and necrosis resulting in supraventricular and ventricular arrhythmias
Pulmonary	Initial	Pulmonary edema from cardiac dysfunction, endothelial damage, and decreased colloid oncotic pressure secondary to hypoalbuminemia
	Late	Acute respiratory distress syndrome
Central nervous	Initial	Decreased cerebral blood flow
	Late	Cerebral edema, cerebral hemorrhage, infarction, cerebellar dysfunction
Renal	Initial	Renal hypoperfusion Thermal injury may result in acute tubular necrosis
	Late	Nephrotoxicity secondary to rhabdomyolysis and hypermyoglobinemia Acute renal failure
Gastrointestinal	Initial	Ischemia leading to compromised mucosa, hematochezia, and hematemesis
	Late	Bacterial translocation, endotoxemia, sepsis
Liver	Initial	Hepatocellular degeneration, cholestasis, centrilobular necrosis Impaired protein synthesis
	Late	Liver failure
Hematologic and coagulation	Initial	Thermal injury may result in destruction of platelets and clotting factors, as well as endothelial damage
	Late	Decreased production of clotting factors owing to impaired hepatic synthesis, endothelial dysfunction, DIC
Musculoskeletal	Initial or late	Myoglobinemia and rhabdomyolysis
Immune	Initial	Inflammation
	Late	Systemic inflammatory response syndrome Immunosuppression secondary to sepsis
Acid-base status	Initial and late	Metabolic acidosis from lactic or uremic acidosis Respiratory alkalosis from hyperventilation

DIC, Disseminated intravascular coagulation.

A. Packed cell volume (PCV), total protein (TP), blood urea nitrogen (BUN), blood glucose, electrolytes, lactate, arterial blood gas analysis, prothrombin time (PT), partial thromboplastin time (PTT), or activated clotting time (ACT)
B. Blood drawn before fluid therapy for complete blood count and a biochemistry panel
C. Urinalysis
D. Indirect blood pressure, pulse oximetry (SpO_2), electrocardiography, colloid osmotic pressure

III. Clinicopathologic findings vary, depending on severity and progression.
A. Hemoconcentration secondary to dehydration
B. Elevated total protein initially, followed by hypoproteinemia
C. Prolonged PT/PTT or ACT
D. Increased BUN and creatinine from prerenal or renal azotemia
E. Decreased blood glucose from increased metabolic demand or sepsis
F. Metabolic acidosis with decreased bicarbonate, most likely from lactic acidosis
G. Respiratory alkalosis with decreased $Paco_2$ secondary to hyperventilation

Differential Diagnosis

Any cause of true fever, such as infection, inflammation, immune-mediated diseases, neoplasia, and paraneoplastic syndromes

Treatment

I. Early and aggressive goal-directed therapy of any potential heat-related injury and proactive management of complications are the keys to a successful outcome.
II. Start initial cooling measures *before* transport of the animal.
A. Wet the animal with cool tap water and use a fan to increase convective heat loss.
B. Avoid ice baths because they are uncomfortable to the animal and they increase metabolic demands from shivering, which increases cellular oxygen consumption.
C. Transport the animal in a well-ventilated vehicle.

III. Institute initial resuscitation measures immediately upon arrival to the hospital.
A. If the animal is hyperthermic, continue cooling methods.
1. In addition, apply ice packs to the jugular vein and inguinal areas.
2. Apply alcohol to the footpads.
3. Terminate cooling once the body temperature reaches 103° F (39.5° C).
B. Initiate oxygen therapy via one of the following methods:
1. Flow-by oxygen is delivered by mask or oxygen tent.
2. Oxygen may also be delivered via nasal tube.
3. If upper airway obstruction is present, consider transtracheal oxygen.
4. Use oxygen cages cautiously, as they can cause overheating.
C. Insert one or two short, large-bore intravenous (IV) peripheral catheters and initiate an isotonic crystalloid solution IV
1. If the animal is in hypovolemic or distributive shock (as determined by tachycardia, weak pulses, tachypnea, hypotension, or decreased mentation), the initial fluid rate is 90 mL/kg IV (dogs) or 60 mL/kg IV (cats) until hemodynamic parameters normalize.
2. If the animal remains hypotensive (systolic blood pressure <80 mm Hg), administer a bolus (5 to 10 mL/kg IV followed by 20 mL/kg/day as a constant rate infusion IV) of a colloid solution (hydroxyethyl starch, dextran 70).
3. If a colloid solution is administered, crystalloid volume may need to be reduced by one third.
4. If hypotension persists despite appropriate fluid resuscitation, consider inotropic therapy (dobutamine 5 to 15 μg/kg/min IV) or vasopressor therapy (dopamine 5 to 15 μg/kg/min IV).
D. If hypoglycemia is present, give 50% dextrose as a bolus (0.5 g/kg IV, diluted 1:1 with sterile water), and supplement dextrose in the IV crystalloid solution.
1. Add 50 mL of 50% dextrose to 1 L crystalloid solution to achieve a final concentration of 2.5% dextrose.
2. Add 100 mL of 50% dextrose to 1 L crystalloid solution to achieve a final concentration of 5% dextrose.
E. Administer diazepam 0.5 mg/kg IV as needed to control seizures.
F. Initiate treatment for life-threatening ventricular arrhythmias.
1. Give dogs lidocaine at 2 mg/kg IV bolus, followed by 50 to 100 μg/kg/min IV as needed.
2. Use lidocaine with extreme caution and in lower doses in cats (0.2 mg/kg IV).
G. Consider giving mannitol 0.5 to 1.5 g/kg IV over 20 minutes for severe neurologic signs suggestive of cerebral edema; mannitol should be avoided in animals that are severely dehydrated.
H. Administer fresh frozen plasma at 10 mL/kg IV over 2 to 4 hours if coagulation tests are prolonged or if there is other evidence suggestive of DIC.

IV. Apply additional treatments and supportive care as indicated.
A. Identify and manage concurrent predisposing conditions associated with heat stroke.
B. Insert a urinary catheter for maintenance of good hygiene and for monitoring of urine output, especially when acute renal failure is suspected.
C. Place a central IV catheter in critically ill animals to facilitate repeated blood sampling and measurement of central venous pressure.
D. Avoid placement of a jugular catheter in animals with severe coagulopathies.
E. Consider broad-spectrum antibiotics, especially if hematemesis and hematochezia are present, or if evidence of sepsis exists (e.g., neutropenia, degenerative left shift, hypoglycemia).

F. Give gastrointestinal protectants, antacids, and antiemetic drugs for nausea, vomiting, or suspected gastrointestinal ulceration.
   1. Sucralfate 0.5 to 1 g PO TID to QID (dogs)
   2. Histamine receptor 2 antagonists (H_2 blockers), such as famotidine 0.5 to 1 mg/kg IV, PO SID to BID, or ranitidine 1 to 2 mg/kg IV, PO BID
   3. Proton pump inhibitors, such as omeprazole 0.7 to 1 mg/kg PO SID or pantoprazole 0.7 to 1 mg/kg IV SID (dogs)
   4. Dopamine antagonists, such as metoclopramide 0.1 to 0.4 mg/kg SC, followed by 1 to 2 mg/kg/day IV as a constant rate infusion (dogs)
   5. Serotonin 5-HT_3 receptor antagonists, such as dolasetron 0.6 mg/kg IV, SC SID

G. Nursing care and good hygiene are indicated for recumbent animals.
   1. Comfortable bedding
   2. Periodic rotation
   3. Frequent cleaning of animal and cage, especially if diarrhea or vomiting occurs
   4. Skin protectants, such as silver-sulfadiazine, zinc oxide ointments, or talc to avoid urine scald

Monitoring of Animal

I. Maintain body temperature in the normal range.

II. Other parameters to monitor include the following:
   A. Blood pressure
      1. If the animal is hypotensive at presentation, measure blood pressure every 30 minutes or after IV fluid boluses until normotension is achieved.
      2. Measure blood pressure BID to QID thereafter.
      3. Systolic blood pressure is maintained >80 mm Hg.
   B. Measure PCV/TP, blood glucose, and electrolytes every 4 to 12 hours.
   C. Assess mentation hourly.
   D. Assess other neurologic parameters SID to BID.
   E. Closely monitor urine output and renal function.
      1. Urine output is maintained > 1 mL/kg/hour.
      2. Measure BUN, creatinine, and urine specific gravity SID.
   F. Record body weight at least SID; it should remain constant once the animal is rehydrated.
   G. Evaluate CBC and coagulation profiles SID and after plasma transfusions.
   H. Measure central venous pressure every 4 to 6 hours (reference range is 2 to 10 cm H_2O).
   I. Measure colloid osmotic pressure SID (reference range is 18 to 24 mm Hg).
   J. Monitor serum lactate every 24 hours (reference range is 1 ± 0.5 mmol/dL).
   K. Monitor electrocardiography continuously or every 4 to 6 hours.

III. Increase or taper the frequency of monitoring according to the progression of the animal.

IV. The main predictor of outcome is the duration and degree of hyperthermia.
   A. Hypothermia and coma at the time of presentation have been associated with a poor prognosis (Drobatz and Macintire, 1996).
   B. Seizures, hypoglycemia, obesity, and serum creatinine >1.5 mg/dL after 24 hours have been associated with increased mortality (Bruchim et al., 2006).
   C. In one study, 80% of dogs that survived the first 24 hours of hospitalization were later discharged (Drobatz and Macintire, 1996).

CHAPTER 136

Envenomations

Alisa N. Reniker

VENOMOUS SNAKES

Definition

I. Envenomation occurs when a poisonous secretion is injected into the victim by bite or sting of a reptile, insect, or arachnid.
II. Morbidity or mortality results from localized or systemic reactions.

Causes and Classification

I. There are >3000 snake species worldwide, with approximately 450 species in five families (Colubridae, Crotalidae, Elapidae, Hydrophiidae, Viperidae) being venomous (Gold et al., 2002).
II. Twenty-five of 120 species in the continental United States are venomous (Gold et al., 2004).
  A. All venomous snakes in the United States are pit vipers except the coral snake.
  B. Alaska, Maine, and Hawaii are the only states without venomous snakes.
    1. Pit vipers
      a. Family Viperidae, subfamily Crotalinae, genus *Crotalus* and *Sistrurus* (rattlesnakes) or *Agkistrodon* (cottonmouths and copperheads)
      b. Identifying features: triangle-shaped head, elliptical pupils, heat-sensing foramen between eyes and nostrils, retractable canalized fangs, single row of subcaudal plates
    2. Coral snake
      a. Family Elapidae, genus *Micrurus* and *Micruroides*
      b. Sonoran coral snake bites unlikely to cause significant clinical symptoms
      c. Identifying features: alternating red, yellow, and black stripes with red and yellow adjacent to each other; rounded head; round pupils; short, fixed fangs; no heat-sensing pits

Pathophysiology

I. Snake venom
  A. Composed of enzymes, low-molecular-weight polypeptides, and proteins of 6 to 100 kD (Gold et al., 2002).
  B. Composition varies by species, age of snake, season, time since last envenomation, and geographic location.
  C. Simplification of venom components into neurotoxins, myotoxins, hemotoxins, or cardiotoxins is misleading, as components bind to numerous receptor sites and affect multiple organ systems (Gold et al., 2004).
II. Crotalid venom
  A. They are cytotoxic and necrolytic owing to endopeptidases/proteolytic enzymes.
  B. Immobilization of prey is achieved through induction of hypovolemic shock.
    1. Polypeptides damage vascular endothelial cells, causing loss of intravascular fluid into the interstitium.
    2. Hyaluronidase breaks collagen bonds and facilitates venom dispersion.
    3. Metalloproteinases destroy basement membrane architecture and cause edema, extravasation, and ecchymotic hemorrhages.
    4. Endogenous and exogenous phospholipase A_2 acts upon membrane phospholipids to liberate arachidonic acid and initiate the inflammatory cascade.
    5. Vasodilatory prostaglandins and bradykinins exacerbate hypotension.
III. Elapid venom
  A. It is neurotoxic through the actions of acetylcholinesterase.
    1. Immobilization of prey occurs via nondepolarizing neuromuscular blockade of the postsynaptic junction.
    2. Generalized flaccid paralysis, central nervous system (CNS) depression, and vasomotor tone instability result.
  B. Minimal tissue damage occurs, but hemolysis develops in dogs because of phospholipase A_2 activity.

Clinical Signs

I. Crotalid envenomation
  A. Local wound
    1. Signs usually develop within 30 minutes of the bite and include single or multiple puncture wounds, pain at the bite site, edema or ecchymotic bruising, and serosanguineous to hemorrhagic discharge from puncture wounds.
    2. Up to 25% of pit viper and 50% of coral snake bites may be "dry," with no venom release (Gold et al., 2004).
  B. Systemic effects
    1. Hypovolemic shock leads to tachycardia, weakness, tachypnea, pallor, mental dullness, poor pulse quality,

cold extremities, hypotension, and prolonged capillary refill time.
2. Up to one third of effective circulating volume can be lost to the envenomated area within 1 hour of the bite (Hudelson and Hudelson, 1997).

C. Hematologic effects
1. Disseminated intravascular coagulation (DIC)-like coagulopathy
   a. Thrombin-like components convert fibrinogen to fibrin without activation of factor XIII and stable crosslink formation.
   b. Unstable clot is degraded by plasminogen, and defibrination and elevation in fibrin degradation products (FDP) result because of a net anticoagulative effect.
   c. Effects differ from true DIC in that platelets and Factor VIII are not consumed and D-dimers are not formed.
   d. Normal coagulation and fibrin crosslinking are not inhibited, so life-threatening hemorrhage is rare.
2. Thrombocytopenia
   a. It may occur initially or up to 2 weeks after appropriate therapy.
   b. Possible pathophysiologic mechanisms include platelet aggregating properties of Western diamondback, blacktail, and timber rattlesnake venoms; prostaglandins and endogenous and exogenous phospholipase A_2; and severe polypeptide-mediated endothelial injury, with platelet consumption at the envenomation site.
3. Echinocytes
   a. Erythrocytes with uniformly sized, regularly spaced membrane projections that appear similar to crenation artifact
   b. Possibly from adenosine triphosphate depletion of membrane pumps, alteration of red blood cell (RBC) membrane by phospholipase, or dehydration of RBC via electrolyte depletion
   c. Occur in 89% of envenomated dogs within 24 hours of bite (Walton et al., 1997)
   d. Supportive, but not definitively diagnostic for envenomation

D. Cardiac effects
1. No specific cardiotoxic constituent
2. Hypotension from hypovolemia with subsequent decreased coronary perfusion: multitude of arrhythmias
3. Hyperkalemia from rhabdomyolysis: bradycardia, atrial standstill, potentially cardiac arrest
4. Coagulopathy-induced myocardial hemorrhage: arrhythmias from disrupted conduction

E. Pulmonary effects
1. Acute respiratory distress syndrome (ARDS): tachypnea, progressive hypoxemia, pulmonary crackles, coughing, and cyanosis in the absence of left-sided heart failure or volume overload
2. Severe pulmonary congestion secondary to prostaglandin and phospholipase A_2-mediated endothelial injury, increased vascular permeability, alveolar hemorrhage

F. Neuromuscular effects
1. Hypoventilation or respiratory muscle paralysis
2. Mojave toxin: presynaptic nerve blockade, with greatest effect on the motor axon terminals of the diaphragm (Hudelson and Hudelson, 1997)
3. Crotoxin: neurotransmitter release inhibited through leakage of acetylcholine vesicles at the presynaptic membrane (Hudelson and Hudelson, 1997)

G. Muscular and soft tissue changes
1. Tissue necrosis and wound sloughing occur within 6 to 24 hours of bite.
   a. Rhabdomyolysis may be more common with Mojave and Western diamondback envenomations.
   b. Phospholipase A_2 damages sarcolemma and myocyte mitochondria, with vacuolation and loss of muscle striation.
   c. Collagenase facilitates spread of venom through destruction of connective tissue barriers.
2. Compartment syndrome (constriction of nerves, blood vessels, or tendons from swelling within a closed anatomic space) is more effectively treated by antivenom administration than fasciotomy, and is an uncommon complication in dogs and cats.

H. Nephrotoxicity
1. Azotemia, hyperphosphatemia, hyperkalemia, metabolic acidosis, dehydration, polyuria, or oliguria/anuria may occur secondary to hypotension and hypovolemia.
2. Acute renal failure is more likely with Mojave rattlesnake venom-induced rhabdomyolysis.
   a. Venom toxin causes proximal tubular injury.
   b. Myoglobinuria and hemoglobinuria can result in tubular damage.

II. Elapid envenomation

A. Local wound
1. Elapids envenomate by chewing rather than striking.
2. Fang wounds often are not evident, but small puncture wounds are possible.
3. They differ from crotalid wounds in that substantial tissue necrosis, petechiation, edema, and pain are not characteristic, but local paresthesia is possible.

B. Systemic effects
1. Neurotoxicity occurs secondary to motor axon terminal damage or from a competitive, nondepolarizing, postsynaptic acetylcholine blockade at the neuromuscular junction.
2. Clinical signs include generalized muscle weakness or fasciculations, cranial nerve palsy, vomiting, seizures, tremors, drowsiness or disorientation, dysphagia, salivation, and dyspnea.
3. Aspiration pneumonia, hypotension, and ventricular tachycardia may occur.

4. Death from respiratory failure can occur as quickly as 4 hours after the snakebite.
5. Weakness and progressive paralysis generally begin within 3 hours after the bite, but onset may be delayed up to 48 hours after envenomation.

Diagnosis

I. Crotalid envenomations
   A. Local signs: puncture wounds, edema, pain, serosanguineous discharge
   B. Complete blood count (CBC)
      1. Supportive evidence includes echinocytes and thrombocytopenia.
      2. Hemolysis, anemia, or hemoconcentration are also possible.
   C. Coagulation profiles
      1. Envenomation coagulopathy does not produce D-dimers.
      2. Partial thromboplastin time, prothrombin time, fibrin degradation products, and activated clotting time are potentially elevated.
   D. Urinalysis: renal tubular casts, myoglobinuria, hemoglobinuria
   E. Other diagnostic tests as indicated by clinical signs
      1. Arterial blood pressure: hypotension common with hypovolemia
      2. Serum biochemistry panel: prerenal or renal azotemia, hypoalbuminemia, hyperkalemia, creatine kinase elevations possible
      3. Blood gases
         a. Evaluate ventilatory and oxygenation capabilities of dyspneic animals.
         b. Metabolic acidosis may arise secondary to hypoperfusion, renal disease, or rhabdomyolysis.
         c. Hypoventilation with hypercapnia may occur with Mojave envenomation.
         d. Hypoxemia can occur with ARDS.
      4. Electrocardiography: arrhythmias
      5. Thoracic radiography: diffuse, bilateral pulmonary infiltrates with ARDS

II. Elapid envenomations
   A. Clinical signs: progressive weakness, flaccid paralysis, coma, or dyspnea in conjunction with small puncture wounds and little or no soft tissue swelling
   B. CBC and serial hematocrits: hemolytic anemia (dogs)
   C. Arterial blood gas analysis: elevated carbon dioxide (CO_2), reduced oxygenation
   D. Thoracic radiography to rule out primary pulmonary diseases, respiratory muscle paralysis, or aspiration pneumonia

Differential Diagnosis

I. Crotalid envenomations: animal bites, allergic reactions, insect envenomation, trauma
II. Elapid envenomations: polyradiculoneuritis, tick paralysis, botulism, bromethalin or ionophore poisoning, acute polyneuritis, myasthenia gravis, head or spinal trauma

Treatment and Monitoring

I. Crotalid envenomations
   A. First aid
      1. Incision and suction, tourniquets, constriction bands, and cryotherapy are not recommended owing to high complication rates.
      2. Keep the animal quiet and restrict activity.
   B. Intravenous fluids therapy
      1. Hypovolemic shock occurs with any moderate to severe envenomation, which makes fluid therapy crucial.
      2. Give crystalloid (60 to 90 mL/kg IV) or colloidal solutions (5 to 20 mL/kg IV) as boluses, to effect.
   C. Inotropic and pressor support for persistent hypotension
      1. Inotropic agent: dobutamine 5 to 15 μg/kg/min IV continuous rate infusion (CRI)
      2. Pressor agents: dopamine 5 to 20 μg/kg/min IV as CRI or norepinephrine 0.01 to 0.02 μg/kg/min IV as CRI
      3. Antivenin: helpful for hypotension refractory to above therapies
   D. Analgesia
      1. Nonsteroidal antiinflammatory drugs are contraindicated because they interfere with platelet function and may cause gastrointestinal irritation and nephrotoxicity.
      2. Opioids are safe and efficacious.
         a. Morphine
            (1) Dogs: 0.5 to 2.0 mg/kg IM, SC every 3 to 4 hours or 0.05 to 0.1 mg/kg/hr IV as CRI
            (2) Cats: 0.1 to 0.4 mg/kg IM, SC every 3 to 6 hours with concomitant sedation as needed; may cause histamine release
         b. Hydromorphone
            (1) Dogs: 0.05 to 0.2 mg/kg IV, IM, SC every 2 to 4 hours
            (2) Cats: 0.02 to 0.05 mg/kg IV, IM, SC every 2 to 4 hours with concurrent sedation as needed
         c. Buprenorphine
            (1) Dogs: 0.005 to 0.02 mg/kg IV, IM SC every 6 to 12 hours
            (2) Cats: 0.005 to 0.01 mg/kg IM, IV, SC every 6 to 12 hours; concurrent sedation as needed
   E. Antivenin/antivenom
      1. *Antivenin Crotalidae Polyvalent* (ACP) (Fort Dodge Laboratories, Fort Dodge, Ind.) is an antivenom of equine origin with neutralizing effects against the venom of rattlesnakes; the copperhead and cottonmouth moccasins; Fer-de-lance and other *Bothrops* spp.; tropical rattler, and bushmaster snakes.
         a. There are no controlled trials of antivenom use in companion animals.
         b. Information regarding appropriate case selection and dose is anecdotal.
         c. Reported doses vary from 1 to 10 vials (10 to 100 mL) (Hackett et al., 2002; Willey et al., 2005).

d. As little as 18% of each vial contains protective immunoglobulin (Ig) G, so large doses are often required (Hudelson and Hudelson, 1997).
e. Because of high glycosylation of equine IgG in the antivenin, immune reactions such as anaphylaxis (type I) or serum sickness (type III) are possible.

2. Crotalidae polyvalent immune Fab, ovine (*CroFab;* Savage Laboratories, Melville, N.Y.) is a mixed, monospecific, polyvalent antivenom created via immunization of sheep with Western diamondback, Eastern diamondback, Mojave rattlesnake, and cottonmouth venoms.
a. It is approximately 5.2 times more potent and much less antigenic than ACP.
b. Clinical improvement in coagulation, CNS, gastrointestinal, and cardiovascular abnormalities is common after administration.
c. CroFab has been subject to evidence-based research, and more definitive dosing recommendations are available for humans, who are given an initial IV loading dose (4 to 6 vials) followed by maintenance doses at 6, 12, and 18 hours, as needed.
d. No controlled animal trials or dosing information for CroFab have been published.

3. General recommendations for antivenin administration are as follows:
a. Cottonmouth or copperhead bites are less likely to require antivenin than Eastern diamondback, Western diamondback, or Mojave rattlesnake envenomations.
b. Antivenin is reconstituted with the diluent, warmed to body temperature, and diluted in 50 to 250 mL of crystalloid fluids.
c. Initial vial is infused IV over 30 minutes, watching for allergic reactions (hyperemia, hyperthermia, nausea, vomiting, angioedema).
d. A negative intradermal test does not preclude severe reactions.
e. Administer additional vials as needed based on the clinical response (see Table 136-1).
f. Antivenin is given as soon as possible but may be useful in reversing venom-induced coagulopathies even days after the bite.
g. Consider antivenin in any animal with evidence of progressive injury (e.g., rapidly worsening local injury, clinically significant uncontrolled coagulopathy, and unabated systemic signs, such as hypotension or altered mental status).
h. Smaller pets or animals suffering envenomations of extremities and the tongue or injection of venom intravascularly may require larger doses.

F. Prophylactic antibiotics
1. Antibiotics have been recommended owing to the presence of pathogenic microbes in the oral cavities of venomous and nonvenomous snakes.
2. Although common isolates include *Pseudomonas* spp., *Proteus* spp., *Escherichia coli*, *Enterobacter* spp., *Klebsiella* spp., *Clostridium* spp., *Corynebacterium* spp., and other anaerobes, recent studies indicate very low wound infection rates in people, so prophylactic antibiotic administration is no longer standard (Clark et al., 1993).
3. Wound culture is advocated if evidence of infection is present after local venom effects have subsided.

G. Corticosteroids
1. Administration is controversial.
2. Steroids may block endogenous and exogenous (venom) phospholipase A_2 effects and diminish the inflammatory response.
3. Detrimental effects include immune suppression and gastrointestinal irritation.
4. If corticosteroids are administered, short, rapid-acting preparations (e.g., prednisolone sodium succinate) should be given as soon as possible after envenomation or used only for treatment of anaphylaxis or serum sickness.

H. Antihistamines
1. Although venom components can induce histamine release, neither determination of systemic histamine levels or evaluation of antihistamine efficacy has been undertaken.
2. Hypovolemia and hypotension are relative contraindications for antihistamine use.
3. Antihistamines may be administered in dogs and cats for their sedative effects or for treatment of allergic reactions to antivenin.

I. Blood products
1. Antivenin is the most effective treatment for venom coagulopathy and thrombocytopenia.
2. If venom components are circulating, transfusion efficacy is diminished and antivenom administration to bind the venom is indicated.
3. Because the half-life of venom may exceed that of the antivenin, recurrent coagulopathies may occur.

J. Intubation and mechanical ventilation
1. If $Paco_2$ is >50 to 60 mm Hg, Po_2 <50 mm Hg
2. If substantial breathing effort is noted

K. Monitoring parameters
1. Frequent monitoring is required within the first 24 to 48 hours.
2. Upon admission, measure the wound and submit preliminary laboratory tests.
3. Perform serial evaluations of vital parameters (e.g., heart rate, respiratory rate, blood pressure, capillary refill time, etc.), hematocrit, total solids, coagulation panel, wound progression, and mentation at 1- to 6-hour intervals.

II. Elapid envenomations
A. First aid treatment is no longer advocated.
B. Hospitalize and closely monitor the animal for at least 48 hours, as onset of clinical signs can be delayed for 10 to 18 hours (Peterson and McNally, 2006).

Text continued on p. 1268.

TABLE 136-1

Modified Snakebite Severity Score*

Pulmonary System	Score
No abnormal signs	0
Panting; closed mouth respiration >30 breaths/min; mild increase in inspiratory/expiratory effort	1
Rapid panting; closed mouth respiration >60 breaths/min; moderate increase in effort (abdominal push, use of accessory muscles)	2
Cyanosis; orthopnea; harsh panting; or respiratory arrest	3
Cardiovascular System	
No abnormal signs	0
Tachycardia (giant breeds >140 beats/min, medium to large breeds >160 beats/min, small and toy breeds >180 beats/min, puppies >220 beats/min); benign dysrhythmias (unifocal ventricular premature contractions); hypertension (systolic BP >180 mm Hg, mean BP >120 mm Hg), or injected mucous membranes or hyperdynamic pulses	1
Tachycardia (see above) with mild hypotension (systolic BP <100 mm Hg, mean BP >60 mm Hg) or pallor, or mild decrease in pulse pressure	2
Tachycardia or bradycardia (<60 beats/min) or moderate to severe hypotension (systolic BP <80 mm Hg, mean BP <60 mm Hg), pale mucous membranes, weak pulses, or severe arrhythmias	3
Local Wound Features	
Puncture wounds and mild serosanguineous discharge, with minimal swelling or pain	0
Edema/swelling, pain, petechia, bleeding, erythema within 2 to 4 cm of bite site; wound has not worsened since previous assessment	1
Local wound swelling/pain extending >4 cm past bite site, but involving <50% length of extremity (or not extending past the thoracic inlet for facial bites); minimal worsening of wound since previous assessment	2
Severe ecchymosis, edema, extensive bleeding or necrosis of bite site; swelling involves >50% the length of extremity (or past thoracic inlet); substantial worsening of wound pain, swelling, or bruising since previous assessment	3
Gastrointestinal System	
No abnormal signs	0
Abdominal pain, tenesmus, or nausea	1
Vomiting or diarrhea	2
Repeated vomiting, diarrhea, hematemesis, or hematochezia	3
Hematological System	
Coagulation profile (prothrombin time, partial thromboplastin time, or activated clotting time), platelet count, and PCV all normal	0
Mild elevations of coagulation values (<1.5 × normal value) *or* mild thrombocytopenia (100,000 to 150,000/μL) *or* mild hemoconcentration (PCV >56% but <64%)	1
Moderate elevation of coagulation values (1.5 to 3 × normal value) *or* moderate thrombocytopenia (50,000 to 100,000/μL); *or* PCV >65% but <70%	2
Severe alterations of coagulation values (>3 × normal values) *or* severe thrombocytopenia (<50,000/μL) *or* PCV >70%	3
Central Nervous System	
Normal mentation	0
Lethargic or anxious, but responsive to external stimuli	1
Moderate to severe depression, ataxia, or responsive only to noxious stimuli	2
Loss of consciousness or seizures	3

BP, Blood pressure; *PCV,* packed cell volume.

*Although not validated for animals, a scoring system, such as the modified Snakebite Severity Score, may provide more objective serial assessment of envenomations. Total score is derived by adding scores for each category. Animals with low or static scores are likely to have mild to moderate envenomations, whereas those with high or rapidly increasing scores are likely to have suffered a more severe envenomation and require aggressive intervention. Evaluate upon admission, then at 1, 2, 6, 12, and 18 hours after initial hospitalization. This tool is also useful when comparing severity of envenomation and outcomes.

TABLE 136-2

Insect, Scorpion, and Spider Envenomations

ORDER	INSECT CLASSIFICATION	PATHOPHYSIOLOGY	CLINICAL SIGNS	DIFFERENTIAL DIAGNOSIS	TREATMENT AND MONITORING
Hymenoptera	Families: 1. Apidea: bees 2. Vespidae: hornets, yellow jackets, wasps 3. Formicidae: fire ants	Localized or generalized hypersensitivity or toxic reactions arise from vasoactive substances (e.g., histamine, serotonin, acetylcholine, apamin, phospholipase, hyaluronidase, melittin, kinins), immunoglobulin E antibodies, mast cells, and basophils	Localized reaction: pain/swelling Localized hypersensitivity reaction: angioedema of face, pinnae, oropharynx, extremities Generalized signs: urticaria to anaphylaxis Possible neurologic signs: ataxia, cranial nerve abnormalities, seizures GI signs: melena, hematemesis, hematochezia Coagulation abnormalities Shock, hypotension Serum sickness: type III immune reaction develops 3 days to 2 weeks after sting and causes vasculitis, glomerulonephritis, or neuropathy Massive envenomation: lethal dose = 20 stings/kg Rhabdomyolysis, acute renal failure, immune-mediated hemolytic anemia, neurologic deficits, and GI bleeding may occur	Other causes of anaphylactic shock Contact dermatitis Drug reaction Crotalid envenomation	Localized reaction: Remove stinger, apply cool compress Localized hypersensitivity: Diphenhydramine 1 mg/kg SC, IM BID Dexamethasone sodium phosphate 0.1 to 0.2 mg/kg IV or prednisolone sodium succinate 0.5 to 1 mg/kg IV once, followed by prednisone 0.5 to 1 mg/kg PO SID and tapered over 5 to 7 days for severe swelling Hospitalization and observation for rapid progression of swelling Generalized signs: Provide supplemental oxygen and ensure patent airway (oral intubation or tracheostomy) as needed for respiratory distress Fluid administration as needed for hypovolemic shock Anaphylactic shock: IV fluid resuscitation Epinephrine (1:10,000) 0.01 to 0.1 mL/kg IV once Diphenhydramine 1 mg/kg IM Prednisolone sodium succinate 5 to 10 mg/kg IV Possible supportive measures include blood transfusions, inotropic or pressor support, treatment for cardiac arrhythmias, and analgesics Hospitalization is recommended for at least 24 hours after resolution of clinical symptoms

GI, Gastrointestinal.

TABLE 136-2

Insect, Scorpion, and Spider Envenomations—*cont'd*

ORDER	INSECT CLASSIFICATION	PATHOPHYSIOLOGY	CLINICAL SIGNS	DIFFERENTIAL DIAGNOSIS	TREATMENT AND MONITORING
Scorpion	Most native scorpions are harmless In certain states (Arizona, Texas New Mexico, Nevada, California), and Mexico, *Centruroides exilicauda (sculpturatus)* is venomous	Venom contains phosphodiesterase, hyaluronidase, histamine, glycosaminoglycan, serotonin, and tryptophan	Most stings result in localized pain and swelling *Centruroides* stings cause immediate pain followed by tachycardia, hypotension, tachypnea, hypersalivation, and weakness Adverse effects on neurological, renal, cardiac, and hemolymphatic systems are caused by altered ion channel permeability	Organophosphate, carbamate, or pyrethrin toxicity Idiopathic epilepsy	Specific antivenom is not available. Provide supportive care with IV fluids, seizure control (benzodiazepines or barbiturates), and analgesia
Arachnid	Black widow: *Latrodectus* spp. Brown recluse: *Loxosceles* spp. cause significant envenomation of small animals	Female black widow: Alpha-latrotoxin causes excessive neurotransmitter release Brown recluse: Cytotoxic and necrolytic reactions arise from hyaluronidase, sphingomyelinase D, and other proteolytic enzymes. Chemotaxis of neutrophils by sphingomyelinase D mediates tissue injury	Black widow: Some bites (15%) are dry Severity depends on spider size, season, victim size and age, and bite location Cats are more severely affected than dogs, with death from respiratory muscle paralysis Vocalization, salivation, restlessness, muscle spasms, cramping, abdominal and pelvic rigidity may occur and be followed by flaccid paralysis, vomiting, seizures, or ataxia Brown recluse: "Bull's eye" lesion (necrotic center surrounded by concentric ischemic/erythematous rings) may be confined or be accompanied by extensive tissue necrosis Fever, arthralgia, hemolytic anemia, renal dysfunction, DIC, or seizures are possible	Black widow: Acute abdominal conditions Arterial thromboembolism Intervertebral disk disease Rabies Brown recluse: Toxic epidermal necrolysis Decubital ulcer Third-degree burn Bacterial skin infection Idiopathic immune-mediated hemolytic anemia	Black widow: Lyovac antivenin is available Dose is reconstituted in 50 to 100 mL of 0.9% NaCl and administered IV over 15 to 30 minutes Fluid resuscitation with IV crystalloids and colloids is given as needed Narcotic analgesics Calcium gluconate (10%) for hypocalcemic muscle spasms (0.5 to 1.5 mL/kg IV) Benzodiazepines for muscle tremors if normocalcemic Glucocorticoids and antihistamines are indicated if allergic reaction to antivenin occurs Brown recluse: No specific antivenin is available Surgical wound excision is not recommended Serial wound lavage and debridement may be necessary Broad-spectrum antibiotics are given for secondary pyoderma Dapsone 1 mg/kg PO SID × 14 days may help to ameliorate wound injury by inhibiting neutrophils

DIC, disseminated intravascular coagulopathy.

C. Care is largely supportive and may include IV fluid therapy, nutritional support, and mechanical ventilation.
D. Antibiotic usage is controversial.
E. An equine origin *Micrurus* spp. antivenin is no longer in production, and no other approved North American coral snake antivenin is available.
F. Murine studies suggest Australian tiger snake and Mexican coral snake antivenin may be protective.
   1. Antivenin administration is considered in any animal with suspected coral snake envenomation.
   2. Once signs of neurotoxicity have appeared, reversal of clinical abnormalities may not be possible.
   3. Dosage of antivenin depends upon the amount of venom injected relative to the body mass.
      a. As little as 4 to 5 mg of venom is lethal to a person, and a large coral snake may inject up to 20 mg (Peterson and McNally, 2006).
      b. Each vial of antivenin neutralizes approximately 2 mg of venom.

Appendix I
Normal Physiologic Values

Normal Parameters for Patient Monitoring*

PARAMETER	NORMAL VALUE
Body temperature	101.5° F (38.6° C)
Heart rate (beats/min)	
Dog	70-160
Cat	140-210
Respiratory rate (breaths/min)	
Dog	16-20
Cat	20-24
Capillary refill time (CRT) (sec)	<2
Blood pressure (mm Hg)†	
Systolic	130-170
Diastolic	60-100
Urine output (mL/kg/hr)	1-2
Central venous pressure (CVP) (cm H_2O)	
Normal	0-10
Shock	0
Overhydration	8-12
Heart failure	20
Cardiac tamponade	22-25
Arterial blood gases (room air)	
pH	7.35-7.45
$Paco_2$ (mm Hg)	29-36
Pao_2 (mm Hg)	85-95
HCO_3 (mEq/L)	17-25
Venous blood gases	
pH	7.35-7.45
Pco_2 (mmHg)	29-42
Po_2 (mmHg)	40-60
Lactic acid (mmol/L)	<1.0

*Modified from Morgan (1985).

†Data from Weiser et al. (1977) and Morgan (1986).

Normal Cerebrospinal Fluid Values

PARAMETER	DOG	CAT
Color	Clear, colorless	Clear, colorless
Pressure (mm H_2O)	<170	<100
Cell count/μL		
Mononuclear WBCs	<5-8	<5-8
RBCs	None	None
Cell types	Small lymphocytes, few monocytes	
Protein (mg/dL)	<25	<20
Glucose (mg/dL)	61-116	85

Modified from Bentinck-Smith (1983).

WBCs, White blood cells; *RBCs*, red blood cells.

Normal Hematologic Values

PARAMETER	DOG	CAT
PCV (%)	37-55	27-45
Hemoglobin (g/dL)	12-18	9-15
Erythrocytes (10^6/μL)	5.5-8.5	6-10
MCV (fL)	60-77	37-50
MCHC (g/dL)	32-36	30-36
RBC life span (days)	120	70
Reticulocyte count (%)	0-1.5	0-0.4
Platelets (10^3/μL)	175-500	190-400
Leukocytes (/μL)	6000-17,000	5000-19,500
Segmented neutrophils (/μL)	3000-11,500	2500-12,500
Band neutrophils (/μL)	0-300	0-300
Lymphocytes (/μL)	1000-4800	1500-7000
Monocytes (/μL)	150-1350	0-850
Eosinophils (/μL)	100-750	0-750
Basophils (/μL)	Rare	Rare
Total solids (g/dL)	6-8	6-8

PCV, Packed cell volume; *MCV*, mean cell volume; *MCHC*, mean corpuscular hemoglobin concentration; *RBC*, red blood cell.

Corrections for Reticulocyte Counts

(1) Corrected reticulocyte count (%) = observed reticulocyte count (%) × actual PCV ÷ normal PCV

(2) $$\text{Reticulocyte index} = \text{reticulocyte count (\%)} \times \frac{\text{actual PCV}}{\text{normal PCV}} \times \frac{1}{\text{Reticulocyte maturation time (days)}}$$

Reticulocyte Maturation Time for Various Packed Cell Volumes

PACKED CELL VOLUME (%)	MATURATION TIME (days)
45	1.0
35	1.5
25	2.0
15	2.5

Insert corresponding maturation time into Equation 2.

Normal Urinalysis Values

PARAMETER	DOG	CAT
Color	Light yellow	Yellow

From Bentinck-Smith J: A roster of normal values for dogs and cats. p. 1206. In Kirk RW (ed): Current Veterinary Therapy VIII: Small Animal Practice. WB Saunders. Philadelphia, 1983; with permission.

Commonly Used Equations

Serum Osmolality

$$2\,(\text{Na} + \text{K}\ [\text{mEq/L}]) + \frac{\text{glucose (mg/dL)}}{20} + \frac{\text{BUN (mg/dL)}}{3}$$

Normal = 305 mOsm/kg

Adjusted Calcium Values (Dogs)

Adjusted calcium = calcium (mg/dL) – albumin (g/dL) + 3.5
= calcium (mg/dL) – 0.4 × total protein + 3.3

Hypocalcemia: <6.5 mg/dL
Hypercalcemia: >12.0 mg/dL

Base Deficit

Bicarbonate need (mEq/L) = base deficit × 0.3 × body weight (kg)

Fluid Therapy

I. Replacement needs:

Need (L) = % dehydration × body weight (kg) × 1 L + losses from vomiting, diarrhea

II. Maintenance requirements:

Maintenance = 10 – 15 mL × body weight (kg) QID

Appendix IV
Recommended Drug Dosages

Every effort has been made to provide precise dosages for specific clinical situations; however, individual needs or circumstances may necessitate alterations in both the dosage and the frequency of administration of any of the medications listed on the following pages.

Multiple uses for a drug are listed in order under the original drug entry. Dosages are designated for either the dog or cat. If no species is listed before the dose, that dose is applicable to both dogs and cats.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Acarbose *(Precose)*	Diabetes mellitus	44	Dog: <10 kg: 25-50 mg PO BID ≥10 kg: 50-100 mg PO BID Use with insulin Cat: 12.5 mg PO BID Use with insulin
Acetazolamide *(Diamox)*	Hydrocephalus, (decrease volume of CSF) hydranencephaly, porencephaly	23	Dog: 0.1 mg/kg PO TID
	Diuretic	24	Dog: 10 mg/kg PO TID-QID Use with caution; side effects common
Acetylcysteine 5%-10% *(Mucomyst PO, Acetadote IV)*	Degenerative myelopathy	24	Dog: 70 mg/kg PO TID × 2 wk, then TID q 48 hr
	Liver protectant, acetaminophen and zinc phosphide toxicoses	64, 124, 127	140-280 mg/kg PO, IV as loading dose; then 70 mg/kg PO, IV TID-QID × 7-17 Rx
Acetylpromazine *(Acepromazine)*	Preanesthetic, restraint, sedation	1, 4, 15	Dog: 0.01-0.05 mg/kg IV, SC, IM; max = 2.5 mg Cat: a) 0.05 mg/kg IV, with ketamine b) 0.01-0.03 mg/kg SC, IM, IV; max = 1 mg
	Arterial thromboembolism, vasodilator, acute feline idiopathic cystitis	10, 50	Cat: a) 0.05-0.1 mg/kg SC, IV, IM q 4-6 hr b) 0.25-1 mg/kg PO BID
	Urine retention disorders, decrease urethral sphincter tone	51	Cat: a) 0.1 mg/kg SC, IV SID-BID b) 1-2 mg/kg PO SID-BID
	Increase milk production	60	Dog: 0.125-0.5 mg/kg PO BID-TID
	Nausea from vertigo	108	Dog: 1 mg/kg PO SID
	Agitation, restlessness from ephedrine/ pseudoephedrine toxicosis	129, 130	Dog: 0.05-1 mg/kg IV, IM, SC PRN Use with caution

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Acetylsalicylic acid (Aspirin)	Arterial thromboembolism, anticoagulation therapy, acquired platelet dysfunction	10, 67, 68	Dog: 0.5 mg/kg PO BID Cat: 6-10 mg/kg PO q 2-3 days
	Glomerulonephritis	48	Dog: 0.5-2 mg/kg PO SID Cat: 0.5-2 mg/kg PO QOD
	Immune-mediated hemolytic anemia (unresponsive)	64	Dog: 0.5 mg/kg PO SID, with azathioprine
	Antipyretic, analgesic, anti-inflammatory ocular effects	73, 98, 99, 103	Dog: 5-20 mg/kg PO SID-BID Cat: 3-6 mg/kg PO q 2-3 days
	Musculoskeletal pain, inflammation	127	Dog: 10-20 mg/kg PO BID Cat: 6-10 mg/kg PO q 2-3 days
Acitretin *(Soriatane)*	Primary seborrhea, sebaceous adenitis	93	Dog: 0.5-1 mg/kg PO SID indefinitely
	Ichthyosis	93	Dog: 1-2 mg/kg PO SID × 3 mo or until remission; then decrease to QOD
Aclarubicin	Myelodysplastic syndrome	66	Dog: 5 mg/m^2 IV SID × 5 days
Actinomycin D *(Cosmegen)*	Chemotherapy	72	Dog: 0.5-0.9 mg/m^2 IV slowly q 3 wk
Activated charcoal *(Toxiban, Actidose-Aqua, CharcoAid)*	Ingestion of vitamin K antagonists	68	2-5 g/kg PO, with sorbitol
	GI adsorbent and decontamination	123, 124, 126, 127, 129-131	Powdered form: a) 1-2 g/kg PO BID-TID, mixed with 50-200 mL of water (given as slurry); repeat q 6-12 hr at half the original dose b) 1-2 g/kg PO TID-QID for 24 hr Oral suspension: 10-20 mL/kg PO; repeat q 6-12 hr at half the original dose
	Rodenticide toxicoses	124	6.6-11 mL/kg PO, with sorbitol
	Avermectin toxicosis	125	6.6-11 mL/kg PO initially; then 3.3-5.5 mL/kg PO TID × 1-2 days
Acyclovir *(Zovirax)*	Feline herpesvirus keratitis	98	Cat: 200 mg PO BID-QID × 2 wk Caution: Not labeled for use in cats; potentially toxic
Aglépristone *(Alizine)**	Mammary fibroadenomatous hyperplasia	60	10 mg/kg SC SID × 4-5 days
Albendazole *(Albenza)*	Giardiasis	116	Dog: 25 mg/kg PO BID × 2 days Use with caution; do not use in cats
Albuterol *(Albuterol, Ventolin, Proventil)*	Sinus bradycardia	6	Dog: 0.02-0.05 mg/kg PO BID-TID
	Bronchodilator	16-18, 114	20-50 μg/kg PO BID-TID or aerosolized and inhaled Cat: a) 90 μg per inhalation q 30 min for up to 4-6 hr via metered dose inhaler, then SID-QID b) 0.5 mL of 2.5 mg/3 mL soln in 3.5 mL saline by delivered nebulization via face mask SID-QID

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

*Not available in the United States.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Allopurinol *(Allopurinol, Aloprim)*	Ammonium urate urolithiasis	48-50	Dog: 10-15 mg/kg PO BID × 4 wk, then SID Cat: 9 mg/kg PO SID × 4 wk; use with caution
	Leishmaniasis	89, 90, 116	Dog: 10-20 mg/kg PO SID-BID × ≥6 mo, with antimonials
D-Alpha-tocopheryl-1000-polyethylene glycol succinate *(Liqui-E)*	Antioxidant for canine chronic hepatitis/cirrhosis, feline chronic cholangiohepatitis, hepatic necrosis/failure, pansteatitis	37	25 IU/kg PO BID
Alprazolam *(Alprazolam, Xanax)*	Certain behavioral disorders	117	Dog: 0.02 mg/kg PO q 4 hr; max = 4 mg/day Cat: 0.2-1 mg/kg PO BID
	Appetite stimulant	122	Dog: 0.01-0.1 mg/kg PO PRN; max = 4 mg/day Cat: 0.05-0.2 mg/kg PO SID-BID
Altrenogest *(Regumate)*	Hypoluteoidism	61	Dog: 0.088 mg/kg PO SID
Aluminum carbonate *(Basalgel)*	Hyperphosphatemia	48	30-90 mg/kg/day PO dd BID-QID; give with food
Aluminum hydroxide *(AlternaGEL, Amphojel)*	Hyperphosphatemia, dietary phosphorus binder	48, 127	30-90 mg/kg/day PO dd BID-QID, give with food
	Cholecalciferol toxicosis	124	10-30 mg/kg PO TID
Aluminum/magnesium hydroxide *(Maalox)*	Zinc phosphide toxicosis, to increase gastric pH	124	90-180 mg/kg PO TID
Amantadine *(Symmetrel)*	Analgesic	72	Dog: 3-4 mg/kg PO BID Cat: 3 mg/kg PO SID
Amikacin *(Amikin)*	Acute endocarditis, bartonellosis	9	Dog: 20 mg/kg IV SID × 1-2 wk, with Timentin or imipenem
	Bacterial gastroenteritis, salmonellosis	33	6-8 mg/kg IM, IV SID alone or with a cephalosporin
	Serious infections, septic peritonitis, acute abdominal syndrome, resistant bacterial cystitis	38, 112	Dog: 15-30 mg/kg IV, IM, SC SID Cat: 10 mg/kg IV SID
	Bacterial keratitis	98	25-125 mg subconjunctivally
Amino acid supplements	Hepatocutaneous syndrome	37	Dog: 1-2 g/5-10 kg PO TID
Aminocaproic acid *(Amicar)*	Degenerative myelopathy	24	Dog: 500 mg PO TID
Aminophylline *(Aminophylline, Phyllocontin)*	Bronchodilator	17, 18, 133	Dog: 6-11 mg/kg IV, IM, PO TID Cat: 4-8 mg/kg IV, IM, PO BID-TID Use caution with IV administration
Aminopromazine fumarate (not currently available)	Urge incontinence	51	2 mg/kg PO BID
Amiodarone *(Cordarone)*	Refractory ventricular tachycardia	6	Dog: a) 10 mg/kg PO BID × 1 wk, then 5 mg/kg PO SID b) 5-10 mg/kg IV bolus
	Cardiopulmonary arrest electroconversion	7	Dog: 5 mg/kg IV; may repeat once at half of initial dose
Amitraz *(Mitaban)*	Canine demodicosis	86	Dog: Mix 1 bottle with 2 gal water; dip wet dog and air dry; repeat q 2 wk × 3-6 Rx
Amitriptyline *(Elavil, Amitriptyline)*	Cataplexy	22	1-2 mg/kg PO BID
	Chronic feline idiopathic cystitis	50	Cat: 2.5-12.5 mg PO SID
	Feline psychogenic alopecia	87	Cat: 5 mg PO BID
	Certain behavioral disorders, tricyclic antidepressant	117	Dog: 1-6 mg/kg PO BID Cat: 0.5-2 mg/kg PO SID-BID

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Amlodipine *(Norvasc)*	Congestive heart failure, hypertension, reduce left-to-right shunting	8, 9, 48	Dog: 0.05-0.4 mg/kg PO SID-BID Cat: 0.625-1.25 mg PO SID
Ammonium chloride (NH_4Cl)	Strychnine, ephedrine/pseudoephedrine toxicoses; urine acidification	124, 130	Dog: 50 mg/kg PO QID Cat: 20 mg/kg PO BID
Amoxicillin *(Amoxidrops, Amoxitabs)*	Serious infections	24, 27, 34, 37, 48, 98, 103, 113, 114	20-22 mg/kg PO, SC, IM BID-TID
	Routine infections	50, 114, 126	10-20 mg/kg PO, IM, SC, BID-TID
	Actinomycosis	89	20-40 mg/kg IM, SC, PO QID
Amoxicillin/clavulanate *(Clavamox)*	Chronic endocarditis, bacterial pneumonia, osteomyelitis	9, 18, 81	Dog: 20 mg/kg PO TID
	Stomatitis, gingivitis, glossitis	27	Dog: 12.5-25 mg/kg PO BID Cat: 62.5 mg PO BID
	Sialadenitis, salivary gland fistula, feline acute cholangiohepatitis, canine chronic hepatitis/cirrhosis, canine bacterial pyoderma, mucocutaneous pyoderma, upper respiratory infections	16, 29, 37, 88, 90, 91, 114	13.75 mg/kg PO BID
	Subcutaneous abscesses and cellulitis, chorioretinitis	88, 102, 103	15-22 mg/kg PO BID
Amphotericin B deoxycholate *(Fungizone, Amphocin)*	Systemic mycotic and algal infections	14, 23, 24, 89, 102, 111	Dog: 0.5-0.8 mg/kg IV 2-3 times/wk to total dose of 5-10 mg/kg Cat: 0.1-0.5 mg/kg IV q 48-72 hr, to total dose of 4-8 mg/kg Discontinue if azotemia occurs
Amphotericin B lipid complex *(Abelcet)*	Gastric pythiosis	31	Dog: 2-3 mg/kg IV QOD to total dose of 24-27 mg/kg
	Systemic mycoses	89, 111	Dog: 1-2 mg/kg IV q 48-72 hr to total dose of 12-24 mg/kg Discontinue if azotemia occurs
Ampicillin *(Amp-Equine, Polyflex)*	Various infections, borreliosis, leptospirosis	33, 48, 50, 103, 112-114	10-22 mg/kg IV, IM, SC TID-QID
	Acute colitis, hepatic abscess, feline acute cholangiohepatitis, canine chronic hepatitis/cirrhosis, hepatic encephalopathy	34, 37	22 mg/kg PO TID
	Septic peritonitis, nocardiosis, acute abdominal syndrome	38, 39, 89	20-40 mg/kg IV, IM, SC, PO TID-QID, possibly combined with amikacin or gentamicin
	Metritis	61	Dog: 20 mg/kg PO TID × 14 days
	Bacterial keratitis	98	50-100 mg subconjunctivally
Amprolium *(Corid)*	Enteric coccidiosis	116	60-100 mg (total per day) PO SID × 5 days
Antivenin Crotalidae Polyvalent *(CroFab)*	Antivenom	136	10-100 mL (1-10 vials); dilute in 50-250 mL of crystalloid fluids; initial vial infused IV over 30 min, then additional vials PRN
Antidiuretic hormone *See* Desmopressin acetate			
Apomorphine hydrochloride (compounding pharmacies)	Emesis, decontamination	123, 130	Dog: a) ≤1 tab in conjunctival sac or dissolve tab in water and instill in eye b) 0.03-0.04 mg/kg IV c) 0.04-0.08 mg/kg IM, SC

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Ascorbic acid (Vitamin C)	Reduction of methemoglobin, acetaminophen toxicosis	127	30 mg/kg PO BID-QID
	Urine acidification, ephedrine/ pseudoephedrine toxicosis	130	20-30 mg/kg PO, IM, IV TID
L-Asparaginase *(Elspar)*	Lymphoma	69, 72	Dog: a) 10,000-20,000 IU/m^2 IM, SC in a protocol b) 400 IU/kg IM, SC in a protocol Cat: 400 IU/kg SC, IP in a protocol
Atenolol *(Tenormin)*	Atrial flutter, ventricular tachycardia, orthodromic atrial reciprocating tachycardia	6, 48	Dog: 0.25-2 mg/kg PO SID-BID Cat: 6.25-12.5 mg PO SID-BID
	Pulmonic/subaortic stenosis, right ventricular hypertrophy	8	1-2 mg/kg PO BID
	Feline hypertrophic cardiomyopathy, feline hyperthyroidism	10, 42	Cat: 6.25-12.5 mg PO SID-BID
Atipamezole *(Antisedan)*	Amitraz toxicosis	125	0.05 mg/kg IM PRN
Atovaquone *(Malarone)*	*Babesia gibsoni* infection	64, 116	Dog: 13.3 mg/kg PO TID × 10 days, with azithromycin
Atropine (Atropine sulfate)	Atropine response test, empirical vagolytic therapy	6, 7	0.01-0.04 mg/kg IM, IV
	Sinus bradycardia	7, 76, 129, 130	0.02-0.04 mg/kg IV, IM, SC PRN
	Cardiopulmonary arrest	7	0.08 mg/kg IT
	Cholinergic crisis	25	0.05 mg/kg IV
	Ptyalism	29	a) 0.02-0.04 mg/kg SC PRN b) 0.04 mg/kg PO TID-QID *(Sal-Tropine)*
	Preanesthetic	61, 71	Dog: 0.04 mg/kg IM Cat: 0.01 mg/kg IV, with ketamine and diazepam
	Relaxation of gastric smooth muscle for enterogastric lavage	123	0.02 mg/kg IV
	Muscarinic signs from insecticide toxicosis	125	a) 0.05-0.5 mg/kg IV to effect b) 0.15-1.5 mg/kg SC, IM to effect
Atropine 1% (ophthalmic)	Bacterial/fungal keratitis, corneal ulceration, anterior uveitis, hyphema	98, 99	Apply to affected eye SID-QID
	Feline corneal sequestration	98	Apply to affected eye SID-BID
Aurothioglucose (Gold salts, *Solganal*)	Lymphoplasmacytic stomatitis	27	1 mg/kg IM weekly × 10-20 wk, then taper to once monthly
	Rheumatoid arthritis	80	Dog: 1 mg/kg IM weekly
	Feline plasma cell pododermatitis	90	Cat: 1 mg/kg IM q 7 days × 2-3 mo, then q 14 days for 2-3 Rx, then q 30 days for maintenance
	Pemphigus complex	91	Test dosage of 1 mg (dog ≤10 kg) or 5 mg (dog >10 kg) IM; then 1-2 mg/kg IM weekly, then taper to q 2-4 wk PRN
Azathioprine (*Imuran*)			*Not* recommended in cats
	Pulmonary eosinophilic diseases	18	Dog: 2 mg/kg PO SID × 7-10 days, then QOD
	Refractory canine meningeal polyarteritis	23	Dog: 1.5 mg/kg PO SID-QOD, then alternate with prednisone QOD
	Refractory acquired myasthenia gravis, chronic inflammatory demyelinating neuropathy	25	Dog: 1-2 mg/kg PO SID

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Azathioprine *(Imuran)—cont'd*	Lymphoplasmacytic stomatitis, inflammatory bowel disease, chronic hepatitis/cirrhosis, membranous glomerulonephritis, proliferative urethritis	27, 33, 37, 48, 52	Dog: 1-2 mg/kg PO SID, taper to QOD
	Chronic histiocytic ulcerative colitis	34	Dog: 2 mg/kg PO SID × 2 wk, then QOD
	Perianal fistula	35	Dog: a) 50 mg PO SID × 4-6 wk b) 1.5-2.2 mg/kg PO SID × 2-4 wk then QOD, with prednisone
	Immune-mediated hemolytic anemia, immune-mediated thrombocytopenia	64, 76	Dog: 1-2 mg/kg PO SID, then taper to 0.5-1 mg/kg PO QOD, with prednisone
	Chronic idiopathic myelofibrosis	66	Dog: 2 mg/kg PO QOD
	SLE, refractory erosive/nonerosive arthritis	76, 80	Dog: 2 mg/kg PO SID × 7-21 days, then QOD × 1 mo beyond remission
	Cutaneous histiocytosis, masticatory myositis, polymyositis, extraocular myositis, sterile granuloma and pyogranuloma	77, 82, 89, 103	Dog: 2 mg/kg PO SID until remission, then taper
	Cutaneous immune-mediated diseases, uveodermatologic syndrome	90-92	Dog: a) 1.0-2.5 mg/kg PO SID, then taper b) 50 mg/m^2 PO SID, then taper to QOD
	Blepharitis, episcleritis, immune-mediated uveitis, ligneous conjunctivitis, chorioretinitis	95, 96, 98, 99, 102	Dog: 2-2.2 mg/kg PO SID, then taper to QOD
Azithromycin *(Zithromax)*	Chronic endocarditis	9	Dog: 5 mg/kg PO SID × 7 days, then QOD × 6-8 wk
	Bacterial meningoencephalitis	23	5-10 mg/kg PO, IV SID
	Campylobacter spp., *Helicobacter* spp. infections	33	5 mg/kg PO SID
	Leptospirosis carrier state	48	Dog: 20 mg/kg PO SID × 1 wk
	Babesia gibsoni infection	64, 116	Dog: 10 mg/kg PO SID, with atovaquone
	Cryptosporidiosis	116	Dog: 5-10 mg/kg PO BID × 5-7 days Cat: 7-15 mg/kg PO BID × 5-7 days
Bacitracin-neomycin-gramicidin (ophthalmic)	Conjunctivitis	96	Apply to affected eye TID-QID
Bacitracin-neomycin-polymyxin (ophthalmic)	Neonatal ophthalmia, conjunctivitis	95, 96	Apply to affected eye TID-QID
Bacitracin-neomycin-polymyxin-hydrocortisone (ophthalmic ointment)	Conjunctivitis	96	Apply to affected eye SID-QID
Benazepril *(Lotensin)*	Chronic congestive heart failure	9, 10	Dog: 0.25-0.5 mg/kg PO SID Cat: 0.5 mg/kg PO SID
	Glomerulonephritis, chronic renal failure	48	Dog: 0.25-1 mg/kg PO SID-BID

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Benzoyl peroxide gel *(Pyoben gel, Oxydex gel)*	Acute moist dermatitis, deep bacterial pyoderma and furunculosis	85, 88	Shampoo and leave on for 10-15 min, then rinse; repeat 1-3 times/wk until resolution
	Canine demodicosis, canine/feline acne, staphylococcal pyoderma and folliculitis, impetigo, intertrigo	86, 88	Dog: Apply topically SID to affected areas × 7-14 days or until lesions resolve Cat: Apply topically SID-QOD until acne lesions resolve, then PRN
Betamethasone *(Celestone Soluspan)*	Episcleritis, severe pannus	96, 98	Apply 1-2 mg subconjunctivally BID-QID
Betamethasone valerate 0.14% cream *(DVM Max)*	Cutaneous or discoid lupus erythematosus, Pemphigus erythematosus	90, 91	Apply topically initially BID × 5-7 days, then taper
Betaxolol 0.5% *(Betoptic)*	Glaucoma	100	Apply 1 drop to affected eye BID, with other therapy
Bethanechol chloride *(Urecholine)*	Urine retention disorders, enhance detrusor muscle contraction	51	Dog: 5-25 mg PO TID Cat: 1.25-5 mg PO TID
	Dysautonomia (Key-Gaskell Syndrome)	105	a) 2.5-5 mg PO BID-TID b) 0.0375 mg/kg SC
Bimatoprost 0.03% *(Lumigan)*	Glaucoma	100	Dog: Apply 1 drop to affected eye SID-BID
Biotin	Idiopathic claw disorders	90	5 µg/kg/day PO indefinitely
Bisacodyl *(Dulcolax)*	Stool softener		Dog: 10 mg PO PRN Cat: 5 mg PO PRN
Bismuth subsalicylate *(Pepto-Bismol)*	GI tract protectant, acute colitis, helicobacteriosis	31, 33, 34, 113	Dog: 0.5-2 mL/kg PO q 4-8 hr Cat: 0.25 mL/kg PO BID; use with caution
Brinzolamide 1% *(Azopt)*	Glaucoma	100	Apply 1 drop to affected eye BID-TID
Bromocriptine (Bromocriptine mesylate)	Galactorrhea, decrease milk production in pseudocyesis	60, 61	Dog: 20-30 µg/kg PO SID for up to 10-16 days
Bupivacaine 0.5% *(Marcaine, Sensor)*	Local, regional blockade anesthesia	1, 19, 81	Dog: a) 0.5-2 mg/kg SC, perilesional or perineural infiltration b) 0.3 mg/kg or 1 mL/15 kg with morphine, given as epidural c) 1 mL/15 kg with morphine, given as epidural for pelvic limb fracture d) 1 mL/20 kg with morphine and saline, given as epidural for thoracic limb fracture e) Max = 2 mg/kg Cat: a) 0.2-0.5 mg/kg SC, perilesional or perineural infiltration b) 0.1 mg/kg with morphine, given as epidural
Buprenorphine *(Buprenex)*	Sedation, analgesia, pain control	1, 10, 32, 39, 50, 72, 81, 126, 128, 133, 136	Dog: 0.005-0.02 mg/kg IV, IM, SC, PO BID-QID Cat: 0.005-0.01 mg/kg IV, IM, SC, PO BID-QID
Buspirone *(BuSpar)*	Chronic feline idiopathic cystitis	50	Cat: 5-10 mg PO BID-TID
	Anxiolytic drug	117	Dog: 0.5-2 mg/kg PO BID-TID Cat: 0.5-1 mg/kg PO BID
Busulfan *(Myleran)*	Chronic granulocytic leukemia	66	Dog: 0.1 mg/kg/day PO

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Butorphanol *(Torbutrol, Torbugesic)*	Analgesia, sedation, pain control	1, 3, 8, 10, 15, 36, 39, 50, 71, 72, 81,103, 126, 127, 133	Dog: a) 0.2-0.6 mg/kg IV, IM, SC, PO q 1-6 hr b) 0.1-0.4 mg/kg/hr IV as CRI Cat: a) 0.005-0.01 mg/kg IV, IM, SC, PO q 4-12 hr b) 1-2.5 mg PO SID-BID
	Cough suppressant	9, 15-17, 114	Dog: 0.5-1.1 mg/kg PO BID-QID
	Emesis	46	0.4 mg/kg IM PRN
Cabergoline *(Galastop, Dostinex)*	Galactorrhea, decrease milk production in pseudocyesis	60, 61	Dog: 1.5-5.0 µg/kg PO SID × 2-10 days
	Induce estrus	61	Dog: 5 µg/kg PO SID × 7-10 days
Calcitonin *(Calcimar)*	Hypercalcemia, cholecalciferol toxicosis, calcipotriene toxicosis	124, 127	4-7 IU/kg SC, IM BID-TID
Calcitriol *(Rocaltrol)*	Hypoparathyroidism, hypocalcemia	43	20-30 ng/kg PO SID × 3-4 days; then 5-15 ng/kg PO SID
	Chronic renal disease, secondary hyperparathyroidism	48, 127	Dog: 2.5-3.5 ng/kg PO SID
	Primary seborrhea to inhibit keratinocyte proliferation	93	Dog: 10 ng/kg PO SID Use with caution
Calcium acetate *(PhosLo GelCaps)*	Hyperphosphatemia	48	60-90 mg/kg/day PO
Calcium carbonate, elemental *(Monocal, Tums, Calcifol)*	Hypoparathyroidism, hypocalcemia	43	25-50 mg/kg/day PO dd BID-QID
	Eclampsia	61	Dog: 1-3 g/day PO, with vitamin D
Calcium EDTA *(Versenate)*	Lead poisoning	126	100 mg/kg/day × 5 days SC = total dose; make soln of 10 mg/mL in 5% D/W, divide into 20 aliquots and give 1 dose SC QID × 5 days Dog: Do not exceed 2 g/day
Calcium gluconate (*Calcet,* Ca gluconate injection)	Atrial standstill, asystole	6	10% soln: 0.5 mL/kg IV slowly
	Hypoparathyroidism, hypocalcemia, severe hyperkalemia, calcium channel-blocker intoxication	7, 43, 45, 48, 49	10% soln: a) 0.4-1.5 mL/kg slowly IVto effect over 10-20 min b) 5-15 mg/kg slowly IV to effect over 10-15 min
	Hypocalcemia, dystocia, eclampsia	61	Dog: a) 10% soln: 0.2-0.4 mL/kg IM, SC; severe case: 1-10 mL IV to effect b) Oral: 1-3 g/day, with vitamin D
Carboplatin *(Paraplatin)*	Chemotherapy, in a protocol	27, 72	Dog: a) Large dog: 300 mg/m^2 IV q 3 wk b) Small dog: 250 mg/m^2 or 10 mg/kg IV q 3 wk Cat: 180 mg/m^2 IV q 4 wk
Carprofen *(Rimadyl)*	Anterior uveitis, antiinflammatory, analgesia	1, 24, 80-82, 98, 99, 103, 127	Dog: a) 2.2-4 mg/kg SC, slowly IV once b) 2-2.2 mg/kg PO BID Cat: 2.2 mg/kg SC once
L-Carnitine	Nutritional supplement, cardiomyopathy	10	Dog: 50 mg/kg PO BID-TID
	Carnitine deficiency	122	Dog: 50-100 mg/kg PO TID
Cefadroxil *(CefaTabs, Duricef)*	Canine chronic hepatitis/cirrhosis, bacterial pyoderma	37, 88	Dog: 22 mg/kg PO BID
	Oral infections	126	20 mg/kg PO BID

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Cefazolin *(Ancef, Kefzol)*	Discospondylitis, osteomyelitis, *Staphylococcus* spp. infection, bacterial arthritis, serious infections	24, 80, 81, 112	Dog: 20 mg/kg IV, IM, SC TID-QID
	Perioperative antibiotic	32	Dog: 22 mg/kg IV
	Hepatic abscess, feline acute cholangiohepatitis, septic peritonitis	37, 38	22 mg/kg IV TID
	Bacterial keratitis	98	100 mg subconjunctivally
Cefotaxime *(Claforan)*	Infectious meningomyelitis, bacterial infections, septic peritonitis	24, 38	Dog: 30-40 mg/kg IV, IM, SC TID-QID
Cefoxitin *(Mefoxin)*	Septicemia, endotoxemia, hepatic abscess, feline acute cholangiohepatitis, septic peritonitis, acute abdomen syndrome	33, 37-39, 112	15-30 mg/kg IV, IM TID-QID
	Perioperative antibiotic	35	30 mg/kg IV 30 min before surgery, then 30 mg/kg IM q 1.5 hr for 2 more doses
	Canine infectious tracheobronchitis, feline upper respiratory infection complex	114	22 mg/kg IV TID
Cefpodoxime proxetil *(Simplicef)*	Bacterial pyoderma, blepharitis	88, 95	Dog: 5-10 mg/kg SID
Ceftazidime *(Cefazima)*	Infectious meningomyelitis, bacterial infections, septic peritonitis	24, 38	20-50 mg/kg IV BID-TID
Cephalexin *(Keflex, Biocef)*	Serious infections	18, 37, 90, 95, 102, 103	20-40 mg/kg PO, SC, IM, IV BID-TID
	Discospondylitis, osteomyelitis, *Staphylococcus* spp. infection	24, 80, 88, 91	Dog: 20-30 mg/kg PO TID
	Stomatitis, gingivitis, glossitis, hepatic abscess, canine chronic hepatitis/ cirrhosis, bacterial cystitis	27, 37, 50	22 mg/kg PO, IM, SC TID
	Sialadenitis, salivary gland fistula	29	30 mg/kg PO BID
	Perianal fistula	35	20 mg/kg PO BID
	Bacterial arthritis	80	11-33 mg/kg PO TID
Charcoal, activated *See* Activated charcoal			
Chlorambucil *(Leukeran)*	Lymphoplasmacytic stomatitis	27	Dog: 0.1-0.2 mg/kg PO SID-QOD, with corticosteroids Cat: 0.25-0.33 mg/kg PO q 72 hr, with corticosteroids
	Feline small cell GI lymphoma	31, 34, 72	Cat: a) 4-6 mg/m^2 PO SID-QOD b) 6-15 mg/m^2 PO SID × 4 days; repeat q 3 wk Dosage varies greatly among protocols
	Inflammatory bowel disease	33	Cat: 1.5 mg/m^2 PO SID-QOD
	Chronic lymphocytic leukemia	65, 72	Dog: 0.2 mg/kg or 6 mg/m^2 PO SID × 7-14 days, then 0.1 mg/kg or 3 mg/m^2 PO SID, then long-term maintenance at 2.0 mg/m^2 QOD, with prednisone Cat: 0.2 mg/kg or 2 mg/cat PO QOD, with prednisone
	Lymphoma	69	Cat: 1.4 mg/kg PO in a protocol
	Primary macroglobulinemia	77	Dog: 0.2 mg/kg PO SID
	SLE, Pemphigus vulgaris or foliaceus, other cutaneous immune-mediated diseases	90, 91	Dog: a) 0.1-0.2 mg/kg PO SID b) 2-6 mg/m^2 PO SID, then taper to QOD Cat: 0.1-0.2 mg/kg PO SID-QOD
	FIP	112	Cat: 20 mg/m^2 PO q 2-3 wk

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Chloramphenicol 1% (ophthalmic)	Conjunctivitis from *Chlamydophila* spp. or *Mycoplasma* spp.	96	Apply to affected eye TID-QID
Chloramphenicol *(Chloromycetin)*	Bronchiectasis, bacterial and rickettsial infections, chronic prostatitis, infectious tracheobronchitis, chorioretinitis	17, 24, 53, 102, 114, 115	Dog: 15-50 mg/kg IV, PO, SC, IM TID
	Bacterial meningoencephalitis	23	Dog: 50 mg/kg IV, IM, SC, PO BID
	Resistant bacterial cystitis	50	Dog: 33 mg/kg PO TID Cat: 25 mg/kg PO BID
Chlordiazepoxide-clindinium *(Librium, Mitran)*	Anxiety with irritable bowel syndrome	34	Dog: 0.10-0.25 mg/kg of clidinium PO BID-TID
	Certain behavioral disorders	117	Dog: 2-6.5 mg/kg PO TID Cat: 0.2-1 mg/kg PO BID
Chlorhexidine (shampoo, ointment, cream, or spray)	Staphylococcal pyoderma and folliculitis, impetigo, intertrigo	88	Dog: Apply topically SID-QOD × 7-14 days
Chlorhexidine 2%/ Miconazole 1% shampoo *(Malaseb)*	*Malassezia* dermatitis	85	Use 1-2 times/wk until resolution
Chlorothiazide *(Diuril)*	Nephrogenic diabetes insipidus	41	10-40 mg/kg PO BID
Chlorpheniramine *(Chlor-Trimeton, Chlo-Amine)*	Antihistamine, atopic dermatitis	85	Dog: 0.4 mg/kg PO TID Cat: 2 mg PO BID
Chlorpromazine *(Thorazine)*	Antiemetic	31, 33, 39, 48, 126-128	Dog: a) 0.1-0.5 mg/kg IM, SC BID-QID b) 0.05 mg/kg IV TID-QID
	Agitation, restlessness from ephedrine/ pseudoephedrine toxicosis	129, 130	Dog: 0.1-1 mg/kg IV, IM PRN
Chlorpropamide *(Diabinese)*	Central diabetes insipidus	41, 127	a) 125-250 mg/day PO b) 10-40 mg/kg/day PO
Cholestyramine *(Questran)*	Binding of bile acids	33	Dog: 200-300 mg/kg PO BID
Chondroitin sulfate	Canine hip dysplasia, osteoarthritis	80	Dog: 8.8 mg/kg PO SID, with glucosamine hydrochloride
	Corneal erosions	98	Dog: 100 mg/mL, with tobramycin or ciprofloxacin, applied to affected eye BID-QID
Chorionic gonadotropin, human *(APL, Profasi)*	Luteinize an ovarian follicular cyst, induce ovulation	55, 62	Dog: 22 IU/kg IM; may repeat once 48 hr later Cat: 250-500 IU IM; give 15-30 hr before artificial insemination
Cimetidine *(Tagamet)*	Esophagitis, acid reflux	30	Dog: 10 mg/kg PO TID-QID Cat: 5 mg/kg PO TID
	Chronic gastritis, GI tract ulceration and erosion, enteritis, acetaminophen toxicosis	31, 32, 39, 48, 73, 112, 127	4-10 mg/kg PO, IV, SC, IM BID-QID
Ciprofloxacin with chondroitin sulfate	Corneal erosions	98	Dog: 3 mg/mL applied to affected eye TID-QID
Cisapride (compounding pharmacies)	Gastric acid reflux, megacolon, gastric motility disorders	30, 31, 34, 37, 48	Dog: 0.1-0.5 mg/kg PO BID-TID Cat: 2.5-5 mg PO BID-TID
	Urine retention disorders, enhance detrusor muscle contraction	51	Dog: a) 0.5 mg/kg PO TID b) 2.5-10 mg PO TID Cat: 1.25-5 mg PO TID
Cisplatin *(Platinol)*	Chemotherapy, in a protocol	19, 27, 72	Dog: 50-70 mg/m^2 IV q 3 wk, with saline infusion

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Clarithromycin *(Biaxin)*	Atypical mycobacteriosis	89	5-15 mg/kg PO BID
	Feline leprosy, *Nocardia farci* infection	113	Cat: 62.5 mg PO BID, with clofazimine or rifampin
Clemastine *(Tavist)*	Antihistamine, atopic dermatitis	85	Dog: 0.05-0.1 mg/kg PO BID Cat: 0.67 mg PO BID
Clindamycin *(Antirobe)*	Bronchiectasis	17	10 mg/kg PO BID
	Toxoplasma gondii, *Hepatozoon americanum* or *Neospora caninum* infections; protozoal polyradiculoneuritis or myositis	23-25, 33, 82, 102, 116	10-25 mg/kg PO, IM BID-TID
	Stomatitis, gingivitis, glossitis, sialadenitis, salivary gland fistula, *Clostridium* spp. infection, acute abdominal syndrome, chronic prostatitis	27, 29, 33, 39, 53	5-11 mg/kg PO BID
	Osteomyelitis	81	11 mg/kg IV, IM, PO BID-TID
	Mucocutaneous pyoderma	88, 91	Dog: a) 5-33 mg/kg PO BID b) 11 mg/kg PO SID
	Actinomycosis	89	5 mg/kg SC BID
Clofazimine *(Lamprene)*	Feline leprosy	113	Cat: 25 mg PO SID or 50 mg PO QOD, with clarithromycin or rifampin
Clomipramine *(Clomicalm, Anafranil)*	Chronic feline idiopathic cystitis	50	Cat: 0.5 mg/kg PO SID
	Feline psychogenic alopecia	87	Cat: 1.25-2.5 mg PO SID
	Certain behavioral disorders, tricyclic antidepressant	117	Dog: 1-3 mg/kg PO BID Cat: 0.25-1.3 mg/kg PO SID
Clonazepam *(Klonopin)*	Certain behavioral disorders	117	Dog: 0.1-0.5 mg/kg PO TID Cat: 0.015-0.2 mg/kg PO TID
Clopidogrel *(Plavix)*	Thrombosis, inhibit platelet aggregation	10, 68	Cat: 18.75 mg PO SID
Clorazepate *(Tranxene-SD)*	Certain behavioral disorders	117	Dog: 0.5-2 mg/kg PO QID Cat: 0.5-2 mg/kg PO BID
Clotrimazole 1% *(Lotrimin)*	Nasal aspergillosis	14	Dog: Apply 50 mL per nasal cavity and allow contact time of 60 min; repeat Rx PRN
Codeine (guaifenesin with codeine)	Cough suppressant	17	Dog: 1-2 mg/kg PO BID-QID
Coenzyme Q (CO-Q 10)	Canine cardiomyopathy	10	Dog: 30-90 mg PO BID
Colchicine *(Colchicine)*	Chronic hepatic fibrosis	37	Dog: 0.03 mg/kg PO SID
	Amyloidosis	48	Dog: 0.01-0.03 mg/kg PO SID
Coumarin (nonanticoagulant form)	Lymphedema		Dog: 400 mg/kg/day PO
Crotalidae Polyvalent immune Fab, ovine *(CroFab)* *See* Antivenom			
Cryoprecipitate	Platelet disorders, von Willebrand disease	67	1 U/10 kg IV; repeat q 6-12 hr PRN
	Coagulopathy, Factor VIII deficiency, fibrinogen deficiency	68	1-5 mL/kg IV over 1 hr
Cyanocobalamin (Vitamin B_{12}, *Neogen*)	Cobalamin malabsorption	33, 65	Dog: 0.25-1 mg SC, IM weekly × 1 mo, then q 3-6 mo
	Dietary supplement, B_{12} deficiency	33, 36	250 µg SC, IM weekly or 1 mg SC q 2 wk × 1-3 mo
			Cat: 250 µg SC q 7 days × 6 wk, then q 14 days × 6 wk, then q 28 days

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Cyclophosphamide *(Cytoxan)*	Pulmonary eosinophilic diseases	18	Dog: 50 mg/m^2 PO QOD, with prednisone
	Infectious meningomyelitis, granulomatous urethritis	24, 52	2 mg/kg PO SID × 4 days/wk
	Membranous glomerulonephritis	48	50 mg/m^2 PO SID × 3-4 days, then off for 3-4 days
	Feline mammary cancer	60	Cat: 50-100 mg/m^2 PO, in a protocol with doxorubicin
	Immune-mediated hemolytic anemia	64	Dog: a) Initial single dose: 200 mg/m^2 IV, PO b) Maintenance dose: 50 mg/m^2 PO, IV SID × 4 days/wk or 75-90 mg/m^2 PO SID
	Immune-mediated thrombocytopenia	67	Dog: 50 mg/m^2 PO SID × 4 days/wk, with prednisone Use with caution
	Lymphoma	69, 72	Dog: a) 50 mg/m^2 PO SID-QOD or once weekly, in a protocol b) 250 mg/m^2 IV once weekly, in a protocol Cat: a) 10 mg/kg IV once weekly, in a protocol b) 300 mg/m^2 PO once weekly, then q 3 wk × 1 yr, in a protocol c) 200 mg/m^2 IV once weekly, in a protocol
	Refractory erosive/nonerosive arthritis, masticatory myositis, polymyositis	80, 82	Dog: 1.5-2.5 mg/kg PO SID × 4 days/wk, with prednisone
	FIP	112	Cat: 2.2 mg/kg PO 4 days/wk
Cyclosporine *(Sandimmune, Neoral)*	Feline allergic bronchitis	17	Cat: 10 mg/kg PO BID
	Granulomatous meningoencephalomyelitis	23	Dog: 5-10 mg/kg PO BID
	Gingivitis, glossitis, lymphoplasmacytic stomatitis	27	Dog: 2-5 mg/kg BID initially, then SID-QOD Cat: 1-4 mg/kg PO SID or dd BID × 4-6 wk
	Inflammatory bowel disease, feline chronic cholangiohepatitis	33, 37	5 mg/kg PO SID-BID
	Perianal fistula	35	Dog: 4-8 mg/kg PO BID × 6-12 wk, then taper, for a total of 18-20 wk
	Immune-mediated hemolytic anemia	64	Dog: a) 10 mg/kg PO SID b) 6 mg/kg PO BID
	Myelodysplastic syndrome	66	Cat: 2.5-5 mg/kg PO SID, with prednisolone
	Cutaneous histiocytosis, exfoliative cutaneous lupus erythematosus, vasculitis, other cutaneous immune-mediated diseases, nodular panniculitis, atopic dermatitis	77, 85, 89, 91	Dog: 5 mg/kg PO SID-QOD × 4-6 wk until remission, then taper

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Cyclosporine *(Sandimmune, Neoral)—cont'd*	Feline eosinophilic granuloma complex	91	Cat: 25 mg PO SID
	Sebaceous adenitis	93	Dog: 5 mg/kg PO BID Cat: 5 mg/kg PO SID, then taper to QOD
	Idiopathic facial dermatitis	93	Cat: 6-7 mg/kg PO SID
	Allergic blepharitis	95	Dog: 5 mg/kg PO SID × 2-4 wk, then taper
Cyclosporine 0.2% *(Optimmune)* or 1%-2% soln (compounding pharmacies)	KCS, pannus, ligneous conjunctivitis	96-98	Apply to affected eye BID-TID
Cyproheptadine *(Ciplactin, Periactin)*	Allergic bronchitis	17	Cat: 2 mg PO BID
	Appetite stimulant	48, 73, 111, 122	Cat: 1-4 mg PO SID-BID
	Vocalization, serotonin syndrome, psilocybin/amphetamine toxicoses, hyperthermia	127, 129, 130	Dog: 1.1 mg/kg PO QID or dissolve tablet in saline and give rectally TID Cat: 2-4 mg PO QID or dissolve tablet in saline and give rectally TID
Cytarabine or Cytosine arabinoside *(Cytosar, DepoCyt)*	Granulomatous meningoencephalomyelitis	23	Dog: 50 mg/m^2 SC BID × 2 days, then q 3 wk
	Myelodysplastic syndrome	66	Cat: a) 0.7-1.4 mg/kg SC SID × 2-4 wk, with prednisolone b) 100 mg/m^2 SC SID × 4 days over 3 wk, with other drugs
	Renal, CNS lymphoma	72	a) 200-300 mg/m^2 SC BID × 2 days b) 100 mg/m^2/day CRI IV × 3-4 days
Dacarbazine *(DTIC-Dome)*	Chemotherapy, in a protocol	72	Dog: 200 mg/m^2 IV slowly SID × 5 days q 3 wk
Dalteparin *(Fragmin)*	Arterial thromboembolism	10, 68	Dog: 150 U/kg SC BID Cat: a) 100-150 U/kg SC BID b) 1 mg/kg SC BID-TID
Danazol *(Danocrine)*	Immune-mediated hemolytic anemia	64	Dog: 3-12 mg/kg PO BID then slowly taper, with prednisone
	Immune-mediated thrombocytopenia	67	Dog: 5 mg/kg PO BID, with prednisone
Dantrolene *(Dantrium)*	Urine retention disorders, decrease urethral sphincter tone	51	Dog: 3-15 mg/kg PO TID Cat: 0.15-0.6 mg/kg PO TID
	Urethral spasms	52	Dog: 0.5-2 mg/kg PO TID, with diazepam
	Skeletal muscle relaxant, malignant hyperthermia	82, 126, 131	Dog: a) 2-5 mg/kg IV once b) 3.5 mg/kg PO BID × 3 days
Dapsone *(Dapsone)*	Jack Russell terrier vasculopathy, vasculitis, sterile eosinophilic pustulosis, subcorneal pustular dermatosis	88, 91, 93	Dog: 1 mg/kg PO TID × 2-4 wk until resolution, then taper; use alone or with prednisone and vitamin E
Darbepoetin *(Aranesp)*	Anemia	48	0.45 µg/kg SC once weekly, then taper to q 2-3 wk
Daunorubicin *(Cerubidine)*	Myelodysplastic syndrome	66	Cat: 20 mg/m^2 IV SID × 3 days over 3 wk, with other drugs
Decoquinate *(Deccox)*	*Hepatozoon americanum*	116	10-20 mg/kg PO BID in food × 2 yr or indefinitely
Deferoxamine *(Desferal)*	Iron toxicosis, chelation therapy	127	40 mg/kg IM TID-QID
Delmadinone acetate *(Tardak)**	Galactorrhea	60	Dog: 1-1.5 mg/kg SC

*Not available in the United States.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Demecarium bromide 0.125% (compounding pharmacies)	Glaucoma	100	Dog: Apply 1 drop to affected eye BID
l-Deprenyl *See* Selegiline			
Deracoxib *(Deramaxx)*	Analgesia	80-82, 127	Dog: 1-2 mg/kg PO SID
Desipramine *(Norpramin)*	Cataplexy	22	3 mg/kg PO BID
Desmopressin acetate (DDAVP)	Cardiopulmonary arrest	7	a) 1.6 U/kg IT b) 0.8 U/kg IV once
	Central diabetes insipidus	41	Intranasal form: a) 0.1 mL (2-4 drops) in each nostril or conjunctival sac SID-BID, with frequency titrated b) 2-5 μg SC administered through bacteriostatic filter Oral tab: 0.1 mg PO TID, then decrease to effect Parenteral form: 0.5-2 μg SC SID-BID
	von Willebrand disease	67	Dog: 1 μg/kg SC
Desoxycorticosterone pivalate (DOCP; *Percorten V*)	Hypoadrenocorticism, post-adrenalectomy therapy	45	Dog: 1.5-2.2 mg/kg IM, SC q 25 days Cat: 12.5 mg IM q 3-4 wk
Dexamethasone 0.1% (ophthalmic)	Conjunctivitis	96	Apply to affected eye BID-QID
	Feline eosinophilic keratitis	98	Cat: Apply to affected eye 2-6 times/day, then PRN
	Pannus, episcleritis, anterior uveitis, hyphema	98, 99	Apply to affected eye 1-8 times/day, taper slowly
Dexamethasone ($NaPO_4$ = *Dexajet SP, Azium SP;* polyethylene glycol = *Azium*)	Inflammation	15, 103	a) 0.5-2.2 mg/kg IV, SC, IM; repeat in 4-6 hr b) 0.5-1 mg/kg IV, SC once
	Acute bronchitis, airway inflammation	17, 111	0.1-0.2 mg/kg IV, IM, SC, PO BID × 3 days
	Feline allergic bronchitis	17	Cat: 0.2-2.2 mg/kg IV, IM
	Hydrocephalus, hydranencephaly, porencephaly	23	0.05 mg/kg PO SID, then taper to QOD
	Intracranial myiasis	23	0.1 mg/kg IV; repeat in 24-48 hr
	Canine chronic hepatitis/cirrhosis	37	Dog: 0.2-0.4 mg/kg PO SID
	Hyperparathyroidism, hypercalcemia	43, 127	a) 0.1-0.22 mg/kg IV, SC BID b) 0.25 mg/kg PO, SC QID
	Hypoadrenocorticism	45	2-4 mg/kg IV
	Anaphylaxis	76	1-2 mg/kg IV
	Feline plasma cell pododermatitis, eosinophilic granuloma complex	90, 91	Cat: 0.5 mg/kg PO SID, then taper
	Cutaneous immune-mediated diseases	90, 91	0.2-0.6 mg/kg PO SID or dd BID, then taper to QOD
	Envenomation with severe swelling	136	0.1-0.2 mg/kg IV once
Dexmedetomidine *(Precedex)*	Sedation, analgesia	1	Dog: 0.001-0.005 mg/kg SC, IM, IV Cat: 0.002-0.015 mg/kg SC, IM, IV

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Dextran 70 (Macrodex, Gentran 70)	Hypovolemia from gastric dilatation-volvulus	32	Dog: 5 mL/kg IV over 5-15 min, combined with hypertonic (7%) saline
	Shock, hypotension, fluid loss from burns, hypoproteinemia, heat prostration	132, 134, 135	Dog: a) 10-20 mL/kg IV b) 20 mL/kg/day IV as CRI Cat: 5-10 mL/kg IV
Dextroamphetamine *(Adderall, Dexedrine)*	Narcolepsy	22	Dog: 5-10 mg PO BID-TID
	CNS stimulant	117	Dog: 0.2-1.3 mg/kg PO BID-TID
Dextrose 50%	Hyperkalemia	7, 48	a) 1 g/kg IV b) 1-2 g/U insulin IV quickly, then 1-2 g/U insulin IV over 4-6 hr
	Glycemic control	39	Dogs: Blood glucose <80 mg/dL: 2.5%-5% dextrose in isotonic fluids IV as CRI Blood glucose <50 mg/dL: 0.25-0.5 g/kg dextrose as IV bolus
	Hypoglycemia, xylitol toxicosis	45, 46, 126, 127, 135	a) 0.5 g/kg IV bolus, diluted 1:1 with sterile water b) 0.5-1 mL/kg slow IV bolus
Diazepam *(Valium)*	Preanesthetic, sedation, analgesia	1, 3, 4, 32, 71	0.1-0.5 mg/kg IV to effect, alone or in combination with other drugs
	Status epilepticus, cluster seizures, tremors, hyperesthesia from certain toxicoses	22, 23, 112, 125-128, 130, 135	Dog: a) 0.5-2 mg/kg IV, slowly to effect b) 0.5-2 mg/kg/hr IV in 0.9% NaCl as CRI × 4-6 hr; increase in increments of 0.5 mg/kg/hr Cat: a) 0.3-2 mg/kg IV slowly to effect b) 0.25-2 mg/kg PO BID for long-term use Rectal administration: Dog: 1-2 mg/kg Cat: 0.5-1 mg/kg
	Idiopathic tremor syndrome, muscle relaxant for spinal cord disorders	23, 24	Dog: 0.25 mg/kg PO BID-TID
	Urethral spasms, to decrease urethral sphincter tone	51, 52	Dog: a) 2-10 mg PO TID b) 0.1-0.25 mg/kg PO BID-TID, with dantrolene Cat: a) 0.2-0.5 mg/kg IV TID b) 2-5 mg PO TID
	Appetite stimulant	73, 122	Cat: a) 0.05-0.15 mg/kg IV, IM, PO SID-QOD or PRN b) 1 mg PO SID
	Muscle relaxant for exertional myopathy in greyhounds	82	Dog: 0.5 mg/kg IV
	Vertigo	108	Dog: 0.1-0.2 mg/kg PO SID-BID
	Certain behavioral disorders	117	Dog: 0.5-2 mg/kg PO q 4 hr Cat: 0.1-0.5 mg/kg PO q 4 hr
Diazoxide *(Proglycem)*	Hypoglycemia from insulinoma	46, 73	Dog: 5-13 mg/kg PO BID initially, then increase to 20 mg/kg PO BID (max)
Diclofenac 0.1% *(Voltaren)*	Anterior uveitis	99	Apply to affected eye BID-QID
Diethylcarbamazine citrate *(Hetrazan)*	Heartworm chemoprophylaxis	12	Dog: 6.6 mg/kg PO SID

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Diethylstilbestrol (compounding pharmacies)	Hormone-responsive urinary incontinence	51	Dog: 0.1-1 mg PO × 3-5 days, then once weekly
	Induce estrus	61	Dog: 5 mg PO SID × 6-9 days
Difloxacin *(Dicural)*	Canine bacterial pyoderma	88	Dog: 5-10 mg/kg PO SID
Digoxin *(Lanoxin)*	Atrial fibrillation, dilated cardiomyopathy, mitral regurgitation	6, 9, 10	Dog: a) 0.003-0.005 mg/kg PO, IV BID b) 0.22 mg/m^2 PO BID Cat: a) <4 kg: 0.031 mg PO q 2-3 days b) >4 kg: 0.031 mg PO SID-QOD
Digoxin immune Fab *(Digibind)*	Cardiotoxic plant poisoning	131	1-2 vials IV over 30 min
Dihydrotachysterol (DHT; *Hytakerol*)	Hypoparathyroidism, hypocalcemia	43	0.02 mg/kg/day PO × 3 days, then 0.01 mg/kg/day PO SID-QOD × 1 wk
1,25-Dihydroxyvitamin D_3 *See* Calcitriol			
Diltiazem *(Cardizem)*	Acute atrial fibrillation/ flutter, orthodromic atrial reciprocating tachycardia	6, 10	Dog: a) 0.5 mg/kg PO TID, titrate to max dose of 1.5-2 mg/kg PO TID b) 0.1-0.2 mg/kg IV bolus, then 2-6 µg/kg/min IV as CRI c) *Cardizem-CD* or *Dilacor XR:* 3-4 mg/kg PO BID initially, then titrate Cat: a) 0.5-1 mg/kg PO BID-TID b) *Cardizem-CD:* 10 mg/kg PO SID c) *Dilacor XR:* 30-60 mg PO SID-BID
	Hypertrophic cardiomyopathy	10	Cat: a) 7.5 mg PO TID b) *Cardizem-CD:* 45 mg or 10 mg/kg PO SID
Dimenhydrinate *(Dramamine)*	Motion sickness, drug-induced vomiting	31, 126	2-4 mg/kg PO 30 min before giving D-penicillamine Dog: 4-8 mg/kg PO SID-TID Cat: 12.5 mg PO SID-TID
Dimethyl sulfoxide (DMSO)	Amyloidosis	48	90 mg/kg PO, SC 3 times/wk
Diminazene aceturate *(Berenil)**	*Babesia canis*	116	Dog: 3.5-5 mg/kg IM, SC once
	Cytauxzoon felis	116	Cat: 2 mg/kg IM, SC once
Diphenhydramine *(Benadryl)*	Rhinitis/sinusitis	14	Dog: 2-4 mg/kg PO TID Cat: 2-4 mg PO BID-TID
	Intracranial myiasis	23	4 mg/kg IM as pretreatment
	Drug-induced vomiting	31, 126	Dog: 2-4 mg/kg PO, IM TID 30 min before other drug
	Anaphylaxis, urticaria, angioneurotic edema, envenomation	71, 73, 76, 136	Dog: 1-2 mg/kg IV slowly, IM Cat: 2 mg/kg IM
	Atopic dermatitis, effects of mast cell tumors	85, 89	Dog: 2.2 mg/kg PO TID
Diphenoxylate *(Lomotil)*	Acute colitis	34	Dog: 0.05-0.1 mg/kg PO TID-QID Cat: 0.063 mg/kg PO TID
Dipivalyl epinephrine 0.5%-1% *(Dipivefrin)*	Glaucoma	100	Apply 1 drop to affected eye BID-QID, with other therapy

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

*Not available in the United States.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Dobutamine *(Dobutrex)*	Acute sinus bradycardia, severe or refractory hypotension, shock, dilated cardiomyopathy	6, 37, 76, 132, 135, 136	Dog: 5-20 µg/kg/min IV as CRI Cat: 0.5-2 µg/kg/min IV as CR
	Inotropic agent	10, 32	Dog: 1-5 µg/kg/min IV as CRI
	Pulmonary hypertension	18	Dog: 5-7 µg/kg/min IV as CRI
Docusate sodium or dioctyl sodium sulfosuccinate *(Colace, Surfak, Docusate)*	Megacolon, stool softener	34	Dog: 50-100 mg PO SID-BID Cat: 50 mg PO SID-BID
Dolasetron *(Anzemet, Anemet)*	Serotonin 5-HT_3 receptor antagonist, refractory vomiting, GI ulceration	33, 36, 37, 39, 48, 135	Dog: 0.3-1 mg/kg PO, SC, IV SID-TID Cat: 0.6 mg/kg IV SID
Dopamine *(Inotropin)*	Vasopressor agent, refractory or severe hypotension, shock, dilated cardiomyopathy	1, 7, 37, 132, 135, 136	2-25 µg/kg/min IV as CRI
	Acute sinus bradycardia	6, 32	Dog: 1-3 µg/kg/min IV as CRI
	Pulmonary hypertension	18	Dog: 5-7 µg/kg/min IV as CRI
	Feline hypokalemic polymyopathy	82	Cat: 0.5 µg/kg/min IV as CRI
Dorzolamide 2% *(Trusopt)*	Glaucoma	100	Apply 1 drop to affected eye BID-TID
Doxapram *(Dopram-V)*	Respiratory stimulant		a) 1-10 mg/kg IV b) 0.1 mL IV into umbilical vein (neonate) c) 1-2 drops under tongue (neonate)
Doxepin *(Sinequan)*	Certain behavioral disorders	117	Dog: 3-5 mg/kg PO BID-TID; max = 150 mg BID Cat: 0.5-1 mg/kg PO BID
Doxorubicin *(Adriamycin)*	Chemotherapy for mammary tumors	60	Cat: 20-30 mg/m^2 IV slowly q 3 wk
	Chemotherapy for lymphoma	69, 72	Dog: a) Medium to large dogs: 30 mg/m^2 IV over 20 min q 3 wk b) Small dogs: 1 mg/kg or 25 mg/m^2 IV q 3 wk Cat: a) 25 mg/m^2 IV q 3 wk × 5 Rx b) 1 mg/kg IV q 3 wk, in a protocol
Doxycycline *(Vibramycin, Vibra-Tabs)*	Chronic endocarditis	9	Dog: 5 mg/kg PO SID
	Various bacterial and rickettsial infections	16, 23, 24, 48, 64, 80, 102, 113-116	Dog: 5-10 mg/kg PO SID-BID; may stain teeth of young dogs Cat: 5 mg/kg PO, IV BID
	Bronchiectasis, pneumonia	17, 18	Dog: 5-10 mg/kg PO BID Cat: 5 mg/kg PO BID
	Discospondylitis, osteomyelitis	24	Dog: 25 mg/kg PO SID; may cause vomiting
	Stomatitis, gingivitis, glossitis	27	5 mg/kg PO BID
	Chronic prostatitis	53	Dog: 4.4-11 mg/kg PO BID
	Feline plasma cell pododermatitis, eosinophilic granuloma complex	90, 91	Cat: 25 mg/day PO
	Cutaneous immune-mediated diseases	90	Dog: <10 kg: 100 mg PO SID, with niacinamide >10 kg: 100 mg PO BID, with niacinamide
Edrophonium Cl *(Tensilon, Enlon)*	Tensilon test	25	Dog: 0.2-5 mg IV; max = 5 mg Puppy: 0.1-0.5 mg IV
EDTA 1% ophthalmic (compounding pharmacies)	Calcium keratopathy	98	Administer to affected eye BID-TID

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Enalapril *(Enacard, Vasotec)*	Chronic congestive heart failure, hypertension, to reduce left-to-right shunting	8-10	Dog: 0.5 mg/kg PO BID
	Glomerulonephritis, chronic renal failure	48	Dog: 0.25-1 mg/kg PO SID-BID
Enilconazole 1%-2% soln *(Imaverol)*	Nasal aspergillosis	14	Dog: Apply 120-200 mL intranasally; allow contact time of 45-60 min × 2-3 Rx
Enoxaparin *(Lovenox)*	Arterial thromboembolism	10	Cat: 1 mg/kg SC BID-TID
Enrofloxacin *(Baytril)*	Chronic endocarditis	9	Dog: 5-10 mg/kg PO BID
	Various bacterial and rickettsial infections	16, 23, 35, 50, 64, 80, 102, 112-115	Dog: 2.5-10 mg/kg PO, SC, IV, IM SID-BID; may cause cartilage deformation in young dogs Cat: 2.5 mg/kg PO, SC BID; doses >5 mg/kg/day associated with acute blindness
	Discospondylitis, osteomyelitis	24, 81	Dog: 5-15 mg/kg PO BID
	Stomatitis, gingivitis, glossitis, chronic prostatitis, canine pyoderma	27, 53, 88	Dog: 5-10 mg/kg PO SID Cat: 4 mg/kg PO SID; use with caution
	Chronic histiocytic ulcerative colitis	34	Dog: 5-15 mg/kg PO BID alone or with metronidazole and amoxicillin
	Hepatic abscess, feline acute cholangiohepatitis, canine chronic hepatitis/cirrhosis, acute abdominal syndrome	37, 39	Dog: 5-20 mg/kg IV SID Cat: 5 mg/kg IV SID; use with caution
Ephedrine *(Broncholate, Marax)*	Urinary incontinence	49	Dog: 2-4 mg/kg PO BID-TID Cat: 2-4 mg PO BID-TID
Epinephrine *(Adrenalin, EpiPen)*	Acute sinus bradycardia	6	0.05-0.2 mg IV
	Cardiopulmonary arrest	7	0.2 mg/kg IT
	Vasopressor	7	0.01-0.02 mg/kg IV q 3-5 min
	Anaphylaxis	76, 136	1:10,000 soln: 0.05-0.1 mL/kg IV; max = 2 mL
Epsiprantel *(Cestex)*	Tapeworms: *Dipylidium* spp., *Taenia* spp.	33	Dog: 5 mg/kg PO once Cat: 2.5 mg/kg PO once
Ergocalciferol *See* Vitamin D_2			
Erythromycin *(E-Mycin, Ery-Tab)*	Gastric motility disorders, megacolon	31, 34	Dog: 0.5-1 mg/kg PO, IV TID
	Campylobacter spp., *Helicobacter* spp. infections	33	Dog: 20 mg/kg PO BID-TID Cat: 10 mg/kg PO TID
	Chronic prostatitis, canine bacterial pyoderma	53, 88	Dog: 10-22 mg/kg PO TID
	Actinomycosis, nocardiosis	89	10 mg/kg PO TID
Erythromycin o.o. *(Erythromycin)*	Neonatal ophthalmia, conjunctivitis from *Chlamydophila* spp., *Mycoplasma* spp.	95, 96	Apply to affected eye TID-QID
Erythropoietin, human recombinant *(Epogen, Procrit)*	Anemia from renal failure, FeLV, or toxic plant poisoning	48, 112, 131	100 U/kg SC 3 times/wk, then 50-100 U/kg SC q 4-7 days
	Myelodysplastic syndrome	66	Dog: 100 U/kg SC QOD

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Esmolol *(Brevibloc)*	Acute atrial fibrillation, flutter or tachycardia	6	a) 50-100 µg/kg IV slowly as bolus; repeat q 5 min, up to max dose of 500 µg/kg IV b) 50-200 µg/kg/min IV as CRI
Esomeprazole *(Nexium)*	GI ulceration	39	Dog: 0.5-1 mg/kg PO SID-BID
Essential fatty acids (*See also* Fish oil; Omega-3, Omega-6 Fatty Acid supplements)	Hepatocutaneous syndrome	37	Dog: 30-90 mg/kg PO SID
Ethanol 20%-30% (grade alcohol)	Ethylene glycol toxicosis	48, 128	20% soln: Dog: 5.5 mL/kg in 0.9% saline IV q 4 hr × 5 Rx, then QID × 4 Rx Cat: 5 mL/kg IV QID × 5 Rx, then TID × 4 Rx 30% soln: 1.3 mL/kg IV as loading dose, followed by 0.42 mL/kg/hr IV CRI × 48 hr
Ethyl lactate shampoo *(Etiderm)*	Staphylococcal pyoderma and folliculitis, impetigo, intertrigo, feline acne	88	Dog: Apply topically SID-QOD × 7-14 days Cat: Apply topically SID-QOD until resolution, then PRN
Etidronate disodium *(Didronel)*	Hypercalcemia	43	Dog: 10-40 mg/kg/day PO dd BID
Etodolac *(Etogesic)*	Musculoskeletal pain or inflammation	80, 127	Dog: 10-15 mg/kg PO SID
Etomidate *(Amidate)*	Anesthesia induction	1, 32	Dog: 1 mg/kg IV to effect, alone or with diazepam or fentanyl
Etretinate *(Tegison)*	Primary seborrhea, sebaceous adenitis	93	Dog: 1-2 mg/kg PO SID
	Vitamin A–responsive dermatoses	122	Dog: 0.75-1 mg/kg PO SID
Famciclovir *(Famvir)*	Feline herpesvirus keratitis	98	Cat: 1/4 of 125-mg tab PO BID × 8 days
Famotidine *(Pepcid)*	Esophagitis, GI tract ulceration, uremic gastritis, helicobacteriosis	15, 30-33, 37, 39, 48, 67, 73, 89, 112, 113, 124, 127, 128, 131, 135	a) 0.5-1 mg/kg IV, PO, SC, IM SID-BID b) 10-20 mg PO SID Do not give IV in cats
Felbamate *(Felbatol)*	Seizures	22	Dog: 15-70 mg/kg PO BID-TID; increase in 15 mg/kg increments up to 70 mg/kg/day PO
Fenbendazole *(Panacur)*	*Capillaria aerophila*, *Paragonimus kellicotti*, *Aelurostrongylus abstrusus*, *Oslerus osleri*	14, 16, 18	Dog: 25-50 mg/kg PO BID × 10-14 days Cat: 25-50 mg/kg PO BID × 14 days
	Parasitic gastritis: *Ollulanus* spp.	31	10 mg/kg PO SID × 3 days
	Strongyloides spp., *Giardia lamblia*, *Entamoeba histolytica*, *Balantidium coli*	31, 33, 34, 48, 50, 116	Dog: 50 mg/kg PO SID × 3-10 days
	Ascarids, hookworms, whipworms	33, 34	Dog: 50 mg/kg PO SID × 3 days; repeat in 3 wk and possibly 3 mo later
	Pancreatic fluke: *Euryterma procyonis*	36	Cat: 30 mg/kg PO SID × 6 days
	Mesocestoides spp. infections	38	Dog: 100 mg PO BID × 4-12 wk
	Renal parasite: *Capillaria felis cati*	48	Cat: 22 mg/kg PO BID × 3-10 days
Fentanyl transdermal patch *(Duragesic)*	Analgesia, pain control	81, 128	3-5 µg/kg q 3-4 days; apply 18-24 hr before surgery Dog: a) <10 kg: 25 µg/hr b) 10-20 kg: 50 µg/hr c) 20-30 kg: 75 µg/hr d) >30 kg: 100 µg/hr Cat: 25 µg/hr

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Fentanyl citrate *(Sublimaze)*	Analgesia, pain control	1, 39, 134	Dog: a) 0.02 mg/kg IV, with midazolam b) 0.3-0.7 µg/kg/min IV as CRI c) 3-10 µg/kg IV initial bolus, then 0.5-1 µg/kg/min IV as CRI Cat: a) 0.01 mg/kg IV, with midazolam b) 0.3 µg/kg/min IV as CRI
	Anesthesia for gastric dilatation-volvulus surgery	32	Dog: 5-15 µg/kg/hr IV as CRI
Ferrous sulfate *(Feosol, Feratab)*	Chronic blood loss, iron deficiency anemia	64	10 mg/kg PO SID, with food
Filgrastim *(Neupogen)* *See* Granulocyte colony-stimulating factor			
Finasteride *(Propecia)*	Benign prostatic hyperplasia	53	Dog: 0.1-0.5 mg/kg PO SID
Fipronil *(Frontline Plus, Topspot)*	Flea control	85	Apply topically q 2-4 wk; wait 24-48 hr after bathing
	Otodectic mange, ear mites	85	Apply 2-3 drops in each ear; repeat in 7 and 30 days
	Cheyletiellosis	85	Apply topically q 4 wk × 2 Rx
	Sarcoptic mange	85	Apply topically q 2 wk × 3 Rx
Firocoxib *(Previcox)*	DJD	80	Dog: 5 mg/kg PO SID
Fish oil (eicosapentaenoic acid, docosahexaenoic acid) *See also* Omega 3 and 6 Fatty Acids	Hyperlipidemia	46	Dog: 200 mg/kg/day PO
	Primary seborrhea	93	Dog: 35 mg/kg PO SID
Fluconazole *(Diflucan)*	Nasal aspergillosis	14	Dog: 1.25-2.5 mg/kg PO BID
	Systemic and CNS mycotic or algal infections	14, 23, 24, 27, 50, 89, 102, 111	Dog: a) 5-15 mg/kg PO, IV SID b) 2.5-5 mg/kg PO, IV BID Cat: 25-50 mg PO BID
	Malassezia spp. dermatitis	85	Dog: 2.5 mg/kg PO SID
	Dermatophytosis	86	2.5-10 mg/kg PO SID-BID
Flucytosine *(Ancobon)*	Cryptococcosis	14, 89, 111	Dog: a) 25-50 mg/kg PO QID b) 50-75 mg/kg PO TID Cat: a) 100 mg PO QID b) 30 mg/kg PO QID c) 50 mg/kg PO TID
Fludrocortisone acetate *(Florinef)*	Hypoadrenocorticism	45	0.02 mg/kg PO SID
Flumazenil *(Romazicon)*	Benzodiazepine toxicosis	129	0.1 mg/kg IV
Fluocinolone (*Tri-Luma* cream)	Cutaneous or discoid lupus erythematosus, pemphigus erythematosus	90, 91	Dog: Apply topically BID × 5-7 days, then taper
Fluoxetine *(Prozac)*	Certain behavioral disorders	117	Dog: 1-2 mg/kg PO SID Cat: 0.5-1.5 mg/kg PO SID
Flurazepam *(Dalmane)*	Certain behavioral disorders	117	Dog: 0.1-0.5 mg/kg PO BID Cat: 0.1-1 mg/kg PO BID
	Appetite stimulant	122	0.2-0.4 mg/kg PO q 4-7 days
Flurbiprofen 0.03% *(Ocufen)*	Anterior uveitis	99	Apply to affected eye BID-QID

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Fluticasone propionate *(Flovent)*	Chronic or allergic tracheobronchitis	16, 17	Dog: <20 kg: 110 µg BID >20 kg: 220 µg BID Cat: 110-220 µg BID Administer via spacing chamber/ metered dose inhaler and face mask; 1 puff = 110 µg
Fluvoxamine *(Fluvoxamine)*	Certain behavioral disorders	117	Dog: 1-2 mg/kg PO SID Cat: 0.5-1.5 mg/kg PO SID
Folic acid (Folic acid, Folate)	Dietary supplement, folate deficiency	33	1-5 mg PO, SC weekly × 1 mo
Fomepizole *(Antizol-Vet)*	Ethylene glycol toxicosis	48, 128	Dog a) 20 mg/kg IV as loading dose, followed by 15 mg/kg IV at 12 and 24 hr, then 5 mg/kg IV at 36 hr b) 3 mg/kg IV BID as additional doses if needed Cat: 125 mg/kg IV as loading dose, then 31.25 mg/kg IV at 12, 24, and 36 hr NOTE: Not approved for use and unknown efficacy in cats
Furazolidone *(Furoxone, Giarcid)*	*Giardia lamblia*, *Entamoeba histolytica*, *Balantidium coli*	33	4 mg/kg PO BID × 7 days
Furosemide *(Salix, Lasix)*	Enhanced diuresis	1, 73	1-2 mg/kg IV SID-BID
	Acute congestive heart failure	8-10	Dog: a) Moderate: 1-4 mg/kg IV, IM, SC, PO BID-TID b) Severe or fulminant: 4-8 mg/kg IV, IM, SC q 2-6 hr Cat: 1-2 mg/kg IV, IM, SC q 2-8 hr
	Chronic congestive heart failure	9, 10	Dog: a) Mild to moderate: 1-4 mg/kg PO SID-TID b) Moderate to severe: 2-4 mg/kg PO BID-TID Cat: a) Mild: 1 mg/kg PO SID-BID b) Moderate: 2-3 mg/kg PO BID c) Severe: 3-4 mg/kg IV, IM, SC, PO BID-TID
	Diuresis: pulmonary edema	18, 37, 133	a) 2-4 mg/kg IV once b) 2-4 mg/kg IM, PO q 4-12 hr
	Hydrocephalus, hydranencephaly, porencephaly	23	Dog: 1-2 mg/kg PO BID
	Diuresis: brain edema	23	0.7 mg/kg IV, 15 min after mannitol administration
	Diuresis: ascites from hepatic failure	37	Dog: 1 mg/kg PO BID
	Hypercalcemia, cholecalciferol toxicosis	1, 43, 73, 124, 127	a) 1-4.5 mg/kg IV, SC, PO, IM SID-QID b) 5 mg/kg IV initial dose, then 5 mg/kg/hr IV as CRI
	Diuresis: acute renal failure, certain toxicoses	48, 128	a) 1-2 mg/kg IV; double the dose if no response in 20-30 min b) Follow with 0.25-1 mg/kg/hr IV as CRI or 1-2 mg/kg IV QID
Gabapentin (*Neurontin)*	Seizures	22	Dog: 25-60 mg/kg PO BID-QID Cat: ≤30 mg/kg PO TID
	Neuropathic pain, paraesthesia	24	Dog: 10 mg/kg PO BID

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Gamma globulin, human *(Iveegam)*	Immune-mediated hemolytic anemia	64	Dog: 0.5-1.5 g/kg IV as 12-hr CRI
	Pemphigus complex	91	Dog: 1 g/kg IV over 6-12 hr × 1-2 days
Gemfibrozil *(Lopid)*	Hyperlipidemia	46	Dog: 200 mg/day PO
Gentamicin *(Gentocin, Legacy)*	Infectious tracheobronchitis	16, 114	Dog: 3-5 mg/kg SID × 5 days as aerosolization or IT injection Cat: 6-8 mg/kg diluted 1:5 to 1:10 in 0.9% saline, delivered by face mask SID
	Serious bacterial infections, septic peritonitis, osteomyelitis	38, 50, 81, 112	6-6.6 mg/kg IV, IM, SC SID × 10-14 days
	Bacterial keratitis	98	20-40 mg applied subconjunctivally
	Brucellosis	113	5 mg/kg IM, SC SID, in a protocol with doxycycline or minocycline
Gingko biloba extract	Rodenticide toxicosis	124	100 mg/kg PO
Glipizide *(Glucotrol)*	Diabetes mellitus	44, 127	Cat: a) 2.5-5 mg PO BID b) 0.25-0.5 mg/kg PO BID
Glucagon *(Glucagon)*	Induce gastric hypomotility	4	Dog: 0.1-0.35 mg/kg IV, repeat PRN; max dose = 1 mg Cat: 0.1 mg IV, repeat PRN; max dose = 1 mg
	Hypoglycemia, neuroglycopenic crisis	46	50 ng/kg IV as initial bolus; then 10-15 ng/kg/min IV as CRI, PRN to maintain euglycemia
Glucosamine/chondroitin sulfate (*Cosequin DS, Cosequin* for cats)	Chronic feline idiopathic cystitis	50	Cat: 1 capsule PO SID
	DJD	80	Dog: 22 mg/kg PO SID
Glycerin *(Osmoglyn)*	Acute glaucoma	100	Dog: 1-2 g/kg PO × 1-2 Rx
Glycopyrrolate *(Robinul)*	Preanesthetic	1	Dog: 0.003-0.01 mg/kg SC, IM, IV Cat: 0.003-0.007 mg/kg SC, IM, IV
	Ptyalism	29	0.01 mg/kg SC PRN
Gonadotropin-releasing hormone *(Cystorelin, Factrel)*	Luteinize an ovarian follicular cyst	55, 62	Dog: 50-100 µg IM SID × 1-3 Rx Cat: 25 µg IM
	Vaginal edema	58	Dog: 2.2 µg/kg IM
	Poor libido in male dogs	61	Dog: 1-2 µg/kg IM 1 hr before breeding
	Induce ovulation	62	Cat: 25 µg IM; give 15-30 hr before artificial insemination
Granulocyte colony-stimulating factor or Filgrastim *(Neupogen)*	Bone marrow suppression (neutropenia, leukopenia)	65, 112, 127, 131	Dog: 1-10 µg/kg/day SC × 3-5 days Cat: 5 µg/kg/day SC for ≤ 2 wk
	Cyclic hematopoiesis, sepsis	65, 75	Dog: 5 µg/kg SC BID × 3-5 days
Griseofulvin *(Fulvicin-U/F, Gris-PEG)*	Dermatophytosis	86	Microsized product: Dog: a) 25 mg/kg PO BID b) 50 mg/kg PO SID Cat: 12.5-25 mg/kg PO BID Ultramicrosized product: Dog: 5-10 mg/kg PO SID Cat: 5-15 mg/kg PO SID
Growth hormone (Porcine GH)	Pituitary dwarfism, adult hyposomatotropism	41	Dog: 0.1 IU/kg SC 3 times/wk × 1-2 mo
Haloperidol *(Haldol)*	Vomiting, dopaminergic antagonist	31	Dog: 0.02 mg/kg PO BID

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Heparin (Heparin sodium)	Arterial thromboembolism, DIC	10, 18, 38, 64, 68	Dog: a) 200 U/kg IV, then 75-200 U/kg SC TID-QID b) 15-20 IU/kg/hr IV as CRI Cat: 50-100 U/kg SC QID
	Pyothorax	19	1500 U/100 mL lavage soln
	Thrombosis prevention	68	a) 100-200 U/kg SC QID b) 200-300 U/kg SC TID
Hetastarch *(Hetastarch)*	Shock, hypoalbuminemia, severe fluid loss from burns	1, 32, 33, 37, 112, 132, 134, 135	Dog: a) 5-20 mL/kg IV bolus, then 1 mL/kg/hr IV b) 20-30 mL/kg/day IV as CRI Cat: a) 5-10 mL/kg IV bolus b) 20-30 mL/kg/day IV as CRI
Human gamma globulin *See* Gamma globulin, human *(Iveegam)*			
Hydralazine *(BiDil)*	Severe hypertension, reduce left-to-right shunting	8-10, 48	Dog: 0.25-2 mg/kg PO BID
Hydrochlorothiazide *(Aldoril)*	Chronic, refractory congestive heart failure	9, 10	Dog: 2-4 mg/kg PO BID Cat: 1-2 mg/kg PO BID
	Nephrogenic diabetes insipidus	41	0.5-1 mg/kg PO BID
	Chronic calcium oxalate urolithiasis	50	Dog: 2 mg/kg PO BID
Hydrocodone bitartrate *(Hycodan)*	Cough suppressant	9, 15-17, 114	Dog: a) 0.22-0.25 mg/kg PO SID-QID b) 2.5-10 mg PO BID-QID
Hydrocortisone 1% *(Resicort)*	Flea allergic, atopic, contact, and acute moist dermatitides	85	Apply conditioner 1-2 times/wk after bathing; do not rinse
Hydrogen peroxide 3%	Emesis, decontamination	123, 130	0.5-2 mL/kg PO; may repeat once; max = 45 mL
Hydromorphone *(Dilaudid, Hydromorphone)*	Analgesic, preanesthetic, sedation	1, 10, 15, 32, 39, 81, 133, 134, 136	Dog: 0.05-0.2 mg/kg SC, IM, IV q 4-6 hr Cat: 0.02-0.2 mg/kg IV, SC, IM QID
Hydroxyurea *(Hydroxyurea)*	Primary polycythemia vera, chronic myelogenous leukemia	64, 66, 72	Dog: a) 15 mg/kg PO SID until PCV normalizes b) 80 mg/kg PO q 3 days c) 500 mg/m^2 PO per day × 3 wk, then increase to 2000 mg/m^2 PO per day if needed; use with vincristine Cat: 25 mg/kg PO 3 times/wk
	Chronic granulocytic leukemia, basophilic leukemia	66	a) 20-25 mg/kg PO BID, then taper to 10-12 mg/kg PO SID or to 50 mg/kg PO q 3-4 days b) 50 mg/kg PO SID × 14 days, then taper to QOD and then q 3 days
	Eosinophilic leukemia	66	Cat: 40 mg/kg/day PO × 7 days, then QOD or q 3 days, with prednisone
Hydroxyzine *(Hydroxyzine)*	Atopic dermatitis, allergic blepharitis	85, 95	Dog: 2.2 mg/kg PO BID-TID Cat: 10 mg PO BID-TID
Hyperimmune plasma (from recovered dogs)	Canine herpesvirus protection in puppies, canine parvovirus	112	Dog: a) 1-2 mL IP b) 1.1-2.2 mL/kg IV slowly
Hypertonic saline (7%-7.5%)	Cerebral edema	23	1-5 mL/kg IV over 10-15 min
	Acute abdominal syndrome	39	4-5 mL/kg IV over 10-15 min
Idoxuridine 0.1% soln (compounding pharmacies)	Ocular herpesvirus infection	96, 98, 114	Cat: Apply soln to affected eye q 5 min for 30 min, then 5-6 times daily

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Ifosfamide *(Ifex)*	Chemotherapy, in a protocol	72	Dog: 350 mg/m^2 IV q 2-3 wk, with mesna Cat: 900 mg/m^2 IV q 3 wk, with mesna
Imidacloprid *(Advantage, Advantix)*	Flea control	85	Dog: Apply topically q 2-4 wk
Imidocarb dipropionate *(Imizol)*	Babesiosis	64, 116	Dog: 5-7.5 mg/kg IM once; may repeat in 14 days
	Cytauxzoonosis, ehrlichiosis, hepatozoonosis	64, 115, 116	Dog: 5 mg/kg IM; repeat in 1-3 wk Cat: 2-5 mg/kg IM once, or repeat in 14 days
Imipenem *(Primaxin)*	Endocarditis	9	Dog: 10 mg/kg IV, SC TID
	Septicemia, endotoxemia, peritonitis	33, 38	Dog: 2-10 mg/kg IV, IM TID
Imipramine *(Imipramine, Tofranil)*	Cataplexy	22	Dog: 0.5-1 mg/kg PO BID-TID
	Urinary incontinence, increase urethral sphincter tone	51	Dog: 5-15 mg PO BID Cat: 2.5-5 mg PO BID
	Certain behavioral disorders	117	Dog: 0.5-2 mg/kg PO BID-TID
Insulin, intermediate *(NPH: Humulin N, Novolin N; Vetsulin)*	Diabetes mellitus	44	0.5 U/kg SC BID
Insulin, PZI *(PZI Vet)*	Diabetes mellitus	44	0.5 U/kg SC BID
Insulin, regular *(Humulin R, Novolin R)*	Diabetes mellitus	44	0.5 U/kg SC BID or PRN
	Diabetic ketoacidosis, transient hyperglycemia	39, 44, 46	a) 0.2 U/kg IM, then 0.1 U/kg IM hourly until glucose <250 mg/dL b) 2.2 U/kg in 250 mL 0.9% NaCl IV as CRI
	Severe hyperkalemia	6, 7, 45, 48, 49	0.06-0.5 U/kg IV, with 4 mL of 50% dextrose/unit insulin
Interferon-α *(Intron A, Roferon-A)*	Immune modulator, antiviral therapy for FeLV, FIP, herpesvirus	112, 114, 122	Cat: a) 30 U PO SID on alternating wk b) 10^6 U/kg/day SC for 5 days, beginning on days 0, 14, and 60
Interferon omega	Canine parvovirus	112	Dog: 2.5 million U/kg IV SID × 3 days
Iodine	Stabilization prior to feline hyperthyroidism surgery	42	Cat: 30-100 mg PO SID or dd BID Use in combination with β-adrenergic blocking agent 10-14 days before surgery
Ipecac syrup *(Ipecac)*	Emetic	123	Dog: 1-2.5 mL/kg PO diluted 50:50 with water Cat: 3.3 mL/kg PO diluted 50:50 with water Not routinely recommended in animals
Ipodate *(Solu-Biloptin)*	Feline hyperthyroidism in methimazole-intolerant cats	42	Cat: 100 mg PO SID or dd BID
Iron dextran complex (*INFeD* injection)	Chronic blood loss, iron deficiency anemia	64	50 mg iron/mL: max dose = 2 mL IM SID
Isoproterenol *(Isuprel)*	Acute sinus bradycardia	6	0.01-0.2 μg/kg/min IV as CRI
Isotretinoin *(Accutane)*	Severe feline acne	88	Cat: 2 mg/kg PO SID
	Vitamin A–responsive dermatoses	122	Dog: 1-3 mg/kg/day PO

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Itraconazole *(Sporanox)*	Systemic mycotic and algal infections	14, 23, 33, 89, 102, 111	Dog: 5-10 mg/kg PO BID Cat: a) 25-50 mg PO SID-BID b) 5-10 mg/kg PO SID
	Mycotic stomatitis, gingivitis, glossitis; gastric pythiosis	27, 31	5-10 mg/kg PO SID
	Fungal cystitis, *Malassezia* spp. otitis and dermatitis, dermatophytosis	50, 85, 86, 90, 107, 108	5 mg/kg PO SID-BID
Ivermectin *(Heartgard Plus, Tru-Heart Plus)*	Heartworm prophylaxis	12	Dog: 6-12 µg/kg PO once monthly Cat: 24 µg/kg PO once monthly
	Elimination of heartworm microfilariae	12	Dog: 50 µg/kg PO, may repeat in 2 wk; do not exceed 200 µg/kg; do not use in ivermectin-sensitive breeds Cat: 24 µg/kg PO
	Nasal capillariasis, *Pneumonyssoides caninum, Oslerus osleri*, *Strongyloides* spp., *Aelurostrongylus abstrusus*	14, 16, 18, 33	Dog: 0.2-0.4 mg/kg PO, SC once; do not use in ivermectin-sensitive breeds Cat: 0.2 mg/kg SC, PO
	Intracranial myiasis	23	400 µg/kg SC; repeat in 24-48 hr; do not use in ivermectin-sensitive dog breeds
	Renal parasite: *Capillaria plica*	48, 50	Dog: 0.2 mg/kg PO once; do not use in ivermectin-sensitive breeds
	Cheyletiellosis, notoedric and sarcoptic mange, demodectic blepharitis	85, 95	0.2-0.3 mg/kg PO, SC q 2 wk × 3 Rx; do not use in ivermectin-sensitive dog breeds
Ivermectin (*Ivomec* 1%)	Otodectic mange	85	0.2-0.4 mg/kg PO, SC q 2 wk × 3 Rx Not approved in United States for this use; do not use in ivermectin-sensitive dog breeds
	Canine demodicosis	86	Dog: 0.1 mg/kg PO SID × 7 days; then increase to 0.2-0.6 mg/kg PO SID × 3-9 wk; do not use in ivermectin-sensitive breeds
Ivermectin 0.01% otic soln *(Acarexx)*	Otodectic mange, ear mites	85	Apply 0.5 mL in each ear once; repeat in 2 wk
Ketamine *(Ketaject, Ketaset)*	Anesthesia	1	Dog: a) 3-5 mg/kg IV, IM, in combination with other drugs b) 0.01-0.02 mg/kg/min IV as CRI Cat: a) 3-5 mg/kg IV, IM, in combination with other drugs b) 0.01 mg/kg/min IV as CRI
	Restraint, sedation	3, 4, 71	Cat: 1-4 mg/kg IV, with acepromazine or diazepam and atropine
	Anesthesia induction	32	Dog: 6.6 mg/kg IV to effect, with diazepam
Ketoconazole *(Nizoral, Ketoconazole)*	Systemic mycotic infections	14, 27, 89, 111	Dog: a) 5-15 mg/kg PO BID b) 30 mg/kg PO SID Cat: a) 5-10 mg/kg PO BID b) 10-20 mg/kg PO
	CNS fungal infections	24	Initial dose: 15-20 mg/kg PO BID × 2-3 mos Maintenance dose: 10 mg/kg PO SID

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Ketoconazole *(Nizoral, Ketoconazole)—cont'd*	Pituitary-dependent hyperadrenocorticism, pre-adrenalectomy therapy	45	Dog: 7.5 mg/kg PO BID; increase over 3 wk to 15 mg/kg PO BID
	Fungal cystitis	50	Dog: 10-20 mg/kg PO SID or dd BID Cat: 10 mg/kg PO BID
	Malassezia spp. dermatitis and otitis, dermatophytosis	85, 86, 90, 107, 108	Dog: 5-10 mg/kg PO SID-BID Cat: 5-10 mg/kg PO SID-BID; use with caution
Ketoconazole shampoo *(Nizoral, KetoChlor)*	*Malassezia* spp. dermatitis, seborrhea oleosa	85	Use 1-2 times/wk until resolution
Ketoprofen *(Anafen, Ketoprofen)*	Pain, inflammation	1, 24, 127	Dog: 2 mg/kg PO, SC, IM, IV once, then 1 mg/kg PO SID × 4-5 days Cat: 1 mg/kg SC, IM, IV
Ketorolac 0.5% *(Acular)*	Allergic conjunctivitis	96	Apply soln to the affected eye BID-QID
Ketotifen fumarate 0.025% *(Zaditor)*	Conjunctivitis	96	Apply soln to the affected eye BID-TID
Lactulose *(Kristalose, Lactulose)*	Megacolon, laxative therapy	34	2-10 mL PO TID; titrate to produce soft stools
	Congenital portosystemic shunts, hepatic encephalopathy, canine chronic hepatitis/cirrhosis	37	Emergency Rx: 100 mL in 200 mL water, given as an enema at 5-15 mL/kg QID Long-term Rx: 0.5-1 mL/kg PO TID; titrate to produce soft stools
Lansoprazole *(Prevacid)*	Severe gastric ulceration	73	Dog: 1-2 mg/kg PO SID; max = 20 mg/day
Latanoprost 0.005% *(Xalatan)*	Glaucoma	100	Emergency Rx (dog): Apply 1 drop to affected eye; repeat in 5-10 min Maintenance Rx (dog): Apply 1 drop to affected eye SID-BID
Leflunomide *(Arava)*	Cutaneous histiocytosis	77	Dog: 2-4 mg/kg PO SID
Levamisole *(Levasol, Tramisol)*	*Capillaria aerophila*	14, 18	Dog: a) 8-10 mg/kg PO SID × 5 days; repeat in 9 days b) 8-10 mg/kg PO SID × 10-20 days
	Parasitic cystitis, epidermolysis bullosa	50, 91	2.5 mg/kg PO SID-QOD × 5 days
Levetiracetam *(Keppra)*	Seizures	22	Dog: a) 5-30 mg/kg PO BID-TID, as an add-on therapy b) 25-60 mg/kg PO BID-TID
Levocabastine 0.05% *(Livostin)*	Conjunctivitis	96	Apply soln to affected eye QID
Lidocaine *(Lidocaine, Xylocaine)*	Local, regional blockade anesthesia	1	Dog: 2-5 mg/kg SC, perilesional or perineural infiltration Cat: 2-3 mg/kg SC, perilesional or perineural infiltration
	Analgesia	1	Dog: 0.05 mg/kg/min IV as CRI Cat: 0.005 mg/kg/min IV as CRI
	Topical anesthesia, nasal cannulation	3	2% soln: 0.1-1 mL instilled into nares/nostril
	Cardiopulmonary arrest, premature ventricular arrhythmias	6, 7, 32, 126, 130, 135	Dog: a) 1-2 mg/kg IV bolus; repeat up to 3 ×; then 25-100 µg/kg/min IV as CRI or PRN b) 4 mg/kg IT Cat: 0.2-1 mg/kg IV bolus; use with extreme caution in cats

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Lime sulfur suspension *(LymDyp)*	Sarcoptic and notoedric mange, dermatophytosis, cheyletiellosis, pruritus, itching	85, 86	2%-3% dip (4 oz lime dip/gal water): apply to skin 1-2 times/wk × 6-8 wk until resolution
Lincomycin *(Lincocin)*	Canine bacterial pyoderma	88	Dog: a) 22 mg/kg PO BID b) 15.4 mg/kg PO TID
	Bacterial blepharitis	95	20 mg/kg PO BID
Lisinopril *(Prinivil)*	Chronic congestive heart failure	9, 10	Dog: 0.5 mg/kg PO SID
Lithium carbonate *(Eskalith, Lithobid)*	Marrow hypoplasia with pancytopenia or neutropenia, cyclic hematopoiesis	65, 75	Dog: 11 mg/kg PO BID
Lomustine (CCNU; CeeNU)	Mast cell tumor, CNS tumors, lymphoma rescue protocol	72, 89	Dog: Medium to large dogs: 70-80 mg/m^2 PO q 4-6 wk Small dogs: 50-60 mg/m^2 PO q 4-6 wk Cat: 50-60 mg/m^2 PO q 4-6 wk
	Cutaneous T cell lymphoma	91	10 mg/kg PO q 3 wk
Loperamide *(Imodium)*	Noninfectious diarrhea, acute colitis	33, 34	Dog: 0.08-0.2 mg/kg PO BID-QID Cat: 0.04 mg/kg PO SID-BID; use with caution
Lorazepam *(Lorazepam)*	Certain behavioral disorders	117	Dog: 0.02-0.5 mg/kg PO TID Cat: 0.03-0.08 mg/kg PO BID
Lufenuron *(Program, Sentinel)*	Inhibit flea growth	85	Dog: 10 mg/kg PO monthly Cat: 30 mg/kg PO monthly
	Coccidioidomycosis	89	Dog: 5 mg/kg PO SID
L-Lysine *(Viralyis, Enisyl)*	Ocular herpesvirus infection	96, 98, 114	Cat: 250-500 mg PO SID-BID
Lysine-8 vasopressin *(Diapid)*	Central diabetes insipidus	41	1-2 sprays in a nostril SID-TID to effect
Magnesium hydroxide *(Milk of Magnesia, Maalox)*	Iron toxicosis	123, 127	30-90 mg/kg PO; repeat in 6 hr
Magnesium sulfate	Ventricular arrhythmias	7, 32	Dog: a) 50 mg/kg IV bolus over 5 min, followed by 100 μg/kg/min IV as CRI for 6 hr b) 20 mg/kg in 5% D/W over 5 min IV
	Serum magnesium deficit	44	1 mEq/kg/day IV
Mannitol 20% *(Am-Vet Mannitol, Mannject)*	Cerebral edema, acute renal failure, diuresis	1, 23, 37, 48, 128, 135	0.25-1.5 g/kg IV slowly over 10-20 min q 4-6 hr or BID-TID
	Acute glaucoma	100	1-2 g/kg IV over 20-40 min; repeat in 2-4 hr if needed
Marbofloxacin *(Zeniquin)*	Hepatic abscess	37	Dog: 5 mg/kg PO BID
	Bacterial pyoderma	88	2.75-5.5 mg/kg PO SID
Mechlorethamine *(Mustargen)*	Lymphoma, lymphoid leukemia rescue chemotherapy	72	Dog: 3.0 mg/m^2 IV, in a protocol
Meclizine *(Bonine, Antivert)*	Vertigo	108	0.5 mg/kg PO BID
Medetomidine *(Domitor)*	Sedative	1	Dog: 0.001-0.01 mg/kg SC, IM, IV, alone or in combination with other drugs Cat: 0.005-0.03 mg/kg SC, IM, IV, alone or in combination with other drugs
Medium-chain triglycerides (MCT Oil; *Liprocil*)	Exocrine pancreatic insufficiency	36	1-2 mL/kg/day PO, with low-fat diet
Medroxyprogesterone acetate *(Amen, Depo-Provera, Provera)*	Pituitary dwarfism	41	Dog: 2.5-5 mg/kg PO q 3 wk; taper to q 6 wk
	Galactorrhea	60	Dog: 5-11 mg/kg SC, IM; max = 3 doses per yr

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Megestrol acetate *(Ovaban, Megace)*	Lymphoplasmacytic stomatitis, eosinophilic granuloma complex	27	Cat: 0.25 mg/kg PO SID-QOD × 3 doses, then 1-2 times/wk PRN Use with caution
	Galactorrhea, pseudocyesis	60	Dog: 2-2.5 mg/kg PO SID × 5-8 days
	Feline eosinophilic keratitis, conjunctivitis	96, 98	Cat: 0.5 mg/kg PO SID × 7-14 days Use with caution
Meglumine antimonate *(Glucantime)*	Leishmaniasis	89, 90, 116	a) 20-50 mg/kg SC BID b) 200-300 mg/kg IV QOD c) 75 mg/kg SC BID, with allopurinol
Melarsomine HCl *(Immiticide)*	Heartworm disease	12	Dog with class 1 and 2 disease: 2 injections of 2.5 mg/kg IM, 24 hr apart Dog with class 3 disease: 1 injection of 2.5 mg/kg IM; wait 30 days, then give 2 injections of 2.5 mg/kg IM, 24 hr apart (split-dosing regimen) Cat: 2.5 mg/kg IM
Melatonin *(Melatonin)*	Growth hormone deficiency-related alopecia	41	Dog: 3-6 mg PO BID
	Color dilute alopecia, pattern baldness, cyclical flank alopecia, alopecia X	87	Dog: <10 kg: 3 mg PO SID-BID >10 kg: 6 mg PO SID-BID
Meloxicam *(Metacam)*	Pain, inflammation	1, 80-82, 99, 127	Dog: a) 0.2 mg/kg SC, PO, IM, IV once, then 0.1 mg/kg PO SID b) 0.1 mg/kg PO SID × 3-4 days Cat: 0.2-0.3 mg/kg SC, IM, IV once, then 0.1 mg/kg PO q 2-3 days
Melphalan *(Alkeran)*	Essential (primary) thrombocythemia	66	Cat: 0.5 mg PO SID × 4 days, then QOD
	Multiple myeloma	72, 77	0.1 mg/kg PO SID × 10 days, then 0.05 mg/kg PO SID
2-Mercaptopropionyl glycine or Tiopronin *(Thiola)*	Cystine urolithiasis	50	Dog: 15-20 mg/kg PO BID
Methazolamide *(Neptazane)*	Glaucoma	100	Dog: 2-4 mg/kg PO BID-TID Cat: 1-2 mg/kg PO BID
Methimazole *(Tapazole)*	Feline hyperthyroidism	42	Cat: a) 2.5-5 mg PO BID b) 1.25-2.5 mg PO BID if renal insufficiency present c) Transdermal gel form: 2.5-5 mg on ear pinna BID
Methocarbamol *(Robaxin)*	Urine retention disorders, decrease urethral sphincter tone	51	Dog: 15-20 mg/kg PO TID Cat: 33 mg/kg PO TID initially, then 20 mg/kg PO TID
	Muscle relaxation from certain toxicoses	124-126, 128	Dog: 50-220 mg/kg IV slowly to effect; repeat PRN; max = 330 mg/kg/day
Methoprene *(Frontline Plus)*	Inhibit flea growth	85	Apply to the skin once monthly, as directed
Methotrexate *(Trexall, Rheumatrex)*	Chemotherapy for lymphoma, in a protocol	69, 72	Dog: 0.6-0.8 mg/kg IV q 3 wk Cat: 0.5-0.8 mg/kg IV q 4 wk
	SLE, refractory erosive/nonerosive arthritis	80	Dog: 2.5 mg/m^2 PO SID, with prednisone

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Methylene blue *(Methylene blue)*	Severe methemoglobinemia	64	Cat: 0.2 mg/kg IV once slowly
Methylphenidate *(Ritalin)*	Narcolepsy	22	Dog: 0.25 mg/kg PO BID-TID
	CNS stimulant	117	Dog: 2-4 mg/kg PO BID-TID
Methylprednisolone *(Medrol)*	Inflammatory bowel disease	33	Cat: 1 mg/kg PO BID
	Severe canine acne	88	Dog: 0.5 mg/kg PO SID × 7 days, then taper
Methylprednisolone acetate *(Depo-Medrol)*	Feline allergic bronchitis	17	Cat: 10-20 mg IM q 2-8 wk
	Lymphoplasmacytic stomatitis	27	Cat: 2-4 mg/kg IM q 2-6 wk
	Hypoadrenocorticism	45	Cat: 10 mg IM q 3-4 wk
	Tenosynovitis of biceps brachii tendon, mosquito bite hypersensitivity, reactive fibrohistiocytic nodule	82, 88, 89	Dog: 10-40 mg sublesional injection Cat: 20 mg IM q 2-4 wk PRN
	Feline eosinophilic granuloma complex, idiopathic facial dermatitis	91, 93	Cat: 4 mg/kg or 20 mg IM, SC q 2-3 wk, then taper to q 2-3 mo PRN
	Pannus, anterior uveitis	98, 99	Apply 4-8 mg subconjunctivally
Methylprednisolone sodium succinate *(Solu-Medrol)*	Intervertebral disc disease, fibrocartilaginous embolic myelopathy, spinal cord trauma	24	30 mg/kg IV, then 15 mg/kg IV at 2 and 6 hr, then continued QID for max of 48 hr
4-Methyl-pyrazole *See* Fomepizole			
Methyltestosterone *(Estratest)*	Galactorrhea	60	Dog: 1-2 mg/kg PO × 5-7 days; max = 25 mg/kg
Methyltestosterone plus estradiol *(Sesoral)**	Galactorrhea	60	Dog: 0.7 mg/kg PO SID × 5-10 days
Metoclopramide *(Reglan)*	Esophagitis, gastric acid reflux, GI ulceration, delayed gastric emptying	15, 30, 31, 33, 36, 37, 39, 48, 112, 126-128, 131, 135	Dog: a) 0.1-0.4 mg/kg PO, IV, SC, IM TID-QID b) 1-2 mg/kg/day IV as CRI c) 0.01-0.02 mg/kg/hr IV as CRI Cat: a) 0.1-0.2 mg/kg PO, IV, SC, IM TID b) 0.01-0.02 mg/kg/hr IV as CRI
	Increase milk production	60	Dog: 0.2-0.5 mg/kg IM, SC, PO BID-TID
Metoprolol *(Metoprolol)*	Cardiac arrhythmias from Guarana toxicosis	130	0.02-0.06 mg/kg IV slowly
Metronidazole *(Flagyl)*	Bacterial meningoencephalitis, anaerobic bacterial CNS infections	23, 24	Dog: 10-15 mg/kg PO, IV TID Cat: 8-15 mg/kg PO, IV BID
	Stomatitis, gingivitis, glossitis	27, 126	5-15 mg/kg PO BID-TID, then taper to SID
	GI tract bacterial overgrowth, clostridial enterocolitis	33, 36	5-15 mg/kg PO BID
	Giardia lamblia, *Entamoeba histolytica*, *Balantidium coli* infections, trichomoniasis, *Helicobacter* spp.	33, 116	Dog: a) 15-25 mg/kg PO BID × 5-7 days b) 25-50 mg/kg PO SID × 5 days Cat: 10 mg/kg PO BID
	Acute and chronic colitis, pancreatic insufficiency, acute abdominal syndrome, septic peritonitis, perianal fistula, various chronic liver diseases	34-39, 113	10-15 mg/kg PO, IV BID
	Hepatic abscess	37	20-30 mg/kg IV, PO SID
	Osteomyelitis	81	15 mg/kg IV, PO BID

*Not available in the United States.

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Mexiletine *(Mexitil)*	Ventricular tachycardia	6	Dog: 4-8 mg/kg PO TID, with other drugs
Mibolerone *(Cheque Drops)*	Galactorrhea	60	Dog: 16 µg/kg PO SID × 5 days
Miconazole 1% shampoo/ conditioner *(Miconazole, Resizole)*	*Malassezia* spp. dermatitis	85	Apply topically 1-2 times/wk
Midazolam *(Versed)*	Preanesthetic, sedation, analgesia	1, 32	Dog: 0.1-0.5 mg/kg SC, IM, IV, alone or with other drugs
	Status epilepticus, cluster seizures	22	Dog: a) 0.07-0.22 mg/kg IV, IM, intranasally, rectally b) 0.5-2 mg/kg/hr IV as CRI × 4-6 hr; increase in 0.5 mg/kg/hr increments
Milbemycin oxime *(Interceptor)*	Elimination of heartworm microfilariae, chemoprophylaxis of roundworm, hookworm, whipworm, heartworm infections	12, 34	500 µg/kg PO monthly
	Pneumonyssoides caninum infection	14	0.5-1 mg/kg PO once weekly × 3 wk
	Sarcoptic mange	85, 95	2 mg/kg PO q 7-14 days × 3 Rx
	Canine demodicosis	86	Dog: 1-2 mg/kg PO SID × 60 days; may double dosage if needed
Milk thistle *(Silymarin)*	Antioxidant, liver protectant, hepatic necrosis/failure, amanita mushroom poisoning	37, 124	20-50 mg/kg PO SID
Minocycline *(Dynacin)*	Actinomycosis, nocardiosis	89	Dog: 5-25 mg/kg PO, IV BID
	Brucellosis, ehrlichiosis	113, 115	Dog: 12.5 mg/kg PO BID
	Q Fever	115	5 mg/kg PO SID
Misoprostol *(Arthrotec)*	Hemorrhagic gastroenteritis, GI protectant	31, 39, 124, 127	Dog: 1-5 µg/kg PO BID-QID Do not use in pregnant animals; should not be handled by pregnant women
Mitotane *(Lysodren)*	Pituitary-dependent hyperadrenocorticism	45	Dog: a) Normal induction protocol: 25-50 mg/kg/day PO × 5-10 days b) Slow induction protocol: 25 mg/kg PO weekly × 1 mo c) Maintenance dose: 50 mg/kg/wk PO dd into 2 doses, 3-4 days apart
	Functional adrenocortical tumors	72	Dog: a) Induction protocol: 25 mg/kg PO BID b) Maintenance protocol: 50 mg/kg PO per wk, dd into 2-3 doses
Mitoxantrone *(Novantrone)*	Chemotherapy, in a protocol	72	Dog: 5.5-6 mg/m^2 IV q 3 wk Cat: 5-6.5 mg/m^2 IV q 3 wk
Montelukast sodium *(Singular)*	Pulmonary effects of chronic heartworm disease	12	Cat: 5 mg PO SID
Morphine *(Infumorph, Astramorph)*	Analgesia	1, 39, 81, 107, 134, 136	Dog: a) 0.1-1.0 mg/kg SC, IM, IV q 3-6 hr b) 0.002 mg/kg/min IV as CRI c) 1.5 mg/kg/24 hr as CRI in 0.9 % saline

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Morphine *(Infumorph, Astramorph)—cont'd*			Cat: a) 0.05-0.5 mg/kg SC, IM b) 0.002 mg/kg/min IV as CRI
	Local, regional blockade anesthesia (epidural)	1, 81	Dog: 0.1-0.05 mg/kg, with bupivacaine Cat: a) 0.07 mg/kg (pelvic limb fracture) b) 0.1 mg/kg, with 0.9% saline (thoracic limb fracture)
Morphine, oral sustained-release *(MS-Contin)*	Narcotic analgesic	72	Dog: 1.5-3 mg/kg PO BID
Moxidectin *(ProHeart-6);* currently unavailable	Heartworm chemoprophylaxis	12	Dog: 0.17 mg/kg SC q 6 mo
Mupirocin *(Bactroban)*	Staphylococcal pyoderma and folliculitis, impetigo, intertrigo, canine acne, mucocutaneous pyoderma	88, 91	Dog: Apply topically SID-BID × 1-4 wk or until lesions resolve
Mycophenolate mofetil *(Cellcept)*	Acquired myasthenia gravis	25	Dog: 20 mg/kg PO BID
Naloxone *(Narcan)*	Cardiopulmonary arrest	7	0.04 mg/kg IT
	Reverse CNS effects of apomorphine	123	Dog: 0.04 mg/kg IV, IM, SC Cat: 0.05-0.1 mg/kg IV
	Antidote for opioid drug toxicosis	129	0.1-0.2 mg/kg IV; repeat PRN
Nandrolone decanoate *(Deca-Durabolin)*	Bone marrow stimulant, chronic idiopathic myelofibrosis	66	Dog: 2 mg/kg IM weekly × 3 wk, then q 3 wk; max = 200 mg/wk Cat: 15 mg IM once weekly
	Appetite stimulant	122	Dog: 5 mg/kg IM weekly; max = 200 mg/wk
Naphazoline 0.027%/ pheniramine 0.315% *(Opcon-A)*	Allergic conjunctivitis	96	Apply soln to affected eye BID-QID
Neomycin *(Neomycin, Neo-fradin)*	Congenital portosystemic shunts, hepatic encephalopathy	37	20 mg/kg PO BID-TID × 10-14 days
Neomycin-polymyxin B-dexamethasone (ophthalmic)	Blepharitis, conjunctivitis	95, 96, 103	Apply to affected eye TID-QID
Neostigmine *(Prostigmin)*	Acquired myasthenia gravis	25	Dog: 0.04 mg/kg IM QID
Niacin	Hyperlipidemia	46	Dog: 100 mg/day PO
Niacinamide *(Nicotinamide)*	Immune-mediated diseases, episcleritis	90, 98	Dog: <10 kg: 250 mg PO TID, with tetracycline >10 kg: 500 mg PO TID, with tetracycline
	Sebaceous adenitis	93	Dog <10 kg: a) 250 mg PO TID, with tetracycline b) 250 mg PO in morning, then 500 mg PO in evening, with tetracycline Dog >10 kg: a) 500 mg PO TID, with tetracycline b) 500 mg PO in morning, then 1000 mg PO in evening, with tetracycline
Nitenpyran *(Capstar)*	Flea adulticide		Dog or cat 1-11.4 kg: 11.4 mg Dog 11.5-57 kg: 57.0 mg

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Nitrofurantoin *(Macrodantin, Furadantin)*	Resistant bacterial cystitis, UTI prevention	50	4.4 mg/kg PO TID
Nitrofurazone *(Furacin)*	Enteric coccidiosis	116	8-20 mg/kg PO SID-BID × 5 days; decrease dose by 50% when used with sulfonamides
Nitroglycerin 2% ointment *(Nitro-Bid)*	Vasodilator for acute congestive heart failure	9, 10	Dog: a) 1/8-1/2 inch topically QID on ear pinna or inguinal area b) 4-12 mg topically on ear pinna BID-TID Cat: 1/8-1/4 inch topically q 4-6 hr
Nitroprusside *(Sodium Nitroprusside, Nitropress)*	Arterial vasodilator for acute heart failure	8-10	Dog: 0.5-5 µg/kg/min IV as CRI, titrate to effect; max = 10 µg/kg/min IV
Nizatidine (Axid)	Megacolon	34, 73	Cat: a) 2-5 mg/kg PO SID b) 1-3 mg/kg SC, IM, IV TID
	Gastric ulcers	31	Dog: 5 mg/kg PO SID
Norepinephrine bitartrate *(Levophed)*	Vasopressor for hypotension	7, 136	Dog: 0.01-0.5 µg/kg/min IV as CRI
Olopatadine 0.1% *(Patanol)*	Allergic conjunctivitis	96	Apply soln to affected eye BID-TID
Olsalazine *(Dipentum)*	Chronic idiopathic colitis	34	Dog: 5-10 mg/kg PO BID × 3-4 wk, then taper to lowest effective dose Use with caution in cats
Omega-6, Omega-3 fatty acid supplements (*Heska F.A.* granules, *Derma-Form*)	Atopic dermatitis	85	1 capsule per 10 kg PO SID
	Immune-mediated diseases, symmetrical lupoid onychodystrophy	90	Give at twice the manufacturer's dosage instructions × 3-4 mo
Omeprazole *(Prilosec)*	Severe reflux esophagitis, GI ulceration	30, 31, 33, 39, 48, 73, 127, 135	Dog: 0.5-2 mg/kg PO, SC SID-BID; max = 20 mg/day Cat: 0.7 mg/kg PO SID
Ondansetron *(Zofran)*	Antiemetic	31, 33, 36, 37, 39, 48, 127	Dog: a) 0.5-1 mg/kg PO, IV slowly SID-BID or 30 min before chemotherapy b) 0.1-1 mg/kg PO, IM, SC BID-TID c) 0.1-0.3 mg/kg PO, IV slowly TID-QID
Orbifloxacin *(Orbax)*	Bacterial pyoderma	88	2.5-7.5 mg/kg PO SID
Ormetoprim-sulfadimethoxine *(Primor)*	Protozoal CNS diseases	24	Dog: 15 mg/kg PO BID
	Canine bacterial pyoderma	88	Dog: 55 mg/kg PO on day 1, then 22 mg/kg PO SID
	Enteric coccidiosis	116	Dog: 66 mg/kg PO SID
Oseltamivir phosphate *(Tamiflu)*	Parvoviral enteritis	112	Dog: 2 mg/kg PO BID × 5 days
Oxacillin (oxacillin sodium)	Perioperative antibiotic	81	22 mg/kg IV q 2 hr
	Canine bacterial pyoderma	88	Dog: 22 mg/kg PO TID
Oxazepam *(Serax)*	Appetite stimulant	48, 111, 122	Dog: 0.2-1 mg/kg PO SID-BID Cat: 2-3 mg PO SID-BID
	Certain behavioral disorders	117	Dog: 0.04-0.5 mg/kg PO QID Cat: 0.2-1 mg/kg PO BID
Oxibendazole *(Anthelcide EQ)*	*Trichuris vulpis* infection	34	Dog: 6 mg/kg PO SID

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Oxybutynin chloride *(Ditropan)*	Urinary incontinence, decrease detrusor muscle contraction	51	Dog: 1.25-5 mg PO BID-TID Cat: 0.5 mg PO BID
Oxyglobin, purified bovine hemoglobin *(Oxyglobin)*	Red blood cell substitute	71	Dog: 10-30 mL/kg IV at max rate of 10 mL/kg/hr IV
Oxymorphone *(Numorphan)*	Analgesia, sedation	1, 15, 36, 81	Dog: 0.025-0.2 mg/kg SC, IM, IV q 4-6 hr Cat: 0.025-0.05 mg/kg SC, IM q 4-6 hr
	Anesthesia induction	61	Dog: 0.1-1 mg/kg IV to effect
Oxytetracycline *(Medamycin, Biomycin)*	Ehrlichiosis, hemoplasmosis	115	Dog: 20-25 mg/kg PO, IV TID × 21-28 days Cat: 22 mg/kg PO TID × 21 days
	Salmon poisoning disease	115	Dog: 7 mg/kg PO, IV TID × 3-5 days
Oxytetracycline-polymyxin o.o. *(Terramycin)*	Neonatal ophthalmia, conjunctivitis *Cytauxzoon felis*, *Mycoplasma* spp.–associated conjunctivitis	95, 96 114	Apply to affected eye TID-QID Cat: Apply to affected eye TID
Oxytocin *(Pitocin, Syntocinon)*	Uterine prolapse	57	Dog: 5-10 U SC once
	Stimulate milk letdown	60	Dog: 2-20 IU SC, IM Cat: 1-10 IU SC, IM
	Dystocia from uterine inertia; not to be used unless cervix is open	61, 62	Dog: 2-5 IU SC, IM; may repeat in 20-30 min, up to 3 doses Cat: 1-3 IU SC, IM; may repeat in 20-30 min
	Metritis, evacuate uterine contents	61	Dog: 1 IU/kg IM
Pamidronate *(Aredia)*	Hypercalcemia, cholecalciferol toxicosis, calcipotriene toxicosis	43, 124, 127	Dog: 1-2 mg/kg in 0.9% NaCl IV over 2-4 hr; repeat in 5-7 days
Pancreatic enzymes, powdered *(Viokase-V, Pancrezyme)*	Exocrine pancreatic insufficiency	36	Dog: 2 tsp/20 kg initially with each meal BID, then taper slowly Cat: 0.5 tsp/5 kg initially with food, then taper slowly
Pantoprazole *(Protonix)*	GI tract ulceration	15, 39, 135	Dog: 0.7-1 mg/kg IV, PO SID-BID
Paromomycin *(Humatin)*	Cryptosporidiosis	33, 116	125-165 mg/kg PO SID-BID × 5 days Use with extreme caution
Paroxetine *(Paxil)*	Certain behavioral disorders	117	Dog: 1-1.5 mg/kg PO SID Cat: 0.5-1.5 mg/kg PO SID
D-Penicillamine *(Cuprimine)*	Copper hepatopathy, canine chronic hepatitis/cirrhosis	37	Dog: 10-15 mg/kg PO BID
	Lead poisoning	126	Dog: 30-50 mg/kg/day PO dd QID × 7 days; wait 7 days, then repeat Cat: 125 mg PO BID × 5 days
Penicillin G (Penicillin G potassium = IV; Crysticillin procaine = SC, IM)	Infectious meningomyelitis, bacterial infections	24	10-30 mg/kg IV, IM BID-QID
	Leptospirosis	48, 113	Dog: 25,000-40,000 U/kg IM, SC, IV BID × 2 wk
	Actinomycosis	89, 113	a) 60,000 U/kg SC, IM, IV TID b) 40 mg/kg PO TID
	Tetanus	113	a) 20,000 U/kg IV QID × 10 days b) 20,000-100,000 U/kg IV, SC, IM BID-TID × 10 days
Penicillin V *(Veetids)*	Actinomycosis	89, 113	a) 60,000 U/kg PO TID b) 40 mg/kg PO TID
Pentamidine (Phenamidine) isethionate*	*Babesia canis* infection	116	Dog: 15-20 mg/kg SC SID × 2 days

*Not available in the United States.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Pentobarbital (sodium pentobarbital)	Status epilepticus, cluster seizures	22	2-15 mg/kg IV over several min, then 0.5 mg/kg/hr IV as CRI × 4-6 hr
Pentosan polysulfate sodium *(Elmiron, Cartrophen-Vet)*	Chronic feline idiopathic cystitis	50	Cat: 50 mg PO BID on food
Pentoxifylline *(Trental)*	Dermatomyositis	82	Dog: 25 mg/kg PO BID
	Contact dermatitis	85	Dog: 15-20 mg/kg PO TID
	Vasculitis, ischemic dermatopathy, vesicular cutaneous lupus erythematosus, pinnal seborrhea	86, 90, 91, 93	Dog: 10-20 mg/kg PO BID-TID
Permethrin 2% *(Long-Acting Knock Out)*	Flea adulticide, repellant	85	Dog: Apply 1-2 times/wk to dry hair coat
Phenobarbital (*Luminol Sodium, Phenobarbital* injection; *Solfoton* tablets)	Seizures, tremors	22, 23, 112, 126-128, 130	1-6 mg/kg PO, IV, IM BID-TID Dog: 3-30 mg/kg IV slowly to effect Cat: 2.5 mg/kg PO SID
	Status epilepticus, cluster seizures	22	Loading dose: 12-15 mg/kg IV dd into 2-4 mg/kg doses q 1-2 hr × 24 hr Emergency Rx: 2 mg/kg PO, IV, IM BID, with diazepam or midazolam
	Necrotizing sialometaplasia, sialadenosis	29	Dog: 2 mg/kg PO BID
Phenoxybenzamine *(Dibenzyline)*	Hypertension from pheochromocytoma	45	Dog: 0.2-1.5 mg/kg PO BID
	Urine retention disorders, urethral spasms, to decrease urethral sphincter tone	51, 52	Dog: a) 0.5 mg/kg PO BID b) 2.5-30 mg PO TID c) 2.5-7.5 mg PO SID-BID, with prazosin Cat: 1.25-5 mg PO SID-BID
Phenylephrine injectable *(Neo-Synephrine)*	Vasopressor	7	Dog: 1-10 µg/kg/min IV
Phenylephrine topical 1.25% *(Neo-Synephrine)* or ophthalmic 2.5%-10% *(Ak-Dilate)*	Rhinitis/sinusitis	14	Apply as nose drops BID-TID
	Anterior uveitis, hyphema	99	Apply to affected eye 2-6 times/day, with atropine
Phenylpropanolamine *(Proin)*	Urinary incontinence, increase urethral sphincter tone	49, 51, 116	Dog: a) 12.5-50 mg PO TID b) 1 mg/kg PO TID Cat: 12.5 mg PO TID
Physostigmine 0.25% o.o. *(Eserine)*	Dysautonomia	105	Apply to affected eye BID-TID
Phytomenadione, Phytonadione *See* Vitamin K_1			
Pilocarpine ophthalmic *(Piloptic)*	Neurogenic KCS	97	1%-2% soln: 1-4 drops on food PO BID-TID
	Glaucoma	100	2% soln: Apply 1 drop to affected eye TID-QID
	Dysautonomia	105	0.1%-1% soln: Apply 1 drop to both eyes BID-TID
Pimobendan	Dilated cardiomyopathy, congestive heart failure	9, 10	Dog: 0.25-0.5 mg/kg PO BID Cat: 0.3 mg/kg PO BID
Piroxicam *(Feldene)*	Transitional cell carcinoma, pain, inflammation	50, 52, 53, 72, 97, 127	Dog: 0.3 mg/kg PO SID-QOD
Plasma, fresh frozen	Protein-losing enteropathy, hypoproteinemia	33, 134, 135	Dog: 10-20 mL/kg IV
	Platelet disorders, von Willebrand disease, clotting factor deficiencies, thrombosis	37, 67, 68	6-15 mL/kg IV over 0.5-2 hr or BID; repeat q 8-12 hr PRN

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Polymyxin-neomycin cream *(Neosporin)*	Mucocutaneous pyoderma	91	Dog: Apply topically BID × 2-4 wk
Polysulfated glycosaminoglycan *(Adequan)*	Chronic feline idiopathic cystitis	50	Cat: 1.1-4.8 mg/kg IM q 4 days × 6 doses
	DJD		Dog: 5 mg/kg IM once weekly × 6-8 wk
Potassium bromide (compounding pharmacies)	Seizures	22, 23	Dog: Loading dose: total = 400-600 mg/kg PO or rectally, dd into 6 doses given over 1-5 days Maintenance dose: 20-40 mg/kg PO SID, slowly increased to effect; max = 60 mg/kg PO SID Use with caution in cats
Potassium chloride injectable (KCl)	Severe electrolyte loss, hypokalemia	33, 37, 44, 46	Dog: 10-40 mEq/L of crystalloid soln; not to exceed 0.5 mEq/kg/hr IV
	Feline hypokalemic polymyopathy	82	Cat: 0.4 mEq/kg/hr IV in lactated Ringer's soln; reduce dose when serum potassium is >3.5 mEq/L
Potassium citrate *(Nutrived, Citrolith)*	Hypokalemia, metabolic acidosis	48	Cat: 40-75 mg/kg PO BID
	Urine alkalization	50	Dog: 50-75 mg/kg PO BID
Potassium gluconate *(Tumil-K)*	Hypokalemia	48	Cat: 0.45 mEq/kg/day PO
	Feline hypokalemic polymyopathy	82	Cat: 5-8 mEq PO dd BID if serum potassium is <3 mEq/L Maintenance dose: 2-6 mEq PO SID-BID
Potassium iodide (*Thyroblock;* SSKI soln)	Stabilization before feline hyperthyroidism surgery	42	Cat: 30-100 mg PO SID or dd BID, with β-adrenergic blocking agent 10-14 days before surgery
	Sporotrichosis	89	Dog: 40 mg/kg PO TID Cat: 20 mg/kg PO BID
Potassium phosphate (Potassium phosphate injection)	Hypophosphatemia	44, 64	0.01-0.03 mmol/kg/hr IV; max = 0.06 mmol/kg/hr
Povidone iodine (Betadine soln)	Congenital portosystemic shunts, hepatic encephalopathy	37	Emergency Rx: 1:10 dilution with water, give as enema at 20 mL/kg QID
Pralidoxime, 2-PAM chloride *(Protopam)*	Organophosphorus and carbamate toxicoses	125	10-15 mg/kg IM, SC BID
Praziquantel *(Droncit, Drontal Plus)*	Ascarids, whipworms, tapeworms (*Dipylidium* spp., *Taenia* spp.)	33, 116	Dog: 5-7.5 mg/kg PO once Cat: 5 mg/kg PO once
	Giardia lamblia	33	Dog: Use at labeled dose PO × 3-5 days Cat: Give 2 small dog tabs PO SID × 5 days
	Pancreatic, biliary duct flukes	36, 37	Cat: 20-40 mg/kg PO SID × 3 days
	Salmon poisoning disease	115	Dog: 10-30 mg/kg PO, SC once
Prazosin *(Minipress)*	Urine retention disorders, urethral spasm, to decrease urethral sphincter tone	51, 52	Dog: a) 1 mg/15 kg PO BID-TID b) 0.25 mg PO SID-BID, with phenoxybenzamine Cat: 0.25-0.5 mg PO SID-BID
Prednisolone, prednisone *(Deltasone)*	Pulmonary parenchymal inflammation from heartworm disease	12	1-2 mg/kg PO BID, then taper over 7-14 days
	Laryngitis, laryngeal edema, tracheitis, acute/allergic bronchitis, airway inflammation	15, 16	Dog: 0.5-2 mg/kg PO SID-BID, then taper Cat: 0.5-1 mg/kg PO BID, then taper

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Prednisolone, prednisone *(Deltasone)—cont'd*	Pulmonary eosinophilic diseases	18	1-2 mg/kg PO BID
	Hydrocephalus, hydranencephaly, porencephaly	23	0.25-0.5 mg/kg PO BID, then taper to QOD
	FIP, meningoencephalitis, for palliative relief	23	Cat: 2-4 mg/kg PO SID-BID
	Granulomatous meningoencephalomyelitis, necrotizing meningoencephalitis and leukoencephalitis, eosinophilic meningoencephalitis, canine meningeal polyarteritis	23, 24	Dog: 1-4 mg/kg PO BID × 1 mo, then slowly taper over 3-6 mo to 0.5 mg/kg PO SID-QOD
	Idiopathic tremor syndrome	23	Dog: 1-2 mg/kg PO SID × 4 wk, then taper to 0.5-1 mg/kg PO q 24-72 hr
	Caudal occipital malformation, syringohydromyelia, spinal intraarachnoid cysts, intervertebral disk disease, cervical spondylomyelopathy, spinal stenosis, distemper myelitis, demyelinating neuropathy	23-25	Dog: 0.5-1 mg/kg PO, IV SID-QOD, then taper
	Acquired myasthenia gravis	25	Dog: 0.5 mg/kg PO SID-BID initially, then 2-4 mg/kg PO SID-BID × 7-10 days
	Lymphoplasmacytic stomatitis	27	Cat: 2 mg/kg PO SID-BID, then taper
	Sialadenitis, necrotizing sialometaplasia	29	Dog: 0.5-2.2 mg/kg PO SID-BID
	Chronic idiopathic gastritis, atrophic gastritis, hypertrophic gastritis	31	Dog: 1-2 mg/kg PO SID, then slowly taper Cat: 2-4 mg/kg PO SID, then slowly taper Dog/cat: Chronic low dose: 0.5-1 mg/kg PO QOD
	Small cell GI lymphoma	31, 34	Cat: 5 mg PO BID, with chlorambucil
	Inflammatory bowel disease	33	Dog: 1-2 mg/kg PO BID, then taper Cat: 2-3 mg/kg PO BID, then taper
	Chronic lymphocytic-plasmacytic colitis, eosinophilic and granulomatous colitis, chronic histiocytic ulcerative colitis	34	Dog: 2-4 mg/kg PO SID or dd BID, then slowly taper
	Perianal fistula	35	Dog: 3-4 mg/kg PO SID, then slowly taper to 1 mg/kg SID-QOD
	Exocrine pancreatic insufficiency, canine chronic hepatitis/cirrhosis	36, 37	Dog: 1-2 mg/kg PO SID, then taper
	Feline chronic cholangiohepatitis	37	Cat: 2-4 mg/kg PO SID, then slowly taper
	Hypoadrenocorticism, hypopituitarism, postadrenalectomy	41, 45	Dog: a) 0.1-0.2 mg/kg, with DOCP b) 0.2-0.4 mg/kg PO SID-QOD, with fludrocortisone
	Hyperparathyroidism, hypercalcemia	43, 73, 124, 127	a) 1-3 mg/kg PO SID-BID b) 0.25 mg/kg PO, SC QID
	Insulinoma, hypoglycemia	46, 73	0.5-2 mg/kg/day PO
	Granulomatous urethritis	52	Dog: 1.1 mg/kg PO BID, then taper to 0.07 mg/kg PO BID
	Immune-mediated hemolytic anemia	64	1-2 mg/kg PO BID, then taper

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Prednisolone, prednisone *(Deltasone)—cont'd*	Chronic lymphocytic leukemia	65	Dog: 30 mg/m^2 PO SID × 7 days, then 20 mg/m^2 SID, then 10 mg/m^2 QOD, with chlorambucil Cat: 1 mg/kg PO SID, with chlorambucil
	Myelodysplastic syndrome, chronic idiopathic myelofibrosis	66	Dog: 2-3 mg/kg PO SID, then taper to QOD Cat: 1-4 mg/kg PO, IM SID, in a protocol
	Eosinophilic leukemia	66	Cat: 2 mg/kg PO BID, with hydroxyurea
	Immune-mediated thrombocytopenia	67	Dog: 1-3 mg/kg PO BID, then taper
	Lymphoma	69, 72	Dog: a) 2 mg/kg/day PO alone b) 40 mg/m^2 PO SID, in a protocol c) 20 mg/m^2 PO SID × 1 wk, then QOD × 7 wk, in a protocol d) 20 mg/m^2 PO BID for 6 wk, in a protocol e) 1-2 mg/kg PO SID × 1-3 wk, then 0.5 mg/kg QOD × 1 wk; in a protocol Cat: a) 2 mg/kg PO SID, in a protocol b) 50 mg/m^2 PO SID × 1 yr, in a protocol c) 1-2 mg/kg PO SID × 1-3 wk, then 1 mg/kg QOD; in a protocol
	Mast cell tumors	72, 73	1-2 mg/kg PO SID-BID × 30 days, then QOD, in a protocol
	Primary seborrhea, angioneurotic edema, urticaria	73, 76, 93	1-2 mg/kg PO SID-BID, then taper
	Cutaneous histiocytosis	77	Dog: 1-2 mg/kg PO BID until remission, then taper
	Multiple myeloma, in a protocol	77	0.5 mg/kg PO SID × 10 days, then 0.5 mg/kg PO QOD
	Nonerosive and erosive arthritis, SLE	76, 80	1-2 mg/kg PO BID, then taper slowly to 1 mg/kg PO QOD
	Hypertrophic osteopathy	81	Dog: 0.25-0.5 mg/kg PO SID
	Masticatory myositis, polymyositis, dermatomyositis, extraocular myositis	82, 103	Dog: 1-2 mg/kg PO SID-BID, then taper over 2-6 mo
	Flea allergic, atopic, and contact dermatitides; mosquito bite hypersensitivity	85, 88	Dog: 1 mg/kg PO SID × 5 days, then 0.5 mg/kg PO QOD Cat: 2-5 mg/kg PO SID × 5 days
	Severe canine acne, enhance zinc absorption	88, 93	Dog: 0.5 mg/kg PO SID
	Juvenile cellulitis, sterile eosinophilic pustulosis, sterile granuloma, pyogranuloma	88, 89	Dog: 1-2 mg/kg PO SID-BID
	Immune-mediated skin diseases, nodular panniculitis, uveodermatologic syndrome, blepharitis	89-92, 95, 99	Dog: 2-4 mg/kg PO SID-BID, then taper
	Feline plasma cell pododermatitis, eosinophilic granuloma complex	90, 91	Cat: 4.4 mg/kg PO SID-BID, then taper
	Idiopathic facial dermatitis	93	Cat: 1-3 mg/kg PO SID × 4 wk; then 1-3 mg/kg PO QOD

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Prednisolone, prednisone *(Deltasone)—cont'd*	Jack Russell terrier vasculopathy	93	Dog: 1 mg/kg PO SID, alone or with dapsone and vitamin E
	Ligneous conjunctivitis, episcleritis	96, 98	0.5-2 mg/kg PO SID-BID, then taper
	Feline eosinophilic keratitis	98	Cat: 5-10 mg PO SID or dd BID × 7-14 days
	Anterior uveitis, chorioretinitis, optic neuritis, retinal detachments	99, 102	Antiinflammatory dose: 0.25-0.5 mg/kg PO BID Immunosuppressive dose: 1-2 mg/kg PO SID-BID
	Otitis externa, media	107, 108	Dog: 0.25-2.2 mg/kg PO SID-BID, then taper over 1-3 wk
	FIP	112	Cat: 2-4 mg/kg PO BID
	Appetite stimulant	122	0.2-0.5 mg/kg PO SID-QOD
	Envenomation with severe swelling	136	0.5-1 mg/kg PO SID, tapered over 5-7 days
Prednisolone acetate 1% *(Econopred-Plus, Pred Forte)*	Conjunctivitis	96, 103	Apply soln to affected eye BID-QID
	Anterior uveitis, hyphema, pannus, episcleritis, eosinophilic keratitis	98, 99	Apply soln to affected eye 1-8 times/day, taper slowly
Prednisolone sodium succinate *(Solu-Delta-Cortef)*	Feline allergic bronchitis	17	Cat: 10-20 mg/kg IV
	Hypoadrenocorticism, glucocorticoid replacement	45	15-20 mg/kg IV
	Shock, anaphylaxis	45, 76, 136	5-25 mg/kg IV
	Envenomation with severe swelling	136	0.5-1 mg/kg IV once
Prednisolone-Trimeprazine *(Temaril-P)*	Allergic dermatitis	85	Capsules/Tablets = 2 mg prednisone and 5 mg trimeprazine Dog: a) <5 kg: 1 capsule PO SID × 4 days or ½ tab PO BID × 4 days, then reduce dose by 50% b) ≥5-10 kg: 2 capsules PO SID × 4 days or 1 tab PO BID × 4 days, then reduce dose by 50% c) ≥10-20 kg: 4 capsules PO SID × 4 days or 2 tabs PO BID × 4 days, then reduce dose by 50% d) ≥20 kg: 6 capsules PO SID × 4 days or 3 tabs PO BID × 4 days, then reduce dose by 50%
Primaquine phosphate *(Primaquine)*	*Babesia felis* infection	116	Cat: a) 0.5 mg/kg PO SID × 3 days b) 1 mg IM q 36 hr × 2-3 doses Caution: 1 mg/kg = lethal to cats
Proanthozone nutrient and antioxidant supplement	Antioxidant	64	Cat: 10 mg/day PO
Procainamide *(Procan)*	Acute ventricular arrhythmias and/or tachycardia	6, 32	Dog: a) 10-20 mg/kg PO TID-QID b) 6-15 mg/kg IV bolus over 2-5 min c) 25-50 µg/kg/min IV as CRI in 5% D/W d) 8-20 mg/kg IM QID Cat: a) 2-5 mg/kg PO BID-TID b) 1-2 mg/kg IV bolus slowly c) 10-20 µg/kg/min IV as CRI in 5% D/W

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Procarbazine *(Matulane)*	Chemotherapy, in a protocol	72	Dog: 50 mg/m^2 PO SID × 14 days q 4 wk
Prochlorperazine *(Compazine)*	Antiemetic	31, 33, 39, 112	Dog: 0.1-0.5 mg/kg IM, SC BID-QID Cat: 0.125 mg/kg IM BID
Progesterone in oil	Hypoluteoidism	61	Dog: 2 mg/kg IM q 3 days
Proligestone *(Delvosteron)**	Pituitary dwarfism	41	Dog: 10 mg/kg SC q 3 wk
	Galactorrhea	60	Dog: 20-30 mg/kg SC
Propantheline bromide *(Pro-Banthine)*	Sinus bradycardia	6	0.25-0.5 mg/kg PO BID
	Urinary incontinence, decrease detrusor muscle contraction	51	Dog: a) 0.2 mg/kg PO TID-QID b) 5-30 mg PO TID
Propofol *(PropoFlo, Rapinovet)*	Anesthesia induction	1	3-6 mg/kg IV to effect
	Status epilepticus, seizures, tremors	22, 127	a) 4-8 mg/kg IV to effect b) 0.1-0.6 mg/kg/min IV as CRI × 4-6 hr
Propranolol *(Inderal)*	Tetralogy of Fallot, pulmonic stenosis	8	Dog: 0.25 mg/kg PO TID initially, then increase over 4 wk to 1 mg/kg PO TID
	Refractory idiopathic tremor syndrome	23	Dog: 1 mg/kg PO TID
	Tachycardia, severe hypertension from pheochromocytoma	45	Dog: 0.15 mg/kg PO TID, with phenoxybenzamine
	Tachycardia, especially from certain toxicoses; serotonin antagonism	48, 126, 129, 130	Dog: a) 0.02-0.06 mg/kg IV slowly b) 5-80 mg PO BID-TID Cat: 2.5-10 mg PO BID-TID
	Urine retention disorders, enhance detrusor muscle contraction	51	Dog: 2.5-20 mg PO BID-TID Cat: 2.5-5 mg PO BID-TID
Prostaglandin $F_{2\alpha}$ *(Lutalyse)*	Open-cervix pyometra/metritis, evacuate uterine contents	57, 61, 62	Dog: 0.1-0.25 mg/kg SC SID × 5-7 days Cat: 0.1 mg/kg SC SID Limit use to healthy animals ≤6-8 yr of age
	Cystic endometrial hyperplasia	62	Cat: 0.1-0.25 mg/kg SC SID-TID
Protamine sulfate *(Protamine sulfate)*	Antagonize heparin overdose	18	1 mg IV slowly per 100 U of heparin to be inactivated; reduce dose by 50% q 30 min
Protriptyline *(Vivactil)*	Cataplexy	22	Dog: 5-10 mg/kg PO SID
Pseudoephedrine *(Sudafed)*	Rhinitis/sinusitis	14	Dog: 15-50 mg PO BID-TID; max = 4 mg/kg Cat: 2-4 mg/kg PO BID-TID
	Retrograde ejaculation	61	Dog: 4-5 mg/kg PO, 1 and 3 hr before breeding
Psyllium *(Metamucil)*	Chronic histiocytic ulcerative colitis, fiber-responsive colitis, irritable bowel syndrome	34	Dog: 0.5-3 tbsp/day PO
	Bulk cathartic	123	Dog: 3-10 g PO SID-BID mixed with food Cat: 3 g PO SID-BID mixed with food
Pyrantel pamoate *(Nemex, Strongid-T)*	Parasitic gastritis: *Physaloptera* spp.	31	5 mg/kg PO q 3 wk × 2 Rx
	Ascarids, hookworms	33	Dog: 5 mg/kg PO; repeat in 3 wk Cat: 10 mg/kg PO; repeat in 3 wk
Pyrethrin otic soln	Otodectic mange	85	Apply in each ear SID × 7 days; repeat in 7 days
Pyrethrin spray	Mosquito bite hypersensitivity, mosquito repellant	88	Cat: Apply spray topically SID to affected areas
Pyridostigmine bromide *(Mestinon)*	Acquired myasthenia gravis	25	Dog: 0.5-3 mg/kg PO BID-TID; begin with low dose, then increase PRN

*Not available in the United States.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Pyrimethamine *(Daraprim)*	*Toxoplasma gondii,* protozoal CNS diseases and myositis, *Hepatozoon americanum*	23, 24, 82, 116	Dog: 0.25-0.5 mg/kg PO SID, with sulfonamides Cat: 0.25-0.5 mg/kg PO SID, with trimethoprim-sulfadiazine
	Protozoal polyradiculoneuritis, chorioretinitis, *Neospora caninum*	25, 102, 116	Dog: 1 mg/kg PO SID, with sulfonamides
Ramipril *(Altace)*	Chronic congestive heart failure	9, 10	Dog: 0.25-0.5 mg/kg PO SID Cat: 0.5 mg/kg PO SID
Ranitidine *(Zantac)*	Esophagitis, gastric reflux, GI tract ulceration, chronic gastritis, megacolon	15, 30-34, 39, 48, 73, 112, 135	Dog: 0.5-2 mg/kg PO, SC, IV BID-TID Cat: 0.1-2.5 mg/kg IV, PO, SC BID-TID
Remifentanil *(Ultiva)*	Preanesthetic, anesthetic agent	1	Dog: a) 0.001-0.003 mg/kg IV b) 0.01-0.03 µg/kg IV as CRI Cat: a) 0.001-0.003 mg/kg IV b) 0.01-0.03 µg/kg IV as CRI
Rifampin *(Rimactane, Rifadin)*	CNS fungal infections, tuberculosis	24	Dog: 10-20 mg/kg PO TID
	Feline leprosy	113	Cat: 10-15 mg/kg PO SID, with clofazimine or clarithromycin
	Brucellosis	113	Dog: 10 mg/kg PO BID-TID, with doxycycline
Ronidazole*	*Tritrichomonas foetus* infection	33, 116	Cat: 10-50 mg/kg PO BID × 14 days CAUTION: Can be neurotoxic
Rotenone ointment *(Goodwinol)*	Canine demodicosis	86	Dog: Apply topically SID-BID to alopecic regions
Rutin	Lymphedema, chylothorax	19	Dog: 50 mg/kg PO TID
S-Adenosyl-L-methionine (SAMe; *Denosyl*)	Antioxidant for canine chronic hepatitis/cirrhosis, feline chronic cholangiohepatitis, hepatic necrosis/failure, acetaminophen and Saint John's Wort toxicoses	37, 124, 126, 127, 130, 131	Dog: 17-20 mg/kg PO SID, on an empty stomach Cat: a) 200 mg PO SID, on an empty stomach b) 20 mg/kg PO SID, on an empty stomach
Selamectin *(Revolution)*	Heartworm chemoprophylaxis	12	6 mg/kg applied topically once monthly
	Flea adulticide; cheyletiellosis; sarcoptic, notoedric, and otodectic mange; *Pneumonyssoides caninum*	85, 95	Apply 6-15 mg/kg topically q 30 days or q 2 wk × 2-3 Rx
	Linognathus setosus		8 mg/kg applied topically
Selegiline *(Anipryl)*	Narcolepsy	22	Dog: 1 mg/kg PO SID
	Pituitary-dependent hyperadrenocorticism	45	Dog: 1 mg/kg/day PO
	Cognitive dysfunction	117	Dog: 0.5-1 mg/kg PO SID
Selenium	Nutritional myodegeneration	82	Dog: 100-400 IU PO BID
Selenium sulfide 1% shampoo *(Selsun Blue)*	*Malassezia* spp. dermatitis	85	Dog: Use 1-2 times/wk until resolution
Sertraline *(Zoloft)*	Certain behavioral disorders	117	Dog: 0.5-4 mg/kg PO SID Cat: 0.5-1.5 mg/kg PO SID
Sildenafil *(Viagra)*	Pulmonary hypertension, polycythemia	8, 18	Dog: 0.5-3 mg/kg PO BID-TID
Sodium bicarbonate	Cardiopulmonary arrest, metabolic acidosis, hyperkalemia	7, 45, 48	1 mEq/kg IV initially, then 0.5 mEq/kg IV q 10 min Cat: 10 mg/kg PO BID
	Hypercalcemic crisis	43	1 mEq/kg IV slow bolus infusion
	Urine alkalinization	127	10-90 gr/day PO

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

*Not available in the United States.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Sodium bicarbonate—*cont'd*	Certain toxicoses Shock, metabolic acidosis	128 132	1-2 mEq/kg per L of crystalloid soln IV Administer half of bicarbonate deficit slowly IV over 4-6 hr
Sodium nitrite injectable	Cyanogenic glycoside plant poisoning	131	Dog: 16 mg/kg IV, followed by sodium thiosulfate CAUTION: Use only in cyanide poisoning cases
Sodium phosphate injectable	Severe hypophosphatemia	64	Cat: 0.01-0.03 mmol/kg/hr IV; max = 0.06 mmol/kg/hr
Sodium stibogluconate *(Pentostam)*	Leishmaniasis	116	Dog: 30-50 mg/kg SC SID × 3-4 wk, with allopurinol
Sodium sulfate (Glauber's salts; compounding pharmacy)	Osmotic cathartic	123	250 mg/kg PO added to activated charcoal slurry
Sodium thiosulfate *(Sodium thiosulfate)*	Cyanogenic glycoside plant poisoning	131	Dog: 30-40 mg/kg IV following sodium nitrite CAUTION: Use only in cyanide poisoning cases
Sorbitol 70% soln *(Toxiban with Sorbitol, Sorbitol Solution)*	Osmotic cathartic	123	1-2 mL/kg, with activated charcoal soln
Sotalol *(Betapace)*	Atrial fibrillation or flutter, supraventricular and ventricular arrhythmias	6	Dog: 0.5-2.5 mg/kg PO BID Cat: 10 mg PO BID
Spironolactone *(Spironolactone)*	Chronic heart failure, ascites from hepatic failure	9, 37	Dog: 1-2 mg/kg PO SID-BID
Stanozolol *(Winstrol-V)*	Appetite stimulant	122	Dog: a) 1-4 mg PO BID b) 25-50 mg IM q 7 days Cat: a) 1-2 mg PO BID b) 25 mg IM q 7 days
Streptokinase *(Streptase)*	Arterial thromboembolism	10	Cat: 90,000 U IV over 30 min, then 45,000 U/hr IV × 3 hr
Streptomycin *(Streptomycin)*	Brucellosis	61	Dog: 20 mg/kg IM SID × 14 days
Streptozocin *(Zanosar)*	Insulinoma	46	500 mg/m^2 mixed with 0.9% NaCl, given at 18.3 mL/kg/hr IV × 2 hr
Succimer *(Chemet)*	Lead poisoning	126	Dog: 10 mg/kg PO TID × 10 days Cat: 10 mg/kg PO TID × 5 days, then 10 mg/kg PO or rectally BID × 10 days
Sucralfate *(Carafate)*	Esophagitis, GI tract ulceration, uremic gastritis	30, 31, 33, 37, 39, 45, 48, 73, 124, 126-128, 130, 131, 135	Dog: a) 250 mg/15 kg PO TID-QID b) 0.5-1 g/25 kg PO BID-QID c) 0.25-1 g PO BID-QID (as slurry) Cat: 0.125-0.5 g PO BID-TID Give 30-60 min after Histamine$_2$ blockers
Sulfadiazine *See also* Trimethoprim-sulfadiazine	Nocardiosis Toxoplasmosis, neosporosis	89 102, 116	Dog: a) 80 mg/kg PO TID b) 110 mg/kg PO BID Dog: 15-20 mg/kg PO BID × 2-4 wk, with pyrimethamine
Sulfadimethoxine *(Albon)*	Coccidiosis	33, 116	55 mg/kg PO once, then 27.5 mg/kg PO SID × 10-14 days
Sulfadimethoxine-Ormetoprim *(Primor)* *See* Ormetoprim			

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Sulfamethazine *(Sulmet Soluble Powder)*	Coccidiosis	33	100 mg/kg PO once, then 50 mg/kg PO BID × 14 days
	Nocardiosis	89	50 mg/kg PO TID
Sulfasalazine *(Azulfidine)*	Chronic idiopathic colitis	34	Dog: 15-20 mg/kg PO TID; max = 3 g/day Use with caution in cats
	Chronic histiocytic ulcerative colitis, vasculitis	34, 91	Dog: 20-40 mg/kg PO TID; doses >3 g/day potentially toxic
Sulfisoxazole *(Gantrisin)*	Nocardiosis	89	Dog: 50 mg/kg PO TID
Suprofen 1% *(Profenal)*	Anterior uveitis	99	Apply 1 drop to affected eye BID-QID
Tacrolimus 0.1% cream *(Protopic)*	Cutaneous or discoid lupus erythematosus, pemphigus erythematosus, KCS	90, 91, 98	Apply topically SID-BID × 14 days, then taper to 2-3 times/wk
Tacrolimus 0.02%-0.03% (compounding pharmacies)	Tear stimulation, KCS	97	Apply soln to affected eye BID-TID
Taurine	Taurine deficiency, dilated cardiomyopathy	10, 122	Dog: 500-1000 mg PO BID-TID Cat: 250-500 mg PO SID-BID
	Feline central retinal degeneration	102	Cat: 250-500 mg PO SID-BID
Tepoxalin *(Zubrin)*	Musculoskeletal pain and inflammation	80, 127	Dog: 10-20 mg/kg PO once, then 10 mg/kg PO SID
Terbinafine *(Lamisil)*	Gastric pythiosis, oomycosis	31, 111	Dog: 5-10 mg/kg PO SID
	Malassezia spp. dermatitis	85	Dog: 15-30 mg/kg PO SID
Terbutaline *(Brethine, Terbuatline)*	Sinus bradycardia	6	Dog: 0.2 mg/kg PO BID-TID
	Bronchodilator	16-18, 133	Dog: a) 1.25-5 mg PO BID-TID b) 0.01 mg/kg SC, IM BID-QID Cat: a) 0.625-1.25 mg PO BID b) 0.01 mg/kg SC, IM BID-QID
Testosterone cypionate *(Depo-Testosterone)*	Hormone-responsive urinary incontinence	51	Dog (male): 2.2 mg/kg IM monthly
	Decrease milk production in pseudocyesis	61	Dog: 0.5-1 mg/kg IM
Testosterone propionate *(Testosterone propionate)*	Hormone-responsive urinary incontinence	51	Cat: 5-10 mg IM PRN
Tetanus antitoxin (equine)	Tetanus treatment	113	Test dose: 0.1-0.2 mL SC, ID; observe for 30 min for signs of anaphylaxis Treatment dose: 100-1000 U/kg IV or IM, SC near the wound site, once
Tetracycline *(Achromycin)*	Rickettsial diseases, leptospirosis carrier state, canine hemoplasmosis	24, 48, 102, 115	Dog: 22-30 mg/kg PO TID Cat: 15 mg/kg PO TID
	GI bacterial overgrowth, bacterial cystitis or arthritis	33, 50, 80	Dog: 10-22 mg/kg PO TID
	Brucellosis	61	Dog: 30 mg/kg PO BID × 28 days
	Immune-mediated dermatological diseases, nodular panniculitis, sterile granuloma, sebaceous adenitis, episcleritis	77, 89-91, 93, 98	Dog: <10 kg: 250 mg PO TID, with niacinamide >10 kg: 500 mg PO TID, with niacinamide
	Salmon poisoning disease	115	Dog: 22 mg/kg PO, IV TID × 3-5 days

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Theophylline *(Theolair, Aquaphyllin)*	Bronchodilator	6, 12, 16-18	Dog: 10–20 mg/kg PO BID Cat: 25 mg/kg PO SID *Theochron-Extended Release:* Dog: 10 mg/kg PO BID *Theo-Dur tablets:* Dog: 20 mg/kg PO BID Cat: 20-25 mg/kg PO SID in evening *Slo-Bid Gyrocaps:* Dog: 25 mg/kg PO BID Cat: 25 mg/kg PO SID in evening
Thiabendazole *(Mintezol)*	Nasal aspergillosis *Oslerus osleri*	14 16	Dog: 10 mg/kg PO BID Dog: 32-140 mg/kg/day PO × 10-23 days
Thiabendazole *(Tresaderm)*	Otodectic mange	85	Apply to the ears SID × 7 days; repeat in 7 days
Thiamine HCl (Vitamin B_1)	Adjunctive therapy for seizures Thiamine deficiency, malabsorption	22 23, 33	25-50 mg IM, IV Dog: 25-50 mg IM SID Cat: 10-20 mg IM SID
Thiopental *(Pentothal)*	Anesthetic induction	1, 61	4-10 mg/kg IV, to effect
Tiopronin *(Thiola)* *See* 2-Mercaptopropionyl glycine			
Thymosin fraction 5	Growth hormone deficiency	75	Dog: 1 mg/kg SC SID × 7 days (in the puppy)
L-Thyroxine, T_4 *(Soloxine, Synthroid)*	Hypothyroid-related neuropathy Hypothyroidism Myxedema stupor or coma	25 41, 42, 61, 87 42	Dog: 0.02 mg/kg PO BID Dog: 0.02-0.04 mg/kg PO BID initially, then possibly SID Cat: 0.05-0.1 mg/cat PO SID-BID Dog: 1-5 µg/kg IV BID
Ticarcillin/clavulanate *(Timentin)*	Acute endocarditis, bartonellosis Septicemia, endotoxemia, acute abdomen syndrome Feline acute cholangiohepatitis	9 33, 39 37	Dog: 50 mg/kg IV QID, with amikacin Dog: 40-50 mg/kg IV TID-QID Cat: 33-50 mg/kg IV QID
Tiletamine/zolazepam *(Telazol)*	Short-duration anesthesia		Dog: 6-13 mg/kg IM Cat: 9-12 mg/kg IM
Timolol maleate 0.5% *(Timoptic)*	Glaucoma	100	Apply 1 drop to affected eye BID
Tissue plasminogen activator, alteplase *(Activase)*	Intraocular fibrinous clots	99	Inject 25 µg (0.1 mL of 250-µg/mL soln) in anterior chamber of affected eye
Tobramycin *(Nebcin)*	Resistant *Pseudomonas* spp. infections		1-2 mg/kg IM, SC, IV TID
Tocopherol *See* Vitamin A			
Tramadol *(Ultracet, Tramadol)*	Pain relief	72, 81	Dog: 1-4 mg/kg PO BID-QID Cat: 12.5 mg PO BID
Transfusion therapy *See also* Cryoprecipitate	Platelet disorders, von Willebrand disease, severe anemia	37, 67	a) Whole blood: 10-20 mL/kg IV SID PRN b) Platelet-rich plasma: 6-10 mL/kg IV; repeat BID-TID PRN c) Platelet concentrate: 1 U/10 kg IV; repeat BID-TID PRN d) Fresh or fresh-frozen plasma: 6-12 mL/kg IV; repeat BID-TID PRN

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Travoprost 0.004% *(Travatan)*	Glaucoma	100	Dog: Apply 1 drop to affected eye SID-BID
Tretinoin *(Retin-A Micro Cream)*	Vitamin A-responsive dermatoses	122	Apply topically SID-BID
Triamcinolone *(Vetalog)*	Feline immune-mediated cutaneous diseases, plasma cell pododermatitis, eosinophilic granuloma complex	90, 91	Cat: 0.4-0.8 mg/kg PO SID, then taper
	Appetite stimulant	122	0.11-0.22 mg/kg PO SID, then quickly taper to 0.028-0.055 mg/kg PO SID
Triamcinolone injectable suspension *(Kenalog)*	Pannus, feline eosinophilic keratitis, anterior uveitis, episcleritis	98, 99	Apply 4-8 mg subconjunctivally to affected eye
Triamcinolone 0.0125% *(Genesis Spray)*	Flea allergic, atopic, contact, and acute moist dermatitides	85	Apply topically SID × 7 days, then QOD
	Severe canine acne	88	Dog: Apply topically SID × 14 days
Trientine *(Syprine)*	Copper hepatopathy	37	Dog: 10-15 mg/kg PO BID
Trifluridine 1% *(Viroptic)*	Ocular herpesvirus infection	96, 98	Apply soln to affected eye 5-8 times daily
Trilostane*	Alopecia associated with adult-onset growth hormone deficiency	41, 87	Dog: <2.5 kg: 20 mg PO SID 2.5-5 kg: 30 mg PO SID 5-10 kg: 60 mg PO SID
	Pituitary-dependent hyperadrenocorticism	45	Dog: a) 6 mg/kg PO SID b) 3 mg/kg PO BID
Trimethoprim/sulfadiazine *(Tribrissen)*	Bacterial upper respiratory infections and pneumonia, nocardiosis, toxoplasmosis, neosporosis, coccidiosis, *Pneumocystis carinii* and *Cyclospora cayetanensis* infections	18, 89, 113, 114, 116	15-30 mg/kg PO BID
	Protozoal polyradiculoneuritis, bacterial and protozoal CNS diseases	23-25	Dog: 15-30 mg/kg PO, SC BID
	Routine infections, bacterial cystitis, prostatitis and pyoderma	33, 50, 53, 88, 90, 91	15 mg/kg PO, SC BID
	Protozoal myositis	82	Dog: 30 mg/kg PO BID, with pyrimethamine Cat: 30 mg/kg PO BID
	Hepatozoon americanum infection	116	15 mg/kg PO BID, with other drugs
	Acanthamoeba castellani, Acanthamoeba culbertsoni infections	116	Dog: 30 mg/kg PO BID
Trimethoprim/sulfamethoxazole *(Bactrim, Septra)*	Canine bacterial pyoderma	88, 90	Dog: 15 mg/kg PO BID
Trypan blue 1% *(Trypan Blue 1X Solution)*	*Babesia canis*	116	Dog: 10 mg/kg IV once, followed by imidocarb
Tylosin tartrate powder (*Tylan,* 2.27 g of tylosin per teaspoon)	GI bacterial overgrowth, histiocytic ulcerative colitis	33, 34	Dog: 40-80 mg/kg PO SID-BID in food
	Cryptosporidiosis	33, 116	Dog: 11 mg/kg PO BID-TID in food Cat: 11 mg/kg PO BID in food
	Acute colitis, chronic lymphocytic-plasmacytic colitis	34	10-20 mg/kg PO BID in food
	Exocrine pancreatic insufficiency	36	Dog: 25 mg/kg PO BID in food

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.

*Not available in the United States.

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Ursodiol *(Actigall)*	Improve bile flow, reduce toxic bile acids in chronic hepatitis/cirrhosis, cholangiohepatitis, gallbladder mucocele	37	10-15 mg/kg PO SID
Vanadium *(Super Vanadyl Fuel)*	Diabetes mellitus	44	Cat: 45 mg PO SID, with insulin
Vasopressin *See* Desmopressin and Lysine-8-vasopressin			
Vidarabine (compounding pharmacies)	Ocular herpesvirus infection	96	Apply ointment to the affected eye 5-8 times daily
Vinblastine *(Velban)*	Mast cell tumor, lymphoma	72	2-3 mg/m^2 IV q 1-3 wk, in a protocol
Vincristine *(Oncovin)*	Transmissible venereal tumor	58, 72, 89	Dog: a) 0.5-0.6 mg/m^2 IV once weekly b) 0.025 mg/kg IV once weekly
	Myelodysplastic syndrome, essential (primary) thrombocythemia	66	Dog: 0.7 mg/m^2 once IV, with hydroxyurea Cat: 0.025 mg/kg IV weekly, with other drugs
	Immune-mediated thrombocytopenia	67	Dog: 0.02 mg/kg IV once, with prednisone
	Lymphosarcoma	69, 72	Dog: 0.5-0.75 mg/m^2 IV once weekly, in a protocol Cat: a) 0.5-0.75 mg/m^2 IV once weekly, in a protocol b) 0.025 mg/kg IV once weekly, in a protocol
Vinorelbine *(Navelbine)*	Rescue chemotherapy for lymphoma, lung tumors	72	Dog: 15-18 mg/m^2 IV q 1-2 wk, in a protocol
Vitamin A *(Visutein)*	Dietary supplement	33	Dog: 100-500 IU PO, IM SID, with food
	Severe feline acne	88	Cat: 8000 IU PO SID
	Vitamin A–responsive dermatitis	93	Dog: 10,000 IU PO SID × 8-10 wk, with a fatty meal
	Primary seborrhea	93	Dog: 400 IU/kg/day PO indefinitely (max dose)
Vitamin B_1 *See* Thiamine			
Vitamin B_{12} *See* Cyanocobalamin			
Vitamin C *See* Ascorbic acid			
Vitamin D_2, ergocalciferol *(Drisdol, Calciferol)*	Hypoparathyroidism, hypocalcemia	43	1000-2000 U/kg PO SID, taper to once weekly
Vitamin D_3 *See* Calcitriol			
Vitamin E *(E-Gems Soft Gels)*	Nutritional myodegeneration	82	Dog: 100-400 IU PO BID
	Dermatomyositis, vitamin E deficiency	82, 122	200-800 IU PO BID-TID
	Symmetrical lupoid onychodystrophy, discoid lupus erythematosus	90	Dog: a) 400 IU PO BID b) 800 IU PO SID
	Jack Russell terrier vasculopathy	93	Dog: 200-400 IU PO SID, alone or with prednisolone and dapsone
D-Alpha-tocopheryl-1000-polyethylene glycol succinate *(Liqui-E)*	Antioxidant for canine chronic hepatitis/cirrhosis, feline chronic cholangiohepatitis, hepatic necrosis/failure, pansteatitis	37	25 IU/kg PO BID

Continued

DRUG (BRAND NAME OR ABBREVIATION)	PURPOSE OR USE	CHAPTERS WHERE CITED	DOSAGE
Vitamin K_1 *(AquaMEPHYTON, Mephyton)*	Vitamin K deficiency	33, 68	1-5 mg/kg SC, PO SID
	Vitamin K–dependent multifactor coagulopathy	68	Dog: 1 mg/kg PO SID Cat: 5 mg PO SID initially
	Anticoagulant rodenticide toxicosis	124	1-1.5 mg/kg PO TID × 2-6 wk
Warfarin *(Coumadin)*	Prevent thromboembolism	10, 18	Dog: 0.1 mg/kg PO SID Cat: 0.25 mg PO SID
Xylazine hydrochloride *(Rompun)*	Emetic	123	Cat: 0.44 mg/kg IM
Yohimbine *(Yobine)*	Reverse effects of xylazine, amitraz toxicosis	123, 125	Dog: 0.1-0.2 mg/kg IV slowly; repeat if needed
	Coma, general CNS stimulant	128	Dog: 0.1 mg/kg IV
Zinc acetate or gluconate	Canine chronic hepatitis/cirrhosis, copper storage hepatopathies, hepatocutaneous syndrome, hepatic encephalopathy	37	Dog: a) 5-10 mg/kg PO SID of elemental zinc 1 hr before or 2 hr after a meal b) Medium- and large-breed dogs: 50-100 mg SID
	Zinc-responsive dermatoses	90, 93	Dog: 5 mg/kg PO SID
Zinc methionine *(Zin Pro, Nutrived Chewable Zinpro)*	Zinc-responsive dermatoses	93, 122	1.7-2 mg/kg elemental zinc PO SID Do not give with food
Zinc sulfate *(Zinc-220, Zinca-Pak)*	Zinc-responsive dermatoses	93, 122	a) 10-15 mg/kg/day PO; crush tab, mix with food b) 10-15 mg/kg IM weekly × 4 wk
Zonisamide *(Zonegran)*	Seizures	22	Dog: 10 mg/kg PO BID

CNS, Central nervous system; *CRI,* constant rate infusion; *CSF,* cerebrospinal fluid; *dd,* divided; *DIC,* disseminated intravascular coagulopathy; *DJD,* degenerative joint disease; *DOCP,* desoxycorticosterone pivalate; *D/W,* dextrose in water; *EDTA,* ethylenediamine tetraacetic acid; *FeLV,* feline leukemia virus; *FIP,* feline infectious peritonitis; *GI,* gastrointestinal; *ID,* intradermally; *IP,* intraperitoneally; *IT,* intratracheally; *KCS,* keratoconjunctivitis sicca; *max,* maximum; *o.o.,* ophthalmic ointment; *PCV,* packed cell volume; *PRN,* as needed; *Rx,* treatment(s); *SLE,* systemic lupus erythematosus; *soln,* solution; *tab,* tablet; T_4, thyroxine; *UTI,* urinary tract infection.
