• Subsequent meniscal injury can occur in 6–22% of patients. • Incisional and/or implant-related infection. • Tibial tuberosity avulsion and/or fractures. • Patellar luxation. • Delayed bone healing (osteotomy procedures). • Pivot shift—unknown clinical significance <2% (self-limiting).

EXPECTED COURSE AND PROGNOSIS
Regardless of surgical technique, success rate better than 85%.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Meniscal damage.

AGE-RELATED FACTORS
See Pathophysiology.

CRYPTOCOCCOSIS

BASICS

DEFINITION
A localized or systemic fungal infection caused by the environmental yeast *Cryptococcus* spp., most commonly *C. neoformans* and *C. gattii*.

PATHOPHYSIOLOGY
• *C. neoformans*—grows in bird droppings and decaying vegetation; soil disturbance increases risk of infection. • Dogs and cats inhale the yeast and a focus of infection is established, usually in nasal passages; smaller dried, shrunken organisms may reach the terminal airways (uncommon). • There may be colonization or subclinical infection of nasal passages that spontaneously resolves. • Stomach and intestinal infections suggest that primary gastrointestinal entry can occur. • Dissemination—hematogenously spread via macrophages from nasal passages to brain, eyes, lungs, and other tissues; by extension to skin of nose, eyes, retro-orbital tissues, and draining lymph nodes.

SYSTEMS AFFECTED
• Cats—mainly respiratory (nose, nasopharynx, and sinuses), skin (nasal planum), nervous, ophthalmic, and lymphatic.
• Dogs—mainly skin (over nose and sinuses), respiratory (nasal passages, occasionally lungs), nervous (brain), lymphatic, and ophthalmic.

INCIDENCE/PREVALENCE
• Dogs—rare in United States; prevalence 0.00013%. • Cats—7–10 times more common than in dogs; most common systemic mycoses of cats.

GEOGRAPHIC DISTRIBUTION
• Worldwide. • Some areas of southern California and Australia have an increased incidence and an outbreak has occurred on Vancouver Island in British Columbia, Canada. • *C. gattii* grows well around eucalyptus trees.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
• Dogs—American cocker spaniels (United States), Doberman pinschers and German shepherd dogs (Australia) may be overrepresented. • Cats—Siamese may be at increased risk.

Mean Age and Range
• Most commonly cats and dogs <6 years of age. • Can occur at any age.

Predominant Sex
• Dogs—none. • Cats—males may be overrepresented.

SIGNS
Historical Findings
• Lethargy. • Varies depending on organ systems involved. • May have signs/problems for weeks to months.

Dogs
• Neurologic—seizures, ataxia, paresis. • Ocular signs—periorbital swelling, blindness, uveitis, hyphema. • Skin ulceration. • Lymphadenopathy. • Respiratory—upper respiratory signs, labored breathing, coughing. • Vomiting, diarrhea, and anorexia.

Cats
• Nasal discharge and ocular signs. • Neurologic signs—seizures, disorientation, vestibular signs. • Granulomatous tissue seen at the nares. • Firm swellings over the bridge of the nose. • Lymphadenopathy. • Respiratory abnormalities less commonly noted.

Physical Examination Findings
• Mild fever—<50% of patients. • Dogs—nasal discharge, multifocal CNS abnormalities, ataxia, anterior uveitis. • Cats—respiratory noise (stertor), nasofacial swelling, ulcerated crusting skin lesions on the head, lymphadenopathy, neurologic abnormalities (behavior change, circling, vestibular signs, ataxia), ocular abnormalities (blindness, optic neuritis, retinal detachment).

CAUSES
Exposure to cryptococcal organisms and inability of immune system to prevent colonization and tissue invasion.

RISK FACTORS
• Exposure to disrupted soil. • Infection with feline leukemia virus (FeLV) or feline immunodeficiency virus (FIV).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Dogs
• Other causes of focal or diffuse neurologic disease—distemper, inflammatory meningoencephalomyelitis, infectious meningoencephalitis (bacterial, rickettsial, protozoal), neoplasia, fungal diseases (depending on geography). • Nasal lesions, especially at mucocutaneous junction—immune-mediated, neoplasia (squamous cell carcinoma). • Lymphadenopathy—lymphoma, fungal disease. • Chorioretinitis and optic neuritis—fungal infections, distemper, neoplasia.

Cats
• Nasal disease—nasal tumors, chronic rhinitis, chronic sinusitis. • Ulcerative skin changes—bacterial infection, trauma, neoplasia (squamous cell carcinoma). • Ocular and neurologic abnormalities—lymphoma, feline infectious peritonitis (FIP), other infections (fungal, *Toxoplasma*).

CBC/BIOCHEMISTRY/URINALYSIS
• Mild anemia in some cats. • Eosinophilia occasionally seen. • Chemistry usually normal.

OTHER LABORATORY TESTS
• Latex agglutination or ELISA—detect cryptococcal capsular antigen in serum or cerebrospinal fluid (CSF); highly sensitive assay; most infected animals have measurable capsular antigen titers; magnitude of titer correlates with extent of infection. • May be less sensitive in dogs. • May be positive with colonization alone; antigen titers 1 : 32 or greater seen with fungal invasion.

IMAGING
• Nasal radiographs (cats)—soft tissue density material in nasal passage; bone destruction of nasal dorsum. • Contrast-enhanced CT or MRI best for identifying brain and nasal lesions. • Thoracic radiographs—can identify lower respiratory tract disease.

DIAGNOSTIC PROCEDURES
Dogs
Neurologic disease—additional procedures: cytologic examination and culture of CSF, other CSF infectious disease testing, measurement of CSF capsular antigen.

Cats
• Cytology of impression smears or aspirates of mucoid material from nasal passages, or biopsy of granulomatous tissue protruding from nares—characteristic yeast with large negatively- staining (clear) capsule. • Aspirates of lymph nodes or subcutaneous swellings often high yield. • Sedated oropharyngeal exam—in patients with upper respiratory obstruction/noise: may identify granuloma in nasopharynx (spay hook or endoscope to expose the mass). • Biopsy—skin lesions. • Cultures—confirm diagnosis; determine drug susceptibility.

PATHOLOGIC FINDINGS
• Gross lesions—gray, gelatinous mass produced by polysaccharide capsule; in nose, sinuses, and nasopharynx of cats; skin lesions usually ulcerative. • Neurologic lesions—more common in dogs; diffuse or focal CNS granulomas. • Chorioretinitis with or without retinal detachment or optic neuritis. • Histologic response—usually pyogranulomatous; inflammatory cell infiltrate may be mild as polysaccharide capsule interferes with neutrophil migration; organism characterized by capsulate yeast with narrow-neck budding.

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient if stable. • Neurologic signs—may initially require inpatient supportive care.

(CONTINUED) CRYPTOCOCCOSIS

C

NURSING CARE
Cats—nasal obstruction influences appetite; encourage to eat by offering warmed, palatable food.

ACTIVITY
N/A

DIET
Patients treated with itraconazole—give medication in fatty food (e.g., canned food) to improve absorption.

CLIENT EDUCATION
• Inform client that this is a chronic disease that requires months of treatment. • Reassure client that infection is not zoonotic.

SURGICAL CONSIDERATIONS
Remove granulomatous masses in nasopharynx to reduce respiratory difficulties.

MEDICATIONS

DRUG(S) OF CHOICE
• Fluconazole—preferred for ocular or CNS disease (water soluble and better penetrates CNS); cats: 50 mg/cat PO q12–24h; dogs: 5 mg/kg PO q12h; most economical drug choice. • Itraconazole—cats: 10 mg/kg PO q24h; dogs: 5 mg/kg PO q12h; pellets in capsule can be mixed with fatty food; itraconazole liquid has better absorption on empty stomach and compounded itraconazole is not recommended. • Amphotericin B may have some advantage in severe disease at a dosage of 0.25 mg/kg IV q48h, given slowly over 3–4h, up to a total cumulative dose of 4–16 mg/kg; monitor renal function closely. • Terbinafine (5 mg/kg PO q12h, 10 mg/kg PO q24h) effective for treatment of cats with resistant infections. • Flucytosine—25–50 mg/kg PO q6h; synergistic with amphotericin B, may allow lower doses and decrease renal toxicity. Do not use as single agent.

CONTRAINDICATIONS
Caution with concurrent steroid use (immunosuppression).

PRECAUTIONS
• Triazoles—hepatotoxicity; anorexia signals problems; monitor liver enzyme activities monthly initially. • Itraconazole—ulcerative dermatitis (differentiate from skin lesions of cryptococcosis); new skin lesions after disease is much improved should be considered a drug reaction. • Amphotericin B—nephrotoxicity; caution if patient is azotemic, but not absolute contraindication if life-threatening infection. • Terbinafine—monitor for hepatic toxicity and anorexia.

ALTERNATIVE DRUG(S)
Cryptococcal organisms are prone to becoming resistant to antifungal treatment.

FOLLOW-UP

PATIENT MONITORING
• Monitor liver enzyme activities monthly (especially early in treatment) in patients receiving triazole antifungal agent. • Improvement in clinical signs, resolution of lesions, improvement in wellbeing, and return of appetite measure response to treatment. • Capsular antigen titers—after 2–3 months of treatment, titers should decrease if treatment is effective; if ineffective, try terbinafine, because organism may become resistant. • Continue monitoring antigen titers every 1–2 months during treatment and after discontinuing treatment. • Ideally treat until cryptococcal antigen titers reach zero (may take >2 years).

PREVENTION/AVOIDANCE
The organism is ubiquitous and cannot be avoided.

POSSIBLE COMPLICATIONS
Patients with neurologic disease may have seizures and permanent neurologic deficits.

EXPECTED COURSE AND PROGNOSIS
Treatment—anticipated duration 4 months to ≥1 year; patients with CNS disease may require lifelong maintenance; median time of successful treatment with fluconazole 4 months; median time for itraconazole treatment 8 months.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
• Not considered zoonotic, but possibility of transmission through bite wounds. • Inform client that organism was acquired from the environment and that he or she could be at increased risk, especially if immunosuppressed.

PREGNANCY/FERTILITY/BREEDING
Azole drugs can be teratogenic and should be used in pregnant animals only if the potential benefit justifies the potential risk to offspring.

ABBREVIATIONS
• CSF = cerebrospinal fluid.
• FeLV = feline leukemia virus.
• FIP = feline infectious peritonitis.
• FIV = feline immunodeficiency virus.

CRYPTORCHIDISM

BASICS

OVERVIEW

- Incomplete scrotal descent of one or both testes; most common testicular congenital anomaly.
- Abdominal or inguinal location for undescended testis or testes.
- Diagnosis usually made at 2 months of age (i.e., descent to scrotal position should occur before this time), with some exceptions of full descent occurring between 2 and 6 months of age.
- Abdominally retained testicles typically lack spermatozoa and have only Sertoli cells in the seminiferous tubules; estradiol (E2) and testosterone (T) can be present in normal systemic concentrations in affected animals.
- Unilaterally cryptorchid animals are typically fertile.

SIGNALMENT

- Cats—purebred cats have higher incidence.
- Dogs—toy and miniature breeds at 2.7 times greater risk than large breeds of being affected; high rates in miniature schnauzers with persistent Müllerian duct syndrome (PMDS).
- Incidence—rates up to 24.1% in some purebred dogs (compared to 2.1% in overall population) with 50% incidence in dogs with PMDS; in cats observed rates range from 1.3 to 6.2%.
- Unilateral more common than bilateral; right testis retained twice as often in dogs, but with equal frequency in cats.
- Genetics—estimated medium level of heritability with multifactorial genetic basis; females act as genetic carriers for the trait.

SIGNS

- Absence of one, or both, testicles from the scrotum in a patient without history of castration.
- Cats—strong urine odor, tom cat marking behavior, presence of penile spines.
- Abdominal pain, lameness, vomiting—increased risk exists for spermatic cord torsion of neoplastic, retained testes.
- Feminizing paraneoplastic syndrome—estrogen-secreting Sertoli cell tumors produce feminizing signs including gynecomastia, symmetric alopecia of trunk and flanks, hyperpigmentation of inguinal skin, pendulous preputial sheath, prostatic squamous metaplasia.

CAUSES & RISK FACTORS

- Affected males or carriers (i.e., females or nonaffected males of cryptorchid littermates) present in breeding lines.
- Carriers produce increased number of males per litter and increased litter size; efforts to eliminate cryptorchidism difficult in these circumstances.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bilateral—previously castrated patient.
- Unilateral—remaining abdominal or inguinal testis after removal of single scrotal testis.

DIAGNOSTIC PROCEDURES

Transrectal prostate exam—intact males have pronounced prostate; prostate of larger breeds may be beyond reach.

OTHER LABORATORY TESTS

- Human chorionic gonadotropin (hCG) or gonadotropin-releasing hormone (GnRH) stimulation test (differentiate cryptorchidism from castrated)—collect blood sample for baseline T analysis; administer 750 IU hCG IV or 50 µg GnRH IM; repeat sample collection for T analysis in 2–3 hours; twofold increase in T from baseline indicates presence of testicular tissue.
- Canine anti-Müllerian hormone concentration—increased level indicates testicular Sertoli cells present.

IMAGING

Ultrasonography—highly sensitive for identification of inguinal or abdominal testes.

TREATMENT

- Identification and removal of undescended testis or testes.
- Orchiopexy—surgical tacking of retained testis into scrotum; results in misrepresentation of individual's true phenotype and genotype.
- hCG or GnRH—little controlled evidence establishing efficacy or protocol; ethical concerns same as with orchiopexy.
- Failure to remove retained testis—increased risk of testicular neoplasia (13.6 times greater), spermatic cord torsion; 53% of Sertoli cell tumors and 36% of seminomas occur in retained testes.

MEDICATIONS

DRUG(S) OF CHOICE

To possibly induce descent of retained testicle:

- hCG (dogs)—100–1,000 IU IM 4 times in 2-week period before 16 weeks of age.
- GnRH (dogs)—50–750 µg IM 1–6 times between 2 and 4 months of age.
- Buserelin (GnRH analogue; dogs)—10 µg, once weekly, for 3 doses.

FOLLOW-UP

Migration of testes into the scrotum after 4 months is unlikely; rare after 6 months.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Inguinal or umbilical hernia.
- Hip dysplasia.
- Patellar luxation.
- Penile and preputial defects (e.g., hypospadias).

SEE ALSO

- Seminoma.
- Sertoli Cell Tumor.
- Sexual Development Disorders.

ABBREVIATIONS

- E2 = estradiol.
- hCG = human chorionic gonadotropin.
- GnRH = gonadotropin-releasing hormone.
- PMDS = persistent Mullerian duct syndrome.
- T = testosterone.

CRYPTOSPORIDIOSIS

BASICS

OVERVIEW

• *Cryptosporidium* spp.—apicomplexan protozoan causing gastrointestinal disease; ubiquitous in nature with worldwide distribution.
• Infection—sporulated oocysts are ingested, sporozoites are released and penetrate intestinal epithelial cells; after asexual reproduction, merozoites released to infect other cells, sexual reproduction follows, then oocyst shedding.
• Prepatent period—5–10 days (cats).
• Immunocompetent animals—intestinal disease.
• Immunocompromised animals—intestinal, liver, gallbladder, pancreatic, respiratory infection.
• Dogs—prevalence 0.5% worldwide; 2–17% in the United States.
• Cats—prevalence 0–29% worldwide; 2–15% in the United States.

SIGNALMENT

• No sex or breed predilection.
• Dogs—virtually all clinical cases in immunocompromised animals or animals <6 months of age; older dogs can excrete oocysts without clinical signs.
• Cats—more common in immunocompromised cats or kittens <6 months of age.

SIGNS

• Most infections subclinical.
• Principally small bowel diarrhea; large bowel diarrhea reported.

CAUSES & RISK FACTORS

• *C. canis* (dogs), *C. felis* (cats)—ingestion of contaminated water or feces.
• Morphologically, intestinal *Cryptosporidium* species very similar.
• Some species are host specific (*C. canis*, *C. felis*); others (*C. parvum*, *C. muris*) infect multiple species.
• Immunosuppression—major risk factor; common causes feline leukemia virus, canine distemper virus, canine parvovirus, intestinal lymphoma.
• Immunocompetent animals—usually asymptomatic infection with fecal oocyst shedding.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Parasites—giardiasis, trichuriasis.
• Infectious agents—parvovirus, coronavirus, feline infectious peritonitis, *Salmonella*, *Campylobacter*, *Rickettsia*, *Histoplasma*.
• Metabolic—hypoadrenocorticism, hyperthyroidism (cats).
• Infiltrative diseases—e.g., inflammatory bowel disease, intestinal lymphoma.
• Dietary indiscretion or intolerance.
• Toxicities—medications, lead, etc.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal, can reflect underlying disease.

DIAGNOSTIC PROCEDURES

• Sugar and zinc sulfate centrifugal flotation—specific gravity = 1.18–1.3; concentrates fecal oocysts (oocysts are 5 µm, routine salt flotation often fails); oocysts best seen with modified acid-fast stain, may have slight pink color.
• Fecal antigen detection test (ProSpecT *Cryptosporidium* Microtiter Assay, Color-Vue *Cryptosporidium*) available for humans.
• Fluorescent antibody assay—veterinary diagnostic laboratories.
• PCR—commercial laboratories; more sensitive for diagnosis than other techniques.
• Submitting feces to laboratory—laboratory-specific protocols; can mix 1 part 100% formalin with 9 parts feces to inactivate oocysts and decrease health risk to laboratory personnel.

PATHOLOGIC FINDINGS

• Gross lesions—enlarged mesenteric lymph nodes, hyperemic intestinal (especially ileal) mucosa; fix specimens in Bouin's or formalin solution within hours of death; autolysis causes rapid loss of intestinal surface with organisms.
• Microscopic lesions—villous atrophy, reactive lymphoid tissue, inflammatory infiltrates in lamina propria; parasites throughout intestines, most numerous in distal small intestine.

TREATMENT

• Outpatient.
• In immunocompetent animals—diarrhea usually mild and self-limiting; withhold food for 24–48h to control diarrhea; oral glucose-electrolyte solution if mild diarrhea; parenteral fluids (isotonic with potassium added) if severe diarrhea.

MEDICATIONS

DRUG(S) OF CHOICE

• No drugs currently labeled for animal use in United States.
• Paromomycin (Humatin®)—125–165 mg/kg PO q12h for 5 days; aminoglycoside effective in humans with acute intestinal symptoms; may cause nephropathy in young animals with damaged gastrointestinal barrier; monitor urine for casts during therapy.
• Tylosin—11 mg/kg PO q12h for 28 days; reported effective in cat with concurrent lymphocytic duodenitis.
• Nitazoxanide (Alinia®)—25 mg/kg PO q24h for 7–28 days; reduces oocyst shedding in cats; associated with vomiting (responsive to antiemetics); used in limited number of cats.

FOLLOW-UP

• Treatment efficacy based on clinical improvement.
• Monitor oocyst shedding in feces 2 weeks after treatment completion or if signs persist.
• Prognosis excellent if underlying disease treated.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Possible—transmission of infection from dogs and cats to humans possible; in general, transmission from pets to people rare.

Disinfection

• 10% formaldehyde solution or 5% ammonia solution will kill oocysts, but requires 18 hours of exposure; 50% ammonia solution kills oocysts in 30 minutes.
• Resistant to commercial bleach (5.25% sodium hypochlorite) and chlorination of drinking water.
• Moist heat (steam or pasteurization, >55 °C), freezing and thawing or thorough drying also effective.

Consulting Editor Amie Koenig

CRYSTALLURIA

BASICS

DEFINITION
Appearance of crystals in urine. This finding may be normal, clinically significant or artifactual.

PATHOPHYSIOLOGY
- Identification of crystals formed in vitro does not justify therapy.
- Crystals form only in urine that is, or recently has been, supersaturated with crystallogenic substances; thus in vivo crystalluria represents risk factor for urolithiasis.
- Certain crystal types such as cystine, urate, or 2,8-dihydroxyadenine may indicate underlying disease; proper identification and interpretation of urine crystals important in formulation of medical protocols to dissolve uroliths.
- Crystalluria in individuals with anatomically and functionally normal urinary tracts usually harmless because crystals eliminated before they grow large enough to interfere with normal urinary function; however, they represent a risk factor for urolithiasis.
- Crystals that form following elimination or removal of urine from the patient often are of little clinical importance; in recent studies following time and temperature changes, crystals formed in 28% of dog and cat samples that were initially free of crystals.
- Detection of some types of crystals (e.g., cystine and ammonium urate) in clinically asymptomatic patients or detection of any form of crystals in fresh urine collected from patients with confirmed urolithiasis may have diagnostic, prognostic, or therapeutic importance.
- Drug crystals detected in patients administered high doses of medications such as allopurinol, sulfadiazines, or fluoroquinolones should prompt therapy changes due to risk for formation of drug-containing uroliths.

SYSTEMS AFFECTED
Renal/urologic/hepatic.

SIGNALMENT
- Calcium oxalate in miniature schnauzer, bichon frisé, Yorkshire terrier, Lhasa apso, miniature poodle dogs; Burmese, Himalayan, Persian cats.
- Cystine in dachshunds, English bulldogs, Newfoundlands, and others.
- Ammonium urate in Dalmatians and English bulldogs.
- Struvite in any dog with concomitant urinary tract infection (UTI).
- Struvite in cats not typically associated with UTIs.
- Xanthine in cavalier King Charles spaniels.
- 2,8-dihydroxyadenine in North American indigenous dogs and wolves.

SIGNS
None, or those caused by concomitant urolithiasis.

CAUSES
In Vivo Variables
- Concentration of crystallogenic substances in urine (in turn influenced by rate of excretion and urine concentration).
- Urine pH (struvite and calcium phosphate most common in neutral-to-alkaline urine; ammonium urate, sodium urate, calcium oxalate, cystine, and xanthine crystals most common in acid-to-neutral urine).
- Solubility of crystallogenic substances in urine.
- Excretion of diagnostic agents (e.g., radiopaque contrast agents) and medications (e.g., sulfonamides).
- Dietary influence—hospital diet may differ from home diet; timing of sample collection (fasting vs. postprandial) may influence evidence of crystalluria.

In Vitro Variables
- Temperature.
- Evaporation.
- pH changes following sample collection.
- Technique of specimen preparation—centrifugation versus noncentrifugation, volume of urine examined.
- Important in vitro changes that occur following urine collection may enhance formation or dissolution of crystals; when knowledge of in vivo urine crystal type and quantity especially important, examine fresh specimens, ideally at body temperature; if not possible, they should be at room temperature, not refrigeration temperature.
- Collection container—spurious crystals may be contaminants from unclean collection containers.

RISK FACTORS
See preceding discussion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Ammonium Urate, Sodium Urate, and Amorphous Urate Crystalluria
- Uncommonly seen in apparently healthy dogs and cats.
- Frequently seen in dogs and occasionally in cats with portal vascular anomalies, with or without concomitant ammonium urate uroliths.
- Observed in some dogs and cats with urate uroliths caused by disorders other than portal vascular anomalies, such as canine breeds identified as carriers of hyperuricosuria gene.

Bilirubin Crystalluria
- Observed in highly concentrated urine from some healthy dogs.
- Large numbers in serial samples raises suspicion of abnormality in bilirubin metabolism.
- Usually associated with underlying diseases in cats.

Calcium Oxalate Monohydrate and Calcium Oxalate Dihydrate Crystalluria
- May be observed in apparently healthy dogs and cats and in dogs and cats with uroliths primarily composed of calcium oxalate.
- Calcium oxalate monohydrate crystals most commonly associated with ethylene glycol toxicity, but calcium oxalate dihydrate may be observed, or ethylene glycol toxicity may occur without crystalluria.

Calcium Phosphate Crystalluria
- Large numbers of crystals presumed to be composed of calcium phosphate have been observed in apparently healthy dogs, dogs with persistently alkaline urine, dogs with calcium phosphate uroliths, and dogs with uroliths composed of mixture of calcium phosphate and calcium oxalate.
- Small numbers of calcium phosphate crystals may occur in association with infection-induced struvite crystalluria.
- May be observed in dogs and cats with primary hyperparathyroidism, and renal tubular acidosis.

Struvite Crystalluria
- Observed in many dogs and cats that are healthy and as an artifact.
- Observed in dogs and cats with urinary tract disease without uroliths.
- Observed in dogs and cats with infection-induced struvite uroliths, sterile struvite uroliths, nonstruvite uroliths, and uroliths of mixed composition (e.g., nucleus composed of calcium oxalate and shell composed of struvite).

Cystine Crystalluria
Observed in dogs and cats with inborn errors of metabolism characterized by abnormal transport of cystine and other dibasic amino acids; this metabolism defect can also lead to dilated cardiomyopathy in cats.

Uric Acid Crystalluria
- Uncommon in dogs and cats.
- Importance as described for ammonium and amorphous urates.

Xanthine Crystalluria
- Suggests administration of excessive dosages of allopurinol in conjunction with consumption of relatively high amounts of dietary purine precursors.
- Primary xanthinuria has been observed in cavalier King Charles spaniels.
- Primary xanthinuria and xanthine uroliths occur in cats.

(CONTINUED) CRYSTALLURIA

Miscellaneous Crystalluria

- Uric acid monohydrate crystals from melamine/cyanuric acid toxicosis.
- Cholesterol crystals—observed in humans with excessive tissue destruction, nephrotic syndrome, and chyluria; observed in apparently healthy dogs.
- Hippuric acid crystals—apparently rare in dogs and cats; importance unknown.
- Leucine crystals in dogs—importance not determined; may occur in association with cystinuria.
- Tyrosine crystals—occur in association with severe liver disease in humans; uncommonly observed in dogs and cats with liver disorders; sodium urate needle-like appearance commonly misinterpreted as tyrosine needles.
- 2,8-dihydroxyadenine—a genetic disorder, the result of metabolic abnormality due to deficiency of enzyme adenine phosphoribosyl transferase (APRT).

Drug-Induced Crystalluria

- May be observed following administration of radiopaque contrast agents.
- May be observed following treatment with sulfadiazine, fluoroquinolones, xanthine oxidase inhibitors, and tetracycline.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results

- Urinary acidifiers (e.g., d-, l-methionine and ammonium chloride).
- Urinary alkalinizers (e.g., sodium bicarbonate and potassium citrate).

CBC/BIOCHEMISTRY/URINALYSIS

- Bilirubin crystals may be associated with bilirubinemia and other laboratory abnormalities of hepatic disorders.
- Most dogs and cats with calcium oxalate and calcium phosphate crystalluria are normocalcemic; some are hypercalcemic; calciuria may be used as a future index for calcium oxalate stone formation and treatment evaluation.
- Some dogs and cats with calcium oxalate crystalluria may be acidemic.
- Serially examine fresh specimens for knowledge of in vivo urine crystals.
- Definitive identification of crystal composition depends on one or more of optical crystallography, infrared spectroscopy, X-ray diffraction, and electron microprobe analysis.

OTHER LABORATORY TESTS

- Struvite crystalluria is not synonymous with infection and may be the result of normal in vivo or in vitro factors; when accompanied by elevated pH, bacteriuria, or pyuria on cystocentesis, UTI should be considered; imaging must be performed to assess for stones.
- Dogs and cats with ammonium urate crystalluria and portosystemic shunts often have high serum bile acid levels and hyperammonemia.
- Ammonium urate and amorphous urate crystals are insoluble in acetic acid; addition of 10% acetic acid to urine sediment containing these crystals often yields uric acid and sometimes sodium urate crystals.
- Dogs and cats with calcium oxalate monohydrate crystalluria secondary to ethylene glycol poisoning have detectable levels of ethylene glycol in serum and urine up to 48 hours after ingestion.
- Cystine crystals are insoluble in acetic acid while struvite crystals are soluble; a urine nitroprusside test is positive for cystine.
- Sulfonamide crystalluria may be associated with a positive lignin test.

IMAGING

- Crystalluria may be associated with radiographically or ultrasonographically detectable uroliths.
- Abdominal radiographs should include the entire urethra.
- 25% of radiopaque stones are not seen on ultrasound.

DIAGNOSTIC PROCEDURES

- Empirical therapy for struvite urolithiasis if stone identified on radiographs and concurrent UTI caused by urease-producing bacteria.
- Basket retrieval, voiding urohydropropulsion, or aspiration through a transurethral catheter to retrieve small urocystoliths.

TREATMENT

- Manage clinically important in vivo crystalluria by managing underlying cause(s) or associated risk factors.
- Minimize clinically important crystalluria by increasing urine volume, encouraging complete and frequent voiding, modifying diet, appropriate drug therapy, neutering where appropriate, and in some instances modifying pH.

MEDICATIONS

DRUG(S) OF CHOICE

See comments on urate crystalluria and cystinuria.

FOLLOW-UP

PATIENT MONITORING

- Recheck urinalysis to determine if crystalluria is persistent.
- Re-radiograph or ultrasound, depending on crystal type, to determine if crystalluria has clinical significance or not.
- See specific urolith types for monitoring urolithiasis.

POSSIBLE COMPLICATIONS

- Persistent crystalluria may contribute to formation of uroliths.
- Crystalluria may solidify crystalline-matrix plugs as in male pugs and cats, resulting in urethral obstruction.

MISCELLANEOUS

SEE ALSO

- Nephrolithiasis.
- Urolithiasis, Calcium Oxalate.
- Urolithiasis, Calcium Phosphate.
- Urolithiasis, Cystine.
- Urolithiasis, Pseudo (Dried Blood, Ossified Material).
- Urolithiasis, Struvite—Cats.
- Urolithiasis, Struvite—Dogs.
- Urolithiasis, Urate.
- Urolithiasis, Xanthine.

ABBREVIATIONS

- APRT = adenine phosphoribosyl transferase.
- UTI= urinary tract infection.

Acknowledgment The author and book editors acknowledge the prior contributions of Carl A. Osborne and Lisa K. Ulrich.

CUTANEOUS DRUG ERUPTIONS

BASICS

OVERVIEW
- A wide spectrum of diseases and clinical signs that vary markedly in clinical appearance.
- Mild eruptions may go unnoticed or unreported; incidence rates for specific drugs are unknown.

SIGNALMENT
- Dogs and cats.
- May have a familial basis (e.g., rabies vaccine reactions in canine littermates).

SIGNS
- Pruritus.
- Macular and papular rashes—commonly accompany pruritus as nonspecific sign of inflammation.
- Exfoliative erythroderma—diffuse erythematous response caused by vasodilation; often leads to exfoliation (diffuse scaling).
- Urticaria/angioedema—immediate (type I) hypersensitivity; requires prior sensitization; increased vascular permeability leads to fluid leakage.
- Hypersensitivity vasculitis—type III response; inflammation of cutaneous vasculature; results in poor blood flow and anoxic injury to recipient tissue.
- Eosinophilic dermatitis with edema (Wells-like syndrome) of dogs—deeply erythematous plaques or macules (may be targetoid) accompanied by marked edema; localized, regional, or generalized distribution; clinical appearance of lesions may be indistinguishable from vasculitis and erythema multiforme (EM).
- EM—erythematous macules or plaques expand peripherally and may clear in center (targetoid); multiple shapes/forms noted.
- Stevens-Johnson syndrome (SJS)—similar to toxic epidermal necrolysis (TEN) with less extensive epidermal detachment (<30%) and often involvement of oral mucosa.
- TEN—extensive (>30%) necrosis and sloughing of epidermis in sheets; results in moist and intensely inflamed skin surface.
- Drug-induced pemphigus/pemphigoid—least common drug reaction in animals; can closely mimic autoimmune (spontaneous) disease; symptoms may persist after drug withdrawal.

CAUSES & RISK FACTORS
- Any drug.
- Can occur after first dose or after weeks to months of administration.
- Exfoliative erythroderma—most often associated with shampoos and dips; also reaction to topical ear medications (in ear canals and on concave pinnae).
- Eosinophilic dermatitis with edema—strong association with concurrent acute gastrointestinal disease.
- Pemphigus foliaceus—may be triggered by specific topical flea and tick control products; lesions may include "splash zone" where product was applied.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Pruritus, macular/papular rashes, and urticaria/angioedema—allergic and parasitic diseases (atopic diseases, contact hypersensitivity, flea-bite hypersensitivity, scabies, stinging insects).
- Exfoliative erythroderma—epitheliotropic lymphoma in old dogs and cats.
- Vasculitis—infectious, neoplastic, autoimmune disease and idiopathic.
- EM/SJS/TEN—respiratory infections, herpes virus, parvovirus, bacterial infection (noncutaneous), and internal neoplasia; idiopathic/chronic form of EM occurs in older adult dogs.
- Pemphigus/pemphigoid—consider drug reaction whenever these diseases diagnosed; however, spontaneously occurring disease more common.

CBC/BIOCHEMISTRY/URINALYSIS
Potential for concurrent hepatic, renal, and gastrointestinal disease with cases of vasculitis.

OTHER LABORATORY TESTS
- Dogs with vasculitis—rickettsial serology.
- Cats with vasculitis—feline immunodeficiency virus (FIV) and feline leukemia virus (FeLV) serology, rule out feline infectious peritonitis (FIP).
- Bacterial and fungal cultures with vasculitis or pyogranulomatous inflammation.

DIAGNOSTIC PROCEDURES
Skin biopsy—mandatory for diagnosis of most drug-induced diseases.

PATHOLOGIC FINDINGS
Determined by specific disease process.

TREATMENT
- Discontinue use of offending or suspect drug.
- SJS/TEN—intensive supportive care and fluid/nutritional support because of fluid and protein exudation and risk of sepsis.
- Pain relief when indicated—minimal drug use recommended when drug eruption suspected.

MEDICATIONS

DRUG(S) OF CHOICE
Most conditions respond to immunosuppressive therapy if withdrawal of offending drug alone is insufficient (controversial in case of SJS/TEN).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Avoid offending drug or any other drug in same class or family.

FOLLOW-UP

PATIENT MONITORING
Inpatient—if debilitated.

POSSIBLE COMPLICATIONS
- Secondary infection.
- Electrolyte and plasma protein depletion (SJS/TEN).

EXPECTED COURSE AND PROGNOSIS
- Some reactions appear to activate self-perpetuating immune responses.
- Some drug metabolites may persist for days to weeks and provoke continued response.
- TEN—prognosis poor.
- Vasculitis—prognosis guarded when systemic complications.

MISCELLANEOUS

ABBREVIATIONS
- EM = erythema multiforme.
- FeLV = feline leukemia virus.
- FIP = feline infectious peritonitis.
- FIV = feline immunodeficiency virus.
- SJS = Stevens-Johnson syndrome.
- TEN = toxic epidermal necrolysis.

CUTEREBRIASIS

BASICS

OVERVIEW

• Flies of the genus *Cuterebra* are found in the Americas, where they are obligatory parasites of rodents and lagomorphs. Adult flies lay eggs on blades of grass or in nests; they hatch and crawl onto the skin of passing host. The small maggots enter a body orifice, migrate through various internal tissues, and ultimately over several weeks to months make their way to the skin, where they establish a warble. The mature maggots, which may be an inch long, then drop out of the rodent or rabbit host and pupate in the soil.
• Dogs and cats become infected when they contact a blade of grass upon which an egg containing an infective maggot is stimulated to hatch and attach onto the passing animal. The maggots then crawl around on the cat or dog until they find an orifice in which to enter.
• Dogs and cats can develop maggots in warbles or can develop signs associated with larvae migrating within their tissues.
• Dogs and cats can present with respiratory signs, neurologic signs, ophthalmic lesions, or maggots in their skin.

SIGNALMENT

• Dogs and cats—all ages.
• In northern United States, most cases occur in late summer and early autumn, based on time of emergence of adult egg-laying females in spring and early summer.

SIGNS

• Dermatologic—warble containing bot with protruding spiracles.
• Neurologic—ataxia, circling, paralysis, blindness, recumbency.
• Ophthalmic lesions—larva in conjunctiva.
• Respiratory—eosinophilic respiratory disease.

CAUSES & RISK FACTORS

• Dogs and cats with access to outdoors, where they contact eggs and larvae.
• Neonatal cats have been infected, presumably with larvae carried on queen's fur.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Respiratory—allergies, lungworms, migrating ascarids or hookworms.
• Neurologic—rabies, distemper, angiostrongylosis.
• Ophthalmic lesions—larval *Hypoderma* or *Oestrus*.
• Dermatologic—mature warble unmistakable, young warble may present as pustule or papule.

CBC/BIOCHEMISTRY/URINALYSIS

Eosinophilia may be present, otherwise no specific findings.

OTHER LABORATORY TESTS

N/A

IMAGING

CT, MRI—may show intracranial lesions in cats.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

• Can remove maggots from subcutaneous lesions, eyes, or nares (see Web Video 1).
• Manifestations of lung migration may be alleviated by corticosteroids.
• Neurologic disease has poor prognosis.

MEDICATIONS

DRUG(S) OF CHOICE

• Ivermectin 0.2 mg/kg SC should kill migrating maggots; can be administered either to alleviate signs caused by maggots suspected of migrating in lungs, or to kill larvae in other tissues, including CNS; pretreatment with corticosteroids may mitigate inflammatory reaction to dying worms.
• Products containing isoxazolines (i.e., afoxolaner, fluralaner, lotilaner, andsarolaner), when routinely given to cats and and dogs, may prevent migration and warble formation by *Cuterebra* spp. Efficacy and potential side effects in patients with migrating maggots has not been reported.

FOLLOW-UP

Good return of function following ivermectin treatment is possible.

MISCELLANEOUS

• In northern United States disease is seasonal, with most cases occurring in late summer and early fall when adult flies are active; seasonality is less demarcated in areas where warmer temperatures and active flies occur through longer periods of the year.
• Does not appear to result in prolonged immunity; the same animal can develop skin lesions several years in a row.
• Application of monthly heartworm preventatives (avermectin-containing products), flea development control products (lufenuron-containing products), or topical flea and tick treatments may either prevent the maggots from developing, or may kill them before they access an orifice for entry. However, based on anecdotal information, some cats and dogs on these products still develop warbles with maggots.

ZOONOTIC POTENTIAL

The maggots in the dog or cat pose no zoonotic threat.

Author Dwight D. Bowman
Consulting Editor Amie Koenig

CYANOSIS

BASICS

DEFINITION

A bluish discoloration of the skin and mucous membranes owing to an increase in the amount of reduced, or deoxygenated, hemoglobin within the blood.

PATHOPHYSIOLOGY

• Concentration of deoxygenated hemoglobin—must be >5 g/dL to detect condition; thus anemia may obscure recognition of cyanosis. • Central—associated with systemic arterial hypoxemia or hemoglobin abnormalities. • Peripheral—limited to one or more extremities of the body; associated with diminished peripheral blood flow; arterial oxygen tension and saturation typically normal.

Arterial Hypoxemia

• Low partial pressure of inspired oxygen (e.g., high altitude). • Hypoventilation due to primary neurologic disorders affecting brain, cervical spinal cord, or lower motor neuron; centrally acting respiratory depressant drugs; chest wall injuries; pleural space diseases; upper airway obstructions. • Ventilation–perfusion mismatching resulting in impaired gas exchange (e.g., pulmonary parenchymal or thromboembolic diseases). • Diffusion impairment fromthickening of alveolar barrier through which oxygen must pass to reach red blood cells (RBCs); interstitial lung disease may cause this. • Addition of deoxygenated venous blood to arterial circulation—congenital right-to-left shunting cardiac defects (e.g., tetralogy of Fallot, transposition of great vessels); reversed shunting cardiac defects caused by high pulmonary vascular resistance (e.g., right-to-left shunting patent ductus arteriosus [PDA], atrial septal defect [ASD], ventricular septal defect [VSD]).

Abnormal Hemoglobin

• Methemoglobin—most common abnormal heme pigment; unable to bind oxygen; normally formed at low rate in erythrocytes; cats with significant exposure to acetaminophen will appear cyanotic. • Nicotinamide adenine dinucleotide dependent methemoglobin reductase (NADH-MR)—intracellular reductive enzyme; maintains methemoglobin : hemoglobin ratio at <2%; deficiency and/or exposure to oxidizing agents causes methemoglobinemia. • Hypoxia—when >20–40% of hemoglobin has been oxidized to methemoglobin.

Other

• Peripheral cyanosis—results from increased oxygen extraction from arterial supply to an area (e.g., a limb); caused by severe vasoconstriction, poor peripheral blood flow, obstruction to flow associated with arterial thromboembolism, or stagnation or obstruction of venous blood flow; difficult to see, with exception of discolored paw pads in cats with arterial thromboembolism.
• Differential cyanosis—with reverse shunting PDA, head and neck receive oxygenated blood via brachiocephalic trunk and left subclavian artery, which arise from aortic arch; rest of the body receives desaturated blood through ductus located in descending aorta.

SYSTEMS AFFECTED

• Central—all systems affected.
• Peripheral—may diminish or abolish neuromuscular function of affected limb(s).

SIGNALMENT

• Right-to-left cardiac shunts in association with high pulmonary vascular resistance and pulmonary hypertension (Eisenmenger physiology)—dogs: Keeshond, English bulldog, klee kai, and beagle; some cats; generally young animals. • Tracheal collapse—usually young or middle-aged small-breed dogs (e.g., Pomeranian, Yorkshire terrier, poodles). • Acquired laryngeal paralysis—most common in old large-breed dogs (e.g., retrievers). • Hypoplastic trachea—identified in young English bulldogs; occasionally other breeds. • Brachycephalic airway syndrome—dogs: English and French bulldogs, Pekinese, pugs, Boston terrier, and other brachycephalic breeds. • Asthma—cats: higher incidence reported in Siamese.

SIGNS

Historical Findings

• Central—stridor; respiratory distress; cough; voice change; episodic weakness; syncope; exposure to oxidizing substances or drugs causing methemoglobinemia.
• Peripheral—limb paresis or paralysis.

Physical Examination Findings

• Heart murmur or splitting of second heart sound—with cardiac disease or pulmonary hypertension. • Pulmonary crackles or wheezes—with pulmonary edema or respiratory disease. • Muffled heart sounds—owing to pleural space or pericardial disease.
• Upper airway stridor with laryngeal paralysis.
• Honking cough—typical of tracheal collapse; often induced by tracheal palpation.
• Dyspnea—may be inspiratory, expiratory, or a combination (see Differential Diagnosis).
• Limbs—may be cyanotic, cool, pale, painful, and edematous; can lack a pulse in conditions causing peripheral cyanosis. • Weakness—can be generalized and persistent with severe cardiac diseases; can be episodic and especially noticeable with exercise or excitement.
• Posterior paresis or paralysis—can be seen with distal aorta arterial thromboembolism; differentiated from primary neuromuscular disease by absence (or near absence) of pulses.

CAUSES

Respiratory System

• Larynx—paralysis (acquired or congenital); collapse; spasm; edema; trauma; neoplasia; granulomatous disease. • Trachea—collapse; neoplasia; foreign body; trauma; hypoplasia.
• Lower airway and parenchyma—pneumonia (viral, bacterial, fungal, eosinophilic, mycobacteria, aspiration); chronic bronchitis; hypersensitivity bronchial disease or asthma; bronchiectasis; neoplasia; foreign body; parasites (*Filaroides*, *Paragonimus, Pneumocystis jiroveci*, toxoplasmosis, *Aelurostrongylus* spp.); pulmonary contusion or hemorrhage; noncardiogenic edema (smoke inhalation, snake bite, electric shock); near drowning.
• Pleural space—pneumothorax; infectious (bacterial, fungal, feline infectious peritonitis [FIP]); chylothorax; hemothorax; pyothorax; neoplasia; trauma. • Thoracic wall or diaphragm—congenital (pericardial, diaphragmatic hernia); trauma (diaphragmatic hernia, fractured ribs, flail chest); neuromuscular disease (tick bite paralysis, coonhound paralysis).

Cardiovascular System

• Congenital defects—Eisenmenger physiology (right-to-left shunting PDA, VSD, ASD); tetralogy of Fallot; truncus arteriosus; double outlet right ventricle; anomalous pulmonary venous return; atresia of aortic or tricuspid or pulmonary valves. • Acquired disease—mitral valve disease; cardiomyopathy.
• Pericardial effusion—idiopathic disease; neoplasia. • Pulmonary thromboembolic disease—hyperadrenocorticism; immune-mediated hemolytic anemia; protein-losing nephropathy; dirofilariasis; severe, acute pancreatitis. • Pulmonary hypertension—idiopathic; right-to-left cardiac shunts.
• Peripheral vascular disease—arterial thromboembolism (feline cardiomyopathies); venous obstruction; reduced cardiac output; shock, arteriolar constriction.

Neuromusculoskeletal System

• Brainstem dysfunction—encephalitis; trauma; hemorrhage; neoplasia; drug-induced depression of respiratory center (morphine, barbiturates). • Cervical spinal cord dysfunction—edema; trauma; vertebral fractures; disk prolapse. • Neuromuscular dysfunction—overdose of paralytic agents (succinylcholine, pancuronium); tick bite paralysis; botulism; tetanus; acute polyradiculoneuritis (coonhound paralysis); dysautonomia; myasthenia gravis.

Methemoglobinemia

• Congenital—NADH-MR deficiency (dogs).
• Ingestion of oxidant chemicals—acetaminophen; nitrates; nitrites; phenacetin; sulfonamides; benzocaine; aniline dyes; dapsone.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Generalized—systemic hypoxemia or heme abnormality. • Peripheral only—reduced

blood flow to extremities. • Caudal body—right-to-left shunting PDA. • Cardiac versus respiratory causes—differentiation can be difficult; cardiac murmur may suggest cardiac disease, but murmurs are often heard in older patients with primary respiratory disease; higher hematocrit may make murmurs harder to hear; thoracic radiography and echocardiography useful for differentiation. • Central or peripheral neurologic signs—should prompt concern for arterial hypoxemia owing to primary neuromuscular disease.

Breathing Pattern

• May help define cause. • Inspiratory effort—often associated with obstructive upper airway or pleural space disease; stridor frequently localizes problem to larynx or cervical trachea. • Expiratory effort—generally seen with obstructive lower airway disease. • Rapid shallow (restrictive)—may be associated with pleural space disease or neuromuscular abnormalities of thoracic wall.

CBC/BIOCHEMISTRY/URINALYSIS

• Color of blood—may be darkened; chocolate brown with methemoglobinemia. • Polycythemia—often accompanies congenital heart disease; may occur with chronic hypoxemia owing to severe respiratory disease. • Proteinuria—accompanies protein-losing nephropathies, which may result in secondary pulmonary thromboembolism. • Panhypoproteinemia—accompanies protein-losing enteropathies, which may lead to pulmonary thromboembolism.

OTHER LABORATORY TESTS

• Co-oximetry to estimate percent of methemoglobin or carboxyhemoglobin. • Arterial blood gas analysis. • Urine protein : creatinine ratio—with suspected pulmonary thromboembolism secondary to protein-losing nephropathy.

IMAGING

• Radiography—essential for determining cause. • Echocardiography—aids in diagnosis of congenital or acquired cardiac disease, pulmonary hypertension, and pulmonary thromboembolism. • CT/angiography—can further define obstructive nasal, pulmonary, or pleural space disease; gold standard for diagnosing pulmonary embolism in humans.

DIAGNOSTIC PROCEDURES

• Pulse oximetry to estimate oxygen saturation; inaccurate when carboxyhemoglobin or methemoglobin present. • Laryngoscopic examination—evaluate laryngeal structure and arytenoid function. • Bronchoscopy—often useful in diagnosis of airway and pulmonary diseases. • Transtracheal wash, bronchoalveolar lavage, or fine-needle lung aspirate—often required to characterize bronchopulmonary diseases. • Thoracocentesis—required for diagnosis and treatment of pleural space disorders. • Electrocardiography—may reveal heart enlargement changes; unreliable; echocardiography better. • Lung biopsy—can be necessary for diagnosis of interstitial lung disease.

TREATMENT

• Inpatient—immediate diagnostic testing and treatment. • Stabilization therapy (e.g., oxygen, thoracocentesis, tracheostomy)—usually instituted before aggressive diagnostics. • Specific therapy—depends on ultimate diagnosis; usually exercise restriction and dietary modification required. • Surgical treatment—depends on primary disease process and extent of cardiac or respiratory involvement. • Warn the client when admitting the patient that diseases associated with cyanosis can have dire outcomes.

MEDICATIONS

DRUG(S) OF CHOICE

• Oxygen therapy—provide as soon as possible. • Additional drug therapy depends on final diagnosis. • Furosemide—aggressive use indicated with suspected cardiogenic pulmonary edema. • Methemoglobinemia as result of ingestion of oxidizing substances (acetaminophen)—give acetylcysteine as soon as possible (140 mg/kg PO/IV; then 70 mg/kg q4h for five treatments); cimetidine (10 mg/kg PO; then 5 mg/kg PO q6h for 48h) is useful adjunct to acetylcysteine; ascorbic acid (30 mg/kg PO q6h for seven treatments) may be of some value, but do not use as sole agent; methylene blue given IV followed by oral supplementation reported as successful treatment modality in dogs. • Sildenafil citrate—phosphodiesterase type 5 inhibitor used to treat pulmonary arterial hypertension at 1–3 mg/kg PO q8–12h.

CONTRAINDICATIONS

Avoid using paralytic agents (succinylcholine, pancuronium) and agents that cause profound depression of respiratory center (morphine, barbiturates).

FOLLOW-UP

PATIENT MONITORING

• Patients in an oxygen cage should be disturbed as infrequently as possible for monitoring. • Assess efficacy of therapy—changes in depth and rate of respiration; color of mucous membranes (should return to normal pink color if cause is not anatomic shunt and patient has adequate reserves); pulse oximetry or arterial blood analysis. • Instruct client to monitor mucous membrane color and respiratory effort, and advise immediate veterinary care if cyanotic condition returns.

POSSIBLE COMPLICATIONS

Advanced pulmonary or airway disease and severe cardiac disease—poor long-term prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Obesity—can complicate or exacerbate underlying respiratory or cardiac diseases. • Ascites—can complicate or exacerbate respiratory effort and reduce lung capacity due to cranial displacement of diaphragm.

AGE-RELATED FACTORS

Congenital cardiac abnormalities—usually the cause in young patients.

PREGNANCY/FERTILITY/BREEDING

• Advanced pregnancy may exacerbate signs because of pressure on diaphragm and reduced lung expansion. • Fetuses likely to be harmed or aborted by hypoxemia associated with cyanosis.

SEE ALSO

• Dyspnea and Respiratory Distress.
• Panting and Tachypnea.
• Stertor and Stridor.

ABBREVIATIONS

• ASD = atrial septal defect.
• FIP = feline infectious peritonitis.
• NADH-MR = nicotinamide adenine dinucleotide dependent methemoglobin reductase.
• PDA = patent ductus arteriosus.
• RBC = red blood cell.
• VSD = ventricular septal defect.

Client Education Handout available online

CYCLIC HEMATOPOIESIS

BASICS

OVERVIEW

• Cyclic hematopoiesis in color-dilute gray collie pups, also known as gray collie syndrome, is characterized by frequent episodes of infection with failure to thrive and early death. Systems affected are hematopoietic, ocular, respiratory, gastrointestinal, and skin. Pups may appear normal for the first 4–6 weeks and then develop diarrhea, conjunctivitis, gingivitis, pneumonia, skin infections, joint pain, and fever.
• Episodes of illness, varying from inactivity accompanied by fever to life-threatening infection, repeat at 11–14-day intervals.
• Affected pups are usually smaller than their littermates at birth, weak, and often pushed aside by their mothers.

SIGNALMENT

• Cyclic hematopoiesis in the collie breed is present only in the color-dilute pups. The color dilution and bone marrow disorder are inherited as an autosomal recessive trait. This condition has also been reported in crossbred collie/beagle pups.
• Clinical signs occur as early as 1–2 weeks of age and are always apparent by 4–6 weeks of age. Affected dogs rarely live beyond 2–3 years of age.
• An apparently similar disease was reported in normal-colored pups in two border collie litters in the UK. Cyclic hematopoiesis has also been reported in Pomeranians, Cocker Spaniels, and a Basset Hound, but the disease is not well characterized in these breeds.
• Cyclic hematopoiesis has been observed in two cats with feline leukemia virus (FeLV) infection.

SIGNS

Historical Findings

• Weakness.
• Failure to thrive.
• Conjunctivitis.
• Gingivitis.
• Diarrhea.
• Pneumonia.
• Skin infections.
• Joint pain.
• Coagulopathies.

Physical Examination Findings

• Dilute coat color with color dilution of nasal epithelium.
• Smaller and weaker than normal-colored littermates.
• Fever.
• Watery eyes, reddened gums, tonsillitis, and diarrhea nearly always present during phase of hematopoietic cycle when clinical signs are evident; other signs vary depending on presence of infection in various body systems.
• Signs and symptoms of FeLV in cats.

CAUSES & RISK FACTORS

• Inherited disease in purebred or crossbred collie dogs.
• FeLV infection in cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Coat color dilution and nasal epithelial color dilution are always present in collies or collie mixed breeds with cyclic hematopoiesis.
• Coat color dilution as a result of dilute gene expression is also observed in collies. These dogs have blue or lilac coat color with normal color intensity on nose and do not develop cyclic hematopoiesis.
• Trapped neutrophil syndrome is another autosomal recessive inherited neutropenia in border collie pups who present with recurrent infections and musculoskeletal disease, usually between 6 and 12 weeks of age. Unlike cyclic neutropenia, affected pups have persistent neutropenia. A DNA test for this disease is available.
• Cats will present with signs and symptoms consistent with FeLV infection.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—severe neutropenia, lasting 2–5 days, followed by neutrophilia, and occurring at 11–14-day intervals with mild normocytic to microcytic anemia in dogs; slight to moderate normocytic or macrocytic anemia in cats.
• Local swelling, redness, and systemic signs of infection usually occur during first days of neutrophilic phase of disease cycle; therefore, on initial CBC examination, neutrophilia with moderate monocytosis is usually observed.

OTHER LABORATORY TESTS

A DNA mutation test is available for canine cyclic hematopoiesis from Animal Genetics.

TREATMENT

• Recombinant G-CSF or lentivirus-mediated G-CSF can be administered to shorten period of neutropenia and reduce infections.
• Antibiotics and supportive therapy to treat or relieve symptoms.
• Bone marrow transplantation eliminates cyclic hematopoiesis and can be curative.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics and intravenous fluids as indicated for infections.

FOLLOW-UP

PATIENT MONITORING

Owner advised to watch for signs of infection.

PREVENTION/AVOIDANCE

Dogs should not be boarded with other animals.

POSSIBLE COMPLICATIONS

Infections can be life threatening if untreated.

EXPECTED COURSE AND PROGNOSIS

Intermittent infections are expected. Prognosis is guarded.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Carriers or affected collies should not be bred.

SEE ALSO

• Neutropenia.
• Thrombocytopathies.

ABBREVIATIONS

• FeLV = feline leukemia virus.
• G-CSF = granulocyte colony-stimulating factor.

Suggested Reading

Harvey JW. Veterinary Hematology: A Diagnostic Guide and Color Atlas. St. Louis, MO: Elsevier Health Sciences, 2012, p.148.

Author June C. Huang
Consulting Editor Melinda S. Camus
Acknowledgment The author and book editors acknowledge the prior contribution of Alan H. Rebar.

CYLINDRURIA

BASICS

OVERVIEW

• Increased number of casts in urine sediment. • Occasional hyaline and granular casts can be found in clinically normal animals. • High numbers of casts indicate tubular pathology, but do not correlate with degree of damage. • Can develop with primary renal disease or systemic disorders that secondarily affect kidneys. • Absence of casts does not exclude possibility of renal tubular disease. • Systems affected—renal/urologic.

SIGNALMENT

Dog and cat.

CAUSES & RISK FACTORS

Nephrotoxicosis

• Toxins—ethylene glycol, grape/raisin ingestion (dogs), lily ingestion (cats), hypercalcemia. • Nephrotoxic drugs—e.g., aminoglycosides, amphotericin B, cisplatin, nonsteroidal anti-inflammatory drugs, angiotensin-converting enzyme inhibitors, radiocontrast agents.

Renal Ischemia

• Dehydration. • Low cardiac output. • Renal vessel thrombosis. • Hemoglobinuria. • Myoglobulinuria.

Renal Inflammation

Infectious diseases (e.g., pyelonephritis, leptospirosis, feline infectious peritonitis, tick/vector-borne disease).

Glomerular Disease

• Glomerulonephritis. • Amyloidosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Cylindruria with azotemia and adequately concentrated urine (specific gravity >1.030 in dogs and >1.040 in cats)—consider prerenal disorders such as dehydration. • Cylindruria with azotemia and inadequately concentrated urine—consider renal failure. • Cylindruria with leukocytosis—consider pyelonephritis or other infectious and inflammatory disorders. • Cylindruria with glucosuria and proteinuria—consider renal tubular necrosis. • Transient hyaline and/or granular casts can be seen after strenuous exercise.

CBC/BIOCHEMISTRY/URINALYSIS

• Casts classified by appearance and quantified per low power field. • Granular casts (fine or coarse) associated with tubular degeneration, inflammation, or necrosis. • Hyaline casts can be seen with proteinuria, dehydration, and after diuresis. • Waxy casts usually seen with chronic kidney disease. • Epithelial casts formed from degeneration of renal tubular epithelial cells; most commonly seen with acute tubular injury. • White blood cell (WBC) casts indicate renal inflammation (e.g., pyelonephritis). • Red blood cell (RBC) casts indicate renal hemorrhage. • Fatty casts suggest renal tubular injury. • Chemistry profile may show azotemia and hyperphosphatemia. • CBC may show anemia, erythrocytosis, leukocytosis, and/or thrombocytopenia depending on underlying pathology.

OTHER LABORATORY TESTS

• Determine urine protein : creatinine ratio to evaluate magnitude of proteinuria. • Perform urine culture to rule out urinary tract infection in patients with pyuria or WBC casts. Also consider ultrasound ± radiography to assess for pyelonephritis, nephroliths, etc. • Test for systemic infections as indicated. • If thrombocytopenic or RBC casts are present, perform coagulation studies to rule out consumptive coagulopathy such as disseminated intravascular coagulation.

Disorders That May Alter Laboratory Results

• Delayed processing of urinalysis and examination of urine sediment may result in disappearance of casts; ideally should be examined within 30 minutes of collection. • Alkaline urine can cause dissolution of casts. • Low speed centrifugation necessary to prevent cast destruction.

Valid If Run in Human Laboratory?

Yes

DIAGNOSTIC PROCEDURES

Consider renal biopsy if kidney disease persists or progresses and cause cannot be determined from routine diagnostic tests.

TREATMENT

• Manage as outpatient unless patient is dehydrated or has decompensated kidney failure. • Acute kidney injury and chronic kidney disease should be managed according to standard recommendations. • If patient cannot maintain hydration, administer parenteral fluid therapy. • Consider dialysis if toxin exposure or leptospirosis infection.

MEDICATIONS

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid nephrotoxic drugs.

FOLLOW-UP

PATIENT MONITORING

• Physical examination including patient's weight to assess hydration status. • Blood pressure monitoring. • CBC/chemistry/urinalysis monitoring.

PREVENTION/AVOIDANCE

Avoid or correct risk factors (e.g., exposure to toxins, infectious disease prevention, etc.).

POSSIBLE COMPLICATIONS

Irreversible renal disease, depending on underlying cause of cylindruria.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Possible in patients with leptospirosis. Use safety precautions when handing urine.

SEE ALSO

Nephrotoxicity, Drug-Induced.

ABBREVIATIONS

• RBC = red blood cell. • WBC = white blood cell.

CYTAUXZOONOSIS

BASICS

OVERVIEW
- Infection with the protozoan *Cytauxzoon felis*.
- Affects vascular system of lungs, liver, spleen, kidneys, and brain; bone marrow and developmental stages of red blood cells (RBCs) affected as well.
- Uncommon in most regions, but common during the spring and summer in endemic regions.
- Affects feral and domestic cats in south-central, southeastern, and mid-Atlantic United States; range appears to be expanding towards eastern and northeastern United States.
- Related *Cytauxzoon* spp. have been identified in Europe and Asia, but have not been associated with classic Cytauxzoonosis (see Signs) as seen in North America.

SIGNALMENT
- Domestic cats of all ages.
- Wild felids are also at risk.
- No breed or sex predilection, although most cases are diagnosed in young cats that have access to outdoors.

SIGNS
- Most cats have severe illness at presentation.
- Pale mucous membranes.
- Depression.
- Anorexia.
- Dehydration.
- High fever.
- Icterus.
- Splenomegaly.
- Hepatomegaly.
- Some cats may be infected but asymptomatic.

CAUSES & RISK FACTORS
- Bite of infected tick (primarily *Amblyomma americanum* or *Dermacentor variabilis*).
- Roaming in areas shared by reservoir hosts (bobcats).
- Living in same household/region as cat diagnosed with cytauxzoonosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other causes of pancytopenia such as sepsis and panleukopenia.
- Other causes of fever and jaundice such as pancreatitis, hepatitis, and cholangitis.

CBC/BIOCHEMISTRY/URINALYSIS
- Bicytopenia or pancytopenia are the most common findings; thrombocytopenia is almost always present.
- Moderate hyperbilirubinemia and bilirubinuria.
- Mild hyperglycemia.
- If present, anemia is believed to be secondary to hemolysis.

OTHER LABORATORY TESTS
- Fresh blood smear—*Cytauxzoon* erythrocytic form; 1–3 µm in diameter; shape of signet ring or safety pin.
- Schizont-infected monocyte/macrophages may be observed on feathered edge of thin blood smears.
- Splenic, lymph node, liver, or bone marrow aspirate—best suited to demonstrate extra-erythrocytic schizont forms.
- PCR assay is commercially available.
- Blood type in all cats prior to transfusion.

IMAGING
Radiographs or ultrasound may assist in identifying pleural effusion or pulmonary edema.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
Organisms inside myeloid cells in bone marrow aspirate and in dramatically enlarged myeloid cells in vessels of multiple organs including lung, liver, spleen, kidney, and brain.

TREATMENT
- Inpatient with aggressive supportive therapy including supplemental oxygen.
- Blood transfusion.
- Feeding tube for medication and nutritional support.

MEDICATIONS

DRUG(S) OF CHOICE
- Combination of atovaquone (15 mg/kg PO q8h with a fatty meal) and azithromycin (10 mg/kg PO q24h) and supportive care is associated with survival rates of 60%.
- Imidocarb dipropionate—5 mg IM two injections 14 days apart has been recommended, but is associated with survival rates of approximately 27%.
- Heparin (100–300 U/kg SC q8h or 300–900 U/kg/day as IV CRI) until time of discharge (longer if significant thrombosis such as pulmonary thromboembolism is present).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- With aggressive supportive care and treatment, expect 3–7 days of hospitalization with severe illness.
- Some cats develop pleural effusion and require thoracocentesis.
- Cats that survive will return to normal within 2–4 weeks of discharge and appear immune to reinfection.
- Some cats remain persistently infected with the intraerythrocytic form without overt signs.
- Without treatment, most cats with acute cytauxzoonosis have died within 5 days of presentation.

MISCELLANEOUS

ZOONOTIC POTENTIAL
- No known risk to humans.
- Cannot be directly transmitted to another cat except by blood or tissue inoculation.

ABBREVIATIONS
- RBC = red blood cell.

Suggested Reading

Cohn LA, Birkenheuer AJ, Brunker JD, et al. Efficacy of atovaquone and azithromycin or imidocarb dipropionate in cats with acute cytauxzoonosis. J Vet Intern Med 2011, 25(1):55–60.

Reichard MV, Thomas JE, Arther RG, et al. Efficacy of an imidacloprid 10%/flumethrin 4.5% collar (Seresto®, Bayer) for preventing the transmission of *Cytauxzoon felis* to domestic cats by *Amblyomma americanum*. Parasitol Res 2013, 112(Suppl. 1):11–20.

Consulting Editor Amie Koenig

DEAFNESS

BASICS

DEFINITION
- Partial or complete hearing loss.
- Two forms:
  - Sensorineural deafness—caused by damage to receptors in cochlea, cochlear nerve, or auditory pathways in CNS.
  - Conduction deafness—caused by inability to conduct sound vibration through external to inner-ear structures.

PATHOPHYSIOLOGY

Sensorineural Deafness
- Hereditary—breed-related cochlear degeneration closely associated with the recessive alleles of the piebald locus and the dominant allele of the merle locus in dogs and with the dominant allele of the white locus in cats. These genes alter the ability of neural crest melanocytes to populate regions of the body including skin, hair, iris, ocular tapetum, and portions of the cochlea. The absence of melanocytes in the stria vascularis of the cochlea is associated with early postnatal degeneration of this structure. Can also be non-pigment-associated and in some cases also affect the vestibular system, such as in Doberman pinschers (associated with a mutation in the PTPRQ gene).
- Acquired—cochlear degeneration due to chronic infection, ototoxicity, neoplasia, chronic exposure to loud noises, anesthesia-associated, or age-related loss of hair cells and spiral ganglion cells (presbycusis).

Conduction Deafness
- Congenital defects in external ear canal, tympanic membrane, or ossicles that transmit vibration in middle ear are rare. Hereditary predisposition in primary secretory otitis media in the cavalier King Charles spaniel.
- Acquired defects resulting in stenosis/obstruction of external ear canal, rupture of tympanic membrane, or fusion of bony ossicles; most commonly associated with chronic otitis or middle ear polyps.

SYSTEMS AFFECTED
Nervous—inner ear.

GENETICS
Genetics of congenital deafness not fully understood, although strong association with the piebald and the merle locus in dogs and dominant white locus in cats (pigment-associated genes related to coat color).

INCIDENCE/PREVALENCE
Prevalence of congenital deafness in one or both ears available for the following breeds—Dalmatian: 30% in United States, 18% in UK, 17% in Switzerland, 20% in Germany; Jack Russell terrier: 4% in United States; Australian cattle dog: 15% in United States, 10% in Australia; English bull terrier: 11% (20% if white) in UK; English setter: 8% in United States; English cocker spaniel: 7% in United States; border collie: 2–3% in UK; purebred white cats: 20% in United States and Germany; non-purebred white cats: 50% in UK and United States.

GEOGRAPHIC DISTRIBUTION
Prevalence for different breeds varies between countries.

SIGNALMENT
- Breed-related congenital cochlear degeneration described in >90 breeds of dogs. Most breeds have a large amount of white pigmentation associated with merle or piebald genes, except for Doberman pinscher, puli, Shropshire terrier. Congenital sensorineural deafness present by 6 weeks of age, although has late onset in border collie (5 years) and Rhodesian ridgeback (4–12 months).
- No association with gender. Dogs with blue iris color have a higher incidence of congenital deafness.
- Mixed-breed cats with white hair coat and blue irises—high incidence of deafness. Purebred white cats that carry the Siamese gene for blue eyes have a lower incidence of congenital deafness.
- Acquired deafness may occur in any breed or age of dog and cat.

SIGNS
- Unilateral deafness often goes unnoticed. Rarely, dogs have difficulty localizing sound.
- With bilateral disease, animals do not respond to auditory cues such as calling their name or rattling food dish. Often they are easily startled. Commonly have heightened response to vibration and visual cues.

CAUSES

Sensorineural Deafness
- Genetic etiology likely in neonates.
- Acquired cochlea and cochlear nerve damage—infectious (otitis interna), neoplasia of bony labyrinth or nerve, trauma (physical or noise), systemic or topically applied drugs or toxins (antibiotics: aminoglycosides, polymyxin, erythromycin, vancomycin, chloramphenicol; antiseptics: ethanol, chlorhexidine, cetrimide; antineoplastics: cisplatin, carboplatin; diuretics: furosemide; heavy metals: arsenic, lead, mercury; miscellaneous: ceruminolytic agents, propylene glycol, salicylates), presbycusis, anesthesia-induced.

Conduction Deafness
- Otitis externa and other external ear canal disease (e.g., stenosis of canal, foreign bodies, neoplasia, or ruptured tympanum).
- Otitis media, middle-ear polyps, primary secretory otitis media.

RISK FACTORS
- Merle, piebald gene, or white coat color; blue eye color.
- Chronic otitis externa, media, or interna.
- Use of ototoxic drugs.
- General anesthesia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Early age of onset—suggests congenital causes in predisposed breeds.
- Use of ototoxic drugs, recent anesthesia, or chronic ear disease—suggests acquired causes.
- Evaluate for brain disease.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS
- Bacterial culture and sensitivity of ear canal if otitis externa.
- Myringotomy with culture of aspirates if otitis media.

IMAGING
- Tympanic bullae and skull radiographs—may show soft tissue opacity and bone remodeling of tympanic bulla; often unremarkable in cases with otitis media/interna.
- Ultrasound of tympanic bullae—may show anechoic content in cases with otitis media/interna, but low sensitivity.
- CT/MRI—higher sensitivity for middle–inner ear disease and intracranial pathology.

DIAGNOSTIC PROCEDURES
- Brainstem auditory evoked response (BAER)—gold standard test for evaluation of hearing. Measures electrical response of cochlea and auditory pathways in the brain to an auditory stimulus; reliable to identify dogs with unilateral disease or partial hearing loss. Bone conduction stimulation can be useful to distinguish sensorineural from conduction deafness. Can be used to determine the hearing threshold.
- Otoacoustic emissions (OAEs)—low-level sounds produced by inner ear as part of the normal hearing process that can be measured by placing a probe containing a microphone in the external ear canal. Two forms have been used in dogs for assessment of sensorineural deafness—transient evoked OAEs (TEOAEs) and distortion product OAEs (DPOAEs). OAE is best suited for cases with congenital deafness, as it tests outer hair cell function and is not affected by inner hair cell, synapse, or cochlear nerve deficiencies. DPOAEs may show benefits in assessing age-related and noise-induced hearing loss and may reduce cost and testing times in congenital sensorineural deafness compared to BAER.

PATHOLOGIC FINDINGS
- Congenital deafness—degeneration of the stria vascularis with subsequent collapse of membranous labyrinth structures. Bony labyrinth remains intact.

DEAFNESS (CONTINUED)

• Acquired deafness—related to primary disease such as otitis or neoplasia.
• Ototoxicity—degeneration of otic hair cells, cochlear nerve degeneration, and loss of stria vascularis.

TREATMENT

CLIENT EDUCATION
Deaf animals may be functional pets, but require patience, specialized training, and extra protection from traffic.

SURGICAL CONSIDERATIONS
• Directed toward acquired causes; congenital deafness irreversible.
• Otitis externa, media, or interna—medical or surgical approaches depend on culture and sensitivity test results, response to antibiotics, and imaging findings. Conduction may improve as otitis externa or media resolves.
• Cochlear implants can be used in dogs with moderate to profound deafness, but only preliminary data available and very expensive.

MEDICATIONS

DRUG(S) OF CHOICE
• None for congenital deafness.
• Treat otitis based on culture and sensitivity results.

PRECAUTIONS
• Aminoglycosides or other ototoxic drugs—use with caution.
• Topical treatment of external ear canal—avoid if tympanic membrane is ruptured.

FOLLOW-UP

PATIENT MONITORING
As needed for management of otitis.

POSSIBLE COMPLICATIONS
Deaf dogs need protected environments and training to be functional pets.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
Dogs homozygous for recessive merle gene can be blind and sterile.

ABBREVIATIONS
• BAER = brainstem auditory evoked response.
• DPOAE = distortion product OAE.
• OAE = otoacoustic emission.
• TEOAE = transient evoked OAE.

Author Rita Gonçalves

Client Education Handout available online

DECIDUOUS TEETH, PERSISTENT (RETAINED)

BASICS

OVERVIEW

• A persistent (retained) deciduous tooth is one that is still present when the permanent tooth begins to erupt or has fully erupted. • Numerous factors influence the exfoliation of deciduous teeth—lack of a permanent successor; ankylosis of the deciduous crown or root to the alveolus; failure of the developing permanent crown to contact the deciduous root, preventing resorption of the deciduous root during eruption.

SIGNALMENT

• More common in dogs than cats. • More common in small-breed dogs (e.g., Maltese, poodle, Yorkshire terrier, Pomeranian, etc.). • Occurs during permanent tooth eruption phase, which begins at 3 months of age for incisors and 5–7 months of age for canine teeth and molars. • Persistent deciduous teeth may not be detected or diagnosed until later in life. • No sex predilection.

SIGNS

General Comments

• Persistent deciduous teeth can cause the permanent teeth to erupt in an abnormal position resulting in a malocclusion; early recognition and intervention are essential. • Maxillary canine teeth erupt mesial (rostral) to the persistent deciduous canine teeth; this can result in a diastema (space) between the maxillary canine tooth and the third incisor that is too narrow to accommodate the crown zcanine position is referred to as mesioversion. • Mandibular canine teeth erupt lingual to the persistent deciduous teeth; this can result in a narrow space between the lower canines resulting in impingement on the soft tissue of the hard palate. The mandibular canine position is referred to as linguoversion. • All permanent incisors erupt lingual to the persistent deciduous incisors; this can result in a rostral crossbite.

Physical Examination Findings

• Presence of a deciduous tooth with the permanent tooth erupting or fully erupted. • Abnormal position of the permanent tooth due to persistence of the deciduous tooth. • Oral malodor from accumulation of debris and plaque due to crowding of the permanent tooth and the persistent deciduous tooth. • Local gingivitis and periodontal disease due to plaque accumulation from crowding. • Oronasal fistula from linguoversion of the permanent mandibular canine teeth. • Deciduous tooth crown is usually smaller than the permanent tooth. • Deciduous tooth might not have an underlying permanent tooth, and will often remain intact and vital.

CAUSES & RISK FACTORS

• Cause is unknown, but is suspected to have a genetic basis. • Small-breed dogs are predisposed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Supernumerary teeth. • Gemination of the crown.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

IMAGING

Intraoral Radiography

• Distinguish between permanent tooth and deciduous tooth. • Provide evidence or extent of root resorption of the deciduous tooth. • Identify dental abnormalities prior to extraction, including persistent deciduous tooth with no permanent successor, retained root with crown missing, and unerupted permanent tooth. • Identify relationship of deciduous root and permanent crown prior to extraction.

DIAGNOSTIC PROCEDURES

• Complete oral examination—chart oral cavity to indicate presence of persistent deciduous teeth, malpositioned teeth, missing teeth, soft tissue trauma, and other oral abnormalities. • Appropriate preoperative diagnostics prior to procedure to include intraoral radiography.

PATHOLOGIC FINDINGS

N/A

TREATMENT

Client Education

• Persistent deciduous teeth may be prevalent in certain breeds. • Start looking at teeth from the first puppy or kitten visit. • Inform owners that you will be evaluating for exfoliation of deciduous teeth as well as for proper eruption of permanent teeth.

Surgical Considerations

• Extract the deciduous tooth as soon as the permanent tooth has erupted through the gingiva. • Pain management - local/regional and systemic. • Intraoral radiographs. • General anesthesia with endotracheal tube in place and cuff inflated. • Elevation of deciduous tooth. • Careful, gentle elevation is critical; excessive force or pressure can damage the developing permanent tooth (and other underlying structures). • A fractured or retained root may need to be removed with a gingival flap. • If a permanent tooth has erupted in an abnormal position, full root extraction of the deciduous tooth is necessary. • If the deciduous root has undergone resorption, it may not need to be extracted.

MEDICATIONS

DRUG(S) OF CHOICE

• Topical oral antimicrobial rinse prior to extraction. • Pain management prior to, during, and following extraction.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

• After surgery, restrict activity for the rest of the day. • Analgesia (nonsteroidal anti-inflammatory drug [NSAID]) for 24–36 hours postop. • Soft diet for 3 days—canned food or moistened dry kibble. • No chew toys for 3 days; no "tug of war" for 1 week. • Oral chlorhexidine rinse for 3–5 days. • Continue daily tooth brushing after 24 hours.

PREVENTION/AVOIDANCE

May be prevalent in certain breeds and lines—avoid similar breeding.

POSSIBLE COMPLICATIONS

• Malocclusion that results after full eruption of permanent teeth may require treatment. • Linguoversion of one or both mandibular canine teeth. • Mesioversion of one or both maxillary canine teeth.

EXPECTED COURSE AND PROGNOSIS

• Once extracted, there should be no further problems. • Resulting malocclusion needs further evaluation. • Gingiva generally heals uneventfully.

MISCELLANEOUS

SEE ALSO

Malocclusions—Skeletal and Dental.

ABBREVIATIONS

• NSAID = nonsteroidal anti-inflammatory drug.

DEEP CUTANEOUS MYCOSES

BASICS

DEFINITION
• Fungal infections that may secondarily disseminate by hematogenous route to the skin.
• Most often caused by cryptococcosis, blastomycosis, and coccidioidomycosis.

PATHOPHYSIOLOGY

Cryptococcosis
Main route of infection is inhalation and colonization of nasal mucosa, followed by hematogenous spread to lymph nodes, skin, bones, and CNS.

Blastomycosis
• Infection by inhalation of spores produced from mycelial growth in the environment.
• Spores settle in airways, transform into yeast forms, and establish a primary infection of the lungs, followed by dissemination via blood and lymphatic vessels.
• Colonize lymph nodes, skin, eyes, bones, CNS, and testes.

Coccidioidomycosis
• Infection by inhalation of arthroconidia.
• In the lungs, arthroconidia transform into spherules filled with endospores, which disseminate by hematogenous routes to bones, skin, eyes, heart, testes, CNS, liver, and kidneys, among others.

SYSTEMS AFFECTED
Systemic infections via inhalation with hematogenous dissemination to multiple organs—skin, lymph nodes, eyes, bones, CNS, testes.

GENETICS
N/A

INCIDENCE/PREVALENCE
• Uncommon diseases,
• Incidence depends on geographic location; can be very high (e.g., coccidioidomycosis in areas of Arizona).

GEOGRAPHIC DISTRIBUTION

Cryptococcosis
• *C. neoformans* worldwide distribution.
• *C. gattii* associated with tropical and subtropical climates.
• Recognized also in North America and British Columbia (Vancouver Island).

Blastomycosis
Areas of the United States and Canada surrounding the Ohio and Mississippi River valleys, the Great Lakes, and the Saint Lawrence River.

Coccidioidomycosis
Southwestern United States, Mexico, and areas of Central and South America.

SIGNALMENT

Cryptococcosis
• Young dogs and cats; more common in cats.
• Siamese, Birman, and ragdoll cats
• Doberman pinscher, German shepherd dogs, and cocker spaniels.

Blastomycosis
• Young dogs (1–3 years); rare in cats.
• Doberman pinscher.
• Increased incidence in male dogs

Coccidioidomycosis
• Young dogs; rare in cats.
• Boxer and Doberman pinscher predisposed.
• Increased incidence in males.

SIGNS

Historical Findings
• Nonspecific clinical signs (asthenia, weakness, anorexia, weight loss), respiratory signs, or the appearance of skin lesions in the animal.
• Upper respiratory signs—cryptococcosis and blastomycosis.
• Lameness—coccidioidomycosis.

Physical Examination Findings (Skin)
Cryptococcosis
• Cat—multiple papules, nodules, abscesses, and ulcers; bridge of nose/dorsal muzzle (primary site) or any skin ara; lesions may drain a serous exudate.
• Dog—papules, dermal-subcutaneous nodules or ulcers; located on any portion of the integument, lips, tongue, or claw beds.

Blastomycosis
Dog—draining tracts and abscesses in one-third of cases; *Planum nasale*, face, and claw bed most frequent locations.

Coccidioidomycosis
Dog—dermal nodules that progress to abscesses and ulcers, or draining tracts over sites of infected bone; *Coccidioides* infection may also be asymptomatic.

CAUSES

Cryptococcosis
• Dimorphic fungi.
• Filamentous form in the environment.
• Yeast phase in mammalian tissues.
• Genus *Cryptococcus* includes 40 species—most infections in dogs and cats caused by *C. neoformans* and *C. gattii*.
• *C. neoformans* often found in soils associated with bird excrement.
• *C. gattii* found in soils, especially in those covered with leaves of some tree species (eucalyptus), and in the bark of some trees (oak, maple, cedar).

Blastomycosis
• Dimorphic fungus.
• Mycelial form lives in moist soil and in decomposing organic matter such as wood and leaves.
• Yeast form in the mammal host causes disseminated infection.

Coccidioidomycosis
• Dimorphic saprophytic fungi.
• Found in sandy, alkaline soils with high environmental temperature.
• Main infectious species *Coccidioides immitis* and *C. posadasi*.

RISK FACTORS
• Immunosuppressed hosts are more predisposed to develop cryptococcosis caused by *C. neoformans*.
• Living in or visiting endemic areas increases risk of cryptococcosis (*C. gattii*), blastomycosis, and coccidioidomycosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Deep staphylococcal pyoderma.
• Nocardiosis.
• Actinomycosis.
• Mycobacterial infections.
• Pseudomycetoma (cat).
• Chromoblastomycosis.
• Pheohyphomycosis.
• Hyalohyphomycosis.
• Leishmaniasis.
• Sterile nodular panniculitis.
• Sterile pyogranuloma syndrome.
• Eosinophilic granuloma.

CBC/BIOCHEMISTRY/URINALYSIS
• Generally nonspecific—nonregenerative anemia, leukocytosis, monocytosis, eosinophilia.
• Serum biochemical profile may reflect specific organ involvement; hypoalbuminemia and hyperglobulinemia common.

OTHER LABORATORY TESTS

Cryptococcosis
• Detection of cryptococcal polysaccharide capsular antigen in serum using a latex agglutination technique.
• Organism can be cultured in Sabouraud agar from skin lesions.

Blastomycosis
Measuring antibodies in serum (agar gel immunodiffusion [AGID], ELISA) assists in diagnosis of blastomycosis when organisms cannot be specifically identified in cytologic or histologic specimens.

Coccidioidomycosis
• Conclusively diagnosed by cytologic or histologic visualization of the organism.
• Detection of antibodies (AGID, ELISA) commonly used when the organism cannot be demonstrated in cytology or biopsy samples.
• *Coccidioides* grows in common culture media.

(CONTINUED) DEEP CUTANEOUS MYCOSES

• Exposure to mycelial growth in cultures a potential hazard to humans—organism should not be cultured outside of qualified laboratories with proper warning of the differential diagnosis.

IMAGING
• Radiographs-- evaluate for the presence of lesions in the upper airways, lungs, and bones.
• Ultrasound imaging—to evaluate for the presence of lesions in the abdominal cavity.

DIAGNOSTIC PROCEDURES
• Cytologic evaluation of all cutaneous lesions (papules, nodules, abscesses) by fine-needle aspirate of solid lesions or impression smears of exudates.
• Cytologic preparations usually reveal a pyogranulomatous exudate with the presence of the causal organism.
• Cryptococcosis—number of organisms is very high and they are easily detected.
• Blastomycosis and coccidioidomycosis—detection of the fungal elements more difficult. If cytologic preparations are inconclusive, a skin biopsy for histopathologic examination should be obtained.
• Histologically, these diseases are characterized by a nodular to diffuse pyogranulomatous dermatitis and panniculitis, with the presence of the causal organisms.

PATHOLOGIC FINDINGS
Chronic pyogranulomatous reaction with the presence of organisms in tissues.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient medical management, unless severe internal lesions (meningoencephalitis, severe kidney disease).

NURSING CARE
N/A

ACTIVITY
Normal activity.

DIET
N/A

CLIENT EDUCATION
Owners should be informed of the risk involved in visiting areas where these infections are endemic.

SURGICAL CONSIDERATIONS
Surgical excision of large tissue masses infected with *Cryptococcus* (skin nodules, lymph nodes, nasopharyngeal masses) when possible.

MEDICATIONS

DRUG(S) OF CHOICE
Cryptococcosis
• Itraconazole (5 mg/kg PO q12–24h).
• Fluconazole (10 mg/kg PO q12–24h).
• Treatment maintained for 6–18 months—until resolution of clinical disease.
• Some authors recommend continued antifungal therapy until the cryptococcal antigen is zero.

Blastomycosis
• Itraconazole (5 mg/kg PO q12–24h).
• Fluconazole (10 mg/kg PO q12–24h).
• Treatment continued for at least 60 days and at least 1 month after all signs of disease have resolved.

Coccidioidomycosis
• Fluconazole (10 mg/kg PO q12–24h).
• Itraconazole (5 mg/kg PO q12–24h).
• Treatment is prolonged—treat for at least 1 year and/or until resolution of clinical disease.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
Azole antifungals, especially ketoconazole, are inhibitors of cytochrome P450 (CYP) and can increase serum levels of other drugs that are metabolized by this route (e.g., cyclosporine).

ALTERNATIVE DRUG(S)
Cryptococcosis
Amphotericin B and flucytosine for CNS and/or resistant infection.

Blastomycosis
Amphotericin B for resistant infection.

Coccidioidomycosis
• Ketoconazole (5–10 mg/kg PO q12–24h)—if fluconazole or itraconazole is not available.
• Side effects more common and more severe with ketoconazole than with the other two azoles in cats.

CONTRAINDICATIONS
• Ketoconazole is hepatotoxic and should not be prescribed to patients with liver damage.
• Amphotericin B is nephrotoxic and is contraindicated in patients with kidney damage.

FOLLOW-UP

PATIENT MONITORING
The frequency of monitoring depends on the severity and location of the lesions.

PREVENTION/AVOIDANCE
Avoid visiting areas where these infections are endemic.

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
• Prognosis is guarded; depends on the affected organs.
• Poor prognosis with CNS involvement in cryptococcosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

ZOONOTIC POTENTIAL
• Cryptococcosis, blastomycosis, and coccidioidomycosis are not considered zoonoses.
• Infected dogs and cats pose no public health threat because infective forms are not produced in tissues.
• Handling mycelial cultures of the organism in the laboratory is dangerous.

PREGNANCY/FERTILITY/BREEDING
• Vertical transmission of cryptococcosis and blastomycosis has been reported in humans—considered extremely rare and not reported in dogs and cats.
• Intrauterine transmission of coccidioidomycosis not likely to occur because of the large size of the spherules.

SYNONYMS
• Cryptococcosis—torulosis, European blastomycosis.
• Blastomycosis—Gilchrist disease, Chicago disease.
• Coccidioidomycosis—valley fever, San Joaquín Valley fever.

ABBREVIATIONS
• AGID = agar gel immunodiffusion.

DEMODICOSIS

BASICS

DEFINITION
An inflammatory parasitic disease of dogs and cats characterized by an increased number of demodectic mites in the hair follicles and on the epidermis.

PATHOPHYSIOLOGY
Dogs
• Three species of mites identified in the dog: ○ *Demodex canis*—follicular mite; part of the normal fauna of the skin; typically present in small numbers; resides in the hair follicles and sebaceous glands of the skin, transmitted from the mother to the neonate during the first 2–3 days of nursing. ○ *Demodex injai*—large, long-bodied mite found in the pilosebaceous unit, mode of transmission unknown; only associated with adult-onset disease, with highest incidence noted in the terrier breeds often along the dorsal midline (West Highland white terrier and wirehaired fox terrier).○ *Demodex cornei*—lives in the stratum corneum of the epidermis; mode of transmission unknown; most likely a morphologic variant of *D. canis*. • Proliferation of mites may be the result of immunologic disorder, either genetic or iatrogenic. • Pruritus occurs when a secondary bacterial infection is present.

Cats
• Two species of mites identified in the cat: ○ *Demodex gatoi*—contagious; can be asymptomatic, but most commonly is associated with pruritic dermatitis leading to self-trauma, alopecia, and barbering. ○ *Demodex cati*— often associated with immunosuppressive and metabolic disease; these mites cause folliculitis and alopecia, but are rarely pruritic.

SYSTEMS AFFECTED
Skin/exocrine.

GENETICS
Initial proliferation of mites may be the result of a genetic disorder.

INCIDENCE/PREVALENCE
• Dogs—*D. canis* is very common. • Cats—depending on geographic location, *D. gatoi* may be common or rare; *D. cati* is rare.

SIGNALMENT
Species
Dogs and cats.

Breed Predilections
• *D. canis*—American Staffordshire terrier, shar-pei, Boston terrier, English bulldog, and West Highland white terrier. • *D. injai*—West Highland white and wirehaired fox terriers, shih tzu. • Potential increased incidence in Siamese and Burmese cats.

Mean Age and Range
• Juvenile onset, localized—usually in dogs <1 year of age; median 3–6 months, typically <5 lesions. • Generalized—both young and old animals. • *D. cati* may be more common in middle-aged or older cats; *D. gatoi* seems to be more common in younger cats and kittens, but any age can be affected.

SIGNS
Dogs
• Patchy alopecia—most common site is the face, especially around the perioral and periocular areas and forelegs; may also be seen on the trunk and feet. • Pododemodicosis—lesions localized to the feet. • Disease can progress to become or begin with a generalized distribution. • Usually not pruritic unless secondarily infected. • Hair follicles distended with large numbers of mites, lose hair and develop secondary bacterial folliculitis, followed by rupturing of the follicles (furunculosis). • With progression, the skin becomes severely inflamed, exudative, and granulomatous. • *D. injai* may be associated with greasy seborrheic dermatitis of the dorsal trunk, comedones, erythema, alopecia, and hyperpigmentation.

Cats
• *D. cati*—partial to complete alopecia of the eyelids, periocular region, head, neck, flank, and ventrum. • *D. gatoi*—pruritus with dramatic scaling, erythema, and/or crusting due to inflammation and self-trauma. • Ceruminous otitis externa has been reported. • *D. cati* often associated with immunosuppressive disease.

CAUSES
• Dog—*D. canis*, *D. injai*, and *D. cornei*.
• Cat—*D. cati* and *D. gatoi*.

RISK FACTORS
Dogs
• Exact immunopathologic mechanism unknown. • Dogs with generalized demodicosis may have abnormal or depressed T-cell function. • Development associated with oclacitinib treatment. • Genetic factors (especially juvenile onset), immunosuppression, and/or metabolic diseases may predispose animal.

Cats
• *D. cati*—often associated with metabolic diseases that affect the immune system (e.g., feline immunodeficiency virus [FIV], hyperadrenocorticism, diabetes mellitus).
• *D. gatoi*—considered contagious; cats in contact with other cats are at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Dogs
• Bacterial folliculitis/furunculosis. • Dermatophytosis. • Any cause of inflammatory alopecia.

Cats
• Allergic dermatitis. • Dermatophytosis.
• Any cause of alopecia or pruritus.

CBC/BIOCHEMISTRY/URINALYSIS
Normal unless there is an underlying process.

OTHER LABORATORY TESTS
• Feline leukemia virus (FeLV) and FIV serology. • Fecal samples—rare finding of mites in feces; more common with cats.

DIAGNOSTIC PROCEDURES
• Skin scrapings diagnostic for finding mites in most cases—*D. gatoi* may be difficult to find. • Hair plucking can be used in areas such as eyelids. • Skin biopsy—may be needed when lesions are chronic, granulomatous, and fibrotic (especially on the foot); may be needed to diagnose demodicosis in the shar pei breed.

TREATMENT

APPROPRIATE HEALTH CARE
• Localized *D. canis* lesions often (90%) resolve spontaneously. • Evaluate the health status of patients presenting with generalized lesions of demodicosis.

CLIENT EDUCATION
• Localized—most cases resolve spontaneously. • Generalized—frequent management problem due to chronicity. Juvenile onset considered to have an inheritable predisposition—breeding of affected animals is not recommended.

MEDICATIONS

DRUG(S) OF CHOICE
Dogs
Isoxazolines antiparasitics
• Treatment of choice—excellent efficacy against demodicosis at label doses for fleas; safe for avermectin-sensitive dogs. • Side effects uncommon—vomiting, diarrhea, inappetence, or neurologic signs including seizures.

Ivermectin
• 0.3–0.6 mg/kg q24h PO very effective; initiate therapy with a test dose of 0.12 mg/kg q24h for first week to observe for any signs of sensitivity. • Treat for 30–60 days beyond negative skin scrapings (average 3–8 months). • Non-FDA-approved usage—do not use in avermectin-sensitive (ABCB-1 mutation) breeds.

Milbemycin Oxime
• 1–2 mg/kg PO q24h cures 50% of cases; 2 mg/kg PO q24h cures 85% of cases.

• ABCB-1 mutation individuals may have neurologic signs with higher doses; tolerate milbemycin better than other drugs in this class. • Non-FDA-approved usage.

Moxidectin

• 0.3 mg/kg PO q24h or topical application once weekly. • Non-FDA-approved usage—do not use in avermectin-sensitive (ABCB-1 mutation) breeds.

Amitraz

• Applied in the United States as a 250 ppm (0.025%) dip every 14 days and in Europe as a 500 ppm (0.05%) dip every 7 days. See adverse effects below. • Clipping the hair coat and bathing with a benzoyl peroxide shampoo before application of the rinse assist response. • Amitraz-containing collars and spot-ons are not effective. • Efficacy is proportional to the frequency of administration and the concentration of the rinse. • Poor compliance limits efficacy. • 11% and 30% of cases will not be cured; may need to try an alternative therapy or control with maintenance rinse every 2–8 weeks.

DRUG(S) OF CHOICE

Cats

Isoxazoline antiparasitics

• Treatment of choice at label doses for fleas. • Side effects uncommon but include drooling, vomiting, diarrhea, inappetence, or neurologic signs including seizures.

2% lime sulfur

• Can be diluted, sponged over the cat, and allowed to dry without rinsing once weekly for 6 treatments. • Malodorous, staining, and difficult to apply to the face. • Patient should be restricted from grooming after application.

Alternatives

Alternative but less effective options for the treatment of *D. gatoi*:

• Milbemycin oxime—1 mg/kg PO q24h.
• Doramectin—0.6 mg/kg SC weekly
• Ivermectin—0.2–0.3 mg/kg PO q24–48h.

Neurologic side effects such as ataxia are possible with ivermectin.

CONTRAINDICATIONS

Do not use ivermectin in avermectin-sensitive breeds—collies, Shetland sheepdogs, Old English sheepdogs, Australian shepherds, other herding breeds, and crosses with these breeds. Screening for the ABCB-1 mutation is recommended.

PRECAUTIONS

Amitraz

• Side effects—somnolence, lethargy, depression, anorexia seen in 30% of patients for 12–36 hours after treatment. • Rare side effects—vomiting, diarrhea, pruritus, polyuria, mydriasis, bradycardia, hypoventilation, hypotension, hypothermia, ataxia, ileus, bloat, hyperglycemia, convulsions, death. • Yohimbine at 0.11 mg/kg IV is an antidote, as is atipamezole. • Incidence and severity of side effects do not appear to be proportional to dose or frequency of use. • Apply in a well-ventilated area; owners should wear aprons and gloves so they do not come in contact with the dip. • Human beings can develop dermatitis, headaches, and respiratory difficulty after exposure. Amitraz should not be used by people taking monoamine oxidase (MAO) inhibitors (e.g., some antihistamines, antidepressants, and antihypertensives). • Can dysregulate blood sugar in diabetics.

Ivermectin and Milbemycin

Signs of toxicity—salivation, vomiting, mydriasis, confusion, ataxia, hypersensitivity to sound, weakness, recumbency, coma, and death.

POSSIBLE INTERACTIONS

• Amitraz—may interact with heterocyclic antidepressants, xylazine, benzodiazepines, and macrocyclic lactones. • Ivermectin and milbemycin—cause elevated levels of monoamine neurotransmitter metabolites, which could result in adverse drug interactions with amitraz and benzodiazepines. • Spinosad and other drugs in that class are contraindicated with ivermectin therapy.

FOLLOW-UP

PATIENT MONITORING

Repeat skin scrapings and evidence of clinical resolution are used to monitor progress, generally repeated every 2–4 weeks until resolution, and then treatments are continued 1–2 months beyond negative scrapings.

PREVENTION/AVOIDANCE

Do not breed animals with generalized disease.

POSSIBLE COMPLICATIONS

Secondary bacterial folliculitis and furunculosis.

EXPECTED COURSE AND PROGNOSIS

Prognosis is very good for elimination of the demodicosis with isoxazoline treatment. Prognosis depends heavily on compliance, and genetic, immunologic, and underlying diseases. Severe, generalized cases with underlying disease may be refractory to treatments other than isoxazoline.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Adult-onset demodicosis—sudden occurrence is associated with internal disease, malignant neoplasia, and/or immunosuppressive disease; approximately 25% of cases are idiopathic over a follow-up period of 1–2 years. • *D. cati* associated with FeLV, FIV, toxoplasmosis, iatrogenic immune suppressants, papillomaviral plaques, and systemic lupus erythematosus (SLE).

AGE-RELATED FACTORS

Young dogs are often predisposed to a localized form.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

Do not breed animals with the generalized form.

SYNONYMS

• Mange. • Red mange.

SEE ALSO

Ivermectin and Other Macrocyclic Lactones Toxicosis.

ABBREVIATIONS

• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.
• MAO = monoamine oxidase.
• SLE = systemic lupus erythematosus.

DENTAL CARIES

D

BASICS

OVERVIEW

- Caries is the decay of the dental hard tissues (enamel, cementum, and dentin) due to the effects of oral bacteria on fermentable carbohydrates on the tooth surface.
- The word "caries" is Latin for rottenness and is both the singular and plural form.
- Oral bacteria ferment carbohydrates on the tooth surface, resulting in the production of acids leading to demineralization of the hard tissues, thus allowing bacterial and leukocytic digestion of the organic matrix of the tooth.
- Caries has been very common in humans in "westernized" society, where diets rich in highly refined carbohydrates are the norm. Aggressive public education and preventive measures have resulted in a decline in incidence over the past several decades.
- In humans, *Streptococcus mutans* is particularly implicated in the development of caries.
- For various reasons (e.g., diet lower in refined carbohydrates, higher salivary pH, lower salivary amylase, conical crown shape, wider interdental spacing, different indigenous oral flora), caries is not common in the domestic dog, but it does occur and should be looked for.
- A study published in the *Journal of Veterinary Dentistry* in 1998 (see Suggested Reading) reported that 5.3% of dogs 1 year of age or older had one or more caries lesions, with 52% having bilaterally symmetric lesions.
- Caries can affect the crown or roots of the teeth and is classified as pit-and-fissure, smooth-surface, or root caries.

SIGNALMENT

- Caries occurs in dogs.
- Reported in cats; tooth resorption (feline odontoclastic resorptive lesions [FORL]) has sometimes been misnamed feline caries. To the author's knowledge, there are no published reports of true dental caries occurring in the domestic cat, though it is theoretically possible.
- There is no reported breed, age, or gender predilection.
- Anecdotally, the author has observed a higher incidence of pit-and-fissure lesions in the occlusal tables of the maxillary first molar teeth in large-breed dogs such as Labrador retrievers and German shepherds.

SIGNS

- Incipient smooth-surface caries—appears as an area of dull, frosty-white enamel.
- Clinical caries—appears as a structural defect on the surface of the crown or root.
- The defect is frequently filled with or lined by dark, soft necrotic dentin. The defect may also trap and hold food debris.
- Affected dentin will yield to a dental explorer and can be removed with a dental excavator or curette.

CAUSES & RISK FACTORS

- Caries is caused by oral bacteria fermenting carbohydrates on the tooth surface, leading to the production of acids (acetic, lactic, propionic) that demineralize the enamel, cementum, and dentin, followed by digestion of the organic matrix of the tooth by oral bacteria and/or leukocytes.
- There is a constant exchange of minerals between the tooth surfaces (enamel, any exposed dentin or root cementum) and the oral fluids; if there is a net loss of mineral, caries develops.
- Early (incipient) caries may be reversible through remineralization.
- Once the protein matrix collapses, the lesion is irreversible.
- Any factors that allow prolonged retention of fermentable carbohydrates and bacterial plaque on the tooth surface predispose to the development of caries.
- A deep occlusal pit on the maxillary first molar is the most common place for caries to develop.
- Dental surfaces in close contact with an established caries are at risk of developing a lesion by extension.
- Deep occlusal pits and developmental grooves on the crown surface predispose to pit-and-fissure caries.
- Tight interdental contacts predispose to smooth-surface caries.
- Deep periodontal pockets predispose to root caries.
- Animals with poorly mineralized enamel, lower salivary pH, diets high in fermentable carbohydrates, and poor oral hygiene are at risk of developing caries.
- Loss of enamel through any means (hypocalcification at the developmental stage, abrasive wear or attrition, traumatic fracture) that exposes the softer, underlying dentin may increase the risk for the development of caries.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Crown fracture, abrasive wear or attrition with exposed tertiary dentin, or extrinsic staining.
- Enamel hypocalcification with exposed and stained dentin.
- Tooth resorption (FORL) has been misnamed feline caries in the past.
- Tooth resorption can also occur in dogs and may be mistaken for caries.
- Sound dentin is hard and will not yield to a dental explorer, whereas carious dentin is soft and will yield to a sharp instrument.
- Root caries may be confused with external root resorption, though the distinction would often be academic, as either usually indicates the need for extraction.
- The lesion should be staged as to the depth of the pathology.
- Table 1 is adapted from the American Veterinary Dental College approved nomenclature for tooth resorption as published on its website.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

IMAGING

Intraoral Dental Radiography

- Areas of demineralization and tissue loss will appear as lucent areas contrasted against radiodense normal dental tissues.
- If the lesion has penetrated into the pulp chamber, there will be endodontic disease, and periapical disease may be evident if the lesion is sufficiently longstanding.

Table 1

Stage 1	Defect involves enamel or cementum only.
Stage 2	Defect extends into dentin but not into pulp chamber.
Stage 3	Deep dental hard tissue loss (cementum and/or enamel with loss of dentin that extends to the pulp cavity); most of the tooth retains its integrity.
Stage 4	Extensive dental hard tissue loss (cementum and/or enamel with loss of dentin that extends to the pulp cavity); most of the tooth has lost its integrity.
Stage 5	Majority of crown lost; root remnants remaining.

(CONTINUED) DENTAL CARIES

• Small lesions may be difficult to demonstrate due to superimposition of normal, radiodense tissues (dental and skeletal).

DIAGNOSTIC PROCEDURES

• Visual examination of the clean, dry tooth surface under good light and with the aid of magnification.
• Exploration with a sharp dental explorer—the explorer will sink into carious dentin and stick, providing the sensation of "tug-back" upon withdrawal.
• Subgingival exploration—reveals irregularities in the root surface.
• Caries detection dyes have been used by human and veterinary dentists to aid in the differentiation between sound and carious dentinal tissue. However, their use may lead to false-positive results and overtreatment through the removal of excess tissue. Reliance on visual, tactile, and radiographic findings is preferable.

TREATMENT

• Focus on prevention—examine the adult dentition of adolescent dogs (6–8 months of age) to identify anatomically compromised areas at risk for the development of caries. Deep pits in the occlusal surface of the maxillary first molar (for example) can be filled with a pit-and-fissure sealant or fluoride-releasing dental bonding agent to prevent caries development if identified prior to the development of any decay.
• Incipient caries—can be arrested and possibly reversed by application of a fluoride varnish or fluoride-releasing dental bonding agent and modification of the risk factors.
• Lesions that result in mild to moderate coronal tissue loss (stage 1 or 2)—remove carious dentin and unsupported enamel using hand instruments and power rotary dental instruments, then restore the coronal anatomy with a bonded, composite restoration or prosthetic restoration.
• Lesions that extend into pulp tissue (stage 3)—endodontic treatment must precede restorative treatment. Alternatively, extraction may be indicated. As the pulp tissue in the roots will be contaminated, complete removal of all root remnants is essential if extraction is performed.
• Lesions that result in extensive coronal tissue loss (stage 4 or 5)—extraction is typically the only treatment option. As the pulp tissue in the roots will be contaminated, complete removal of all root remnants is essential.
• Root caries—if the periodontal disease can be managed and the restoration placed supragingivally, restoration may be possible; however, for most teeth with root caries, extraction will be the treatment of choice.
• If only one root of a multirooted tooth is carious—extraction of the affected root with endodontic treatment of the remaining root(s) is also an option.
• For high-risk patients—application of a pit-and-fissure sealant and/or fluoride-releasing dental bonding agent on remaining teeth with occlusal surfaces may be considered.

MEDICATIONS

DRUG(S) OF CHOICE

• Postoperative broad-spectrum antibiotics—may be indicated if there is pulp involvement necessitating endodontic treatment or extraction.
• Postoperative analgesia with nonsteroidal anti-inflammatory drugs and/or narcotics is indicated following endodontic or exodontic treatment or extensive restorative work of vital teeth.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

• Examine and radiograph treated teeth 6 months postoperatively, then annually or as the opportunity presents.
• Evaluate the integrity of the restorations, assess for further decay at the margins or under the restorations, assess for the development of endodontic disease.
• As affected individuals frequently have more than one caries, examine all teeth carefully (clinically and radiographically) at any opportunity to monitor for the development of new lesions.

PREVENTION/AVOIDANCE

Avoidance of diet and treats high in refined carbohydrates may reduce the risk of the development of further caries.

EXPECTED COURSE AND PROGNOSIS

If a lesion has been properly debrided and restored it should have an excellent prognosis. Appropriate staging and case selection, thorough removal of all carious tissues, and adherence to restorative principles are essential.

MISCELLANEOUS

SYNONYMS

• Cavities.
• Dental decay.

ABBREVIATIONS

• FORL = feline odontoclastic resorptive lesions.

DENTIGEROUS CYST

BASICS

OVERVIEW
Cyst formation originating from tissue surrounding the crown of an unerupted tooth.

SIGNALMENT
- Any breed that is at an increased risk for impaired eruption.
- Boxers, bulldogs—mandibular first premolars, often bilateral.
- Unerupted teeth at 6–7 months of age, but cystic development may not occur until much later, if at all.

SIGNS
- Cystic changes may be initially unapparent without diagnostic imaging.
- "Missing" tooth.
- Formation of a soft swelling at the site of a missing tooth, often fluctuant with fluid.
- Patient may present, with no previous indication of a problem, for a pathologic fracture of the mandible due to cystic destruction of the surrounding bone.

CAUSES & RISK FACTORS
Unerupted teeth.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Odontogenic keratocyst—cyst of the jaw demonstrating aggressive expansion that may, or may not, be associated with unerupted teeth.
- Primordial cyst—cystic degeneration of a tooth bud before enamel/dentin formation (cyst without a tooth).
- Oral mass—odontoma (complex or compound): tooth structures (enamel, dentin, cementum, and pulp) sometimes contained within cystic structure, but with different levels of organization.
- Transformation to ameloblastomas have been reported in humans; histologic evaluation of the cyst lining is highly recommended.

CBC/BIOCHEMISTRY/URINALYSIS
- No abnormalities typically found.
- Preoperative diagnostics where appropriate for safe administration of general anesthesia.

IMAGING
- Definitive diagnosis from radiography.
- Radiographs are essential in any instance of missing or unerupted teeth.
- Radiographically—radiolucent cyst originating from the remnant enamel organ at the neck of the tooth and encompassing the crown (a halo).
- CT studies of the head should evaluate for presence of unerupted teeth.

DIAGNOSTIC PROCEDURES
Histopathologic assessment if atypical radiographic findings (any unerupted teeth demonstrating radiolucency surrounding the unerupted crown should be submitted for histologic evaluation).

TREATMENT

- Appropriate preoperative antimicrobial and pain management therapy when indicated.
- Appropriate patient monitoring and support during anesthetic procedure.
- If cystic formation is present—surgical extraction, complete debridement of cyst lining, and histologic evaluation.
- If an embedded tooth has been present in a mature animal—assess for any cystic structure or other pathologic changes involving the tooth; continued monitoring (minimally yearly) may be reasonable if surgical extraction would damage large amounts of bone.
- If a nonstrategic tooth can be easily extracted, it would be best to do so, even if cystic changes are not present.

MEDICATIONS

DRUG(S) OF CHOICE
Postoperative analgesics, as necessary.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

POSSIBLE COMPLICATIONS
- Pathologic fracture may occur if dentigerous cyst is not diagnosed and treated.
- Fracture of mandible at time of extraction, due to compromised supporting bone.
- Cyst development and expansion result in weakening of the bone at that location and may risk causing root resorption or devitalization of neighboring teeth.

EXPECTED COURSE AND PROGNOSIS
- Extraction should be performed to avoid risk for future cyst development.
- Good with early detection and extraction.
- Fair to guarded with extensive bone destruction or pathologic fracture.

DERMATOMYOSITIS

BASICS

DEFINITION
An inheritable inflammatory disease of the skin, muscles, and vasculature that develops in young collies, Shetland sheepdogs, and their crossbreeds.

PATHOPHYSIOLOGY
- The exact pathogenesis of dermatomyositis is unknown.
- A familial predisposition has been reported in collies and Shetland sheepdogs; however, possible triggers for the disease include infectious agents (especially viral), vaccines, drugs, malignancy, toxins, infection—as seen with ischemic dermatopathy in other breeds.
- Based on the clinical and histopathologic evidence, an immune-mediated or autoimmune process may be involved.

SYSTEMS AFFECTED
- Skin/exocrine.
- Musculoskeletal.

GENETICS
Autosomal dominant inheritance, with variable expression in collies and Shetland sheepdogs.

INCIDENCE/PREVALENCE
Exact prevalence is unknown.

SIGNALMENT

Species
Dogs

Breed Predilections
- Inheritable disease in collie, Shetland sheepdog and their crossbreeds, Beauceron shepherd, Belgian Tervuren, Rottweiler, kelpie, and Portuguese water dog.
- Similar symptoms reported in the mongrel, Welsh corgi, Lakeland terrier, chow chow, German shepherd dog, schipperke, and kuvasz.
- Dogs of other breeds with similar signs are classified as ischemic dermatopathy (dermatomyositis-like), and not dermatomyositis as previously reported.

Mean Age and Range
- Cutaneous lesions typically develop before 6 months, and may develop as early as 7 weeks of age.
- Full extent of lesions usually present by 1 year of age, and may lessen thereafter.
- Adult-onset dermatomyositis can occur, but is rare, and is usually less severe.

Predominant Sex
None reported.

SIGNS

General Comments
- Clinical signs vary from subtle skin lesions and subclinical myositis to severe skin lesions with generalized muscle atrophy, abnormal gait, and megaesophagus.
- Several littermates may be affected, but the severity of the disease often varies significantly among affected dogs.

Physical Examination Findings
- Waxing and waning lesions.
- Usually seen in affected dogs before 6 months of age.
- Begins around the eyes and lips, face, inner ear pinnae, tip of the tail, and bony prominences—the entire face may be involved.
- Pressure points over bony prominences, especially the carpal and tarsal regions.
- Characterized by variable degrees of crusted erosions, ulcers, and alopecia, with erythema, scaling, and scarring.
- Foot pad and oral ulcers, as well as nail abnormality or loss may occur.
- Scarring—often a sequela to the initial skin lesions.
- Atrophy of the masseter and temporal muscles—severe cases may have difficulty eating, drinking, and swallowing.
- Stiff or high-stepping gait.
- Myositis—signs may be absent or vary from subtle decrease in the mass of the temporalis muscles to generalized symmetric muscle atrophy and stiff high-stepping gait.
- Dogs with megaesophagus may present with aspiration pneumonia.

CAUSES
- Hereditary in collies, Shetland sheepdogs, and their crosses.
- Infectious agents, toxins, malignancy, vaccines, or drugs may be a triggering event.
- Immune-mediated disease in other breeds.

RISK FACTORS
Mechanical pressure and trauma, and ultraviolet light exposure may worsen cutaneous lesions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Demodicosis.
- Dermatophytosis.
- Bacterial folliculitis.
- Juvenile cellulitis.
- Discoid lupus erythematosus.
- Systemic lupus erythematosus.
- Polymyositis.
- Ischemic dermatopathy.
- Epidermolysis bullosa simplex.

CBC/BIOCHEMISTRY/URINALYSIS
Serum creatine kinase may be elevated due to muscle damage.

OTHER LABORATORY TESTS
- Antinuclear antibody titers—rule out systemic lupus erythematosus.
- Elevated levels of immunoglobulin G and circulating immune complex correlated with disease severity.

DIAGNOSTIC PROCEDURES
- Skin biopsy—may be diagnostic for dermatomyositis, although this disease can be difficult to definitively diagnose; avoid infected and scarred lesions.
- Muscle biopsy—proper muscle selection can be difficult because pathologic changes may be mild consisting of muscle necrosis and atrophy.
- Electromyography (EMG)—ideally, used to select affected muscles for biopsy; if EMG is not available, atrophied muscles should be biopsied.

PATHOLOGIC FINDINGS

Skin Biopsy
- Scattered apoptosis or vacuolation of individual and follicular basal cells; may lead to intrabasal or subepidermal clefting.
- Mild pigmentary incontinence.
- Superficial, mild, diffuse dermal and perivascular cellular infiltrates—composed of lymphocytes, plasma cells, and histiocytes.
- Follicular atrophy and perifollicular fibrosis in chronic cases.
- Secondary epidermal ulceration and dermal scarring—may be present.
- Histopathologic features may be subtle and consist mostly of atrophic changes; however, the combination of epidermal and follicular basal cell degeneration, perivascular inflammation, and follicular atrophy with fibrosis is highly suggestive of dermatomyositis.

Muscle Biopsy
- Variable multifocal accumulations of inflammatory cells, including lymphocytes, plasma cells, macrophages, and neutrophils.
- Myofibril degeneration—characterized by fragmentation, vacuolation, atrophy, fibrosis, and regeneration.

EMG
EMG abnormalities are present especially in the muscles of the head and distal limbs; findings include fibrillation potentials (rapid, irregular, and unsynchronized contraction of muscle fibers) and positive sharp waves.

TREATMENT

APPROPRIATE HEALTH CARE
- Most dogs treated as outpatients.
- Dogs with severe myositis and megaesophagus may need hospitalization for supportive care.
- Severe cases may warrant euthanasia.
- Assist to eat if muscles of mastication are affected; feed at an elevated position if megaesophagus develops.
- Nonspecific supportive therapy includes gentle bathing and soaking to remove crusts, and treatment of secondary bacterial folliculitis (if present).

DERMATOMYOSITIS (CONTINUED)

ACTIVITY
• Avoid activities that may traumatize the skin.
• Keep indoors during the day to avoid solar radiation.

DIET
N/A

CLIENT EDUCATION
• Discuss the hereditary nature of the disease.
• Note that affected dogs should not be bred.
• Inform the owner that the disease is not curable, although spontaneous resolution or waxing and waning of symptoms may occur.
• Discuss prognosis and possible complications, especially in severely affected dogs.
• Therapeutic efficacy of medical treatment can be difficult to assess because the disease tends to be cyclic in nature and is often self-limiting.

MEDICATIONS

DRUG(S) OF CHOICE
• Vitamin E 200–800 IU PO q12–24h.
• Essential fatty acid supplement.
• Prednisolone 1–2 mg/kg PO q12–24h until remission, then alternate-day to twice-weekly administration using the lowest dosage possible for long-term control.
• Nonsteroidal anti-inflammatory medication (if steroids contraindicated).
• Pentoxifylline 10–20 mg/kg PO q12h.
• Tetracycline (250 mg >10 kg, 500 mg <10 kg PO q8–12h), doxycycline (10 mg/kg q24h), minocycline (5 mg/kg q12h), with niacinamide (250 mg >10kg, 500 mg <10 kg PO q8–12h).
• Tacrolimus 0.1% applied q12h.
• Oclacitinib 0.4-0.6mg/kg BID.

PRECAUTIONS
• Pentoxifylline—rarely causes gastric irritation; can affect clotting times (prothrombin time [PT]/partial thromboplastin time [PTT] prolongation and thrombocytopenia) and dogs receiving anticoagulant therapy should be monitored carefully when treated with this drug; possible rare seizure or reduction of seizure threshold in epileptics.
• Glucocorticoids—discuss possible side effects with the owner.
• Tacrolimus can cause local irritation.

POSSIBLE INTERACTIONS
Glucocorticoids and nonsteroidal anti-inflammatory medications can cause gastrointestinal bleeding if used concurrently.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PREVENTION/AVOIDANCE
• Do not breed affected animals.
• Neuter intact animals to reduce hormonal influence on symptoms.
• Minimize trauma and exposure to sunlight.

POSSIBLE COMPLICATIONS
• Secondary bacterial folliculitis.
• Mildly to moderately affected dogs may have residual scarring.
• Severely affected dogs may have trouble chewing, drinking, and swallowing due to scarring of the masticatory and esophageal muscles.
• Megaesophagus may develop, predisposing the dog to aspiration pneumonia.
• Dogs may be lame due to damage of the muscles of the extremities.

EXPECTED COURSE AND PROGNOSIS
• Long-term prognosis—variable, depending on severity of disease.
• Minimal disease—prognosis good; tends to spontaneously resolve with no evidence of scarring.
• Mild to moderate disease—tends to resolve spontaneously, but residual scarring is common.
• Severe disease—prognosis for long-term survival is poor as damage to the skin and muscle may be lifelong.

MISCELLANEOUS

ASSOCIATED CONDITIONS
None

AGE-RELATED FACTORS
• Initial clinical signs usually occur in dogs younger than 6 months.
• Adult onset—rare; more commonly seen in dogs that had subtle lesions as puppies.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
• Do not breed affected dogs.
• Pregnancy may exacerbate clinical symptoms.
• Estrus may exacerbate clinical symptoms.

SYNONYMS
• Familial canine dermatomyositis.
• Canine familial dermatomyositis.
• Ischemic dermatopathy in collies and Shetland sheepdogs.

SEE ALSO
• Lupus Erythematosus, Cutaneous (Discoid).
• Lupus Erythematosus, Systemic (SLE).

ABBREVIATIONS
• EMG = electromyography, electromyographic.
• PT = prothrombin time.
• PTT = partial thromboplastin time.

DERMATOPHILOSIS

BASICS

OVERVIEW

• "Mud rash" or "mud fever." • Caused by *Dermatophilus congolensis*. • Rare crusting dermatitis (dogs). • Rare nodular subcutaneous and oral disease (cats). • Systems affected—skin/exocrine.

SIGNALMENT

• Dogs and cats. • No age, breed, or sex predilection.

SIGNS

Historical Findings

• Association with cattle, sheep, or horses. • Occasionally free-roaming dogs. • Cats with subcutaneous disease—episode of trauma; existence of a foreign body; lesions generally chronic; no systemic clinical signs, except when internal organs or large oral lesions develop.

Physical Examination Findings

• Dogs—lesions: circular to coalescent, papular, crusted skin lesions on the head and/or trunk, lesions resemble superficial bacterial pyoderma caused by *Staphylococcus pseudintermedius*; lesions may resemble dermatophilosis in horses (adherent thick, gray-yellow crusts that incorporate hair and leave a circular, glistening, shallow erosion when removed); pruritus is variable. • Cats—subcutaneous, oral, or internal ulcerated and fistulated nodules or abscesses similar to lesions caused by other actinomycetes in this species; superficial pyogenic crusting disease of the face has been reported.

CAUSES & RISK FACTORS

• *D. congolensis*—causative agent; Gram-positive, branching filamentous bacterium classified as an actinomycete; very common cause of crusting dermatoses in hoofed animals; persists in the environment within crusts. • Dogs, cats, and humans can be exposed directly from lesions on large animals or from environmental exposure. • Infectious stage—requires wetting for activation; cannot penetrate intact epithelium; minor trauma or mechanical transmission by biting ectoparasites (*Amblyomma variegatum*) may help in establishing infection. • Deeper infections—require traumatic inoculation of infectious material.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dogs

• Staphylococcal folliculitis. • Acute moist dermatitis. • Dermatophytosis. • Pemphigus foliaceus. • Keratinization disorder.

Cats

• Infections—actinomycosis, nocardiosis, sporotrichosis, cryptococcosis, opportunistic mycobacterial granuloma, *Rhodococcus equi*.• Foreign body. • Bite wound abscess. • Cutaneous or mucosal neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

DIAGNOSTIC PROCEDURES

Dogs

• Cytologic examination of exudate from under crusts or of macerated crusts. • Biopsy—crusts contain organisms; submit with tissue samples. • Distinctive morphology of organism in cytologic and histopathologic preparations; bacterium forms branching chains of small diplococci resembling "railroad tracks." • Real-time quantitative polymerase chain reaction (RT-qPCR)—crust samples and hair.

Cats

• Histopathologic examination—biopsy of nodules; procedure of choice. • Culture from crusts or tissues—alert laboratory of differential; requires use of special selective medium; isolation is possible but usually very difficult. • RT-qPCR—crust samples and hair.

PATHOLOGIC FINDINGS

• Dogs—crusting and superficial pustular dermatitis; palisading of the crusts with orthokeratotic and parakeratotic hyperkeratosis; organism visualized within the crusts. • Cats—pyogranulomatous inflammation; central necrosis; fistulous tract formation; organism visualized near the necrotic center of granulomas, especially with Gram stain.

TREATMENT

• Dogs—antibacterial shampoo with gentle removal of crusts: iodine or lime-sulfur may also be used. • Cats—for pyogranulomas and abscesses: surgical debridement; exploration for foreign body; establishment of drainage for exudate.

MEDICATIONS

DRUG(S) OF CHOICE

• Treatment should be continued for 10–20 days. • Penicillin V (10 mg/kg PO q12h) for 10–20 days; drug of choice. • Tetracycline (22–30 mg/kg PO q8h); doxycycline (5–10 mg/kg PO q12h); minocycline (5–12 mg/kg PO q12h. • Ampicillin 10–20 mg/kg PO q12h. • Amoxicillin 10–20 mg/kg PO q12h.

FOLLOW-UP

PATIENT MONITORING

• Dogs—reexamine after 2 weeks of treatment to ensure complete resolution; give an additional 7 days of systemic therapy if indicated. • Cats—monitor biweekly for 1 month after apparent resolution of lesions, depending on location.

EXPECTED COURSE AND PROGNOSIS

• Dogs—excellent. • Cats—varies with the location of lesions and extent of surgical debridement; complete resolution can be achieved with early diagnosis and medical/surgical therapy.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Veterinarians and animal care workers—infection uncommon even with exposure to infected farm animals. • Dogs and cats—very unlikely to serve as a source for human infection; caution is warranted for exposure of immunocompromised individuals.

ABBREVIATIONS

• RT-qPCR = real-time quantitative polymerase chain reaction.

DERMATOPHYTOSIS

BASICS

DEFINITION
• Cutaneous fungal infection affecting the cornified regions of hair, claws, and occasionally the superficial layers of the skin.
• *Microsporum* and *Trichophyton* dermatophytes are most commonly isolated.

PATHOPHYSIOLOGY
• Dermatophytes—grow in the keratinized layers of hair, claw, and skin; do not thrive in living tissue.
• Exposure to or contact with a dermatophyte does not necessarily result in an infection. Infection may not result in clinical signs.
• 2–4-week incubation period.
• Infective spores must contact the skin surface and defeat host-protective mechanisms (innate immunity, normal flora, sebum, grooming) in order for infection to occur.
• Factors that favor the development of disease—stress, trauma, ectoparasite infestations, and immunosuppression.
• Infected animals may remain as asymptomatic (inapparent) carriers for a prolonged period of time; some animals never become symptomatic.

SYSTEMS AFFECTED
Skin/exocrine.

INCIDENCE/PREVALENCE
• Lesions may mimic many dermatologic conditions; overdiagnosis is likely common.
• Infection rates (inapparent and clinical) vary widely, depending on the population studied.

GEOGRAPHIC DISTRIBUTION
• More common in hot, humid climates.
• Incidence of dermatophyte species may vary seasonally and geographically.
• *M. canis*—cats: UK, southern United States, Italy, and Brazil; source most often infected cat.
• *M. gypseum*—dogs: southern United States; less than 1% in UK; source most often soil.
• *M. persicolor*—India, Brazil, and North America; source most often associated with rodents.
• *T. mentagrophytes*—India and UK; less common in southern United States, Italy, and Brazil; source most often associated with rodents.

SIGNALMENT

Species
Dog, cat, and many others.

Breed Predilections
• Cat—longhaired breeds (Persian and Himalayan).
• Dog—Yorkshire terrier and Manchester terrier. Increased exposure in working and hunting dogs.

Mean Age and Range
• *M. canis* is more common in younger animals.
• Generalized dermatophytosis in older dogs associated with immunosuppression.

SIGNS

Physical Examination Findings
• Inapparent carrier state—cats.
• Extreme variability of clinical signs.
• Classic lesion—slowly expanding circular patch of alopecia with scale.
• Seborrheic or greasy hair coat.
• Papular or pustular eruptions.

CAUSES
Multiple species identified; majority of cases caused by *M. canis*, *M. gypseum*, *T. mentagrophytes*, and *M. persicolor* (nonfollicular).

RISK FACTORS
• Immunocompromise caused by medications or disease.
• High population density.
• Poor management practices.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Staphylococcal folliculitis.
• Demodicosis.
• Allergic dermatitis.
• Pemphigus foliaceus.
• Keratinization defect.

DIAGNOSTIC PROCEDURES

Wood's Lamp Examination
• Can be misleading—not all *M. canis* isolates fluoresce; most other pathogenic dermatophytes do not fluoresce.
• True positive reaction—apple-green fluorescence of the hair shaft. False-positive and false-negative results commonly due to debris on the hair and skin, inadequate equipment, and/or poor technique.

Microscopic Examination of Hair
• Choose hairs that fluoresce under Wood's lamp illumination to increase success.
• Hyphae and arthrospores seen invading hair shafts.

Fungal Culture with Identification
• Choose hairs that fluoresce under Wood's lamp if possible.
• Pluck hairs from the periphery of an alopecic area or brush haircoat with a sterile toothbrush or carpet square (especially inapparent or treated patients).
• Dermatophyte test media—dermatophytes change media color to red during the early growing phase of the culture; saprophytes cause color change after significant colony growth; examine inoculated media daily.
• Fungal colonies are nonpigmented/white to slightly yellow. Contaminants are often darker.
• Microscopic examination of the growth for microconidia and macroconidia—necessary to confirm pathogenic dermatophyte and to identify genus and species; helps identify source of infection.
• Positive culture—indicates presence of a dermatophyte; however, organisms may be transient (i.e., geophilic dermatophytes on the feet).

Skin Biopsy
• Not usually required for diagnosis.
• Can be helpful in confirming true invasion and infection, or to diagnose suspicious cases with negative fungal culture.

PCR
PCR of the dermatophyte DNA on the hair samples may be helpful. Positive PCR does not necessarily indicate active infection—dead fungal organisms from a successfully treated infection may be detected on PCR, as will inapparent carriers.

PATHOLOGIC FINDINGS
• Folliculitis, perifolliculitis, or furunculosis.
• Fungal hyphae seen in H&E-stained sections; special stains allow easier visualization of the organism.

TREATMENT

APPROPRIATE HEALTH CARE
Quarantine owing to the infective and zoonotic nature of the disease.

CLIENT EDUCATION
• Many shorthaired cats and many dogs will undergo spontaneous remission within 3 months.
• Longhaired animals should be clipped to reduce environmental contamination.
• Decontamination of the environment reduces the risk of false positive fungal cultures, which can lead to prolonged treatment and confinement.
• Infective spores are shed into the environment, but do not multiply in the environment; transmission of the disease strictly from a contaminated environment (i.e., no direct contact with an infected animal) is extremely rare.
• Effective disinfectants.
• Diluted sodium hypochlorite (0.5%)—concentrations ranging from 1 : 10 to 1 : 100 effective with short contact times.
• Enilconazole (0.2%)—available as a concentrated spray or fogger; 10-minute contact time recommended. Not available in the United States.
• Accelerated hydrogen peroxide—should not be mixed with concentrated sodium hypochlorite products; 10-minute contact time recommended.
• Washable textiles—decontaminate via mechanical washing; two washings on the

longest wash cycle in a washing machine found to be effective.
• Treatment can be both frustrating and expensive, especially in multianimal households or with recurrent cases; consider referral to a veterinary dermatologist.

MEDICATIONS

DRUG(S) OF CHOICE

• Topical therapy and clipping— recommended concurrently with systemic therapy; may help prevent environmental contamination.
• Lime-sulfur (1 : 16 dilution or 8 oz per gallon of water), miconazole/chlorhexidine (0.2%), or enilconazole (0.2%) applied once to twice weekly; lime sulfur is odoriferous and can stain; enilconazole is not currently approved for use in companion animals in the United States. Shampoos containing 1–2% ketoconazole, miconazole, or 0.5% climbazole; a minimum of a 3-minute contact time is recommended; little to no residual effect.
• Use of an Elizabethan collar, particularly in cats, is recommended to prevent ingestion of these products.
• Itraconazole—dogs and cats: 5–10 mg/kg PO q24h in one-week-on, one-week-off schedule for minimum of 3 cycles; manufactured drug preferred over compounded formulations due to absorption/concentration variability. Compounded formulations have been shown to be of extremely variable efficacy.
• Ketoconazole—resistance reported (10 mg/kg q24h PO); not recommended in cats.
• Griseofulvin—effective, but use declining due to cost and requirement for monitoring.
• Terbinafine—effective, may be helpful in cases resistant to azole drugs; dogs: 20–30 mg/kg q12–24h for 4–8 weeks; cats: 20–40 mg/kg q24–48h for 4–8 weeks; dermatophyte carriers: 8.25 mg/kg q24h for 4–8 weeks; side effects may include gastrointestinal upset, hepatotoxicity, neutropenia, and pancytopenia.
• Antifungal vaccines have not been shown to protect against challenge exposure.

CONTRAINDICATIONS

• Corticosteroids—can modulate inflammation and prolong the infection.
• Griseofulvin—do not administer to cats with feline leukemia virus (FeLV) or feline immunodeficiency virus (FIV); teratogen.

PRECAUTIONS

Ketoconazole

• Hepatopathy has been reported and can be severe in cats.
• Inhibits endogenous production of steroid hormones in dogs.

Itraconazole

• Rare vasculitis and ulcerative skin lesions at doses of 5 mg/kg q12h; not noted in patients receiving 5 mg/kg q24h.
• Hepatotoxicity reported infrequently in dogs.

Terbinafine

• Gastrointestinal upset, hepatotoxicity, and bone marrow suppression (pancytopenia, neutropenia).
• Decrease dosage with renal and/or hepatic insufficiency.
• Concurrent administration with Cimetidine increases blood concentration; rifampin decreases blood concentration.

Lime-Sulfur Solution

Ingestion of lime-sulfur may lead to oral erosions.

ALTERNATIVE DRUG(S)

• Lufenuron—a chitin synthesis inhibitor used in flea control; not effective in controlled studies.
• Fluconazole—less effective option, but less expensive than itraconazole.

FOLLOW-UP

PATIENT MONITORING

• Dermatophyte culture required to monitor response to therapy; many animals clinically improve but remain culture-positive.
• Continue treatment until at least two subsequent cultures are negative.
• In resistant cases, cultures should be repeated weekly using the toothbrush technique.
• Weekly or biweekly CBC if treating with griseofulvin; periodic evaluation of liver enzymes if treating with ketoconazole, itraconazole, or terbinafine.
• Depending on which systemic medications used, appropriate follow-up should be performed due to potential side effects.

PREVENTION/AVOIDANCE

• Initiate a quarantine period and obtain dermatophyte cultures of all animals entering the household to prevent reinfection from inapparent carriers.
• Consider exposure based on species isolated.
• Decontaminate the environment.
• Consider prophylactic treatment of exposed animals.

POSSIBLE COMPLICATIONS

False-negative dermatophyte culture.

EXPECTED COURSE AND PROGNOSIS

• Many animals will "self-clear" infection over a period of a few months.
• Treatment hastens clinical cure and helps reduce environmental contamination.
• Some infections, particularly in longhaired cats or multianimal situations, can be persistent.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Dermatophytosis is zoonotic.
• Considered a low-level pathogen; disease is not life-threatening, can be easily treated, but may cause scarring.

PREGNANCY/FERTILITY/BREEDING

• Griseofulvin is teratogenic.
• Ketoconazole can affect steroidal hormone synthesis, especially testosterone.

SYNONYMS

Ringworm

ABBREVIATIONS

• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.

DERMATOSES, DEPIGMENTING DISORDERS

BASICS

DEFINITION

• Pathologic or cosmetic condition involving loss of pigmentation of the skin and/or hair coat, either by lack of pigmentation or by melanocyte damage. • Leukotrichia—whitening of the hair (nonspecific location). • Poliosis—whitening of hair on the head/face. • Leukoderma—whitening of the skin.

PATHOPHYSIOLOGY

• Melanocytes may be damaged or destroyed by toxins (including toxic melanin precursors), inflammatory mediators, auto-antibodies, and/or inhibitors of melanogenesis. • Diseases may be distinguished clinically by depigmentation as the initial symptom versus depigmentation occurring secondary to inflammation.

SYSTEMS AFFECTED

• Skin/exocrine. • Ophthalmic.

SIGNALMENT

• Mucocutaneous pyoderma—German shepherd dog. • Systemic lupus erythematosus (SLE)—German shepherd dog. • Discoid lupus erythematosus (DLE)—collie, Shetland sheepdog, German shepherd dog, Siberian husky; may occur more often in females. • Pemphigus foliaceus (PF)—chow chow, Akita, cocker spaniel, dachshund, Labrador retriever. • Uveodermatologic syndrome—Akita, Samoyed, Siberian husky. • Vitiligo—dogs: Belgian Tervuren, German shepherd dog, Doberman pinscher, Rottweiler, German shorthaired pointer, Old English sheepdog, dachshund; usually less than 3 years of age; cats: Siamese. • Seasonal nasal hypopigmentation—Siberian husky, Alaskan Malamute, Labrador retriever, golden retriever. • Epitheliotropic lymphoma (mycosis fungoides)—typically dogs >10 years old. • Proliferative arteritis of the nasal philtrum—Saint Bernard, giant schnauzer. • Periocular leukotrichia—Siamese cat. • Chediak-Higashi syndrome—Persian cat.

SIGNS

• Leukotrichia. • Leukoderma. • Lightening of the pigmentation in the skin (seen as a "graying" or "browning" of previously pigmented areas). • Erythema. • Erosion and ulcerations.

CAUSES

• Mucocutaneous pyoderma. • DLE. • SLE. • PF. • Pemphigus erythematosus (PE). • Uveodermatologic syndrome. • Contact hypersensitivity. • Vitiligo. • Seasonal nasal depigmentation. • Albinism. • Schnauzer gilding syndrome. • Endocrinopathy. • Drug reaction. • Erythema multiforme (EM). • Proliferative arteritis of the nasal philtrum. • Postinflammatory depigmentation. • Immune-mediated pigmentary incontinence. • Oculocutaneous albinism.

RISK FACTORS

• Sun exposure—DLE, SLE, and PE. • Drug triggered—PF, EM.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Mucocutaneous Pyoderma

• Biopsy—epidermal hyperplasia with superficial pustulation. • Depigmentation is secondary and develops with chronicity. • Skin lesions—affects the lips, perioral area, and nasal/alar folds. • Clinically similar to intertrigo (skinfold bacterial folliculitis). • Swelling and fissuring lead to erosions and crusts. • ++Biopsy—epidermal hyperplasia with superficial pustulation. • Antibiotic responsive. • Frequent recurrence if due to an underlying cause.

Nasal Solar Dermatitis

• Depigmentation is secondary and develops with chronicity. • Lesions confined primarily to dorsal muzzle and precipitated by sun exposure. • Begins in poorly pigmented skin at the junction of the nasal planum and dorsal muzzle. • Negative for direct immunofluorescence. • Solar vasculopathy may appear similar.

DLE

• Depigmentation is a primary symptom. • Primarily affects nasal area, eyelid margins, and lip margins. • Exacerbated by sun exposure. • Positive direct immunofluorescence at basement membrane zone. • Biopsy—interface dermatitis.

SLE

• Depigmentation is a primary symptom. • Multisystemic disease. • Skin lesions—often involve nose, face, and mucocutaneous junctions; multifocal or generalized. • Antinuclear antibody (ANA)—may be positive. • Positive direct immunofluorescence at basement membrane zone.

PF

• Depigmentation develops with chronicity. • Initial lesions on face and ears; commonly involve footpads; eventually generalized. • Biopsy—subcorneal pustules with acantholysis. • Positive direct immunofluorescence in intercellular spaces of epidermis.

PE

• Depigmentation is a primary symptom. • Lesions—primarily confined to face and ears, nasal planum, and lip margins. • Depigmentation often precedes significant lesions. • Exacerbated by sun exposure. • Biopsy—intraepidermal pustules with acantholysis and interface dermatitis. • Positive direct immunofluorescence at basement membrane zone and intercellular spaces. • ANA—occasionally positive.

Uveodermatologic Syndrome

• Depigmentation is a primary symptom. • Uveitis—usually precedes dermatologic disease. • Cutaneous macular depigmentation with inflammation on nose, lips, and eyelids. • Striking poliosis and leukotrichia. • Biopsy of early lesions—interface dermatitis, pigmentary incontinence.

Others

• Contact dermatitis (uncommon)—depigmentation secondary due to chronicity; erythema of rostral nasal planum and lips; no ulceration and minimal crusting; history of exposure. • Vitiligo—depigmentation often without inflammation; cutaneous macular depigmentation on nose, lips, eyelids, footpads, and nails; concurrent leukotrichia. • Seasonal nasal hypopigmentation—depigmentation is a primary symptom; normal black coloration of nasal planum fades to light tan or pink; usually seasonal or slowly progressive with age. • Albinism—hereditary lack of pigment of the skin, hair coat, and irises (not a depigmenting process). • Aurotrichia—young miniature gray schnauzers may develop idiopathic golden hair coat coloration, primarily of the trunk. • Endocrinopathy may cause coat color change, mainly from black to reddish-brown. • Drug reaction—depigmentation is often secondary; resembles many cutaneous disorders such as DLE, SLE, PF, and PE; pruritus is variable; onset of symptoms is usually within 2 weeks of administration. • Proliferative arteritis of the nasal philtrum—depigmentation is secondary and develops with chronicity; marked focal ulceration of the nasal planum often resulting in acute, severe hemorrhage; no additional skin lesions noted; this may be an idiopathic syndrome associated with allergy. • Dermatophytosis— depigmentation is secondary and develops with chronicity; especially develops on the dorsal muzzle and face; hyperpigmentation may also occur, especially with *Tricophyton mentagrophytes* infection. • Epitheliotropic lymphoma—depigmentation is secondary and develops with chronicity; occurs in mucocutaneous areas, nose, and skin. • EM in dogs—classic annular lesions with a clear center; depigmentation is secondary and develops with chronicity. • Zinc deficiency—depigmentation may be a primary or secondary symptom; zinc is required for normal melanin synthesis. • Chediak-Higashi syndrome—depigmentation is a primary symptom; young Persian cats (blue smoke color); ophthalmologic signs, prolonged bleeding. • Cyclic neutropenia in young silver-gray collie dogs with light-colored nose.

(CONTINUED) DERMATOSES, DEPIGMENTING DISORDERS

CBC/BIOCHEMISTRY/URINALYSIS

• Usually normal. • SLE—may see hemolytic anemia, thrombocytopenia, or evidence of glomerulonephritis. • Hematologic abnormalities in Persian cats with Chediak-Higashi syndrome. • Cyclic neutropenia in collie dogs (cyclic hematopoiesis anomalies).

OTHER LABORATORY TESTS

• Fungal culture—dermatophytosis.
• ANA—positive in SLE.

DIAGNOSTIC PROCEDURES

• Cytology—acantholytic cells (pemphigus), neoplastic lymphocytes (epitheliotropic lymphoma). • Joint tap—evidence of polyarthritis in SLE. • Ocular examination—uveitis in uveodermatologic syndrome. • Direct immunofluorescence—deposition of immunoglobulin at the basement membrane zone with DLE, SLE, and PE, and in the intercellular spaces of the epidermis with PF and PE. • Skin biopsy. • Genetic testing for oculocutaneous albinism.

PATHOLOGIC FINDINGS

Histopathologic Examination of the Skin

• Interface dermatitis—DLE, SLE, uveodermatologic syndrome. • Pigmentary incontinence—DLE, PE. • Intraepidermal pustules with acantholysis—PF and PE. • Hypomelanosis—vitiligo, uveodermatologic syndrome, seasonal nasal hypopigmentation, and Auriotrichosis. • Apoptosis (individual cell necrosis of keratinocytes)—drug reaction and EM. • Proliferation of spindle cells of dermal arteries and arterioles—proliferative arteritis. • Infiltration of neoplastic lymphocytes— epitheliotropic lymphoma.

TREATMENT

• Outpatient, except for SLE, EM, and cutaneous lymphoma with systemic involvement. • Reduce exposure to sunlight—DLE, SLE, and PE. • Immunosuppressive therapy—SLE, PF, and PE. • Avoid contact with topical drugs. • Contact dermatitis—avoid irritant; replace plastic or rubber dishes: particularly if roughened edges cause abrasions. • Application of water-resistant sunblock ointments or gels with an SPF/UVA and UVB >30 to depigmented and sun-exposed areas of skin. • Uveodermatologic syndrome—management by veterinary ophthalmologist recommended. • Appropriate antibiotics—pyoderma. • Appropriate antifungals— dermatophytosis.

MEDICATIONS

DRUG(S) OF CHOICE

• Auto-immune dermatoses—immunosuppressive therapy with prednisolone or dexamethasone and azathioprine (dogs) or chlorambucil (cats); see specific diseases.
• Topical corticosteroids—PE, DLE.
• Vitiligo and nasal depigmentation—no treatment. • Epitheliotropic lymphoma—multiple treatment protocols.

CONTRAINDICATIONS

Azathioprine therapy—not recommended in cats; may cause fatal leukopenia or thrombocytopenia.

ADVERSE REACTIONS

Ketoconazole may cause lightening of the hair coat, elevated alkaline phosphatase, and gastrointestinal distress.

ALTERNATIVE DRUG(S)

• Cyclosporine, modified—5 mg/kg/day for auto-immune disorders. • Tacrolimus—0.1% gel applied daily to lesions in combination with or to replace corticosteroids; may sting; avoid licking; wear latex gloves to apply.
• Pimecrolimus—1% cream applied daily to lesions in combination with or to replace corticosteroids; may sting; avoid licking; wear latex gloves to apply.

FOLLOW-UP

PATIENT MONITORING

• Varies with specific disease and treatment prescribed. • Postinflammatory depigmentation should resolve when the cause of inflammation is treated.

POSSIBLE COMPLICATIONS

• Sunburn in areas of depigmentation.
• Squamous cell carcinoma—in cases of solar damage and actinic keratosis of depigmented areas. • SLE—associated scarring with ulcerative dermatitis.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Dermatophytosis—can cause infection in humans.

SEE ALSO

• Cutaneous Drug Eruptions.
• Lupus Erythematosus, Cutaneous (Discoid).
• Lupus Erythematosus, Systemic (SLE).
• Lymphoma, Cutaneous Epitheliotropic.
• Pemphigus.
• Uveodermatologic Syndrome (VKH).

ABBREVIATIONS

• ANA = antinuclear antibody.
• DLE = discoid lupus erythematosus.
• EM = erythema multiforme.
• PE = pemphigus erythematosus.
• PF = pemphigus foliaceus.
• SLE = systemic lupus erythematosus.

DERMATOSES, EROSIVE OR ULCERATIVE

BASICS

DEFINITION
A heterogenous group of skin disorders characterized by disruption of the epidermis (erosions) or, if the basement membrane is compromised, the epidermis and dermis (ulcers).

PATHOPHYSIOLOGY
Varies widely, depending on the cause; may include congenital or developmental disorders that compromise tissue cohesion; cell-mediated (inflammatory or neoplastic) injury; anoxic injury; antigen-specific auto-immune disorders; and necrosis due to trauma, toxins, contactants (irritants), microbial organisms, or parasitic migration.

SYSTEMS AFFECTED
Skin/exocrine.

GENETICS
Some diseases are likely heritable due to breed predilections; however, there are no genetic screening tests available for any of the diseases listed.

INCIDENCE/PREVALENCE
Rare to common, depending on the cause.

SIGNALMENT

Species
Dogs and cats.

Breed Predilections
Some specific causes (see below) have strong breed predilections, e.g., lupoid disorders, familial dermatomyositis, and zinc-responsive dermatosis.

Mean Age and Range
• Highly variable according to etiology. • Canine juvenile cellulitis and several congenital diseases (see below) are diagnosed in very young animals.

Predominant Sex
Sex predispositions may vary according to the disease in question.

SIGNS

Historical Findings
• Pruritus may result in ulcers or erosions due to self-trauma; especially ectoparasitism, superficial pyoderma, and *Malassezia* dermatitis. • Exposure to caustic chemicals, burns, cold stress, venomous reptiles and insects, etc. • Some infectious diseases (e.g., pythiosis, coccidioidomycosis, feline cow pox) have very restricted ranges. • Previous or concurrent systemic signs or illness.

Physical Examination Findings
• Lesions may be heterogenous in gross appearance; some diseases result in erythematous erosions with minimal crust or scale, while others cause scale or crusting that (when removed) results in erosion. • Ulcers may be shallow/superficial or deep; deep ulceration can present as sinuses with draining tracts, cavitated lesions with well-demarcated borders, or exudative crusted lesions. • Some specific diseases are typically accompanied by fever and malaise, especially auto-immune disorders and infectious etiologies. • May be associated with extracutaneous disease (e.g., superficial necrolytic dermatitis and hypereosinophilic syndrome of cats).

CAUSES

Autoimmune
• Pemphigus foliaceus—crusting with erosion. • Pemphigus vulgaris—superficial ulcerative. • Bullous pemphigoid and epidermolysis bullosa acquisita—superficial ulcerative. • Discoid lupus erythematosus and mucocutaneous lupus erythematosus—erosive or superficial ulcerative. • Exfoliative lupus (German shorthaired pointers)—scaling with erosion. • Vesicular lupus (rough collies and Shetland sheepdogs)—superficial ulcerative. • Cold agglutinin disease—deep ulcerative.

Immune-Mediated
• Erythema multiforme, Stevens–Johnson syndrome, and toxic epidermal necrolysis (may be drug induced)—erosive to superficial ulcerative. • Vasculitis—superficial to deep ulcerative (may be cavitated). • Idiopathic panniculitis—deep ulcerative (usually exudative with crusting). • Canine eosinophilic furunculosis of the face (may be insect related)—ulcerative and crusting. • Canine juvenile cellulitis (puppy strangles)—erosive to superficial or deep ulcerative. • Feline indolent ulcer (rodent ulcer)—erosive to superficial or deep ulcerative.

Infectious
• Surface pyoderma—acute moist pyotraumatic dermatitis: erosive. • Superficial staphylococcal folliculitis—erosive to superficial ulcerative. • Bacterial folliculitis/furunculosis—deep ulcerative. • Superficial fungal (*Malassezia* dermatitis, dermatophytosis)—erosive to superficial ulcerative. • Deep fungal (sporotrichosis, cryptococcosis, histoplasmosis, blastomycosis, coccidioidomycosis)—deep ulcerative with or without sinuses and draining tracts. • Opportunistic mycobacteriosis—deep ulcerative nodules with sinuses and draining tracts. • Actinomycetic bacteria (*Nocardia* spp., *Actinomyces* spp., *Streptomyces* spp.)—deep ulcerative nodules with sinuses and draining tracts. • Pythiosis/lagenidiosis and protothecosis— ulcerative, proliferative with or without draining tracts. • Leishmaniasis—erosive to superficial or deep ulcerative. • Feline cow pox—deep ulcerative. • Feline immunodeficiency virus (FIV)/feline leukemia virus (FeLV) related—erosive to superficial ulcerative. • Feline herpesvirus-associated dermatosis—ulcerative with crusting.

Parasitic
• Demodicosis—ulcerative with crusting (especially with secondary bacterial folliculitis). • Sarcoptic/notoedric mange—erosive with crusting. • Flea bite allergy—erosive to ulcerative. • Feline mosquito bite hypersensitivity—erosive to superficial or deep ulcerative. • *Pelodera* and hookworm migration—deep ulcerative.

Congenital/Hereditary
• Canine familial dermatomyositis (predominantly in collies and Shetland sheepdogs)—erosive. • Epidermolysis bullosa—superficial ulcerative. • Cutaneous asthenia (Ehlers–Danlos syndrome)—skin tears easily.

Metabolic
• Superficial necrolytic dermatitis (usually associated with advanced hepatic disease or pancreatic glucagonoma)—crusting with erosion. • Hyperadrenocorticism—erosive to ulcerative when complicated by secondary infections or calcinosis cutis. • Uremia (mucous membranes)—superficial ulcerative.

Neoplastic
• Squamous cell carcinoma—erosive to ulcerative with scale or crust. • Feline squamous cell carcinoma in situ (Bowenoid in situ carcinoma)—erosive with scale or crust. • Mast cell tumors—superficial to deep ulcerative. • Epitheliotropic lymphoma (mycosis fungoides)—erosive to superficial ulcerative. • Feline thymoma-associated exfoliative dermatosis—scaling with erosion. • Feline paraneoplastic alopecia—erosive.

Nutritional
Zinc-responsive dermatosis—crusting with erosion.

Physical/Conformational

Dermatoses
• Pressure point ulcers—deep ulcerative. • Intertrigo (skinfold pyoderma)—erosive.

Idiopathic
• Feline dorsal neck ulcer—deep ulcerative with crusting. • Canine and feline acne—erosive to ulcerative. • Feline plasma cell pododermatitis—superficial to deep ulcerative.

Miscellaneous
Thermal (heat/cold), electrical, solar, or chemical irritant/burns—depth of lesions depends on severity of insult.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Depends upon presentation.

CBC/BIOCHEMISTRY/URINALYSIS
May be abnormal with metabolic or systemic disease.

(CONTINUED) DERMATOSES, EROSIVE OR ULCERATIVE

IMAGING
• Rarely indicated. • Thoracic radiographs—deep/systemic fungal diseases, feline thymoma-associated exfoliative dermatitis, or systemic neoplasia. • Abdominal ultrasound—superficial necrolytic dermatitis (dogs) or paraneoplastic alopecia (cats).

DIAGNOSTIC PROCEDURES
• Skin scraping—ectoparasitism. • Direct impression cytology—bacteria, yeast, or acantholytic keratinocytes in pemphigus. • Fine-needle aspirate with cytology— indurated or nodular lesions. • Culture: bacterial (aerobic and anaerobic), mycobacterial, and/or fungal—suspected infectious disease. • Fungal serology and serology for pythiosis and lagenidiosis may be indicated on a case-by-case basis and depending upon geographic location. • PCR and immunohistochemistry are adjuncts to the histologic diagnosis of feline herpesvirus-associated dermatitis.

PATHOLOGIC FINDINGS
Skin Biopsy
• For cavitated lesions, the leading edge (elliptical full-thickness biopsy) should be harvested with a scalpel blade if the defect is too large to be excised in total. • Punch biopsy sufficient for diffuse erosive lesions; should take normal skin near a lesion and lesions that are both early and late in development.

TREATMENT
APPROPRIATE HEALTH CARE
• Outpatient for most diseases. • Varies widely according to the cause.

DIET
• Nutritional support may be necessary in debilitated animals, especially those with superficial necrolytic dermatitis. • Correcting dietary deficiencies is the only treatment for generic dog-food dermatosis. • Supplementation of zinc is necessary for zinc-responsive dermatosis.

CLIENT EDUCATION
Variable by diagnosis; most important with suspected or confirmed zoonotic disease.

SURGICAL CONSIDERATIONS
• Indicated as curative treatment for feline thymoma-associated exfoliative dermatitis. • May be curative for nonmetastatic pancreatic or hepatobiliary tumors causing paraneoplastic alopecia. • Radical surgical excision of nodules and draining tracts may be an adjunct to antimicrobial therapy of infections caused by rapid-growing *Mycobacteria* spp. and *Nocardia* spp. in cats and pythiosis or lagenidiosis in dogs.

MEDICATIONS
DRUG(S) OF CHOICE
Variable by cause.

PRECAUTIONS
Side effects—associated with many antimicrobial, immunosuppressive, and antineoplastic drugs.

POSSIBLE INTERACTIONS
Dependent on medications administered.

FOLLOW-UP
PATIENT MONITORING
Dependent on disease process, concurrent systemic disease(s), drugs used, and potential side effects expected.

PREVENTION/AVOIDANCE
• Incidence of many feline infectious diseases can be minimized by restricting outdoor activity. • Some autoimmune diseases (lupus and pemphigus) are aggravated by ultraviolet light exposure; patients should be restricted from sun exposure during peak hours of the day.

POSSIBLE COMPLICATIONS
• Determined by cause. • Some diseases are potentially life-threatening. • Some diseases have zoonotic potential. • Infections and drug side effects are possible in cases requiring immunosuppression.

EXPECTED COURSE AND PROGNOSIS
• Some infectious diseases (nocardiosis, atypical mycobacteriosis) may be controlled with chronic antimicrobial therapy, but are generally not curable if lesion progression is extensive by the time of diagnosis. • Pythiosis/lagenidiosis—prognosis is extremely poor for response to therapy and survival when lesions are extensive.

MISCELLANEOUS
ZOONOTIC POTENTIAL
• Sarcoptic acariasis. • Dermatophytosis. • Sporotrichosis. • Mycelial phase of some fungi (e.g., *Coccidioides immitis*, *Blastomyces dermatitidis*), when grown on culture media, can be infectious to humans through inhalation. In-clinic fungal culturing (other than for dermatophytes) is not advised.

PREGNANCY/FERTILITY/BREEDING
• Due to the potential severity of clinical signs and syndromes, any patient diagnosed with an erosive/ulcerative disease that occurs with moderate to strong breed predilections should not be used for breeding. • Many drugs used to treat the auto-immune, immune-mediated, and infectious diseases listed may be teratogens.

SYNONYMS
Superficial necrolytic dermatitis = necrolytic migratory erythema, metabolic epidermal necrosis, hepatocutaneous syndrome.

SEE ALSO
• Acne—Cats.
• Acne—Dogs.
• Actinomycosis & Nocardia.
• Azotemia and Uremia.

DERMATOSES, EXFOLIATIVE

BASICS

DEFINITION
Excessive or abnormal shedding of epidermal cells resulting in the clinical presentation of cutaneous scaling.

PATHOPHYSIOLOGY
- An increase in the production, an increase in the desquamation, or a decrease in the cohesion of keratinocytes results in abnormal shedding of epidermal cells individually (fine scale) or in sheets (coarse scale).
- Primary exfoliative disorders—keratinization defects: genetic control of epidermal cell proliferation and maturation is abnormal.
- Secondary exfoliative disorders—disease alters the normal maturation and proliferation of epidermal cells.
- Anomalies in sebaceous or apocrine gland function may be present or causative.

SYSTEMS AFFECTED
Skin/exocrine.

SIGNALMENT
- Dog and cat.
- Primary—apparent by 2 years of age; characteristic in affected breeds.
- Secondary—any age; any breed of dog or cat.

SIGNS

Physical Examination Findings
- Dry or greasy collections of fine or coarse scale located diffusely throughout the hair coat or focally in keratinaceous plaques.
- Oily skin and hair.
- Malodor.
- Comedones.
- Follicular casts.
- Candle wax–like deposits on hair.
- Silver scales, mostly affecting nose, face, and ears.
- Alopecia.
- Pruritus.
- Secondary bacterial folliculitis and/or *Malassezia* dermatitis.

CAUSES

Primary
- Primary idiopathic seborrhea (primary keratinization disorder)—primary cellular defect; accelerated epidermopoiesis and hyperproliferation of the epidermis, follicular infundibulum, and sebaceous gland; cocker and springer spaniel, West Highland white terrier, basset hound, Doberman pinscher, Irish setter, and Labrador retriever.
- Vitamin A–responsive dermatosis—young cocker spaniels; clinically similar to severe idiopathic seborrhea; identified by response to oral vitamin A supplementation.
- Zinc-responsive dermatosis—alopecia, dry scaling, crusting, and erythema around the eyes, ears, feet, lips, and external orifices; two syndromes: young adult dogs (mainly Siberian husky and Alaskan Malamute) and rapidly growing large-breed puppies; nutritionally responsive.
- Ectodermal defects—follicular dysplasias; color mutant or dilution alopecia; represent anomalies in melanization of the hair shaft and structural hair growth; keratinization defects theorized as causative for several syndromes; Doberman pinscher, Irish setter, dachshund, chow chow, Yorkshire terrier, poodle, Great Dane, whippet, saluki, and Italian greyhound; failure to regrow blue or fawn hair with normal "point" hair growth, excessive scaliness, comedone formation, secondary pyoderma.
- Idiopathic nasodigital hyperkeratosis—excessive build-up of scale and crusts on the nasal planum and footpad margins; possibly a senile change; generally asymptomatic; spaniels and retrievers; cracking and secondary bacterial infection can cause pain.
- Sebaceous adenitis—inflammatory disease targeting sebaceous glands and ducts causing patchy or diffuse hair loss and excessive scaling; tightly adherent follicular casts; standard poodle, Akita, Samoyed, German shepherd, Havanese, Bernese Mountain dog, and vizsla.
- Ichthyosis—rare and severe congenital disorder of keratinization; West Highland white terrier, golden retriever, cavalier King Charles spaniel, and Norfolk terrier; generalized accumulations of scale and crusts at an early age; secondary infections (bacterial and yeast) common.
- Primary seborrhea in Persian kittens.

Secondary
- Cutaneous hypersensitivity—with pruritus, secondary skin trauma, and irritation.
- Ectoparasitism—scabies, demodicosis, and cheyletiellosis; with inflammation and exfoliation.
- Bacterial folliculitis—bacterial enzymatic disadhesion with increased exfoliation of keratinocytes.
- Dermatophytosis—increased exfoliation as a skin mechanism in resolving infection.
- Cutaneous Leishmaniasis in endemic regions of the world; systemic signs might be present.
- Endocrinopathy—hypothyroidism: abnormalities in keratinization, failure to regrow hair, and excessive sebum production; hyperadrenocorticism: abnormal keratinization and decreased follicular activity; excessive scaling and secondary pyoderma common in both syndromes; other hormonal abnormalities may also be associated with excessive scaling.
- Age—dull, brittle, and scaly hair coat due to alterations caused by natural changes in epidermal metabolism associated with age; no specific defect identified.
- Nutritional disorders—malnutrition and generic dog food dermatosis; auto-immune dermatoses—pemphigus complex: may appear exfoliative; vesicles become scaly and crusty; cutaneous and systemic lupus erythematosus: cutaneous signs often appear as areas of alopecia and scaling.
- Neoplasia—primary epidermal neoplasia (epitheliotropic lymphoma): with alopecia and scaling as epidermal structures are damaged by infiltrating lymphocytes; preneoplastic conditions (actinic keratosis): initially appear exfoliative.
- Miscellaneous—any disease process may result in excessive scale formation due to a metabolic disorder or to cutaneous inflammation.
- Exfoliative disorders—rare in cats: tail gland hyperplasia, feline thymoma-associated exfoliative dermatitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Based on signalment and history (breed-associated vs. age of onset), presence/absence of pruritus (hypersensitivity vs. secondary infection), and concurrent signs (endocrinopathy).

CBC/BIOCHEMISTRY/URINALYSIS
- Normal with primary keratinization disorders.
- Mild, nonregenerative anemia and hypercholesteremia are consistent with hypothyroidism.
- Neutrophilia, monocytosis, eosinopenia, lymphopenia, elevated serum alkaline phosphatase, hypercholesterolemia, and hyposthenuria suggest hyperadrenocorticism.

OTHER LABORATORY TESTS
Thyroid hormone levels and adrenal function tests if an endocrinopathy is suspected; see specific chapters for test recommendations. Serology, PCR, cytology, and histopathology for Leishmaniasis; see specific chapter.

IMAGING
Thoracic radiographs—feline thymoma-associated exfoliative dermatitis.

DIAGNOSTIC PROCEDURES
- Skin scraping.
- Skin biopsy—rule out particular differential diagnoses; strongly recommended for most cases.
- Intradermal allergy test.
- Restricted ingredient food trial.
- Cytology of skin surface.
- Microscopic examination of plucked hairs—macromelanosomes and structural anomalies in follicular dysplasia and color dilution alopecia.

TREATMENT

- Frequent and adequate topical therapy.
- Diagnose and control treatable primary and secondary diseases.
- Recurrence of secondary infections may require repeated therapy and further diagnostics.
- Maintaining control is often lifelong.
- Prioritize restoration of epidermal barrier integrity and function.

MEDICATIONS

DRUG(S) OF CHOICE

Shampoos

- Contact time—5–15 minutes required; >15 minutes discouraged, may result in epidermal maceration, loss of barrier function, and excessive epidermal drying and irritation.
- Relative keratolytic activity—hypoallergenic < sulfur/salicylic acid < benzoyl peroxide.
- Ethyl lactate—less keratolytic/less drying; useful for moderate bacterial folliculitis and dry scale.
- Chlorhexidine—antimicrobial; mildly drying; useful for moderate bacterial folliculitis and *Malassezia* dermatitis.
- Tar—keratolytic, keratoplastic, and antipruritic; useful for moderate scale associated with pruritus.

Moisturizers/Barrier Restoration

- Restore skin hydration and increases effectiveness of subsequent shampoos.
- Humectants—enhance hydration of the stratum corneum by attracting water from the dermis; at high concentrations may be keratolytic.
- Propylene glycol spray (50–75% dilution with water) applied frequently.
- Microencapsulation—may improve residual activity of moisturizers by allowing sustained release after bathing.
- Emollients—coat the skin; smooth the roughened surfaces produced by excessive scaling; usually combined with occlusives to promote hydration of the epidermis.
- Barrier restoration—phytosphingosines, ceramides.

Systemic Therapy

- Specific disease (e.g., thyroxine replacement for hypothyroidism).
- Systemic antibiotics—secondary pyoderma.
- Retinoids—varied success for idiopathic or primary seborrhea; reports of individual response in refractory cases; isotretinoin (1 mg/kg PO q12–24h); if response is seen, taper dosage (1 mg/kg q48h or 0.5 mg/kg q24h); difficult to dispense due to strict prescription procedures.
- Cyclosporine (modified) 5 mg/kg/day until controlled, then decreased to minimal effective maintenance dosage for individual cases of keratinization disorder associated with hypersensitivity, sebaceous adenitis, epidermal dysplasia, ichthyosis, and/or *Malassezia* dermatitis.

PRECAUTIONS

- Corticosteroids—use judiciously to control the inflammation resulting from exfoliative disorders; may mask signs of pyoderma and prevent accurate diagnosis of primary disease.
- Vitamin A and D analogues—side effects can be severe; patients should be referred to a dermatologist before being treated with these drugs; teratogenic.

FOLLOW-UP

PATIENT MONITORING

- Antibiotics and topical therapy—monitor response every 3 weeks; patients may respond differently to the various topical therapies.
- Development of additional diseases and recurrence of pyoderma—reevaluation critical to determine if new factors are involved and if changes in therapy are necessary.
- Endocrinopathy—specific laboratory testing for disease management.
- Selective autoimmune disorders—clinical evaluation and laboratory monitoring frequent initially; based on diagnosis and treatment protocols.
- Retinoid drugs—serum chemistries, including triglycerides, and Schirmer tear tests.

MISCELLANEOUS

AGE-RELATED FACTORS

Skin aging might be related to increase in exfoliative disorders or relapses.

ZOONOTIC POTENTIAL

- Dermatophytosis and several ectoparasites have zoonotic potential.
- Leishmaniasis is a reportable disease.

PREGNANCY/FERTILITY/BREEDING

Systemic retinoids and vitamin A in therapeutic dosages—extreme teratogen; do not use in intact females because of severe and predictable teratogenicity and extremely long withdrawal period; women of childbearing age should not handle these medications.

SYNONYMS

- Keratinization disorder, seborrhea, idiopathic seborrhea, keratinization defect, dyskeratinization.
- Eczema, psoriasis, dandruff—incorrect human terms.
- Sebopsoriasis—correct term to describe similarities between some human and canine keratinization defects.

SEE ALSO

- Atopic Dermatitis.
- Demodicosis.
- Hyperadrenocorticism (Cushing's Syndrome)—Cats.
- Hyperadrenocorticism (Cushing's Syndrome)—Dogs.
- Hypothyroidism.
- Leishmaniosis
- Malassezia Dermatitis.
- Pyoderma.
- Sarcoptic Mange.

DERMATOSES, NEOPLASTIC

BASICS

DEFINITION

• Neoplastic proliferation of cells derived from the skin or migrating to the skin. • Epidermal tumors include those arising from keratinocytes, melanocytes, Merkel cells, and Langerhans cells, and epitheliotropic lymphoma. • Adnexal tumors include those arising from hair follicles, sebaceous glands, and sweat glands. • Dermal and subcutaneous skin tumors include those of mesenchymal origin and tumors of round cell origin. • Secondary or metastatic skin tumors result from the proliferation of cells from primary neoplasms of other organs in the skin.

PATHOPHYSIOLOGY

• Neoplasia develops as a result of changes in genes controlling cell proliferation and homeostasis. • More than 100 cancer-related genes have been identified. • Oncogenes encode proteins that promote cell growth; tumor-suppressor genes encode proteins that restrict cell proliferation and differentiation. • Mutations in *p53*, a tumor-suppressor gene, are found in approximately 50% of cancers in humans and have also been found in many tumors affecting dogs and cats. • Ultraviolet light promotes tumor development by damaging DNA and suppressing the immune system. • Many viruses promote tumor growth through stimulating cell proliferation and/or suppressing the immune system. • Reports of specific cutaneous neoplasia associated with medications and/or vaccinations.

SYSTEMS AFFECTED

Skin/exocrine.

GENETICS

• Breed predispositions have been reported for specific tumors, but the mode of inheritance in these breeds has not been determined. Mutations in oncogenes and/or tumor-suppressor genes (e.g., *p53*) are present in many types of skin tumors.

INCIDENCE/PREVALENCE

• The combined incidence rate for skin tumors has been reported as 728/100,000 (0.728%) for dogs and 84/100,000 (0.084%) for cats. • The skin is the most common site of occurrence of neoplasia in the dog (30% of total tumors) and the second most common site in the cat (20% of total tumors).
• Canine skin tumors are approximately 55% mesenchymal, 40% epithelial, and 5% melanocytic. • The most frequently reported cutaneous or subcutaneous tumors in descending order for dogs are lipoma, sebaceous gland adenoma, mast cell tumor, papilloma, and histiocytoma. • Feline skin tumors are approximately 50% epithelial, 48% mesenchymal, and 2% melanocytic. • The most frequently reported cutaneous or subcutaneous tumors in cats are basal cell tumor, squamous cell carcinoma, mast cell tumor, and fibrosarcoma. • Skin tumors in cats are more frequently malignant; skin tumors in dogs are more frequently benign.

GEOGRAPHIC DISTRIBUTION

Geographic regions near the equator, with high altitude, or with sand or other reflective surfaces, have a higher incidence of solar-induced neoplastic dermatoses.

SIGNALMENT

Species

Dogs and cats.

Breed Predilections

• Canine breeds with the highest overall incidence of skin tumors include boxer, Scottish terrier, bullmastiff, basset hound, Weimaraner, Kerry blue terrier, and Norwegian elkhound. • Feline breeds with the highest overall incidence of skin tumors include Siamese and Persian. • Certain breeds are predisposed to specific types of tumors (see Suggested Reading). • Dog—breeds associated with the most common cutaneous neoplasms: ○ Lipoma—cocker spaniel, dachshund, Doberman pinscher, Labrador retriever, miniature schnauzer, Weimaraner. ○ Sebaceous gland tumor—beagle, cocker spaniel, dachshund, Irish setter, Lhasa apso, Malamute, miniature schnauzer, poodle, shih tzu, Siberian husky. ○ Mast cell tumor—American Staffordshire terrier, beagle, Boston terrier, boxer, bull terrier, dachshund, English bulldog, fox terrier, golden retriever, Labrador retriever, pug, shar-pei, Weimaraner. ○ Histiocytoma—American Staffordshire terrier, Boston terrier, boxer, cocker spaniel, dachshund, Doberman pinscher, English springer spaniel, Great Dane, Labrador retriever, miniature schnauzer, Rottweiler, Scottish terrier, shar-pei, Shetland sheepdog, West Highland white terrier. ○ Papilloma—cocker spaniel, Kerry blue terrier. • Cat—breeds associated with the most common cutaneous neoplasms: ○ Basal cell tumor—Persian, Himalayan (basal cell carcinoma—Siamese). ○ Squamous cell carcinoma—no predisposed breed reported. ○ Mast cell tumor—Siamese. ○ Fibrosarcoma—no predisposed breed reported.

Mean Age and Range

• The median age for cutaneous neoplasia is 10.5 years in dogs and 12 years in cats. • The peak age period for cutaneous neoplasia in dogs and cats is 6–14 years.

Predominant Sex

• Females have a higher incidence of tumors in dogs (56%). • Males have a higher incidence of tumors in cats (56%).

SIGNS

General Comments

Most common clinical sign is a cutaneous or subcutaneous nodule; some tumors have an ulcerated surface; others may result in excessive scaling or in the formation of cutaneous plaques.

Historical Findings

• Tumors are most often slow growing; the owner may find them during petting, bathing, or grooming of the pet. • Tumors may be rapidly growing and appear (or increase in size) quickly (e.g., histiocytoma).

Physical Examination Findings

• Nodules—cutaneous or subcutaneous. • Cutaneous ulcers. • Excessive scaling. • Cutaneous papillomas. • Cutaneous plaques.

CAUSES

• Genetic (gene mutations). • Environmental (e.g., ultraviolet light, radiation exposure). • Viruses (e.g., papillomaviruses, feline leukemia virus, feline immunodeficiency virus). • Toxins (e.g., tars). • Drugs (e.g., immunosuppressive agents, chemotherapeutic agents). ○ Epidermal neoplasms: ○ Keratinocytes—papillomas, squamous cell carcinoma, basal cell carcinoma, basosquamous carcinoma. ○ Melanocytes—melanoma. ○ Merkel cells—Merkel cell carcinoma. ○ Langerhans cells—histiocytoma and malignant histiocytosis. ○ Epitheliotropic lymphoma—T lymphocytes. • Adnexal neoplasms: ○ Hair follicles—trichofolliculoma, trichoepithelioma, infundibular keratinizing acanthoma, tricholemmoma, pilomatrixoma, trichoblastoma. ○ Sebaceous glands—sebaceous adenoma, sebaceous epithelioma, sebaceous adenocarcinoma, perianal gland epithelioma, perianal gland carcinoma. ○ Sweat glands—apocrine cystadenoma, apocrine secretory adenoma/adenocarcinoma, apocrine ductal adenoma/carcinoma, eccrine carcinoma. • Dermal and subcutaneous neoplasms: ○ Mesenchymal origin—soft tissue sarcoma: fibroma/fibrosarcoma, myxoma/myxosarcoma, hemangiopericytoma, lymphangioma/lymphangiosarcoma, hemangioma/hemangiosarcoma, lipoma/liposarcoma, neurofibrosarcoma, leiomyoma/leiomyosarcoma, synovioma/synovial sarcoma, rhabdomyoma/rhabdomyosarcoma. ○ Round cell origin—transmissible venereal tumor, mast cell tumor, plasmacytoma, lymphoma, histocytoma, and histocytic tumors. • Secondary or metastatic skin tumors result from the metastasis or primary neoplasms in other organs to the skin.

RISK FACTORS

• Hair coat color and length (e.g., hairless breeds, white hair coat, lightly pigmented skin—increased risk for squamous cell carcinoma). • Age (e.g., young animals

highest risk for viral infections, older animals at highest risk for environment-associated neoplasia). • Sunlight exposure (e.g., dogs and cats that sunbathe or spend time outdoors on reflective surfaces have higher risk of ultraviolet light–induced skin tumors). • Genetics—certain breeds have higher risk of developing specific types of tumors (see above and Suggested Reading).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Cyst. • Abscess. • Inflammatory nodule/granuloma/plaque—sterile granulomatous and pyogranulomatous disease, sterile panniculitis, fungal infection, mycobacterial infection, foreign body. • Trauma/self-induced skin ulceration. • Hamartoma/nevus.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

• Cytology (fine-needle aspirate or impression smear). • Regional lymph node aspirate (for staging).

IMAGING

Thoracic radiographs and abdominal ultrasonography useful for staging (evaluate for metastatic disease or underlying primary neoplasia).

DIAGNOSTIC PROCEDURES

• Cytology. • Biopsy with histopathologic examination. • Immunohistochemistry (useful in confirming certain types of tumors).

PATHOLOGIC FINDINGS

Varies with tumor type; see specific tumors for additional information.

TREATMENT

APPROPRIATE HEALTH CARE

• Varies with tumor type. • Observation is appropriate for some benign tumors. • Surgical excision, cryosurgery, radiation therapy, and/or tumor-specific chemotherapy or immunotherapy may be curative or palliative.

NURSING CARE

• Varies with tumor type and location. • Traumatized tumors may become secondarily infected.

ACTIVITY

Varies with tumor type and location.

DIET

Diets high in omega-3 fatty acids, arginine, and protein may be beneficial in boosting the immune response and preventing cancer-associated cachexia.

CLIENT EDUCATION

Varies with tumor type and location.

SURGICAL CONSIDERATIONS

• Vary with tumor type and location—wide margins may be needed to prevent reoccurrence of infiltrative tumors. • Pretreatment with antihistamines appropriate when excising mast cell tumors.

MEDICATIONS

DRUG(S) OF CHOICE

Vary with tumor type—chemotherapy protocols are useful in some cases.

CONTRAINDICATIONS

Vary with tumor type and presence of concurrent disease.

PRECAUTIONS

Vary with tumor type and location.

POSSIBLE INTERACTIONS

Vary with tumor type and location.

ALTERNATIVE DRUG(S)

Vary with tumor type and location.

FOLLOW-UP

PATIENT MONITORING

Varies with tumor type and location.

PREVENTION/AVOIDANCE

• Varies with tumor type and location. • Minimize exposure to ultraviolet light to help prevent some types of tumors.

POSSIBLE COMPLICATIONS

Vary with tumor type and location.

EXPECTED COURSE AND PROGNOSIS

Vary with tumor type and location.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Vary with tumor type and location.

AGE-RELATED FACTORS

Vary with tumor type and location.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

Varies with tumor type; some may have a genetic predisposition.

SYNONYMS

N/A

DERMATOSES, PAPULONODULAR

BASICS

DEFINITION
- Diseases whose primary lesions manifest as papules and nodules.
- Papule—solid, elevated lesion of the skin less than 1 cm in diameter.
- Nodule—solid, elevated lesion of the skin more than 1 cm in diameter that extends into deeper layers of the skin.

PATHOPHYSIOLOGY
- Papules—usually the result of tissue infiltration by inflammatory cells; accompanying intraepidermal edema or epidermal hyperplasia and dermal edema.
- Nodules—usually the result of a massive infiltration of inflammatory or neoplastic cells into the dermis or subcutis.

SYSTEMS AFFECTED
Skin/exocrine.

GENETICS
Determined by cause; specific diseases may be more commonly seen in certain breeds.

INCIDENCE/PREVALENCE
Determined by cause.

GEOGRAPHIC DISTRIBUTION
Determined by cause.

SIGNALMENT
Species
Dogs and cats.

Breed Predilection
Determined by cause.

Mean Age and Range
Determined by cause.

Predominant Sex
Determined by cause.

SIGNS
- Papules and/or nodules with distribution characteristic of the cause.
- Accompanying crusting, inflammation, pigmentation changes, and hair coat changes often noted; also characteristic of the cause.

CAUSES
- Superficial and deep bacterial folliculitis (e.g., *Staphylococcus*).
- Other bacterial—mycobacterial, actinomycosis, nocardiosis, abscess.
- Fungal—dermatophytosis (including pseudomycetoma/kerion), histoplasmosis, cryptococcosis, coccidiomycosis, sporotrichosis, blastomycosis, phaeohyphomycosis.
- Sebaceous adenitis, granulomatous.
- Canine and feline acne.
- Parasitic—demodicosis, Leishmaniasis, flea bite hypersensitivity, sarcoptic mange, pelodera dermatitis.
- Sterile nodular—sterile pyogranulomatous dermatitis and panniculitis, reactive histiocytosis.
- Metabolic—cutaneous xanthomatosis, calcinosis circumscripta.
- Hypersensitivity—feline eosinophilic dermatitis.
- Neoplasia.

RISK FACTORS
- Bacterial folliculitis, dermatophytosis, and demodicosis—any disease or medication that causes immune compromise or interferes with the barrier function of the skin.
- Pelodera dermatitis—may be associated with contact with decaying organic debris (straw or hay) containing *Pelodera strongyloides*.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Determined by cause.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal—determined by cause.

OTHER LABORATORY TESTS
Determined by cause.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- Skin scraping—parasites.
- Dermatophyte cultures—dermatophytes.
- Pustule (if present) impression smear cytology—bacteria and degenerative neutrophils compatible with bacterial folliculitis; eosinophils can be compatible with hypersensitivity and/or with rupturing folliculitis or furunculosis; acantholytic keratinocytes consistent with an inflammatory folliculitis or pemphigus disease.
- Culture from tissue (fungal, bacterial, mycobacterial)—identify deep/systemic infection; possible susceptibility report for treatment.
- Aspirate and cytology from nodule—identify cellular infiltrate; presence of organisms.
- Skin biopsy— determine definitive diagnosis; especially if baseline diagnostic procedures are normal and/or initial empiric treatment is ineffective.

PATHOLOGIC FINDINGS
Depends upon underlying disease process.

TREATMENT

APPROPRIATE HEALTH CARE
- Outpatient for nearly all causes (except some cases of neoplasia).
- Generalized demodicosis with secondary sepsis requires hospitalization.

NURSING CARE
Depends upon underlying issue.

ACTIVITY
No specific alteration of activity recommended.

DIET
No specific alteration of diet recommended.

CLIENT EDUCATION
- For fungal infections, treatment may be expensive and prognosis can be guarded for deep/systemic fungal infections.
- For immune-mediated processes, treatment may be for the duration of the patient's life.

SURGICAL CONSIDERATIONS
Rarely necessary unless neoplasia is diagnosed.

MEDICATIONS

DRUG(S) OF CHOICE
Bacterial Folliculitis
- Superficial pyoderma—appropriate antibiotics based on bacterial culture and susceptibility testing for at least 3–4 weeks, or 1 week beyond resolution of clinical signs.
- Deep pyoderma—appropriate antibiotics based on bacterial culture and susceptibility testing for at least 6–8 weeks, or 2 weeks beyond resolution of clinical signs.
- Identify and control underlying cause to prevent recurrence.
- See Pyoderma for additional recommendations.

Sebaceous Adenitis
- Appropriate antibiotics if secondary bacterial infection present.
- Propylene glycol and water (50–75% dilution) once daily as a spray to affected areas helpful in mild cases.
- Essential fatty acid dietary supplements (omega-3 and omega-6 PO).
- Topical therapy—antiseborrheic shampoos, emollient rinses (baby oil), and humectants.
- Cyclosporine, modified (5 mg/kg PO q24h).
- Vitamin A (10,000–30,000 IU PO daily or 1000 IU/kg PO daily).
- Refractory cases—isotretinoin (1 mg/kg PO q12–24h); if response is seen, taper dosage (1 mg/kg q48h or 0.5 mg/kg q24h); the synthetic retinoids have become difficult to dispense due to strict prescription procedures.
- Most cases are refractory to corticosteroids.
- See Sebaceous Adenitis, Granulomatous for additional recommendations.

Canine and Feline Acne
- May resolve without therapy in mild cases.
- Warm water soaks or Epsom salt solution (2 T/quart or 30 m/L of water) for 5–10 min.
- Chlorhexidine-based pads, or acetic acid/boric acid pads/wipes, or benzoyl peroxide gels used daily or alternated daily; topical ceramide/EFA preparations may be helpful.

(CONTINUED) DERMATOSES, PAPULONODULAR

• Topical creams/ointments—mupirocin 2% ointment: topical antibiotic; apply q24h; should not be used in cats with deep lesions; metronidazole, 0.05% Vitamin A acid cream, clindamycin are alternative options.
• Secondary bacterial infection—systemic antibiotics.
• Underlying cause(s) should be determined and treated accordingly.
• Refractory cases—isotretinoin (1–2 mg/kg PO q24h); oral synthetic retinoids have become difficult to dispense due to strict prescription procedures; prednisolone PO (1–2 mg/kg/day for 10–14 days and taper) may reduce scar tissue formation.
• See Acne—Cats and Acne—Dogs for additional recommendations.

Pelodera Dermatitis

• Remove and destroy bedding.
• Wash kennels, beds, and cages and treat with a premise insecticide or flea spray.
• Bathe affected animal and remove crusts.
• Parasiticidal dip or ivermectin as recommended for sarcoptic mange.
• Corticosteroids as needed for inflammation.
• Severe infection—may require use of antibiotics.

Sterile Nodular Dermatoses

• Attempt to identify underlying cause.
• Cyclosporine, modified 5 mg/kg PO q24h.
• Tetracycline (250 mg <10 kg, 500 mg >10 kg q8–12h), doxycycline (10 mg/kg q24h), or minocycline (5 mg/kg q12h) with niacinamide (250 mg <10 kg, 500 mg >10 kg q8–12h).
• Corticosteroids at immunosuppressive doses and taper according to response.
• Chemotherapeutic drugs (chlorambucil or azathioprine or mycophenolate mofetil).

Other

• Dermatophytosis—itraconazole, ketoconazole, or terbinafine; see Dermatophytosis.
• Kerion—see Dermatophytosis.
• Demodicosis/sarcoptic mange—see Demodicosis, Sarcoptic Mange.
• Other bacterial infection—antibiotics dependent upon culture and sensitivity results.
• Deep/systemic fungal infection.
• Feline eosinophilic dermatitis—look for underlying cause.
• Neoplasia—see Dermatoses, Neoplastic.

CONTRAINDICATIONS

Corticosteroids and immunosuppressive medications should be avoided with folliculitis, dermatophytosis, kerion, and demodicosis.

PRECAUTIONS

• Side effects more common and more severe with ketoconazole than with other azoles in cats.
• Cats can be sensitive to the irritant effects of benzoyl peroxide.
• Fatty acids—use with caution in dogs with inflammatory bowel disease or recurrent pancreatitis.
• Isotretinoin—may cause keratoconjunctivitis sicca, hyperactivity, pinnal pruritus, erythematous mucocutaneous junctions, swollen tongue, lethargy with anorexia or vomiting, abdominal distension, or collapse; CBC and chemistry screen abnormalities include high platelet count, hypertriglyceridemia, hypercholesterolemia, and high alanine transaminase; teratogen.
• Cyclosporine—may cause vomiting and diarrhea, gingival hyperplasia, B lymphocyte hyperplasia, hirsutism, papillomatous skin eruptions, and increased incidence of infection; decreased glucose homeostasis; potential toxic reactions rare and include nephrotoxicity and hepatotoxicity.
• Azathioprine, mycophenolate mofetil, and chlorambucil—potential for bone marrow suppression, gastrointestinal upset; azathioprine can cause hepatotoxicity and possibly pancreatitis.

POSSIBLE INTERACTIONS

• Cyclosporine and corticosteroids interact with several medications; an appropriate drug formulary should be consulted prior to usage.
• Referral to a veterinary dermatologist should be considered if the etiology remains undetermined and/or prior to prescribing unfamiliar medications.

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

• CBC, chemistry screen, urinalysis, and urine cultures—monitor periodically in patients receiving immunosuppressive medications; monitoring will depend upon medication and dosage.
• CBC, chemistry screen, and urinalysis—monitor monthly for 4–6 months in patients receiving synthetic retinoid therapy.
• Tear production—monitor monthly for 4–6 months, then every 6 months in patients receiving synthetic retinoid therapy or sulfonamide-containing antibiotics.
• Skin scraping—monitor therapy in patients with Demodicosis (see Demodicosis).
• Repeat fungal culture—monitor therapy in patients with dermatophytosis (see Dermatophytosis).
• Resolution of lesions—monitor progress of sebaceous adenitis, actinic conditions, and all other diseases.

POSSIBLE COMPLICATIONS

Dependent upon specific disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

• Dermatophytosis—incidence in humans reported in 30–50% of cases of *Microsporum canis*, but possible with all dermatophytosis cases.
• Fungal infections—potential depends upon organism.
• Sarcoptic mange.

PREGNANCY/FERTILITY/BREEDING

• Synthetic retinoids—teratogens; do not use in pregnant animals, animals intended for reproduction, or intact female animals; should not be handled by women of childbearing age.
• Corticosteroids—avoid use in pregnant animals.
• Cyclosporine—avoid during pregnancy unless necessary; dosages two to five times normal have been fetotoxic and embryotoxic in rats and rabbits.
• Antifungal agents should be avoided in pregnant animals.
• All drugs should be used with caution in pregnant and breeding animals.

SEE ALSO

• Acne—Cats.
• Acne—Dogs.
• Demodicosis.
• Dermatophytosis.
• Pyoderma.
• Sebaceous Adenitis, Granulomatous.

DERMATOSES, STERILE NODULAR/GRANULOMATOUS

BASICS

DEFINITION
Sterile diseases with primary lesions of nodules and/or plaques.

PATHOPHYSIOLOGY
- Nodules/plaques—usually result from an infiltration of inflammatory cells into the dermis and subcutis; may be secondary to endogenous or exogenous stimuli.
- Inflammation is typically, but not always, granulomatous to pyogranulomatous.

SYSTEMS AFFECTED
Skin/exocrine.

GENETICS
Oligogenic transmission is proposed for histiocytic sarcoma for Bernese mountain dogs.

SIGNALMENT
- Collagenous nevi—German shepherd dogs 3–5 years old.
- Calcinosis circumscripta—German shepherd dogs <2 years old.
- Systemic histiocytosis and malignant histiocytosis—Bernese mountain dogs (primarily), Rottweilers, and retrievers (golden and Labrador).
- Eosinophilic granuloma—Siberian huskies <3 years, males.

SIGNS
- Characterized by single to multiple dermal to subcutaneous nodules and/or plaques.
- Firm to fluctuant.
- Occasionally painful.
- Overlying epidermis may be normal to ulcerated.

CAUSES
- Amyloidosis.
- Foreign body reaction.
- Spherulocytosis.
- Idiopathic sterile granuloma and pyogranuloma.
- Canine eosinophilic granuloma.
- Calcinosis cutis.
- Calcinosis circumscripta.
- Reactive (cutaneous, systemic) or malignant histiocytosis (disseminated histiocytic sarcoma).
- Sterile nodular panniculitis.
- Collagenous nevi (nodular dermatofibrosis).
- Cutaneous xanthoma.

RISK FACTORS
- Foreign body reaction—induced by exposure to any irritating material.
- Calcinosis cutis—increased risk with exposure to high doses of exogenous or endogenous glucocorticosteroids.
- Panniculitis—increased risk with vitamin E–deficient diet.
- Cutaneous xanthoma—high-fat treats or diet, diabetes mellitus, hyperlipidemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Sterile nodular dermatoses must be differentiated from deep bacterial and fungal infections and dermal neoplasia.
- Diagnosis by histopathology and deep tissue cultures.
- Immunohistochemistry—differentiating histiocytic conditions.
- Immunohistochemical staining and PCR testing—diagnose Leishmaniasis and mycobacterial infections.

CBC/BIOCHEMISTRY/URINALYSIS
- Amyloidosis—possible changes in biochemistry and/or urinalysis if internal organs are affected.
- Malignant histiocytosis—pancytopenia.
- Calcinosis cutis—changes characteristic of hyperglucocorticoidism.
- Cutaneous xanthomas—may have glucosuria, hyperglycemia, and/or lipid profile abnormalities.
- Sterile panniculitis—possible biochemistry changes associated with pancreatitis, hepatic disease, or systemic lupus erythematosus.

IMAGING
Radiology and ultrasonography—involvement of internal organs in amyloidosis and histiocytosis; areas of dystrophic calcification and/or adrenal enlargement or tumor in dogs with calcinosis cutis; renal or uterine tumors in German shepherd dogs with collagenous nevi.

DIAGNOSTIC PROCEDURES
- Skin biopsy for histopathology and cultures (fungal, aerobic, anaerobic, and mycobacterial).
- Biopsies should be excisional and taken from an intact or early (nondraining) nodule if possible.
- Culture samples should be taken from nodular tissue, not exudates.
- Special histopathologic stains for bacteria, mycobacteria, and fungi.

PATHOLOGIC FINDINGS
- Amyloidosis—accumulation of amorphous eosinophilic deposits that may extend into the subcutis; deposits stain apple green with Congo red in polarized light.
- Foreign body reaction—suppurative to pyogranulomatous inflammation that affects the dermis, subcutis, and occasionally the underlying muscle.
- Spherulocytosis—histiocytes surrounding thin-walled parent bodies filled with homogeneous eosinophilic spherules.
- Idiopathic sterile granuloma and pyogranuloma—granulomatous to pyogranulomatous inflammation that can extend from the dermis to the panniculus; differentiated from infectious diseases by obtaining negative cultures.
- Canine eosinophilic granuloma—accumulation of eosinophils with edema, possible mucin, and collagen degeneration.
- Calcinosis cutis—diffuse calcium deposition of the dermal collagen and adnexa that may extend into the deeper tissue.
- Calcinosis circumscripta—focal to multifocal deposits of mineral that efface the soft tissue.
- Reactive histiocytosis (cutaneous and systemic)—markedly angiocentric infiltrate of histiocytes that do not form granulomas or pyogranulomas.
- Malignant histiocytosis (disseminated histiocytic sarcoma)—dense pleomorphic cell proliferation of spindle or round cells that efface normal tissue architecture; tumors from other spindle and round cell tumors differentiated by immunohistochemistry; see specific chapters.
- Sterile nodular panniculitis—neutrophilic to pyogranulomatous inflammation that affects the deep dermis and panniculus predominantly; adipocytes may be necrotic or may be infiltrated by foamy macrophages; differentiated from infectious diseases by obtaining negative cultures.
- Collagenous nevi—focal but often subtle dermal thickening of normal collagen bundles.
- Cutaneous xanthoma—diffuse granulomatous inflammation composed of large foamy macrophages; lakes of extracellular amorphous lipid deposits and cholesterol clefts.

TREATMENT

APPROPRIATE HEALTH CARE
- Most of these disorders can be treated on an outpatient basis.
- Neoplastic or metabolic disorders may require hospitalization and supportive care.

NURSING CARE
Gentle bathing and soaking to clean the skin and remove debris.

DIET
Animals with xanthoma should be on a low-fat diet.

CLIENT EDUCATION
- Malignant histiocytosis, amyloidosis, collagenous nevi of German shepherd dogs, and systemic reactive histiocytosis are almost always fatal.
- Prognoses for cutaneous reactive histiocytic disease, sterile panniculitis, and sterile pyogranuloma are guarded since they may

(CONTINUED) # DERMATOSES, STERILE NODULAR/GRANULOMATOUS

require long-term immunosuppressive therapy; a few of these cases will not respond to therapy at all.

MEDICATIONS

DRUG(S) OF CHOICE

- Amyloidosis—no known therapy, unless the lesion is solitary and can be surgically removed.
- Spherulocytosis—only effective treatment is surgical removal.
- Idiopathic sterile granuloma and pyogranuloma:
  - Prednisolone (2.2–4.4 mg/kg divided PO q12h) is the first line of therapy; continue steroids for 7–14 days after complete remission, then taper dose.
  - Azathioprine (2.2 mg/kg q48h) or cyclosporine (modified, 5–10 mg/kg q24h) added as a steroid-sparing drug.
- Foreign body reactions—removal of the offending substance; secondary deep bacterial infections require treatment with both topical and systemic antibiotics.
- Canine eosinophilic granuloma—prednisolone (1.1–2.2 mg/kg PO q24h) usually effective.
- Cutaneous/systemic or malignant histiocytosis—no effective long-term therapy; see Histiocytosis, Cutaneous.
- Calcinosis cutis—underlying disease must be controlled if possible; most cases require antibiotics to control secondary bacterial infections; hydrotherapy and frequent bathing in antibacterial shampoos minimize secondary infection; topical dimethyl sulfoxide (DMSO) is useful (applied to no more than one-third of the body once daily until lesions resolve); if lesions are extensive, serum calcium levels should be monitored closely while using DMSO.
- Calcinosis circumscripta—surgical excision.
- Sterile nodular panniculitis:
  - Single lesions can be removed surgically.
  - Prednisolone (2.2–4.4 mg/kg PO q24h or divided PO q12h) treatment of choice; administer until lesions regress, then taper; some dogs remain in long-term remission, others require prolonged alternate-day therapy.
  - Azathioprine (2.2 mg/kg q48h) can be used together with prednisolone as a corticosteroid-sparing agent.
  - Cyclosporine, modified (5–10 mg/kg 24h) can be used together with prednisolone or as an alternative to glucocorticosteroid therapy if the patient is steroid intolerant or steroids are not sufficiently effective.
  - Tetracycline (250 mg <10 kg, 500 mg >10 kg q8–12h), doxycycline (10 mg/kg q24h), or minocycline (5 mg/kg q12h) with niacinamide (250 mg <10 kg, 500 mg >10 kg q8–12h) can also be used as an alternative to glucocorticoid therapy; this is effective only in mild cases.
- Collagenous nevi—no therapy for most cases since cystadenocarcinomas are usually bilateral; for rare unilateral case of cystadenocarcinoma or cystadenoma, removal of single affected kidney may be helpful; ovariohysterectomy should be performed in intact females to remove leiomyomas.
- Cutaneous xanthoma—correction of underlying diabetes mellitus or hyperlipoproteinemia usually curative.

CONTRAINDICATIONS

Corticosteroids and other immunosuppressive drugs should be avoided, if possible, in any animal with secondary bacterial folliculitis.

PRECAUTIONS

DMSO—handle with care; monitor serum calcium levels if used to treat calcinosis cutis.

FOLLOW-UP

PATIENT MONITORING

- Patients on long-term immunosuppressive therapy should have CBC, chemistry screen, urinalysis, and urine culture performed at least every 6 months.
- Dogs treated with DMSO for calcinosis cutis should have calcium levels checked every 7–14 days for first month of therapy if large areas are affected.

POSSIBLE COMPLICATIONS

Long-term use of immunosuppressive therapy (especially glucocorticosteroids) may make patients more susceptible to other dermatoses such as bacterial folliculitis, demodicosis, and dermatophytosis, as well as systemic side effects.

EXPECTED COURSE AND PROGNOSIS

- Systemic amyloidosis, malignant histiocytosis, systemic reactive histiocytosis, and nodular dermatofibrosis—invariably fatal.
- Many of the other conditions have a guarded prognosis; many require lifelong immunosuppressive therapy to remain in remission.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Calcinosis cutis—hyperglucocorticoidism, chronic renal failure, and diabetes mellitus.
- Calcinosis circumscripta—(occasionally) hypertrophic osteodystrophy and idiopathic polyarthritis.
- Collagenous nevi—renal cystadenoma/cystadenocarcinoma and uterine, leiomyoma/leiomyosarcoma.
- Cutaneous xanthoma—diabetes mellitus and hyperlipoproteinemia.

SEE ALSO

- Adenocarcinoma, Renal.
- Amyloidosis.
- Hyperadrenocorticism (Cushing's Syndrome)—Dogs.

ABBREVIATIONS

- DMSO = dimethyl sulfoxide

DERMATOSES, SUN-INDUCED

BASICS

OVERVIEW

The hair coat and epidermal pigmentation protect the skin from damage caused by UV light radiation. Excessive UV exposure damages keratinocytes (producing mutation), causes inflammation, and decreases cutaneous immune system surveillance. UVA (320–400 nm) penetrates more deeply than UVB (290–320 nm). Prolonged and repeated damage leads to preneoplastic changes and eventual neoplasia. Prolonged sun exposure in darkly pigmented individuals may cause thermal burn. UV exposure may exacerbate symptoms of pemphigus erythematosus (PE), discoid lupus erythematosus (DLE), systemic lupus erythematosus (SLE), and dermatomyositis.

SIGNALMENT

- Dogs—Dalmatian, bull terrier, boxer, bulldog, basset hound, beagle, whippet, American Staffordshire terrier, Australian shepherd (nasal solar dermatitis).
- Cats—white cats.

SIGNS

- Dogs—glabrous areas especially axillae, flanks, ventral abdomen, lateral extremities.
- Cats—pinnae, nasal planum, dorsal muzzle, eyelids.
- Solar dermatitis—photodermatitis.
  - Nasal—erythema and scaling at junction of haired and hairless skin of nose; expands caudally followed by scarring.
  - Truncal—erythema, scaling, and lichenification; gradual palpable thickening of white areas (adjacent dark areas are normal), comedones; secondary deep pyoderma.
- Actinic keratosis— premalignant epithelial dysplasia capable of becoming invasive squamous cell carcinomas (SCC); indurated, crusted, hyperkeratotic plaques.
- Hemangioma—well-circumscribed plaques or nodules, firm to fluctuant, bluish to purplish.
- Hemangiosarcoma—poorly circumscribed dermal dark red to purple, fluctuant nodules; may become large; commonly ulcerate and bleed; subcutaneous hemangiosarcomas usually not solar induced.
- SCC—proliferative and ulcerated plaques; easily traumatized; secondary pyoderma common; locally invasive and slow to metastasize.
- Solar-induced thermal burn (dorsal thermal necrosis)—alopecia, erythema, ulceration, eschars/necrosis, and crusts on the dorsal parts of the body; dogs with dark shorthair coats at increased risk.
- Cutaneous horns—firm hornlike projections, may originate from actinic keratoses, SCC, or other neoplasia; the base of a horn must be inspected for underlying cause.

CAUSES & RISK FACTORS

- White-haired and lightly haired individuals with poorly pigmented skin.
- History of sunbathing.
- Outdoor housing.
- Regions with greater sun exposure, high altitudes; usually occurs in summer, but also in winter as result of reflection from snow.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dermatophytosis.
- Demodicosis.
- DLE.
- PE.
- Pemphigus foliaceus.
- Drug eruption.
- Contact dermatitis.
- Chemical burn.

DIAGNOSTIC PROCEDURES

- Biopsy/histopathology—definitive diagnosis.
- Solar dermatitis—epidermal hyperplasia, apoptotic keratinocytes, perivascular inflammation, vascular dilatation, dermal fibrosis and elastosis.
- Actinic keratosis—parakeratotic hyperkeratosis with epidermal atypia and solar elastosis.
- Hemangioma—proliferative blood-filled vascular channels with minimal atypia or mitosis.
- Hemangiosarcoma—invasive proliferation of atypical endothelial cells with areas of vascular space formation.
- SCC—invasion of dermis by keratinocytes; keratin "pearls," mitoses, atypia.
- Solar-induced thermal burn—partial/full thickness necrosis of the epidermis, adnexa, dermis; coagulation necrosis.

TREATMENT

- Sun avoidance—keep indoors during day; avoid reflected sunlight; apply waterproof (>30 SPF) sunscreen (without zinc oxide and PABA); sun-protective clothing.
- Surgical excision of neoplastic lesions.

MEDICATIONS

DRUG(S) OF CHOICE

- Cyclooxygenase-2 (COX2) inhibitors—overexpression by sun-damaged cells; inhibition of COX2 demonstrated improvement: firocoxib 5 mg/kg/day PO.
- Glucocorticoids—reduced inflammation noted in acute cases; prednisolone 0.5–1 mg/kg PO tapering dosage; discontinue when possible.
- Imiquimod 5% cream—induces local immune response; for individual lesions, esp. actinic keratosis; apply q48h until resolution.
- Cryosurgery—actinic keratosis, SCC.
- Antibiotics—control secondary pyoderma (see Pyoderma).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Firocoxib—gastrointestinal upset; elevated liver enzymes.

FOLLOW-UP

- Patients should be regularly screened for development and removal of new lesions.
- Sun-induced dermatoses rarely metastasize.
- Long-term therapy necessary following extended periods of sun damage.

ABBREVIATIONS

- COX2 = cyclooxygenase-2.
- DLE = discoid lupus erythematosus.
- PE = pemphigus erythematosus.
- SCC = squamous cell carcinoma.
- SLE = systemic lupus erythematosus.

Acknowledgment The author acknowledges the prior contribution of Alexander H. Werner Resnick.

DERMATOSES, VESICULOPUSTULAR

BASICS

DEFINITION
• Pustule—small (<1 cm), circumscribed elevation of the epidermis filled with pus.
• Vesicle—small (<1 cm), circumscribed elevation of the epidermis filled with clear fluid.

PATHOPHYSIOLOGY
Pustules and vesicles—produced by edema, acantholysis (pemphigus), ballooning degeneration (viral infections), proteolytic enzymes from neutrophils (pyoderma), degeneration of basal cells (lupus), or dermoepidermal separation (bullous pemphigoid).

SYSTEMS AFFECTED
Skin/exocrine.

SIGNALMENT
• Lupus—collies, Shetland sheepdogs, and German shepherd dogs may be predisposed.
• Pemphigus erythematosus—collies and German shepherd dogs may be predisposed.
• Pemphigus foliaceus—Akitas, chow chows, dachshunds, bearded collies, Labrador retrievers, Newfoundlands, Doberman pinschers, and schipperkes may be predisposed.
• Bullous pemphigoid—collies and Doberman pinschers may be predisposed.
• Dermatomyositis—young collies and Shetland sheepdogs.
• Subcorneal pustular dermatosis—schnauzers affected most frequently.
• Linear immunoglobulin (Ig) A dermatosis—dachshunds exclusively; very rare.
• Dermatophytosis—young animals.

SIGNS
N/A

CAUSES

Pustules/Vesicles
• Superficial pyoderma—impetigo, superficial spreading pyoderma, superficial bacterial folliculitis, canine or feline acne.
• Pemphigus complex—pemphigus foliaceus, pemphigus erythematosus, panepidermal pemphigus; pemphigus vulgaris produces deep clefts that rapidly erode into ulcers.
• Subcorneal pustular dermatosis.
• Dermatophytosis.
• Demodicosis.
• Sterile eosinophilic pustulosis.
• Linear IgA dermatosis.
• Systemic lupus erythematosus (SLE).
• Discoid lupus erythematosus (DLE).
• Bullous pemphigoid
• Dermatomyositis.
• Cutaneous drug eruption.
• Epidermolysis bullosa.

RISK FACTORS
• Drug exposure—SLE and bullous pemphigoid.
• Bacterial folliculitis usually secondary to a predisposing factor (e.g., demodicosis, hypothyroidism, allergy, or corticosteroid administration).
• UV light—pemphigus erythematosus, bullous pemphigoid, SLE, DLE, and dermatomyositis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Superficial Pyoderma
• Most common cause.
• Readily responds to appropriate antibiotic therapy if underlying cause is effectively managed.
• Intact pustule—direct smear reveals neutrophils engulfing bacteria; most often *Staphylococcus pseudintermedius*; biopsy demonstrates intraepidermal neutrophilic pustules or folliculitis with bacteria.

Pemphigus Complex
• Group of immune-mediated diseases characterized histologically by disadhesion of keratinocytes within the epidermis (acantholytic keratinocytes).
• Direct smears—many acantholytic keratinocytes, nondegenerate neutrophils, eosinophils, and few to no bacteria.
• Culture of an intact pustule negative.
• Direct immunofluorescence—deposits in the intercellular spaces of the epidermis in approximately 50% of cases.
• Tends to wax and wane irrespective of antibiotic therapy; responds to immunosuppressive therapy.
• Pemphigus foliaceus and erythematosus—superficial acantholysis leading to erosions; face, pinnae, and footpads (foliaceus) commonly affected; mucous membranes not affected; biopsy: subcorneal acantholysis; interface and lichenoid inflammation with pemphigus erythematosus.
• Pemphigus vulgaris—severe and deep form of pemphigus; characterized by erosions rapidly leading to ulcerations of oral cavity, mucocutaneous junctions, and skin; biopsy: suprabasal acantholysis and cleft formation.
• Direct immunofluorescence positive at the intercellular spaces of the deeper epidermis.

Subcorneal Pustular Dermatosis
• Rare idiopathic pustular dermatosis of dogs.
• Tends to wax and wane.
• Intact pustules—direct smears reveal numerous neutrophils, no bacteria, and occasional acantholytic keratinocytes; cultures negative.
• Direct immunofluorescence negative.
• Poor response to glucocorticosteroids and antibiotics.

Dermatophytosis
• Common disease of both dogs and cats.
• Dermatophyte culture positive.
• Secondary bacterial folliculitis common.
• Skin biopsy—folliculitis with fungal elements.

Sterile Eosinophilic Pustulosis
• Rare idiopathic dermatosis of dogs.
• Direct smears—numerous eosinophils, nondegenerate neutrophils, occasional acantholytic keratinocytes, and no bacteria.
• Biopsy—eosinophilic intraepidermal pustules, folliculitis, and furunculosis.
• Direct immunofluorescence negative.
• Rapid response to glucocorticosteroids.

Linear IgA Dermatosis
• Rare idiopathic dermatosis of dachshunds.
• Tends to wax and wane.
• Pustules—sterile and subcorneal.
• Direct immunofluorescence positive for IgA at basement membrane zone.

SLE
• Multisystemic disease with variable clinical signs and cutaneous manifestations, including mucocutaneous ulceration.
• Direct immunofluorescence positive at the basement membrane zone.
• Antinuclear antibody (ANA) positive.

DLE
• Affects only the skin; lesions usually confined to the head.
• Depigmentation, erythema, and ulceration of the nasal planum common.
• Skin biopsy—interface and lichenoid dermatitis.
• Direct immunofluorescence positive at the basement membrane zone.
• ANA negative.

Bullous Pemphigoid
• Ulcerative disorder of the skin and/or mucous membranes.
• Skin biopsy—subepidermal cleft formation.
• Direct immunofluorescence positive at the basement membrane zone.
• No acantholysis.

Dermatomyositis
• Idiopathic inflammatory disease of the skin and muscle of young collies and Shetland sheepdogs; seen rarely in adult animals.
• Lesions affect the face, ear tips, tail tip, and pressure points of the extremities.
• Characterized by alopecia, crusting, pigmentation disturbances, erosions/ulceration, and scarring.
• Skin biopsy—follicular atrophy, perifolliculitis, and hydropic degeneration of the basal cells.
• Direct immunofluorescence negative.
• Muscle biopsy and electromyography (EMG)—evidence of inflammation.

CBC/BIOCHEMISTRY/URINALYSIS
• Usually unremarkable.
• SLE—possible anemia, thrombocytopenia, or glomerulonephritis.

DERMATOSES, VESICULOPUSTULAR (CONTINUED)

• Eosinophilic pustular dermatosis—most affected dogs have peripheral eosinophilia.

OTHER LABORATORY TESTS
ANA titer—may be positive with SLE.

DIAGNOSTIC PROCEDURES
• Direct smear from intact pustule/vesicle.
• Culture of intact pustule/vesicle.
• Skin biopsy for histopathology.
• Direct immunofluorescence, including IgA.
• EMG—fibrillation potentials (rapid, irregular, and unsynchronized contraction of muscle fibers) and positive sharp waves in dermatomyositis.
• Muscle biopsy—myofibril degeneration, characterized by fragmentation, vacuolation, atrophy, fibrosis, and regeneration in dermatomyositis.

TREATMENT

APPROPRIATE HEALTH CARE
• Periodic bathing with an antimicrobial shampoo—helps remove surface debris and control secondary bacterial folliculitis.
• Usually treated as outpatient.
• SLE, pemphigus vulgaris, and bullous pemphigoid may be life-threatening and require inpatient intensive care.

MEDICATIONS

DRUG(S) OF CHOICE
See specific disease chapters for more information.

Bacterial Folliculitis
• Empiric choices—cephalexin (22 mg/kg PO q12h); clindamycin (11 mg/kg PO q24h); amoxicillin–clavulanic acid (12.5–15 mg/kg PO q12h).
• Appropriate antibiotic choice based on cultures from intact pustules.

Pemphigus Complex/Bullous Pemphigoid
Immunosuppressive/combination therapy:
• Corticosteroids—prednisolone 2.2–4.4 mg/kg PO tapering dosage; see Pemphigus.
• Azathioprine—2 mg/kg PO q48h to twice weekly.
• Chlorambucil—2 mg/m^2 PO q48h.
• Tetracycline—250 mg <10 kg, 500 mg >10 kg PO q8–12h.
• Doxycycline—10 mg/kg PO q24h.
• Minocycline—5 mg/kg PO q12h with niacinamide: 250 mg <10 kg, 500 mg >10 kg PO q8–12h.
• Cyclosporine, modified—5 mg/kg PO q24h.

Subcorneal Pustular Dermatosis
• Dapsone—1 mg/kg PO q8h until remission; tapered to 1 mg/kg q24h or twice weekly.
• Sulfasalazine—10–20 mg/kg PO q8h until remission; then as needed.

Linear IgA Dermatosis
• Prednisolone—2.2–4.4 mg/kg PO q24h until remission; taper to alternate-day therapy.
• Dapsone—1 mg/kg PO q8h until remission; taper and give as needed.

Sterile Eosinophilic Pustulosis
Prednisolone—2.2–4.4 mg/kg PO q24h until remission; then as needed to prevent relapses (usually long-term, alternate-day therapy required).

PRECAUTIONS

Prednisolone
• Secondary infection.
• Iatrogenic Cushing's syndrome.
• Muscle wasting.
• Steroid hepatopathy.
• Behavioral changes.
• Polydipsia, polyuria.
• Polyphagia.

Dapsone
• Dogs—mild anemia, mild leukopenia, and mild elevation of alanine aminotransferase (ALT), not associated with clinical signs; usually return to normal when dosage is reduced for maintenance.
• Rare fatal thrombocytopenia or severe leukopenia.
• Occasional vomiting, diarrhea, or pruritic skin eruption.
• Cats—more susceptible to dapsone toxicity; hemolytic anemia and neurotoxicity reported.

Sulfasalazine
Keratoconjunctivitis sicca.

Azathioprine and Chlorambucil
Potential for bone marrow suppression, gastrointestinal upset; azathioprine can cause hepatotoxicity and possibly pancreatitis.

Cyclosporine
May cause vomiting and diarrhea, gingival hyperplasia, B-lymphocyte hyperplasia, hirsutism, papillomatous skin eruptions, and increased incidence of infection; decreased glucose homeostasis; potential toxic reactions rare and include nephrotoxicity and hepatotoxicity.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Dapsone—monitor hemogram, platelet count, and ALT every 2 weeks initially and if any clinical side effects develop.
• Long-term sulfasalazine therapy—monitor tear production.
• Immunosuppressive therapy—monitor every 1–2 weeks initially; then every 3–4 months during maintenance therapy.

MISCELLANEOUS

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
Dermatophytosis: may infect human beings in the household.

PREGNANCY/FERTILITY/BREEDING
N/A

SEE ALSO
• Acne—Cats.
• Acne—Dogs.
• Dermatomyositis.
• Dermatophytosis.
• Lupus Erythematosus, Cutaneous (Discoid).
• Lupus Erythematosus, Systemic (SLE).
• Pemphigus.
• Pyoderma.

ABBREVIATIONS
• ALT = alanine aminotransferase.
• ANA = antinuclear antibody.
• DLE = discoid lupus erythematosus.
• EMG = electromyography.
• Ig = immunoglobulin.
• SLE = systemic lupus erythematosus.

DERMATOSES, VIRAL (NON-PAPILLOMATOSIS)

BASICS

OVERVIEW
• Dermatoses caused by viral infection within keratinized structures. • Viral replication may cause cytosuppressive effects or upregulate keratinization, resulting in hyperplastic or crusted conditions.

SIGNALMENT
• Young to young adult dogs. • Cats of any age.

SIGNS
• Facial involvement or involvement of head is common. • Lesions often asymmetric in distribution. • Paws and/or foot pads may be affected as well as mucocutaneous junctions. • Acute or gradual onset; lesions may be associated with bite wound or fight. • Variable pruritus; can progress to self-mutilation. • Crusts. • Abscess. • Paronychia. • Poor wound healing. • Seborrhea. • Exfoliative dermatitis. • Cutaneous horns. • Gingivitis/stomatitis. • Cutaneous or oral ulceration. • Nasodigital hyperkeratosis. • Pigmented macules or plaques. • Progression to bowenoid in situ carcinoma (feline immunodeficiency virus [FIV], papillomavirus). • Multiple mast cell tumors (FIV). • Systemic signs of illness may be present. • Signs consistent with upper respiratory infection may or may not be present prior to development of skin lesions.

CAUSES & RISK FACTORS
• Feline leukemia virus (FeLV). • FIV. • Feline cowpox virus infection. • Feline infectious peritonitis. • Feline papillomavirus. • Canine papillomavirus. • Canine distemper. • Contagious viral pustular dermatitis (orf [parapoxvirus]). • Pseudorabies (α-herpesvirus). • Feline rhinotracheitis infection (α-herpesvirus-1). • Feline calicivirus infection. • Fighting or hunting behavior, multiple animal households, exposure to infected animals, and/or ingestion of infected material increases risk of exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Crusting diseases—drug eruption, actinic keratoses, pemphigus foliaceus, systemic lupus erythematosus, other causes for exfoliative dermatitis. • Allergic disorders—usually pruritic: atopy, fleas, food. • Feline herpesvirus dermatitis lesions can mimic lesions of eosinophilic granuloma complex. • Parasitic diseases—canine and/or feline scabies, demodicosis, cheyletiellosis. • Infectious diseases—superficial and deep bacterial and fungal infections, leishmaniasis. • Dogs—zinc deficiency syndromes, hepatocutaneous syndrome, nasal hyperkeratosis. • Neoplasia—with extensive crusting and ulceration; squamous cell carcinoma, mast cell tumor, epitheliotropic lymphoma.

CBC/BIOCHEMISTRY/URINALYSIS
Nonspecific

OTHER LABORATORY TESTS
• Skin biopsy—necessary to prove viral origin of skin lesions; not always conclusive; if considering herpesvirus dermatitis, inform pathologist of suspicion. • Virus isolation. • Serology—confirms FeLV, FIV, or other viral infection.

DIAGNOSTIC PROCEDURES
• Skin scrapings, trichograms—parasitic infestations. • Dermatophyte culture—fungal infections. • Epidermal cytology—bacterial folliculitis. • Skin biopsy is definitive diagnostic test. • Immunohistochemical staining for viral particles. • Viral serology and/or PCR.

PATHOLOGIC FINDINGS
• Irregular hyperplasia. • Ballooning degeneration. • Hydropic interface dermatitis. • Syncytial-type giant cell formation within epidermis and/or outer root sheath of hair follicle with associated apoptotic keratinocytes. • Keratinocyte inclusion bodies. • Epidermal ulceration with dermal necrosis, necrosis of epitrichial sweat glands, neutrophilic and/or eosinophilic inflammation.

TREATMENT
• Usually outpatient, except for systemically ill patients. • Prevent exposure to other animals that could become infected.

MEDICATIONS

DRUG(S) OF CHOICE
• Supportive care and treatment of secondary infections. • Cats—herpesvirus: L-lysine 200–500 mg/cat q12h (questionable efficacy); interferon-α 30 units/cat/day PO; famcyclovir 125 mg q12h or 40–90mg/kg q12h, use of topical acyclovir reported. • Cats—bowenoid in situ carcinoma: imiquimod. • Dogs—individual papillomas: surgical excision; imiquimod.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Immunosuppressive therapies.

FOLLOW-UP

PATIENT MONITORING
Varies based on viral infection and presence or absence of systemic involvement.

PREVENTION/AVOIDANCE
Prevent hunting behavior and exposure to potentially infectious materials and infected animals.

EXPECTED COURSE AND PROGNOSIS
• Skin lesions may not respond to therapy. • Systemic signs may eventually develop as result of viral infection. • Dependent on causal virus, animals may self-cure. • In cats, papillomavirus infection may progress to bowenoid in situ carcinoma.

MISCELLANEOUS

AGE-RELATED FACTORS
Dependent on viral cause.

ZOONOTIC POTENTIAL
Feline cowpox virus and contagious viral pustular dermatitis (parapoxvirus) can be transmitted to other dogs, humans, and cats.

SEE ALSO
• Canine Distemper.
• Feline Herpesvirus Infection.
• Feline Immunodeficiency Virus (FIV) Infection.
• Feline Leukemia Virus (FeLV) Infection.

ABBREVIATIONS
• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.

Author Elizabeth R. Drake
Consulting Editor Alexander H. Werner Resnick

DESTRUCTIVE AND SCRATCHING BEHAVIOR—CATS

BASICS

OVERVIEW

• Behavior that causes damage to an owner's home or belongings. • Primary destructive behaviors are normal feline behaviors that occur during exploration and play; scratching may be part of normal nail maintenance and communication with visual and scent marks. • Secondary destructive behavior may be a sign of other behavioral conditions and disease states.

Systems Affected

• Gastrointestinal—damage to teeth; vomiting, diarrhea, obstruction if items ingested.
• Ingestion of toxic material could affect any organ system.

SIGNALMENT

• Any breed or gender; may be genetic basis for sucking or chewing fabric in Siamese, Burmese, and Birman. • Primary destructive behavior is more common in young cats.

SIGNS

Primary Destructive Behavior

• No specific environmental trigger.
• Common targets for scratching are furniture, door frames, carpet, speakers.
• Curtains and furniture may be damaged when cats climb to explore or play. • May chew houseplants. • Items resembling string, including thread, shoelaces, and rubber bands, are often chewed and ingested; small items that are batted about may be accidentally swallowed.

Secondary Destructive Behavior

• Attention-seeking—destructive behavior in presence of owner. • Separation-related distress—destructive behavior in absence of the owner. • Compulsive behavior—licking, chewing, sucking, or ingesting nonfood items.
• Scratching may occur secondary to household conflict.

CAUSES & RISK FACTORS

• Lack of suitable outlets for scratching, climbing, perching, play, and resting. • Inadequate supervision, particularly in young cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Rule out medical conditions, especially if onset in mature cat. • Conditions affecting digestion, absorption, and appetite, including recent diet change. • Gastrointestinal disease and medical conditions associated with pain or anxiety.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

OTHER LABORATORY TESTS

As indicated to rule out medical conditions (T_4).

IMAGING

As indicated to rule out medical conditions.

DIAGNOSTIC PROCEDURES

For chewing/ingestive behavior, attention to oral cavity and scoping if indicated to rule out gastrointestinal causes.

TREATMENT

Treat underlying disease.

Primary Destructive Behavior

• Keep claws trimmed. • Supervise/confine until appropriate behavior patterns have been established; provide food, litter, toys, and scratching posts in confinement area. • Prevent access to potential targets. • Provide acceptable scratching substrate such as sisal, cardboard, and loosely woven carpet in locations and orientation (horizontal or vertical) based on cat's preference.
• Apply feline interdigital pheromone to scratching posts. • Provide climbing towers, interactive play, feeding stations at different levels, food-dispensing toys, and multiple small meals.
• Reward appropriate behavior. • Reduce appeal of target areas and objects—e.g., double-sided sticky tape. • Provide indoor grass gardens.
• Declawing is banned in a number of countries and jurisdictions for ethical and humane reasons; where still legally permissible it should be a last resort after owners have been counseled on all alternative options. • While behavior modification is being implemented, plastic claw covers may be applied to prevent further damage.

Secondary Destructive Behavior

• Attention-seeking behavior—provide owner-initiated interactions. • Separation-related distress—provide opportunities for independent play and exploration.
• Compulsive disorder—identify and reduce sources of anxiety; offer appropriate outlets for play, chewing, and food-filled toys; some cats will chew rawhide; prevent access to target items. • Reduce household conflict.

MEDICATIONS

DRUG(S) OF CHOICE

• Medication is not indicated for primary destructive or attention-seeking behaviors.
• Medication may be indicated in combination with behavior management and modification for anxiety-based conditions and compulsive disorders. • See Fear, Phobias, and Anxieties—Cats; Compulsive Disorders—Cats.

Pheromones and Nutraceuticals

• Feline interdigital pheromone applied to scratching posts to encourage scratching. • F3 facial pheromone, cat-appeasing pheromone, alpha-casozepine, and l-theanine may reduce anxiety.

FOLLOW-UP

PATIENT MONITORING

Weekly follow-up to support owners.

PREVENTION/AVOIDANCE

• Destructive behavior is normal and self-rewarding. • Frequency may be reduced through client education during the first well-care visit, regardless of the age of the patient. • Provide information on suitable outlets for scratching, chewing, exploration, play, and enrichment.

POSSIBLE COMPLICATIONS

• Owners become frustrated, resulting in declawing or relinquishment. • Punishment can trigger fear or aggression. • Obstruction due to foreign body, including string foreign body.

EXPECTED COURSE AND PROGNOSIS

• Resolution of normal exploratory behavior usually within weeks. • Anxiety-based conditions and compulsive disorders often require long-term management, including psychotropic medication.

MISCELLANEOUS

AGE-RELATED FACTORS

Rule out medical conditions in adult onset.

PREGNANCY/FERTILITY/BREEDING

Preparturient destructive behavior (nesting).

SEE ALSO

• Compulsive Disorders—Cats.
• Fears, Phobias, and Anxieties—Cats.
• Kitten Behavior Problems.

DESTRUCTIVE BEHAVIOR—DOGS

BASICS

DEFINITION
- Behavior that causes damage to an owner's home, property, or belongings.
- Primary destructive behavior is normal behavior that includes exploratory and play-based behavior.
- Secondary destructive behavior is a clinical sign of another behavior condition.

PATHOPHYSIOLOGY
- Dogs normally explore and engage with their environment. When access to appropriate outlets and enrichment is not readily available and in the absence of supervision and guidance, owner's property may be targeted.
- Insufficient opportunities for social interactions can contribute to destructive behavior.
- Dogs may dig for comfort or cooling, and to escape confinement. Digging can be triggered by sounds of burrowed animals and scents of food sources.
- Though manipulating the environment results in property damage, it may be self-rewarding and self-soothing.
- Conditions causing distress, including pain, fear, anxiety, and frustration, can contribute to destructive behavior.

SYSTEMS AFFECTED
- Behavioral—frustration or anxiety.
- Gastrointestinal (GI)—damage to teeth or oral mucosa; pharyngitis or esophagitis; vomiting, diarrhea, or obstruction if ingested.
- Musculoskeletal—trauma caused by scratching, chewing, or digging.
- Skin—excoriation, nail damage secondary to trauma.
- Ingestion of toxic material could affect any organ system.

GENETICS
None

INCIDENCE/PREVALENCE
Normal canine behavior—problem reported by approximately 12% of owners.

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT
- Species—dog.
- Breed predilections—certain breeds are by nature more active and, if insufficient outlets for exploratory and/or social engagement, may engage in destructive behavior. Northern breeds may dig for resting and thermoregulation. Some terrier and hound breeds may dig when burrowing for prey.
- Mean age and range—primary destructive behavior most often seen in puppies and young dogs; secondary destructive behavior seen at any age.
- Predominant sex—N/A.

SIGNS
- Destructive behavior is a clinical sign rather than a diagnosis.
- Dogs may use their teeth or claws to damage floors, furniture, walls, or frames of doors and windows or dig at fencing. Some dogs chew or even ingest small personal items.
- Clients may ascribe the underlying motivation to spite or suggest a diagnosis such as separation anxiety. Though barriers are often targeted in association with separation-related distress or territorial behavior, no focus of damage is pathognomonic.
- Knowledge of the contexts in which destructive behavior occurs is critical for diagnosis.
- Physical examination findings—fractured teeth; excoriations on nose; broken front claws; digital pain.

CAUSES
- Primary destructive behavior:
  - Inadequate supervision provides access to self-rewarding behavior.
  - Lack of access to preferred chewable and/or interactive toys.
  - Insufficient cognitive enrichment.
  - Inadequate social enrichment.
- Secondary destructive behavior:
  - Confinement in presence of an inciting trigger.
  - Confinement frustration.
  - Separation-related distress—inadequate habituation to absence of owner.
  - Noise phobia.
  - Territorial behavior.
  - Unintentional reinforcement by owner.
  - Medical conditions associated with pain.

RISK FACTORS
Early environmental experiences including prior emotional trauma are risk factors for development of fear and anxiety-related conditions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Pathologic conditions—index of suspicion for underlying medical condition should be high in adult patients with sudden onset of destructive behavior in absence of notable environmental changes.
- GI disease—if pica accompanies destructive chewing: rule out conditions affecting digestion, absorption, and polyphagia, including recent diet changes that can affect satiety; licking of surfaces such as floors, carpet, and nonfood items may be associated with upper GI disease.
- Separation-related distress.
- Noise phobia, storm phobia—distress in response to stimulus.
- Territorial behavior—destructive behavior related to presence of triggers; window frames and doorways are damaged.
- Cognitive dysfunction syndrome—destructive behavior related to agitation, anxiety, and abnormal repetitive behaviors with onset or progression in patients 7 years or older; other signs of cognitive dysfunction are typically present.

CBC/BIOCHEMISTRY/URINALYSIS
No pathology expected.

OTHER LABORATORY TESTS
As indicated to rule out medical conditions.

DIAGNOSTIC PROCEDURES
As indicated to rule out medical conditions.

PATHOLOGIC FINDINGS
N/A except lesions secondary to self-trauma.

TREATMENT

APPROPRIATE HEALTH CARE
- Traumatic injuries are typically minor and can be managed with outpatient care. Traumatic dental injuries and GI foreign bodies may require surgical intervention.
- Behavioral treatment protocols include behavior modification to address frustration or anxiety; determination of safe methods for supervision, confinement; and customized enrichment protocol based on patient preferences and owner lifestyle.
- All toys carry a potential risk of injury to the patient, including inadvertent ingestion and dental injury.
- Environmental management:
  - Prevent or supervise access to potential targets of destruction.
  - Provide thermoregulation options (kiddie pool, dog house) to reduce digging.
- Behavior modification may include:
  - Providing for and reinforcing alternative desirable activities and outlets.
  - Relaxation exercises to reduce inadvertent reinforcement of undesirable behavior.
  - Habituation to crate or gate confinement.
- Environmental enrichment:
  - Preference testing of appropriate toys and chew items.
  - Provide acceptable substrate and location for digging—treats and toys can be buried to encourage digging in area.
- Design a schedule for provision of exercise, cognitive enrichment, social enrichment, and reward-based training.
- Design a behavioral log to record progress and preferences.

NURSING CARE
Behavioral appointments can be scheduled with veterinarian or trained nursing staff.

ACTIVITY
- Aerobic exercise schedule should consider the patient's physical health. Healthy dogs may benefit from two half-hour exercise sessions each day.

DESTRUCTIVE BEHAVIOR—DOGS (CONTINUED)

• Cognitive stimulation may be provided with reward-based training and food puzzles.
• Provide opportunities for dogs to engage in breed-typical normal behaviors, including sniffing and "hunting" (tracking, nosework).

DIET
• Some patients benefit from feeding via puzzles and food-stuffed toys.
• Food toys may not be appropriate for pets that exhibit possessive or food-related aggression.

CLIENT EDUCATION
• Clients should take an active role in managing destructive behavior.
• Preadoption counseling provides an opportunity to educate clients regarding providing for pets' needs, including social and exploratory play and safe toys.
• Provide a plan for supervision and enrichment.
• Teach clients to communicate expectations by reinforcing desired behaviors and preventing access to undesirable behaviors, including dog proofing and confinement training.
• Provide references for local trainers who support positive reinforcement rather than confrontation.

Aversive Products and Punishment
• Application of nontoxic bitter-tasting products to targeted objects is sometimes used to manage primary destructive behavior in conjunction with supervision.
• It is essential that, upon discovering an unpleasant taste, the dog has immediate access to an appropriate item; it is more effective and appropriate to supervise and quietly guide dogs toward appropriate items.
• Punishment is not an accepted tool for managing destructive behavior; it does not address the underlying motivation and can lead to fear, anxiety, or aggression.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
• Medication is not indicated for treating primary destructive behaviors or attention-seeking behavior.
• Medication complements behavior modification and may provide more rapid resolution when treating anxiety-based conditions.

Selective Serotonin Reuptake Inhibitors (SSRIs)
Fluoxetine—0.5–2 mg/kg PO q24h.

Tricyclic Antidepressants (TCAs)
Clomipramine—1–3 mg/kg PO q12h.

For Situational Anxiety (Alone or Together with SSRI or TCA)
• Alprazolam—0.01–0.1 mg/kg PO prior to event.
• Trazodone—3–10 mg/kg PO prior to event.
• Clonidine—0.01–0.05 mg/kg PO prior to event.

CONTRAINDICATIONS
TCAs—contraindicated in animals with cardiac conduction disturbances or glaucoma.

PRECAUTIONS
Benzodiazepines may disinhibit aggression—use with caution in dogs with a history of aggressive behavior.

POSSIBLE INTERACTIONS
• SSRIs, TCAs, and trazodone should not be used with monoamine oxidase inhibitors, including amitraz and selegiline.
• Combining drugs that increase serotonin (e.g., SSRI or TCA with trazodone) should be done with caution to avoid serotonin syndrome.

ALTERNATIVE DRUGS
Dog-appeasing pheromone, nutraceuticals containing L-theanine or alpha-casozepine, or a calming probiotic may be used to reduce mild anxiety. The safety margin is wide.

FOLLOW-UP

PATIENT MONITORING
Weekly calls to confirm compliance and adjust enrichment based on patient preferences. Most patients benefit from one-on-one behavior modification sessions every 2 weeks.

PREVENTION/AVOIDANCE
Client education during the first visit, regardless of the age of the patient. Provide information on suitable outlets for chewing, digging, exercise, reward training, and the importance of both cognitive and social enrichment.

POSSIBLE COMPLICATIONS
Without adequate support, owners may become frustrated, resulting in relinquishment of the dog. Owners may seek advice from individuals offering "quick fixes" that could ultimately jeopardize the patient.

EXPECTED COURSE AND PROGNOSIS
Prognosis is excellent. Resolution of normal exploratory behavior is usually rapid.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Destructive behavior is often associated with attention-seeking behavior.

AGE-RELATED FACTORS
Young dogs are at increased risk for normal destructive behavior.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Preparturient destructive behavior (nesting).

SEE ALSO
• Cognitive Dysfunction Syndrome.
• Marking, Roaming, and Mounting Behavior—Dogs.
• Puppy Behavior Problems.
• Separation Anxiety Syndrome.
• Thunderstorm and Noise Phobias.
• Unruly Behaviors: Jumping, Pulling, Chasing, Stealing—Dogs.

ABBREVIATIONS
• GI = gastrointestinal.
• SSRI = selective serotonin reuptake inhibitor.
• TCA = tricyclic antidepressant.

Consulting Editor Gary M. Landsberg

DIABETES INSIPIDUS

BASICS

DEFINITION
Diabetes insipidus (DI) is a disorder of water metabolism characterized by polyuria (PU), urine of low specific gravity or osmolality (so-called insipid, or tasteless, urine), and polydipsia (PD).

PATHOPHYSIOLOGY
- Central DI (CDI)—deficiency in the secretion of antidiuretic hormone (ADH).
- Nephrogenic DI (NDI)—renal insensitivity to ADH.

SYSTEMS AFFECTED
- Endocrine/metabolic.
- Renal/urologic.

INCIDENCE/PREVALENCE
- Primary CDI—rare.
- Primary NDI—rare.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
- Congenital forms <1 year.
- Acquired forms, any age.

SIGNS
- PU.
- PD.
- Incontinence—occasional.
- Signs of intracranial mass if due to pituitary tumor.
- Dehydration and weakness in animals with uncompensated free water loss.

CAUSES
Inadequate Secretion of ADH
- Congenital defect.
- Idiopathic.
- Trauma.
- Neoplasia.

Renal Insensitivity to ADH
- Congenital—defect in aquaporin (renal tubular channel that allows free water reabsorption).
- Secondary to drugs (e.g., lithium, demeclocycline).
- Secondary to endocrine and metabolic disorders (e.g., hyperadrenocorticism, hyponatremia, hypercalcemia).
- Secondary to renal disease or infection (e.g., pyelonephritis, chronic kidney disease, pyometra).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Polyuric Disorders
- Hyperadrenocorticism.
- Diabetes mellitus.
- Renal disease.
- Hyperthyroidism—cats.
- Hyperadrenocorticism.
- Liver disease—portosystemic shunt.
- Pyometra.
- Pyelonephritis.
- Hypercalcemia.
- Primary PD.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal; hypernatremia in patients with excessive free water loss.
- Urinary specific gravity low (<1.006, hyposthenuria).

OTHER LABORATORY TESTS
Plasma ADH (not commercially available).

IMAGING
- MRI or CT scan if pituitary tumor is suspected.
- Abdominal radiographs or ultrasound may help rule out other polyuric disorders.

DIAGNOSTIC PROCEDURES
- ADH supplementation trial—preferred to water deprivation test; therapeutic trial with synthetic ADH (desmopressin [DDAVP]); positive response (water intake decreases by 50% in 5–7 days).
- Modified water deprivation test (see Appendix II for protocol)—not routinely recommended due to risk of complications.
- Rule out all other causes of PU/PD before considering primary CDI.

PATHOLOGIC FINDINGS
Degeneration and death of neurosecretory neurons in neurohypophysis (primary CDI).

TREATMENT

APPROPRIATE HEALTH CARE
- Patients should be hospitalized for modified water deprivation test; the ADH trial is often performed as an outpatient procedure.
- Animals with NDI should have underlying disease diagnosed and treated.

ACTIVITY
Not restricted.

DIET
Normal, with free access to water.

CLIENT EDUCATION
- Review dosage of DDAVP and administration technique.
- Importance of having water available at all times.

SURGICAL CONSIDERATIONS
Pyometra is a surgical emergency and should be removed as soon as the patient is stabilized.

MEDICATIONS

DRUG(S) OF CHOICE
- CDI—DDAVP (1–2 drops of intranasal preparation in conjunctival sac q12–24h to control PU/PD); alternatively, intranasal preparation may be given SC (2–5 µg, q12–24h). Oral preparation of DDAVP is available in 0.1–0.2 mg tablets, with each 0.1 mg comparable to 1 large drop of intranasal preparation.
- NDI—hydrochlorothiazide (2–4 mg/kg PO q12h), in addition to treatment of any underlying cause.

CONTRAINDICATIONS
None

PRECAUTIONS
Overdose of DDAVP can cause water intoxication.

FOLLOW-UP

PATIENT MONITORING
- Adjust treatment according to patient's signs; ideal dosage and frequency of DDAVP administration based on water intake.
- Laboratory tests such as PCV, total solids, and serum sodium concentration, and patient weight to detect dehydration (inadequate DDAVP replacement).

PREVENTION/AVOIDANCE
Circumstances that might increase water loss.

POSSIBLE COMPLICATIONS
Anticipate complications of primary disease (e.g., pituitary tumor).

EXPECTED COURSE AND PROGNOSIS
- CDI usually permanent, except in patients in which condition was trauma induced.
- NDI usually resolves with treatment of underlying disorder.
- Prognosis generally good, depending on underlying disorder.
- Without treatment, dehydration can lead to stupor, coma, and death.

MISCELLANEOUS

AGE-RELATED FACTORS
- Congenital CDI and NDI usually manifest before 6 months of age.
- CDI related to pituitary tumors usually seen in dogs >5 years old.

DIABETES INSIPIDUS (CONTINUED)

SYNONYMS

- Cranial diabetes insipidus.
- ADH-responsive diabetes insipidus.

SEE ALSO

Hyposthenuria

ABBREVIATIONS

- ADH = antidiuretic hormone.
- CDI = central diabetes insipidus.
- DI = diabetes insipidus.
- NDI = nephrogenic diabetes insipidus.
- PD = polydipsia.
- PU = polyuria.

DIABETES MELLITUS WITH HYPEROSMOLAR HYPERGLYCEMIC STATE

BASICS

DEFINITION
• The hyperosmolar hyperglycemic state (HHS) is a complicated form of diabetes mellitus (DM) characterized by severe hyperglycemia and dehydration that produces a marked elevation in serum osmolarity. Unlike diabetic ketoacidosis (DKA), ketone production and metabolic acidosis are not major features of HHS. • Specific guidelines for HHS diagnosis are lacking in dogs and cats, but serum effective osmolarity >320 mOsm/L, glucose concentration >600 mg/dL, and bicarbonate concentration >18 mEq/L, along with minimal ketonuria, are criteria in humans.

PATHOPHYSIOLOGY
• Hyperglycemia is due to insulin deficiency from DM; insulinopenia reduces tissue glucose utilization and increases hepatic glucose production, leading to increased extracellular glucose concentrations; the magnitude of hyperglycemia in HHS is usually greater than in DKA. • Hyperosmolarity develops secondary to hyperglycemia and is exacerbated by dehydration and reduced extracellular fluid volume; the contribution of glucose to total plasma osmolarity is significant in HHS. • Dehydration and volume deficit are typically severe and are caused by several factors, including reduced water intake and volume losses via gastrointestinal and renal systems. • Reduced plasma volume decreases glomerular filtration rate and urine production, leading to azotemia; in HHS, severe volume contraction with reduced urinary glucose excretion results in severe hyperglycemia and plasma hyperosmolarity. • Hyperketonemia and ketonuria are not major features of HHS; lactic acidosis secondary to volume depletion, tissue hypoperfusion, and impaired glucose metabolism is the major cause of acidosis in patients with HHS.

SYSTEMS AFFECTED
• Endocrine. • Renal/urologic—prerenal azotemia due to decreased extracellular fluid volume; urine production usually maintained by glucose-induced diuresis unless volume deficit is severe or acute kidney injury is present. • Cardiovascular—hypovolemia; metabolic acidosis and electrolyte abnormalities may contribute to hypotension and poor myocardial contractility. • Nervous—hyperosmolarity promotes intracellular dehydration and neuronal dysfunction.

GENETICS
N/A

INCIDENCE/PREVALENCE
Uncommon

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat (more frequent).

Breed Predilections
N/A

Mean Age and Range
Most common in middle-aged dogs (mean 9 years) and cats (mean 12 years).

Predominant Sex
N/A

SIGNS

Historical Findings
• All patients have DM; in some, diagnosis of DM occurs prior to HHS. • Some patients have concurrent chronic illness. • Signs caused by DM—may not be appreciated after HHS onset: ○ Polydipsia. ○ Polyuria. ○ Polyphagia. ○ Weight loss. • Signs caused by HHS: ○ Weakness/lethargy. ○ Vomiting. ○ Reduced appetite. ○ Neurologic complaints—abnormal responsiveness, coma.

Physical Examination Findings
• Findings associated with dehydration and hypovolemia: ○ Decreased skin turgor. ○ Prolonged capillary refill time. ○ Reduced pulse pressure. ○ Tachycardia. ○ Hypothermia. • Findings associated with hyperosmolarity: ○ Lethargy, depressed mentation, stupor, or coma. ○ Seizure. • Findings associated with DM: ○ Low body condition score. ○ Cataracts (dogs).

CAUSES
• Develops in patients with DM and severe dehydration/volume loss. • Reduced water intake may precede onset of HHS. • Comorbid conditions common.

RISK FACTORS
Risk for HHS may be higher in diabetic animals with concurrent disorders, including heart disease, renal insufficiency, hyperadrenocorticism, acute pancreatitis, and neoplasia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• DM—may be uncomplicated to complicated, including DKA and HHS; all have similar clinical signs and laboratory findings, but can be subcategorized based on magnitude of hyperglycemia and hyperketonemia. • Hypernatremia—severe hypernatremia produces CNS signs similar to HHS, but with sodium as major osmole; polyuria and polydipsia may be present, particularly if hypernatremia develops secondary to diabetes insipidus. • Hyperosmolarity of any cause—may produce similar CNS abnormalities; toxins (e.g., ethylene glycol or alcohol) or CNS lesions (e.g., causing adipsia) may cause hyperosmolarity. • CNS disease—primary CNS disorders may produce clinical signs of HHS; marked fluid deficits are not expected. • Myxedema coma—manifestation of severe hypothyroidism with similar clinical signs without hyperosmolarity or hyperglycemia; low total thyroxine and elevated thyroid-stimulating hormone present.

CBC/BIOCHEMISTRY/URINALYSIS
• Hyperglycemia—blood glucose concentration frequently exceeds 600 mg/dL and severe hyperglycemia (1500–2000+ mg/dL) exists in some patients. • Azotemia—elevated blood urea nitrogen (BUN) and serum creatinine concentrations are common, usually prerenal, but renal azotemia occurs in some patients. • Sodium—hypo- or hypernatremia may be observed; hyperosmolarity is most severe with concurrent hyperglycemia and hypernatremia. • Potassium—hypokalemia is common; hyperkalemia is associated with acute kidney injury or reduced urine output. • Acidosis—metabolic acidosis is less severe than DKA; hypobicarbonemia and hyperlactatemia occur secondary to hypovolemia or renal failure. • Glucosuria—present; mild ketonuria possible. • Urine specific gravity (USG) variable; may be misleading due to glucosuria, which increases USG.

OTHER LABORATORY TESTS
• Blood and urine osmolarity—serum osmolarity >320 mosm/L consistent with HHS; urine osmolality elevated due to glucosuria. • Serum osmolarity can be estimated from routine serum chemistry results: 2 ([Na^+]+[K^+]) + [BUN]/2.8 + [Glucose]/18; if results are in IU, equation is modified: 2 ([Na^+]+[K^+]) + [BUN] + [Glucose].

IMAGING
N/A

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Pancreas—consistent with DM: islet atrophy and loss (dogs and cats) and islet amyloid (cats). • Brain—changes not specific for HHS; evidence of CNS edema.

TREATMENT

APPROPRIATE HEALTH CARE
Life-threatening medical emergency requiring inpatient treatment. After HHS resolution, patients require treatment and follow-up for DM.

NURSING CARE
• Correction of fluid deficits—major treatment goal, begin prior to insulin replacement; IV fluid replacement indicated for ill patients; enteral water can assist with free water replacement in patients that tolerate oral intake. • Fluid type and rate depend on patient's hydration and volume status and magnitude of metabolic derangements; fluid

DIABETES MELLITUS WITH HYPEROSMOLAR HYPERGLYCEMIC STATE (CONTINUED)

deficit is estimated using the equation: %volume depletion * body weight(kg) = fluid deficit (L). • Hypo- and normonatremic patients—isotonic crystalloid solution is appropriate for initial volume replacement; replacement of volume deficit should occur over 12–24h; patients with hypotension or shock due to hypovolemia should receive fluid bolus of 20–25% of estimated blood volume (dog: 80 mL/kg; cat: 50 ml/kg), which can be repeated until blood pressure is adequate; once blood pressure is restored, the remaining deficit is replaced over 12–24h. • Hypernatremic patients—hypernatremia implies a free water deficit and its occurrence with hyperglycemia in HHS may result in life-threatening hyperosmolarity; isotonic (0.9%) saline solution appropriate for initial volume replacement in hypernatremic patients with hypovolemic hypotension; if hypernatremia persists after blood pressure and urine output are restored, use of hypotonic (0.45%) saline solution indicated to replace free water and reduce sodium, unless oral water intake possible; recommended that serum sodium concentration reduction should not exceed 12 mEq/day (see Hypernatremia). • Electrolyte replacement—potassium deficiency is expected, and should be replaced unless hyperkalemia is present; dosage based on magnitude of hypokalemia; potassium replacement by IV infusion should not exceed 0.5 mEq K^+/kg/h and fluids with supplemented K^+ should be avoided during rapid volume infusion; supplementation of other electrolytes (e.g., magnesium, phosphorous) may also be necessary. • Glucose supplementation—some protocols recommend using dextrose infusion to prevent hypoglycemia during insulin therapy; 2.5–5% dextrose CRI used as needed to maintain blood glucose concentrations between 150 and 250 mg/dL.

ACTIVITY
N/A

DIET
N/A

CLIENT EDUCATION
• Patients frequently have a serious concurrent disorder(s) that affects prognosis. • Permanent DM is expected and survivors will require lifelong treatment for DM.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
• CRI of regular insulin is recommended for initial glucose control; insulin therapy should be started 2–6h after starting fluid therapy so initial decrease in serum glucose is not extreme. • CRI preparation—regular insulin at 2.2 U/kg/24h (some protocols recommend 1.1 U/kg/24h dose in cats) added to 250 mL of 0.9% NaCl; prior to beginning CRI, 50 mL of solution should pass through plastic administration tubing and be discarded (insulin binds to some plastics); CRI started at 5 mL/h (cat) or 10 mL/h (dog) and infusion rate adjusted as needed to reduce hyperglycemia at desired rate and maintain target glucose concentration. • Once HHS is resolved and patient stable, discontinue insulin CRI and transition to longer-acting insulin to be used for chronic DM management.

CONTRAINDICATIONS
N/A

PRECAUTIONS
• Brain edema may occur when hyperosmolarity is corrected too rapidly; patients with edema develop worsening neurologic status during treatment; minimizing rapid decreases in glucose and sodium during treatment lowers edema risk. • Insulin administration can result in hypokalemia; electrolytes should be monitored frequently (q4–6h) until stable.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
• Ultrashort-acting insulins (insulin aspart or insulin lispro) may be substituted for regular insulin in CRI protocols. • Protocol for intermittent IM use of regular insulin (when CRI not available)—0.2 U/kg IM initially, followed by 0.1 U/kg IM q1h until glucose <250 mg/dL; subsequent doses 0.5–1.0 U/kg IM q4–6h to maintain glucose concentration between 150 and 250 mg/dL.

FOLLOW-UP

PATIENT MONITORING
• Volume and hydration status—monitor heart rate, pulse quality, capillary refill time, blood pressure, bodyweight, and urine output. • Blood glucose—monitor q1–2h to guide insulin therapy; aim for gradual reduction of serum glucose (50–100 mg/dL/h) to 150–250 mg/dL without hypoglycemia. • Monitor serum Na^+ and K^+ concentrations, especially during correction of hypernatremia or K^+ supplementation; magnesium and phosphorous should be monitored, especially after start of insulin therapy. • After stabilization, long-term monitoring appropriate for DM is indicated.

PREVENTION/AVOIDANCE
• Adequate insulin therapy and monitoring of glycemia in patients with DM may reduce risk of HHS. • Early recognition and effective treatment of new-onset DM may reduce risk of DKA or HHS.

POSSIBLE COMPLICATIONS
• Hypoglycemia or electrolyte disturbances may develop during treatment. • Severe neurologic signs, including coma and death, may occur. • Dehydration and shock can precipitate acute kidney injury. • Death due to shock or coma may occur in untreated animals.

EXPECTED COURSE AND PROGNOSIS
• Hydration and blood pressure should improve within a few hours of initiating fluid therapy and resolve over 12–24h; hyperglycemia is corrected over 6–12h once insulin therapy started. • Electrolyte derangements must be managed to avoid osmotic complications secondary to sodium fluctuations, and to avoid hypo-/hyperkalemia, hypophosphatemia, or hypomagnesemia. • Depending on patient response, prognosis is guarded; worse if severe neurologic compromise or renal failure is present.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• DKA and HHS have significant overlap in clinical signs and laboratory abnormalities. • Patients with HHS should be evaluated for concurrent conditions (cardiac or renal failure, pancreatitis, neoplasia, etc.).

SYNONYMS
• Diabetic coma. • Hyperosmolar nonketotic syndrome.

SEE ALSO
• Diabetes Mellitus With Ketoacidosis. • Diabetes Mellitus Without Complication—Cats. • Diabetes Mellitus Without Complication—Dogs. • Hyperglycemia. • Hyperosmolarity.

ABBREVIATIONS
• BUN = blood urea nitrogen. • DKA = diabetic ketoacidosis. • DM = diabetes mellitus. • HHS = hyperosmolar hyperglycemic state. • USG = urine specific gravity.

DIABETES MELLITUS WITH KETOACIDOSIS

BASICS

DEFINITION
A medical emergency secondary to absolute or relative insulin deficiency, characterized by hyperglycemia, ketonemia, metabolic acidosis, dehydration, and electrolyte depletion.

PATHOPHYSIOLOGY
- Insulin deficiency causes an increase in lipolysis, resulting in excessive ketone body production and metabolic acidosis; an inability to maintain fluid and electrolyte homeostasis causes dehydration, prerenal azotemia, electrolyte disorders, obtundation, and death.
- Many patients with diabetic ketoacidosis (DKA) have underlying conditions such as infection, inflammation, or heart disease that cause stress hormone (e.g., glucagon, cortisol, growth hormone, epinephrine) secretion; this probably contributes to development of insulin resistance and DKA by promoting lipolysis, ketogenesis, gluconeogenesis, and glycogenolysis.
- Dehydration and electrolyte abnormalities result from osmotic diuresis, promoting the loss of total body water and electrolytes.

SYSTEMS AFFECTED
- Endocrine/metabolic.
- Gastrointestinal.
- Hematologic (cats).

GENETICS
None

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT

Species
Dog and cat.

Breed Predilections
- Dog—miniature poodle and dachshund.
- Cat—none.

Mean Age and Range
- Dog—mean age 8.4 years.
- Cat—median age 11 years (range: 1–19 years).

Predominant Sex
- Dogs—females 1.5 times more prevalent than males.
- Cats—males 2 times more prevalent than females.

SIGNS
- Shock.
- Dehydration.
- Hypothermia.
- Polyuria.
- Polydipsia or adipsia.
- Anorexia.
- Weakness.
- Vomiting.
- Lethargy.
- Tachypnea.
- Muscle wasting and weight loss.
- Unkempt haircoat.
- Thin body condition.
- Ketone odor on breath.
- Icterus.
- Dandruff.

CAUSES
- Diabetes mellitus.
- Infection (e.g., pyoderma, pneumonia, urinary tract infection, prostatis, pyelonephritis, pyometra).
- Concurrent disease (e.g., heart failure, pancreatitis, renal insufficiency or failure, asthma, neoplasia, acromegaly).
- Estrus.
- Idiopathic.
- Medication noncompliance.
- Stress.
- Surgery.

RISK FACTORS
- Any condition that leads to absolute or relative insulin deficiency.
- History of corticosteroid or beta blocker administration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Hyperosmolar hyperglycemic state.
- Acute hypoglycemic coma/insulin overdose.
- Uremia/azotemia due to renal disease or postrenal obstruction.
- Other cause of metabolic acidosis (e.g., lactic acidosis, ethylene glycol intoxication, renal tubular acidosis).

CBC/BIOCHEMISTRY/URINALYSIS
- Leukocytosis with mature neutrophilia.
- Hyperglycemia—blood glucose concentration usually >250 mg/dL.
- High liver enzyme activity.
- Hypercholesterolemia and lipemia.
- Azotemia.
- Hypochloremia.
- Hypokalemia.
- Hyponatremia.
- Hypophosphatemia.
- Hypomagnesemia.
- High anion gap—anion gap = (sodium + potassium) – (chloride + bicarbonate); normal is 16 ± 4.
- Glucosuria and ketonuria.
- Variable urinary specific gravity with active or inactive sediment.
- Hyperproteinemia.
- Heinz body anemia (cats).

OTHER LABORATORY TESTS
- Metabolic acidosis—HCO_3^- <15 mEq/L (total CO_2 estimates HCO_3^-).
- Hyperosmolarity (>330 mOsm/kg).
- Bacterial culture of urine and blood.

DIAGNOSTIC PROCEDURES
- Abdominal and thoracic radiography and ultrasound may be necessary to identify comorbid diseases.
- ECG and blood pressure monitoring indicated for patients with shock or electrolyte abnormalities.

PATHOLOGIC FINDINGS
Pancreatic islet cell atrophy.

TREATMENT

APPROPRIATE HEALTH CARE
- If the animal is bright, alert, and well hydrated, intensive care and IV fluid administration are not required; start SC administration of insulin (short- or intermediate-acting insulin), offer food, and supply constant access to water; monitor closely for signs of illness (e.g., anorexia, lethargy, vomiting).
- Treatment of animals with DKA that are systemically ill requires intensive inpatient care; goals are to correct depletion of water and electrolytes, reverse ketonemia and acidosis, and increase rate of glucose use by insulin-dependent tissues.

NURSING CARE
- Fluids—necessary to ensure adequate cardiac output and tissue perfusion and to maintain vascular volume; also reduce blood glucose concentration.
- IV administration of isotonic crystalloid supplemented with potassium is initial fluid of choice; volume and rate determined by fluid replacement needs plus maintenance requirements; replace over 24–48h.

ACTIVITY
N/A

DIET
Following stabilization, diet should be adjusted to account for patient's diabetes, concurrent disease, and body condition. High-fiber diets are not recommended in underweight pets.

CLIENT EDUCATION
Serious medical condition requiring lifelong insulin administration in most patients. Confirm that client is prepared to inject twice daily insulin prior to treatment of DKA.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE

Insulin
- Regular insulin is the insulin of choice until eating; lispro insulin may also be considered.
- Initial dosage—0.2 U/kg IM (or SC if hydration normal).
- Subsequent dosage 0.1–0.2 U/kg IM given 3–6h later—may be given hourly if patient is closely monitored; response to previous insulin dosage should be considered when calculating

DIABETES MELLITUS WITH KETOACIDOSIS (CONTINUED)

subsequent dosages; ideally, glucose concentration should drop by 50–100 mg/dL/h.
• Regular insulin can also be administered as CRI via designated catheter. Dogs: 2.2 units/kg in 250 mL of 0.9% NaCl; Cats: 1.1 units/kg in 250 mL 0.9% NaCl. Then, allow 50 mL of dilute insulin to flow through IV tubing and discard. If blood glucose >250 mg/dL, administer at 10 mL/h; if blood glucose 200–250 mg/dL, administer at 7 mL/h; if blood glucose 150–200 mg/dL, administer at 5 mL/h; if blood glucose 100–150 mg/dL, administer at 5 mL/h and add 2.5% dextrose to IV crystalloid fluids; if blood glucose <100 mg/dL, discontinue IV insulin infusion and continue 2.5–5% dextrose in IV crystalloid infusion.
• Check blood glucose q1–3h using automated test strip analyzer (Accu-Chek® III, Alpha Trak® II glucometer), corrected for patient's PCV as indicated.
• Monitor urine or serum ketones daily.
• Administer longer-acting insulin once patient is eating, drinking, and ketosis is resolved; the dosage is based on that of short-acting insulin given in hospital.

Potassium Supplementation

• Total body potassium is depleted and treatment (e.g., fluids and insulin) will further lower serum potassium.
• If possible, check potassium concentration before initiating insulin therapy to guide supplementation; if extremely low, insulin therapy may need to be delayed (hours) until serum potassium concentration increases.
• Refractory hypokalemia may indicate hypomagnesemia, requiring magnesium replacement at 0.75–1 mEq/kg/24h IV as magnesium chloride or magnesium sulfate.
• Supplementation of potassium should start at 0.2 mEq/kg/h, which can be adjusted to max 0.5 mEq/kg/h. Potassium concentration should be measured q6-8h until stabilized.

Dextrose Supplementation

• Because insulin is required to correct the ketoacidotic state, the supplementation of dextrose allows continuous insulin administration without hypoglycemia.
• Whenever blood glucose <200 mg/dL, 50% dextrose should be added to fluids to produce 2.5% dextrose solution (increase to 5% dextrose if glucose <100 mg/dL). Discontinue dextrose once glucose is maintained above 250 mg/dL.
• Insulin therapy is continued as long as blood glucose >100 mg/dL

Bicarbonate Supplementation

• Controversial; consider if patient's venous blood pH <7.0 or HCO_3^- <11 mEq/L; of little benefit if pH >7.0.
• Dosage—bodyweight (kg) × 0.3 × base deficit (base deficit = normal serum bicarbonate – patient's serum bicarbonate); *slowly* administer ¼ to ½ of dose IV and give remainder in fluids over 3–6h.
• Recheck blood gas or serum total carbon dioxide (TCO_2) before further supplementation.

Phosphorus Supplementation

• Pretreatment serum phosphorus is usually normal; however, treatment of ketoacidosis reduces phosphorus, and serum concentrations should be checked q12–24h once supplementation is initiated.
• Dosage—0.01–0.03 mmol/kg/h for 6–12h in IV fluids (may need to increase dose to 0.06 mmol/kg/h). Remember to account for additional potassium in potassium phosphate if supplemented.

CONTRAINDICATIONS

If the patient anuric or oliguric or if blood potassium concentration >5 mEq/L, do not supplement potassium until urine flow is established or potassium concentration decreases.

PRECAUTIONS

• Use bicarbonate with caution in patients without normal ventilation (cannot excrete carbon dioxide created during treatment).
• Acidosis results in falsely elevated blood ionized calcium concentrations; calcium should be rechecked as acidosis resolves and supplemented as necessary.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

None

FOLLOW-UP

PATIENT MONITORING

• Attitude, hydration, cardiopulmonary status, urine output, and bodyweight.
• Blood glucose q1–3h initially; q6h once stable.
• Electrolytes q4–8h initially; q24h once stable.
• Acid-base status q8–12h initially; q24h once stable.

PREVENTION/AVOIDANCE

Appropriate insulin administration.

POSSIBLE COMPLICATIONS

• Hypokalemia.
• Hypoglycemia.
• Hypophosphatemia.
• Cerebral edema.
• Pulmonary edema/heart failure.
• Renal failure.

EXPECTED COURSE AND PROGNOSIS

Guarded

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Pancreatitis.
• Hyperadrenocorticism.
• Diestrus.
• Bacterial infection.
• Electrolyte depletion.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

• Risk of fetal death may be relatively high.
• Glucose regulation is often difficult in pregnant animals.

SYNONYMS

Client Education Handout available online

DIABETES MELLITUS WITHOUT COMPLICATION—CATS

BASICS

DEFINITION
• Disorder of carbohydrate, fat, and protein metabolism caused by an absolute or relative insulin deficiency, resulting in the hallmark abnormality of persistent hyperglycemia.
• The most common form in cats resembles Type II or non-insulin-dependent diabetes mellitus (DM) of humans.

PATHOPHYSIOLOGY
• Insulin resistance impairs the ability of tissues (especially muscle, adipose tissue, and liver) to use carbohydrates, fats, and proteins.
• Impaired systemic glucose utilization coupled with ongoing hepatic gluconeogenesis causes persistent hyperglycemia, which directly impairs insulin secretion by reducing functional beta cell mass ("glucose toxicity").
• Initial beta cell dysfunction progresses to irreversible failure of insulin production as reactive oxidative species, inflammatory cytokines, and amyloid deposition perpetuate beta cell injury and loss.

SYSTEMS AFFECTED
• Endocrine/metabolic—electrolyte depletion, metabolic acidosis.
• Hepatobiliary—chronic pancreatitis, hepatic lipidosis.
• Neuromuscular—muscle wasting, peripheral neuropathy.
• Renal/urologic—osmotic diuresis with compensatory polydipsia (PD); urinary tract infection.

GENETICS
Genetic susceptibility suspected in certain breeds (e.g., European Burmese cats).

INCIDENCE/PREVALENCE
Reported at between ~1 : 250 (0.4%) to ~1 : 100 (1.2%) cats.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Species
Cat

Breed Predilections
Breeds with possible increased susceptibility include Burmese (Europe, Australia, and New Zealand), Maine Coon, Russian Blue, Siamese, and Norwegian Forest cats.

Mean Age and Range
Over 80% of cases are 7 years or older at diagnosis; range: 1–19 years.

Predominant Sex
Males are overrepresented, but common in both sexes.

SIGNS
Historical Findings
• Obesity often present prior to diagnosis.
• Polyuria (PU)/PD, polyphagia, weight loss, generalized muscle wasting, poor coat quality.
• Signs suggesting a complication—anorexia, lethargy, depression, vomiting, jaundice.

Physical Exam Findings
Hepatomegaly, dehydration, plantigrade stance (diabetic neuropathy).

CAUSES
• Genetic susceptibility.
• Islet amyloid deposition.
• Pancreatitis.
• Diseases causing insulin resistance (e.g., hyperadrenocorticism and acromegaly).
• Drugs (e.g., glucocorticoids and progestogens).

RISK FACTORS
• Obesity.
• Advanced age.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Stress hyperglycemia—no PU/PD or weight loss; blood glucose concentration normal if sample taken when cat is not stressed; normal fructosamine concentration.
• Renal glucosuria—absence of hyperglycemia; usually does not cause PU/PD or weight loss.

CBC/BIOCHEMISTRY/URINALYSIS
• Mild normocytic, normochromic anemia possible.
• Glucose >150 mg/dL.
• High alkaline phosphatase (ALP), alanine aminotransferase (ALT), and aspartate aminotransferase (AST) activities.
• Hypercholesterolemia, hyperbilirubinemia, and hypertriglyceridemia.
• Total CO_2 or HCO_3 low with ketoacidosis or severe dehydration.
• Glucosuria, ketonuria uncommon in uncomplicated DM.
• Isosthenuria, proteinuria.

OTHER LABORATORY TESTS
• Fructosamine >350 µmol/L—confirms persistence of hyperglycemia.
• Feline pancreas-specific lipase >3.50 µg/L—identifies presence of pancreatitis.
• Urine culture—positive in 10–15% of newly diagnosed DM.

IMAGING
• Thoracic and abdominal radiography— to evaluate for concurrent or underlying disease (e.g., neoplasia, cystic or renal calculi, emphysematous cystitis, or cholecystitis).
• Abdominal ultrasonography—in selected patients, particularly those with jaundice, to evaluate for hepatic lipidosis, cholangiohepatitis, and pancreatitis.

DIAGNOSTIC PROCEDURES
Liver fine-needle aspiration—if concern for hepatic lipidosis.

PATHOLOGIC FINDINGS
• Usually no gross necropsy changes; pancreatic weight may be increased.
• Histopathology—normal, more likely to reveal islet amyloidosis, vacuolar or hydropic degeneration of the islets of Langerhans; lymphoplasmacytic pancreatic infiltration rare in cats.

TREATMENT

APPROPRIATE HEALTH CARE
• Compensated cats can be managed as outpatients if they are alert, hydrated, and eating and drinking without vomiting.
• For decompensated patients, see Diabetes Mellitus With Ketoacidosis.

NURSING CARE
Fluid therapy—in decompensated patients.

ACTIVITY
Strenuous activity may lower insulin requirements; consistent daily activity level is helpful.

DIET
Ultra-low-carbohydrate (<12% metabolizable energy) and high protein (>40% metabolizable energy) canned diets may improve glycemic control, and increase the likelihood of diabetic remission in newly diagnosed diabetic cats.

CLIENT EDUCATION
• Discuss maintaining a consistent daily feeding and medication schedule, home glucose monitoring, signs of hypoglycemia and what to do, and when to seek veterinary assistance.
• Clients are encouraged to chart pertinent daily information about the pet, such as any home-obtained glucose readings or patterns of exhibited clinical signs (e.g., PU/PD or appetite).

SURGICAL CONSIDERATIONS
Intact females should have ovariohysterectomy when stable; progesterone secreted during diestrus makes management of DM difficult.

MEDICATIONS

DRUG(S) OF CHOICE
• Insulin is treatment of choice and should be initiated at 1–2 units per cat SC q12h; based on routine monitoring, some cats may eventually be reduced to once-daily dosing.
• Two U-40 insulin formulations are FDA-approved for use in cats—protamine zinc (PZI) and porcine zinc lente insulin suspension.

DIABETES MELLITUS WITHOUT COMPLICATION—CATS (CONTINUED)

• Most consensus recommendations support the use of PZI or glargine (U-100) as first-choice insulin therapy for cats.

PRECAUTIONS

Glucocorticoids, megestrol acetate, and progesterone cause insulin resistance. If steroid therapy is necessary, use oral methylprednisolone. Avoid injectable steroids.

POSSIBLE INTERACTIONS

• Drugs that may increase insulin sensitivity—angiotensin-converting enzyme inhibitors, sulfonamides, tetracycline, beta blockers, monoamine oxidase inhibitors, salicylates.
• Drugs that increase insulin resistance—glucocorticoids, estrogen supplements, furosemide, thiazide diuretics, and calcium channel blockers.
• Always consult a new medication's product insert.

ALTERNATIVE DRUG(S)

• Oral sulfonylureas (e.g., glipizide)—only considered when insulin therapy is not possible (e.g., owner considering euthanasia instead of injections). Initial does of 2.5 mg PO q12h can be used and monitored similar to insulin. If DM is not controlled after 2 weeks, dose of 5 mg PO q12h may be tried; however, response is seen in <40% of cats and often not sustained long term. Potential side effects are hypoglycemia, hepatic enzyme alterations, icterus, and vomiting.
• Acarbose—an alpha-glucosidase inhibitor used to limit intestinal glucose absorption. Often used in combination with diet and insulin at a starting dose of 12.5 mg PO q12h; diarrhea is most common side effect.
• Drugs warranting further study for utility in managing feline DM include once-weekly injected glucagon-like peptide 1 analogues and oral renal tubular transporter inhibitors.

FOLLOW-UP

PATIENT MONITORING

• Owner-assessed clinical signs (PU/PD, appetite, attitude) and bodyweight—if signs are normal and weight stable to increasing, disease is likely to be regulated.
• Glucose curves—ideally generated by the owner at home. Perform 5–14 days after starting insulin or after any dose adjustments until controlled, then again at 1 month, and every 3–6 months thereafter.
• Fructosamine—maintain <400 µmol/L. Recheck monthly during initial regulation, then every 3–6 months as part of routine monitoring visits.
• Urinary monitoring—useful for identifying ketones in chronically unregulated patients or persistently negative glucose in cats likely entering remission.
• Flash glucose monitoring system (FreeStyle Libre®)—24-hour glucose monitoring system that measures blood glucose BG every 5 minutes for up to 14 days; use reported in dogs, but not cats. Anecdotal evidence suggests the device is not 100% accurate, but helpful in assessing BG trends in cats in which a BG curve is not possible.

PREVENTION/AVOIDANCE

Prevent or correct obesity; avoid unnecessary use of glucocorticoids or megestrol acetate.

POSSIBLE COMPLICATIONS

• Seizure, blindness, or coma with insulin overdose.
• Diabetic ketoacidosis or hyperglycemic hyperosmolar syndrome.

EXPECTED COURSE AND PROGNOSIS

• Prognosis with treatment and monitoring is good; most animals have a normal lifespan.
• Some cats may recover insulin-secreting ability ("diabetic remission"), typically if glycemic control is achieved within 6 months of diagnosis; however, relapse is common (~30%).
• Reported remission rates vary greatly (0–100%); however, studies surveying general practitioners have suggested ~25–30% is reasonable expectation.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Urinary tract infection, chronic pancreatitis.

AGE-RELATED FACTORS

Congenital and juvenile forms of DM are rare (<3% of cases are under 2 years of age) and may be more difficult to manage.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

• Insulin requirements should be monitored closely during pregnancy as they are expected to fluctuate.
• Severe maternal hypoglycemia can negatively impact fetal viability and neonatal neurologic function, therefore should be avoided during gestation.

SYNONYMS

N/A

SEE ALSO

• Diabetes Mellitus With Ketoacidosis.
• Diabetes Mellitus With Hyperosmolar Hyperglycemic State.

ABBREVIATIONS

• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• AST = aspartate aminotransferase.
• BG = blood glucose.
• DM = diabetes mellitus.
• PU/PD = polyuria and polydipsia.
• PZI = protamine zinc insulin.

DIABETES MELLITUS WITHOUT COMPLICATION—DOGS

BASICS

DEFINITION

• Fasting hyperglycemia of sufficient magnitude to result in characteristic clinical signs including weight loss with normal or increased appetite, polydipsia (PD), and polyuria (PU) caused by glucosuria. • Disorder of carbohydrate, fat, and protein metabolism caused by absolute or relative insulin deficiency. • Generally canine diabetes mellitus (DM) is characterized by loss of insulin-secreting ability through presumed immune-mediated destruction of pancreatic beta cells. • Far less frequently, canine DM may develop as result of combination of relative insulin-deficient state with concurrent peripheral insulin resistance.

PATHOPHYSIOLOGY

• Absolute or relative insulin deficiency results in accelerated tissue catabolism, impaired ability to maintain carbohydrate, lipid, and protein homeostasis, as well as insulin resistance. • Reduced insulin-secreting ability, peripheral insulin resistance, and continued hepatic gluconeogenesis result in persistent hyperglycemia of sufficient severity to overload renal tubular glucose resorption; leading to glucosuria, osmotic diuresis, PU accompanied by compensatory PD. • Loss of insulin-dependent glucose-mediated hypothalamic satiation signaling results in polyphagia. • Decreased insulin-dependent utilization of glucose results in catabolic protein breakdown with weight loss and increased lipid mobilization (hyperlipidemia, hepatic lipidosis, production of ketoacids). • Accumulation of large amounts of ketone bodies leads to metabolic acidosis (see Diabetes Mellitus With Ketoacidosis).

SYSTEMS AFFECTED

• Endocrine/metabolic—electrolyte depletion and metabolic acidosis. • Hepatobiliary—hepatic lipidosis. • Ophthalmic—cataracts. • Renal/urologic—glucosuria resulting in osmotic diuresis and increased likelihood of bacterial urinary tract infections, particularly of upper urinary tract.

GENETICS

Certain breeds dramatically over- and underrepresented, suggesting inherited susceptibility to immune-mediated "isletitis."

INCIDENCE/PREVALENCE

• Prevalence varies between 1 : 400 and 1 : 500. • Onset has seasonal incidence; more animals diagnosed in autumn and winter.

SIGNALMENT

Species

Dog

Breed Predilections

• Samoyed, Tibetan terrier, Cairn terrier, golden retriever (United States only) overrepresented. • Keeshond, poodle, dachshund, miniature schnauzer, beagle may have increased predisposition. • Boxer, German shepherd, golden retriever (UK only) underrepresented.

Mean Age and Range

Mean ~8 years; range: 4–14 years (excluding rare juvenile form).

Predominant Sex

Female

SIGNS

• PU/PD, polyphagia with weight loss. • Hepatomegaly. • Cataracts common finding—approximately 80% of dogs with DM for >12 months will have cataracts regardless of level of control. • Lethargy, depression, inappetence, anorexia, and vomiting may occur in animals with ketoacidosis.

CAUSES

• Immune-mediated isletitis. • Disorders that predispose to secondary immune-mediated isletitis—pancreatitis, viral illness.

RISK FACTORS

• Diestrus. • Genetic susceptibility. • Use of glucocorticoids or progestins.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Renal glucosuria—not associated with hyperglycemia, usually no weight loss or polyphagia.

CBC/BIOCHEMISTRY/URINALYSIS

• Hemogram usually normal. • Glucose >200 mg/dL, possible ketonemia. • High serum alkaline phosphatase (ALP) and alanine aminotransferase (ALT) enzyme activities, generally with greater proportionate increase in ALP. • Hypercholesterolemia, lipemia. • Electrolyte alterations vary; hypokalemia and hypophosphatemia may be present. • Total CO_2 or HCO_3 will be low with ketoacidosis or severe dehydration. • Glucosuria, ketonuria in some dogs. • Urinary specific gravity variable depending on degree of glucosuria.

OTHER LABORATORY TESTS

• Anion gap—high in patients with ketoacidosis. • Glycated proteins—fructosamine or glycosylated hemoglobin: extent of glycosylation directly related to blood glucose concentration over lifespan of protein in circulation (10–20 days for fructosamine, 4–8 weeks for hemoglobin). ◦ Glycated protein concentration modified by changes in albumin or hemoglobin concentrations; accelerated albumin turnover (e.g., glomerulonephropathy, liver dysfunction, gastrointestinal disease) will lower fructosamine level for given average blood glucose. ◦ Best used for ongoing management of relatively stable diabetic patients; fructosamine concentration in upper third of reference range reflects excellent diabetic control; concentration in lower third is more suggestive of overzealous diabetic control and possible increased risk of hypoglycemia. • Plasma insulin concentrations not particularly helpful—while low insulin concentration suggests insulin deficiency, may be reflection of reversible islet exhaustion (persistent hyperglycemia can impair insulin secretory activity, even if functional beta cells present).

IMAGING

• Radiography—useful to look for comorbidities (e.g., cystic or renal calculi, emphysematous cystitis, cholecystitis, pancreatitis). • Ultrasonography—indicated in selected patients, particularly those with jaundice, to evaluate for presence of obstructive hepatopathy or pancreatitis.

DIAGNOSTIC PROCEDURES

Liver biopsy (percutaneous)—indicated in some jaundiced patients to evaluate other causes for hepatopathy.

PATHOLOGIC FINDINGS

• Necropsy findings—hepatomegaly with significant hepatic lipid accumulation. • Histopathologic findings generally reveal dramatic reduction in size and number of pancreatic islets with relatively normal exocrine tissue architecture.

TREATMENT

APPROPRIATE HEALTH CARE

• Compensated dogs generally alert, well hydrated, eating and drinking without vomiting, and can be managed as outpatients. • For management of decompensated patients, see Diabetes Mellitus With Ketoacidosis.

DIET

• Diet should be calorically and constitutively consistent. • Ideally glucose-lowering effects of insulin should match glucose-raising effects of the meal. ◦ Most insulins act maximally 2–4h after SC administration, and most food absorbed within 1h of consumption, so glycemic control almost always improved if dog fed 60–90 min *after* q12h insulin dosing. ◦ Animals that "graze" throughout day can be fed dry food ad libitum and given 2 small meals of canned food as above. ◦ If insulin can only be administered once daily, feed total daily caloric intake in 2 or 3 meals within first 6–8h after insulin dosing. • Feed caloric quantity appropriate for animal's ideal

DIABETES MELLITUS WITHOUT COMPLICATION—DOGS (CONTINUED)

bodyweight (~60 kcal/kg); food should be something dog will eat reliably and within short period. • Obese diabetic dogs—feed restricted caloric intake to ensure ideal bodyweight achieved within 2–4 months using high-fiber, low-calorie food; while high-fiber diet may improve patient satiety and possibly owner satisfaction, has no role in improving diabetic control. • While snacks should generally be avoided, small treats given at time of injection to positively reinforce owner–patient interaction should be encouraged.

CLIENT EDUCATION

• Most important that insulin and feeding regime are discussed and agreed with owner and they feel comfortable with plan; effective management requires significant owner–patient interaction; flexibility in establishing best management regime is thus paramount and rigid "one size fits all protocols" should be avoided. • Discuss daily feeding and medication schedule, home monitoring, signs of hypoglycemia and what to do, and when to call or visit veterinarian. • Clients encouraged to keep chart of pertinent information about pet, such as daily water consumption, weekly bodyweight, current insulin dose, and amount of food consumed; use of standardized clinical scoring tool should be encouraged to maintain consistency across veterinary and tech teams involved in managing both dog and owner.

SURGICAL CONSIDERATIONS

Intact females should have ovariohysterectomy when stable; progesterone secreted during diestrus makes management of DM more unpredictable.

MEDICATIONS

DRUG(S) OF CHOICE

• Insulin—almost always required • Vetsulin® (porcine-origin lente) 0.75 units/kg SC q12h initial dose; *note*: U-40 insulin—must use with U-40 insulin syringe; availability may be limited. • Humulin N—intermediate-acting, human insulin; 0.75 units/kg SC q12h initial dose. • Novolin N—intermediate-acting, human insulin; 0.75 units/kg SC q12h initial dose. • PZI Vet® (intermediate- to longer-acting protamine zinc human insulin) rarely used in dogs; *note*: U-40 insulin—must use with U-40 syringe. • Detemir insulin—longer-acting, synthetic insulin; part of reason for its delayed release is because bound to albumin; unlike insulins mentioned above, starting dose should be considerably lower: 0.1 unit/kg SC q12h initial dose. • Glargine insulin—longer-acting, synthetic insulin; 0.75 units/kg SC q12h initial dose. • Species of origin of insulin may affect pharmacokinetics; canine and porcine insulin have identical amino acid sequence, hence Vetsulin does not produce significant insulin antibody response, whereas most other commercially available insulins do; however, no evidence the development of insulin antibodies has any clinical significance.

PRECAUTIONS

• Glucocorticoids, megestrol acetate, and progesterone cause insulin resistance. • Hyperosmotic agents (e.g., mannitol and radiographic contrast agents) should be avoided if patient is already hyperosmolar from hyperglycemia.

ALTERNATIVE DRUG(S)

Oral hypoglycemic agents are generally not recommended.

FOLLOW-UP

PATIENT MONITORING

• Diabetic dogs require regular contact between owner and veterinary team; visits should occur every 3–4 months if animal is stable and clinical signs are controlled, or more frequently if control is poor or variable. Criteria to assess control include: ◦ Clinical signs—degree of PU/PD, appetite, and bodyweight; if within acceptable limits, disease likely well regulated; consider using standardized clinical scoring system to consistently evaluate clinical phenotype. ◦ Glycated proteins—fructosamine or glycosylated hemoglobin; see above. ◦ Glucose curve—provides information on insulin effectiveness, duration of action, nadir (lowest blood glucose level achieved during dosing interval), and potential for rebound hyperglycemia; results subject to influence of stress (hospitalization, multiple blood draws) and "normal" conditions should be mimicked as much as possible; used most effectively when establishing initial control, changing insulin type, dose, or frequency, or problem solving for difficult diabetic; duration of curve ideally matches dosing interval (12 or 24 hours)—identification of nadir (to avoid iatrogenic hypoglycemia) and glucose level at time of dosing are most important aspects of curve; goal is to establish effective insulin dose (decline in blood glucose to 100–200 mg/dL) for appropriate duration (majority of 12- or 24-hour dosing interval) with nadir >80 mg/dL and <150 mg/dL; in dogs average glucose levels for 12-hour period overnight are lower than during daylight period. • Home glucose monitoring using serial blood glucose estimations or real-time measures using SC glucose monitoring devices—requires owner commitment, compliance, and competence; most useful as early indicator of need for reduction in dose in patients with well-controlled clinical signs; should never be used by owner to make independent adjustment of insulin dose; owner-measured urine glucose levels not particularly useful.

PREVENTION/AVOIDANCE

• Neuter females; avoid unnecessary use of megestrol acetate. • No evidence exists to suggest obesity increases risk of DM in neutered dogs.

POSSIBLE COMPLICATIONS

• Cataracts can occur even with good glycemic control. • Weakness, especially with exercise; seizures or coma may occur with insulin overdose.

EXPECTED COURSE AND PROGNOSIS

• Dogs generally have permanent disease unless affected during estrus cycle, where neutering may resolve diabetes for a period. • Prognosis with twice-daily insulin treatment and feeding aligned with insulin's maximum effects is good.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Urinary tract infection. • Cataracts.

AGE-RELATED FACTORS

Juvenile DM is rare and may be more difficult to manage.

PREGNANCY/FERTILITY/BREEDING

• DM can develop during pregnancy, in which case pregnancy is difficult to maintain. • Exogenous insulin administration may cause fetal oversize and dystocia. • Insulin resistance develops, making hyperglycemia difficult to control. • Pregnant bitch is prone to ketoacidosis; emergency ovariohysterectomy may be necessary. • Do not breed dogs with DM.

ABBREVIATIONS

• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• DM = diabetes mellitus.
• PD = polydipsia.
• PU = polyuria.

Consulting Editor Patty A. Lathan

Client Education Handout available online

DIAPHRAGMATIC HERNIA

BASICS

OVERVIEW

• Protrusion of an abdominal organ through an abnormal opening in the diaphragm, either as an acquired injury or as a congenital defect. • Congenital—pleuroperitoneal (PIPDH) or peritoneopericardial diaphragmatic hernia (PPDH). • Traumatic—most often the result of a motor vehicle accident. • Impaired lung expansion. • Myocardial trauma. • Evidence of shock. • Systems affected—respiratory, cardiovascular, gastrointestinal.

SIGNALMENT

• Dogs and cats. • Acquired—no breed predilection. • Congenital (PPDH)—Weimaraner, Maine coon cat, and Persian cats. • Congenital PIPDH—golden retriever, cavalier King Charles spaniel. • Young animals at higher risk for both congenital and traumatic causes (median age 1.2 and 3.1 years, respectively). • No sex predilection.

SIGNS

Traumatic

• Can be acute, subacute, or chronic. • Possible known history of blunt trauma. • Difficulty breathing. • Evidence of shock (tachycardia, pale mucous membranes, weak pulses). • Gastrointestinal sounds ausculted in thorax. • Empty abdomen on abdominal palpation. • Signs may be progressive.

Congenital

• May not have clinical signs or may develop clinical signs later in life. • Difficulty breathing. • Gastrointestinal signs. • Signs may be progressive. • Evidence of shock (tachycardia, pale mucous membranes, weak pulses). • Evidence of cardiac tamponade. • Arrhythmias. • Muffled heart sounds.

CAUSES & RISK FACTORS

Traumatic

• Motor vehicle accident. • Other blunt trauma. • Penetrating trauma (e.g., bite wounds).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Pneumothorax. • Pulmonary contusion. • Hemothorax.

CBC/BIOCHEMISTRY/URINALYSIS

Nonspecific changes due to trauma may be noted.

OTHER LABORATORY TESTS

Serum lactate—may be significantly elevated following trauma.

IMAGING

Point-of-Care Ultrasound (POCUS)

• Thoracic-focused assessment with sonography for trauma (TFAST®). • Abdominal focused assessment with sonography for trauma (AFAST®).

Standard Imaging

• Three-view thoracic and abdominal radiography. • Horizontal beam radiography. • Ultrasonography.

Additional Imaging

• Contrast radiography—upper gastrointestinal positive contrast series; peritoneography. • CT.

Imaging Findings

• Identification of gastrointestinal viscera within pleural space and/or absence from abdominal cavity makes diagnosis of diaphragmatic herniation often uncomplicated. • Other radiographic signs include loss of diaphragmatic outline and cardiac silhouette, displacement of lung fields, presence of gas-filled viscera, and pleural effusion.• For congenital PPDH cardiac silhouette is markedly enlarged and may have evidence of gas-filled structures within it. • Contrast or advanced imaging is often unnecessary.

DIAGNOSTIC PROCEDURES

• Thoracocentesis for pleural effusion. • Pericardiocentesis for pericardial effusion.

TREATMENT

Emergency Inpatient Intensive Care Management

• Address shock. • Improve ventilation and cardiac output. • Manage concurrent injury. • Gastric decompression if indicated.

Surgical Management

• Exploratory laparotomy. • Reduction and assessment of herniated abdominal viscera. • Surgical repair of diaphragmatic rent. • Additional surgical procedures (e.g., splenectomy, intestinal resection and anastomosis, liver lobectomy). • Pleural space evacuation (thoracostomy tube placement, thoracocentesis).

Nursing Care

• IV fluid therapy. • Oxygen supplementation. • Pain management.

Surgical Considerations

• Anesthesia and surgery should be delayed until animal is hemodynamically stable. • Emergency surgery indicated with evidence of gastrothorax, gastrointestinal entrapment, or persistent respiratory distress. • Long lasting absorbable monofilament suture (e.g., Maxon® or PDS®) should be used to close the diaphragm in a full-thickness simple continuous pattern. • Care should be taken around caval foramen, esophageal hiatus, and aortic hiatus.

MEDICATIONS

DRUG(S) OF CHOICE

• Appropriate postoperative pain medications; consider local analgesia. • Antiarrhythmic agents as indicated.

CONTRAINDICATIONS

Avoid nonsteroidal anti-inflammatories for at least 24–48 hours following trauma.

FOLLOW-UP

PATIENT MONITORING

• Frequent or continuous ECG monitoring. • Observation of ventilation. • Pulse oximetry. • Serial arterial blood gas evaluation.

POSSIBLE COMPLICATIONS

• Respiratory distress—due to concurrent injury or pneumothorax. • Reexpansion pulmonary edema (RPE) is uncommon but often fatal complication; to minimize risk of RPE, avoid aggressive positive-pressure ventilation following reduction of herniated organs, and avoid aggressive evacuation of pleural space in postoperative period. • Recurrence uncommon, but most often associated with inadequate surgical repair.

EXPECTED COURSE AND PROGNOSIS

If animal survives for first 12–24 hours after surgery, prognosis is excellent. Reported survival rates range from 80 to 90%. Death most often due to concurrent injury.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Congenital PPDH may be associated with other congenital midline defects. • Animals suffering trauma may have significant concurrent injuries.

ABBREVIATIONS

• AFAST® = abdominal focused assessment with sonography for trauma. • PIPDH = pleuroperitoneal diaphragmatic hernia. • POCUS = point-of-care ultrasound. • PPDH = peritoneopericardial diaphragmatic hernia. • RPE = reexpansion pulmonary edema. • TFAST® = thoracic-focused assessment with sonography for trauma.

Author Catriona M. MacPhail
Consulting Editor Elizabeth Rozanski

DIARRHEA, ANTIBIOTIC RESPONSIVE

BASICS

OVERVIEW

• Defined as chronic diarrhea with no identifiable underlying etiology that responds to antibiotic therapy. • Antibiotic-responsive diarrhea (ARD) was previously termed idiopathic (primary) small intestinal bacterial overgrowth (SIBO); this term is no longer used as it was based on quantitative culture of bacteria in the upper gastrointestinal tract that could not be confirmed by newer PCR-based methods; secondary SIBO is a result of concurrent gastrointestinal diseases (e.g., exocrine pancreatic insufficiency [EPI]). • Current theories center on the possibility of immune dysregulation, possibly associated with abnormal CD4+ T-cells, immunoglobulin (Ig) A plasma cells, cytokine expression, and, in German shepherd dogs, mutations in pattern recognition receptors.

SIGNALMENT

Species

Dog

Breed Predilections

Increased incidence in German shepherd, boxer, and Chinese Shar-Pei.

Mean Age and Range

More common in young dogs, with median age of 2 years.

Predominant Sex

N/A

SIGNS

Historical Findings

• Small bowel signs—inappetence or anorexia, vomiting, weight loss, large-volume diarrhea. • Large bowel signs—tenesmus, hematochezia, increased frequency of defecation.

Physical Examination Findings

Weight loss, poor body condition, borborygmus, and flatulence may be detected; hematochezia may be present if there is large bowel involvement.

CAUSES & RISK FACTORS

• Genetic mutations in pattern recognition genes (*TLR4* and *TLR5*) have been associated with the disease. • Certain enteropathogenic bacteria (*Clostridium perfringens*, *Escherichia coli*, and *Lawsonia intracellularis*) have been suspected but not proven to be etiologic agents.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Secondary SIBO. • EPI. • Parasitic infection. • Inflammatory bowel disease. • Food-responsive diarrhea. • Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

• Typically normal. • Hypoalbuminemia is uncommon finding.

OTHER LABORATORY TESTS

• Fecal examination for parasites should be performed. • Serum cobalamin levels may be low and folate levels may be increased or decreased. • Serum trypsin-like immunoreactivity (measured to rule out EPI) is normal.

IMAGING

Routine abdominal imaging (radiographs and ultrasound) should be performed to rule out other causes for diarrhea. These tests are unremarkable in cases of ARD.

DIAGNOSTIC PROCEDURES

Diagnosis depends upon ruling out all other causes for chronic diarrhea (especially food-responsive diarrhea) and a clinical response to an appropriate course of antibiotic therapy.

TREATMENT

• Hospitalization generally not indicated; treated on outpatient basis. • Role of diet in ARD is unknown; current recommendations are to feed low-fat, highly digestible food or elimination or hydrolyzed diet.

MEDICATIONS

DRUG(S) OF CHOICE

• Several options for antibiotics available—tylosin (5–10 mg/kg PO q24h); metronidazole (10–15 mg/kg PO q12h); oxytetracycline (10–20 mg/kg PO q8h). • In some cases, combination therapy may be necessary. • Antibiotic therapy administered for 4–6 weeks and then discontinued. • If serum cobalamin levels decreased, cobalamin supplementation should be pursued; dogs: 50 µg/kg up to max dose of 1,500 µg parenteral cobalamin; doses given as SC injections once weekly for 6 weeks, then once every other week for 6 weeks; serum cobalamin levels should be reassessed at end of therapy; oral cobalamin supplementation is effective at dosage of 0.25–1.0 mg PO daily.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Oxytetracycline may cause staining of tooth enamel; doses should be decreased in animals with hepatic or renal insufficiency; oxytetracycline has been associated with high incidence of bacterial transfer of resistance genes. • Metronidazole undergoes extensive hepatic metabolism; dosages should be reduced in animals with hepatic insufficiency. • Long-term administration of both tylosin and metronidazole has been found to induce long-term dysbiosis in ARD dogs, which is very difficult to correct; this dysbiosis is associated with changes in bile acid metabolism and serum metabolome, and persists for over 6 months after discontinuing treatment.

FOLLOW-UP

• Clinical resolution of diarrhea is most important criterion. • Weight gain may also be seen; hypoalbuminemia (if present) should resolve. • Relapses usually occur when antibiotics are discontinued; some dogs can be maintained on very low doses of antibiotics long term, however the development of antimicrobial resistance in these dogs is a concern. • Recent studies suggest ARD dogs have poor long-term prognosis, possibly due to induction of dysbiosis; many dogs eventually will become steroid resistant or will be euthanized because of treatment resistance.

MISCELLANEOUS

SEE ALSO

Small Intestinal Dysbiosis.

ABBREVIATIONS

• ARD = antibiotic-responsive diarrhea.
• EPI = exocrine pancreatic insufficiency.
• Ig = immunoglobulin.
• SIBO = small intestinal bacterial overgrowth.

DIARRHEA, CHRONIC—CATS

BASICS

DEFINITION
• A change in the frequency, consistency, and volume of feces for more than 3 weeks or with a pattern of episodic recurrence. • Can be either small bowel, large bowel, or mixed in origin.

PATHOPHYSIOLOGY
• High solute and fluid secretion—secretory diarrhea. • Low solute and fluid absorption—osmotic diarrhea. • High intestinal permeability. • Abnormal gastrointestinal (GI) motility. • Many cases involve various combinations of these four basic pathophysiologic mechanisms.

SYSTEMS AFFECTED
• Endocrine/metabolic—fluid, electrolyte, and acid-base. • Exocrine. • GI. • Lymphatic.

GENETICS
N/A

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Cat

Breed Predilections
None

Mean Age and Range
Any age.

Predominant Sex
None

SIGNS

General Comments
• Underlying disease process determines extent of clinical signs. • 2–3% increase of water content of stool results in gross description of diarrhea. • Classification of small, large, and mixed bowel types of diarrhea may have overlap of descriptive findings.

Historical Findings
• Small bowel diarrhea can include—normal to increased volume; normal to moderately increased (2–4 times/day) defecation frequency; weight loss; polyphagia; melena; flatulence and borborygmus; vomiting: variable. • Large bowel diarrhea can include—smaller volume; frequency of defecation is increased (>4 times/day); often hematochezia and mucus; tenesmus, urgency, dyschezia; flatulence and borborygmus: variable; vomiting: variable.

Physical Examination Findings

Small Bowel
• Poor body condition associated with malabsorption, maldigestion, and protein-losing enteropathy (PLE). • Variable dehydration. • Abdominal palpation may reveal segmental or diffusely thickened small bowel loops associated with infiltrative disease, abdominal effusion, foreign body, neoplastic mass, intussusception, or enlarged mesenteric lymph nodes. • Rectal palpation typically unremarkable.

Large Bowel
• Body condition typically unremarkable. • Dehydration—uncommon. • Abdominal palpation may reveal thickened large bowel, foreign body, neoplastic mass, intussusception, or enlarged mesocolic lymph nodes. • Rectal palpation may reveal irregularity of rectal mucosa, intraluminal or extraluminal rectal masses, rectal stricture, or sublumbar lymphadenopathy.

CAUSES

Small and Large Intestinal Diseases

Primary Disease
• Inflammatory bowel disease (IBD)—e.g., lymphoplasmacytic enteritis, eosinophilic enteritis, granulomatous enteritis. • Neoplasia—e.g., lymphoma, including large cell (B-cell lymphoma) and small cell alimentary lymphoma (T-cell), adenocarcinoma, mast cell neoplasia. • Bacterial—e.g., *Salmonella* spp., enterotoxic *Escherichia coli*, other enterobacteriaceae species, *Clostridia* spp.: usually acute diarrhea. • Viral—e.g., enteric coronavirus (usually acute diarrhea unless combined with other viral infections or co-factors), feline infectious peritonitis, feline leukemia virus (FeLV) associated, feline immunodeficiency virus (FIV) associated. • Mycotic—e.g., histoplasmosis. • Algal—e.g., protothecosis, pythiosis. • Parasites—e.g., *Giardia*, *Toxocara* spp., *Ancylostoma*, *Toxascaris leonina*, *Cryptosporidium* spp., *Cystoisospora* spp., *Tritrichomonas foetus*. • Partial obstruction—e.g., foreign body, intussusception, neoplasia. • Secondary lymphangiectasia—very rare in cats. • Intestinal microbial dysbiosis—cause vs. effect. • Short bowel syndrome. • GI ulceration—rare in cats.

Maldigestion
• Hepatobiliary disease—lack of bile salts needed for intraluminal digestion. • Exocrine pancreatic insufficiency (EPI).

Dietary
• Dietary intolerance (food-responsive diarrhea). • Food allergy.

Metabolic Disorders
• Hyperthyroidism. • Cobalamin deficiency—typically secondary to underlying IBD or lymphoma. • Renal disease. • Hepatobiliary disease. • Adverse drug reactions.

Congenital Anomalies
• Short colon. • Portosystemic shunt. • Persistent pancreaticomesojejunal ligament.

RISK FACTORS
Dietary changes, feeding poorly digestible or high-fat diets.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
First localize the origin of the diarrhea to the small or large bowel (or both) on the basis of historical signs.

CBC/BIOCHEMISTRY/URINALYSIS
• Eosinophilia in some cats with parasitism, eosinophilic enterocolitis, hypereosinophilic syndrome, or neoplasia. • Macrocytosis in some cats with hyperthyroidism or FeLV infection. • Anemia that is variably regenerative and may show microcytosis suggests chronic GI bleeding and iron deficiency. • Leukopenia in some cats with FeLV or FIV infection.
• Panhypoproteinemia caused by PLE is uncommon in cats with intestinal disease, but can occur; hypoalbuminemia can be seen.
• Biochemical profiles and urinalysis abnormalities may suggest renal disease, hypoproteinemia, hepatobiliary disease, or endocrinopathy.

OTHER LABORATORY TESTS

Fecal and/or Rectal Scraping Exam
• Direct wet prep, routine centrifugation fecal flotation, fecal ELISA testing may indicate GI parasites. • Cytologic examination of rectal scrapings may reveal specific organisms, such as *Histoplasma*, *Prototheca*, or *Tritrichomas*. • PCR fecal testing should be interpreted with caution, because positive results for toxin genes or infectious agents may or may not correlate with clinical disease; interpret PCR results in light of patient signalment, history, clinical presentation, vaccination history, and other laboratory data.
• PCR for *Tritrichomonas*—most sensitive test; be certain to send fresh fecal sample, colonic lavage fluid, or loop scraping for testing.
• Culture feces if *Salmonella* is suspected—special media required.

Thyroid Function Tests
• High total T_4 or free T_4 concentration indicates hyperthyroidism. • If hyperthyroidism is suspected but T_4 is normal, perform a T_3 suppression test, repeat the T_4 a few months later, or perform a technetium scan of the thyroid glands.

Serologic Testing
Test for FeLV and FIV—especially if hematologic abnormalities are present.

Test for Exocrine Pancreatic Function
Feline-specific trypsin-like immunoreactivity—test of choice for diagnosis of EPI.

IMAGING
• Survey abdominal radiography may indicate abnormal intestinal pattern, organomegaly, mass, foreign body, pancreatic disease, hepatobiliary disease, urinary disease, or abdominal effusion; low yield in most cats with chronic diarrhea. • Contrast radiography (upper GI series or barium enema) may indicate bowel wall thickening, intestinal ulcers, mucosal irregularities, mass, radiolucent foreign body, or stricture; procedure performed infrequently in cats in light of advantages of abdominal ultrasonography. • Abdominal ultrasonography may demonstrate bowel wall thickening, abnormal bowel wall layering, GI or extra-GI masses, intussusception, foreign body, ileus, abdominal effusion, hepatobiliary

DIARRHEA, CHRONIC—CATS (CONTINUED)

disease, pancreatitis, renal disease, or mesenteric or mesocolic lymphadenopathy.

DIAGNOSTIC PROCEDURES

If maldigestive (EPI), metabolic, parasitic, dietary, and infectious causes have been excluded, consider empiric dietary therapy, utilizing an elimination diet for 2 weeks before performing endoscopy and biopsy or a laparotomy for definitive diagnosis.

Endoscopy/Laparoscopy

• Upper GI flexible endoscopy allows examination and biopsy of gastric and duodenal mucosa; always obtain multiple (8–10) mucosal specimens from each segment/area. • Flexible colonoscopy allows examination of entire rectum, colon, cecum, and ileum; always obtain multiple mucosal specimens (8–10) from each segment. • Visual impressions of GI mucosal detail may not reflect histopathologic changes; always take biopsies. • Endoscopic biopsies rely upon infiltrative and inflammatory diseases being represented in first two layers of the intestinal wall, and segments biopsied being representative of disease process. • Full-thickness biopsies can be obtained via laparoscopy from one or more segments of small intestine (not large intestine) via exteriorization of the segment(s), but are not typically necessary as most diseases can be diagnosed endoscopically.

Surgical Biopsy

Surgical approach beneficial if biopsies of multiple organs (small intestine, lymph nodes, stomach, pancreas, liver) are desired.

Ultrasound-Guided GI Aspiration or Biopsy

• Can perform ultrasound-guided fine-needle aspiration on some GI mass lesions, but cytologic interpretation accuracy is subject to sample quality, expertise, and limitations of technique; small cell alimentary lymphoma cannot be diagnosed by cytology, as cells will be small lymphocytes. • Paracentesis of peritoneal fluid for fluid analysis, culture, and cytology is recommended. • Concern has been expressed for risk of translocation of cancer cells or infective organisms with these procedures.

PATHOLOGIC FINDINGS

Vary with underlying disease.

TREATMENT

APPROPRIATE HEALTH CARE

• Outpatient medical management most common. • Treat underlying cause.

NURSING CARE

• Give fluid therapy with balanced electrolyte solution as needed. • Correct electrolyte and acid-base imbalances.

ACTIVITY

No restriction.

DIET

• Feeding elimination diet (intact novel protein source or hydrolyzed protein) will resolve diarrhea in 40–60% of cats with chronic enteropathy; response should be detected within 2–3 weeks following dietary implementation. • Repeated changes of diet made in order to maintain a symptom-free situation suggest that further testing needed.

CLIENT EDUCATION

Complete resolution of signs is not always possible in cats with IBD, neoplasia, or fungal disease despite proper treatment.

SURGICAL CONSIDERATIONS

Pursue exploratory laparotomy and surgical biopsy if evidence of obstruction, intestinal mass, or mid-small bowel disease unreachable via endoscopic procedure.

MEDICATIONS

DRUG(S) OF CHOICE

• Disease specific. • Prednisolone (1–2 mg/kg BID) for management of IBD; chlorambucil (2 mg/cat q48–72h) should be considered together with prednisolone in severe IBD cases that are refractory to steroids alone or for management of small cell intestinal lymphoma. • Supplementation with cyanocobalamin at 250 ug SC per cat on a weekly basis for 6 consecutive weeks, followed by every 3 weeks for the indefinite future. • Probiotics can be beneficial in some patients with chronic nonspecific diarrhea.

CONTRAINDICATIONS

Anticholinergics exacerbate most types of chronic diarrhea and should not be used for empirical treatment.

PRECAUTIONS

Opiate antidiarrheals such as diphenoxylate and loperamide can cause hyperactivity and respiratory depression in cats and should not be used for more than 3 days.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

• Assess changes in frequency and severity of diarrhea and bodyweight. • Resolution usually occurs within 2–3 weeks following successful implementation of dietary therapy; consider reevaluating diagnosis if diarrhea does not resolve.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

• Dehydration. • Lowered body condition. • Abdominal effusions as related to specific cause of chronic diarrhea.

EXPECTED COURSE AND PROGNOSIS

Vary with underlying disease.

Client Education Handout available online

DIARRHEA, CHRONIC—DOGS

BASICS

DEFINITION
• A change in the frequency, consistency, and volume of feces for more than 3 weeks. • Can be small bowel, large bowel, or mixed.

PATHOPHYSIOLOGY
• Secretory diarrhea. • Osmotic diarrhea. • Increased permeability. • Abnormal gastrointestinal (GI) motility. • Many cases involve combinations of these pathophysiologic mechanisms.

SYSTEMS AFFECTED
• Endocrine/metabolic. • Exocrine. • Cardiovascular (fluid balance). • GI. • Lymphatic.

GENETICS
N/A

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
Pythiosis occurs often in young, large-breed dogs living in rural areas, with a higher incidence in states bordering the Gulf of Mexico.

SIGNALMENT

Species
Dog

Breed Predilections
• Yorkshire terrier, West Highland white terrier, Rottweiler, soft-coated wheaten terrier—lymphangiectasia secondary to inflammatory bowel disease (IBD). • Boxer and French bulldog—granulomatous colitis.

Mean Age and Range
Any age.

Predominant Sex
None

SIGNS

General Comments
• Disease processes determine extent of clinical signs. • 2–3% increase of water content of stool results in gross description of diarrhea. • Classification of small, large, and mixed bowel types of diarrhea may have overlap of descriptive findings.

Historical Findings
• Small bowel diarrhea can include—normal to increased volume; normal to moderately increased (2–4 times/day) defecation frequency; weight loss; polyphagia; melena; flatulence and borborygmus; vomiting—variable. • Large bowel diarrhea can include—smaller volume; frequency of defecation increased (>4 times/day); often hematochezia and mucus; tenesmus, urgency, dyschezia; flatulence and borborygmus—variable; vomiting—variable.

Physical Examination Findings

Small Bowel
• Poor body condition associated with malabsorption, maldigestion, and protein-losing enteropathy (PLE). • Variable dehydration. • Abdominal palpation may reveal thickened small bowel loops (diffuse or segmental) associated with infiltrative disease, abdominal effusion, foreign body, neoplastic mass, intussusception, or enlarged mesenteric lymph nodes. • Rectal palpation typically unremarkable.

Large Bowel
• Body condition more typically normal. • Dehydration—uncommon. • Abdominal palpation may reveal thickened large bowel, foreign body, neoplastic mass, intussusception, or enlarged mesocolic lymph nodes. • Rectal palpation may reveal irregularity of colorectal mucosa, intraluminal or extraluminal rectal masses, rectal stricture, or sublumbar lymphadenopathy.

CAUSES

Small Bowel

Primary Small Intestinal Disease
• Inflammatory bowel disease (e.g., lymphoplasmacytic enteritis, eosinophilic enteritis, granulomatous enteritis, immunoproliferative enteropathy of Basenjis). • Primary or secondary lymphangiectasia. • Neoplasia. • Bacterial (*Campylobacter jejuni*, *Salmonella* spp., invasive adherent or enterotoxic *Escherichia coli*, other enterobacteriaceae species). • Mycotic (e.g., histoplasmosis). • Algal (e.g., protothecosis, pythiosis). • Parasites (e.g., *Giardia*, *Toxocara* spp., *Ancylostoma*, *Toxascaris leonina*, *Cryptosporidium* spp., *Cystoisospora* spp.). • Partial obstruction (e.g., foreign body, intussusception, neoplasia). • Antibiotic-responsive diarrhea (ARD; intestinal microbial dysbiosis). • Short bowel syndrome.

Maldigestion
• Exocrine pancreatic insufficiency (EPI). • Hepatobiliary disease—lack of intraluminal bile.

Dietary
• Food-responsive enteropathy. • Food allergy.

Metabolic Disorders
• Hepatobiliary disease. • Hypoadrenocorticism. • Uremic gastroenteritis. • Toxins—enterotoxins, aflatoxins, exotoxins, food poisoning. • Adverse drug reactions.

Large Bowel

Primary Large Intestinal Disease
• Inflammatory bowel disease (e.g., lymphoplasmacytic colitis, eosinophilic colitis, granulomatous colitis). • Neoplasia. • Infection (e.g., histoplasmosis, adherent invasive *E. coli* [granulomatous colitis], *Prototheca*, pythiosis). • Parasites (e.g., *Trichuris vulpis*, *Giardia intestinalis*, *Entamoeba histolytica*, *Balantidium coli*). • Ileocolic intussusception and cecal inversion.

Dietary
• Diet—dietary indiscretion, diet changes, food-responsive enteropathy, foreign material (e.g., bones, plastic, wood, hair). • Fiber-responsive large bowel diarrhea.

Miscellaneous
Irritable bowel syndrome.

RISK FACTORS

Small Bowel
• Large-breed, younger, and less severely affected dogs have higher risk of food-responsive diarrhea. • Yorkshire terrier, West Highland white terrier, Rottweiler, soft-coated wheaten terrier predisposed to lymphangiectasia secondary to IBD.

Large Bowel
• Dietary changes or indiscretion, stress, and psychological factors may play a role. • Granulomatous colitis (invasive adherent *E. coli*–associated)—boxer, French bulldog <3 years old. • Pythiosis more common in large-breed dogs that spend more time outside (roaming, hunting).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
First localize the origin to the small or large bowel (or both).

CBC/BIOCHEMISTRY/URINALYSIS
• Eosinophilia may be associated with parasitism, eosinophilic enterocolitis, hypoadrenocorticism, paraneoplastic causes, or pythiosis. • Lymphopenia and hypocholesterolemia may be associated with lymphangiectasia. • Anemia and microcytosis suggest chronic GI bleeding and iron deficiency. • Panhypoproteinemia resulting from PLE associated with infiltrative small bowel disorders and lymphangiectasia. • Biochemical profiles and urinalysis abnormalities may suggest renal disease, hepatobiliary disease, or endocrinopathy.

OTHER LABORATORY TESTS

Fecal and/or Rectal Scraping Exam
• Direct wet-prep examination, fecal ELISA testing, and zinc sulfate centrifugation (for *Giardia*) may indicate GI parasites; multiple samples may be required for whipworm infestations. • Cytologic examination of rectal scrapings may reveal specific organisms, such as *Histoplasma* or *Prototheca*. • PCR fecal testing can be helpful when screening for uncommon or difficult to diagnose infections; interpret with caution as many of the microorganisms can be found in healthy, nondiarrheic animals (e.g., viral enteritis, cryptosporidiosis, *Giardia*, *Salmonella*, *C. perfringens* enterotoxin gene, *C. difficile, Campylobacter jejuni*); PCR testing should be interpreted in light of patient signalment, history, clinical presentation, vaccination history, and other laboratory data. • Culture feces if *Campylobacter* or *Salmonella* suspected—special media required; check with laboratory prior to submission.

Tests of Exocrine Pancreatic Function
Canine-specific trypsin-like immunoreactivity (TLI)—test of choice for confirming EPI.

Tests for Malabsorption
• Serum folate—low serum folate may be associated with proximal small intestinal malabsorption. • Cobalamin—low serum

DIARRHEA, CHRONIC—DOGS (CONTINUED)

cobalamin may be associated with EPI or ileal malabsorption; primary cobalamin deficiency syndromes are rare (border collie, giant schnauzer).

Tests for Metabolic Disease

• Resting cortisol—value <2.0 µg/dL should be followed up with adrenocorticotrophic hormone stimulation test to evaluate for hypoadrenocorticism. • Fasting and 2-hour postprandial serum bile acids—test if hepatobiliary disease suspected; significantly increased values suggest hepatic dysfunction or portosystemic shunting.

IMAGING

• Survey abdominal radiography may indicate abnormal intestinal pattern, organomegaly, mass, foreign body, pancreatic disease, hepatobiliary disease, urinary disease, or abdominal effusion. • Contrast radiography (upper GI series or barium enema) may indicate bowel wall thickening, intestinal ulcers, mucosal irregularities, mass, radiolucent foreign body, or stricture; utility of contrast radiography has been replaced with ultrasound in most patients. • Abdominal ultrasonography may demonstrate bowel wall thickening, abnormal bowel wall layering, GI or extra-GI masses, intussusception, foreign body, ileus, abdominal effusion, hepatobiliary disease, or mesenteric or mesocolic lymphadenopathy.

DIAGNOSTIC PROCEDURES

If maldigestive (EPI), metabolic, parasitic, dietary, and infectious causes have been excluded, then consider dietary trial using elimination diet (novel, single protein source) or hydrolyzed diet for 2 weeks in stable dogs prior to performing advanced diagnostics (endoscopy or laparotomy and biopsy). Up to 75% of dogs in referral practices have been shown to be diet responsive.

Endoscopy/Laparoscopy

• Upper GI flexible endoscopy allows examination and biopsy of gastric and duodenal mucosa; always obtain multiple (8–10) mucosal specimens from each segment. • Flexible colonoscopy allows examination of rectum, colon, cecum, and ileum; always obtain multiple mucosal specimens (8–10) from each segment. • Gross appearance of mucosa does not always correlate with histopathology; always take biopsies. • Endoscopic biopsies rely upon diseases being represented in first two layers of intestinal wall and segments biopsied being representative of others not reached. • Full-thickness biopsies not indicated as most diseases can be diagnosed endoscopically. • Surgical approach can be advantageous if biopsies of multiple organs (e.g., small intestine, lymph nodes, stomach, pancreas, liver) are desired

Ultrasound-Guided GI Aspirates

• Ultrasound-guided fine-needle aspiration of GI mass lesions can be helpful for diagnosing mast cell tumors, carcinomas, and large-cell lymphoma. • Seeding of neoplastic cells is a concern.

Capsule Endoscopy

Capsule endoscopy procedures can help identify location of bleeding ulcers in the jejunum.

TREATMENT

APPROPRIATE HEALTH CARE

• Outpatient medical management most common. • Treat underlying cause.

NURSING CARE

• Fluid therapy with balanced electrolyte solutions as needed. • Correct electrolyte and acid-base imbalances.

ACTIVITY

No restrictions.

DIET

• Therapy with elimination diets or hydrolyzed diets can be beneficial in up to 75% of dogs with uncomplicated chronic enteropathies. • Feeding lower-fat, novel (for the patient) protein source, highly digestible, or fiber-supplemented diets for 3–4 weeks may resolve diarrhea due to dietary intolerance or allergy; repeated changes of diet to maintain symptom-free situation suggests further testing needed.

CLIENT EDUCATION

Complete resolution of signs is not always possible in dogs with severe IBD, lymphangiectasia, intestinal neoplasia, and pythiosis.

SURGICAL CONSIDERATIONS

Pursue laparotomy and biopsy if evidence of obstruction, intestinal mass, or mid-small bowel disease unreachable via ultrasound-guided procedure, or if diagnosis based on endoscopic biopsy or ultrasound-guided procedure is questioned because of poor response to therapy.

MEDICATIONS

DRUG(S) OF CHOICE

• Disease-specific. • Prednisone (2 mg/kg BID for 2 weeks, with slow tapering over 6 weeks) for IBD. • Cyclosporine has shown to rescue dogs with steroid-refractory IBD. • Need for cyanocobalamin supplementation must be assessed in all dogs with chronic enteropathy. • Probiotics beneficial in some dogs with chronic enteropathy.

CONTRAINDICATIONS

Anticholinergics can exacerbate the situation with many causes of chronic diarrhea; they are sometimes used to relieve cramping associated with irritable bowel syndrome.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

• Frequency and consistency of stool, appetite, and bodyweight. • In dogs with PLE—serum proteins, cholesterol, and clinical signs (ascites, subcutaneous edema, pleural effusion). • Resolution of diarrhea usually gradual with treatment; if does not resolve, reevaluate diagnosis.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

• Dehydration. • Lowered body condition. • Abdominal effusions as related to specific cause of chronic diarrhea. • Ascites, subcutaneous edema, and/or pleural effusion with hypoalbuminemia from PLE.

EXPECTED COURSE AND PROGNOSIS

Vary with underlying disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

• Giardiasis (low risk of transmission). • Salmonellosis. • *Campylobacter jejuni*. • Ascaridiasis.

DIGOXIN TOXICITY

BASICS

OVERVIEW
Not uncommon in patients treated with digoxin due to digoxin's narrow therapeutic index and prevalence of renal impairment in elderly patients with cardiac disease. Becoming less common in clinical practice as use of digoxin has decreased in management of heart failure.

SIGNALMENT
- Dog and cat.
- More common in geriatric patients.

SIGNS
Historical Findings
- Anorexia.
- Vomiting.
- Diarrhea.
- Lethargy.
- Depression.

Physical Examination Findings
Heart rate may range from severe bradycardia to severe tachycardia.

CAUSES & RISK FACTORS
- Renal disease—impairs digoxin elimination.
- Chronic pulmonary disease—results in hypoxia and acid-base disturbances.
- Obesity—if dosage not calculated on lean bodyweight.
- Drugs and conditions that alter digoxin metabolism or elimination (e.g., quinidine and hypothyroidism).
- Rapid IV digitalization.
- Overdosage or accidental ingestion of owner's medication.
- Administration of diuretic leading to hypokalemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Arrhythmias and conduction disturbances—may reflect structural heart disease, not digoxin toxicity.
- Anorexia—common in animals with heart failure.

CBC/BIOCHEMISTRY/URINALYSIS
Animals with hypokalemia, hypercalcemia, hypomagnesemia, and renal failure are predisposed to toxicity.

OTHER LABORATORY TESTS
- Consider checking thyroid status.
- Obtain digoxin serum concentration 8–10 hours after an oral dose—therapeutic range is 0.5–1.5 ng/mL. A recent study in humans found digoxin levels greater than 1 mg/ml were associated with increased mortality; not all patients with concentrations >1.5 ng/mL have signs of toxicity; some with values in the normal range have signs of toxicity, especially if hypokalemic. To minimize the risk of toxicity, the author aims to achieve a digoxin level between 0.5 and 1 ng/mL.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
ECG
- Conduction disturbances—atrioventricular (AV) block, arrhythmias, and ST segment depression in some patients.
- Digoxin can cause any arrhythmia.

TREATMENT
- Discontinue digoxin until signs of toxicity resolve (24–72 hours); reevaluate need for the medication; if necessary, resume treatment at a dosage based on the serum digoxin concentration.
- Maintain hydration and correct any electrolyte disturbance (especially hypokalemia) with parenteral fluid administration.
- Discontinue drugs that slow digoxin metabolism or elimination (e.g., quinidine, verapamil, amiodarone).
- Severe arrhythmias (ventricular tachycardia) and conduction disturbances—can be life-threatening; require hospitalization for treatment and monitoring.

MEDICATIONS

DRUG(S) OF CHOICE
- Treat clinically important bradyarrhythmias with atropine or a temporary transvenous pacemaker.
- Treat clinically important ventricular arrhythmias with lidocaine or phenytoin; phenytoin also reverses high-degree AV block.
- Digoxin-binding antibodies (e.g., Digibind®) rapidly drop digoxin concentration in critically ill animals; the use of these products is limited in veterinary practice by their exorbitant cost.
- Thyroxin supplementation if hypothyroidism confirmed.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Avoid or discontinue drugs that slow digoxin elimination or metabolism (e.g., quinidine, verapamil, and diltiazem).
- Avoid drugs that could worsen conduction disturbances (e.g., beta blockers and calcium channel blockers).
- Class 1A antiarrhythmic drugs (e.g., quinidine and procainamide) may worsen AV block.

FOLLOW-UP
- Inform owner that reduction in appetite is an early indication of digoxin toxicity.
- Monitor renal function and electrolytes frequently in patients receiving digoxin; lower digoxin dose if renal disease develops.
- Monitor serum digoxin concentration periodically.
- Monitor ECG periodically to assess for arrhythmias or conduction disturbances that may suggest digoxin toxicity.
- Monitor bodyweight frequently; alter digoxin dosage accordingly; patients with congestive heart failure often lose weight.

MISCELLANEOUS

SEE ALSO
- Atrioventricular Block, Complete (Third Degree).
- Atrioventricular Block, First Degree.
- Atrioventricular Block, Second Degree—Mobitz Type I.
- Atrioventricular Block, Second Degree—Mobitz Type II.
- Ventricular Tachycardia.

ABBREVIATIONS
- AV = atrioventricular.

Consulting Editor Michael Aherne

DIISOCYANATE GLUES

BASICS

OVERVIEW
- Diisocyanate glues include wood glue, construction glue, and some "high-strength or extra strength" glues.
- Gorilla Glue is one popular brand name. There are non-Gorilla brand glue types that contain diisocyanate as the active ingredient and not all types of Gorilla Glue contain diisocyanates. Confirm the actual product with the owner, using the packaging if necessary.
- Typically, the owner finds a chewed bottle of glue or glue stuck on the animal.
- Diisocyanate glue rapidly expands in the moist environment of the stomach, causing bloat and foreign body obstruction (FBO). The glue is not absorbed and does not cause systemic toxicity. Ingestions as small as 2 oz (56 g) can require surgical intervention to resolve obstruction.
- Glue is also adhesive and an irritant to the paws, oral cavity, and stomach lining.
- Inhalation may cause irritation to the lungs.

SIGNALMENT
Dogs and less commonly cats, birds, and small mammals. Young animals are more often affected.

SIGNS
- Occur within 15 minutes to 24 hours after ingestion.
- Ingestion—consistent with FBO and may include gagging, retching, vomiting, anorexia, abdominal distension, abdominal pain; hematemesis in prolonged or severe cases.
- Inhalation—coughing, sneezing, increased secretions within 4–8 hours.
- Dermal—irritation, redness, rash.

CAUSES & RISK FACTORS
Pets with access to diisocyanate glue products.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- History of exposure and clinical signs generally facilitate diagnosis.
- Presenting signs are consistent with gastric dilatation-volvulus (GDV), bloat, pancreatitis, inflammatory bowel disease, and other causes of FBO.
- Radiographs are highly suggestive of FBO (see Web Figure 1).

CBC/BIOCHEMISTRY/URINALYSIS
- CBC—generally no significant changes.
- Electrolyte disturbances—consistent with gastrointestinal (GI) obstruction and anorexia.
- Elevated total proteins/prerenal azotemia—may occur secondary to dehydration from vomiting.

IMAGING
Survey radiographs (4–24 hours post exposure)—glue appears as a mottled gas and soft tissue opacity distending the stomach. The appearance can resemble recent food ingestion (see Web Figure 1).

TREATMENT
- Generally, not recommended due to risk of esophageal or GI obstruction. Potential use immediately after a large ingestion.
- Gastric lavage is rarely of benefit as glue expands too rapidly.
- Dilution with water or other fluids should be avoided as excess moisture allows further expansion of the glue.
- IV fluids as needed for dehydration.
- Wash exposed skin with warm soapy water, rub vegetable oil into the hair, or clip hair to remove as much glue as possible. Glue can be left adhered to the skin if nonirritating and will fall off over time.
- Oxygen as needed for signs related to inhalation.
- Surgical removal of the expanded glue foreign body is almost always indicated in ingestions greater than 2 oz or with lesser amounts in smaller animals.

MEDICATIONS

DRUG(S) OF CHOICE
- Antiemetic—maropitant citrate 1 mg/kg SC/IV q24h.
- H2 blocker (for gastric inflammation or ulceration)—ranitidine 1–2 mg/kg PO/IM/SC/IV q6–12h; famotidine 0.5–1.1 mg/kg PO q12h; pantoprazole 0.7–1 mg/kg IV over 15 minutes q24h.
- Sucralfate (for a gastric ulcer if present)—0.5–1 g PO TID on an empty stomach.

CONTRAINDICATIONS
- Emetics—emesis should not be performed unless done immediately after a witnessed ingestion. Expansion of the glue is rapid: late emesis stresses the stomach wall and could damage the esophagus.
- Do *not* dilute with water as exposure to moisture leads to rapid expansion of the glue.

FOLLOW-UP

PATIENT MONITORING
Monitor in hospital until eating and drinking normally. Recheck 10–14 days post surgery.

PREVENTION/AVOIDANCE
Prevent exposure.

EXPECTED COURSE AND PROGNOSIS
- With removal of FBO, prognosis is excellent.
- Without surgical removal, the FBO is not expected to resolve on its own.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Gastritis.
- Dermatitis.

ABBREVIATIONS
- FBO = foreign body obstruction.
- GDV = gastric dilatation-volvulus.
- GI = gastrointestinal.

Client Education Handout available online

DISCOLORED TOOTH/TEETH

BASICS

DEFINITION

• Normal tooth color varies and depends on the shade, translucency, and thickness of enamel. Translucent enamel is bluish-white, opaque enamel is gray-white.
• Extrinsic—from surface accumulation of exogenous pigment.
• Intrinsic—secondary to endogenous factors discoloring the underlying dentin.

PATHOPHYSIOLOGY

Extrinsic Discoloration

• Bacterial stains—chromogenic bacteria: green to black-brown to orange color, usually 1 mm above the gingival margin on the tooth.
• Plaque related—a black-brown stain; usually secondary to the formation of ferric sulfide from the interaction of bacterial ferric sulfide and iron in the saliva. Plaque is usually white.
• Foods—charcoal biscuits and similar products penetrate the pits and fissures of the enamel; food with abundant chlorophyll can produce a green discoloration.
• Gingival hemorrhage—green or black staining from the breakdown of hemoglobin into green biliverdin.
• Dental restorative materials—amalgam: black-gray discoloration.
• Medications—products containing iron or iodine give a black discoloration; sulfides, silver nitrate, or manganese: gray-to-yellow to brown-to-black discoloration; copper or nickel: green discoloration; cadmium, yellow to golden brown discoloration (e.g., 8% stannous fluoride combines with bacterial sulfides, giving a black stain; chlorhexidine gives a yellowish-brown discoloration).
• Metals—wear from chewing on cages or food dishes.
• From removed orthodontic brackets or bands.
• Crown fragments—less translucency due to dehydration of fragment.
• Discolored restorations.
• Tooth wear with dentin exposure—tertiary dentin, reparative dentin, secondary dentin.
• A calculus-covered crown ranges in color from dark yellow to dark brown.

Intrinsic Discoloration

• Hyperbilirubinemia—affects all teeth; during dentin formation bilirubin accumulates in the dentin from excess red blood cell breakdown; extent of discoloration depends on the length of hyperbilirubinemia (lines of resolution occur once the condition has been resolved); green discoloration.
• Localized red blood cell destruction, one tooth or focal area—usually follows a traumatic injury to the tooth; discoloration from hemoglobin breakdown within the pulp with release into adjacent dentinal tubules; discoloration goes from pink to purple (pulpitis) to gray (pulpal necrosis) to black (liquefactive necrosis).
• Amelogenesis imperfecta—developmental alteration in the structure of enamel affecting all teeth; chalky appearance with a pinkish hue; problem in the formation of the organic matrix, mineralization of the matrix, or the maturation of the matrix.
• Dentinogenesis imperfecta—developmental alteration in dentin formation; enamel separates easily from the dentin, resulting in grayish discoloration.
• Infectious agents (systemic)—parvovirus, distemper virus, or any agent that causes a sustained body temperature rise; affects the formation of enamel; a distinct line of resolution is visible on the teeth; affects all teeth developing at the time of the insult; results in enamel hypoplasia or hypocalcification where the abnormal enamel can have black edges and the dentin is brownish.
• Dental fluorosis—affects all teeth; excess fluoride consumption affects the maturation of enamel, resulting in pits (enamel hypoplasia) with black edges; the enamel is a lusterless, opaque white, with yellow-brown zones of discoloration.
• Tooth erosion from constant vomiting results in enamel pitting and darkened staining.
• Attrition—tooth-to-tooth wear results in crown loss and reparative dentin formation (yellow-brown color).
• Abrasion—tooth wear against another surface; chewing on tennis balls or from a dermatologic condition. Reparative dentin (yellow-brown color) forms.
• Aging—older animals' dentition is more yellow and less translucent.
• Malnutrition (generalized, vitamin D deficiency, and vitamin A deficiency)—if severe can result in demarcated opacities on the enamel.

Internal/External Resorption

• Internal—follows pulpal injury (trauma) causing vascular changes with increased oxygen tension and decreased pH, resulting in destruction (resorption) of the tooth from within the pulp from odontoclasts; tooth has pinkish hue.
• External—many factors possible: trauma, orthodontic treatment, excessive occlusal forces, periodontal disease (and treatment), tumors, periapical inflammation, and unknown factors; resorption can start anywhere along the periodontal ligament and can extend to the pulp and into the crown causing a pinkish discoloration; osteoclasts and odontoclasts resorb the tooth structure.

Medications and Discoloration

• Tetracycline—during enamel formation, it binds to calcium, forming a calcium orthophosphate complex in the collagen matrix of enamel; occurs on multiple teeth; results in a yellow-brown discoloration. Long-term use of tetracyclines in mature animals can involve secondary dentin formation.
• Amalgam (as with extrinsic stains).
• Iodine/essential oils.
• In endodontically treated teeth from the medicants penetrating the dentinal tubules.
• Macrolide antibiotic (reported in humans)—results in vacuolar degeneration of the ameloblast and cystic change at maturation and hypocalcification, giving a white discolored lesion with horizontal stripes on the enamel.
• Bacterial "creeping" (leakage)—occurs around the margins of a restoration and usually is blackish in color.

SYSTEMS AFFECTED

Gastrointestinal—oral cavity.

GENETICS

• Amelogenesis imperfecta and dentinogenesis imperfecta in humans are inherited conditions that have many modes of inheritance. The mode of inheritance in animals has not been studied.
• Congenital hypothyroidism.
• Metabolic diseases.

INCIDENCE/PREVALENCE

• Discoloration of the teeth or a tooth is extremely common in all animals.
• Extrinsic staining is very common, especially bacterial stains; others are less common.
• Intrinsic staining is likewise very common, especially internal and external resorption, followed by localized red blood cell destruction; the other causes are rare.

GEOGRAPHIC DISTRIBUTION

• Heavy metals from mining operations.
• Fluoridation forms areas of excessive fluoride in the drinking water.
• Otherwise none.

SIGNALMENT

Species

Dogs and cats.

Mean Age and Range

The reported age range varies—when the condition affects the developing enamel or dentin it can be first noted after tooth eruption (6 months of age).

Predominant Sex

None

SIGNS

Historical Findings

Owner reports a variation in color of a tooth or teeth.

Physical Examination Findings

• Abnormal coloration of tooth or teeth.
• Pitted enamel with staining.

DISCOLORED TOOTH/TEETH (CONTINUED)

• Fractured tooth.
• Rings or lines of discoloration around tooth or teeth.
• Wear on crowns of the dentition or in selected areas as in behavioral causes (cage biters—distal aspect of the canines is affected).
• Erosion of enamel.

CAUSES & RISK FACTORS

• Extrinsic discoloration—bacterial stains from plaque and calculus; foods; gingival hemorrhage; dental restorative materials, medications (chlorhexidine, 8% stannous fluoride), metal.
• Intrinsic discoloration—internal (trauma); external tooth resorption; localized red blood cell destruction in the tooth (trauma); systemic infections; medications (tetracycline); fluorosis; hyperbilirubinemia; amelogenesis imperfecta; dentinogenesis imperfecta.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Calculus on the teeth.
• Normal tooth aging—increased translucence.
• Food debris lodged in the spaces between the teeth (diastema).

CBC/BIOCHEMISTRY/URINALYSIS

• Anemia—blood-related disorders.
• Bilirubin—increased with liver diseases.

OTHER LABORATORY TESTS

• T_3/T_4—low in congenital hypothyroidism.
• Specific metabolic enzyme decrease or absence—tyrosinemia.

IMAGING

Dental radiography is extremely useful in identifying internal or external resorption, restorative materials, or bacterial stain from coronal percolation.

DIAGNOSTIC PROCEDURES

• If many teeth are affected, one tooth can be extracted and sent for histologic evaluation (see below).
• Transillumination with a strong fiberoptic light may help distinguish between vital and necrotic pulp.
• Appropriate preoperative diagnostics when indicated prior to procedure.

PATHOLOGIC FINDINGS

See Pathophysiology.

TREATMENT

APPROPRIATE HEALTH CARE

• Extrinsic stain removal—mainly cosmetic.
• Intrinsic stain treatment—functional and pain relieving.

NURSING CARE

• Extrinsic stain—remove inciting cause.
• Intrinsic stain—soft food; remove chew toys.

ACTIVITY

Curtail or treat specific behavioral abnormalities (cage biting).

DIET

N/A

CLIENT EDUCATION

• To prevent it in future animals or litters if preventable (medication use).
• Intrinsic causes—irregular enamel surfaces are more likely to accumulate plaque and calculus, leading to subsequent periodontal disease. Abnormally formed teeth or teeth that have localized red blood cell destruction are more prone to fracture or development of tooth abscessation.
• Some causes are painful (tooth resorption).

SURGICAL CONSIDERATIONS

• Extrinsic stain (cosmetic)—internal and/or external bleaching; veneers or crowns. Polishing the affected teeth with 3% hydrogen peroxide in pumice will help remove external stain. Also good home care with plaque control will minimize redevelopment of some stains (plaque/calculus/bacteria stain).
• Intrinsic stain (functional and pain relief)—possible endodontic treatment (internal resorption and localized red blood cell destruction).
• Restorative procedures such as crowns or veneers to protect both tooth and pulp.
• Extraction of affected teeth may be required, especially with external resorption.

MEDICATIONS

DRUG(S) OF CHOICE

N/A

FOLLOW-UP

PREVENTION/AVOIDANCE

• See Pathophysiology.
• Good oral care at home will help prevent the reoccurrence of certain specific stains.

POSSIBLE COMPLICATIONS

See Client Education.

EXPECTED COURSE AND PROGNOSIS

Vary dependent upon the etiology, but can range from mere aesthetics to significant pain.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Enamel hypoplasia/hypocalcification
• Juvenile purpura.

AGE-RELATED FACTORS

All ages affected, depends on the cause.

ZOONOTIC POTENTIAL

None.

PREGNANCY/FERTILITY/BREEDING

• Tetracycline administration during pregnancy may result in permanent tooth discoloration in offspring.
• See Genetics.

SYNONYMS

• Chlorhexidine staining.
• Extrinsic staining.
• Intrinsic staining.
• Tetracycline staining.

DISCOSPONDYLITIS

BASICS

DEFINITION
A bacterial, fungal, and rarely algal infection of the intervertebral end plates, discs, and adjacent vertebral bodies.

PATHOPHYSIOLOGY
- Hematogenous spread of bacterial or fungal organisms—most common cause.
- Seeding secondary to migrating foreign body (grass awn) is also reported.
- Neurologic dysfunction—may occur; usually the result of spinal cord compression caused by proliferation of bone and fibrous tissue; less commonly owing to luxation or pathologic fracture of the spine, epidural abscess, or extension of infection to the meninges and spinal cord.

SYSTEMS AFFECTED
- Musculoskeletal—infection and inflammation of the spine.
- Nervous—compression and/or infection of the spinal cord.

GENETICS
- No definite predisposition identified.
- An inherited immunodeficiency has been detected in a few cases.

INCIDENCE/PREVALENCE
Approximately 0.1–0.8% of dog hospital admissions.

GEOGRAPHIC DISTRIBUTION
- More common in the southeastern United States.
- Grass awn migration and coccidiomycosis—more common in certain regions.

SIGNALMENT

Species
Dog; rare in cat.

Breed Predilections
Large and giant breeds, especially German shepherd and Great Dane.

Mean Age and Range
- Mean age—4–5 years.
- Range—5 months–12 years.

Predominant Sex
Males outnumber females by ~2 : 1.

SIGNS

Historical Findings
- Onset usually relatively acute; however, some patients may have mild signs for several months before presenting for examination.
- Pain—difficulty rising, reluctance to jump, and stilted gait are most common signs.
- Ataxia or paresis.
- Weight loss and anorexia.
- Lameness.

Physical Examination Findings
- Focal or multifocal areas of spinal pain in >80% of patients.
- Any disc space may be affected; lumbosacral space is most commonly involved.
- Paresis or paralysis, especially in chronic, untreated cases.
- Fever in ~30% of patients.
- Lameness.

CAUSES
- Bacterial—*Staphylococcus pseudintermedius* is most common. Others include *Streptococcus*, *Brucella canis*, and *Escherichia coli*, but virtually any bacteria can be causative.
- Fungal—*Aspergillus*, *Paecilomyces*, *Scedosporium apiospermum*, and *Coccidioides immitis*.
- Grass awn migration is often associated with mixed infections, especially *Actinomyces*; tends to affect the L2–L4 disc spaces and vertebrae.
- Other causes—surgery, bite wounds.

RISK FACTORS
- Urinary tract infection; reproductive tract infection.
- Periodontal disease.
- Bacterial endocarditis.
- Pyoderma.
- Immunodeficiency.
- Recent steroid administration.
- Intact male status.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Intervertebral disc protrusion—may cause similar clinical signs; differentiated on the basis of radiography and myelography.
- Vertebral fracture or luxation—detected on radiographs.
- Vertebral neoplasia—usually does not affect adjacent vertebral end plates.
- Spondylosis deformans—rarely causes clinical signs; has similar radiographic features, including sclerosis, ventral spur formation, and collapse of the disc space; rarely causes lysis of the vertebral end plates.
- Focal meningomyelitis—often identified by cerebrospinal fluid (CSF) analysis.

CBC/BIOCHEMISTRY/URINALYSIS
- Hemogram—often normal; may see leukocytosis.
- Urinalysis—may reveal pyuria and/or bacteriuria with concurrent urinary tract infections.

OTHER LABORATORY TESTS
- Aerobic, anaerobic, and fungal blood cultures identify the causative organism in about 35% of cases; obtain if available.
- Sensitivity testing—indicated if cultures are positive.
- Urine cultures—indicated; positive in about 30% of patients.
- Organisms other than *Staphylococcus* spp.—may not be the cause.
- Serologic testing for *Brucella canis*—indicated as this presents zoonotic potential.

IMAGING
- Spinal radiography—usually reveals lysis of vertebral end plates adjacent to the affected disc, collapse of the disc space, and varying degrees of sclerosis of the end plates and ventral spur formation; may not see lesions until 3–4 weeks after infection (therefore normal radiographs do not rule out).
- Myelography—indicated with substantial neurologic deficits; determine location and degree of spinal cord compression, especially if considering decompressive surgery; spinal cord compression caused by discospondylitis typically displays an extradural pattern.
- CT or MRI—more sensitive than radiography; indicated when radiographs are normal or inconclusive.

DIAGNOSTIC PROCEDURES
- CSF analysis—occasionally indicated to rule out meningomyelitis; usually normal or reveals mildly high protein.
- Bone scintigraphy—occasionally useful for detecting early lesions; helps clarify if radiographic changes are infectious or degenerative (spondylosis deformans).
- Fluoroscopically guided fine-needle aspiration of the disc—valuable for obtaining tissue for culture when blood and urine cultures are negative and there is no improvement with empiric antibiotic therapy.

PATHOLOGIC FINDINGS
- Gross—loss of normal disc space; bony proliferation of adjacent vertebrae.
- Microscopic—fibrosing pyogranulomatous destruction of the disc and vertebral bodies.

TREATMENT

APPROPRIATE HEALTH CARE
- Outpatient—mild pain managed with medication.
- Inpatient—severe pain or progressive neurologic deficits require intensive care and monitoring.

NURSING CARE
Nonambulatory patients—keep on clean, dry, well-padded surface to prevent decubital ulceration.

ACTIVITY
Restricted

CLIENT EDUCATION
- Explain that observation of response to treatment is very important in determining the need for further diagnostic or therapeutic procedures.

DISCOSPONDYLITIS (CONTINUED)

• Instruct the client to immediately contact the veterinarian if clinical signs progress or recur or if neurologic deficits develop.

SURGICAL CONSIDERATIONS

• Curettage of a single affected disc space—occasionally necessary for patients that are refractory to antibiotic therapy.
• Goals—remove infected tissue; obtain tissue for culture and histologic evaluation.
• Decompression of the spinal cord by hemilaminectomy or dorsal laminectomy—indicated for substantial neurologic deficits and spinal cord compression evident on MRI or myelography when there is no improvement with antibiotic therapy; also perform curettage of the infected disc space; it may be necessary to perform surgical stabilization if more than one articular facet is removed from a disc site.

MEDICATIONS

DRUG(S) OF CHOICE

Antibiotics

• Selection based on results of blood cultures and serology or end plate aspirate culture and sensitivity.
• Negative culture and serology—assume causative organism is *Staphylococcus* spp.; treat with a cephalosporin (e.g., cephalexin 22 mg/kg PO q8h) for 8–12 weeks.
• Acutely progressive signs or substantial neurologic deficits—initially treated with parenteral antibiotics (e.g., cefazolin; dogs and cats: 22 mg/kg IV q8h).
• Brucellosis—treated with tetracycline (dogs: 15 mg/kg PO q8h) and streptomycin (dogs: 3.4 mg/kg IM q24h) or enrofloxacin (dogs: 10 mg/kg PO q24h).
• One study suggested that antibiosis be continued until radiographic signs were resolved (range of 40–80 weeks). The roll of imaging in definitively determining length of treatment has not been proven, however.

Analgesics

• Signs of severe pain—treated with an analgesic (e.g., oxymorphone; dogs: 0.05–0.2 mg/kg IV/IM/SC q4–6h).
• Taper dosage after 3–5 days to gauge effectiveness of antibiotic therapy.

CONTRAINDICATIONS

Glucocorticoids

PRECAUTIONS

Use nonsteroidal anti-inflammatory drugs (NSAIDs) and other analgesics cautiously—may cause temporary resolution of clinical signs even when infection is progressing; when used, discontinue after 3–5 days to assess efficacy of antibiotic therapy.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

• Initial therapy—cephradine (dogs: 20 mg/kg PO q8h); amoxicillin trihydrate/clavulanate potassium (dogs: 13.75–22 mg/kg PO q12h).
• Refractory patients—clindamycin (dogs and cats: 10 mg/kg PO q12h), enrofloxacin (dogs: 10 mg/kg PO q24h; cats: 5 mg/kg PO q24h), orbifloxacin (dogs and cats: 2.5–7.5 mg/kg PO q24h).

FOLLOW-UP

PATIENT MONITORING

• Reevaluate after 5 days of therapy.
• No improvement in pain, fever, or appetite—reassess therapy; consider a different antibiotic, percutaneous aspiration of the affected disc space, or surgery.
• Improvement—evaluate clinically and radiographically every 4 weeks.

PREVENTION/AVOIDANCE

Early identification of predisposing causes and prompt diagnosis and treatment—help reduce progression of clinical symptoms and neurologic deterioration.

POSSIBLE COMPLICATIONS

• Spinal cord compression owing to proliferative bony and fibrous tissue.
• Vertebral fracture or luxation.
• Meningitis or meningomyelitis.
• Epidural abscess.

EXPECTED COURSE AND PROGNOSIS

• Recurrence is common if antibiotic therapy is stopped prematurely (before 8–12 weeks of treatment).
• Some patients require prolonged therapy (1 year or more).
• Prognosis—depends on causative organism and degree of spinal cord damage.
• Mild or no neurologic dysfunction (dogs)—usually respond within 5 days of starting antibiotic therapy.
• Substantial paresis or paralysis (dogs)—prognosis guarded; may note gradual resolution of neurologic dysfunction after several weeks of therapy; treatment warranted.
• *Brucella canis*—signs usually resolve with therapy; infection may not be eradicated; recurrence common.

MISCELLANEOUS

ASSOCIATED CONDITIONS

See Risk Factors.

AGE-RELATED FACTORS

DISSEMINATED INTRAVASCULAR COAGULATION

BASICS

DEFINITION
An acquired complex hemostatic defect arising from a variety of inciting causes that leads to intravascular activation of coagulation and consumption of clotting factors. It results in widespread formation of microthrombi with clinical manifestations of thrombosis and/or hemorrhage. Non-overt disseminated intravascular coagulation (DIC) is the early, compensated form of DIC that features consumption of coagulation factors and generation of microthrombi without clear clinical signs. Overt (decompensated) DIC refers to the classic phenotype associated with hemorrhage, thrombosis, and organ failure.

PATHOPHYSIOLOGY
- DIC represents a complication of a variety of primary conditions. It begins with a hypercoagulable state that leads to production or embolization of microthrombi in small vessels.
- The primary conditions act through increased exposure/production of tissue factor (TF) that activates the extrinsic coagulation pathway.
- TF is normally restricted from intravascular exposure. Increased TF exposure occurs through widespread endothelial injury and/or inflammation.
- Inflammation activates endothelial cells, platelets, and monocytes leading to membrane expression of TF. Inflammatory cytokines also induce vesiculation of these membranes, releasing large quantities of microparticles into circulation that are enriched with both TF and phosphatidylserine (PS) and facilitate initiation of coagulation. Some neoplastic cells constitutively produce membrane TF and also release microparticles.
- Microparticles provide a suitable membrane surface for amplifying intrinsic and common pathway coagulation, potentially leading to uncontrolled production of thrombin that overwhelms endogenous coagulation inhibitors. Fibrin clots generated by thrombin can cause vascular occlusion and lead to organ dysfunction.
- Widespread microthrombus formation consumes coagulation factors and platelets while initiating fibrinolysis. By-products of fibrinolysis (fibrin degradation products [FDPs]) have anticoagulant properties and inhibit platelet function. Hemorrhage at a variety of sites can follow.
- Uncontrolled progression leads to widespread tissue hypoxia, multiorgan dysfunction, and death.

SYSTEMS AFFECTED
Multisystemic syndrome.

INCIDENCE/PREVALENCE
Associated with severe systemic inflammatory disease.

SIGNALMENT
Species
Dogs and cats; diagnosed more in dogs.

Breed Predilections
None

Mean Age and Range
Depends on the primary disease.

Predominant Sex
None

SIGNS
- Vary with the primary disease and with DIC-associated organ dysfunction.
- Petechiae.
- Bleeding from venipuncture sites, mucosa, or into body cavities.
- Bleeding is infrequent in cats, possibly leading to underdiagnosis.

CAUSES
- Gastric dilatation-volvulus.
- Heart failure.
- Heartworm disease.
- Heat stroke.
- Hemolysis, especially immune mediated.
- Hemorrhagic gastroenteritis.
- Infectious diseases, systemic (especially endotoxemia).
- Inflammation, severe—regardless of underlying cause.
- Liver disease, severe.
- Malignancies, especially hemangiosarcoma, mammary carcinoma, and pulmonary adenocarcinoma in dogs and lymphoma in cats.
- Pancreatitis.
- Protein-losing nephropathy.
- Shock, hypoxia, acidosis.
- Thrombocytopenia, especially immune-mediated.
- Transfusion incompatibility.
- Trauma.
- Envenomation.

RISK FACTORS
Vary with cause.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Key differentials—immune-mediated thrombocytopenia, anticoagulant toxicity, coagulation factor deficiency, paraproteinemia.
- Highly variable diagnostic pattern includes thrombocytopenia, prolonged clotting times (prothrombin time [PT], activated partial thromboplastin time [APTT]), decreased fibrinogen, decreased antithrombin (AT), and increased products of fibrinolysis (FDPs, D-dimers).
- Suspect DIC any time thrombocytopenia and prolonged clotting tests are seen together.
- Patients showing predisposing conditions should have laboratory monitoring every 24–48 hours. A sudden drop in platelet count and a 20–30% prolongation in APTT is suspicious for non-overt DIC. This is a critical stage for intervention to prevent progression to overt DIC.
- Hepatic insufficiency may mimic DIC. Decreased production of clotting factors is common. Decreased clearance of normal fibrin(ogen)olytic by-products may increase FDP values. Mild idiopathic thrombocytopenia may also be seen. Spontaneous bleeding is uncommon unless DIC is present.

CBC/BIOCHEMISTRY/URINALYSIS
- Inflammatory leukogram, often with a stress component.
- Mild to moderate thrombocytopenia ($40–100 \times 10^3/\mu L$); less reliable in cats.
- Anemia is possible. Red blood cell (RBC) fragmentation is a supportive finding.
- Biochemical changes reflect affected organs; acute kidney injury may result in isosthenuria, oligo-anuria, or the identification of casts in urine sediment.

OTHER LABORATORY TESTS
- Prolonged clotting tests (PT, APTT); APTT is prolonged first, PT becomes prolonged with transition to overt DIC.
- Hypofibrinogenemia, although inflammatory increase may mask consumption.
- Increased FDPs and D-dimers. D-dimers are very sensitive and specific. DIC is unlikely if D-dimers are low/negative. Neither test is specific enough alone to diagnose DIC.
- Decreased AT; may be a positive acute phase reactant in cats, masking consumption.
- Thromboelastography may provide evidence of hypocoagulability or fibrinolysis.

DIAGNOSTIC PROCEDURES
Diagnostic procedures should be focused on identifying the inciting cause of inflammation, and may include imaging, tissue biopsy, or surgery as dictated by clinical signs.

PATHOLOGIC FINDINGS
- Usually related to the primary disease or DIC-affected organs.
- Petechiae common.

TREATMENT

APPROPRIATE HEALTH CARE
- Requires intensive inpatient treatment.
- Aggressive treatment of the primary disease is essential (e.g., antimicrobials for sepsis).

DISSEMINATED INTRAVASCULAR COAGULATION (CONTINUED)

NURSING CARE
• Maintain tissue perfusion and oxygenation using fluids, transfusions, and oxygen therapy.
• Restore depleted factors by blood/plasma transfusions. Use fresh frozen plasma (10–20 mL/kg) to correct bleeding due to factor deficiency.

ACTIVITY
Limited by disease severity.

DIET
Maintain nutritional support as appropriate for the clinical condition of the patient.

CLIENT EDUCATION
Inform the owner that the condition is life-threatening with a guarded to poor prognosis.

SURGICAL CONSIDERATIONS
Related to primary disease. Plasma or whole blood transfusion to restore clotting factors is a presurgical consideration. Surgery may be contraindicated with uncontrolled bleeding.

MEDICATIONS

DRUG(S) OF CHOICE
• There is no specific pharmacologic therapy for DIC per se.
• Heparin may be used in patients that have overt thrombosis or in those at high risk of thrombosis with normal coagulation times. Unfractionated heparin is preferred to low molecular weight heparin in human patients with DIC.
• Heparin binds to and potentiates the action of AT. Plasma or blood transfusions may be needed to replenish AT for heparin to be an effective anticoagulant.
• Starting doses for unfractionated heparin are 150–200 U/kg SC q8h. It may also be given as a CRI starting at 20–30 U/kg/h IV (i.e., same total daily dosage). Therapy should be monitored using serial measurements of APTT or anti-Xa activity.

CONTRAINDICATIONS
• Heparin therapy should be avoided in patients with coagulopathy.
• Inhibitors of fibrinolysis should not be used.
• The use of antiplatelet medications in thrombocytopenic patients is not indicated.
• Corticosteroids impair function of mononuclear phagocytes and do not have a clear indication for DIC unless important for therapy of the underlying disease (e.g., lymphoma).

PRECAUTIONS
• Heparin may cause hemorrhage, and therapy should be monitored.
• Volume overload may occur in cases with renal or pulmonary compromise.

POSSIBLE INTERACTIONS
None

FOLLOW-UP

PATIENT MONITORING
• Clinical improvement and the arrest of bleeding are key positive findings.
• Daily lab testing (e.g., coagulation tests, fibrinogen, platelet counts) is warranted in severe cases to identify positive or negative trends. Less frequent testing may suffice in milder cases.
• Coagulation times and fibrinogen often normalize more rapidly than FDPs and platelet counts.

PREVENTION/AVOIDANCE
Early detection of non-overt DIC can allow therapy before disease progresses to overt DIC.

POSSIBLE COMPLICATIONS
Aside from the primary disease, affected organs may have permanent dysfunction or marginal reserve capacity.

EXPECTED COURSE AND PROGNOSIS
For overt DIC, mortality rates for dogs range from 50% to 77%. For cats, rates may be >90%.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
Unlike in humans, obstetric complications are not a common cause in dogs and cats.

SYNONYMS
• Consumptive coagulopathy.
• Disseminated intravascular coagulopathy.

SEE ALSO
• Coagulation Factor Deficiency.
• Thrombocytopenia.

ABBREVIATIONS
• APTT = activated partial thromboplastin time.
• AT = antithrombin.
• DIC = disseminated intravascular coagulation.
• FDP = fibrin degradation product.
• PS = phosphatidylserine.
• PT = prothrombin time.
• RBC = red blood cell.
• TF = tissue factor.

DROWNING (NEAR DROWNING)

BASICS

OVERVIEW

• Defined as process of experiencing respiratory impairment from submersion or immersion in liquid; near drowning defined as water submersion followed by survival for at least 24 hours; recent changes in terminology prefer the use of "death, morbidity or no morbidity following a drowning episode." • Following submersion, elevations in CO_2 levels in the bloodstream stimulate respiration, and subsequent aspiration of water occurs. • Fresh water aspiration dilutes pulmonary surfactant, leading to alveolar collapse ± infectious pneumonia; hypertonic seawater aspiration leads to diffusion of interstitial water into alveoli; large volumes of water are not typically aspirated, but any amount results in ventilation–perfusion mismatch, hypoxemia, and metabolic acidosis. • Submersion time, temperature of water, and type of water (fresh vs. salt vs. chemical water) significantly affect development of organ damage.

SIGNALMENT

Dogs and cats. Approximately half of animals involved in immersion accidents are <4 months of age.

SIGNS

• Noted acutely after exposure to water.
• Cyanosis, apnea, respiratory distress.
• Coughing ± clear to frothy red sputum.
• Vomiting. • Obtunded to comatose.
• Crackles or wheezes auscultated over chest.
• Tachycardia or bradycardia, asystole.

CAUSES & RISK FACTORS

• Greater risk near bodies of water (including pools, buckets, bathtubs) or ice. • Owner negligence or inadequate safety precautions vs. purposeful harm. • Animals in or near water at time of seizure, head trauma, hypoglycemic event, cardiac arrhythmia, or syncopal episode are at risk of drowning.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Hypothermia, neck trauma, and meningitis. • With drowning secondary to seizure, head trauma, hypoglycemic event, cardiac arrhythmia, or syncopal episode, history at time of presentation may be informative.

CBC/BIOCHEMISTRY/URINALYSIS

• Fresh water inhalation/ingestion—hemodilution, hemolysis, and decreases in sodium, chloride, and urine specific gravity. • Hypertonic salt water ingestion/inhalation—hemoconcentration and increases in sodium, chloride, and urine specific gravity.

OTHER LABORATORY TESTS

Arterial blood gas reveals hypoxemia (partial pressure of oxygen [PaO_2] <80 mmHg), hypoventilation (partial pressure of carbon dioxide [$PaCO_2$] >50 mmHg), and acid-base derangements.

IMAGING

• Radiographic changes may not be detectable for 24–48 hours. • Focal or diffuse alveolar pattern due to aspiration pneumonia or noncardiogenic pulmonary edema. • Mixed patterns may be present, ± radiopaque material filling the airways ("sand bronchogram"). • Foreign body inhalation may produce segmental atelectasis. • Progression of pulmonary injury to acute respiratory distress syndrome (ARDS) is possible and may appear as bilateral, diffuse, symmetric alveolar infiltrates.

DIAGNOSTIC PROCEDURES

• Endotracheal or transtracheal wash with cytologic evaluation and culture with sensitivity indicated if animal is stable. • ECG monitoring. • Cervical radiographs, CT or MRI of brain, and brainstem auditory evoked response (BAER) assessment in select cases.

TREATMENT

• Initiate mouth-to-muzzle resuscitation on-site. • Emergency inpatient care is required. • Airway clearance, if obstructed, is first priority. • Cardiopulmonary resuscitation (CPR), if necessary. • Oxygen supplementation. • Intubation and mechanical ventilation with positive end-expiratory pressure may be required in animals with severe hypoxemia, hypercapnia, or imminent respiratory fatigue. • Fluid therapy and acid-base/electrolyte management are crucial. • Gradually rewarm (over 2–3 hours) hypothermic animals. • Gravitational drainage or abdominal thrusts (Heimlich maneuver) are not recommended in absence of airway obstruction owing to high risk of regurgitation and subsequent aspiration of stomach contents. • Continuous venovenous filtration may decrease mortality following salt water drowning.

MEDICATIONS

DRUG(S) OF CHOICE

• Mannitol 0.5 g/kg IV over 30 min may be beneficial in animals with suspected cerebral edema. • Broad-spectrum antibiotics (e.g., ampicillin 22 mg/kg IV q8h; enrofloxacin 10–20 mg/kg IV q24h in the dog, 5 mg/kg IV q24h in the cat) for aspiration pneumonia. • Beta-2 agonists may help animals with suspected bronchospasm. • Pentoxifylline decreased incidence of lung injury in dogs with experimental freshwater aspiration.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Corticosteroid therapy not indicated; use could be detrimental in animals with aspiration pneumonia. • Use of enrofloxacin in young animals may result in cartilage erosion.

FOLLOW-UP

PATIENT MONITORING

• Continuous monitoring of heart rate and rhythm, respiratory rate, mucous membrane color and capillary refill time, urine output, arterial blood pressure, rectal temperature, and neurologic status. • Arterial blood gas, CBC, biochemical profile, coagulation profile, and acid-base status checked as needed.

PREVENTION/AVOIDANCE

Close monitoring of animals (especially young and old/debilitated animals) near bodies of water. Place barriers around bodies of water, life jackets on animals, train owners to perform CPR.

POSSIBLE COMPLICATIONS

Aspiration pneumonia, noncardiogenic pulmonary edema, ARDS, gastrointestinal bleeding, diarrhea, vomiting, acute kidney injury, permanent neurologic derangements, disseminated intravascular coagulation, central diabetes insipidus.

EXPECTED COURSE AND PROGNOSIS

Directly related to animal's status at time of admission—animals that present comatose, severely acidotic (pH <7.0), or requiring cardiopulmonary resuscitation or mechanical ventilation have poor prognosis. Animals that present conscious have good prognosis if no complications ensue; 37.5% mortality rate in 15 dogs and 1 cat with freshwater aspiration.

MISCELLANEOUS

ABBREVIATIONS

• ARDS = acute respiratory distress syndrome. • BAER = brainstem auditory evoked response. • CPR = cardiopulmonary resuscitation. • $PaCO_2$ = partial pressure of carbon dioxide. • PaO_2 partial pressure of oxygen.

Consulting Editor Elizabeth Rozanski

DUCTAL PLATE MALFORMATION (CONGENITAL HEPATIC FIBROSIS)

BASICS

DEFINITION

• Ductal plate malformations (DPMs) are congenital noninflammatory hepatopathies subject to complicating bacterial cholangitis; recognized most often in juvenile and young adult dogs or cats and reflect malformation of biliary structures. • DPMs reflect aberrant development, differentiation, proliferation, or intussusceptive resorption of embryonic anlage of bile ducts during development of ductal plate, embryologic precursor of portal tract structures (predominantly bile ducts). • Pathomechanisms leading to DPM interfere with tubulogenesis—may affect kidneys, liver, or pancreatic ductal structures. • Four DPM phenotypes defined based on involved structures and severity of coexistent portal tract fibrosis, severity of fibroductal bridging trabeculae, development of presinusoidal portal hypertension (PH) causing splanchnic hypertension, and development of acquired portosystemic shunts (APSS). • Animals with DPM have propensity for septic suppurative cholangitis, choledochitis, cholelithiasis, or extrahepatic bile duct obstruction (EHBDO).

MAJOR DPM PHENOTYPES

• *Choledochal cyst*—diverticulum protruding from common bile duct (CBD) or cystic duct; propensity for infection similar to appendicitis in humans; may cause systemic sepsis, EHBDO, and cranial abdominal mass effect; complex confusing US appearance. • *Caroli's malformation*—irregular duct silhouettes (sacculation, invagination, or "budding" protrusions) with occasional periductal satellite ductal elements surrounding large ducts; malformations variably involve hepatic, interlobular, or large intralobular bile ducts; biliary epithelium may appear normal, hyperplastic, attenuated, or vacuolated; intraluminal debris in large ducts; develop choleliths, dystrophic mineralization, septic cholangitis. • *Small proliferative-like phenotype*—diffuse intralobular bile duct malformation without *or* with bridging portal-to-portal fibroductular trabeculae: if fibrosis severe may evolve presinusoidal PH and consequent splanchnic hypertension = *congenital hepatic fibrosis (CHF) phenotype*—involves small intralobular bile duct malformation with densely packed proliferative-like ductule structures (± luminal apertures) within excessive extracellular matrix (ECM); ECM accrual varies in severity, but appears progressive with aging; histologic features characterized by amalgamation of proliferative bile ductules with numerous stout (muscular) entangling arterials and inconspicuous portal veins within exuberant ECM that dimensionally expands portal tracts; variable fibroductal bridging partitions may interconnect portal regions; because ECM accrues with aging, transformation to CHF may occur over time. • *von Meyenburg's complexes (VMCs)*—isolated single microscopic DPM composed of clustered proliferative intralobular bile duct profiles embedded in expanded ECM; also termed bile duct hamartomas; usually located adjacent to liver capsule; inconsequential malformation. • Progression of portal tract fibrosis with aging can lead to gradual onset of presinusoidal PH, formation of APSS, ascites, and hepatic encephalopathy (HE). • Gallbladder (GB) agenesis and severe hypoplasia or agenesis of entire liver lobes may occur. • Liver lobes may be variably affected with DPM; unaffected liver lobes possible.

PATHOPHYSIOLOGY

• DPMs not associated with increased liver enzymes or jaundice unless complicated by infection, choleliths, EHBDO, or choledochitis. • Different phenotypes acquire different disease manifestations. • *Choledochal cysts*—not recognized until cystic luminal contents contaminated by bacteria with ensuing infection and cyst expansion, development of choledochitis or EHBDO; until compromised CBD patency patient remains anicteric, usually asymptomatic. • *Caroli's malformation*—serendipitously recognized on abdominal radiography (limy gallbladder, mineralized sacculated intrahepatic large bile ducts), or on abdominal US as distended intra- or extrahepatic bile ducts, mineralized ducts, association with cholelithiasis, or thickened duct walls (infection, choledochitis). • *Diffuse DPM without extensive bridging fibrosis or presinusoidal PH*—not associated with increased liver enzymes or jaundice, usually normal total serum bile acid (TSBA) concentrations; diagnosed when infection increases liver enzyme activity leading to liver biopsy. • *Diffuse DPM with bridging fibrosis (CHF) causes presinusoidal PH*—these patients may present for ascites, increased TSBA concentrations, ± increased liver enzymes reflecting secondary cholangitis, or for HE; not jaundiced unless infected or have concurrent EHBDO.

SYSTEMS AFFECTED

• Liver—variable size (small, normal, large); may have GB agenesis or maldevelopment of entire liver lobe(s); rare concurrent congenital intrahepatic or extrahepatic congenital portosystemic vascular anomaly (shunt, PSVA); jaundice due to EHBDO from choledochal cyst, cholelithiasis, rare cholangiocarcinoma, or due to sepsis (Caroli's malformation, choledochal cyst); increased liver enzymes may reflect suppurative cholangitis or unrelated copper associated hepatopathy (CuAH) in dogs. • Gastrointestinal (GI)—anorexia; intermittent vomiting or diarrhea reflects concurrent inflammatory bowel disease (IBD) or enteric hypertensive vasculopathy (splanchnic hypertension from presinusoidal PH). • Nervous—episodic HE if APSS associated with CHF or if concurrent PSVA. • Musculoskeletal—stunted growth and poor body condition if CHF and APSS or if concurrent PSVA; also may reflect chronic disease, inappetence, or enteric malassimilation. • Urogenital—polyuria and polydipsia (PU/PD); possible polycystic renal phenotype; ammonium biurate urolithiasis reflects APSS or rare concurrent PSVA. • Hemic/lymphatic/immune—red blood cell (RBC) microcytosis reflects APSS or PSVA; neutrophilic leukocytosis with toxic neutrophils and left-shifted leukon reflects sepsis due to suppurative bacterial cholangitis/choledochitis or infected choledochal cyst.

SIGNALMENT

• Dog and cat, no sex predilection. • Juvenile and young adults predominate; dogs: mean age 1.5–2.5 years (0.2–12) years. • May affect multiple littermates. • Boxer dogs may be predisposed. • Persian cats and descendent breeds with or without polycystic renal disease appear predisposed.

SIGNS

• May be asymptomatic. • Stunted growth, poor body condition if CHF with APSS or concurrent PSVA. • GI signs—inappetence, emesis, diarrhea, enteric hemorrhage; especially if concurrent IBD. • PU/PD if APSS or rare concurrent PSVA, or polycystic renal disease. • ± Increased liver enzymes. • ± Fever, leukocytosis, hyperbilirubinemia—due to sepsis evolved from bacterial cholangitis, choledochitis, or choledochal cyst infection or infection-related cholelithiasis. • ± Abdominal distention—ascites with APSS in CHF; CHF with PSVA no ascites unless PSVA attenuated. • ± Episodic CNS signs due to HE if APSS in CHF or rare concurrent PSVA. • ± Urolithiasis (ammonium urates) if APSS in CHF or rare concurrent PSVA.

CAUSES & RISK FACTORS

• In humans (and knockout mouse models) DPM reflects gene mutations influencing structure or function of primary cilia; polycystic kidney disease in Persian cats involves polycystin-1 precursor gene, one gene influencing primary ciliary function; ~15% develop hepatic DPM. • Clinical signs usually reflect acquired complications.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Stunted growth, increased TSBA concentrations—PSVA, severe portal vein

atresia, splanchnic portal vein thromboembolism (TE). • Increased liver enzymes ± hyperbilirubinemia—chronic hepatitis, CuAH, hepatotoxicity, liver abscess, primary hepatic neoplasia, cholangiohepatitis, choledochitis, or cholecystitis. • Jaundice—acute liver injury, hepatotoxicosis, chronic hepatitis, CuAH, cholelithiasis, ruptured GB, EHBDO, hemolysis. • CNS signs—infectious disorders (distemper); toxicities (lead); hydrocephalus; epilepsy; metabolic disorders (severe hypoglycemia, hypokalemia, hyperkalemia, hypophosphatemia); thiamine deficiency. • Ascites—pure transudate, many causes (see Hypertension, Portal). • HE—APSS, PSVA, portal TE, other causes.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—RBC microcytosis: reflects APSS; target cells associated in dogs.
• Biochemistry—if APSS with CHF: ± low albumin, cholesterol, blood urea nitrogen, variable globulin; all DPM phenotypes: ± increased alkaline phosphatase and alanine aminotransferase activity with cholangitis; hyperbilirubinemia: if EHBDO due to choledochal cyst or cholelithiasis or if septic.
• Urinalysis—ammonium biurate crystalluria if APSS in CHF phenotype.

OTHER LABORATORY TESTS

• Routine coagulation tests—variable abnormalities (see Coagulopathy of Liver Disease); low protein C and antithrombin activity may reflect APSS in CHF phenotype.
• TSBA—increased concentrations in anicteric patients reflect APSS or rare concurrent PSVA. • Peritoneal fluid analysis—pure transudate (protein <2.5 g/dL); modified transudate if chronic: only in CHF phenotype.

IMAGING

Radiography

• Abdominal radiography—variable liver size.
• Abdominal effusion—APSS in CHF phenotype. • Ammonium biurate calculi—radiolucent unless radiodense mineral shell.
• Thoracic radiography—normal.

Abdominal US

• Variable liver size—small to large. • GB may not be discovered if atretic or may be tiny. • May disclose intra- or extrahepatic biliary malformations (sacculated or cystic ductal structures); variable liver texture; unremarkable vasculature to portal hypoperfusion. • Choledochal cyst—may be difficult to decipher owing to overlying enteric gas and confusion with CBD and cystic duct. • Abdominal effusion—if APSS in CHF. • APSS—confirm using color-flow Doppler; rule out portal TE and intrahepatic arteriovenous malformations as causes of APSS. • Uroliths—renal pelvis or urinary bladder.

Additional Imaging

• Colorectal or splenoportal scintigraphy with Technetium-^{99m} pertechnetate (see Portosystemic Vascular Anomaly, Congenital)—sensitive noninvasive test confirming macroscopic shunting, but cannot differentiate PSVA from APSS. • Multisector CT—gold standard imaging modality: confirms APSS or PSVA; dual-phase angiogram can reveal asymmetric liver development (liver lobe absence or atresia), GB atresia, choledochal cyst, sacculated interlobular and cystic ducts, cholelithiasis, and APSS.

DIAGNOSTIC PROCEDURES

• Fine-needle aspiration cytology—cannot diagnose DPM, sometimes identifies complicating bacterial infection especially if bile collected. • Liver biopsy—mandatory for definitive diagnosis; open surgical wedge, laparoscopic cup samples; needle core sample may be adequate; collect biopsies from several liver lobes. • Echocardiography—if ascites present.

PATHOLOGIC FINDINGS

• Gross—depends on phenotype.
○ *Choledochal cyst*—predominantly occurs in cats, variable size (as large as 10 cm) with thick or thin wall; contents acholic or mucinous white bile; may be purulent or bile laden; may envelop CBD. ○ *Caroli's malformation*—grossly distended hepatic, interlobular, or segmental bile ducts, thick walls if choledochitis, wall may be mineralized, may have pigmented-calcium carbonate choleliths. ○ *Small-proliferative-type DPM*—firm fibrotic hepatic parenchyma, fine nodular to smooth capsular surface, may have splanchnic APSS if CHF phenotype. ○ *von Meyenburg complexes*—inapparent or tiny pale foci on liver margin. • Possible GB atresia, PSVA, other vascular malformations, liver lobe agenesis. • Microscopic—variable severity as described (see Major DPM Phenotypes); stereotypic histologic features of portal venous hypoperfusion are common; direct intersection of proliferative-like bile ductules and hepatocytes is signature histologic feature of DPM in absence of inflammatory infiltrates; islands of hepatocytes may be encircled or isolated by portal-to-portal fibroductal partitions.

TREATMENT

APPROPRIATE HEALTH CARE

• Inpatient—for septic complications or severe HE. • Surgical intervention—choledochal cyst: best managed by resection but depends on anatomic malformation and location; may be marsupialized or anastomosed to intestine. • Outpatient—stable patients.
• Avoid endoparasitism. • Treat infections promptly—DPM patients (except VMC) predisposed to bacterial cholangitis, choledochitis, and associated cholelithiasis because of blind-ended noncontiguous ductal structures; in CHF with APSS reduced Kupffer cell surveillance increases risk for infection and systemic sepsis. • In CHF—remain vigilant for ammonium biurate obstructive uropathy. • If APSS—avoid nonsteroidal anti-inflammatories that may augment ascites and GI bleeding provoking HE; adjust dosage of drugs with high first-pass hepatic extraction. • CuAH diagnosed by liver biopsy should be treated.

NURSING CARE

• HE—eliminate causal factors; individualize diet, supplement water-soluble vitamins, vitamin E, and K depending on prothrombin/activated partial thromboplastin time tests or presence of EHBDO; provide multiple small feedings daily.
• Ascites—see Hypertension, Portal.

MEDICATIONS

DRUG(S) OF CHOICE

Strategy for DPM is to treat syndrome complications.

HE

• Lactulose (0.5–1.0 mL/kg PO q8–12h)—achieve several soft stools daily; may withdraw with optimal diet modification. • Oral antibiotics—modify encephalogenic enteric toxin production: first choices metronidazole (7.5 mg/kg PO q12h) or amoxicillin (22 mg/kg PO q12h); avoid neomycin (20 mg/kg PO q8–12h): potential for enteric absorption (esp. if concurrent IBD) causing ototoxicity (deafness) and nephrotoxicity.

Ascites

• Dietary sodium restriction. • Diuretics—furosemide (1–4 mg/kg PO/IM/IV q12–24h): potassium wasting effect modulated by combination with spironolactone (1–4 mg/kg PO q12h, loading dose then maintenance dose 2–4 mg/kg PO q24h); potassium sparing; less potent than furosemide.
• Diuretic-resistant ascites—consider therapeutic abdominocentesis (see Hypertension, Portal for other medical options). • Antifibrotic—not proven effective in humans with DPM; liver transplant common, unknown in veterinary medicine; colchicine not effective.
• Telmisartan—angiotensin receptor blocker safe for use in dogs and cats; attenuated progressive ECM accrual in DPM rodent model; adverse effects if coadministered with spironolactone or angiotensin-converting enzyme (ACE) inhibitor: leads to serious hypotension (collapse, acute renal failure); initial dose 0.5 mg/kg/day titrated to max of 1 mg/kg/day.

DUCTAL PLATE MALFORMATION (CONGENITAL HEPATIC FIBROSIS) (CONTINUED)

Antioxidant Medications
Indicated if chronic cholangitis, CuAH, chronic increased liver enzymes, or CHF.

Bleeding Tendencies
Rare in CHF; may encounter if chronic EHBDO caused by choledochal cyst or cholelithiasis.

GI Hemorrhage
Hypertensive enteric vasculopathy may be encountered with CHF because of APSS.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Avoid or reduce dosage of drugs relying on first-pass hepatic metabolism if APSS; avoid drugs reacting with GABA-benzodiazepine receptors if intermittent HE in patients with APSS-CHF phenotype; avoid drugs inhibiting biotransformation and metabolism of other drugs (e.g., cimetidine, chloramphenicol, quinidine, some calcium channel blockers); if jaundiced avoid drugs undergoing biliary elimination. • Avoid metoclopramide if spironolactone used as diuretic (augments aldosterone). • Avoid combination of spironolactone with telmisartan or ACE inhibitor.

FOLLOW-UP

PATIENT MONITORING
• Instruct owners to monitor body temperature, appetite, activity, for jaundice or other signs of infection or complications.
• Biochemistry—initially monitor q2–4 weeks until stabile in animals presenting with sepsis or EHBDO, then q4–6 months or if cyclically ill or febrile; monitor for recurrent septic cholangitis/choledochitis, development of septic effusion; HE decompensation.

POSSIBLE COMPLICATIONS
CHF associated with HE—requires indefinite nutritional and medical management. If concurrent PSVA—likely cannot be attenuated without causing APSS.

EXPECTED COURSE AND PROGNOSIS
• Long-term survival (years) possible.
• Guarded prognosis if CHF phenotype with APSS. • Short-term or lifelong treatments may be required. • Flare-ups of HE and ascites may require hospitalizations for adjustment of nutritional and medical interventions.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• HE. • Ascites. • GI bleeding. • APSS.

AGE-RELATED FACTORS
• Prognosis depends on degree of fibrosis and APSS in CHF; severity of relapsing septic cholangitis or choledochal cyst infection; intrahepatic infected cholelithiasis; evidence of hepatic insufficiency and APSS at initial diagnosis. • Fibrosis progressive with aging in some patients.

DYSAUTONOMIA (KEY-GASKELL SYNDROME)

BASICS

OVERVIEW

• Failure of autonomic function in multiple organs with minimal motor or sensory involvement. • Young adult, rural dogs in specific states at greatest risk. • Treatment is symptomatic and prognosis guarded.

SIGNALMENT

• Dog and less commonly cat. • No breed or sex predilection. • Median age is 18 months but any age animal may be affected.

SIGNS

• Acute to subacute onset (5–14 days).
• Various combinations of signs may be present, but both sympathetic and parasympathetic signs in various organs are necessary to be confident of diagnosis.
• Sensory or motor deficits are minimal.

Presenting Complaints

• Most commonly gastrointestinal (GI) signs of vomiting or regurgitation, diarrhea, or occasionally constipation. • Straining to urinate and dribbling urine. • Photophobia and third-eyelid elevation. • Dyspnea, coughing, and purulent nasal discharge.
• Depression, anorexia, and weight loss.

Examination Findings

• Variable combinations of autonomic dysfunction. • Loss of anal sphincter tone.
• Dry nose and mucous membranes; lack of tear production. • Distended, easily expressed bladder. • Pupils midrange to maximally dilated with no pupillary light reflex but intact vision. • Third-eyelid elevation, ptosis, and enophthalmos. • Lack of gut sounds and occasional abdominal pain. • Heart rate and blood pressure typically in low end of normal range but do not rise in response to stress.
• Secondary aspiration pneumonia or rhinitis. • Cachexia. • Occasionally mild proprioceptive deficits or weakness.

CAUSES & RISK FACTORS

• Cause unknown. • Highest incidence in Missouri, Oklahoma, and Kansas as well as Wyoming and northern Colorado, but occasional cases reported throughout United States.
• Free-roaming, rural dogs at greatest risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Anticholinergic toxicity. • Other differential diagnoses depend upon specific clinical signs: e.g., urinary tract infection for dysuria, corneal ulcer for photophobia, dehydration for dry mucous membranes.

CBC/BIOCHEMISTRY/URINALYSIS

Unremarkable

IMAGING

• Megaesophagus ± aspiration pneumonia.
• Distended bowel loops with no peristalsis.
• Distended urinary bladder.
• Echocardiography may show systolic dysfunction as reduced fractional shortening.

DIAGNOSTIC PROCEDURES

• If pupils affected, 0.05% pilocarpine drops in one eye will produce miosis within 60 minutes; rules out anticholinergic toxicity.
• Atropine (0.03 mg/kg IV) may not produce expected rise in heart rate; suggests loss of vagal tone. • Intradermal histamine may produce no response or wheal but no flare; demonstrates loss of sympathetic innervation of arterioles.

TREATMENT

• IV fluids to prevent dehydration. • High-calorie food; feeding tube to ensure adequate nutrition if megaesophagus present; if GI motility absent, parenteral nutrition may be necessary. • Lubricating eye drops if tear production insufficient. • Humidification of air may help with dry mucous membranes.
• Manual bladder expression.

MEDICATIONS

DRUG(S) OF CHOICE

• Antibiotics as needed to treat secondary infections. • Prokinetic drug such as metoclopramide if GI motility affected.
• Bethanechol to stimulate lacrimation and urination (start at 0.05 mg/kg q8–12h and adjust dose based on response); manual expression of bladder more reliable.
• Ocular pilocarpine to relieve photophobia.
• Pimobendan if poor cardiac contractility.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Animals with dysautonomia develop denervation supersensitivity to direct acting cholinergic or adrenergic drugs. • Great care must be exercised in using such drugs, particularly adrenergic drugs that could precipitate fatal tachyarrhythmias; best to start at <10% of low end of dose range when using direct-acting drugs and escalate dose as needed to produce desired effect.

FOLLOW-UP

• Prognosis guarded; most animals die of aspiration pneumonia or euthanasia due to poor quality of life. • Animals who survive often have some degree of permanent autonomic dysfunction that may require constant care.

MISCELLANEOUS

• Necropsy identification of neuronal loss in ganglia confirms diagnosis. • Clinical diagnosis based on autonomic failure in multiple organs without underlying cause or significant motor or sensory involvement and appropriate response to pharmacologic testing.

ABBREVIATIONS

• GI = gastrointestinal.

DYSCHEZIA AND HEMATOCHEZIA

BASICS

DEFINITION
- Dyschezia—painful or difficult defecation.
- Hematochezia—bright red blood in or on the feces.

PATHOPHYSIOLOGY
Results from inflammatory, infectious, or neoplastic conditions affecting the colon, rectum, or anus.

SYSTEMS AFFECTED
Gastrointestinal

SIGNALMENT
- Dog and cat.
- No breed or sex predilection.

SIGNS

Historical Findings
- Vocalizing and whimpering during defecation.
- Tenesmus.
- Decreased frequency of defecation in association with severe dyschezia (animal resists defecating due to pain), resulting in constipation or obstipation.
- Mucoid, bloody diarrhea with a marked increase in frequency and scant fecal volume in patients with colitis.
- Scooting behavior in association with anal gland infection or impaction.
- It is pivotal to differentiate hematochezia secondary to colitis from hematochezia secondary to a colorectal mass—the histories are profoundly different and a rectal examination should always be performed to further differentiate these two disorders (see below).

Physical Examination Findings
- Rectal examination may reveal hard feces (constipation or obstipation), diarrhea (colorectal disease), colorectal masses, anorectal thickening, rectal or colonic strictures, anal sac enlargement/pain, prostatomegaly, or perineal hernias.
- Fistulous tracts around anus occur with perianal fistulae.
- Anal occlusion with matted hair and feces occurs with pseudocoprostasis.

CAUSES

Rectal/Anal Disease
- Stricture or spasm.
- Anal sacculitis or abscess.
- Perianal fistulae.
- Rectal or anal foreign body.
- Pseudocoprostasis.
- Rectal prolapse.
- Trauma—bite wounds, etc.
- Neoplasia—adenocarcinoma, lymphoma, and anal sac tumors.
- Rectal polyps.
- Mucocutaneous lupus erythematosus.

Colonic Disease
- Neoplasia—adenocarcinoma, lymphoma, other tumors.
- Idiopathic megacolon—cats.
- Inflammation—inflammatory bowel disease, infectious parasitic agents, colitis secondary to dietary-responsive enteropathy (see Colitis and Proctitis).
- Constipation (see Constipation and Obstipation).

Extraintestinal Disease
- Fractured pelvis or pelvic limb.
- Prostatic disease.
- Perineal hernia.
- Intrapelvic neoplasia.

RISK FACTORS
- Ingestion of hair, bone, or foreign material may contribute to constipation and subsequent dyschezia.
- Environmental factors such as a dirty litter pan or infrequent outside walks may contribute to constipation and subsequent dyschezia.

DIAGNOSIS

It is pivotal to recognize that hematochezia in animals can be seen with both diffuse colitis as well as with focal or discrete colorectal neoplasms. The fundamental differences in the clinical presentation between the two disorders can usually be recognized during the history and following a thorough physical examination, including a rectal examination. Dogs with colorectal neoplasms do not have diarrhea, and the most important and frequent clinical sign is hematochezia in the absence of an increase in defecation frequency or change in stool consistency. Pencil-thin or ribbon-like stools can be seen when the colorectal neoplasm is advanced, causing a change in the shape of the stool. *A rectal examination must be performed on every patient with a history of hematochezia or dyschezia.*

DIFFERENTIAL DIAGNOSIS
- Dysuria, stranguria, or hematuria—abnormal findings on urinalysis, such as pyuria, crystalluria, or bacteriuria. The history and physical examination should differentiate whether the animal is having difficulty urinating or defecating.
- Dystocia—differentiate with history and imaging.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually unremarkable, unless there is a history of chronic blood loss with secondary iron deficiency causing a microcytic and hypochromic nonregenerative anemia.
- Mild neutrophilia (with or without a left shift) with infection or inflammation.

OTHER LABORATORY TESTS
Centrifugation fecal flotation to help rule out parasitic causes of colitis.

IMAGING
- Pelvic radiographs may reveal intrapelvic disease, foreign body, or fracture.
- Ultrasonography may demonstrate prostatic disease or caudal abdominal masses; however, a portion of the descending colon cannot be visualized because of the pelvis.

DIAGNOSTIC PROCEDURES
Colonoscopy/proctoscopy to evaluate for inflammatory or neoplastic disease.

TREATMENT
- Depends on the underlying cause.
- Colonic strictures secondary to neoplasms can be managed via surgical excision or balloon catheter dilation.
- Consider laxatives (lactulose) to ease defecation and discomfort in animals with colorectal strictures or masses.
- Colorectal masses are best removed surgically or via endoscopy (snare and cauterization for polyps).

MEDICATIONS

DRUG(S) OF CHOICE
- Antibiotics—if bacterial infection (e.g., anal sac abscess); amoxicillin/clavulanic acid 15 mg/kg PO q12h for 7–10 days.
- Anti-inflammatory drugs—sulfasalazine or prednisone (dogs) and prednisolone (cats) if colitis is present (see Colitis and Proctitis; Colitis, Histiocytic Ulcerative).
- Cyclosporine (5 mg/kg q12h for 3–4 months with gradual taper thereafter) for dogs with perianal fistulae.
- Laxatives—lactulose 1 mL/4.5 kg PO q8–12h to effect; docusate sodium or docusate calcium: dogs: 50–100 mg PO q12–24h; cats: 50 mg PO q12–24h.
- Cisapride—prokinetic indicated for cats with moderate to severe megacolon (and no evidence of obstruction) in conjunction with lactulose and dietary therapy at a dose of 5 mg/cat q12h.

CONTRAINDICATIONS
Avoid agents that cause increased fecal bulk (insoluble fiber), unless specifically indicated (colitis).

FOLLOW-UP
- The need for follow-up depends on the underlying cause. Dogs and cats that are undergoing balloon dilation of colorectal strictures usually require multiple procedures to manage the stricture properly. Animals should always be rechecked at suture removal

or 10–14 days following surgical resection of colorectal masses.
• Animals with hematochezia secondary to colitis should have a marked improvement or resolution of their clinical signs within 5–7 days following implementation of elimination dietary therapy.

PATIENT MONITORING
Daily monitoring by the owner with periodic phone calls to the clinician every 2–3 weeks during the beginning of treatment.

POSSIBLE COMPLICATIONS
• May see fecal incontinence following surgical resection of anal sacs or colorectal tumors if anal sphincter is compromised.
• Secondary megacolon may occur if obstipation is severe and long term.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

PREGNANCY/FERTILITY/BREEDING
Caution with corticosteroids, antibiotics.

SEE ALSO
• Colitis and Proctitis.
• Constipation and Obstipation.

DYSPHAGIA

BASICS

DEFINITION
• Dysphagia refers to difficulty in swallowing and is far more commonly seen in dogs than cats.
• Dysphagia is divided into three main categories—oropharyngeal, esophageal, and gastroesophageal causes.
• Oropharyngeal causes of dysphagia can be further subcategorized into oral, pharyngeal, or cricopharyngeal.
• Any disorder causing difficulty with prehension or mastication can cause dysphagia.
• Odynophagia refers to painful swallowing and is most commonly seen in association with pharyngitis, pharyngeal foreign bodies, esophageal foreign bodies, or severe esophagitis.
• Esophageal dysphagia is discussed in Megaesophagus and in Regurgitation.

PATHOPHYSIOLOGY
• The *oral preparatory phase* is voluntary and begins as food or liquid enters the mouth. Mastication and lubrication of food are the hallmarks of this phase. Abnormalities of the oral preparatory phase usually are associated with dental disease, xerostomia, weakness of the lips (cranial nerves [CN] V and VII), tongue (CN XII), and cheeks (CN V and VII).
• The *oral phase* of swallowing consists of the muscular events responsible for movement of the bolus from the tongue to the pharynx and is facilitated by tongue, jaw, and hyoid muscle movements.
• The *pharyngeal phase* begins as the bolus reaches the tonsils and is characterized by elevation of the soft palate to prevent the bolus from entering the nasopharynx, elevation and forward movement of the larynx and hyoid, retroflexion of the epiglottis and closure of the vocal folds to close the entrance into the larynx, contraction of the muscles of the pharynx, and relaxation of the cricopharyngeus muscle that makes up much of the proximal esophageal sphincter (PES) to allow passage of the bolus into the esophagus. Respiration is briefly halted (apneic moment) during the pharyngeal phase.
• Abnormalities of the pharyngeal phase of swallowing are associated with pharyngeal weakness secondary to neuropathies or myopathies, pharyngeal tumors or foreign bodies, or cricopharyngeus muscle disorders.
• The *esophageal phase* is involuntary and begins with relaxation of the PES and movement of the bolus into the esophagus.

SYSTEMS AFFECTED
• Gastrointestinal.
• Nervous.
• Neuromuscular.
• Respiratory.

GENETICS
Breeds that have a hereditary predisposition or high incidence of dysphagia include golden retriever (pharyngeal weakness, cricopharyngeal muscle dysfunction), cocker and springer spaniels (cricopharyngeal muscle dysfunction), Bouvier des Flandres and cavalier King Charles spaniel (muscular dystrophy), and boxer (inflammatory myopathy). In addition, large and giant-breed dogs are predisposed to acquired megaesophagus.

INCIDENCE/PREVALENCE
Variable depending on underlying etiology. Megaesophagus one of the most common causes of dysphagia in dogs.

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT
• Dog and cat.
• Congenital disorders that cause dysphagia (e.g., cricopharyngeal muscle achalasia, cleft palate, hiatal hernia) usually diagnosed in animals <1 year old.
• Acquired esophageal dysmotility and pharyngeal weakness more common in older patients.

SIGNS

Historical Findings
• Drooling (due to pain or inability to swallow saliva), gagging, ravenous appetite, repeated or exaggerated attempts at swallowing, swallowing with head in abnormal position, nasal discharge (due to nasal reflux of food and liquids into nasopharynx), coughing (due to aspiration), regurgitation, painful swallowing, and occasionally anorexia and weight loss. If tongue is not functioning normally, problems with prehension and mastication may be seen.
• Ascertain onset and progression. Foreign bodies cause acute dysphagia; pharyngeal dysphagia may be chronic and insidious in onset.

Physical Examination Findings
• Physical examination must include careful examination of oropharynx using sedation or anesthesia if necessary to help rule out morphologic abnormalities such as dental disease, foreign bodies, cleft palate, glossal abnormalities, and oropharyngeal tumors.
• Evaluation of cranial nerves should be performed, including assessment of tongue and jaw tone, and of laryngeal function.
• Complete physical and neurologic examination may identify clinical signs supporting generalized neuromuscular disorder, including muscle atrophy, stiffness, or decreased or absent spinal reflexes.
• Evaluate gag reflex by placing a finger in the pharynx; however, presence or absence of gag reflex does not correlate with efficacy of pharyngeal swallow nor adequacy of deglutitive airway protection.
• The importance of the clinician's carefully observing the dysphagic animal while eating (kibble and canned food) and drinking in hospital (or at home via video) is pivotal, and such observation helps localize the problem to oral cavity, pharynx, or esophagus.

Oral Dysphagia
• Modified eating behavior (e.g., eating with head tilted to one side or having difficulty prehending the bolus or opening the mouth).
• Tongue paralysis or dystrophy, dental disease, masticatory muscle myositis, temporal muscle atrophy, or pain, and food packed in buccal folds suggest oral dysphagia.

Pharyngeal Dysphagia
• Prehension of food is normal.
• Repeated attempts at swallowing with food falling out of mouth and excessive gagging suggest pharyngeal dysphagia.
• Saliva-coated food retained in buccal folds, diminished gag reflex, and nasal discharge may also exist.

Cricopharyngeal Muscle Dysfunction
• Patients make repeated, nonproductive efforts to swallow, gag, and cough, then forcibly regurgitate immediately after swallowing.
• Gag reflex and prehension are normal.
• Nasal reflux commonly observed when food hits closed PES.
• Coughing commonly observed secondary to aspiration pneumonia.

Esophageal Dysphagia
• Most common causes include megaesophagus, esophagitis, esophageal stricture, esophageal foreign bodies, and esophageal dysmotility.
• Diagnosis made with survey radiographs of thorax and neck followed by videofluoroscopic swallow assessment.

Gastroesophageal Dysphagia
Most common cause is sliding hiatal hernia in brachycephalic breeds, often associated with gastroesophageal reflux and subsequent esophagitis.

CAUSES
• Anatomic or mechanical lesions include pharyngeal inflammation (e.g., abscess, inflammatory polyps, oral eosinophilic granuloma), neoplasia, pharyngeal and retropharyngeal foreign body, sialocele, temporomandibular joint disorders (e.g., luxation, fracture, craniomandibular osteopathy), mandibular fracture, cleft or congenitally short palate, cricopharyngeal muscle achalasia, lingual frenulum disorder, pharyngeal trauma.
• Pain as result of dental disease (e.g., tooth fractures and abscess), mandibular trauma, stomatitis, glossitis, and pharyngeal inflammation may disrupt normal prehension,

(CONTINUED) DYSPHAGIA

bolus formation, and swallowing. Stomatitis, glossitis, and pharyngitis may be secondary to feline viral rhinotracheitis, feline leukemia virus (FeLV)/feline immunodeficiency virus (FIV), pemphigus, systemic lupus erythematosus (SLE), uremia, and ingestion of caustic agents or foreign bodies.
• Neuromuscular disorders that impair prehension and bolus formation include CN deficits (e.g., idiopathic trigeminal neuropathy CN V, lingual paralysis CN XII) and masticatory muscle myositis.
• Pharyngeal weakness, paresis, or paralysis can be caused by infectious polymyositis (e.g., toxoplasmosis and neosporosis), immune-mediated polymyositis, muscular dystrophy, polyneuropathies, and myoneural junction disorders (e.g., myasthenia gravis, tick bite paralysis, botulism).
• Other CNS disorders, especially those involving the brainstem.
• Rabies can cause dysphagia by affecting both brainstem and peripheral nerves.

RISK FACTORS
Many causative neuromuscular conditions have breed predispositions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Differentiate vomiting from regurgitation.
• Vomiting is typically associated with abdominal contractions; dysphagia is not.

CBC/BIOCHEMISTRY/URINALYSIS
• Inflammatory conditions often cause a leukocytosis, sometimes with a left shift.
• High serum creatine kinase activity is usually suggestive of a myopathy.
• May find evidence of renal disease (e.g., azotemia and low urine concentration) in patients with oral and lingual ulcers secondary to uremia.

OTHER LABORATORY TESTS
• Type 2M muscle antibody serology (masticatory muscle myositis).
• Acetylcholine receptor antibody serology (acquired myasthenia gravis).
• Antinuclear antibody serology (immune-mediated diseases).
• T_4, free T_4, thyroid-stimulating hormone (TSH), anti-thyroglobulin antibodies to rule out hypothyroidism.
• Resting cortisol and/or adrenocorticotropic hormone (ACTH) stimulation test to rule out Addison's disease.

IMAGING
• Obtain survey radiographs of thorax (3-views) and neck in all dysphagic animals for which oral cause of dysphagia has been ruled out.
• Ultrasonography of pharynx may be useful in patients with mass lesions and for obtaining ultrasound-guided biopsy specimens.
• Fluoroscopy with barium is useful in evaluating pharyngeal and esophageal motility as well as proper coordination of upper and lower esophageal sphincters.
• CT and/or MRI for suspected intracranial mass.
• Esophagram (liquid barium administered orally followed by immediate survey radiographs of the thorax) is helpful for diagnosing radiolucent esophageal foreign bodies and esophageal strictures, but is insensitive for diagnosing esophageal functional disorders.

DIAGNOSTIC PROCEDURES
• Endoscopy of nasopharynx—retroflexion of endoscope over soft palate to look for foreign bodies and evaluate esophagus and lower esophageal sphincter.
• Electromyography of skeletal musculature to confirm presence of myopathy.
• Repetitive nerve stimulation and edrophonium chloride (0.1–0.2 mg/kg IV) test for suspected myasthenia gravis.
• Cerebrospinal fluid analysis in patients with a CNS disorder.

PATHOLOGIC FINDINGS
Variable depending on underlying etiology. Myopathies can be inflammatory or dystrophic.

TREATMENT

APPROPRIATE HEALTH CARE
• Determine underlying cause to optimize therapy and outcome.
• Most patients can be managed on outpatient basis unless there are other complicating factors such as aspiration pneumonia, dehydration, or weakness.

NURSING CARE
• Supportive care may be necessary if patient is dehydrated (IV fluids).
• Other supportive modalities may be necessary in case of aspiration pneumonia (oxygen, coupage, etc.).
• For patients with generalized weakness due to myopathies, good nursing care is required, such as rotating position, good padding, and physical therapy.

ACTIVITY
Alterations in activity should be based on underlying etiology.

DIET
• Nutritional support is important for all dysphagic patients, and consistency of diet should be altered to optimize swallowing in affected animals.
• Elevating head and neck during feeding and for 10–15 minutes after feeding may help patients with esophageal disease. Consider altering consistency of diet. Dogs with cricopharyngeal muscle dysfunction are able to handle kibble better than canned food or water.
• If nutritional requirements cannot be met orally, gastrostomy tube may be necessary.

CLIENT EDUCATION
• Variable dependent on underlying cause.
• Educate the client that not all diseases can be cured, but managed.
• Changes in feeding (see above) may be long term.
• Clients should be taught to monitor for signs of possible aspiration pneumonia (mucopurulent nasal discharge, increased respiratory rate at rest, coughing, dyspnea, tachypnea).

SURGICAL CONSIDERATIONS
• Cricopharyngeal myectomy (bilateral removal) may benefit patients with cricopharyngeal muscle dysfunction; correct diagnosis is essential using videofluoroscopy before surgery, and to rule out other myopathic or neuropathic causes of dysphagia.
• Hiatal hernia surgery generally involves left-sided gastropexy with esophageal hiatal plication and esophagopexy.

MEDICATIONS

DRUG(S) OF CHOICE
Dysphagia is not immediately life-threatening; direct drug therapy at the underlying cause.

PRECAUTIONS
• Use barium sulfate with caution in patients with evidence of aspiration.
• Use corticosteroids with caution or not at all in patients with evidence of, or at risk for, aspiration.

FOLLOW-UP

PATIENT MONITORING
• Daily for signs of aspiration pneumonia (e.g., lethargy, fever, mucopurulent nasal discharge, coughing, dyspnea).
• Body condition and hydration status daily; if oral nutrition does not meet requirements, use gastrostomy tube feeding.

POSSIBLE COMPLICATIONS
Aspiration pneumonia and malnutrition.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Aspiration pneumonia.
• Megaesophagus.
• Malnutrition.

DYSPHAGIA (CONTINUED)

AGE-RELATED FACTORS

- Puppies are more likely to have congenital abnormalities such as cricopharyngeal muscle achalasia, congenital megaesophagus, vascular ring anomalies, and cleft palates.
- Puppies with vascular ring anomalies will typically present with signs of regurgitation shortly after being weaned onto solid food at 6–8 weeks of age.
- Puppies with cleft palates usually have milk or food refluxing from the nasal passage during mastication and swallowing.
- Puppies with cricopharyngeal muscle achalasia typically present with repeated bouts of swallowing, gagging, and retching during swallowing with nasal reflux of water or food.
- Puppies are more likely to ingest foreign objects that can lodge in the esophagus and cause esophagitis and stricture formation.
- Older dogs, in particular Labrador retrievers, are more likely to have esophageal dsymotility secondary to a polyneuropathy (geriatric onset laryngeal paralysis polyneuropathy or GOLPP).

ZOONOTIC POTENTIAL

- Consider rabies in any patient with oropharyngeal dysphagia, especially if animal's rabies vaccination status is unknown or questionable or it has been exposed to a potentially rabid animal.
- If a dysphagic animal dies of rapidly progressive neurologic disease, submit the head to a qualified laboratory designated by the local or state health department for rabies examination.

SEE ALSO

- Megaesophagus.
- Pneumonia, Bacterial.
- Regurgitation.

ABBREVIATIONS

- ACTH = adrenocorticotropic hormone.
- CN = cranial nerve.
- FeLV = feline leukemia virus.
- FIV = feline immunodeficiency virus.
- GOLPP = geriatric onset laryngeal paralysis polyneuropathy.
- PES = proximal esophageal sphincter.
- SLE = systemic lupus erythematosus.
- TSH = thyroid-stimulating hormone.

DYSPNEA AND RESPIRATORY DISTRESS

BASICS

DEFINITION
Dyspnea—a subjective term that in human medicine means "an uncomfortable sensation in breathing" or a sensation of air hunger; in veterinary medicine, it is used to indicate difficulty breathing or respiratory distress.

PATHOPHYSIOLOGY
Dyspnea and respiratory distress are believed to occur when the CNS notes a difference between the afferent feedback from a given efferent motor drive signal (ventilation demanded) and what the brain had anticipated would be the appropriate afferent response (ventilation achieved).

SYSTEMS AFFECTED
Respiratory

SIGNALMENT
Dogs and cats; age, breed, and sex predisposition vary with inciting cause.

SIGNS

Historical Findings
- Acute or chronic onset.
- Often associated with tachypnea, coughing, exercise intolerance, lethargy, inappetence.

Physical Examination Findings
- General signs of respiratory distress—tachypnea, increased abdominal effort, nasal flaring, open-mouth breathing, cyanosis, orthopnea (neck extension, elbow abduction), altered mentation; other signs depend on underlying cause.
- Nasal disease—stertor, nasal discharge, lack of airflow through nostrils; dyspnea improves with open-mouth breathing.
- Upper airway/laryngeal disease—stridor, panting, cough, hyperthermia, dysphonia, respiratory effort and noise on inspiration, fixed obstruction such as a mass or foreign body in a large airway: dyspnea on inspiration and expiration.
- Tracheal collapse—honking cough, tracheal sensitivity, respiratory effort and noise: inspiratory effort if cervical tracheal collapse, expiratory effort if intrathoracic tracheal collapse.
- Lower airway disease—cough, expiratory wheezes on auscultation, abdominal effort.
- Pulmonary parenchymal disease—may have crackles, harsh or moist lung sounds on auscultation.
- Pneumonia—fever, may have tracheal sensitivity.
- Cardiogenic pulmonary edema—heart murmur, arrhythmia, hypothermia, pale mucous membranes, prolonged capillary refill time.
- Pleural space disease—diminished breath sounds: ventrally—fluid; dorsally—air; unilaterally—space-occupying lesions or pyothorax/chylothorax. Paradoxical respiratory pattern (inward movement of the abdominal wall during inspiration).
- Thoracic wall disease—can have paradoxical respiratory pattern, visible or palpable trauma (open pneumothorax, flail chest).
- Pulmonary thromboembolism (PTE)—may have clinical signs of underlying disease predisposing to thrombosis, e.g., hyperadrenocorticism, immune-mediated hemolytic anemia (IMHA), systemic inflammatory response syndrome (SIRS)/sepsis, protein-losing nephropathy (PLN), protein-losing enteropathy (PLE), neoplasia.
- Other signs will pertain to the underlying disease, e.g., shock, trauma.

CAUSES & RISK FACTORS

Upper Airway Disease
- Nasal obstruction—stenotic nares, nasopharyngeal polyp or stenosis, infection, inflammation, neoplasia, trauma, foreign body, coagulopathy.
- Pharynx—elongated soft palate, foreign body, neoplasia, granuloma, stenosis.
- Larynx—laryngeal paralysis, everted laryngeal saccules, edema, collapse, foreign body, neoplasia, inflammation, trauma, webbing.
- Trachea—collapse, stenosis, trauma, foreign body, neoplasia, parasites, extraluminal compression (lymphadenopathy, enlarged left atrium, heart-base tumors).

Lower Airway Disease
Allergic disease, inflammatory, infectious (*Mycoplasma*), parasitic, neoplastic (bronchogenic carcinoma).

Pulmonary Parenchymal Disease
- Edema—cardiogenic or noncardiogenic.
- Pneumonia—infectious; parasitic; aspiration; eosinophilic; interstitial.
- Neoplasia (primary or metastatic).
- Inflammatory— acute respiratory distress syndrome (ARDS); uremic pneumonitis; smoke inhalation.
- Hemorrhage—trauma; coagulopathy.
- PTE—IMHA; PLN, PLE; heartworm disease; hyperadrenocorticism; neoplasia.
- Others—lung lobe torsion, atelectasis.

Pleural Space Disease
- Pneumothorax—traumatic; iatrogenic; secondary to pulmonary parenchymal disease; ruptured bulla; migrating foreign body; primary spontaneous (no underlying cause).
- Pleural effusion—transudates, exudates; hemothorax; chylothorax.
- Soft tissue—neoplasia; diaphragmatic hernia.
- Fibrosing pleuritis.

Thoracic Wall Disease
- Open pneumothorax—trauma.
- Flail segment—trauma.
- Neoplasia.
- Paralysis due to cervical spinal disease, botulism, polyradiculoneuritis, tick bite paralysis, myasthenia gravis, elapid snake envenomation, hypokalemia.

Diaphragmatic Disease
- Trauma—rupture; hernia.
- Phrenic nerve disease.
- Neoplasia.
- Fibrosis.

Abdominal Distention
Organomegaly—hyperplasia; neoplasia, pregnancy; obesity; ascites; gastric dilatation, torsion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Inspiratory dyspnea—suggests extrathoracic upper airway disease.
- Expiratory dyspnea—suggests intrathoracic airway disease.
- Dyspnea on inspiration and expiration can occur with fixed upper airway obstructions and severe intrathoracic disease.
- Congestive heart failure—murmur, arrhythmia, tachycardia, poor pulse quality, jugular pulses, hypothermia, crackles on auscultation, fluid dripping from nose.

CBC/BIOCHEMISTRY/URINALYSIS
- Anemia—can cause nonrespiratory dyspnea.
- Polycythemia—chronic hypoxia.
- Inflammatory leukogram—pneumonia, pneumonitis, pyothorax.
- Eosinophilia—hypersensitivity or parasitic airway disease.
- Thrombocytosis—hyperadrenocorticism predisposes to PTE.
- Sodium : potassium ratio <27—can be seen with pleural or abdominal effusions.
- Azotemia—if severe may lead to uremic pneumonitis.
- Proteinuria—can predispose to PTE.
- Multiple organ dysfunction—ARDS.
- Hypoproteinemia—may suggest protein-losing disease that can predispose to PTE or pleural effusion.

OTHER LABORATORY TESTS
- Pleural fluid analysis.
- Fecal examination for parasites if indicated
- Serum antigen or antibody titers—heartworm, toxoplasmosis, distemper, feline leukemia virus (FeLV), feline immunodeficiency virus (FIV).
- Increased urine protein : creatinine ratio with PLN could indicate loss of antithrombin and hypercoagulability resulting in PTE.
- PaO_2—partial pressure of oxygen dissolved in arterial blood; normoxemia: PaO_2 80–120 mmHg (room air, sea level); hypoxemia: PaO_2 <80 mmHg; FIO_2—fraction of inspired oxygen ranges from 0.21 (room air) to 1.0; PaO_2/FIO_2 ratio—measure

DYSPNEA AND RESPIRATORY DISTRESS (CONTINUED)

of lung efficiency during oxygen therapy; PaO_2/FIO_2 ≥400—normal lung efficiency; 300–400—mild insufficiency; 200–300—moderate insufficiency; <200—severe insufficiency. Reduction in lung efficiency can be due to venous admixture, hypoventilation, low inspired oxygen.
• $PaCO_2$ or $PvCO_2$—partial pressure of CO_2 dissolved in arterial or venous blood; measure of ventilation; normal 30 mmHg <PCO_2 <40 mmHg. PCO_2 > 45 mmHg = hypercapnia = hypoventilation = decreased alveolar minute ventilation (MV).
• Coagulation testing—if suspect hemothorax and/or pulmonary hemorrhage.
• Plasma NT-proBNP and cardiac troponin-I (cTNI) concentrations may aid in differentiation of cardiac and noncardiac causes of dyspnea.

IMAGING

• Cervical and thoracic radiography—upper airway disease: soft palate elongation, large airway narrowing, lymphadenopathy, intraluminal abnormalities. Lower airway disease: bronchial thickening, middle lung lobe consolidation (cats), atelectasis, hyperinflation, and diaphragmatic flattening (primarily cats). Pneumonia: alveolar infiltrates; aspiration pneumonia usually cranioventral distribution or middle lobe affected. Cardiogenic pulmonary edema: enlarged cardiac silhouette, pulmonary venous distention, enlarged left atrium with perihilar pulmonary infiltrates in dogs; infiltrates can be of any distribution in cats. Noncardiogenic pulmonary edema: usually caudodorsal distribution. ARDS: diffuse, symmetric alveolar infiltrates. Pulmonary vascular abnormalities: PTE, heartworm disease. Pleural space disease: pneumothorax, pleural effusion, mass lesions, diaphragmatic hernias. Thoracic wall disease: rib fractures, neoplasia.
• Thoracic ultrasonography—evaluation of distribution of pleural effusion, pneumothorax (absence of "glide sign"), and parenchymal disease (presence of "comet tail" artifact). Pulmonary mass identification: guide fine-needle aspiration; mediastinal evaluation.
• Echocardiography—evaluate cardiac function and chamber size if cardiogenic pulmonary edema or pleural effusion suspected; elevated pulmonary artery pressure, right ventricular overload with ventricular septal flattening can support diagnosis of PTE; visualize heart-based masses.
• Abdominal radiography or ultrasound—evaluation of abdominal distention.
• Fluoroscopy—evaluate tracheal and bronchial collapse; evaluate diaphragmatic function.
• CT—airway, pulmonary parenchymal, and pleural space disease can be evaluated; can detect lesions not clearly defined on radiographs.
• Pulmonary vascular angiography—gold standard for diagnosis of PTE.
• Ventilation perfusion scintigraphy—abnormal perfusion scan is considered supportive of PTE.

DIAGNOSTIC PROCEDURES

• Pulse oximetry—SpO_2; peripheral capillary hemoglobin oxygen saturation. The relationship between PaO_2 and SpO_2 is defined by the oxygen hemoglobin dissociation curve: PaO_2 of 60 mmHg = SpO_2 of 90%; PaO_2 of 80 mmHg = SpO_2 of 95%; PaO_2 of >100 mmHg = SpO_2 of 100%. Below 95%, small changes in SpO_2 signify large changes in PaO_2. SpO_2 measurements in animals on high inspired oxygen lack sensitivity.
• Thoracentesis—fluid analysis and culture.
• Laryngoscopy/nasopharyngoscopy/tracheoscopy—evaluate upper airway; laryngeal paralysis, tracheal collapse, foreign bodies, masses.
• Bronchoscopy—evaluate upper and lower airways; perform bronchoalveolar lavage for cytology and culture. Requires anesthesia, perform only when stabilized.

TREATMENT

APPROPRIATE HEALTH CARE

• Inpatient care until the cause is identified and treated or determined not to be life-threatening; therapy dependent on underlying cause.
• *Always* administer oxygen and keep patient in sternal recumbency until ability to oxygenate is determined.
• May require intubation and positive-pressure ventilation in patients with severe respiratory distress refractory to oxygen therapy.
• Upper airway disease—use sedation to reduce respiratory effort. Check body temperature and actively cool patients as needed.
• Lower airway disease—bronchodilators; systemic corticosteroids may be required to stabilize cats with acute bronchoconstriction.
• Pulmonary parenchymal disease—antibiotics if pneumonia; treat coagulation disorders; cardiogenic edema requires furosemide ± vasodilators. Noncardiogenic edema requires oxygen therapy, may require positive-pressure ventilation.
• Pleural space disease—thoracocentesis for air and fluid. Place a chest tube if repeated thoracocentesis is necessary to keep patient stable.
• Thoracic wall disease—surgery as indicated, particularly if open chest wound is present; flail chest may require surgery if medical management fails or there is a severe displacement of fractures. Thoracic wall paralysis/muscle fatigue: positive-pressure ventilation if severely hypercapnic.
• Abdominal distention—drain ascites as needed; relieve gastric distention.

NURSING CARE

• Oxygen therapy via cage, nasal cannula, Elizabethan collar covered in plastic wrap, mask, or flow-by. Humidify oxygen source if giving oxygen therapy for more than a few hours.
• Maintain in sternal recumbency and turn hips every 3–4 hours if patient cannot tolerate lateral recumbency.
• Monitor temperature regularly, as excess work of breathing results in hyperthermia, which augments respiratory distress.

DIET

Weight-reducing diet if obesity is a contributing cause.

SURGICAL CONSIDERATIONS

• Anesthesia must be carefully tailored to the patient. Securing an airway is essential and rapid intravenous induction is important. The ability to positive-pressure ventilate patients is often required.
• Animals with upper airway obstruction are fragile and can rapidly decompensate. Have multiple-sized endotracheal tubes available.
• Dyspnea associated with a laryngeal mass can respond to debulking surgery, but edema and hemorrhage can lead to worsened obstruction. Warn owners of increased likelihood of aspiration pneumonia complications in animals with laryngeal disease.
• Avoid positive-pressure ventilation in patients with a closed pneumothorax. Must monitor oxygenation status of anesthetized patients with pulse oximetry and when possible arterial blood gases.

MEDICATIONS

DRUG(S) OF CHOICE

Varies with underlying cause (see Appropriate Health Care).

FOLLOW-UP

PATIENT MONITORING

• Patients receiving oxygen therapy can be monitored by assessing the degree of respiratory effort. As the animal stabilizes, perform a room air trial and reevaluate the level of respiratory difficulty. Arterial and venous blood gases can be a useful assessment.
• Pulse oximetry is an effective and noninvasive tool for monitoring patients on room air.
• Repeat radiographs are often indicated in assessing pulmonary parenchymal disease and pleural space disease.

DYSTOCIA

BASICS

DEFINITION
Difficult birth.

PATHOPHYSIOLOGY
- Dystocia may occur due to maternal or fetal factors and may occur during any stage of labor.
- May be caused by abnormal fetal presentation, posture, or position.
- Normal stages of labor:

Stage 1
- Onset of uterine contractions and relaxation of cervix; ends with rupture of first chorioallantoic sac—averages 6–12h (up to 36h in primiparous bitch).
- Bitch—may be restless, nervous, shiver, pant, pace, and nest.
- Queen—tend to vocalize initially; purr and socialize as Stage 1 progresses.

Stage 2
- Delivery of fetuses.
- Bitch—obvious abdominal contractions; beginning of stage 2 to delivery of first offspring usually <4h; average time to delivery of subsequent fetus 20–60 min (may be as long as 2–3h).
- Queen—average length of parturition 16h, with range of 4–42h (up to 3 days in some cases); important to consider this variability when intervening.
- Number of fetuses present may significantly affect length of stages 2 and 3.

Stage 3
- Delivery of fetal membranes.
- May alternate between stage 2 and 3 with multiple fetuses.

INCIDENCE/PREVALENCE
- Dog—incidence unknown due to breed variability and breeder intervention.
- Cat—3.3–5.8% of parturitions; mixed-breed cats 0.4%, higher in pedigree cats, to 18.2% in Devon Rex.

SIGNALMENT

Breed Predilections

Dogs
- Higher incidence with miniature and small breeds (small litter size, concurrent large fetal size); may occur in large breeds with large or singleton litters.
- Brachycephalic breeds—broad head and narrow pelvis.
- Large fetal head : maternal pelvis ratio—Sealyham terrier, Scottish terrier.
- Uterine inertia—Scottish terrier, dachshund, border terrier, Aberdeen terrier, Labrador retriever.
- Other breeds with increased incidence of dystocia—chihuahua, dachshund, Pekingese, Yorkshire terrier, miniature poodle, Pomeranian.

Cats

Brachycephalic (Persian, Himalayan) or dolichocephalic (Devon Rex) breeds.

SIGNS

Historical Findings
- More than 30 min of persistent, strong, abdominal contractions without fetal delivery.
- More than 4h from onset of stage 2 to delivery of first fetus (bitch).
- More than 2h between delivery of fetuses (bitch).
- Failure to commence stage 1 labor within 24h of rectal temperature drop below 37.2 °C (99 °F) or within 36h of serum progesterone concentration <2 ng/mL (bitch).
- Female cries, displays signs of pain, and constantly licks vulvar area when contracting.
- Prolonged gestation—more than 72 days from day of first mating (bitch); more than 59 days from first day of cytologic diestrus (bitch); more than 66 days from luteinizing hormone (LH) peak (bitch); more than 68 days from last day of mating (queen).

Physical Examination Findings
- Presence of greenish-black discharge (uteroverdin) preceding birth of first fetus by more than 2h or increasing amounts before delivery of first fetus.
- Bloody discharge prior to delivery of first fetus.
- Diminished or absent Ferguson's reflex (stimulation or pressure to dorsal vaginal wall to elicit abdominal straining: "feathering") indicates uterine inertia.

CAUSES

Fetal
- Oversize; fetal monsters, fetal anasarca, fetal hydrocephalus, prolonged gestation due to inability of singleton fetus to initiate labor.
- Abnormal presentation, position, or posture of fetus in birth canal.
- Fetal death.

Maternal
- Inadequate uterine contractions (primary or secondary uterine inertia)—myometrial defect, hypocalcemia electrolyte imbalance, psychogenic disturbance, exhaustion.
- Ineffective abdominal press—pain, fear, debility (exhaustion), diaphragmatic hernia, age.
- Placentitis, metritis, endometritis.
- Pregnancy toxemia, gestational diabetes.
- Abnormal pelvic canal—previous pelvic injury, abnormal conformation, pelvic immaturity.
- Congenitally small pelvis—Welsh corgis, brachycephalic breeds.
- Inguinal hernia.
- Abnormality of vaginal vault—stricture, septae, vaginal hyperplasia, hypoplastic vagina, intra- or extraluminal cysts, neoplasia.
- Abnormal vulvar opening—stricture, fibrosis from trauma, neoplasia.
- Insufficient cervical dilation.
- Lack of adequate lubrication.
- Uterine torsion.
- Uterine rupture.
- Uterine neoplasia, cysts, or adhesions.

RISK FACTORS
- Age.
- Brachycephalic and toy breeds.
- Persian, Himalayan, and Devon Rex breeds.
- Obesity.
- Abrupt changes in peripartum environment.
- Previous history of dystocia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Uterine inertia—hypocalcemia versus hypoglycemia.

Physical Examination
- Complete physical examination—careful abdominal palpation to confirm presence of fetuses.
- Digital vaginal examination—fetus or fetal membranes in vaginal canal, assess maternal pelvic canal, Ferguson's reflex.
- Bitch unresponsive to oxytocin or lacking Ferguson's reflex—uterine inertia more likely than obstructive dystocia unless obstructed for several hours.

CBC/BIOCHEMISTRY/URINALYSIS
Minimum database—packed cell volume (PCV), total protein, serum glucose, urea nitrogen, and calcium (ionized preferable to total concentration corrected for albumin) concentrations. Pregnant females have mild anemia.

OTHER LABORATORY TESTS
Serum progesterone concentration.

IMAGING
- Radiography—determine pelvic conformation, number and position of fetuses, evidence of fetal obstruction, oversize, or death.
- Fetal death—collapse of fetal skeletons, abnormal association of fetal bones to axial skeleton, presence of air/gas surrounding fetus, fetal balling.
- Ultrasonography—recommended for monitoring fetal viability, heart rate (fetal heart rate <180 bpm indicates fetal stress, >260 bpm indicates need for close monitoring), placental separation, and character of fetal fluids (presence of meconium or blood in amniotic fluid).

TREATMENT

APPROPRIATE HEALTH CARE
- Inpatient—until delivery of all fetuses and dam is stable.
- Treat hypoglycemia and hypocalcemia.
- Uterine inertia—medical treatment if no evidence of fetal stress.

• Ecbolic agents contraindicated with possible obstructive dystocia—may accelerate placental separation and fetal death or cause uterine rupture.
• WhelpWise® tocodynamometer monitors fetal heart rates and uterine contraction patterns; useful for bitches with large litters or history of uterine inertia to determine need for intervention.

Manual Delivery

Fetus lodged in vaginal vault:
• Lubricate liberally.
• Digital manipulation—least amount of damage to fetus and dam. Apply traction in postero-ventral direction.
• Instrument delivery not recommended due to inadequate space—may mutilate fetus or lacerate dam.
• Never apply traction to distal extremities or tail of a live fetus.
• Failure to deliver fetus located in vaginal canal within 30 min—Cesarean section (C-section) indicated.

SURGICAL CONSIDERATIONS

• Indications for C-section—uterine inertia unresponsive to oxytocin or uterine inertia with more than four fetuses remaining in utero (maximizes fetal survivability), pelvic or vaginal obstruction, inability to correct fetal malposition, fetal oversize, fetal stress, in utero fetal death.
• Elective C-section—breeds prone to dystocia, bitches with a history of dystocia, bitches with singleton or large litter size, performed to maximize fetal survivability.

General Comments

• Provide fluid therapy with balanced electrolyte solution before, during, and after surgery.
• Gravid uterus can compress great vessels and place pressure on diaphragm, compromising venous return and tidal volume.
• Preoxygenation of patient before anesthesia is indicated.
• Anesthetic protocol for C-section:
  ◦ Premedication can include glycopyrrolate (bitches, queens: 0.01 mg/kg IV/IM) if fetal heart rates are normal; or atropine (bitches, queens: 0.04 mg/kg IM) if fetal bradycardia present.
  ◦ Alpha-2 agonist agents (xylazine, dexmedetomidine) are contraindicated.
  ◦ Rapidly acting induction agents include propofol or alfaxalone; ketamine may cause dose-dependent neonatal respiratory and neurologic depression; severely depressed or exhausted patients may be induced with combination of opioid and benzodiazepine with supplemental propofol or alfaxalone for intubation, if needed.
  ◦ Maintenance may include inhalant anesthetics or propofol IV CRI.
  ◦ Use of a midline lidocaine line block (1–2 mg/kg SC) can decrease inhalant anesthetic requirement.
• Epidural—0.5% bupivacaine (0.2 mg/kg) and preservative-free morphine (0.1 mg/kg) or 2% lidocaine (2–4 mg/kg).
• Postoperative analgesia may be provided with opioids, although they are excreted in the milk to varying degrees.
• Reversal agents—repeated dosing may be necessary until neonate has processed all anesthetic drugs:
  ◦ Opioids used during anesthesia can be reversed in neonate with naloxone (0.04 mg/kg IV/IM/SC/sublingual/intranasal).
  ◦ Benzodiazepines used during anesthesia can be reversed in neonate with flumazenil (0.01 mg/kg IV/IM/SC/sublingual/intranasal).

MEDICATIONS

DRUG(S) OF CHOICE

• Hypoglycemia—treat prior to hypocalcemia:
  ◦ Bolus 0.5 g/kg IV (diluted 1 : 3).
  ◦ Add 5% dextrose to balanced electrolyte solution and infuse IV at 60–80 mL/kg/day.
• Hypocalcemia:
  ◦ Bitch—10% calcium gluconate 0.2 mL/kg IV over 10 min; monitor for bradycardia. Repeat q4–6h as needed.
  ◦ May also be given SC at a dose of 0.5 mL/4.5 kg diluted 1:1 with sterile saline. If using 23% solution, dilute at least 1:3 prior to administration.
  ◦ Queen—10% calcium gluconate 0.5–1.0 mL/cat IV over 10 min—use with caution; risk of uterine rupture increased due to strong uterine contractions following calcium.
• Oxytocin—once calcium and glucose deficits are treated: microdose at 0.5–3.0 IU IM/SC depending on size of bitch and response to treatment. May repeat q30 min as long as delivery progresses. Consider C-section if more than three doses of oxytocin per fetus are required or more than four fetuses remain.

CONTRAINDICATIONS

Oxytocin—contraindicated with obstructive dystocia, fetal stress, longstanding in utero fetal death, uterine rupture, uterine torsion.

FOLLOW-UP

PREVENTION/AVOIDANCE

• Schedule elective C-section for bitches with abnormal pelvic canal, anatomic abnormalities, predisposition to dystocia, previous history of uterine inertia.
• Scheduling surgery—extremely important that D1 diestrus, LH peak, or ovulation is identified during breeding to ensure acceptable fetal survivability. If ovulation timing is not available, ultrasonographic gestational aging and maturation assessment is necessary.

EXPECTED COURSE AND PROGNOSIS

• If dystocia is identified promptly and intervention is successful—good to fair for survival of dam; fair for fetuses.
• If dystocia unrecognized or untreated for 24–48h—poor to guarded for life of dam; fetal survival unlikely.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Dystocia may or may not impact future fertility, but may recur depending on cause. Resolution of dystocia by C-section does not preclude natural whelping for future deliveries.

SEE ALSO

• Breeding, Timing.
• Uterine Inertia.
• Vaginal Malformations and Acquired Lesions.

ABBREVIATIONS

• C-section = Cesarean section.
• LH = luteinizing hormone.
• PCV = packed cell volume.

DYSURIA, POLLAKIURIA, AND STRANGURIA

BASICS

DEFINITION
- Dysuria—difficult or painful urination.
- Pollakiuria—voiding small quantities of urine with increased frequency.
- Stranguria—straining to urinate.

PATHOPHYSIOLOGY
The urinary bladder and urethra normally serve as a reservoir for urine. Inflammatory and noninflammatory disorders of the lower urinary tract including the urethral orifice may decrease bladder compliance and storage capacity by damaging structural components of the bladder wall or by stimulating sensory nerve endings located in the bladder or urethra. Sensations of bladder fullness, urgency, and pain stimulate premature micturition and reduce functional bladder capacity. Dysuria and pollakiuria are caused by lesions of the urinary bladder and/or urethra and provide unequivocal evidence of lower urinary tract disease; these clinical signs do not exclude concurrent involvement of the upper urinary tract or disorders of other body systems. Stranguria may be caused by bladder, intraluminal, and extraluminal urethral disease.

SYSTEMS AFFECTED
Renal/urologic/pelvic structures—bladder, urethra, prostate gland, colon, others.

SIGNALMENT
Dog and cat.

CAUSES

Urinary Bladder
- Urinary tract infection (UTI)—bacterial, fungal, mycoplasmal, parasitic, or viral.
- Cystolithiasis.
- Neoplasia—e.g., transitional cell carcinoma.
- Trauma.
- Anatomic abnormalities—e.g., ureterocele/urethrocele, ectopic ureter, persistent uterus masculinus, perineal hernias containing the urinary bladder, and spay granulomas.
- Detrusor atony—e.g., chronic partial obstruction, neurologic damage, and dysautonomia.
- Chemicals/drugs—e.g., cyclophosphamide.
- Iatrogenic—e.g., catheterization, palpation, reverse flushing, overdistension of the bladder during contrast radiography, urohydropropulsion, urethrocystoscopy, and surgery/interventional hardware (e.g., ureteral stent, subcutaneous ureteral bypass, stent, hydraulic occluder).
- Idiopathic—e.g., feline idiopathic cystitis.

Urethra
- UTI—see above.
- Urethrolithiasis—see above.
- Urethral plugs—e.g., matrix and matrix-crystalline.
- Neoplasia—see above; local invasion by malignant neoplasms of adjacent structures.
- Trauma.
- Anatomic anomalies—e.g., congenital or acquired strictures, urethrorectal fistulas, pseudohermaphrodites.
- Urethral sphincter hypertonicity—e.g., upper motor neuron spinal cord lesions, reflex dyssynergia, urethral spasm/urethritis.
- Proliferative urethritis—secondary to chronic UTI.

Prostate Gland
- Prostatitis, prostatic, or paraprostatic cyst or prostatic abscess.
- Neoplasia—adenocarcinoma, transitional cell carcinoma.

RISK FACTORS
- Diseases, diagnostic procedures, or treatments that alter normal host urinary tract defenses and predispose to infection, predispose to formation of uroliths, or damage urothelium or other tissues of lower urinary tract.
- Mural or extramural diseases that compress bladder or urethral lumen.
- Diseases that encourage repeated urination despite full void such as juvenile vaginitis may present as stranguria.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differentiating from Other Abnormal Patterns of Micturition
- Polyuria—increased frequency and volume of urine >2 mL/kg/h and urine specific gravity <1.025.
- Rule out urethral obstruction—anuria, overdistended urinary bladder, signs of postrenal uremia.
- Urinary incontinence—involuntary urination, urine dribbling, enuresis, incomplete bladder emptying.
- Behavioral causes.

Differentiate Causes of Dysuria, Pollakiuria, Stranguria
- Rule out UTI—hematuria; malodorous or cloudy urine; small, painful, thickened bladder (also evaluate for mineralization or gas in wall).
- Rule out urolithiasis—hematuria; palpable uroliths in urethra or bladder.
- Rule out neoplasia—hematuria; palpable masses in urethra or bladder.
- Rule out neurogenic disorders—flaccid bladder wall; residual urine in bladder lumen after micturition; other neurologic deficits to hind legs, tail, perineum, and anal sphincter.
- Rule out prostatic diseases—urethral discharge, prostatomegaly, pyrexia, depression, tenesmus, caudal abdominal pain, stiff gait.
- Rule out colorectal disease for stranguria.
- Rule out cyclophosphamide cystitis—history.
- Rule out iatrogenic disorders—history of catheterization, reverse flushing, contrast radiography, urohydropropulsion, urethrocystoscopy, or surgery/complications from interventional devices.

CBC/BIOCHEMISTRY/URINALYSIS
- Results of bloodwork often normal. Lower urinary tract disease complicated by urethral obstruction may be associated with azotemia, hyperphosphatemia, acidosis, and hyperkalemia. Patients with concurrent pyelonephritis may have impaired urine-concentrating capacity, leukocytosis, azotemia, and thrombocytopenia if ureteral obstruction occurs concurrently. Patients with acute prostatitis or prostatic abscesses may have leukocytosis, discospondylitis, and/or heart murmur. Dehydrated patients may have elevated total plasma protein.
- Disorders of urinary bladder are best evaluated with urine specimen collected by cystocentesis. Urethral disorders best evaluated with mid-catch voided urine sample or by comparison of results of analysis of voided and cystocentesis samples. (Caution: cystocentesis may induce hematuria.)
- Pyuria, hematuria, and proteinuria indicate urinary tract inflammation, but are nonspecific findings that may result from infectious and noninfectious causes of lower urinary tract disease.
- Identification of bacteria, fungi, or parasite ova in urine sediment suggests, but does not prove, that UTI causing or complicating lower urinary tract disease. Consider contamination of urine during collection and storage when interpreting urinalyses.
- Identification of neoplastic cells in urine sediment indicates urinary tract neoplasia. Use caution in establishing diagnosis of neoplasia based on urine sediment examination. Urinary tract inflammation or extremes in urine pH or osmolality can cause epithelial cell atypia that is difficult to differentiate from neoplasia. Follow up with traumatic catheterization, cystoscopic biopsies, or urine BRAF assay.
- Crystalluria occurs in normal patients, patients with urolithiasis, or patients with lower urinary tract disease unassociated with uroliths. Interpret significance of crystalluria cautiously.
- Hematuria, proteinuria, and variable crystalluria occur in cats with nonobstructive idiopathic cystitis. Significant pyuria is rare.

OTHER LABORATORY TESTS
- Quantitative urine culture—most definitive means of identifying and characterizing bacterial UTI. If not affordable then rapid culture can still be performed for species identification at limited cost.

(CONTINUED) DYSURIA, POLLAKIURIA, AND STRANGURIA

• Cytologic evaluation of urine sediment, prostatic fluid, urethral or vaginal discharges, or biopsy specimens obtained by catheter or needle aspiration—may help in evaluating patients with localized urinary tract disease; may establish definitive diagnosis of urinary tract neoplasia, but cannot rule it out.

IMAGING

Survey abdominal radiography, urinary tract ultrasonography, cystoscopy, and fluoroscopic urography are important means of identifying and localizing causes of dysuria, pollakiuria, and stranguria.

DIAGNOSTIC PROCEDURES

• Use cystoscopy in patients with persistent lesions of lower urinary tract for which no definitive diagnosis has been established by other, less invasive means.
• Use light microscopic evaluation of tissue biopsy specimens from patients with persistent lesions of urinary tract. Tissue specimens may be obtained by traumatic catheterization, cystoscopy and biopsy, or surgery.

TREATMENT

• Patients with nonobstructive lower urinary tract diseases typically managed as outpatients; diagnostic evaluation may require brief hospitalization.
• Dysuria, pollakiuria, and stranguria associated with systemic signs of illness (e.g., pyrexia, depression, anorexia, vomiting, and dehydration) or laboratory findings of azotemia or leukocytosis warrant aggressive diagnostic evaluation and initiation of supportive and symptomatic treatment.
• Treatment depends on underlying cause and specific sites involved.
• Clinical signs of dysuria, pollakiuria often resolve rapidly following specific treatment of underlying cause(s). If not related to infection, stranguria may be more challenging to resolve.

MEDICATIONS

DRUG(S) OF CHOICE

• Patients with urge incontinence, severe or persistent signs, or untreatable lower urinary tract disease may benefit from symptomatic therapy with propantheline or oxybutynin that may reduce the force and frequency of uncontrolled detrusor contractions.
• Propantheline—dogs: 0.2 mg/kg PO q6–8h; cats: 0.25–0.5 mg/kg PO q12–24h. Oxybutynin—dogs: 0.2 mg/kg PO q8–12h; cats: 0.5–1.25 mg/cat PO q8–12h.
• Stranguria due to physiologic causes may be treated with prazosin in female dogs or cats, or in male dogs or cats with tamsulosin. If secondary to inflammation, meloxicam or carprofen can be utilized (caution with elevated liver values and azotemia), although short-term catheterization may also be warranted.
• Patients with transitional cell carcinoma of the urinary bladder or urethra may be treated with piroxicam (0.3 mg/kg PO q24h), which reduces the severity of clinical signs, improves quality of life, and in some cases induces tumor remission. Chemotherapeutic and radiation oncology treatment options are also available, as is urethral stenting.

CONTRAINDICATIONS

• Glucocorticoids or other immunosuppressive agents in patients suspected of having urinary or genital tract infection.
• Potentially nephrotoxic drugs (e.g., gentamicin) in patients that are febrile, dehydrated, or azotemic or that are suspected of having pyelonephritis, septicemia, or preexisting renal disease.

EAR MITES

BASICS

OVERVIEW
Otodectes cynotis mites infest primarily the external ear canal and cause variable degrees of otic discharge and pruritus.

SIGNALMENT
- Common in young dogs and cats, although it may occur at any age.
- No breed or sex predilection.

SIGNS
- Pruritus is usually present, but can be minimal.
- Pruritus primarily located around the ears, head, and neck; occasionally generalized.
- Thick, red-brown, or black otic exudate ("coffee grounds" appearance)—usually seen in the outer ear.
- Otic exudate and pruritus demonstrate individual variability.
- Crusting and scales may occur on the neck, rump, and tail (dogs).
- Excoriations on the convex surface of the pinnae often occur, owing to the intense pruritus.

CAUSES & RISK FACTORS
Otodectes cynotis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Pediculosis.
- *Pelodera* dermatitis.
- Sarcoptic mange.
- Notoedric mange.
- Chiggers.
- Otitis externa secondary to allergy/hypersensitivity.
- Flea bite hypersensitivity.

CBC/BIOCHEMISTRY/URINALYSIS
Normal

OTHER LABORATORY TESTS
N/A

DIAGNOSTIC PROCEDURES
- Ear swabs placed in mineral oil—usually effective means of identification.
- Skin scrapings—may identify mites if signs are generalized.
- Mites may be visualized in external ear canal.
- Diagnosis may be made by response to treatment.

TREATMENT
- Outpatient.
- Diet and activity—no alteration necessary.
- Very contagious—all animals in contact with the affected animal must be treated.
- Thoroughly clean and treat the environment.

MEDICATIONS

DRUG(S) OF CHOICE
- Ears should be thoroughly cleaned with a commercial ear cleaner.
- Otic parasiticides should be used for 7–10 days to eradicate mites and eggs; effective topical commercial products contain pyrethrins, thiabendazole, ivermectin, and milbemycin; treat during alternative weeks for two to three treatment cycles recommended to prevent reinfestation from eggs.
- Selamectin—per label instructions or repeated at 2 weeks.
- Imidacloprid/moxidectin (Advantage Multi/Advocate)—per label instructions.
- Ivermectin—200–300 µg/kg PO (three treatments) or SC (two treatments) at 14-day intervals; non-FDA-approved usage.
- Isoxazolines—per label instructions; non-FDA-approved usage.
- Flea treatments should be applied to animal for elimination of ectopic mites.
- Mites may persist in the environment; environmental treatment may be helpful.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Ivermectin and moxidectin—sensitivity in ABCB-1 mutant dogs; do not use orally or by injection in collies, shelties, their crosses, or other herding breeds; use only if absolutely necessary in animals <6 months of age; an increasing number of toxic reactions have been reported in kittens.
- Ivermectin and milbemycin—cause elevated levels of monoamine neurotransmitter metabolites, which could result in adverse drug interactions with amitraz and benzodiazepines.
- Isoxazolines—use with caution in pets with previous history of seizures.

FOLLOW-UP
- Ear swab and physical examination should be done 1 month after therapy commences.
- Prognosis is good.
- If signs persist after treatment, an additional, underlying cause may be present.
- Repeat infestation indicates an uncontrolled source of mites.

MISCELLANEOUS

ZOONOTIC POTENTIAL
Transient papular dermatitis in human beings.

ECLAMPSIA

BASICS

OVERVIEW
- Postparturient hypocalcemia.
- Usually develops 1–4 weeks postpartum; may occur at term, prepartum, or during late lactation.
- Hypocalcemia alters cell membrane potentials, causing spontaneous discharge of nerve fibers and tonic–clonic contraction of skeletal muscles.
- Life-threatening tetany and convulsions, leading to hyperthermia.
- Cerebral edema possible.

SIGNALMENT
- Dog—postpartum bitch; most common in toy breeds; higher incidence with first litter.
- Most common prior to day 40 postpartum; occasionally occurs prepartum.
- Breeds at increased risk—chihuahua, miniature pinscher, shih tzu, miniature poodle, Xoloitzcuintli, Pomeranian.
- Cat—rare.

SIGNS

Historical Findings
- Poor mothering.
- Restlessness, nervousness.
- Panting, whining.
- Vomiting, diarrhea.
- Ataxia, stiff gait, limb pain.
- Facial pruritis.
- Muscle tremors, tetany, convulsions.
- Recumbency, extensor rigidity—usually seen 8–12 hours after onset of signs.

Physical Examination Findings
- Hyperthermia.
- Rapid respiratory rate.
- Dilated pupils, sluggish pupillary light responses.
- Muscle tremors, muscular rigidity, convulsions.

CAUSES & RISK FACTORS
- Calcium supplementation during gestation, including dairy products.
- Inappropriate Ca : P ratio in gestational diet.
- Low bodyweight : litter size ratio.
- Poor prenatal nutrition.
- First litter.
- Large litter size.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Hypoglycemia—may be concurrent; hypoglycemia alone does not cause muscular rigidity.
- Toxicosis—distinguished by signalment and history.
- Epilepsy or other neurologic disorder—differentiated by signalment; calcium concentration diagnostic.

CBC/BIOCHEMISTRY/URINALYSIS
- Total serum calcium <9 mg/dL in bitches; <8 mg/dL in queens.
- Although ionized calcium (<2.4–3.2 mg/dL) is the form important for normal neuromuscular function, measurement of total serum calcium is usually sufficient for diagnosis.
- Hypoglycemia—may be concurrent.
- Hypomagnesemia has been reported in 44% of affected bitches; may promote tetany.
- Serum potassium elevated in 56% of cases, due to metabolic acidosis or respiratory alkalosis.

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
ECG may show prolonged QT interval, bradycardia, tachycardia, or ventricular premature complexes.

TREATMENT
- Emergency inpatient.
- Hyperthermia—cool by wetting haircoat and exposing to breeze from fan.
- Puppies—remove from dam onto a foster dam or hand-raise; if not possible or undesirable due to behavioral need for contact with dam, remove pups from dam for 24 hours, or until serum calcium is stabilized, and provide supplemental calcium for remainder of lactation; continue to monitor serum calcium level.

MEDICATIONS

DRUG(S) OF CHOICE
- Calcium gluconate—10% solution 0.22–0.44 mL/kg IV given slowly to effect over 5 min; monitor heart rate or ECG during administration; corresponds to dosage of 50–150 mg/kg.
- Correct hypoglycemia—50% dextrose: 0.5 g/kg diluted 1 : 3 with saline IV; can supplement maintenance IV fluids to 2.5% or 5% dextrose for longer-term treatment.
- Diazepam—0.5 mg/kg IV; for unresponsive seizures.
- Cerebral edema—if present, can treat with mannitol: 0.25–0.5 g/kg IV over 20 min, or 7.2% hypertonic saline 1–3 mL/kg IV over 15–20 min.
- Long-term therapy—calcium carbonate or calcium gluconate 10–30 mg/kg PO q8h until lactation ends (calcium carbonate 500 mg tablets supply 200 mg calcium).
- Magnesium supplementation may be helpful in hypomagnesemic bitches.
- Start puppies/kittens on solid food at 3–4 weeks of age.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Corticosteroids—avoid; cause decreased intestinal absorption and increased renal excretion of calcium.

FOLLOW-UP

PATIENT MONITORING
- Serum calcium concentration—monitor until stabilized in the normal range.
- Avoid calcium supplementation during gestation.
- Diet—maternal: ensure calcium : phosphorus ratio of 1.1 : 1 or 1.2 : 1; avoid high-phytate foods (e.g., soybeans); puppies: supplement feeding for large litters.

POSSIBLE COMPLICATIONS
- Cerebral edema.
- Death.
- Hand-raising of puppies.

EXPECTED COURSE AND PROGNOSIS
- Probably will recur with subsequent litters; calcium supplementation can be started after parturition for bitches with history of eclampsia in prior litters.
- Prognosis—good with immediate treatment; poor with delayed treatment.

ECTOPIC URETER

BASICS

OVERVIEW

- Congenital ureteral orifice(s) is inappropriately positioned caudal to the bladder trigone (i.e., trigone, urethra, vagina, vestibule, uterus, or prostate), resulting in incontinence.
- A common cause of urinary incontinence in juvenile female dogs. Also seen in adult dogs.
- Dogs—>95% tunnel intramurally, traversing the urethra in the submucosa.
- Male dogs—commonly associated with severe hydronephrosis and hydroureter due to ureteral opening stenosis.
- Commonly associated with multiple anomalies of the urinary tract—including concurrent urethral sphincter mechanism incompetence (USMI), hydroureter, hydronephrosis, short urethra/intrapelvic bladder.

SIGNALMENT

- Dog and cat.
- Juvenile incontinent dogs.
- Infrequently reported in cats and male dogs; 20 : 1 ratio of female : male dogs.
- Dog breeds may be predisposed—retrievers, Siberian huskies, Newfoundlands, poodles, terriers.

SIGNS

- Constant or intermittent incontinence since birth.
- Normal voiding in some.
- Chronic urinary tract infection(s) (UTIs).
- May be asymptomatic (male dogs) and can have moderate to severe hydroureter/hydronephrosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- USMI.
- Inappropriate urination—urge incontinence, "overactive bladder," behavioral (conscious urination).
- UTI—pollakiuria and urge incontinence.
- Vaginal pooling.
- Congenital hydroureter/hydronephrosis—male dogs with ectopic ureter(s) (EUs) often continent.
- Short urethra/intrapelvic bladder syndrome.

CBC/BIOCHEMISTRY/URINALYSIS

Labwork is typically normal, except when patients have concurrent anomalies (e.g., renal dysplasia, pyelonephritis).

OTHER LABORATORY TESTS

Urine bacterial culture and sensitivity—via cystocentesis.

IMAGING

- Cystoscopy (96% sensitivity).
- CT (91% sensitivity).
- Urinary tract ultrasonography (60–91% sensitivity) can provide accurate diagnosis and anatomic information of the upper urinary tract. Color-flow Doppler ultrasonography can provide location of ureteral jets, but does not guarantee the absence of a multifenestrated ureter.
- Excretory urography (50–75% sensitivity) with positive contrast cystogram or a pneumocystogram.
- Retrograde urethrography (47% sensitivity).

DIAGNOSTIC PROCEDURES

Cystoscopy—definitive diagnosis and characterization of EU, short urethra syndrome, location of ectopic orifice in the genitourinary tract. Also allows for simultaneous treatment.

TREATMENT

- Cystoscopic-guided laser ablation (CLA)—performed for intramural EU only. Opens ureteral tract in a minimally invasive manner; addresses concurrent vaginal defects, which may lead to considerable deviation of the urethra. Patients treated with CLA typically discharged the same day.
- Surgical—treatment of choice for extramural EU: neoureterostomy, reimplantation, or rarely ureteronephrectomy; complication rates range between 14% and 25% including ureteral strictures, leakage, and infection.

MEDICATIONS

DRUG(S) OF CHOICE

- Use if incontinence persists after surgery.
- Phenylpropanolamine (1–1.5 mg/kg PO q8h) will improve continence after surgery/laser therapy in 10–20% of dogs, improving continence levels to 50–60%.
- Testosterone propionate (2.2 mg/kg IM q2–3 days) or methyltestosterone (0.5 mg/kg/day) is administered to male dogs. For longer action, testosterone cypionate (2.2 mg/kg IM q30 days) can be used; this approach is not advised in immature or intact males.
- Estriol (2 mg once daily per dog for 14 days, followed by the lowest effective daily dose tapered every 7 days).

Other

Treatment for persistent incontinence after surgery/laser ablation—transurethral submucosal bulking agent injections: can improve continence to ~60–65%; placement of an artificial urethral sphincter (called a hydraulic occluder) can improve continence to ~80–90%.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Warn owners that incontinence may continue in some patients after surgery. Many patients become continent with the addition of medications, collagen bulking, and/or placement of a hydraulic occlude.
- Dogs—continence with surgery (25–50%) or laser ablation (40–55%) alone, which improves to 60% with medications, 65% with bulking agent injection, and ~80–90% with placement of a hydraulic occlude.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Hydronephrosis.
- Hydroureter.
- Ureterocele.
- Pelvic bladder.
- Persistent paramesonephric remnant.
- Vaginal septum.
- Renal dysplasia.
- Renal agenesis.
- USMI.
- Short urethra/intrapelvic bladder.

SEE ALSO

- Incontinence, Urinary.
- Pelvic Bladder.

ABBREVIATIONS

- CLA = cystoscopic-guided laser ablation.
- EU = ectopic ureter.
- USMI = urethral sphincter mechanism incompetence.
- UTI = urinary tract infection.

Author Ewan D.S. Wolff
Consulting Editor J.D. Foster
Acknowledgment The author and book editors acknowledge the prior contribution of Allyson C. Berent.

ECTROPION

BASICS

OVERVIEW
- Eversion or rolling out of the eyelid margin, resulting in exposure of the palpebral conjunctiva.
- Can be conformational/congenital (primary) or acquired (secondary).
- Exposure and poor tear retention/distribution may predispose patient to irritation, recurrent infections, and sight-threatening corneal disease.

SIGNALMENT
- Dogs, seldom cats.
- Breeds with higher than average prevalence—sporting breeds (e.g., spaniels, hounds, and retrievers); giant breeds (e.g., Saint Bernard, mastiff); any breed with loose facial skin (especially bloodhounds).
- Primary—genetic predisposition in listed breeds; may occur in dogs <1 year old.
- Acquired—noted in other breeds; occurs late in life secondary to age-related loss of facial muscle tone and skin laxity.
- Intermittent—caused by fatigue; may be observed after strenuous exercise or when drowsy.

SIGNS
- Eversion of the lower eyelid with lack of contact of the lower lid to the globe and exposure of the palpebral conjunctiva and third eyelid.
  - Often excessively long palpebral fissure (macroblepharon).
  - Conjunctivitis and history of mucoid to mucopurulent discharge caused by chronic exposure to air and debris. Debris generally located between lid and globe in inferior conjunctival cul-de-sac.
  - Tear staining of periocular skin caused by poor tear drainage.
- History of bacterial conjunctivitis.

CAUSES & RISK FACTORS
- Primary disease—most common due to breed-associated facial conformation and alterations in eyelid support.
- Acquired disease—from marked weight loss or muscle mass loss about the head and orbits, tragic facial expression in hypothyroid dogs, and cicatricial ectropion from scarring of the eyelids secondary to injury or from surgical overcorrection of entropion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Usually clinically obvious.
- Look for any underlying disorder in nonpredisposed breeds and dogs with late-age onset.
- Loss of orbital or periorbital mass—may occur in patients with masticatory myositis.
- Facial nerve paralysis—associated with lack of muscle tone of orbicularis oculi muscles.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
- Possible masticatory myositis—test for auto-antibodies against type 2M muscle fibers.
- Palpebral nerve paralysis or tragic facial expression—consider testing for hypothyroidism.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- Palpebral nerve paralysis—full neurologic evaluation; potential for hypothyroidism.
- Secondary conjunctivitis—flush fornix and examine for follicles.
- Fluorescein or rose Bengal staining of cornea and conjunctiva—to identify corneal ulcerations; may reveal severity of exposure problem.

TREATMENT
- Supportive care (topical lubricant, rinsing eyes with eyewash after being outside to remove debris) and good ocular and facial hygiene—sufficient for most mild disease.
- Surgical treatment—eyelid shortening or radical facelift; necessary for severely affected patients that have chronic ocular irritation.
- Intermittent, fatigue-induced condition—do not treat surgically.

MEDICATIONS

DRUG(S) OF CHOICE
- Topical broad-spectrum ophthalmic antibiotics—bacterial conjunctivitis or corneal ulceration. Neomycin/polymyxin B/bacitracin (or based on culture and sensitivity) q6–8h.
- Lubricant ointments (e.g., Puralube®)—reduce conjunctival and corneal desiccation secondary to exposure.
- Hypothyroid and masticatory myositis-induced conditions—may respond well to appropriate medical treatment of underlying disease.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
- May become more severe as patient ages.
- Nonsurgically treated patient—monitor for signs of infectious conjunctivitis, exposure keratopathy, corneal ulceration, and facial dermatitis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Hypothyroidism.
- Masticatory myositis, extraocular myositis.

AGE-RELATED FACTORS
Old animals more likely to have ectropion secondary to loss of facial muscle tone.

SEE ALSO
- Hypothyroidism.
- Myopathy – Masticatory and Extraocular Myositis.

EHRLICHIOSIS AND ANAPLASMOSIS

BASICS

DEFINITION

Caused by *Ehrlichia* and *Anaplasma*—tick-borne rickettsial disease.

Dogs

• Obligate intracellular pathogens in three genera: *Ehrlichia*, *Anaplasma*, and *Neorickettsia*. • *Ehrlichia*—predominant species: *E. canis*: canine monocytic ehrlichiosis (CME); *E. ewingii*: granulocytic ehrlichiosis; *E. chaffeensis*: primarily human pathogen, may cause canine disease. • *Anaplasma—A. phagocytophilum*: granulocytic anaplasmosis; *A. platys*: thrombocytic anaplasmosis. • *Neorickettsia*—infect mononuclear cells (monocytes and macrophages): *N. risticii*: Potomac horse fever; rarely infects dogs; acquired by ingesting infected vectors; serum from infected dogs does not cross-react with *Ehrlichia*; *N. helminthoeca*: salmon poisoning, primarily northwestern United States.

Cats

Feline ehrlichiosis (rare)—serologic, PCR, and cytologic evidence for *Ehrlichia* (*E. canis*, *E. canis*-like, *E. chaffeensis*, *E. ewingii*) and *Anaplasma* (*A. phagocytophilum*); clinical signs may include fever, lethargy, joint pain, anemia, hyperglobulinemia, and thrombocytopenia; may also be asymptomatic.

PATHOPHYSIOLOGY

• *Anaplasma* and *Ehrlichia* transmitted via tick bite; transmission time between 3h (*E. canis*) and 18h; can occur via blood transfusion. • *E. canis—Rhipicephalus sanguineus* tick vector; infects mononuclear cells; 1–3-week incubation period; three stages of canine disease: ○ Acute (2–4 weeks)—spread to spleen, liver, lymph nodes; causes endothelial cell and perivascular inflammation, thrombocytopenia (possible antiplatelet antibodies), mild anemia; infections may be subclinical. ○ Subclinical (months–years)—organism persists; hyperglobulinemia; mild thrombocytopenia; dogs may eliminate infection, others remain persistently infected or develop chronic disease. ○ Chronic—myelosuppression; pancytopenia. • *E. ewingii—Amblyomma americanum* tick vector; infects granulocytes; dogs can be persistently infected and asymptomatic; acute clinical signs include fever, neutrophilic polyarthritis, neutrophilia, reactive lymphocytes, and proteinuria; bleeding disorders uncommon. • *A. phagocytophilum—Ixodes* spp. tick vector; infects granulocytes; infections can be asymptomatic and self-limiting; acute clinical signs include fever, lameness, thrombocytopenia, and lymphopenia. • *A. platys*—tick vector likely *R. sanguineus*; infects platelets; persistent or cyclic thrombocytopenia.

SYSTEMS AFFECTED

• Multisystemic disease. • Vasculature—bleeding tendencies (thrombocytopenia and vascular inflammation). • Hemic/lymphatic/immune—bone marrow, spleen, lymph nodes. • Nervous (meningitis, cerebral hemorrhage). • Ophthalmic (anterior uveitis). • Joint (neutrophilic arthritis).

PREVALENCE/GEOGRAPHIC DISTRIBUTION

• *E. canis*—year round, worldwide; higher prevalence in warm climates. • *E. ewingii*—warmer months; seroprevalence eastern and midwest United States. • *A. phagocytophilum*—warmer months; eastern, upper midwest, and Pacific coast United States.

SIGNALMENT

Species

Dogs and cats (infrequent).

Breed Predilections

Chronic CME—German shepherd dogs, Belgian Malinois.

Mean Age and Range

• Average age 5.2 years. • Range 2 months–14 years.

SIGNS

General Comments

Vary in severity and duration, dependent on host, coinfections, and strain variations.

Historical Findings

• Fever, lethargy, anorexia, weight loss. • Spontaneous bleeding—sneezing, epistaxis, petechia, ecchymosis. • Ocular discharge/pain. • Lameness. • Ataxia, head tilt

Physical Examination Findings

Acute

• Bleeding diathesis. • Fever. • Generalized lymphadenopathy. • Organomegaly (spleen, liver). • Ocular discharge. • Lameness. • Ticks.

Chronic E. canis

• Pale mucous membranes (anemia). • Ulcerative stomatitis. • Hind limb or scrotal edema. • Uveitis, hyphema, retinal hemorrhages. • Ataxia, vestibular dysfunction, cervical pain.

RISK FACTORS

Coinfection with other vector-borne diseases (VBDs).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Rocky Mountain spotted fever (*Rickettsia rickettsii*)—seasonal (Mar–Oct); diagnose with serology; same treatment. • Immune-mediated thrombocytopenia—no fever or lymphadenopathy; rule out VBD. • Systemic lupus erythematosus—positive antinuclear antibody (ANA) test. • Multiple myeloma—monoclonal gammopathy, bony lesions. • Chronic lymphocytic leukemia—bone marrow cytology; PCR for antigen receptor rearrangements (PARR; *E. canis* infrequently PARR negative). • Brucellosis.

CBC/BIOCHEMISTRY/URINALYSIS

Acute

• Thrombocytopenia, anemia, leukopenia (lymphopenia, neutropenia, and eosinopenia), or leukocytosis (granular lymphocytosis, monocytosis). • Morulae—intracytoplasmic inclusions in leukocytes, rare. • Hyperglobulinemia—progressive increase 1–3 weeks postinfection. • Hypoalbuminemia. • Mild increases in liver enzyme activities, azotemia, hyperbilirubinemia. • Proteinuria.

Chronic

• Pancytopenia—anemia, thrombocytopenia, neutropenia, but monocytosis and lymphocytosis possible. • Hyperglobulinemia—magnitude correlates with duration of infection; usually polyclonal gammopathy, occasionally monoclonal. • Hypoalbuminemia.

OTHER LABORATORY TESTS

Serologic Testing

• Antibodies present ~3 weeks postinfection. • Immunofluorescent antibody test (IFAT)—sensitive; cross-reactivity between *Ehrlichia* species; use same laboratory to compare acute and convalescent titers; fourfold increase paired in convalescent titer indicates active infection; detection at one time-point may represent past exposure or active infection. • Rapid point-of-care (POC) screening test—sensitivity and specificity vary depending on test; overtly healthy dogs with positive POC tests should have CBC, Biochemistry, UA, PCR or paired IFAT to identify evidence of infection before treatment; animals can remain seropositive by POC for years, even after infection cleared.

PCR Testing

• Detects pathogen DNA; sensitive indicator of active or recent infection. • Whole blood or tissue (spleen, lymph node, liver, bone marrow); identifies species; detect as early as 7 days postinfection. • Negative PCR result cannot rule out VBD infections; false negative can occur due to low organism load; genetic variations can prevent PCR detection. • Combining serology and PCR optimal for accurate diagnosis.

Additional Tests

• Coombs' positive anemia; indicates concurrent immune-mediated erythrocyte destruction; may be positive in dogs with babesiosis, other VBD. • Test for VBD

(CONTINUED) EHRLICHIOSIS AND ANAPLASMOSIS

coinfections. • Culture and sensitivity testing (blood, urine) indicated in febrile patients.

DIAGNOSTIC PROCEDURES

Bone Marrow Aspirate

• Acute—hypercellularity of megakaryocytic and myeloid series. • Chronic—erythroid hypoplasia with increased M : E ratio, plasmacytosis. • Increased number of mast cells.

PATHOLOGIC FINDINGS

• Acute—serosal and mucosal petechiae; lymphadenopathy, splenomegaly, hepatomegaly, and red bone marrow; perivascular infiltrates of macrophages and lymphocytes (lung); periportal infiltrates of lymphocytes and macrophages (liver); lymphoid hyperplasia (spleen). • Chronic—pale marrow, subcutaneous edema; histologically, perivascular plasma cell infiltrates in organs; multifocal nonsuppurative meningoencephalitis with lymphoplasmacytic infiltrate.

TREATMENT

APPROPRIATE HEALTH CARE

• Inpatient—medical stabilization for acute signs. • Outpatient—stable patients; frequent monitoring for therapeutic response.

NURSING CARE

• Balanced electrolyte solution IV. • Blood or platelet-rich plasma transfusion for severe anemia or thrombocytopenia.

CLIENT EDUCATION

• Acute—prognosis excellent with appropriate therapy. • Chronic—prognosis guarded; cytopenia resolution may take ≥6 months; prognosis poor if hypoplastic bone marrow. • Progression to chronic prevented by early effective treatment; serological tests may stay positive (IFAT ≤1 year and POC for years); reinfection can occur if animals reexposed. • Breed risks for chronic CME.

MEDICATIONS

DRUG(S) OF CHOICE

• Doxycycline—5 mg/kg PO q12h or 10 mg/kg PO q24h for 3–4 weeks; clinical response usually in 1–2 days; slower response in chronic ehrlichiosis or neurologic disease. • Prednisolone or prednisone, use with antibiotics; anti-inflammatory (0.5–1 mg/kg PO q12–24h for 3–5 days) for polyarthritis; immunosuppressive (1–2 mg/kg PO q12h for 5 days; rarely exceed 60 mg/dog/day) when immune-mediated disease suspected. • For CME, prophylactic antibiotics if neutrophils <1000 cells/µl for >1 week.

CONTRAINDICATIONS

• Glucocorticoids in myelosuppressive CME. • Glucocorticoids in animals with diabetes mellitus, gastrointestinal ulceration, concurrent or recent nonsteroidal anti-inflammatory drug (NSAID) use.

PRECAUTIONS

• Prolonged immunosuppressive corticosteroid use may interfere with elimination of *E. canis*. • Doxycycline in dogs with liver disease or abnormal liver enzyme values.

ALTERNATIVE DRUG(S)

• Minocycline—10 mg/kg PO q12h for 3–4 weeks. • Rifampicin: 10 mg/kg PO q24h for 3 weeks (do not exceed 10 mg/kg/day in dogs); less effective.

FOLLOW-UP

PATIENT MONITORING

• CBC, blood smear examination—2, 4, 8 weeks after starting antibiotics; recurrence of clinical signs post treatment suggests treatment failure, reinfection, or concurrent infection with pathogen partially sensitive to therapy (*Babesia*, *Bartonella*). • IFAT—9 months post treatment; most dogs become seronegative; extended seropositivity may indicate reinfection or ineffective treatment. • PCR—1–2 months post treatment for evidence of pathogen clearance; if PCR positive, repeat antibiotics for 4–6 weeks, ensure use of acaricides; if persistently negative, change drug. • POC assay—not used to monitor treatment response.

PREVENTION/AVOIDANCE

• Control tick infestation—acaricides: topical (spot treatments and collars)—imidacloprid/flumethrin, fipronil, permethrin, deltamethrin, and amitraz (do not use permethrin, deltamethrin, or amitraz on cats); systemic—isoxazolines. • Manually remove ticks; use gloves; ensure removal of mouth parts.

EXPECTED COURSE AND PROGNOSIS

• Acute—excellent prognosis with appropriate treatment; most immunocompetent dogs recover, enter subclinical phase, or clear infection; treatment accelerates recovery, may prevent chronic phase. • Chronic—may take 4 weeks for clinical response, 6 months for cytopenia rebound; prognosis poor and expensive medical management with hypoplastic marrow. • *Ehrlichia* and *Anaplasma* antibodies do not protect against reinfection.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• *Babesia*. • *Bartonella*. • Hemotropic *Mycoplasma*. • *Leishmania*.

ZOONOTIC POTENTIAL

E. canis, *E. ewingii*, *E. chaffeensis*, *A. phagocytophilum*, and *A. platys* can infect humans via tick bite; *R. sanguineus* prefers dogs, will bite humans in living conditions with high vector population; *A. americanum* bites humans; *Ixodes* bite humans and transmit *Borrelia burgdorferi*, *Babesia microti*, likely *E. muris*.

SYNONYMS

• Canine hemorrhagic fever. • Canine rickettsiosis. • Canine typhus. • Tracker dog disease. • Tropical canine pancytopenia.

ABBREVIATIONS

• ANA = antinuclear antibody. • CME = canine monocytic ehrlichiosis. • IFAT = indirect fluorescent antibody test. • NSAID = nonsteroidal anti-inflammatory drug. • PARR = PCR for antigen receptor rearrangements. • POC = point of care. • VBD = vector-borne disease.

ELBOW DYSPLASIA

BASICS

DEFINITION
A group of developmental abnormalities that lead to malformation, degeneration, and secondary osteoarthritis of the elbow joint.

PATHOPHYSIOLOGY
- Four abnormalities—un-united anconeal process (UAP), osteochondritis dissecans (OCD), fragmented medial coronoid process (FMCP), and incongruity; alone or in combination; may be seen in one or both elbows; bilateral disease common (50% of cases).
- Terminology— medial compartment disease (MCompD) involves any pathology within the medial compartment, while medial coronoid process disease (MCD) is used to describe all pathologies of the medial coronoid process such as fissuring, fragmenting, sclerosis, microfracture, and cartilage damage.
- FMCP and incongruity are the most common documented MCompD pathologies.
- UAP—delayed closure of growth plate between anconeal process and proximal ulnar metaphysis (olecranon) by 5 months of age; may be result of abnormal mechanical stress on anconeal process.
- OCD—affects medial aspect of humeral condyle; disturbance in endochondral ossification causes retention of articular cartilage and subsequent mechanical stress leads to cartilage flap lesion.
- FMCP—chondral or osteochondral fragmentation or fissure of medial coronoid process of ulna; possibly manifestation of osteochondrosis of coronoid process; coronoid does not have separate ossification center; may be result of abnormal mechanical stress on medial coronoid process considered to be due to incongruity.
- Incongruity—asynchronous growth between radius and ulna may lead to abnormal loading, wearing, and erosion of cartilage in humeroulnar compartment. Malformation of trochlear notch of ulna; elliptical trochlear notch with decreased arc of curvature is too small to articulate with humeral trochlea—resulting in major points of contact at anconeal process, coronoid process, and medial humeral condyle.

SYSTEMS AFFECTED
Musculoskeletal

GENETICS
High heritability

INCIDENCE/PREVALENCE
- Most common cause for elbow pain and lameness.
- One of the most common causes for thoracic lameness in large-breed dogs.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog

Breed Predilections
Large and giant breeds—Labrador retrievers; Rottweilers; golden retrievers; German shepherds; Bernese mountain dogs; chow chows; bearded collies; Newfoundlands.

Mean Age and Range
- Age at onset of clinical signs—typically 4–10 months.
- Age at diagnosis—generally 4–18 months.
- Onset of symptoms related to degenerative joint disease (DJD)—any age.

Predominant Sex
- FMCP—males predisposed.
- UAP, OCD, incongruity—none established.

SIGNS

General Comments
- Lameness—if no distinct abnormalities noted on physical examination or radiographs, early intervention may demand advanced imaging.
- Any resistance at all in flexion in immature dog should raise suspicion of elbow dysplasia.
- Not all patients are symptomatic when young.
- Intermittent episodes of elbow lameness due to advanced DJD changes in mature patient—common.

Historical Findings
Intermittent or persistent thoracic limb lameness—exacerbated by exercise; progressed from stiffness seen only after rest.

Physical Examination Findings
- Pain—elicited on elbow hyperflexion or extension; elicited when holding elbow and carpus at 90° while pronating and supinating carpus and applying pressure to medial compartment.
- Affected limb—tendency to be held in abduction and supination.
- Joint effusion and capsular distension—especially noted between lateral epicondyle and olecranon.
- Crepitus—may be palpated with advanced DJD.
- Diminished range of motion.

CAUSES
- Genetic.
- Developmental.
- Nutritional.

RISK FACTORS
- Rapid growth and weight gain.
- High-calorie diet.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Trauma.
- Septic arthritis.
- Panosteitis.
- Avulsion or calcification of flexor muscles.
- Synovial sarcoma.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

IMAGING

Radiography
- Image both elbows—high incidence of bilateral disease.
- UAP, OCD, FMCP, and incongruity—elbow DJD recognized by osteophytes on cranial margin of radial head (37%), anconeal process (70%), and epicondyles (medial and lateral), and medial coronoid process; sclerosis of ulna caudal to coronoid process and trochlear notch; stairstep between joint surface of radius and lateral coronoid.
- UAP—best diagnosed from mediolateral hyperflexed view; may see lack of bony union. Comparison to contralateral elbow may be helpful, although high incidence of bilateral disease should be kept in mind.
- OCD—best diagnosed from craniocaudal and craniocaudal-lateromedial oblique views; reveals radiolucent defect or flattening of medial aspect of humeral condyle.
- FMCP—may not be visualized in some cases; diagnosis then presumptive based on DJD and lack of UAP or OCD lesions; commonly see trochlear sclerosis and/or early osteophyte formation on proximal caudal surface of anconeal process with FMCP.

Other
CT, MRI, and linear tomography—can provide more definitive evidence for fissures and nondisplaced fragments. CT is necessary in many cases of MCD as survey radiographs have low sensitivity.

DIAGNOSTIC PROCEDURES
- Joint tap and analysis of synovial fluid—confirm involvement of joint.
- Synovial fluid—should be straw colored with normal to decreased viscosity; cytology reveals <5,000 nucleated cells/μL (>90% are mononuclear cells); normal results do not necessarily rule out the diagnosis.
- Arthroscopy—may help diagnose UAP, MCD, OCD, and incongruity.

PATHOLOGIC FINDINGS
- UAP—fibrous union between anconeal process and proximal ulnar metaphysis; fibrous tissue invasion and degeneration of anconeal process; DJD.
- OCD—chondral flap on medial humeral condyle; sclerosis of underlying subchondral bone with fibrous tissue invasion; erosive lesion on apposing coronoid cartilage; DJD.
- FMCP—chondral or osteochondral fragmentation of cranial tip or lateral margin of medial coronoid; erosive lesion on cartilage of apposing medial aspect of humeral condyle; DJD.

• Incongruity—a step greater than 2 mm noted between medial border of radial head and lateral border of medial coronoid process.
• MCompD—erosive lesions involving part or all of medial coronoid process and apposing articular cartilage of medial aspect of humeral condyle; DJD; linear striations in articular cartilage.

TREATMENT

APPROPRIATE HEALTH CARE
Surgery—controversial but recommended for most patients.

NURSING CARE
• Cold packing elbow joint—perform immediately post surgery to help decrease swelling and control pain; perform at least 20 minutes q8h for 3–5 days.
• Passive range-of-motion exercises—beneficial until patient can bear weight on limb(s), then progress into static and dynamic therapeutic exercises.
• If osteoarthritis is present, then multimodal management is necessary as for arthritic management of any joint.

ACTIVITY
• Restricted for all patients postoperatively.
• Consideration for avoidance of high concussive activities for life.

DIET
• Weight control—important for decreasing load and stress on affected joint(s).
• Restricted weight gain and growth in young dogs—may decrease incidence and severity.

CLIENT EDUCATION
• Discuss heritability of disease.
• Discuss likelihood of DJD progression regardless of intervention.
• Discuss influence of excessive intake of nutrients that promote rapid growth.

SURGICAL CONSIDERATIONS
• Severity of DJD and advanced age of patient—negatively influence outcome. Generally DJD progresses faster without treatment.
• UAP—four options: removal, lag screw fixation, dynamic proximal ulnar osteotomy, and lag screw fixation plus dynamic proximal osteotomy; base decision on degree of DJD, patient's age, and surgical expertise.
• OCD and FMCP—medial approach to elbow (diagnostic differentiation not necessary); removal of loose fragment(s).
• Incongruity—controversial; four options: no surgery, subtotal coronoidectomy, dynamic proximal ulnar osteotomy, intra-articular osteotomy; base decision on type of incongruity, degree of DJD, patient's age, and surgical expertise.
• Arthroscopic diagnosis and treatment—excellent option for FMCP, OCD, and incongruity; benefits: superior visualization, minimally invasive, superior to arthrotomy in outcome.

MEDICATIONS

DRUG(S) OF CHOICE
• None that promotes healing of osteochondral or chondral fragments.
• Nonsteroidal anti-inflammatory drugs (NSAIDs)—minimize pain, decrease inflammation, symptomatically treat associated DJD.
• Deracoxib (3–4 mg/kg PO q24h, chewable).
• Carprofen (2.2 mg/kg PO q12h or q24h).
• Meloxicam (load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h—liquid).
• Tepoxalin (load 20 mg/kg, then 10 mg/kg PO q24h).

CONTRAINDICATIONS
Avoid corticosteroids—potential side effects; articular cartilage damage associated with long-term use.

PRECAUTIONS
NSAIDs—gastrointestinal irritation may preclude use in some patients.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
Chondroprotective drugs (e.g., polysulfated glycosaminoglycans, glucosamine, and chondroitin sulfate)—may help limit cartilage damage and degeneration; may help alleviate pain and inflammation.

FOLLOW-UP

PATIENT MONITORING
• Post surgery—limit activity for minimum of 12 weeks; encourage early, active, controlled movement of affected joint(s); consider formal rehabilitation therapy.
• Yearly to twice-yearly examinations—recommended to evaluate progression of DJD.

PREVENTION/AVOIDANCE
• Discourage breeding of affected animals.
• Do not repeat dam–sire breeding that resulted in affected offspring.

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
• Progression of DJD—expected.
• Prognosis—fair to good for all forms.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

ELECTRIC CORD INJURY

BASICS

OVERVIEW

• Electric cord injury is an uncommon event that occurs when an animal bites an electric cord. • Other causes of electrocution are uncommon in dogs and cats but can occur. • Household electrical currents are alternating (50–60 Hz), 110–120 or 220–240 volts depending on geographic location, and are dangerous. • Injury can be caused due to thermal injury or due to disruption of normal electrophysiologic activity of excitable tissue. • Pulmonary edema can be a sequela to electrocution and the pathophysiology is thought to be neurogenic and centrally mediated, leading to pulmonary hypertension. • Cataract formation is reported following electrocution.

SIGNALMENT

• Most commonly dogs; also cats. • Most commonly young animals; in published report age ranged from 5 months to 1.5 years. • No breed or sex predilections. • No genetic basis.

SIGNS

• Burns associated with gingiva, tongue, palate. • Singed hair or whiskers. • Most common clinical signs are related to acute dyspnea. • Coughing. • Tachypnea. • Orthopnea. • Increased respiratory effort. • Cyanosis. • Crackles during pulmonary auscultation. • Tachycardia. • Muscle tremors. • Tonic–clonic activity. • Collapse.

CAUSES & RISK FACTORS

• Chewing electric cord. • Young animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Left-sided congestive heart failure due to congenital or acquired heart disease; the presence of cardiac murmur or dysrhythmia may help differentiate; however, dysrhythmias may be seen with electric cord injury. • Vitamin K antagonist, rodenticide intoxication history (pulmonary hemorrhage). • Thoracic trauma (pulmonary contusions)—history, thoracic radiographs. • Other causes of noncardiogenic pulmonary edema. • Pleural space disease—muffled lung sounds during auscultation, thoracic radiographs. • Thermal or chemical injuries—history, physical examination, thoracic radiographs. • Exposure to fire and smoke inhalation—history, physical examination. • Atypical pneumonia—history, physical examination, thoracic radiographs.

CBC/BIOCHEMISTRY/URINALYSIS

May help rule out other systemic causes of noncardiogenic pulmonary edema.

OTHER LABORATORY TESTS

Arterial blood gas analysis may be useful to document hypoxemia; this may be difficult to perform in unstable patients.

IMAGING

• Thoracic radiographs may help distinguish between cardiogenic and noncardiogenic causes of pulmonary edema. • Radiographic pattern is usually a generalized, mixed alveolar bronchial pattern; edema is often most notable in caudal dorsal lung fields. • Pulmonary venous congestion is absent with noncardiogenic pulmonary edema. • Echocardiography may help identify or rule out underlying cardiac disease.

DIAGNOSTIC PROCEDURES

• ECG—may help distinguish cardiogenic disease from noncardiogenic disease; however, dysrhythmias may be seen with electrocution and other causes of noncardiogenic pulmonary edema.

PATHOLOGIC FINDINGS

• Pink, frothy fluid in airways. • Fluid-filled, congested lungs. • Subendocardial and subepicardial petechiae. • Circumscribed, pale gray or tan oral lesions.

TREATMENT

• If patient is close to live wire, turn off electricity and/or remove patient to safe area. • Establish patent airway if patient is unconscious. • Oxygen supplementation. • Mechanical ventilation may be required. • Establish venous access.

MEDICATIONS

DRUG(S) OF CHOICE

• If in shock—treat with intravenous crystalloids (90 mL/kg/h in dog, 45–60 mL/kg/h in cat) or colloids (20 mL/kg in dogs, 5–10 mL/kg in cats). • If pulmonary edema is present—furosemide 2–4 mg/kg IV; this is controversial as this is a form of noncardiogenic pulmonary edema. • Anxiolytic therapy if dyspneic—butorphanol 0.1–0.2 mg/kg IV. • Corticosteroids have been employed, but are controversial and of unknown value. • Inotropic support if required. • Antiarrhythmic therapy if required. • Oral and cutaneous burns—treated symptomatically.

FOLLOW-UP

PATIENT MONITORING

• Patient should be monitored until stable. • Physical examination. • Monitor oral lesion; may prevent patient from eating. • ECG. • Central venous pressure. • Blood pressure. • Arterial blood gas. • Thoracic radiographs.

PREVENTION/AVOIDANCE

• Damaged electric cords should be discarded. • Avoid animal exposure to electric cords. • Follow child safety rules for a safe home.

POSSIBLE COMPLICATIONS

• Infected burn wounds can occur but are uncommon. • Oronasal fistula due to severe burns.

EXPECTED COURSE AND PROGNOSIS

• Prognosis based on response to therapy. • Pulmonary edema can develop as soon as 1 hour and as late as 36 hours after incident. • Pulmonary edema associated with electrocution is associated with high mortality (38.5%). • If patient survives first 24 hours, prognosis improves. • Resolution of pulmonary edema may take 3–5 days. • Most oral lesions resolve. • Inappetence related to oral lesions resolves.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Cataracts have been reported in one dog 18 months after electrocution.

ENAMEL HYPOPLASIA/HYPOCALCIFICATION

BASICS

OVERVIEW

- Enamel hypoplasia is the inadequate deposition of normal enamel matrix, affecting one or several teeth.
- The crowns can have areas of normal enamel next to hypoplastic or missing enamel.
- Apparent defect in enamel surfaces, often pitted and discolored; focal or generalized, due to disruption of normal enamel formation.
- Most cases are primarily aesthetic; some have extensive structural damage, even root involvement. The dentin is rarely exposed with hypoplasia.
- Enamel hypoplasia is less common than hypocalcification.
- Enamel hypocalcification refers to inadequate mineralization (calcification) of enamel, affecting several or all teeth. The crowns are covered by poorly formed, rough enamel that may easily be worn or flaked away and have light brown discoloration. There can be areas of normal enamel next to areas of abnormal enamel.
- Systemic influences during enamel formation (e.g., distemper, fever) over an extended time may cause generalized changes; local or focal influences (e.g., trauma, even from deciduous tooth extraction) over a short time may cause specific patterns or bands.
- Teeth may be more sensitive with exposed dentin, and occasionally fractures of severely compromised teeth occur; usually they remain fully functional.

SIGNALMENT

- Dogs and less commonly cats.
- Often apparent at time of tooth eruption (after 6 months of age) or shortly thereafter (with signs of wear).

SIGNS

Historical Findings

Discolored teeth.

Physical Examination Findings

- Irregular, pitted, or flaky enamel surface with discoloration of diseased enamel and potential exposure and staining of underlying dentin (light brown).
- Early or rapid accumulation of plaque and calculus on roughened tooth surface; possible gingivitis and/or accelerated periodontal disease.
- Teeth may fracture easily.
- Animals may show cold sensitivity (avoiding outdoor water or refrigerated food).

CAUSES & RISK FACTORS

- Insult during enamel formation.
- Canine distemper virus, fever, trauma (e.g., accidents, fractured deciduous tooth, excessive force during deciduous tooth extraction).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Enamel staining—discolored but smooth surface (tetracycline).
- Carious lesions—cavities with decay.
- Amelogenesis imperfecta—genetic and/or developmental formation and maturation abnormalities other than hypomineralization.
- Tooth resorption—similar to that found in cats, also found in dogs.

CBC/BIOCHEMISTRY/URINALYSIS

- Usually normal.
- Appropriate preanesthetic diagnostic when indicated.

OTHER LABORATORY TESTS

N/A

IMAGING

- Intraoral radiographs are necessary to determine the structure and viability of roots.
- Cases reported of abnormal root formation, no root formation, or separated crown and root.

DIAGNOSTIC PROCEDURES

None

TREATMENT

- Treatment depends upon extent of lesions and equipment and materials available.
- Goal is to provide the smoothest surface possible.
- Enamel hypoplasia typically does not require treatment as the enamel is normal, just decreased in thickness. Enamel hypocalcification typically benefits from treatment.

Optimal Treatment

- Gently remove diseased enamel (enamel scrub) with white stone burs or finishing disks on high-speed handpiece (adequate water coolant).
- Take care not to damage the tooth—excess enamel/dentin removal; hyperthermic damage to pulp.
- Focal defects may be amenable to composite restoration; many restorative materials (bonding agents, composites) require use of light-curing units and appropriate skill levels.
- Bonding agent recommended to seal exposed dentinal tubules and protect surfaces.
- Extraction is recommended if the root is significantly malformed; extraction or root canal therapy if tooth is radiographically nonvital.

Alternative Treatment

- Soft, diseased enamel can sometimes be removed with ultrasonic scalers or hand instruments, but avoid excessive removal and hyperthermia.
- Fluoride treatment can be used to decrease sensitivity and enhance enamel strength.

MEDICATIONS

DRUG(S) OF CHOICE

N/A

FOLLOW-UP

PATIENT MONITORING

Inform the owner that further degeneration of remaining enamel may occur, necessitating additional therapy in the future, or that affected teeth may become nonvital over time, requiring root canal therapy or extraction.

PREVENTION/AVOIDANCE

- Regular professional dental cleaning and a routine homecare program (brushing); may include weekly application of stannous fluoride at home (minimize ingestion because of toxicity).
- Avoid chewing on hard objects.

ENCEPHALITIS

BASICS

DEFINITION
Inflammation of the brain with or without concurrent inflammation of the meninges and spinal cord.

PATHOPHYSIOLOGY
• Immune-mediated mechanism, usually of unknown triggering factor. • Infection of the brain.

SYSTEMS AFFECTED
• Nervous. • Multisystemic signs—usually seen if infectious cause.

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
• Immune-mediated—worldwide.
• Infectious—varies depending on infectious agent distribution.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Immune Mediated
• Meningoencephalitis of unknown origin (MUO) can happen in any breed.
• Granulomatous meningoencephalitis (GME)—toy poodle and terrier. • Necrotizing meningoencephalitis (NME)—pug and chihuahua. • Necrotizing leukoencephalitis (NLE)—Yorkshire terrier and French bulldog.
• Eosinophilic meningoencephalitis (EME)—golden retriever and Rottweiler. • Idiopathic tremor syndrome—West Highland white terrier, Maltese. • Greyhound nonsuppurative meningoencephalitis—greyhound.

Infectious
• Pyogranulomatous meningoencephalomyelitis—pointer dogs. • Aspergillosis—German shepherd. • Protothecosis—boxer, collie.
• Cryptococcosis—American cocker spaniel.

Feline Infectious Peritonitis (FIP)
Burmese

Mean Age and Range
Immune Mediated
• Peak 3–7 years old; can happen at any age in dogs older than 4 months old. • GME—peak 4–8 years old. • NME and NLE—mean 2.5 years old (6 months–7 years). • Cats—mean 9 years old.

Infectious
Two peaks: <2 years and >8 years.

Predominant Sex
MUO—females slightly predisposed.

SIGNS

Historical Findings
• Immune mediated—acute to chronic onset and progression (days to months).
• Infectious—acute onset with rapid progression (days).

Physical Examination Findings
• Immune mediated—none. • Infectious—fever, lethargy, diffuse pain, ocular lesions, coughing, diarrhea.

Neurologic Examination Findings
• Rostral fossa—seizures, blindness, abnormal mentation, absent menace and nasal septum stimulation responses, delayed postural reactions. • Caudal fossa—lethargy, cranial nerve deficits, ataxia (proprioceptive, vestibular, and/or cerebellar), paresis. • Progression (e.g., anisocoria, pinpoint pupils, decreasing level of consciousness, poor physiologic nystagmus)—suggests increased intracranial pressure with potential brain herniation.

CAUSES

Dogs
• Idiopathic—MUO, GME, NME, NLE, EME, pyogranulomatous meningoencephalomyelitis, greyhound nonsuppurative meningoencephalitis, idiopathic tremor syndrome.
• Postvaccinal—distemper, rabies. • Viral—distemper, rabies, pseudorabies, herpesvirus, parvovirus, coronarivus, parainfluenza, West Nile virus, eastern, western and Venezuelan equine encephalomyelitis virus, *Bunyaviridae*, *Flaviviridae*. • Rickettsial—*Ehrlichia canis*, *Neorickettsia helminthoeca*, *Anaplasma phagocytophilum*, Rocky mountain spotted fever.
• Bacterial—aerobic, anaerobic, mycoplasma, mycobacterium. • Fungal—*Blastomyces*, *Histoplasma*, *Cryptococcus*, *Coccidioidomyces*, *Aspergillus*, *Phaeohyphomyces*. • Protozoal—*Toxoplasma*, *Neospora*. • Algal—*Prototheca*.
• Parasitic—sarcocystis, encephalitozoon, larva migrans (*Dirofilaria*, *Toxocara*, *Ancylostoma*, *Cuterebra*, *Baylisascaris*, *Cysticercus*), trypanosoma.

Cats
• Viral—FIP, rabies, feline immunodeficiency virus (FIV), pseudorabies, paramyxovirus, Borna disease virus, West Nile virus, *Bunyaviridae*. • Bacterial—aerobic, anaerobic, mycoplasma, mycobacterium. • Fungal—*Cryptococcus*, *Blastomyces*, *Histoplasma*, *Coccidioidomyces*. • Protozoal—*Toxoplasma*.
• Algal—*Prototheca*. • Parasitic—larva migrans (*Dirofilaria*, *Toxocara*, *Ancylostoma*, *Cuterebra*, *Baylisascaris*, *Cysticercus*). • Idiopathic—lymphohistiocytic meningoencephalomyelitis.

RISK FACTORS
• Immunosuppressive drugs and FIV or feline leukemia virus (FeLV) infection—infectious encephalitides. • FIP: recent stress, multicat environment. • Tick-infected areas—tick-borne rickettsial and viral infections. • Travel history—geographically localized infectious agents.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Cerebrovascular accident—should not progress after 24 hours. • Congenital anomaly—primarily young animals.
• Trauma—usually reported in history.
• Metabolic encephalopathy—usually symmetric deficits, CBC/biochemistry abnormalities common. • Toxic—usually acute. • Neoplasia—signs may be similar; usually in older patients. • Degenerative—usually slow, progressive signs.

CBC/BIOCHEMISTRY/URINALYSIS
• Immune mediated—usually normal.
• Infectious—CBC: leukocytosis if systemic signs; distemper: lymphopenia; FIP: lymphopenia, anemia; rickettsial disease: anemia, thrombocytopenia; fungal/parasitic: occasionally eosinophilia; biochemistry: FIP: hyperglobulinemia; distemper: hyper/hypoglobulinemia; rickettsial disease: hyperglobulinemia; some fungal diseases: hypoalbuminemia, hyperglobulinemia, hypercalcemia; urinalysis: fungus rarely seen.

OTHER LABORATORY TESTS
• Serology—in serum or cerebrospinal fluid (CSF); available for fungal, protozoal, rickettsial, and viral diseases; may not differentiate exposed/vaccinated animals from active disease; antibodies appear 2–3 weeks after infection; immunoglobulin (Ig) M higher predictive positive value than IgG for *Toxoplasma*, preferred test for *Neospora*, low sensitivity/specificity for FIP. • Histology—postmortem; lacks specificity; may reveal specific inclusion bodies for viral infections (e.g., distemper, rabies). • Immunohistochemistry—postmortem; usually high sensitivity and specificity; best test to confirm FIP. • PCR—available for viral, fungal, rickettsial, protozoal diseases in blood and CSF; highly sensitive for distemper; low sensitivity but high specificity for FIP. • Culture—bacterial culture of CSF commonly unrewarding despite bacterial infection; fungal and viral culture unrewarding and potential zoonoses. • Urine galactomannan assay (ELISA)—high sensitivity and specificity for *Blastomyces*, *Aspergillus*, and *Histoplasma*.
• Blood/urine cultures—low sensitivity and specificity; may help discriminate agent in bacterial encephalitis and help in antibiotics choice. • Rabies—no premortem diagnostic test.

IMAGING
• Thoracic radiographs—may reveal fungal/toxoplasma infection or concurrent bacterial pneumonia. • Spine radiographs—may reveal concurrent fungal/bacterial discospondylitis.
• Brain MRI—shows focal/multifocal lesions.
• Brain CT—may show focal/multifocal brain lesions; less sensitive and specific than MRI

DIAGNOSTIC PROCEDURES
• CSF cytology—used to confirm inflammation; may be normal if meninges not affected. ◦ Immune mediated—increased protein and cellular content (lymphocytes and/or macrophages), increased eosinophils in EME; predominantly neutrophilic in some cases. ◦ Viral—predominantly lymphocytic. ◦ Bacterial—predominantly degenerated neutrophils. ◦ Fungal—mixed inflammation.

• Infectious agent rarely seen (except *Cryptococcus*).

PATHOLOGIC FINDINGS

Findings depend on specific type of immune-mediated inflammation (e.g., granulomatous, necrotic) and infectious agent.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient medical management—may require initial intensive care management if elevated intracranial pressure.

NURSING CARE

• Increased intracranial pressure—hypertonic saline, mannitol, dexamethasone. • Anti-seizure treatment—diazepam, phenobarbital, levetiracetam in boluses or CRI. • Analgesic medication—necessary if painful from associated meningitis: opioids, gabapentin. • Nursing care for nonambulatory patients—bedding, switching sides, physiotherapy.

ACTIVITY

As tolerated.

DIET

No oral intake if unable to swallow, e.g., depressed, dysphagia, vomiting.

CLIENT EDUCATION

Relapse possible with both immune-mediated and infectious encephalitis.

SURGICAL CONSIDERATIONS

Brain biopsy—may be needed in specific cases.

MEDICATIONS

DRUG(S) OF CHOICE

• Apply specific therapy once diagnosis is reached or highly suspected. • Immune mediated—prednisone/prednisolone 2 mg/kg/day until most of recovery achieved (usually 1–2 weeks), then tapered progressively each month over 6 months; initially, dexamethasone 0.25 mg/kg q24h can be given IV. • Viral—no specific: treat symptomatically. • Bacterial—broad-spectrum IV antibiotics initially (e.g., fluoroquinolones + amoxicillin/clavulanate); continue PO depending on sensitivity or with broad-spectrum if agent unknown. • Fungal—itraconazole (*Aspergillus*), fluconazole (may be preferred if intra-axial), amphotericin B, voriconazole. • Protozoal—clindamycin, trimethoprim/sulfamides. • Rickettsial—doxycycline. • Parasitic—ivermectin, albendazole.

CONTRAINDICATIONS

• Prednisone not to be used more than a few days if infectious. • Puppies <6 months of age—doxycycline contraindicated. • Puppies <8 months of age—enrofloxacin contraindicated. • Cats - ocular toxicity with enrofloxacin > 5mg/kg/day.

POSSIBLE INTERACTIONS

Prior corticosteroid treatment may alter MRI and CSF results and decrease chance of diagnosis.

ALTERNATIVE DRUG(S)

• Some patients may have better response if treated with prednisone plus another immunosuppressive drug compared to prednisone alone; no increased benefits of using 3 or more drugs; second immunosuppressive drug progressively tapered once prednisone dose is 0.5 mg/kg/day. • Cytosine arabinoside—first administration IV CRI 100 mg/m^2/24h for 24–48h, then 100 mg/m^2 IV CRI over 8–24h every 3 weeks for 6 months; time between administration progressively lengthened thereafter; SC injection protocol exists but likely less efficient. • Azathioprine—2 mg/kg PO q24h. • Cyclosporine—5–10 mg/kg PO q12h. • Mycophenolate—10–20 mg/kg PO q12h. • Leflunomide—2–4 mg/kg PO q24h. • Radiation therapy—reported.

FOLLOW-UP

PATIENT MONITORING

• Frequent neurologic evaluations in first 48–72 hours to monitor progress. • Recheck CBC/biochemistry every month initially and then every 3–6 months while on immunosuppressive therapy. • Relapse as medication is withdrawn—chance of relapse increased if abnormal recheck MRI and CSF before stopping treatment. • Stop treatment for fungal diseases when antigen titers negative.

PREVENTION/AVOIDANCE

• Avoid outdoor roaming and use effective tick control in endemic areas. • No definitive association between immune-mediated encephalitis and vaccination.

POSSIBLE COMPLICATIONS

• General anesthesia and CSF collection—contraindicated in unstable patients with increased intracranial pressure. • Immunosuppressive drugs—predispose to infections. • Long-term corticosteroid therapy—signs of iatrogenic hyperadrenocorticism and related side effects. • Increased intracranial pressure—poor prognosis factor, increased chance of death early in course of disease.

EXPECTED COURSE AND PROGNOSIS

• Resolution progressive—2–8 weeks. • Rickettsial, bacterial, protozoal—fair chance of survival if treated early. • Fungal, algal, viral—almost always fatal. • Immune mediated—necrotic encephalitis has worse prognosis. • Idiopathic tremor syndrome—excellent prognosis with complete resolution.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Rabies—consider in endemic areas if patient is outdoor animal that has rapidly progressive encephalitis. • Humans may be infected by the same vector tick that affected the patient. • Exudates and diagnostic samples from animals with mycosis can be contagious.

SYNONYMS

• Meningoencephalitis of unknown etiology (MUE). • Idiopathic tremor syndrome—white shaker syndrome.

SEE ALSO

• Seizures (Convulsions, Status Epilepticus)—Cats.
• Seizures (Convulsions, Status Epilepticus)—Dogs.
• Stupor and Coma.
• Vestibular Disease, Geriatric—Dogs.
• Vestibular Disease, Idiopathic—Cats.

ABBREVIATIONS

• CSF = cerebrospinal fluid. • EME = eosinophilic meningoencephalitis. • FeLV = feline leukemia virus. • FIP = feline infectious peritonitis. • FIV = feline immunodeficiency virus. • GME = granulomatous meningoencephalitis. • Ig = immunoglobulin. • MUE = meningoencephalitis of unknown etiology. • MUO = meningoencephalitis of unknown origin. • NLE = necrotizing leukoencephalitis. • NME = necrotizing meningoencephalitis.

ENCEPHALITIS SECONDARY TO PARASITIC MIGRATION

BASICS

OVERVIEW
- Aberrant parasitic migration into the CNS.
- Parasites usually affect another organ system of the same host (e.g., *Dirofilaria immitis*, *Taenia*, *Ancylostoma caninum*, *Angiostrongylus*, or *Toxocara canis*) or a different host species (e.g., raccoon roundworm, *Baylisascaris procyonis*; skunk roundworm, *B. columnaris*; *Coenurus* spp.; or *Cysticercus cellulosae*).
- Access to CNS—hematogenously (dirofilariasis) or through adjacent tissues, including the middle ear, skull foramina, cribriform plate through nasal cavities, or open fontanelles (cuterebraiasis).

SIGNALMENT
- Dirofilariasis—adult animals only.
- Other parasites—young dogs and cats with access to outdoors: rare and sporadic occurrence.

SIGNS
- Vary with the portion of CNS affected.
- Likely asymmetric.
- May suggest a focal mass lesion or a multifocal disease process.
- Cuterebriasis—seasonal (July–October) acute or peracute onset of behavior changes, seizures, visual deficits, etc.; previous history of respiratory disease is common.
- Rat parasite, *Angiostrongylus cantonensis* (Australia)—lumbosacral syndrome (hind limbs, tail, and bladder paralysis/paresis) in puppies that may ascend to thoracic limbs and cranial nerves.

CAUSES & RISK FACTORS
Housing in a cage previously occupied by wildlife (raccoons, skunks).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Rule out other causes of focal encephalopathy—infectious diseases (viral, bacterial, protozoan, or fungal); granulomatous meningoencephalomyelitis; brain tumor.
- Diagnosis often made on necropsy.

CBC/BIOCHEMISTRY/URINALYSIS
Normal unless the parasite also affects non-neural tissues.

OTHER LABORATORY TESTS
Cerebrospinal fluid (CSF)—may show eosinophilic, neutrophilic, or mononuclear pleocytosis (also found in protozoal, fungal, and prototheca encephalitides); may be normal (strictly parenchymal lesions).

IMAGING
CT or MRI—brain; focal lesion and/or cerebral infarction from occlusion of cerebral vessels. Nonspecific and often inconclusive, but could lead to surgical exploration and removal of migrating parasite.

PATHOLOGIC FINDINGS
- The parasite or its tracts may or may not be identified.
- Infarction, vascular rupture, and hemorrhage or vascular emboli may cause local to extensive necrosis and malacia; there may be granulomatous proliferation or/and obstructive hydrocephalus.
- *Dirofilaria immitis*—intravascular or extravascular.
- Worms produce focal inflammation.
- Cuterebriasis is the suspected cause of feline ischemic encephalopathy.

TREATMENT
- Surgical removal of intracranial cuterebra.
- Parasiticides (see below) could potentiate illness.
- Supportive and nursing care.

MEDICATIONS

DRUG(S) OF CHOICE
- Dirofilariasis and neural angiostrongylosis—anthelmintic treatment may cause worsening of signs and sometimes death.
- Mild neural angiostrongylosis—puppies may recover with supportive care and corticosteroid therapy.
- A single dose of ivermectin (400 mg/kg SC) may kill cuterebra larvae in cats with suspected cuterebriasis; pretreatment with diphenhydramine (4 mg/kg) and intravenous dexamethasone (0.1 mg/kg) may mitigate allergic/anaphylactic reactions to dead or dying larvae.
- Treat inflammation and secondary infections—corticosteroids/nonsteroidal anti-inflammatory drugs (NSAIDs), antibiotics.

FOLLOW-UP

PATIENT MONITORING
As necessary.

PREVENTION/AVOIDANCE
- Keep pets indoors or/and segregated from wildlife.
- Use preventive anthelmintics and dirofilaricides.

EXPECTED COURSE AND PROGNOSIS
Acute or insidious onset, then usually progressive.

MISCELLANEOUS

SEE ALSO
- Encephalitis.
- Feline Ischemic Encephalopathy.
- Heartworm Disease—Cats.
- Heartworm Disease—Dogs.

ABBREVIATIONS
- CSF = cerebrospinal fluid.
- NSAID = nonsteroidal anti-inflammatory drug.

Author Christine F. Berthelin-Baker

ENDOCARDITIS, INFECTIVE

BASICS

DEFINITION
The invasion of the cardiac endocardium, usually the valves, by infectious agents. Usually Gram-positive bacteria, especially staphylococci or streptococci. Occasionally *Rickettsia* or *Bartonella* in dogs. Rarely fungi in dogs. Culture-negative cases may be due to *Bartonella* or fungi (e.g., *Aspergillus*). Less likely due to *Brucella*, *Coxiella*, *Corynebacterium*, and *Chlamydia*.

PATHOPHYSIOLOGY
• Bacteremia from various portals of entry; bacteria invade and colonize the heart valves—usually the aortic, occasionally the mitral, and rarely the tricuspid and pulmonic valves. • Endocardial ulceration exposes collagen causing platelet aggregation, activation of the coagulation cascade, and formation of vegetations. • Vegetations on heart valves are composed of an inner layer of platelets, fibrin, red blood cells, and bacteria; a middle layer of bacteria; and an outer layer of fibrin. • Valvular insufficiency develops in virtually all patients; aortic insufficiency almost invariably leads to intractable left-sided congestive heart failure (CHF) within weeks to several months. • CHF is less frequent and latent when only the mitral valve is affected. • Vegetative lesions may dislodge causing infarction or metastatic infection to any organ; organs commonly infected include the spleen, kidneys, brain, and skeletal muscles.

SYSTEMS AFFECTED
• Cardiovascular—valvular insufficiency; arrhythmias, myocarditis. • Nervous—para/tetraparesis; cranial nerve deficits; abnormal mentation. • Hemic/lymphatic/immune—hypercoagulation; disseminated intravascular coagulation. • Musculoskeletal—septic or immune-mediated polyarthropathy; hypertrophic osteopathy; discospondylitis. • Renal/urologic—renal infarction; immune-mediated glomerulonephritis; urinary tract infections. • Respiratory—pulmonary edema and/or emboli.

SIGNALMENT
Species
Dog; rarely cat.

Breed Predilections
• Medium to large breeds. • Breeds predisposed to subaortic stenosis (SAS).

Mean Age and Range
Most affected dogs are 4–8 years of age; infection can occur at any age.

Predominant Sex
Most studies report male predominance—may be as great as 2 : 1.

SIGNS
General Comments
• Gram-negative bacteremia results in peracute or acute signs; Gram-positive bacteremia results in subacute or chronic clinical signs. • Systemic signs secondary to infarction, infection (inflammation), toxemia, or immune-mediated damage; usually override cardiac signs.

Historical Findings
• Infectious disease involving skin, oral, gastrointestinal (GI), or genital tracts (e.g., prostatitis). • Predisposing factors—immunosuppressive drug therapy, SAS, recent surgery, infected wound, abscess, pyoderma, or recent implantation of cardiovascular device (i.e., pacemaker, Amplatz® canine ductal occluder). • Presenting complaints include lethargy, paresis, fever, anorexia, GI disturbance, and lameness; in cats, cardiac decompensation and/or locomotor abnormalities are common presenting complaints.

Physical Examination Findings
• Usually diverse and misleading—the "great imitator." • Pyrexia and general malaise. • Dyspnea due to CHF. • Arrhythmias (ventricular, supraventricular, or heart block). • Single or shifting leg lameness. • Systolic heart murmur. • "To-and-fro" murmur—associated with aortic valve vegetation causing systolic turbulence and diastolic regurgitation. • Diastolic murmur with hyperdynamic femoral pulses are a strong indication of advanced aortic endocarditis.

CAUSES
• Bacterial infection associated with oral cavity, bone, prostate, skin, and other sites. • Invasive diagnostic or surgical procedures causing bacteremia.

RISK FACTORS
• SAS. • Immunosuppression from long-term or high-dose corticosteroids, neoplasia, or cytotoxic drug administration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Bacteremia of any cause. • Polysystemic, immune-mediated disorders. • Left-sided CHF caused by dilated cardiomyopathy or SAS.

CBC/BIOCHEMISTRY/URINALYSIS
• Inflammatory leukogram (i.e., neutrophilia, left shift, and monocytosis)—patients with chronic, relatively inactive, or walled-off infection may have normal or nearly normal leukogram; those with chronic infection may have mature neutrophilia with monocytosis. • Nonregenerative anemia. • Thrombocytopenia—variable severity. • Low-normal or low albumin, low-normal or low glucose, and high serum alkaline phosphatase/bilirubin activity are inconsistently associated with sepsis (septic triad). • Renal azotemia—secondary to renal emboli, pyelonephritis, and/or hypovolemia-induced renal failure. • Proteinuria caused by septic emboli, immune-mediated glomerulonephritis, or renal infarction; hematuria, pyuria, and granular casts associated with pyelonephritis.

OTHER LABORATORY TESTS
• Blood culture—three samples taken at least 1 hour apart over 24 hours; at least two should yield the same microbe; both aerobic and anaerobic cultures recommended; antibiotic removal systems available for diagnosis of patients given antibiotics. • PCR with bacterial 16s primers, in combination with blood culture, increases likelihood of identification of bacteremia. • Culture-negative bacteremia often due to prior antibiotic administration or fastidious microbes, especially *Bartonella*. • Catheter tips—culture. • Urine culture (not a substitute for blood culture)—easy; often positive; does not necessarily incriminate the urinary tract as the source of infection. • Tests for prostate, kidney, and bone infection may be warranted. • Positive antinuclear antibody, lupus erythematosus, rheumatoid factor, and Coombs' test results occasionally found—nonspecific; tend to confound the diagnosis. • Bartonella alpha-Proteobacteria growth medium (BAPGM) and PCR—for *Bartonella*.

IMAGING
Radiography
Left cardiomegaly; rarely, calcification of one or more heart valves.

Echocardiography
Best test—vegetative aortic endocarditis easily discerned; mitral valve infection may be difficult to differentiate from degenerative valve disease; hyperechoic with chronicity.

DIAGNOSTIC PROCEDURES
Arthrocentesis
Joint taps for cytology and culture—cytology usually does not differentiate septic from immune-mediated arthritis; either, though usually not septic, can exist with infective endocarditis; usually nondegenerate neutrophils regardless of cause.

ECG
• May be normal; occasionally reflects left cardiomegaly; often detects ventricular tachyarrhythmias; occasionally heart block of variable severity or supraventricular tachyarrhythmias. • Heart block suggests aortic valve involvement with infection or infarction of the adjacent septum.

PATHOLOGIC FINDINGS
• Cardiomegaly, almost always left sided when present. • Vegetations and thrombi on one or more valves. • Infection, hemorrhage, and infarction of adjacent myocardium. • Renal infarcts usually present. • Primary or secondary sites of infection, especially

ENDOCARDITIS, INFECTIVE (CONTINUED)

kidneys and spleen. • Pulmonary hemorrhage or edema.

TREATMENT

Early index of suspicion with aggressive, rapid diagnostic testing, followed by appropriate treatment are imperative for cure. Cure is a reasonable expectation when mitral valve (alone) endocarditis is identified early in its course and treatment is aggressive.

NURSING CARE

• Aggressive fluid therapy—overt or impending CHF limits fluid volumes that can be administered; this problem is virtually insurmountable in patients with concomitant renal failure. • Imminent CHF—provide no more than maintenance volumes of fluid; alternate 5% dextrose in water (D5W) with lactated Ringer's solution (LRS; or 2.5% dextrose in half-strength LRS); potassium supplementation usually required.

CLIENT EDUCATION

Guarded prognosis if only mitral valve involved. Grave prognosis if aortic valve is involved.

MEDICATIONS

DRUG(S) OF CHOICE

Treatment variable—depends on severity of sepsis and presence or absence of CHF.

Antibiotics

• Backbone of treatment but usually do not eradicate infection before irreversible aortic valve damage occurs; more than minimal damage to the aortic valve is life-threatening because aortic insufficiency tends to be a lethal complication. • High-dose IV administration of bactericidal antibiotics is imperative and recommended for as long as feasible (at least 1 week), followed by SC administration for 1 or more weeks. • Oral administration—recommended only after at least 4 weeks of injectable therapy and at least 1 week after hematologic and clinical signs of infection and inflammation have disappeared; long-term (>4 months) treatment may be required to eradicate the infection from vegetations. • Selection determined by both urgency of septic complications and results of bacterial culture; coagulase-positive staphylococci and streptococci are most often incriminated, so choices can be logically made before culture results are obtained.
• Coagulase-positive staphylococci—usually resistant to penicillin, hetacillin, amoxicillin, and ampicillin. • Streptococci—often resistant to aminoglycosides and fluoroquinolones. • Gram-negative bacteria—often sensitive to third-generation cephalosporins, fluoroquinolones, and aminoglycosides. • *Bartonella*—only aminoglycosides appear bactericidal; can try doxycycline, fluoroquinolone, rifampin, or azithromycin. • First-generation cephalosporins—reasonable choice for stable patients until culture results are obtained. • Treat life-threatening sepsis immediately with drug combinations; pending culture results, one of three regimens is recommended: ◦ Penicillin, ampicillin, ticarcillin, or a first-generation cephalosporin is combined with an aminoglycoside; aminoglycosides are not good choices for animals with overt or impending CHF or those with renal azotemia; gentamicin (2 mg/kg q8h) is recommended for only 5–10 days because of renal toxicity; a fluoroquinolone may be substituted for an aminoglycoside. ◦ Clindamycin (2–10 mg/kg IV q8h) plus enrofloxacin (10 mg/kg q24h given diluted 1 : 1 in sterile water and injected slowly over 15–20 min). ◦ Advanced-generation cephalosporins or ticarcillin–clavulanic acid (Timentin®)—high dosages, but only normal dosages if patient has renal failure.

Treatment of CHF

• Pimobendan, angiotensin-converting enzyme inhibitor, spironolactone, and furosemide (± amlodipine) indicated for patients with overt or impending CHF.
• Oxygen, high-dose furosemide—2–8 mg/kg IV (± nitroglycerin and/or hydralazine 1–2 mg/kg q12h) for patients with acute, severe pulmonary edema.

CONTRAINDICATIONS

• Avoid antibiotics that cannot penetrate fibrin (e.g., sulfonamides). • Corticosteroids.

ALTERNATIVE DRUG(S)

• Anticoagulant therapy—controversial in the prevention of embolization; heparin not recommended in human medicine as it increases risk of hemorrhage. • Aspirin (5–7 mg/kg PO q24h) and/or dalteparin (100 U/kg SC q8h) and/or clopidogrel (2–4 mg/kg PO q24h)—may reduce bacterial dissemination and embolization.

FOLLOW-UP

PATIENT MONITORING

• Emergence of antibiotic resistance—relapsing fever and inflammatory leukogram; imperative to adjust treatment based on culture results. • Frequent examination and CBC after discharge. • Repeat blood cultures 1 week after antibiotics are discontinued or if fever recurs.

PREVENTION/AVOIDANCE

• Indwelling catheters—restrict to appropriate indications; aseptic placement; replace within 3–5 days. • Administer antibiotics to dogs with moderate to severe SAS during dentistry or "dirty" procedures.
• Avoid careless use of corticosteroids.

POSSIBLE COMPLICATIONS

• CHF. • Renal failure. • Septic embolization of many tissues and organs. • Persistent or latent immune-mediated polyarthropathy.

EXPECTED COURSE AND PROGNOSIS

• Best prognosis associated with short history of bacteremia, rapid diagnosis, and aggressive treatment; given that diagnosis is often delayed in cats, prognosis is often grave.
• Mortality relatively higher in animals recently given corticosteroids. • Grave prognosis for patients with aortic valve endocarditis. • Patients with mitral valve endocarditis can be saved with appropriate treatment. • Latent CHF can occur with advanced, late diagnosis, or inadequate treatment for mitral valve endocarditis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Congenital heart defects (usually SAS) in some animals.

SYNONYMS

• Bacterial endocarditis. • Vegetative endocarditis.

SEE ALSO

• Bartonellosis. • Congestive Heart Failure, Left-Sided. • Discospondylitis. • Prostatitis and Prostatic Abscess. • Sepsis and Bacteremia.

ABBREVIATIONS

• BAPGM = Bartonella alpha-Proteobacteria growth medium. • CHF = congestive heart failure. • D5W = 5% dextrose in water.
• GI = gastrointestinal. • LRS = lactated Ringer's solution. • SAS = subaortic stenosis.

BASICS

OVERVIEW

• Endomyocarditis—acute cardiopulmonary disease that typically develops following a stressful event; characterized by interstitial pneumonia and endomyocardial inflammation; pneumonia is usually severe and commonly causes death; one report recorded the incidence of endomyocarditis at postmortem to be equivalent to that of hypertrophic cardiomyopathy.
• Endocardial fibroelastosis—congenital heart disease in which severe fibrous endocardial thickening leads to heart failure secondary to diastolic and systolic failure.
• Excessive moderator bands (EMBs)—a rare and unique pathologic disease; moderator bands are normal muscular bands in the right ventricle, but they can sometimes occur in the left ventricle.

SIGNALMENT

• Cats.
• Endomyocarditis—predominantly males (62%) age 1–4 years.
• Endocardial fibroelastosis—early development of biventricular or left heart failure, usually prior to 6 months of age.
• EMBs—can be seen in any age of cat.

SIGNS

Historical Findings

Endomyocarditis
• Dyspnea following a stressful event in a young, healthy cat.
• Respiratory signs usually occur 5–21 days after the stressor.
• In one report, 73% of cases presented between August and September.

Endocardial Fibroelastosis and EMBs
• Lethargy, weakness, collapse, syncope.
• Poor appetite and weight loss.
• Dyspnea.
• Tachypnea.
• Cyanosis.
• Abdominal distention.
• Paresis or paralysis; signs of thromboembolic disease.

Physical Examination Findings

Endomyocarditis
• Severe dyspnea.
• Occasional crackles.
• May have murmur or gallop; murmur may vary in intensity.
• May have evidence of thromboembolic disease.
• Typically no significant abnormalities prior to the stressful event.

Endocardial Fibroelastosis and EMBs
• Gallop.
• Systolic murmur, possible mitral regurgitation.
• Dyspnea and increased lung sounds or crackles.
• Paresis or paralysis with weak or absent femoral pulses.
• Arrhythmias possible.

CAUSES & RISK FACTORS

• Cause unknown for all three diseases.
• Risk factors for endomyocarditis include stressful incidents such as anesthesia (commonly associated with neutering or declawing), vaccination, relocation, or bathing.
• Endocardial fibroelastosis may be familial in Burmese and Siamese cats.
• Appearance of EMBs in a young cat would suggest a congenital malformation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other Causes of Cardiac Disease

• Hypertrophic cardiomyopathy.
• Unclassified cardiomyopathy.
• Restrictive cardiomyopathy.
• Dilated cardiomyopathy.
• Congenital heart malformations.

Other Causes of Dyspnea

• Other forms of cardiac disease as above.
• Primary respiratory disease.
• Pleural space disease.
• Mediastinal disorders, infection, trauma, neoplasia.
• Hemoglobin disorders, anemia, methemoglobinemia, causes of central cyanosis.

Other Causes of Collapse, Weakness, or Syncope

• Arrhythmias.
• Neurologic or musculoskeletal disease.
• Metabolic disease or electrolyte disorders.
• Other forms of paresis or paralysis.
• Arterial thromboembolism secondary to any form of cardiac disease or neoplasia.
• Neurologic or musculoskeletal disease.
• Neoplasia.

CBC/BIOCHEMISTRY/URINALYSIS

Not diagnostic.

OTHER LABORATORY TESTS

N/A

IMAGING

Thoracic Radiographic Findings for All Three Diseases

• Cardiomegaly.
• Interstitial or alveolar infiltrates or pleural effusion if congestion has developed.

Echocardiographic Findings

Endomyocarditis
• Normal to mildly large left atrium.
• Left ventricular wall thickness can be normal to mildly thick (0.6–0.7 cm).
• Hyperechoic endomyocardium reported—incidence seems to vary and is subjective; in one report it was as high as 86%.

Endocardial Fibroelastosis
• Limited data available.
• Reduced left ventricular function and enlarged left atrium.

EMBs
Many findings can overlap with restrictive cardiomyopathy. A network of false tendons can sometimes be imaged with 2D echocardiography.

DIAGNOSTIC PROCEDURES

ECG Findings

• Endomyocarditis—sinus tachycardia common; ventricular premature complexes, atrial premature complexes, bundle branch block, and complete atrioventricular (AV) block reported.
• Endocardial fibroelastosis—evidence for left-sided enlargement; sinus rhythm typically present, but various arrhythmias possible.
• EMBs—various electrocardiographic findings have been reported: AV block, sinus bradycardia, right bundle branch block, and left axis deviation.

PATHOLOGIC FINDINGS

Endomyocarditis

• Interstitial pneumonia.
• Left heart enlargement and opacity of the left ventricular endomyocardium with foci of hemorrhage; fibroplasia of the endocardium is striking.
• Varying degrees of endomyocardial inflammation with infiltrates of neutrophils, lymphocytes, plasma cells, histiocytes, and macrophages seen histologically.

Endocardial Fibroelastosis

• Left ventricular and atrial dilation with severe diffuse white opaque thickening of the endocardium.
• Diffuse hypocellular, fibroelastic thickening of the endomyocardium; prominent endomyocardial edema with dilation of lymphatics.

EMBs

Changes typically include an irregular left ventricular endocardial contour with a rounded apex and numerous irregular left ventricular false tendons; heart weight can be greater than normal; the moderator bands are composed of central Purkinje fibers and collagen.

TREATMENT

Endomyocarditis

• No single therapy protocol to date.
• Small percentage of cats have survived; these cats do not require long-term therapy.

ENDOMYOCARDIAL DISEASES—CATS (CONTINUED)

• Supportive care with oxygen and possibly ventilation.

Endocardial Fibroelastosis and EMBs

• Oxygen therapy via cage delivery is least stressful.
• Thoracocentesis if pleural effusion.

MEDICATIONS

DRUG(S) OF CHOICE

Endomyocarditis

Steroids, furosemide, and vasodilators have been tried, but efficacy is unknown.

Endocardial Fibroelastosis and EMBs with Acute Congestive Heart Failure (CHF)

• Parenteral administration of furosemide 0.5–1 mg/kg IV/IM q1–6h.
• Dermal application of 2% nitroglycerin ointment one-eighth to one-fourth inch q4–6h has been suggested but is of unknown efficacy.
• Arrhythmias may resolve with stabilization. If there is rapid atrial fibrillation (heart rate >200), a calcium channel blocker or beta blocker can be considered to control the ventricular response. If there is dilated cardiomyopathy, digoxin may be a better choice for controlling the atrial fibrillation rate. For other supraventricular (SV) arrhythmias and ventricular arrhythmias, waiting for a response to heart failure therapy may be wise before starting antiarrhythmic therapy.
• Intractable edema—nitroprusside 1–5 µg/kg/min may be helpful.

Chronic CHF

• Treat as other CHF, with furosemide and angiotensin-converting enzyme inhibitors (e.g., enalapril, benazepril).
• Digoxin can be added for SV arrhythmia control when patient is stable and eating.

CONTRAINDICATIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Endomyocarditis—poor, although some animals survive; animals that survive respiratory phase may progress to left ventricular endocardial fibrosis.
• Endocardial fibroelastosis and EMBs—medical treatment of CHF may prolong life, but recovery is unlikely.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Aortic thromboembolism.
• Relationship possible between endomyocarditis and left ventricular endocardial fibrosis.

SEE ALSO

• Aortic Thromboembolism.
• Congestive Heart Failure, Left-Sided.
• Congestive Heart Failure, Right-Sided.
• Myocarditis.

ABBREVIATIONS

• AV = atrioventricular.
• CHF = congestive heart failure.
• EMB = excessive moderator band.
• SV= supraventricular.

ENTROPION

BASICS

OVERVIEW
- Inversion or rolling in of eyelid margin, resulting in frictional irritation of cornea and/or conjunctiva from contact with outer surface of eyelid.
- May result in keratitis, corneal ulceration, or corneal perforation.
- Can be conformational/congenital (primary) or acquired (secondary).
- Severe corneal disease may threaten vision.

SIGNALMENT
- Common in dogs—seen in chow chow, Chinese Shar-Pei, Norwegian elkhound, sporting breeds (e.g., spaniel, retriever), brachycephalic breeds, toy breeds, and giant breeds; age—puppies as early as 2–6 weeks old; usually identified in dogs <1 year old.
- Cats—usually in brachycephalic breeds, in young cats due to chronic ocular surface disease, and older animals due to retrobulbar fat loss.

SIGNS
- Mild, medial—chronic epiphora and medial pigmentary keratitis (toy dogs and brachycephalic dogs and cats).
- Mild, lateral—chronic mucoid to mucopurulent ocular discharge (giant-breed dogs).
- Upper lid, lower lid, or lateral canthal—severe blepharospasm, purulent discharge, pigmentary or ulcerative keratitis, potential cornea rupture (chow chow, shar-pei, bloodhound, sporting breeds).
- Cats—often have associated keratoconjunctivitis, corneal ulceration, or corneal sequestrum (brown-black corneal opacity).

CAUSES & RISK FACTORS
- Genetic predisposition—based on facial conformation and eyelid support.
- Brachycephalic breeds (dogs and cats)—excessive tension on ligamentous structures of medial canthus plus nasal folds and facial conformation results in rolling inward of medial aspects of upper and lower eyelids at the medial canthus.
- Giant breeds and breeds with excessive eyelid length (macroblepharon), heavy/loose facial skin, or excessive facial folds—laxity of lateral canthus allows entropion of upper and lower eyelids and lateral canthus.
- Spastic entropion—from ocular irritation (e.g., distichia, ectopic cilia, trichiasis, foreign body, irritant conjunctivitis); leads to excessive blepharospasm.
- Non-predisposed breeds—may be primary irritant causing secondary spastic entropion.
- Loss of orbital fat or periorbital musculature may lead to enophthalmos and entropion.
- Secondary cicatricial entropion—from scarring due to eyelid wounds or eyelid surgery.
- Cats—chronic infectious conjunctivitis or keratitis: may lead to functional entropion caused by chronic blepharospasm (spastic entropion); also in older cats due to enophthalmos from retrobulbar fat loss.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Underlying causes of spastic entropion (eyelid hair anomalies, foreign bodies, infectious keratitis/conjunctivitis) should be ruled out and corrected, if possible, before an attempt at surgical correction is made.
- Puppies—common for first-time breeders of chow chows and Chinese Shar-Peis to mistakenly think that eyelids have not opened at 4–5 weeks of age, when puppies actually have severe blepharospasm and spastic entropion.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- Observe patient with minimal restraint to assess degree of entropion without distortion from tension on eyelids or periocular area.
- Apply a topical anesthetic to reduce spastic component to differentiate spastic versus physiologic entropion.

TREATMENT

Puppies
- Do *not* initially perform skin resection surgery.
- If cornea ulcerated—topical antibiotic (e.g., neomycin/polymyxin B/bacitracin) ointment q6–8h.
- If mildly entropic and cornea not ulcerated, lubricate with artificial tear ointment q8–12h.
- If moderate to severe entropion with or without corneal ulceration, temporarily evert eyelid margins with sutures to break the irritation–spasm cycle; if successful, permanent procedure is unnecessary; may need to be repeated every 2–4 weeks until adult facial conformation is achieved.
- Semi-permanent eyelid eversion with hyaluronic acid filler injection—lasts up to several months, often until adult facial conformation is achieved.
- Permanent skin resection technique—postponed until patient's facial conformation matures (usually 1.5–2 years).

Medial Entropion
- Temporary eversion of medial canthus with sutures may aid in determining contribution of medial entropion to epiphora.
- Medial canthoplasty should be considered if entropion results in pigmentary keratitis, chronic epiphora, or corneal scarring.

Mature Dogs and Cats
- Chronic entropion—requires eyelid margin–everting surgery; ranges from simple Hotz-Celsus procedure to more radical lateral canthoplasty procedures; often combined with lid-shortening procedures.
- No history of previous entropion and clinical signs of acute condition—identify cause of spastic condition and correct; may attempt temporary eversion sutures before permanent skin resection.

MEDICATIONS

DRUG(S) OF CHOICE
- Topical ophthalmic ointment—triple antibiotic (in dogs only, q6–12h) or antibiotic based on culture and sensitivity testing; may be used if cornea is ulcerated, postoperatively, or as presurgical lubricant.
- Topical petrolatum-based artificial tear ointments (e.g., Puralube® q8–12h) may be used temporarily in mild cases without corneal ulceration.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
Temporary eversion suture technique—entropion may revert when sutures are removed or spontaneously pull through the skin; repeat as necessary until patient is mature enough to undergo more permanent repair. Consider hyaluronic acid filler injection as alternative.

EOSINOPHILIA

BASICS

OVERVIEW
- Eosinophilia refers to an increased number of circulating eosinophils.
- Reference intervals may be difficult to accurately determine, as numbers do not tend to have normal (Gaussian) distribution. Absolute counts >1.5 x 10^3/µl often indicate clinically significant eosinophilia.
- Diseases associated with eosinophilia are highly variable. However, they often involve those causing release of cytokines including IL-5, IL-2, IL-3, and/or GM-CSF.
- Prevalence varies; 4.8% of cats and 10% of dogs have been identified with eosinophilia in large retrospective studies.

SIGNALMENT
- Breed and sex predilections are directly correlated to the characteristics of specific diseases.
- Rottweilers and German shepherd dogs show the highest overall prevalence of eosinophilia.

SIGNS
- Clinical signs directly associated with eosinophilia per se are lacking.
- Specific clinical signs are dependent on the disease causing the eosinophilia.

CAUSES & RISK FACTORS
- Diseases associated with eosinophilia are widely variable and can be categorized in many ways.
- Infectious diseases typically involve tissues rather than peripheral blood, and are more likely to be parasitic than bacterial.
- Tissues involved are frequently those that contain abundant mast cells, such as skin, lungs, and intestine, and often involve hypersensitivity.
- Metabolic—hypoadrenocortisim.
- Neoplastic—mast cell tumor; eosinophilic leukemia; lymphoma (both T-cell and B-cell); thymoma; mammary carcinoma; oral fibrosarcoma; transitional cell carcinoma.
- Immune mediated—hypereosinophilic syndrome (HES); idiopathic HES in Rottweilers; feline asthma; eosinophilic bronchopneumopathy; feline gastrointestinal eosinophilic sclerosing fibroplasia; flea bite allergy; eosinophilic granuloma complex.
- Infectious—*Angiostrongylus vasorum*; heartworm disease (*Dirofilaria immitis*); *Ehrlichia* spp. infections; *Anaplasma* spp. infections; histoplasmosis; sarcocytosis; *Aelurostrongylus* spp.; larval migration of various parasites.
- Toxic methimazole therapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- HES represents an idiopathic response that may be due to an occult immunologic stimulus.
- Eosinophilic leukemia is a myeloproliferative disease that often has immature forms in circulation and in the bone marrow.
- Differentiation between HES and eosinophilic leukemia can be extremely difficult and is somewhat controversial.

CBC/BIOCHEMISTRY/URINALYSIS
- Caution should be taken in interpreting the results of some in-house hematology analyzers, as they only show good correlation with gold standard instruments. A blood smear should *always* be evaluated as part of the CBC.
- Eosinophils tend to be larger and hypolobulated compared to neutrophils.
- Feline eosinophils have small, rod-shaped granules.
- Sight hounds and sporadic other individuals have "gray eosinophils," which have poorly staining granules and occasionally empty vacuoles in their cytoplasm.
- Eosinophils are grouped into one large category; bands, metamyelocytes, etc. are typically not divided out, as they are with neutrophils.

OTHER LABORATORY TESTS
Additional testing (e.g., adrenocorticotropic hormone (ACTH) stimulation test, fecal flotation, cytology, etc.) are dependent on the differential diagnosis/disease in question.

IMAGING
Diagnostic imaging utilized (e.g., radiographs, ultrasound, CT, etc.) is dependent on the differential diagnosis/disease in question.

DIAGNOSTIC PROCEDURES
Diagnostic procedures utilized (e.g., transtracheal wash, endoscopy, serologic testing, biopsy, etc.) are dependent on the differential diagnosis/disease in question.

PATHOLOGIC FINDINGS
- No specific lesions are ascribed solely to eosinophilia other than peripheral blood findings.
- Lesions are dependent on the disease(s) present.

TREATMENT
- No specific treatment is described exclusively for eosinophilia.
- The treatment employed is dependent on the cause of the eosinophilia.

MEDICATIONS
Dependent on cause.

FOLLOW-UP
Dependent on cause.

MISCELLANEOUS

SEE ALSO
Hypereosinophilic Syndrome (HES).

ABBREVIATIONS
- ACTH = adrenocorticotropic hormone.
- HES = hypereosinophilic syndrome.

EOSINOPHILIC GRANULOMA COMPLEX

BASICS

DEFINITION
• Cats—also called feline eosinophilic skin disease; term used for three distinct syndromes: eosinophilic plaque, eosinophilic granuloma, and indolent ulcer; grouped primarily according to their clinical similarities, their frequent concurrent (and recurrent) development, and their positive response to corticosteroids; reaction pattern and not a final diagnosis unless idiopathic. • Dogs—eosinophilic granuloma in dogs (EGD) rare; specific differences from cats listed separately.

PATHOPHYSIOLOGY
• Eosinophil—major infiltrative cell for eosinophilic granuloma and eosinophilic plaque, but not typically with indolent ulcer; most often associated with allergic or parasitic conditions but has a more general role in inflammatory reactions. • Eosinophilic granuloma complex (EGC)—most often in cats with hypersensitivities to inhaled allergens, food, or insects, but can also be idiopathic with possible genetic causes. • EGD—may have both a genetic predisposition and a hypersensitivity cause (especially in non-genetically susceptible breeds).

SYSTEMS AFFECTED
Skin/exocrine.

GENETICS
• Related individuals with disease development in a colony of specific pathogen-free cats indicate that genetic predisposition (possible inheritable dysfunction of eosinophilic regulation) may be significant component for development. • Genetically predisposed development of hypersensitivity.

GEOGRAPHIC DISTRIBUTION
Seasonal incidence in some geographic locations—insect or environmental allergen exposure.

SIGNALMENT

Species
• Cats—eosinophilic granuloma, eosinophilic plaque, indolent ulcer. • Dogs—eosinophilic granuloma.

Breed Predilections
• Cats—none. • Dogs—EGD: Siberian husky (76% of cases), cavalier King Charles spaniel.

Mean Age and Range
• Eosinophilic granuloma and plaque—younger cats. • Spontaneously regressing eosinophilic granuloma—<1 year. • Indolent ulcer—any age. • EGD— usually <3 years of age (80%).

Predominant Sex
• Cats (eosinophilic granuloma, indolent ulcer)—predilection for females reported; eosinophilic plaque: no sex predilection. • EGD—males (72% of cases).

SIGNS

General Comments—Cats
• Distinguishing among the syndromes depends on clinical signs. • Lesions of more than one syndrome may occur simultaneously or may change over time.

Historical Findings—Cats
• Lesions may develop spontaneously and acutely. • Eosinophilic granuloma—variable but typically nonpruritic. • Eosinophilic plaque—severe pruritus. • Indolent ulcer—pain and pruritus rare. • Seasonal incidence possible (related to insects and allergy). • Waxing and waning of clinical signs common in all syndromes.

Physical Examination Findings
• *Eosinophilic plaque*—single or multiple, alopecic, erythematous, eroded/ulcerated well-demarcated and flat-topped ± white necrotic foci; most commonly seen on the abdomen and medial thighs, but may also see in mucocutaneous junctions and other areas of the skin; frequently moist or glistening; may appear oval or linear due to pattern of licking. • *Eosinophilic granuloma*—caudal thigh (linear granuloma)—distinctly linear orientation on the caudal thigh; chin ("pouting cats")—lip margin and chin swelling; paw pads—footpad swelling, pain, and lameness; oral cavity—ulceration common (especially on the tongue, palate): cats with oral lesions may be dysphagic, have halitosis, and may drool; can be located anywhere on the body; spontaneous regression—especially in young cats with the inheritable form. • *Indolent ulcer*—classically concave and indurated ulcerations with a granular, orange-yellow color, confined to the upper lips near philtrum or upper canine teeth. • Peripheral lymphadenopathy possible for EGC lesions. • *EGD*—ulcerated plaques and nodules; green/orange color; most often affects the tongue and palatine arches; uncommon cutaneous lesions on the abdomen, cheek, digits, prepuce, and flanks. • Cavalier King Charles spaniels—lesions on the soft palate or near the tonsils.

CAUSES
• Hypersensitivity—flea or insect (mosquito bite), food hypersensitivity, and atopy; a heritable dysfunction has been proposed. • Idiopathic. • EGD—unknown; genetics in susceptible breeds; a hypersensitivity reaction often suspected (insect bite) in non-genetically susceptible breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Herpes virus dermatitis. • Feline leukemia virus (FeLV) or feline immunodeficiency virus (FIV). • Unresponsive lesions—pemphigus foliaceus, dermatophytosis and deep fungal infection, demodicosis, pyoderma, and neoplasia (metastatic adenocarcinoma, squamous cell carcinoma, and lymphoma). • EGD—neoplasia, infectious and noninfectious granuloma.

CBC/BIOCHEMISTRY/URINALYSIS
CBC—mild to moderate eosinophilia.

OTHER LABORATORY TESTS
FeLV and FIV.

DIAGNOSTIC PROCEDURES
• Impression smears (cytology) from lesions—large numbers of eosinophils (indolent ulcer may be more neutrophilic). • Comprehensive flea and insect control—assist in excluding flea or mosquito bite hypersensitivity. • Food elimination trial and provocation—appropriate in all cases. • Atopy—intradermal skin testing (preferred) or serum allergy testing followed by immunotherapy. • Biopsy.

PATHOLOGIC FINDINGS
• Histopathologic diagnosis—mainly to rule out other differentials. • Eosinophilic granuloma—nodular to diffuse granulomatous dermatitis with flame figures, eosinophils, multinucleated histiocytic giant cells; mucinosis of epidermis/hair follicle outer root sheath, mural eosinophilic folliculitis/furunculosis, eosinophilic panniculitis possible. • Eosinophilic plaque—superficial to deep perivascular dermatitis with eosinophilia to interstitial to diffuse eosinophilia; mucinosis of epidermis/hair follicle outer root sheath, diffuse spongiosis of outer root sheath, eosinophilic microvesicles/microabscesses possible. • Indolent ulcer—variable; may be predominantly neutrophilic or eosinophilic. • EGD—foci of palisading granulomas and flame figures; infiltrate with eosinophils mixed with macrophages.

TREATMENT

APPROPRIATE HEALTH CARE
• Most patients treated as outpatients unless severe oral disease prevents adequate fluid intake. • Identify and eliminate offending allergen(s) before providing medical intervention. • Atopy—immunotherapy: successful in a majority of cases; preferable to long-term corticosteroid administration.

NURSING CARE
Discourage patient from damaging lesions by excessive grooming.

DIET
No restrictions unless a food allergy is suspected. Elimination diet for suspected food allergy.

EOSINOPHILIC GRANULOMA COMPLEX (CONTINUED)

CLIENT EDUCATION

• Inform clients about the possible allergic or heritable causes. • Discuss the waxing and waning nature of these diseases.

SURGICAL CONSIDERATIONS

EGD—individual lesions may be excised/removed by carbon dioxide laser if being mechanically traumatized and medically unresponsive.

MEDICATIONS

DRUG(S) OF CHOICE

• Cases may improve with antibiotics—amoxicillin trihydrate–clavulanate 10–20 mg/kg q12h; cefovecin 8 mg/kg every 14 days; or clindamycin 11–22 mg/kg q24h. • Oral corticosteroids—ongoing treatment necessary unless the primary cause is controlled; prednisolone 2–4 mg/kg q24h, then as required to control lesions; steroid tachyphylaxis may occur and may be specific to the drug administered; may be useful to change the form; other drugs: methylprednisolone 2–3 mg/kg q24h, dexamethasone 0.1–0.2 mg/kg q24–72h, and triamcinolone 0.2–0.3 mg/kg q24–72h; higher induction dosages may be required but should be tapered as quickly as possible. • Cyclosporine modified, 7 mg/kg q24–48h. • Topical—fluocinolone/dimethyl sulfoxide (DMSO; Synotic® lotion) to individual lesions; not practical and/or may cause systemic effects in patients with large numbers of lesions.

Alternate Therapies

• Chlorambucil 0.1–0.2 mg/kg q24–72h. • α-interferon 300–1000 IU/day; limited success. • Megestrol acetate—significant side effects (e.g., diabetes, mammary cancer, pyometra); use not recommended except in severe, recalcitrant cases.

EGD

• Oral prednisolone 0.5–2.2 mg/kg/day initially; then taper gradually. • Some may undergo spontaneous remission.

FOLLOW-UP

PATIENT MONITORING

• Corticosteroids—baseline and frequent hemograms, serum chemistry profiles, and urinalyses with culture; excessive or too-frequent use of corticosteroids increases risk for development of diabetes mellitus and acquired skin fragility. • Cyclosporine—baseline and frequent hemograms, serum chemistry profiles, and urinalyses with culture; measurement of plasma cyclosporine levels as needed to establish dosage within therapeutic levels (especially cats); avoid raw meat and keep cats indoors. • Selective immunosuppressant drugs—frequent hemograms (biweekly at first, then monthly or bimonthly as therapy continues) to monitor for bone marrow suppression; routine serum chemistry profiles and urinalyses with culture (monthly at first, then every 3 months) to monitor for complications (renal disease, diabetes mellitus, and urinary tract infection).

EXPECTED COURSE AND PROGNOSIS

• Lesions should resolve permanently if a primary cause can be identified and controlled. • Most lesions wax and wane, with or without therapy; an unpredictable schedule of recurrence should be anticipated. • Drug dosages should be tapered to the lowest possible level (or discontinued, if possible) once the lesions have resolved. • Lesions in cats with the inheritable disease may resolve spontaneously after several years. • EGD—lesions may be recalcitrant to medical intervention.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Systemic glucocorticoids and immunosuppressive drugs should not be used during pregnancy.

SYNONYMS

• Eosinophilic granuloma—feline collagenolytic granuloma; feline linear granuloma. • Indolent ulcer—eosinophilic ulcer; rodent ulcer; feline upper lip ulcerative dermatitis.

SEE ALSO

• Atopic Dermatitis.
• Food Reactions, Dermatologic.

ABBREVIATIONS

• DMSO = dimethyl sulfoxide.
• EGC = eosinophilic granuloma complex.
• EGD = eosinophilic granulomas in dogs.
• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.

Client Education Handout available online

EPIDIDYMITIS/ORCHITIS

BASICS

OVERVIEW

• Epididymitis—inflammation of an epididymis; a prominent clinical sign of brucellosis. • Orchitis—inflammation of testis; may be concurrent with epididymitis (orchiepididymitis). • May be acute or chronic.

SIGNALMENT

• Often unilateral. • Infrequent in dogs; rare in cats. • No genetic basis or breed predilections. • Mean age 3.7 years; range: 11 months–10 years.

SIGNS

• Swollen testis. • Pain (if acute). • Pyrexia. • Infertility. • Anorexia. • Listlessness. • Reluctance to walk. • Reluctance to breed. • Scrotal wound or abscess. • Scrotal dermatitis (from licking behavior).

CAUSES & RISK FACTORS

• Infectious—*Brucella canis* (brucellosis), canine distemper virus, *Rickettsia rickettsii* (Rocky Mountain spotted fever). • Urethritis, prostatitis, cystitis. • Blunt abdominal or scrotal trauma, including scrotal bite or puncture wounds. • Auto-immune response to spermatozoa antigens—secondary to trauma or inflammation. • Lymphoplasmacytic auto-immune orchitis with, or without, thyroiditis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Inguinoscrotal hernia. • Scrotal dermatitis. • Torsion of the spermatic cord. • Hydrocele. • Sperm granuloma. • Testicular neoplasia. • Prostatitis. • Cystitis.

CBC/BIOCHEMISTRY/URINALYSIS

• Leukocytosis—may be found with acute or infectious orchitis. • Pyuria, hematuria, proteinuria—may be found if epididymitis/orchitis is secondary to prostatitis or cystitis.

OTHER LABORATORY TESTS

• Serology—tests identifying *B. canis* antibodies or antigens may take up to 12 weeks to become detectable: perform immediate testing in any dog with scrotal enlargement (see Brucellosis). • Rapid slide agglutination test (RSAT)—screening test; sensitive but not specific. • Due to occurrence of false positives with RSAT, retest all positives for *B. canis* with a more specific test method: modified rapid slide agglutination test (ME-RSAT), agar gel immunodiffusion test (AGID), tube agglutination test (TAT), PCR, or bacterial culture of whole blood or lymph node aspirate.

IMAGING

• Ultrasonographic evaluation of testes and epididymides—inflamed testes have patchy hypoechoic areas; inflamed epididymides have irregular contours and hypoechoic or hyperechoic areas; obtain measurements for future comparisons. • Ultrasonographic evaluation of prostate to identify underlying causes (i.e., prostatitis).

DIAGNOSTIC PROCEDURES

• Bacterial culture of semen (differentiate results from normal flora). • Semen cytologic evaluation—leukocytes; bacteria; spermatozoa with morphologic abnormalities; head-to-head agglutination (*B. canis*). • Prostate fluid cytologic examination and bacterial culture; sample collected aseptically by performing prostatic massage (per rectum) after urethral catheter placed where tip can be palpated (per rectum), followed with 5 mL saline infusion and aspiration. • Open wounds—bacterial culture. • Fine-needle aspirate—sample enlarged testes/epididymides for cytology and culture; leukocytes vary from numerous neutrophils (suppurative) to minimal inflammatory cells (granulomatous).

TREATMENT

• Castration—if fertility is not a priority; before castration, culture appropriate specimen; administer antibiotics perioperatively to avoid scirrhous cord. • Unilateral castration—for unilateral orchitis when patient's fertility must be maintained; administer appropriate perioperative antibiotics.

MEDICATIONS

DRUG(S) OF CHOICE

• If *B. canis* is diagnosed, removal of affected testicle(s) is strongly recommended due to zoonotic potential. • If infection present, antibiotic choice should be based on culture and sensitivity if available; broad-spectrum antibiotics (e.g., ampicillin sulbactam 22–30 mg/kg IV q8h) may be administered until cultures are available. • If attempting to treat *B. canis*, combined antibiotic regimes generally more successful; treatments may fail to completely clear infection. • Reported success with doxycycline (10 mg/kg PO q12h), gentamicin (5 mg/kg SC q24h for 7 days and repeated every 3 weeks), rifampin (5 mg/kg PO q24h), or enrofloxacin (5 mg/kg PO q12h) for 1–3 months.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

• Prognosis for fertility—guarded to poor, especially with bilateral orchitis. • Testicular degeneration of remaining contralateral testis may occur due to elevated intrascrotal temperature (inflammation), even following unilateral castration. • Trauma or inflammation can cause obstruction of efferent tubules or epididymal duct, leading to spermatocele or sperm granuloma. • Semen—evaluate characteristics 3 months after treatment for orchitis is completed (dogs).

EPILEPSY, GENETIC (IDIOPATHIC)—DOGS

BASICS

DEFINITION
Syndrome that is only epilepsy, with no demonstrable underlying brain lesion or other neurologic signs or symptoms; age-related; assumed genetic. The term "idiopathic" replaced by "genetic" according to the International League Against Epilepsy (ILAE) classification (see Appendix IX).

PATHOPHYSIOLOGY
• Exact mechanism unknown. • Likely different mechanisms between breeds.

SYSTEMS AFFECTED
Nervous

GENETICS
Genetic basis suspected in Australian shepherd, beagle, Belgian shepherd (Groenendael and Tervuren), Bernese mountain dog, border collie, dachshund, English springer spaniel, Finnish spitz, German shepherd, golden retriever, keeshond, Irish wolfhound, Italian spinone, Labrador retriever, Shetland sheepdog, standard poodle, vizsla.

INCIDENCE/PREVALENCE
0.5–2.3% of all dogs.

GEOGRAPHIC DISTRIBUTION
Widespread

SIGNALMENT

Species
Dog

Breed Predilections
Beagles; all shepherds (German, Australian, Belgian); Bernese mountain dogs; boxers; cocker spaniels; border collies; dachshunds; golden retrievers; Irish setters; Labrador retrievers; poodles (all sizes); Saint Bernards; Shetland sheepdogs; Siberian huskies; springer spaniels; Welsh corgis; wirehaired fox terriers. Can occur in any breed.

Mean Age and Range
• Mean age 10 months–3 years. • Range 6 months–5 years.

Predominant Sex
Male predisposition in Bernese mountain dog.

SIGNS

General Comments
• Seizures may be generalized (convulsive) from onset, or have a short aura (focal onset) with rapid secondary generalization. • An aura (animal appears frightened, dazed, seeks attention, or hides, etc.) frequently precedes the generalized seizure. • Focal seizures reported in the border collie, Finnish spitz, English springer spaniel, Labrador retriever, viszla, Belgian shepherd, standard poodle.

Historical Findings
• First seizure—between 6 months and 5 years. • Seizures—often when patient is resting or asleep; often at night or early morning; frequency tends to increase if left untreated; affected animal falls on its side, becomes stiff, chomps its jaw, salivates profusely, urinates, defecates, vocalizes, and paddles with all limbs in varying combinations; short duration (30–90 seconds). • Postictal behavior—confusion, disorientation; aimless, compulsive, blind, pacing; frequent polydipsia and polyphagia; recovery immediate or may take up to 24 hours. • Dogs with established epilepsy might have clustered generalized seizures at intervals of 1–4 weeks. • No asymmetry should be observed during seizure, e.g., twitching more pronounced on one side, limb contractions on one side, compulsive circling just prior to or after the seizure. • Stimulus-induced seizures—seizures only upon specific stimulus (sound, event).

Physical Examination Findings
• Patients often have recovered at time of presentation. • Patients may have postictal behavior.

CAUSES
Genetic in some breeds; of unknown cause in others.

RISK FACTORS
Known epilepsy in the family line.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Seizure pattern (breed, age at onset, type and frequency of seizures)—most important factor toward diagnosis. • Acute onset of cluster seizures or status epilepticus—rule out toxicity or structural brain disease. • >2 seizures within the first week of onset—consider diagnosis other than genetic epilepsy. • Seizures at <6 months or >5 years of age—consider metabolic or intracranial structural disease; rule out hypoglycemia in older dogs. • Focal seizures or presence of neurologic deficits—rule out intracranial structural disease.

CBC/BIOCHEMISTRY/URINALYSIS
• Usually normal. • Perform before initiating drug therapy as baseline data.

OTHER LABORATORY TESTS
Bile acids to rule out hepatic encephalopathy unnecessary in dogs with seizures without accompanying episodic abnormal behavior.

IMAGING
MRI—if seizure pattern does not fit genetic (idiopathic) epilepsy, neurologic deficits are present, or intracranial structural disease is suspected.

DIAGNOSTIC PROCEDURES
• Cerebrospinal fluid (CSF)—for suspected structural intracranial diseases.
• Electroencephalography—may see interictal spikes, polyspikes, and spike slow wave complexes.

PATHOLOGIC FINDINGS
• No primary lesion. • Secondary neuronal loss and gliosis from prolonged seizures.

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient—recurrence of isolated seizures.
• Inpatient—for cluster seizures (>1 seizure q24h) or status epilepticus.

NURSING CARE
Inpatients with seizure disorders require constant monitoring.

DIET
• Dogs on chronic phenobarbital (PB) and potassium bromide (KBr) treatment often become overweight; weight-reducing program as necessary. • KBr treatment—insure steady levels of salt in diet; increase in salt causes increase in bromide excretion preferentially over chloride, with subsequent decreased serum KBr levels; alternatively, decreased salt content increases KBr serum level. • Trial with high-fat, low-carbohydrate diet—no improvement in seizure control.

CLIENT EDUCATION
• Severe cluster seizures and status epilepticus are life-threatening emergencies requiring immediate medical attention. • Keep seizure calendar noting date, time, length, and severity of seizures to assess response to treatment. • Once treatment instituted, medication is lifelong in most cases. • Abrupt drug withdrawal may cause seizures.

MEDICATIONS

DRUG(S) OF CHOICE
• Initiate treatment at second generalized seizure if dog <2 years; when interictal period gradually shortens in others. • Antiepileptic treatment—decreases frequency, severity, and length of seizures; perfect control rarely achieved. • Tolerance and refractoriness to treatment may develop.

Phenobarbital
• Most efficacious antiepileptic drug (AED) in the dog. • Traditional first-line drug; initial dosage 3–5 mg/kg PO q12h; steady state reached at 12–15 days, but levels decrease significantly in first 6 months owing to activation of lysosomal enzymes. • Optimal therapeutic serum levels—100–120 µmol/L or 23–28 µg/mL. • Oral loading dose (if needed)—6–10 mg/kg PO q12h for 2–3 days to reach therapeutic range rapidly.

Zonisamide
First-line drug when seizure frequency allows (<1/week); 5 mg/kg PO q12h; 10 mg/kg PO q12h as add-on to PB; half-life 15 hours;

steady state 4 days; therapeutic range in human 10–45 µg/mL.

Levetiracetam

First-line drug when seizures have focal onset; <1 seizure/week; 20–70 mg/kg (smaller breeds require higher dosage) PO q8h; must be given q8h to reach adequate levels; no hepatic metabolism; safe; steady state 3 days; therapeutic range in human 10–40 µg/mL.

Potassium Bromide

• Traditional first-line drug; initial dosage 30 mg/kg PO q24h or divided q12h; half-life 24–46 days; steady state 3–4 months; varies with salt concentration in diet; bioavailability differs between dogs. • Optimal therapeutic serum levels—20–25 mmol/L or 1.6–2 mg/mL; if sole antiepileptic drug, 25–32 mmol/L or 2–2.25 mg/mL can be safely used. • Add on to PB if seizures uncontrolled with optimal PB level—beneficial and synergistic effect. • Loading dose—may cause vomiting, diarrhea, profound longstanding sedation; if needed, double daily PO doses for 2 weeks. • Renal insufficiency decreases bromide elimination; half initial dosage.

Diazepam (At-Home Use)

• To abort ongoing seizures—dogs with cluster seizures or status epilepticus. • Insert 0.5–1 mg/kg injectable drug in rectum (or intranasal) via 1 inch teat cannula as soon as a seizure occurs; repeat 20 and 40 minutes later for a total of 3 insertions within 40 minutes; can be safely repeated once more in 24h period. • Given early in course of ongoing seizures, helps abort subsequent seizures. • Intransal midazolam can also be used 0.5 mg/kg. Can be repeated once after 20 minutes.

CONTRAINDICATIONS

Aminophylline, theophylline.

PRECAUTIONS

α-adrenergic agonists (e.g., phenylpropanolamine)—CNS excitation.

POSSIBLE INTERACTIONS

• Cimetidine and chloramphenicol—interfere with PB metabolism; may cause toxic PB levels. • PB lowers serum levels of zonisamide and levetiracetam. • PB may lower T_4 and cause upward trend in thyroid-stimulating hormore (TSH) without signs of hypothyroidism. • PB does not interfere with low-dose dexamethasone suppression tests regardless of dose and treatment. • Zonisamide decreases total T_4. • Whenever animals on lifetime medication, refer to manufacturer's drug profile or to pharmacist for interaction information.

ALTERNATIVE DRUG(S)

• With polypharmacy, initiate add-on gradually to avoid sedation. • Gabapentin 10–20 mg/kg PO q8h; low efficacy as add-on; newer analog pregabalin may be more efficacious, 2–4 mg/kg q8h PO.
• Clorazepate 0.5–1 mg/kg PO q8h.
• Felbamate 30–70 mg/kg q12h–8h.
• Topiramate 2–10 mg/kg PO q12h.
• Phenytoin, valproic acid, carbamazepine, and ethosuximide—unsuitable pharmacokinetics in dogs. • Others—acupuncture, vagal nerve stimulation, transcranial magnetic motor stimulation. • CBD-infused oil 2.5 mg/kg (1.1 mg/lb) q12h.

FOLLOW-UP

PATIENT MONITORING

• Serum drug levels—preferentially at trough, at same time for each sampling; use same laboratory. • Phenobarbital—measure PB level 4 weeks after initiating therapy; adjust dose as needed; then repeat level every 2 weeks until optimal levels reached; with chronic use perform CBC, biochemistry, and PB level every 6–12 months; tabulate albumin, liver enzymes, and serum drug levels to monitor trend; drug essentially hepatotoxic; most dogs eventually develop hepatotoxicity if serum levels >140 µmol/L (>33 µg/mL) for long time (>6–8 months); if hepatotoxicity suspected, perform bile acids. • KBr—serum level (along with PB level) 4–6 weeks after initiating (should be 8–12 mmol/L or 0.5–1 mg/mL) and at 3–4 months; if diet change required, consider diet salt content; monitor level accordingly; monitor KBr level closely if renal insufficiency (isosthenuria or azotemia). • Zonisamide—measure level at 1 week; monitor electrolytes and acid-base status to check for renal tubular acidosis.
• Levetiracetam—measure level at 4 days.

PREVENTION/AVOIDANCE

• Abrupt discontinuation of medication may precipitate seizures. • Avoid salty treats in dogs treated with KBr.

POSSIBLE COMPLICATIONS

• Recurrent episodes of cluster seizures and status epilepticus. • PB and KBr—polyuria, polydipsia, polyphagia, weight gain.
• Phenobarbital-induced corticosteroid alkaline phosphatase (C-AP) elevation occurs frequently; may be early sign of hepatotoxicity, but of less concern if alanine aminotransferase (ALT) is within reference range. • PB-induced hepatotoxicity—after chronic treatment at high serum levels (>140 µmol/L or >33 µg/mL); often insidious in onset; only biochemical abnormality may be decreased albumin.
• Higher incidence of pancreatitis in patients treated with PB and/or KBr; once pancreatitis develops, recurrence is frequent.
• Phenobarbital—rare bone marrow suppression with severe neutropenia (± sepsis) early in course of treatment; discontinue drug.
• Paradoxical hyperexcitability; discontinue drug; risk factor for superficial necrolytic dermatitis. • KBr—when levels are >22 mmol/L or >1.8 mg/mL, owners may complain of patient's unsteadiness while managing stairs.
• Zonisamide—mild sedation, decreased appetite, gastrointestinal signs. • One case of renal tubular acidosis and one case of acute idiosyncratic hepatic necrosis reported.
• Levetiracetam—transient sedation.

EXPECTED COURSE AND PROGNOSIS

• Treatment for life. • Some dogs are well controlled with same drug and dosage for years; others remain poorly controlled despite polypharmacy. • Patient may develop status epilepticus and die. • Early treatment does not decrease occurrence of status epilepticus.
• Normal expected lifespan, but survival time shorter if episodes of status epilepticus.
• Treatment with 2 AEDs not linked to poor prognosis. • Increased risk of premature death. • Marked breed differences in incidence and mortality rates. • Prognosis depends on combined veterinary expertise, therapeutic success, and owner's motivation.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Idiopathic epilepsy can be a reason for euthyroid sick syndrome in dogs.

AGE-RELATED FACTORS

If onset <2 years of age, epilepsy more likely to be difficult to control; condition may become intractable.

PREGNANCY/FERTILITY/BREEDING

• Avoid breeding affected animals. • Reported association between estrus and onset of seizures in intact bitches with presumptive "idiopathic" epilepsy; two hormonally based patterns recognized: during heat; and during a specific time point at the end of diestrus.

SEE ALSO

• Seizures (Convulsions, Status Epilepticus)—Cats. • Seizures (Convulsions, Status epilepticus)—Dogs.

ABBREVIATIONS

• AED = antiepileptic drug.
• ALT = alanine aminotransferase. • C-AP = corticosteroid alkaline phosphatase. • CSF = cerebrospinal fluid. • ILAE = International League Against Epilepsy. • KBr = potassium bromide. • PB = phenobarbital. • TSH = thyroid-stimulating hormone.

EPIPHORA

BASICS

DEFINITION
Abnormal overflow of the aqueous portion of the precorneal tear film.

PATHOPHYSIOLOGY
Caused by one of three common problems: overproduction of the aqueous portion of tears (usually in response to ocular irritation); poor eyelid function secondary to eyelid malformation, breed conformation, or deformity; or blockage of the nasolacrimal drainage system.

SYSTEMS AFFECTED
Eye and periocular skin.

SIGNALMENT
Dogs and (less frequently) cats. See Causes.

SIGNS
N/A

CAUSES

Overproduction of Tears Secondary to Ocular Irritants

Congenital
- Distichiasis or trichiasis—common in young Shetland sheepdogs, shih tzus, Lhasa apsos, cocker spaniels, miniature poodles.
- Entropion—Chinese Shar-Peis, chow chows, Labrador retrievers.
- Eyelid agenesis—domestic shorthair cats.

Acquired
- Corneal or conjunctival foreign bodies—usually young, large-breed, active, outdoor dogs.
- Eyelid neoplasms—old dogs (all breeds).
- Blepharitis—infectious or immune mediated.
- Conjunctivitis—infectious or immune mediated.
- Ulcerative keratitis (traumatic or viral).
- Anterior uveitis.
- Glaucoma.

Eyelid Abnormalities or Poor Eyelid Function
- Abnormal eyelid function does not direct tears toward the medial canthus and nasolacrimal puncta.
- Tears never reach the nasolacrimal puncta and subsequently spill over the eyelid margin.

Congenital
- Macropalpebral fissures—brachycephalic breeds.
- Ectropion—Great Danes; bloodhounds; spaniels.
- Entropion—brachycephalic dogs: medial lower eyelid; Labrador retrievers: lateral lower eyelid.

Acquired
- Post-traumatic eyelid scarring.
- Facial nerve paralysis.

Obstruction of the Nasolacrimal Drainage System

Congenital
- Imperforate nasolacrimal puncta—Bedlington terriers, cocker spaniels, bulldogs, poodles.
- Ectopic nasolacrimal openings—extra openings along the side of the face ventral to the medial canthus.
- Nasolacrimal atresia—lack of distal openings into the nose.
- Punctal displacement.
- Lack of ventral canaliculus, nasolacrimal sac, or nasolacrimal duct.

Acquired
- Rhinitis or sinusitis—causes swelling adjacent to the nasolacrimal duct.
- Trauma—resulting in fractures of the lacrimal or maxillary bones or laceration of the nasolacrimal duct.
- Foreign bodies—grass awns, seeds, sand, parasites.
- Neoplasia—of third eyelid, conjunctiva, medial eyelids, nasal cavity, maxillary bone, or periocular sinuses causing invasion or compression of the nasolacrimal system.
- Dacryocystitis—inflammation of canaliculi, lacrimal sac, or nasolacrimal ducts.

RISK FACTORS
- Breeds prone to congenital eyelid abnormalities (see Causes).
- Active outdoor dogs—at risk for foreign bodies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other ocular discharges (e.g., mucous or purulent)—epiphora is a watery, serous discharge.
- Primary ocular abnormalities—usually the eye is red when the epiphora is caused by overproduction and quiet when secondary to impaired outflow.
- Irritative causes and some congenital causes of obstruction—thorough ocular examination.
- Acute onset, unilateral condition with ocular pain (blepharospasm)—usually indicates a foreign body or corneal injury.
- Chronic, bilateral condition—usually indicates a congenital problem.
- Facial pain, swelling, nasal discharge, or sneezing—may indicate nasal or sinus infection; may indicate obstruction from neoplasm.
- With mucous or purulent discharge at the medial canthus—may indicate dacryocystitis.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
- Skull radiographs—may show a nasal, sinus, or maxillary bone lesion.
- Dacryocystorhinography—radiopaque contrast material to help localize obstruction.
- MRI or CT—may help localize obstruction (usually with contrast media) and characterize associated lesions.

DIAGNOSTIC PROCEDURES
- Bacterial culture and sensitivity testing and cytologic examination of purulent material from the puncta (e.g., dacryocystitis); performed before instilling any substance into the eye.
- Jones test—topical fluorescein dye application to the eye; most physiologic test for nasolacrimal function; should be performed first (after culture); dye flows through the nasolacrimal system and reaches the external nares in approximately 10 seconds (or longer) in normal dogs, 15 seconds to 1 minute in cats.
- Nasolacrimal irrigation—see below.
- Rhinoscopy—with or without biopsy or bacterial culture; may be indicated if previous tests suggest a nasal or sinus lesion.
- Exploratory surgery—may be the only way to obtain a definitive diagnosis.
- Temporary tacking out of the lower medial eyelid with suture—may help determine whether repair of medial lower entropion or repositioning of the eyelid would reduce epiphora secondary to eyelid conformational abnormalities.

Nasolacrimal Irrigation
- Confirms obstruction.
- May dislodge foreign material.
- A nasolacrimal cannula or 22- or 24-gauge IV catheter without stylet is inserted into the upper nasolacrimal punctum.
- Eyewash in a 6 ml syringe is attached and irrigated through the cannula or catheter—if fluid does not exit the lower nasolacrimal punctum, the obstruction is in the upper or lower canaliculi, the nasolacrimal sac, or the lower punctum (imperforate).
- Lower punctum is manually obstructed—if flushed fluid does not exit the external nares, the obstruction is in the nasolacrimal duct or at its distal opening (atresia or blockage from a nasal sinus lesion).

TREATMENT
- Remove cause of ocular irritation—removal of a conjunctival or corneal foreign body, treatment of the primary ocular disease (e.g., conjunctivitis, ulcerative keratitis, and uveitis), cryosurgery or electroepilation for distichiasis, entropion correction, medial or lateral canthoplasty (for medial trichiasis and macropalpebral fissures), correction of cicatricial eyelid abnormalities.

• Treat primary obstruction (e.g., third eyelid mass, nasal or sinus mass, and infection)—successful management may allow normal nasolacrimal flow to resume.
• In patients predisposed to nasolacrimal obstruction, recurrence is common.
• Inform client that early detection and intervention provide better long-term prognosis.

SURGICAL CONSIDERATIONS

Imperforate Puncta

• Surgical opening of the puncta is indicated.
• If one of the puncta is patent (usually the upper punctum), flushing eyewash through the upper opening will cause "tenting" of the conjunctiva at the site of the lower punctum. Place patient under topical or general anesthesia. Grasp conjunctiva overlying the lower canaliculi with forceps and cut with scissors to leave a patent punctum.
• Puncta closed by conjunctival scarring (symblepharon) caused by severe conjunctivitis (e.g., herpesvirus conjunctivitis in cats)—use same procedure.
• Recurrent disease—may be necessary to suture Silastic® tubing in place to prevent stricture formation.

Obstructed or Obliterated Distal Nasolacrimal Duct

• Dacryocystorhinotomy, conjunctivorhinostomy, conjunctival maxiallary sinusostomy, conjunctival buccostomy—create an opening to drain the tears into the nasal cavity or oral cavity.
• See Suggested Reading for surgical technique.

MEDICATIONS

DRUG(S) OF CHOICE

• Topical broad-spectrum antibiotic ophthalmic solutions—while awaiting results of bacterial culture; q4–6h; may try neomycin, gramicidin, polymyxin B triple ophthalmic antibiotic solution, or ophthalmic ciprofloxacin solution.
• Dacryocystitis—based on bacterial culture and sensitivity test results; continue antibiotic therapy for at least 21 days.

CONTRAINDICATIONS

• Topical corticosteroids or antibiotic–corticosteroid combinations—avoid unless a definitive diagnosis has been made.
• Topical corticosteroids—never use if the cornea retains fluorescein stain (corneal ulcer present).

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Dacryocystitis

• Reevaluate every 7 days until the condition is resolved.
• Continue treatment for at least 7 days after resolution of clinical signs.
• If problem persists more than 7–10 days with treatment or recurs soon after cessation of treatment—indicates a foreign body or nidus of persistent infection; requires further diagnostics (e.g., dacryocystorhinography).
• Nasolacrimal catheter; commonly required for persistent dacryocystitis, maintains patency of the duct and prevents stricturing.
• Procedure—pass 2-0 nylon via the upper punctum and thread it through the nasolacrimal duct to exit the external nares; pass Silastic or polyethylene (PE90) tubing retrograde over the suture; suture the upper and lower portions of the tubing to the face. Most dogs tolerate the tubing well; however, an Elizabethan collar may be needed to prevent self-trauma. Continue topical antibiotics as before. Leave in place 2–4 weeks.

Dacryocystorhinotomy/ Conjunctivorhinostomy

• Tubing—reevaluate every 7 days to ensure it remains intact; may need to resuture if it becomes loosened or dislodged.
• After tubing has been removed—reevaluate in 14 days; for this and future examinations, place fluorescein on the eye and check nasolacrimal patency by examining the external nares for fluorescein; may evaluate further by cannulating and flushing with eyewash.
• Dacryocystorhinography contrast study—repeated 3–4 months after surgery to evaluate size of nasal opening; repeated for recurrence or with no nasolacrimal fluorescein drainage.

POSSIBLE COMPLICATIONS

Recurrence—most common complication; caused by recurrence of ocular irritation (e.g., corneal ulceration, distichiasis, entropion), recurrence of dacryocystitis, or closure of the dacryocystorhinotomy or conjunctivorhinostomy openings into the nasal cavity.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Chronic conjunctivitis.
• Recurrent eye "infections."
• Moist dermatitis (hot spots) ventral to the medial canthus.
• Nasal discharge.

EPISCLERITIS

BASICS

OVERVIEW
- Focal or diffuse infiltration of episclera and/or scleral stroma by inflammatory cells and fibroblasts.
- Primary—affects only the eye; probably immune mediated; appears either as a perilimbal episcleral/scleral nodule (nodular episcleritis) or as a diffuse thickening of the episclera (diffuse episcleritis); nodular form may affect cornea and third eyelid with nodules.
- Secondary—usually diffuse; from spillover of inflammatory cells into the episclera from other ocular disorders (e.g., endophthalmitis and panophthalmitis); may affect virtually any other organ system.

SIGNALMENT
- Dog.
- Young to middle-aged collie, Shetland sheepdog.

SIGNS
- Nodular—typically appears as a smooth, painless, localized, raised, pink-tan, firm episcleral/scleral mass.
- Diffuse—less common; appears as a diffuse reddening and thickening of the entire episclera/sclera; accompanied by variable amounts of ocular pain.
- Secondary—uveitis often pronounced.
- Conjunctiva—usually moves freely over the surface of the lesion.
- Nodules—tend to be slowly progressive, bilateral, and prone to recurrence.

CAUSES & RISK FACTORS
- Nodular and diffuse primary—idiopathic; believed to be immune mediated.
- Secondary—may result from deep fungal or bacterial ocular infection, lymphoma, systemic histiocytosis in Bernese mountain dogs, chronic glaucoma, and ocular trauma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other causes of a red eye—differentiated by complete ophthalmic examination.
- Other mass-like lesions—differentiated by biopsy or cytologic examination.
- Neoplasia—lymphoma, squamous cell carcinoma, extension of intraocular mass, other tumors.
- Granuloma—deep fungal infection, retained foreign body.
- Granulation tissue—trauma, healing corneal ulcer, globe perforation with uveal prolapse.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal if lesion is confined to eye or adnexa.
- Secondary—may see abnormalities consistent with systemic disease.

OTHER LABORATORY TESTS
Serologic testing—may help diagnose fungal infection.

IMAGING
- Abdominal ultrasound, thoracic and abdominal radiographs—may help rule out fungal infection or disseminated neoplasia.
- Ocular ultrasound—may reveal other abnormalities if ocular media opacities prevent thorough ocular examination.

DIAGNOSTIC PROCEDURES
- Incisional biopsy and histopathologic examination of affected tissue.
- Nodular—varying numbers of histiocytes, lymphocytes, plasma cells, and fibroblasts.
- If uveitis prominent—see Anterior Uveitis—Dogs.

TREATMENT
- Verify the diagnosis histologically or cytologically before treatment.
- Primary nodular—benign course; observation alone may be appropriate with mild disease.
- Outpatient treatment if ocular pain, diffuse scleral involvement, eyelid function is disrupted, cornea is affected, or vision is threatened.

MEDICATIONS

DRUG(S) OF CHOICE
- Progress down the list only if the previous modality was ineffective.
- Topical 1% prednisolone acetate q4h for 1 week, then q6h for 2 weeks, then tapered.
- Systemic prednisolone 1–2 mg/kg/day PO; taper with improvement.
- Systemic azathioprine 1–2 mg/kg/day PO for 3–7 days; then tapered to as low as possible.
- Cryosurgery or attempted excision.
- Alternative to listed drugs or surgery—may try a combination of tetracycline and niacinamide (q8h PO); 250 mg each for dogs <10 kg; 500 mg each for dogs >10 kg; may not observe good clinical response for at least 8 weeks; side effects uncommon and primarily the result of gastrointestinal upset by niacinamide.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Avoid systemic immunosuppressive drugs with fungal infections.
- Systemically administered prednisolone—may precipitate pancreatitis, iatrogenic hyperadrenocorticism.
- Azathioprine—may induce potentially fatal myelosuppression, hepatotoxicosis.
- Niacin—do not substitute for niacinamide.

FOLLOW-UP

PATIENT MONITORING
- Primary—monitor for nodule regression or reduction in episcleral thickening or reddening every 2–3 weeks for 6–9 weeks and then as needed; prognosis usually good; may require therapy for months to rest of life.
- Secondary—follow-up, prognosis, and complications depend on primary disease.
- Azathioprine—repeat CBC, platelet count, and measurement of liver enzymes every 1–2 weeks for first 8 weeks, then periodically.

POSSIBLE COMPLICATIONS
- Vision loss.
- Chronic ocular pain.
- Uveitis.
- Secondary glaucoma.

MISCELLANEOUS

SYNONYMS
- Collie granuloma.
- Fibrous histiocytoma.
- Limbal granuloma.
- Necrogranulomatous sclerouveitis.
- Nodular fasciitis.
- Nodular granulomatous episcleritis.
- Proliferative keratoconjunctivitis.

EPISTAXIS

BASICS

DEFINITION
Bleeding from the nose.

PATHOPHYSIOLOGY
Results from one of three abnormalities—coagulopathy; local disease or space-occupying lesion; vascular or systemic disease.

SYSTEMS AFFECTED
- Respiratory—hemorrhage; sneezing
- Gastrointestinal (GI)—melena.
- Hemic/lymphatic/immune—anemia.

GENETICS
Varies depending on underlying cause.

INCIDENCE/PREVALENCE
Varies depending on underlying cause.

SIGNALMENT

Species
Dog and cat.

Age, Breed, and Sex Predilections
Vary depending on underlying cause.

SIGNS

Historical Findings
- Nasal hemorrhage—unilateral or bilateral possible.
- Sneezing and/or stertorous respiration.
- Melena.
- With coagulopathy—hematochezia, melena, hematuria, or hemorrhage from other areas of the body.
- With hypertension—possibly blindness, intraocular hemorrhage, neurologic signs, cardiac or renal signs.

Physical Examination Findings
- Nasal hemorrhage.
- Melena—from swallowing blood or concurrent upper GI hemorrhage.
- Nasal stridor—may be present with neoplasia, foreign body, or advanced inflammatory disease.
- With coagulopathy—possibly petechiae, ecchymosis, hematomas, intracavitary bleeds, hematochezia, melena, and hematuria.
- With coagulopathy or hypertension—possibly retinal or intraocular hemorrhages or retinal detachment; with hypertension—possibly heart murmur or arrhythmia.

CAUSES

Coagulopathy

Thrombocytopenia
- Immune-mediated disease—idiopathic disease; drug reaction; modified live virus (MLV) vaccine reaction.
- Infectious disease—ehrlichiosis; anaplasmosis; Rocky Mountain spotted fever, babesiosis, feline leukemia virus (FeLV) or feline immunodeficiency virus (FIV)-related illness.
- Bone marrow disease—neoplasia; aplastic anemia; infectious (fungal, rickettsial, or viral).
- Paraneoplastic disorder.
- Disseminated intravascular coagulation (DIC).

Thrombopathia
- Congenital—von Willebrand disease; thrombasthenia; thrombopathia.
- Acquired—nonsteroidal anti-inflammatory drugs (NSAIDs); clopidogrel; hyperglobulinemia (*Ehrlichia*, multiple myeloma); uremia; DIC.

Coagulation Factor Defects
- Congenital—hemophilia A (factor VIIIc deficiency) and hemophilia B (factor IX deficiency).
- Acquired—anticoagulant rodenticide (warfarin) intoxication, hepatobiliary disease, DIC.

Local Lesion
- Foreign body.
- Trauma.
- Infection—fungal (*Aspergillus*, *Cryptococcus*, *Rhinosporidium*); viral or bacterial. Usually blood-tinged mucopurulent exudate rather than frank hemorrhage.
- Neoplasia—adenocarcinoma; carcinoma; chondrosarcoma; squamous cell carcinoma; fibrosarcoma; lymphoma; transmissible venereal tumor.
- Dental disease—oronasal fistula, tooth root abscess.
- Lymphoplasmacytic rhinitis.

Vascular or Systemic Disease
- Hypertension—renal disease; hyperthyroidism; hyperadrenocorticism; pheochromocytoma; idiopathic disease.
- Hyperviscosity—hyperglobulinemia (multiple myeloma, *Ehrlichia*); polycythemia.
- Vasculitis—immune-mediated and rickettsial diseases.

RISK FACTORS

Coagulopathy
- Immune-mediated disease—young to middle-aged, small-to medium-sized female dogs.
- Infectious disease—dogs living in or traveling to endemic areas; tick exposure.
- Thrombasthenia—otter hounds.
- Thrombopathia—basset hounds, spitz.
- von Willebrand disease—Doberman pinschers, Airedales, German shepherds, Scottish terriers, Chesapeake Bay retrievers, and many other breeds; cats.
- Hemophilia A—German shepherds and many other breeds; cats.
- Hemophilia B—Cairn terriers, coonhounds, Saint Bernards, and other breeds; cats.

Space-Occupying Lesions
- Aspergillosis—German shepherds, Rottweilers, mesocephalic and dolichocephalic breeds.
- Neoplasia—dolichocephalic breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
See Causes.

CBC/BIOCHEMISTRY/URINALYSIS
- Anemia—if enough hemorrhage has occurred.
- Thrombocytopenia—possible.
- Neutrophilia—infection; neoplasia.
- Pancytopenia—if bone marrow disease.
- Hypoproteinemia—if enough hemorrhage has occurred.
- High blood urea nitrogen (BUN) with normal creatinine—possible, owing to blood ingestion.
- Hyperglobulinemia—possible with ehrlichiosis, multiple myeloma.
- Azotemia—with renal failure-induced hypertension.
- High alanine transaminase (ALT), aspartate aminotransferase (AST), and total bilirubin—with coagulopathy from severe hepatic disease.
- Urinalysis—usually normal; possible to see hematuria (if coagulopathy), isosthenuria (if renal failure–induced hypertension), and proteinuria (if glomerulotubular disease and hypertension).

OTHER LABORATORY TESTS
- Coagulation profile—prolonged times with coagulation factor defects; normal with thrombocytopenia and thrombopathia.
- Platelet function testing (e.g., buccal mucosal bleeding time, von Willebrand factor analysis)—may be abnormal with platelet dysfunction (platelet count and coagulation profile may be normal).
- *Ehrlichia*, *Anaplasma*, Rocky Mountain spotted fever, or *Babesia* testing—may be positive in thrombocytopenia or thrombopathia-induced epistaxis.
- *Aspergillus* serology—may help establish a diagnosis of fungal rhinitis; false-negative results are common, so results must be interpreted in light of other clinical and diagnostic findings.
- Thyroid hormone assay—elevated in cats with epistaxis due to hyperthyroid-induced hypertension.

IMAGING
- Thoracic radiograph—screen for metastasis.
- Nasal series—under anesthesia, including open-mouth ventrodorsal and skyline sinus views when space-occupying or local lesion is suspected; osteolysis with neoplasia and fungal sinusitis; foreign bodies usually not seen; dental disease may be identified.
- CT or MRI—more sensitive than radiographs.

DIAGNOSTIC PROCEDURES
- Blood pressure evaluation—indicated when coagulopathies and space-occupying lesions have been ruled out and particularly when azotemia or proteinuria is noted.

EPISTAXIS (CONTINUED)

• Rhinoscopy, nasal lavage, nasal biopsy (blind or guided via rhinoscopy or CT)—indicated for space-occupying disease; aimed at removing foreign bodies and evaluating and sampling nasal tissue for causal diagnosis (e.g., evaluate nasal tissue samples for neoplasia, inflammation, and infection via cytology and/or histopathology and bacterial/fungal culture and sensitivity testing).
• Bone marrow aspiration biopsy—indicated if pancytopenia identified.

TREATMENT

APPROPRIATE HEALTH CARE

• Coagulopathy—usually inpatient management.
• Space-occupying lesion or vascular or systemic disease—outpatient or inpatient management, depending on disease and its severity.
• Nasal tumors—radiotherapy; various response rates.

NURSING CARE

Provide basic supportive care if needed (fluids, nutrition).

ACTIVITY

Minimize activity or stimuli that precipitate hemorrhage episodes.

CLIENT EDUCATION

• Inform client about the disease process.
• Teach client how to recognize a serious hemorrhage (e.g., weakness, collapse, pallor, and blood loss >30 mL/kg bodyweight).

SURGICAL CONSIDERATIONS

• Surgery indicated if a foreign body is unable to be removed by rhinoscopy or blind attempt.
• Fungal rhinitis (e.g., *Aspergillus* and *Rhinosporidium*) require debulking (also see Medications).

MEDICATIONS

DRUG(S) OF CHOICE

General

• Whole blood, packed red blood cell (RBC), or hemoglobin solution transfusion—can be needed with severe anemia.
• Acepromazine (0.05–0.1 mg/kg SC/IV if normothermic and no platelet disorder present) to lower blood pressure and promote clotting; may help control serious hemorrhage.
• Discontinue all NSAIDs.

Coagulopathy

• Immune-mediated thrombocytopenia—prednisone (1.1 mg/kg q12h; taper over 4–6 months); other drugs can be used in addition to prednisone for refractive cases (see Thrombocytopenia, Primary Immune Mediated).
• Infectious disease—rickettsial disease (doxycycline 5 mg/kg PO q12h for 3–6 weeks); *Babesia* (imidocarb 6.6 mg/kg SC 2 doses 2 weeks apart, diminazene aceturate 5 mg/kg IM once, or 10 days of atovaquone 13.3 mg/kg PO q8h with azithromycin 10 mg/kg PO q24h).
• Bone marrow neoplasia—see Myeloproliferative Disorders.
• Thrombopathia and thrombasthenia—no treatment unless lymphoproliferative disease.
• von Willebrand disease—plasma or cryoprecipitate for acute bleeding; 1-desamino-8-d-arginine vasopressin (DDAVP) 1 µg/kg SC/IV diluted in 20 mL 0.9% NaCl given over 10 min may help control or prevent hemorrhage prior to invasive procedures; intranasal formulation (less expensive) may be used after passing through a bacteriostatic filter.
• Hemophilia A—plasma or cryoprecipitate for acute bleeding; no long-term treatment.
• Hemophilia B—plasma for acute bleeding; no long-term treatment.
• Anticoagulant rodenticide intoxication—plasma for acute bleeding; vitamin K at 5 mg/kg loading dose followed by 1.25 mg/kg q12h for 1 week (if warfarin formulation) to 4 weeks (longer-acting formulation).
• Hyperglobulinemia—plasmapheresis.
• Polycythemia—phlebotomy; hydroxyurea.
• Liver disease and DIC—treat and support underlying cause; plasma may be beneficial.

Space-Occupying Lesion

• Secondary bacterial infection—antibiotics based on culture and sensitivity testing.
• Fungal infection—for aspergillosis, topical treatment of nasal cavity and frontal sinuses with 1% clotrimazole in polyethylene glycol (see Precautions) or 1–5% enilconazole (see Aspergillosis, Nasal for protocol); for cryptococcosis—oral and injectable antifungal agents (see Cryptococcosis); for rhinosporidiosis—surgery followed by dapsone (1 mg/kg PO q8h for 2 weeks, then 1 mg/kg PO q12h for 4 months).

Vascular or Systemic Disease

• Hyperviscosity—treat underlying disease (e.g., ehrlichiosis, multiple myeloma, or polycythemia); plasmapheresis.
• Vasculitis— doxycycline for rickettsial disease (5 mg/kg q12h for 3–6 weeks); prednisone for immune-mediated disease (1.1 mg/kg q12h; taper over 4–6 months).

Hypertension

• Treat underlying disease—renal disease, hyperthyroidism, hyperadrenocorticism.
• Reduce weight if overconditioned.
• Restrict sodium.
• Calcium channel blockers—amlodipine (dogs: 0.1 mg/kg PO q12–24h; cats: 0.625–1.25 mg/cat PO q12–24h); treatment of choice.
• ACE inhibitors—benazepril (0.5 mg/kg q24h); enalapril (0.25–0.5 mg/kg q12–24h).
• Beta blockers—propranolol (0.5–1 mg/kg q8h); atenolol (0.25–1.0 mg/kg q12–24h).
• Diuretics—hydrochlorothiazide (2–4 mg/kg q12h); furosemide (0.5–2 mg/kg q8–12h).
• Phenoxybenzamine (0.2–1.5 mg/kg q12h) for pheochromocytoma.

CONTRAINDICATIONS

• Avoid drugs that may predispose patient to hemorrhage—NSAIDs; heparin; clopidogrel; phenothiazine tranquilizers.
• Topical antifungals—do not use in patients with disruption of the cribriform plate.

PRECAUTIONS

• Chemotherapeutic drugs (immune-mediated thrombocytopenia therapy, e.g., azathioprine)—monitor neutrophil counts and liver enzymes weekly until a pattern has been established that shows that the patient is tolerating the drug.
• Enalapril and/or diuretics—closely monitor patients with renal failure; avoid severe salt restriction when using angiotensin-converting enzyme (ACE) inhibitors.
• Avoid topical clotrimazole preparations with propylene glycol, as life-threatening mucosal irritation, ulceration, and nasopharyngeal swelling can occur.

FOLLOW-UP

PATIENT MONITORING

• Platelet count with thrombocytopenia.
• Coagulation profile with coagulation factor defects.
• Blood pressure with hypertension.
• Clinical signs.

PREVENTION/AVOIDANCE

• Restrict access to areas that might contain anticoagulant rodenticides.
• Practice dental preventative care.

POSSIBLE COMPLICATIONS

Anemia and collapse (rare).

EXPECTED COURSE AND PROGNOSIS

Varies depending on underlying cause.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Avoid teratogenic drugs (e.g., itraconazole).

ABBREVIATIONS

• ACE = angiotensin-converting enzyme.
• ALT = alanine transaminase.
• AST = aspartate aminotransferase.
• BUN = blood urea nitrogen.
• DDAVP = 1-desamino-8-d-arginine vasopressin.
• DIC = disseminated intravascular coagulation.
• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.

- GI = gastrointestinal.
- MLV = modified live virus.
- NSAID = nonsteroidal anti-inflammatory drug.
- RBC = red blood cell.

ERYTHROCYTOSIS

BASICS

DEFINITION
An increase in packed cell volume (PCV), hemoglobin concentration, or red blood cell (RBC) count above the reference interval due to a relative or absolute increase in the number of circulating RBCs.

PATHOPHYSIOLOGY
- Circulating RBC numbers are affected by changes in plasma volume, rate of RBC destruction or loss, splenic contraction, erythropoietin (EPO) secretion, and bone marrow production.
- Erythropoiesis is also affected by hormones from the adrenal cortex, thyroid gland, ovary, testis, and anterior pituitary gland; normal PCV is maintained by an endocrine loop.
- Erythrocytosis is either relative or absolute.
- Relative—develops when hemoconcentration or splenic contraction produces an increase in circulating RBCs.
- Absolute—increase in circulating RBC mass due to an increase in bone marrow production; either primary or secondary to an increase in the production of EPO.
- Primary absolute (polycythemia vera)—myeloproliferative disorder characterized by neoplastic proliferation of all marrow cell precursors independent of EPO.
- Secondary absolute—caused by physiologically appropriate release of EPO due to chronic hypoxemia, excessive production of EPO or an EPO-like substance in an animal with normal partial pressure of oxygen (PaO_2), or by excessive exogenous administration of EPO or darbepoetin.

SYSTEMS AFFECTED
Cardiovascular, respiratory, nervous, renal/urologic—blood hyperviscosity causes poor perfusion and oxygen delivery to tissues.

GENETICS
Mutations of the JAK2 gene have been associated with polycythemia vera in humans.

INCIDENCE/PREVALENCE
Relative erythrocytosis due to hemoconcentration or splenic contraction is the most common cause of erythrocytosis.

GEOGRAPHIC DISTRIBUTION
- Reference intervals for PCV, hemoglobin, and RBC count vary with geographic location and breed.
- Animals living at high altitudes have higher PCV than those at sea level.

SIGNALMENT
Species
Dog and cat.

Breed Predilections
- Excitable breeds and cats are prone to splenic contraction.
- Greyhounds have higher PCV values (reference interval is 50–65%).

Mean Age and Range
Primary absolute polycythemia vera—cats 6–7 years; dogs 7 years or older.

Predominant Sex
Male cats, female dogs.

SIGNS
Historical Findings
- Relative—excitement or dehydration.
- Absolute—lethargy, seizures, altered mentation, anorexia, epistaxis, mucous membrane hyperemia.

Physical Examination Findings
- Relative—dehydration and clinical evidence of fluid loss.
- Absolute—lethargy, low exercise tolerance, behavioral change, brick red or cyanotic mucous membranes, sneezing, epistaxis, large size and tortuosity of retinal and sublingual vessels, cardiopulmonary impairment.
- Primary absolute—variable degrees of splenomegaly, hepatomegaly, thrombosis, and hemorrhage; seizures.
- Secondary appropriate absolute—clinical signs of hypoxemia caused by chronic pulmonary disease, cardiac disease with right-to-left shunting, or hemoglobinopathy.
- Secondary absolute (inappropriate EPO secretion)—signs associated with neoplasia, space-occupying renal lesion, or endocrine disorder.

CAUSES
- Relative—hemoconcentration/dehydration or splenic contraction due to excitement.
- Primary absolute—rare myeloproliferative disorder.
- Secondary appropriate absolute—chronic pulmonary disease, cardiac disease or anomaly with right-to-left shunting, high altitude, methemoglobinemia, and impairment of renal blood supply.
- Secondary absolute caused by inappropriate EPO secretion (rare)—neoplasia (e.g., T-cell lymphoma, nasal fibrosarcoma, renal carcinoma, pheochromocytoma, cecal leiomyosarcoma), hyperadrenocorticism, hyperthyroidism, hyperandrogenism.
- Secondary absolute caused by inappropriate EPO or darbepoetin administration in animals undergoing therapy for anemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Moderately high PCV and total plasma protein with concurrent dehydration—suggest relative polycythemia.
- Secondary absolute—caused by diseases that produce chronic hypoxemia or by space-occupying lesions of the kidney, endocrine disorders, neoplasms that produce EPO or an EPO-like substance independent of hypoxia, history of EPO administration.
- Polycythemia vera—diagnosed by elimination of other causes.

CBC/BIOCHEMISTRY/URINALYSIS
- Increased PCV or hematocrit.
- Physiologic leukocytosis (neutrophilia and lymphocytosis) may occur with splenic contraction.

OTHER LABORATORY TESTS
- Serial monitoring of PCV—diagnosis of polycythemia vera requires an unexplained high PCV documented on multiple occasions (several weeks) with no underlying cause.
- Arterial blood gas analysis may demonstrate a low PaO_2 in cases of secondary appropriate absolute erythrocytosis; pulse oximetry may also be used to assess oxygen saturation (SpO_2).
- EPO measurement—not currently recommended due to lack of veterinary-specific assays and extensive overlap in EPO concentration between normal and affected animals.
- Thyroid testing (cats).

IMAGING
Radiography and abdominal ultrasonography to detect cardiopulmonary disease and neoplasia.

DIAGNOSTIC PROCEDURES
- Biopsy of any masses.
- Bone marrow aspirate.

PATHOLOGIC FINDINGS
Polycythemia vera—gross findings: generalized vascular congestion, arterial thrombosis, splenomegaly, diffusely red bone marrow with reduced fat; microscopic findings: hyperplastic bone marrow with normal or reduced myeloid/erythroid ratio and reduced iron content.

TREATMENT

APPROPRIATE HEALTH CARE
- Relative—rehydration with IV fluids appropriate for primary cause; assessment of renal function, gastrointestinal system, acid-base status, and electrolyte balance; if not hemoconcentrated, allow patient to calm down.
- Absolute—phlebotomy recommended (20 mL/kg over 1 to several days) to reduce RBC mass to PCV of 55%; blood volume should be replaced concurrently with isotonic fluids.
- Secondary inappropriate absolute—phlebotomy combined with identification and removal of EPO source.
- Secondary appropriate absolute—phlebotomy and hydroxyurea. The high PCV

is an appropriate compensatory response; thus, phlebotomy may be dangerous; if indicated, remove blood at a lower volume (5 mL/kg). A higher PCV (60–65%) may be necessary to sustain life until the cause of hypoxemia can be corrected.
• Polycythemia vera—phlebotomy (20 mL/kg) and hydroxyurea; frequency of bleeding and dosage adjusted to maintain a PCV of 55% in dogs and 45% in cats.

NURSING CARE
Oxygen therapy may be indicated for patients with cyanosis, hypoxemia, cardiopulmonary disease, or weakness following phlebotomy.

ACTIVITY
Excessive exercise should be avoided.

DIET
Normal diet, free-choice water.

CLIENT EDUCATION
• Patients need to be observed at home for changes in activity, difficulty breathing, or bleeding.
• Patients treated with EPO for anemia must have PCV rechecked and dose adjusted at regular intervals.

SURGICAL CONSIDERATIONS
If surgery is necessary, preoperative phlebotomy and close monitoring of oxygenation and vital parameters may be necessary. Postoperatively, monitor for bleeding or thrombosis.

MEDICATIONS

DRUG(S) OF CHOICE
• Polycythemia vera—hydroxyurea (dogs: 40–50 mg/kg PO divided twice daily; cats: 30 mg/kg PO q24h).
• Erythrocytosis secondary to hypoxemia—hydroxyurea (40–50 mg/kg PO q48h).

CONTRAINDICATIONS
Phlebotomy may be contraindicated in hypoxemic patients.

PRECAUTIONS
• Rapid removal of blood can cause hypotension and cardiovascular collapse.
• Adverse effects of hydroxyurea include bone marrow hypoplasia with thrombocytopenia, anemia, and neutropenia, alopecia, changes in skin pigmentation, and sloughing of toenails.
• Methemoglobinemia and hemolytic anemia reported in cats treated with hydroxyurea.

ALTERNATIVE DRUG(S)
Polycythemia vera—chlorambucil (dogs and cats: 0.2 mg/kg PO q24h) or busulfan (dogs: 2–4 mg/m^2 PO q24h).

FOLLOW-UP

PATIENT MONITORING
• PCV, total protein, urine output, and bodyweight daily in severely dehydrated animals.
• Patients treated for polycythemia vera by chemotherapy—monitor weekly for changes in PCV, leukocytes, and platelets during initial treatment; then monthly for adjustment of chemotherapy and periodic phlebotomy.
• Periodic assessment of bone marrow iron stores or serum iron levels is indicated to detect iron deficiency.

POSSIBLE COMPLICATIONS
• Hyperviscosity in patients with absolute polycythemia, especially polycythemia vera, may lead to thrombosis, infarction, or hemorrhage.
• Chemotherapy may cause bone marrow suppression.
• Patients undergoing repeated phlebotomies can develop iron deficiency, hypoproteinemia, and peripheral edema.

EXPECTED COURSE AND PROGNOSIS
• Relative erythrocytosis—fair to good prognosis depending on primary cause.
• Secondary absolute appropriate erythrocytosis—clinical course and prognosis are determined by the severity of the lesion causing hypoxemia.
• Secondary inappropriate absolute erythrocytosis—if the tissue source of excessive EPO secretion can be identified and removed or corrected, prognosis is good to fair depending on cause.
• Primary absolute erythrocytosis (polycythemia vera)—prognosis is guarded, although cats have had survival times up to 5 years.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
Hydroxyurea may arrest or inhibit spermatogenesis.

SYNONYMS
Polycythemia—although use of this term should be avoided, due to its similarity with polycythemia vera.

SEE ALSO
• Hyperviscosity Syndrome.
• Polycythemia Vera.

ABBREVIATIONS
• EPO = erythropoietin.
• PaO_2 = partial pressure of oxygen.
• PCV = packed cell volume.
• RBC = red blood cell.
• SpO_2 = oxygen saturation.

ESOPHAGEAL DIVERTICULA

BASICS

OVERVIEW
- Pouch-like sacculations of the esophageal wall that accumulate fluids and ingesta.
- Diverticula may be congenital or acquired and are rare.
- Pulsion diverticula occur secondary to increased intraluminal pressure. Seen with esophageal obstructive disorders such as foreign body or mass lesions.
- Traction diverticula occur secondary to periesophageal inflammation where fibrosis contracts and pulls out the wall of the esophagus into a pouch.
- Localized inflammation around (esophagitis) and lining the diverticulum may be present.
- Potential complications include ingesta impaction, mechanical obstruction (large diverticulum), and/or esophageal hypomotility.
- Organ systems affected include gastrointestinal (regurgitation), musculoskeletal (weight loss), and respiratory (aspiration pneumonia).

SIGNALMENT
- Rare; more common in dog than cat.
- Congenital or acquired (no genetic basis proven).
- No important breed or sex predisposition.

SIGNS
- Postprandial regurgitation, dysphagia, anorexia, coughing.
- Weight loss, respiratory distress.

CAUSES & RISK FACTORS

Pulsion Diverticulum
- Embryonic developmental disorders of the esophageal wall.
- Esophageal foreign body, mass or focal motility disturbances (uncommon).

Traction Diverticulum
Inflammatory processes associated with the trachea, lungs, hilar lymph nodes, or pericardium; resultant fibrous connective tissue adheres to the esophageal wall.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Esophageal redundancy—barium contrast accumulation in the region of the thoracic inlet can occur normally in young dogs (especially brachycephalic breeds and Chinese Shar-Pei).
- Periesophageal mass—esophagram or esophagoscopy should differentiate the presence of a mass causing luminal narrowing.
- Esophagitis.
- Esophageal foreign body.
- Hiatal hernia.
- Gastroesophageal intussusception.

CBC/BIOCHEMISTRY/URINALYSIS
Usually within normal limits.

OTHER LABORATORY TESTS
N/A

IMAGING
- Thoracic radiography—may show air or soft tissue opacity cranial to the diaphragm or cranial to the thoracic inlet.
- Contrast esophagram—shows contrast accumulation within the diverticulum.
- Videofluoroscopy—useful to evaluate for disturbances in esophageal motility.

DIAGNOSTIC PROCEDURES
Esophagoscopy confirms ingesta/debris within outpouchings of the esophagus.

TREATMENT

- If the diverticulum is small and not causing significant clinical signs, treat conservatively with elevated feedings of a soft, bland diet followed by copious liquids or a semi-liquid diet.
- If the diverticulum is large or is associated with significant clinical signs, surgical resection is recommended.
- Client education should include the importance of dietary management and the potential for aspiration pneumonia.
- Fluid therapy, antibiotics, and aggressive nursing, if concurrent aspiration pneumonia is present; alternative enteral nutrition via gastrostomy tube may be necessary in patients with aspiration pneumonia.
- Treat for esophagitis if present.

MEDICATIONS

DRUG(S) OF CHOICE
- Drug therapy for esophagitis, if present.
- Proton pump inhibitors, such as omeprazole or pantoprazole, are potent and effective anti-secretory agents (omeprazole: 0.7–1.5 mg/kg PO q12h; pantoprazole: 0.7–1.5 mg/kg IV once daily) for treatment of severe esophagitis.
- Use broad-spectrum antibiotics if patient has concurrent aspiration pneumonia; if recurrent or severe pneumonia is present, base antibiotic selection on culture and sensitivity of samples obtained by transtracheal wash or bronchoalveolar lavage.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
- Evaluate for evidence of infection or aspiration pneumonia.
- Maintain positive nutritional balance throughout disease process.

POSSIBLE COMPLICATIONS
Patients with diverticula and impaction are predisposed to perforation, fistula, stricture, and postoperative incisional dehiscence.

EXPECTED COURSE AND PROGNOSIS
- Prognosis is guarded in patients with large diverticula and overt clinical signs.
- Motility disturbances may persist post-surgery.

ESOPHAGEAL FOREIGN BODIES

BASICS

DEFINITION
Ingestion of foreign material or foodstuffs too large to pass through the esophagus, causing partial or complete luminal obstruction.

PATHOPHYSIOLOGY
Esophageal foreign bodies cause mechanical obstruction, mucosal inflammation with edema, and possibly ischemic necrosis and esophageal perforation.

SYSTEMS AFFECTED
- Gastrointestinal.
- Respiratory—if aspiration pneumonia.

GENETICS
N/A

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Due to the indiscriminate eating habits of many dogs, they have a higher incidence than cats.

Breed Predilections
More common in small-breed dogs; terrier breeds often overrepresented.

Mean Age and Range
More common in young to middle-aged animals.

Predominant Sex
N/A

SIGNS

General Comments
The pet may have been observed ingesting a foreign body.

Historical Findings
Most common include retching, gagging, lethargy, anorexia, ptyalism, regurgitation, restlessness, dysphagia, odynophagia, and persistent gulping.

Physical Examination Findings
- Ptyalism.
- Can be unremarkable.
- Occasional discomfort when palpating the neck or cranial abdomen.

CAUSES
Occurs most often with an object whose size, shape, or texture does not allow free movement through the esophagus, causing it to become lodged before it can pass.

RISK FACTORS
- Indiscriminate eating habits.
- Access to foreign materials.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Esophagitis.
- Esophageal stricture.
- Esophageal neoplasia.
- Megaesophagus.
- Other esophageal disorders.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually unremarkable.
- Occasionally, electrolyte abnormalities, an inflammatory leukogram, and/or hemoconcentration, depending upon the severity of signs and degree of dehydration.

OTHER LABORATORY TESTS
N/A

IMAGING

Thoracic Radiography
- Most esophageal foreign bodies are radiodense and are readily visualized. These objects most commonly lodge at points of minimal esophageal distension, including the thoracic inlet, base of the heart, and esophageal hiatus.
- Esophageal distension with air may be visualized cranial to the foreign body. Retained air in the esophagus is not always associated with esophageal foreign bodies.
- A contrast esophagram or videofluoroscopy is required to identify radiolucent objects. If perforation is suspected, use an aqueous organic iodide contrast agent for imaging studies.
- Air and/or fluid in the mediastinum or pleural space suggests esophageal perforation; depending on severity, this can be an indication for surgery versus esophagoscopy.
- Pulmonary infiltrates suggest aspiration pneumonia.

DIAGNOSTIC PROCEDURES
Esophagoscopy allows removal of most (80%) foreign bodies using retrieval forceps. It also allows for visual inspection of the mucosa for trauma after foreign body removal. Use of an endoscope with an accessory channel diameter of >2.8 mm will allow use of the largest types of retrieval forceps.

PATHOLOGIC FINDINGS
N/A

TREATMENT

APPROPRIATE HEALTH CARE
- Emergencies—treat as inpatient and perform endoscopy as soon as possible after diagnosis.
- If endoscopic retrieval of the foreign body succeeds *and* esophageal damage is minimal, the patient may be discharged the same day.
- Foreign bodies which cannot be removed through the mouth may be pushed aborally into the stomach.

NURSING CARE
- If the procedure to remove the foreign body is atraumatic and the esophagus has sustained minimal damage, no special aftercare is needed.
- Severe mucosal trauma may require placing a gastrostomy tube for enteral nutritional support during esophageal healing. Fluid therapy may also be required to maintain normal hydration status during periods of prolonged esophageal rest.

ACTIVITY
The patient may resume normal activity after a foreign body has been routinely removed.

DIET
- No change needed other than, perhaps, altering the food to a more liquid consistency.
- Feeding should be withheld 12–24 hours following foreign body removal.

CLIENT EDUCATION
Discuss the possibility of complications and repeat offenders.

SURGICAL CONSIDERATIONS
- Surgery is indicated when endoscopy fails to retrieve the foreign body; when endoscopy enables advancement of the object into the gastric lumen but it is too large to pass through the gastrointestinal tract; or when a large esophageal perforation or area of necrosis requires resection.
- The short-term prognosis for esophageal surgery is dogs and cats is favorable (~90%).
- It is often less traumatic to advance a bone foreign body into the stomach than to attempt retrieval transorally via endoscopy. Gastrostomy, if required, may then be performed.
- Most bone foreign bodies can be safely left to dissolve in the stomach without need for surgical removal. Nondigestible foreign objects (wood, metal, plastic) passed into the stomach may need to be removed surgically.

MEDICATIONS

DRUG(S) OF CHOICE
If there is significant mucosal injury (i.e., esophagitis), recommendations include:
- Sucralfate slurry (0.5–1 g/dog PO q8h) for mucosal cytoprotection and healing.
- Proton pump inhibitor (omeprazole or pantoprazole at 1 mg/kg q12h) for robust suppression of gastric acid secretions that may contribute to reflux esophagitis.
- Broad-spectrum antibiotics (amoxicillin or Clavamox®) are only administered to animals with mucosal perforation.

ESOPHAGEAL FOREIGN BODIES (CONTINUED)

• Metoclopramide (0.2–0.5 mg/kg IV/SC/PO q8h) or cisapride (0.5 mg/kg q8–12h PO) to stimulate gastric motility and minimize reflux esophagitis.
• Gastrostomy tube placement for enteral nutrition in animals with severe mucosal trauma.

CONTRAINDICATIONS

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Examine the esophagus closely via endoscopy for mucosal damage after foreign body removal.
• Mild erythema/erosions are not uncommon and tend to heal uneventfully.
• If an esophageal laceration/perforation is detected—gastrostomy tube feedings allow esophageal rest and healing.
• Advise post-procedural survey thoracic radiographs to assess for pneumomediastinum/pneumothorax.
• Monitor at least 2–3 weeks for evidence of stricture formation.
• Esophageal stricture—most common clinical sign is regurgitation with evidence of odynophagia in many animals; esophagram or videofluoroscopy and/or esophagoscopy may be indicated to confirm a stricture.

PREVENTION/AVOIDANCE
Carefully monitor the environment and what is fed to the pet.

POSSIBLE COMPLICATIONS
• Approximately 25% of patients with foreign bodies develop complications.
• Complications most frequently encountered include esophageal perforation, esophageal strictures, esophageal fistulas, and severe esophagitis. Focal, transient esophageal motility disturbances can occur secondary to esophageal trauma.
• Pneumomediastinum, pneumothorax, pneumonia, pleuritis, mediastinitis, and bronchoesophageal fistulas can all occur secondary to perforation.

EXPECTED COURSE AND PROGNOSIS
• Most patients do well and recover uneventfully.
• With complications, the prognosis is guarded.

ESOPHAGEAL STRICTURE

BASICS

DEFINITION
A fixed narrowing of the esophagus resulting in partial or complete obstruction.

PATHOPHYSIOLOGY
• Benign strictures occur when there is circumferential erosion and ulceration of the esophageal mucosa; regardless of the initiating event, once esophagitis develops there is a decrease in the lower esophageal sphincter (LES) tone; this results in more acid reflux and subsequent worsening of esophagitis; once severe esophagitis is present, damage can extend to the lamina propria and muscularis layers of the esophagus; this incites fibroblastic proliferation and contraction, leading to stricture formation. • Malignant strictures occur rarely in dogs and cats, and result from direct tumor invasion.

SYSTEMS AFFECTED
• Gastrointestinal—a single site of stricture is most common, although multiple strictures can occur anywhere through the esophagus. • Respiratory—regurgitation is common with strictures, increasing risk for aspiration pneumonia.

GENETICS
N/A

INCIDENCE/PREVALENCE
Infrequent

GEOGRAPHIC DISTRIBUTION
Spirocerca lupi granuloma occurs in the southern United States, parts of Europe, South Africa, and Israel.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
Any. Puppies and kittens with extraluminal compression of the esophagus from a vascular ring anomaly typically become symptomatic at weaning.

Predominant Sex
None

SIGNS

Historical Findings
• Odynophagia, dysphagia, increased salivation, regurgitation, anorexia, and weight loss; signs tend to be progressive as the stricture progressively narrows. • If regurgitation leads to aspiration pneumonia, cough and dyspnea can develop.

Physical Examination Findings
May have poor body condition secondary to malnutrition.

CAUSES
• Reflux during anesthesia is the most common cause of benign esophageal stricture, accounting for about 65% of cases; decreased LES tone during anesthesia may promote gastroesophageal reflux, resulting in subsequent acid injury to the esophageal mucosa. • Esophageal foreign bodies (if >270° mucosal damage occurs). • Esophagitis from certain tablets and capsules; commonly incriminated drugs are doxycycline, clindamycin, alendronate, and aspirin. • Gastroesophageal reflux. • Prolonged vomiting of gastric contents. • Swallowing of caustic substances. • Esophageal neoplasia (squamous cell carcinoma and lymphoma most common). • *Spirocerca lupi* granuloma. • Iatrogenic trauma during endoscopy. • Vascular ring anomaly as an extraluminal cause for focal esophageal narrowing.

RISK FACTORS
• General anesthesia, especially with drugs that decrease LES tone, when the patient is in Trendelenburg position, and in large-breed, deep-chested dogs positioned in sternal recumbency. • Oral medications given with a dry swallow. • Foreign body ingestion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Megaesophagus. • Esophageal foreign body. • Esophageal neoplasia. • Extrinsic esophageal compression (mass, abscess). • Gastroesophageal reflux. • Vomiting (any cause). • Oropharyngeal dysphagia. • Vascular ring anomaly.

CBC/BIOCHEMISTRY/URINALYSIS
Usually unremarkable.

OTHER LABORATORY TESTS
Usually unremarkable.

IMAGING
• Thoracic radiographs—usually unremarkable unless aspiration pneumonia develops. • Videofluoroscopic barium swallow should identify most strictures; if videofluoroscopy is not available, barium swallow of liquid, paste, or food followed immediately by radiography is performed; peristalsis proximal to the stricture site can be abnormal with concurrent esophagitis; may demonstrate more than one stricture.

DIAGNOSTIC PROCEDURES
• Endoscopy—diagnostic test of choice. • A focal narrowing (single or multiple) is easily identified; there is an abrupt decrease in luminal diameter at the stricture site. • Usually the mucosa is normal (smooth and pink), but can appear hyperemic and ulcerated if esophagitis is present.

PATHOLOGIC FINDINGS
• If an esophageal mass is present, biopsy with histopathology is warranted; otherwise, benign strictures are not typically biopsied. • Strictures can be focal, multifocal, or coalescing.

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient medical management is only successful for mild strictures; most strictures require intervention. • If there are complications (esophageal perforation, aspiration pneumonia), then inpatient care is required.

NURSING CARE
IV fluids may be necessary if the animal is dehydrated.

ACTIVITY
• Exercise restriction is not necessary after dilation. • If pneumonia is present, the degree of hypoxia will determine appropriate activity level.

DIET
• Recommend feeding a fat-restricted diet to enhance gastric emptying. • Canned food can be fed in small frequent amounts following dilation. • If a balloon esophagostomy (BE) tube is placed, supplemental nutrition can be provided as needed through the tube; for refractory cases, placement of a percutaneous endoscopic gastrostomy tube could be considered.

CLIENT EDUCATION
• Owners should be aware that dilation procedures are not always successful, and that multiple attempts are required in many patients; it is important that medical management for esophagitis be diligently employed following dilation procedures to reduce the risk of restricture. • Placement of a BE tube could be discussed if multiple dilation procedures are not feasible or desired, or in the case of severe stricture.

SURGICAL CONSIDERATIONS
• First-line treatment of benign esophageal strictures is mechanical dilatation of the stricture; techniques have evolved from rigid bougienage, to flexible bougies, to balloon dilation; the theoretical advantage of balloon dilatation is that the forces applied to the stricture are a radial stretch, whereas some of the forces applied with bougienage are longitudinal, resulting in possibly greater potential for esophageal perforation. • Esophageal dilatation balloons are made of special plastic that makes the balloon extremely rigid when maximally inflated at high pressures; balloons are positioned within the stricture under direct endoscopic visualization; the balloon is slowly inflated with saline using a commercially available

ESOPHAGEAL STRICTURE (CONTINUED)

inflation device until it reaches the manufacturer's rated pressure for that balloon; to ensure adequate dilation of the stricture has occurred, inflation of the balloon with ioxhexol and fluoroscopic monitoring during inflation is recommended; inadequate stricture effacement is commonly seen if this procedure is only performed with endoscopy. • Initial balloon diameter is ideally selected following measured diameters of normal esophagus obtained via a contrast study during the procedure; if fluoroscopy is not available, a balloon diameter 50–100% larger than the estimated stricture diameter can be selected; it is important to avoid assuming size based on weight of the animal as this can result in under- or overestimation; the sequence of subsequent larger dilations is then determined by the degree of mucosal tearing, ideally visualized fluoroscopically; the final dilation diameter is usually chosen by the degree of mucosal tearing and the size of the normal esophagus for the patient. • BE tube placement is a newer treatment option; this device allows for balloon dilation twice daily for 4–6 weeks at home to prevent stricture recurrence; the small number of reported patients have had improved short- and long-term outcomes compared to other treatments; the BE tube is placed similarly to a standard esophagostomy tube after balloon dilation is performed; placement of the balloon is confirmed with fluoroscopy to ensure the balloon spans the length of the stricture and does not interfere with the upper or lower esophageal sphincter. • For persistent strictures, despite multiple balloon dilations, a salvage procedure with placement of a self-expanding or bioabsorbable stent can be employed; it is important that the stent be secured with sutures to prevent migration; esophageal stenting has been associated with adverse effects including ptyalism, regurgitation, megaesophagus requiring removal, and incision infection/drainage; given the unpredictability for which patients will tolerate stent placement, this procedure should be considered only for highly refractory cases that fail BE tube placement. • Surgical management (resection and anastomosis) is typically only performed as a last resort.

MEDICATIONS

DRUG(S) OF CHOICE

• Following dilation, give sucralfate suspension (0.5–1 g/patient PO q6h) to reduce esophagitis and pain. • Medications for esophagitis are used, including cisapride (0.5–0.75 mg/kg PO q8h) to increase LES tone and enhance gastric emptying, and omeprazole (1 mg/kg PO q12h) to decrease gastric acidity.

CONTRAINDICATIONS

Caustic substances and emetic medications.

PRECAUTIONS

• Esophageal perforation can occur with overzealous balloon dilation of the stricture, therefore incremental increase in balloon diameter is recommended. • Ineffective balloon dilation can occur with incomplete tearing of the stricture; monitoring with videofluoroscopy could be considered to monitor for this. • Using a balloon over a guidewire is the safest way to perform this procedure; perforation is most common when a guidewire is not used through the lumen of the balloon and the balloon tip is advanced accidentally into the esophageal wall—use caution.

POSSIBLE INTERACTIONS

Sucralfate may inhibit the absorption of other drugs.

ALTERNATIVE DRUG(S)

• Metoclopramide can be used to increase LES tone. • Histamine H2-receptor blockers can be used to decrease gastric acid.

FOLLOW-UP

PATIENT MONITORING

Patients are monitored for signs of recurrent stricture, including regurgitation and gagging.

PREVENTION/AVOIDANCE

• Preanesthetic administration of cisapride decreases the number of reflux events in anesthetized dogs. • Preanesthetic administration of omeprazole will minimize the likelihood of acid reflux. • Medications with ulcerogenic potential should be given with at least 6 mL of water or food.

POSSIBLE COMPLICATIONS

• Complications of balloon dilatation include perforation, severe mucosal tearing and esophagitis, and stricture recurrence; with BE tube placement additional complications include infection at the tube site and migration of the tube beyond the stricture; this is typically well tolerated. • Complications with stent placement include hyperplastic tissue ingrowth or overgrowth, dysphagia, gagging, perceived discomfort, and stricture recurrence. • Aspiration pneumonia secondary to regurgitation.

EXPECTED COURSE AND PROGNOSIS

• With standard balloon dilation, reported successful outcomes defined as ability to swallow at least semi-solid food range from 71.4% to 88.0%, with 12–23.1% able to eat a normal diet. • With BE tube placement, the majority (66.7%; 8/12) of patients were able to eat a normal diet with no dysphagia. • The prognosis for esophageal neoplasia is poor, but these cases tolerate esophageal stents well.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Aspiration pneumonia. • Esophagitis.

AGE-RELATED FACTORS

None.

ZOONOTIC POTENTIAL

None.

ESOPHAGITIS

BASICS

DEFINITION
Inflammation of the esophagus typically affecting the esophageal body and lower esophageal sphincter (LES).

PATHOPHYSIOLOGY
- Disruption of esophageal defense mechanisms can result in esophageal inflammation, most commonly due to the effects of gastric acid from gastroesophageal reflux (GER) or vomiting.
- Esophagitis can result in impaired esophageal motility and LES incompetence, which may result in further GER perpetuating esophageal damage.

SYSTEMS AFFECTED
- Gastrointestinal (GI)—esophagus and in the vomiting patient primary or secondary GI disease.
- Respiratory—regurgitation and GER may lead to aspiration pneumonia, reflux laryngitis, pharyngitis and/or rhinitis; respiratory signs may be covert presentation for GER.

INCIDENCE/PREVALENCE
Unknown—relatively common; probably underestimated, as most cases are not definitively diagnosed.

GEOGRAPHIC DISTRIBUTION
Worldwide, except when caused by *Pythium* spp. (US Gulf Coast) and *Spirocerca lupi* (southern states).

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Reflux esophagitis in brachycephalic breeds due to negative intrathoracic pressure upon inspiration increasing the tendency for GER and hiatal hernia (HH).

Mean Age and Range
- Any age.
- Young animals with congenital esophageal HH and older animals that are anesthetized are at greater risk of developing reflux esophagitis.

Predominant Sex
None

SIGNS

Historical Findings
- Regurgitation.
- Ptyalism.
- Dysphagia (difficulty swallowing, gagging, retching).
- Odynophagia (pain when swallowing, repeated swallowing efforts, and extension of head and neck during swallowing).
- Hyporexia or anorexia.
- Weight loss.
- Coughing and/or nasal discharge with aspiration pneumonia, reflux laryngitis, pharyngitis, and/or rhinitis.

Physical Examination Findings
- Often normal.
- Oral and pharyngeal inflammation and/or ulceration with ingestion of caustic substances or oropharyngeal reflux of gastric acid.
- Fever and pain with ulcerative esophagitis or aspiration pneumonia.
- Halitosis, ptyalism, possibly pain on palpation of neck.
- Cachexia and weight loss, with chronicity.
- Nasal discharge and congestion with reflux rhinitis.
- Cough, increased bronchovesicular sound, pulmonary crackles, and dyspnea with aspiration pneumonia.

CAUSES
- Most commonly GER secondary to general anesthesia (Web Figure 1), hiatal hernia (Web Figure 2), persistent or chronic vomiting, and GI disease resulting in delayed gastric emptying.
- Gastroesophageal reflux disease (GERD) secondary to primary LES abnormality is poorly understood in veterinary patients.
- Esophageal retention of tablets or capsules (doxycycline, clindamycin, nonsteroidal anti-inflammatory drugs [NSAIDs], alendronate).
- Esophageal foreign body (Web Figure 3).
- Infectious agents—*Pythium* spp., *Spirocerca lupi*, *Candida* infection secondary to immune suppression.
- Uncommonly esophageal tumors, radiation injury, megaesophagus, vascular ring anomalies, gastrinoma, eosinophilic esophagitis and esophageal tubes.
- Idiopathic.

RISK FACTORS
- General anesthesia.
- HH.
- GI or metabolic/endocrine disease resulting in vomiting or gastric hyperacidity.
- Preanesthetic fasting for prolonged periods (≥24h) increases risk for GER and gastric hyperacidity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Esophageal foreign body—usually detected by survey radiography or esophagoscopy.
- Esophageal stricture—revealed by barium contrast radiography or esophagoscopy.
- Oropharyngeal dysphagia—diagnosed with videofluoroscopic swallow study.
- HH—may be diagnosed by thoracic radiographs or esophagoscopy; contrast esophagram with fluoroscopy may be required to document (Web Figure 2).
- Megaesophagus—survey radiography revealing diffuse dilation of esophageal body.
- Esophageal diverticula—detected by survey or contrast radiography or esophagoscopy.
- Vascular ring anomaly—usually revealed by leftward deviation of trachea at heart base on survey thoracic radiographs, or barium contrast radiography as focal dilation of proximal esophageal body.
- Esophageal neoplasia—mass effect with possible esophageal dilation diagnosed with survey or contrast radiography, thoracic CT, or esophagoscopy.

CBC/BIOCHEMISTRY/URINALYSIS
Usually unremarkable; patients with ulcerative esophagitis or aspiration pneumonia may have leukocytosis and neutrophilia.

IMAGING
- Survey thoracic radiography—often unremarkable, but may reveal mild esophageal dilation or fluid accumulation in distal esophagus; aspiration pneumonia may be evident; dilation of esophagus cranial to a stricture; esophageal foreign body, HH, or esophageal mass may be detected.
- Barium contrast esophagram (static images and/or fluoroscopic)—may reveal esophageal dilation with retention of barium, strictures, foreign bodies, or masses; fluoroscopic studies allow for evaluation of swallowing, esophageal motility, strictures that may not be apparent on a static esophagram, sliding HH (Web Figure 2), and GER (the latter two conditions may require abdominal compressions to demonstrate).
- Thoracic CT can be helpful for esophageal masses, foreign bodies, and HHs.

DIAGNOSTIC PROCEDURES
- Endoscopy and biopsy—most reliable means of diagnosis (Web Figures 1 and 3). Mild cases of esophagitis may appear normal. Visual findings of mucosal hyperemia and edema are common and in more severe cases ulceration. With GER, changes usually most apparent in distal third of esophagus. Gastroduodenoscopy may also be performed to evaluate for GI causes of vomiting that caused esophagitis.
- Histopathology provides most definitive evidence of esophagitis, although endoscopy and biopsies usually reserved for cases unresponsive to therapy. Diagnostic quality esophageal biopsies difficult to obtain endoscopically due to tough stratified squamous epithelium.
- Endotracheal or transtracheal aspiration and/or bronchoalveolar lavage for cytology, and culture and sensitivity testing, may be considered in patients with aspiration pneumonia.

PATHOLOGIC FINDINGS
Mucosal squamous hyperplasia or dysplasia with erosions and ulcers; lymphocytic plasmacytic and neutrophilic inflammation.

ESOPHAGITIS (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

- Mildly affected animals can be managed as outpatients; those with more severe esophagitis (persistent regurgitation, dehydration) and complications (aspiration pneumonia) require hospitalization.
- Successful treatment of esophagitis involves addressing underlying risk factors and predisposing conditions when possible; gastric acid suppression to reduce esophageal mucosal injury; increasing LES pressure and promoting gastric emptying to reduce GER; and protecting esophageal mucosa from further injury.

NURSING CARE

- Upright or elevated feeding will be of benefit with regurgitation associated with abnormal esophageal motility secondary to esophagitis.
- Coupage and nebulization are provided for patients with aspiration pneumonia.
- IV fluids to maintain hydration in severe cases.
- Oxygen therapy may be necessary in patients with aspiration pneumonia.

DIET

- Fat-restricted diets recommended to minimize gastric acid production.
- With severe esophagitis oral food and water may need to be withheld until regurgitation resolved; gastrostomy tube feedings may be required.

CLIENT EDUCATION

- Advise upright or elevated feeding when there is esophageal dysmotility.
- Discuss potential complications, including aspiration pneumonia, esophageal stricture, esophageal perforation, and/or esophageal motility abnormalities.

SURGICAL CONSIDERATIONS

- Percutaneous endoscopic gastrostomy or surgical gastrostomy tube placement in severe cases.
- Surgical correction for HH when medical management not effective.
- Esophageal surgery may be necessary for large perforations, difficult esophageal foreign bodies, or esophageal neoplasia, but should be avoided if possible.

MEDICATIONS

DRUG(S) OF CHOICE

Acid Suppression

- Most important therapy for treatment of GERD and associated esophagitis. H2-receptor antagonists (H2RAs) and proton pump inhibitors (PPIs) are two main classes of acid suppressors. PPIs provide superior gastric acid suppression compared to H2RAs.
- PPIs should be administered at dose of 1 mg/kg PO or IV q12h. Most common PPIs prescribed are omeprazole and pantoprazole. Other choices include lansoprazole and esomeprazole.
- Fractionated enteric-coated omeprazole tablets remain effective despite disruption of the enteric coating. Tablets need to be cleanly split and cannot be crushed.
- In humans widespread media attention has concerned potential adverse effects of PPIs. Current evidence is inadequate to establish cause and effect for most associations. Caution should be exercised when prescribing PPIs as they are among the most overprescribed drugs in humans and veterinary medicine.
- Famotidine is most effective and commonly recommended H2RA given at dose of 0.5–1.0 mg/kg PO/SC/IV q12h. Has diminished effect over time with repeated administration. Is appropriate for short-term gastric acid suppression, but long-term administration not advised.
- When prescribing a PPI, overlap with an H2RA during initial dosing is unnecessary.
- When discontinuing a PPI after >3–4 weeks of therapy, PPI should be gradually tapered by 50% increments over 2–3 weeks to avoid rebound gastric hyperacidity.
- Dosing for metabolic disease (renal failure and liver failure) not established; lower dose or longer dose interval may be appropriate for these conditions.

GI Prokinetics

- Second most common class of drugs used to treat GER and esophagitis. Increase LES pressure and promote gastric emptying, therefore reducing GER.
- Most effective is cisapride at 0.5–1.0 mg/kg PO q8h. Readily available from compounding pharmacies.
- Metoclopramide is GI prokinetic with antiemetic effects in dogs dosed at 0.2–1.0 mg/kg PO/SC q8h or 1.0–3.0 mg/kg/day as CRI.

Mucosal Protectants

- Sucralfate 0.25–1.0 g PO q6–8h is given as suspension mixed into slurry with water and administered on empty stomach. Forms insoluble complex that binds to inflamed tissue, creating protective barrier and preventing further damage caused by pepsin, acid, and bile. Additionally increases mucosal defense and repair mechanisms through stimulation of bicarbonate and prostaglandin E production and binding of epidermal growth factor, at neutral pH. Reported to relieve symptoms in humans.
- Antibiotics indicated with aspiration pneumonia, severe esophageal ulceration, and esophageal perforation.
- Analgesics, especially in severe cases—lidocaine solution (2.0 mg/kg PO q4–6h) for local analgesia; tramadol 2–4 mg/kg PO q8–12h.
- Anti-inflammatory dosage of corticosteroids (e.g., prednisone 0.5–1 mg/kg PO per day or divided q12h) may decrease fibrosis and esophageal stricture formation in severe cases; controversial and efficacy not been supported by literature. Avoid when evidence of aspiration pneumonia.

CONTRAINDICATIONS

None

PRECAUTIONS

None

POSSIBLE INTERACTIONS

Sucralfate may interfere with GI absorption of other drugs and it is best to separate dosing by 2 hours from other drugs; may not be clinically important.

ALTERNATIVE DRUG(S)

- Narcotic analgesics including buprenorphine, methadone, and fentanyl may be necessary in severe cases of painful esophagitis.
- Ranitidine 2.0 mg/kg PO q12h, nizatidine 2.5–5.0 mg/kg PO q24h, and erythromycin 0.5–1.0 mg/kg PO/IV have GI prokinetic effects and may be alternate or additive drugs.

FOLLOW-UP

PATIENT MONITORING

- For patients with mild esophagitis, monitoring of clinical signs is sufficient.
- Consider follow-up endoscopy in patients with ulcerative esophagitis and those at risk for esophageal stricture.

PREVENTION/AVOIDANCE

- Consider two doses of omeprazole 1 mg/kg PO or famotidine 1 mg/kg PO given 12–24h and 1–4h prior to anesthesia to reduce gastric acidity.
- Prokinetic drug (cisapride 1 mg/kg PO; metoclopramide 0.2–1.0 mg/kg PO/SC) with acid suppressor may also help reduce GER during anesthesia and surgery.
- Maropitant useful to prevent vomiting and regurgitation associated with opioid premedications and anesthesia.
- If GER is cause of esophagitis, owners should avoid late-night feedings that tend to diminish LES pressure during sleep.
- Proper patient preanesthesia fasting decreases risk of GER. Withholding water for 4–8h and food for 8–12h prior to anesthesia is recommended.
- Follow oral administration of capsules and tablets with 5–10 mL bolus of water (especially for doxycycline) amd a meal, or give with a treat such as a pill pocket to hasten

transit time of pills to stomach. Coating pills with butter or applying Nutri-Cal® to the nose to stimulate licking after administration of tablets may also be effective.

POSSIBLE COMPLICATIONS

- Esophageal stricture formation.
- Aspiration pneumonia.
- Chronic reflux esophagitis.
- Permanent esophageal dysmotility.
- Chronic cough due to laryngopharyngeal aspiration or tracheal microaspiration.
- Esophageal perforation (rare).
- Barrett's esophagus (rare complication of chronic reflux esophagitis reported in cats).

EXPECTED COURSE AND PROGNOSIS

- Best results when treated with gastric acid suppressant, GI prokinetic, and possibly mucosal protectant.
- Mild esophagitis—good to excellent prognosis.
- Severe or ulcerative esophagitis—greater potential for complications, which warrants guarded prognosis.
- Complete recovery can be expected especially when treated before serious complications develop.

MISCELLANEOUS

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

H2RAs, PPIs, and glucocorticoids should all be used with caution during pregnancy.

SYNONYMS

Esophageal inflammation.

E

ESSENTIAL OILS TOXICOSIS

BASICS

OVERVIEW

- Essential oils—volatile, organic constituents extracted from plants; contribute to fragrance/taste. Often used as natural remedies by owners for their own medical issues. Essential oil insecticides (low %) manufactured for use on animals.
- Known toxicants to *cats*—D-Limonene (citrus oil), pine oil, ylang ylang oil, peppermint oil, cinnamon oil.
- Known toxicants to *cats and dogs*—wintergreen oil, sweet birch oil, eucalyptus oil, clove oil, tea tree (aka melaleuca) oil.
- Known toxicants to *dogs*—pennyroyal oil.

Systems Affected

- Cardiovascular—bradycardia, peripheral vasodilation.
- Endocrine/metabolic—hypothermia.
- Gastrointestinal (GI)—hypersalivation, vomiting.
- Hepatobiliary—elevated liver enzymes (LEs), hepatic failure.
- Nervous—ataxia, tremors, CNS depression.
- Respiratory—respiratory irritation/distress.
- Skin—irritation, possible ulceration.

SIGNALMENT

Cats are more sensitive than dogs. Cats lack glucuronyl transferase; cannot metabolize/eliminate toxins via hepatic glucuronidation.

SIGNS

- Signs vary based on type/concentration of oil. Higher the concentration the greater the risk. Only 7–8 drops of 100% oil may be needed to cause toxicosis.
- Onset—1–8 hours post exposure.
- Animal may smell of oil (hair coat, skin, breath) or feel greasy.
- Nausea, hypersalivation, vomiting, abdominal pain.
- Hypothermia.
- Ataxia, tremors, CNS depression.
- Coughing, wheezing, panting, tachypnea, and dyspnea.
- Bradycardia, hypotension.
- Elevated LEs (cats, sometimes dogs—pennyroyal oil).

CAUSES & RISK FACTORS

- Passive oil diffusers—animals inhale odor, develop mild to severe respiratory irritation/distress.
- Active diffusers—release micro-droplets of oil. Respiratory difficulties, but droplets can land on animal's coat causing direct absorption or ingestion via grooming.
- History of preexisting respiratory issues (e.g., asthmatic cats) places animals at greater risk.
- Indirect ingestion—essential oils used on human skin, animal licks skin.
- Direct dermal or oral use as owners try natural remedies (e.g., flea control) on their animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Aspirin toxicity—wintergreen and sweet birch oil contain methyl salicylate; anemia/GI hemorrhage may develop.
- Hepatotoxins xylitol, acetaminophen, cycads (sago palm), others.
- Toxins or conditions that affect CNS—ethylene glycol, hypoglycemia, hypotension, drug overdoses.

CBC/BIOCHEMISTRY/URINALYSIS

- Most often no specific diagnostic features.
- CBC and chemistry—possible increase in LEs.

IMAGING

- Thoracic radiographs with respiratory irritation/distress.
- Abdominal radiographs if abdominal pain.

PATHOLOGIC FINDINGS

Limited data—lesions of severe hepatic necrosis with pennyroyal oil.

TREATMENT

Appropriate Health Care

Fresh air, emergency examination, bathing, inpatient care until signs resolve.

Nursing Care

- Intravenous crystalloids.
- Prevent aspiration of vomitus.
- Oxygen therapy.
- Monitor BP, heart rate, thermoregulation.

Diet

Do not feed patients that are vomiting, having CNS signs, or are in respiratory distress.

MEDICATIONS

DRUG(S) OF CHOICE

- No specific antidote.
- Bathe with warm water and liquid hand dishwashing detergent.
- Activated charcoal (AC) with a cathartic × 1 in large or concentrated oral ingestions. Repeat AC only q8h × 2 doses if tea tree oil (enterohepatic recirculation).
- Fluid boluses or vasopressors as needed for hypotension.
- Anticholinergics if bradycardic, as long as normotensive.
- Bronchodilators with respiratory distress.
- Anti-emetics.
- Hepatoprotectants with elevated LEs.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Do not induce vomiting. Do not give AC to a patient with CNS signs.

Precautions

Use hepatically metabolized medications with caution in the presence of LE elevation.

FOLLOW-UP

PATIENT MONITORING

Recheck LEs 48–72 hours post discharge, then as needed based on values and clinical signs.

PREVENTION/AVOIDANCE

- Do not apply essential oils directly to animals.
- Use essential oil products manufactured for use on animals with caution.
- Avoid using essential oil diffusers.

POSSIBLE COMPLICATIONS

- Aspiration pneumonia—if neurologic patient with concurrent GI signs.
- Pennyroyal oil—disseminated intravascular coagulation, chronic hepatic insufficiency.

EXPECTED COURSE AND PROGNOSIS

- Prognosis—good if treated early and aggressively. May take several days for complete resolution.
- More guarded prognosis with use of 100% oil (i.e., tea tree oil, pennyroyal oil), especially if treatment is delayed or inadequate. Fatalities can occur.

MISCELLANEOUS

ABBREVIATIONS

- AC = activated charcoal.
- GI = gastrointestinal.
- LEs = liver enzymes.

ETHANOL TOXICOSIS

BASICS

OVERVIEW

• Ethanol (CH3CH2OH)—short-chain alcohol; highly miscible with water; less volatile than comparable hydrocarbons (e.g., ethane); solvent for medications; component of alcoholic beverages; metabolized to acetaldehyde.
• Used intravenously to treat ethylene glycol poisoning.
• Denatured forms may contain other toxic fractions (e.g., acetone, benzene, camphor, castor oil, phthalates, kerosene, sulfuric acid, terpinols); may complicate effects.
• Ethanol concentration—expressed as proof (twice the % concentration).
• Acute oral lowest toxic dosage—5–8 mL/kg as pure alcohol; consider % alcohol in specific product consumed.
• Other alcohols—toxicity of methanol is similar to that of ethanol; the LD_{50} of 70% isopropanol is 2 mL/kg.
• Cell membrane damage; impaired sodium and potassium nerve conduction.
• May inhibit glutamate receptors in brain with reduction of cyclic guanosine monophosphate (GMP).

SIGNALMENT

• Most common in dogs.
• No breed or sex predilections.
• Young, curious animals more susceptible.

SIGNS

• CNS—develop within 15–30 minutes after ingestion on an empty stomach or 1–2 hours on a full stomach; ataxia, reduced reflexes, behavioral changes, excitement, depression.
• Cardiovascular—cardiac arrest.
• Gastrointestinal—flatulence (bread dough).
• Respiratory—respiratory depression, narcosis.
• Urologic—polyuria, incontinence.
• Hypothermia.

CAUSES & RISK FACTORS

• Alcoholic beverages, either accidental or intentional, are most common source.
• Exposure to deicers, sanitizers, mouthwash, dyes, inks, some fuels, paint, varnishes, perfume, pharmaceuticals.
• Exposure to rising bread doughs containing active yeast.
• Fermented products—rotten apples, garbage.
• Dermal exposure—alcohol-containing products.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other alcohols—methanol, isopropanol, butanol.
• Human drugs of abuse—marijuana, barbiturates, benzodiazepines.
• Early stages of ethylene glycol (antifreeze) toxicosis.
• Early stages of xylitol toxicosis.
• Halogenated or aliphatic hydrocarbon solvents.
• Hypoglycemia inducing metabolic and neurologic disorders.
• Pesticides—amitraz, macrolide antiparasiticides.

CBC/BIOCHEMISTRY/URINALYSIS

• PCV and total solids.
• Monitor for hypoglycemia; blood glucose <60 mg/dL considered serious.
• Metabolic acidosis likely from ethanol-induced lactic acidemia.

OTHER LABORATORY TESTS

• Blood ethanol levels routinely available at reference labs—clinical signs in puppies at >0.6 mg/mL and in adults at >1–4 mg/mL.
• Blood methanol and isopropanol levels available at some reference labs.
• Blood gases and increased anion gap—evaluate potential acidosis.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

• Activated charcoal—not effective.
• Emesis or gastric lavage—only in very recent exposures (less than 15 minutes) due to rapid absorption and rapid onset of clinical signs.
• Respiratory depression—provide artificial ventilation.
• IV isotonic crystalloid fluids—correct dehydration.
• Acidosis—sodium bicarbonate if pH <7.0, BE <15 mmHg, HCO_3 <11 mmHg.
• Cardiac arrest—cardiac therapy (see Cardiopulmonary Arrest).
• Hemodialysis—may aid in elimination of ethanol after life-threatening exposure.
• Yohimbine may be effective for CNS depression.

MEDICATIONS

DRUG(S) OF CHOICE

• Dextrose—0.5–1.5 ml/kg 50% dextrose diluted 1 : 4 in 0.9% NaCl as a bolus for immediate correction of severe hypoglycemia; 2.5–5% dextrose supplementation in fluids for hypoglycemia.
• Fomepizole (4-methylpyrazole)—not specifically cleared for use in ethanol intoxication
• Sodium bicarbonate (if needed)—mEq of bicarbonate required = 0.5 × bodyweight in kg × (desired total CO_2 mEq/L – measured CO_2 mEq/L); give half the total calculated dose slowly over 3–4 hours IV; recheck blood gases and clinical status of the animal.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid other CNS depressants.

FOLLOW-UP

• Monitor for metabolic acidosis—blood pH, blood gases, urine pH, anion gap.
• Recovery from clinical signs—usually within 8–12 hours.

MISCELLANEOUS

ABBREVIATIONS

• GMP = guanosine monophosphate.

ETHYLENE GLYCOL TOXICOSIS

BASICS

DEFINITION
Results primarily from ingesting substances containing ethylene glycol (EG; e.g., antifreeze). Rarely from other products.

PATHOPHYSIOLOGY
• EG—rapidly absorbed from the gastrointestinal tract; food in the stomach delays absorption. • Toxicity—initially causes CNS depression, ataxia, gastrointestinal irritation, and polyuria or polydipsia; rapidly metabolized in the liver by alcohol dehydrogenase to glycoaldehyde, glycolic acid, glyoxalic acid, and oxalic acid; leads to severe metabolic acidosis and renal epithelial damage. • Minimum lethal dosage—cats: 1.4 mL/kg; dogs: 6.6 mL/kg.

SYSTEMS AFFECTED
• Gastrointestinal—irritated mucosa. • Nervous—inebriation from EG and glycoaldehyde owing to inhibition of respiration, glucose metabolism, and serotonin metabolism, and alteration of amine concentrations. • Renal/urologic—initially, osmotic diuresis; later, metabolites, especially calcium oxalate monohydrate crystals, are directly cytotoxic to renal tubular epithelium, resulting in renal failure; mechanism of toxicity is now thought to involve attachment of oxalate to cell plasma membrane, activation of enzyme activity, and production of free radicals and lipid peroxidation, leading to cell necrosis.

INCIDENCE/PREVALENCE
• Common in small animals. • Highest fatality rate of all poisons; fatality rates higher for cats than dogs. • Incidence similar in cats and dogs.

GEOGRAPHIC DISTRIBUTION
Higher incidence in colder areas where antifreeze is more commonly used.

SIGNALMENT

Species
Dogs, cats, and many other species, including birds.

Mean Age and Range
• Any age susceptible (3 months–13 years).
• Mean: 3 years.

SIGNS

General Comments
• Dose dependent. • Almost always acute. • Caused by unmetabolized EG and its toxic metabolites (frequently fatal).

Physical Examination Findings
• Early—from 30 minutes to 12 hours post ingestion in dogs: nausea and vomiting; mild to severe depression; ataxia and knuckling; muscle fasciculations; nystagmus; head tremors; decreased withdrawal reflexes and righting ability; polyuria and polydipsia. • Dogs—with increasing depression, patient drinks less but polyuria continues, resulting in dehydration; CNS signs abate transiently after approximately 12 hours, but recur later. • Cats—usually remain markedly depressed; do not exhibit polydipsia. • Oliguria (dogs: 36–72 hours; cats: 12–24 hours) and anuria (72–96 hours post ingestion)—often develop if untreated. • May note severe hypothermia. • Severe lethargy or coma. • Seizures. • Anorexia. • Vomiting. • Oral ulcers. • Salivation. • Kidneys—often swollen and painful, particularly in cats.

CAUSES
Ingestion of EG, the principal component (95%) of most antifreeze solutions.

RISK FACTORS
Access to EG—widespread availability; somewhat pleasant taste; small minimum lethal dose; lack of public awareness of toxicity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Acute (30 minutes–12 hours post ingestion)—ethanol, methanol, and marijuana toxicosis; ketoacidotic diabetes mellitus; pancreatitis; gastroenteritis. • Renal stage—acute renal failure by nephrotoxins, e.g., aminoglycoside antibiotics, amphotericin B, cancer chemotherapeutic drugs, ibuprofen, oxalate-containing plants such as philodendrons, plants of the lily family (cats), cyclosporin, grape and raisin toxicosis (causes hypercalcemia, unlike EG toxicosis), and heavy metals; leptospirosis, tubulointerstitial nephritis; glomerular and vascular disease; renal ischemia (hypoperfusion).

CBC/BIOCHEMISTRY/URINALYSIS
• Packed cell volume (PCV) and total protein—often high owing to dehydration. • Stress leukogram— common. • High blood urea nitrogen (BUN) and creatinine—dog: 36–48 hours post ingestion; cat: 12 hours post ingestion. • Hyperphosphatemia may occur transiently 3–6 hours post ingestion, owing to phosphate rust inhibitors in antifreeze; hyperphosphatemia is also seen with azotemia owing to decreased glomerular filtration. • Hyperkalemia if oliguric or anuric. • Hypocalcemia—occurs in approximately half of patients, owing to chelation of calcium by oxalic acid; clinical signs infrequently observed because of acidosis. • Hyperglycemia—occurs in approximately half of patients, owing to inhibition of glucose metabolism by aldehydes, increased epinephrine and endogenous corticosteroids, and uremia. • Isosthenuria—by 3 hours post ingestion, owing to osmotic diuresis and serum hyperosmolality-induced polydipsia; continues in later stages of toxicosis because of renal dysfunction. • Calcium oxalate crystalluria—consistent finding; as early as 3 hours post ingestion in cats and 6 hours in dogs; monohydrate form more common. • Urine—pH consistently decreases; inconsistent findings—hematuria; proteinuria; glucosuria; may note granular and cellular casts, white blood cells (WBCs), red blood cells (RBCs), and renal epithelial cells.

OTHER LABORATORY TESTS

Blood Gases
• Metabolites cause severe metabolic acidosis. • Total CO_2, plasma bicarbonate concentration, and blood pH—low by 3 hours post ingestion; markedly low by 12 hours. • Partial pressure of CO_2 (PCO_2) decreases, owing to partial respiratory compensation. • Anion gap—increased by 3 hours post ingestion; peaks at 6 hours post ingestion; remains increased for approximately 48 hours (EG metabolites are unmeasured anions. Glycolate, a metabolite of EG, can result in a false increase in plasma lactate, which could lead to the assumption that acidosis is due to increased lactate, rather than EG toxicosis.

Other
• Serum osmolality and osmole gap—high by 1 hour post ingestion, in parallel with serum EG concentrations; dose related; usually remain high for approximately 18 hours post ingestion; EG toxicosis most common cause of high osmolal gap. • EG serum concentration— peaks 1–6 hours post ingestion; usually not detectable in serum or urine by 72 hours. • Commercial kits—PRN Pharmacal REACT EG measures concentrations at >50 mg/dL; estimate by multiplying osmole gap by 6.2. ◦ Test does not detect metabolites, so must be used within the first few hours post ingestion. ◦ Results available in 6 minutes but should not be read over 10 minutes. ◦ Labeled for dogs and cats; some cats may have toxicosis at levels below 50 mg/dL. ◦ False-positive test results can be seen with propylene glycol, glycerol, mannitol, and sorbitol. Ethanol may combine with propylene glycol or glycerol to give a false positive. • Wood's lamp examination of urine, face, paws, or vomitus may detect fluorescein that is sometimes added to antifreeze to detect radiator leaks. This method is nonspecific and may be unreliable; fluorescein has a half-life of approximately 4 hours.

IMAGING
Ultrasonography—renal cortices may be hyperechoic as a result of crystals.

DIAGNOSTIC PROCEDURES
• Kidney biopsy—with anuria; confirm diagnosis. • Cytologic examination of kidney imprints—often diagnostic; numerous calcium oxalate crystals.

(CONTINUED) ETHYLENE GLYCOL TOXICOSIS

PATHOLOGIC FINDINGS

• Kidneys often swollen.
• Postmortem examination of kidney reveals the presence of calcium oxalate crystals in the tubules.

TREATMENT

APPROPRIATE HEALTH CARE

• Cats—usually inpatient.
• Dogs—usually outpatient if <5 hours post ingestion and treated with fomepizole; inpatient if >5 hours for IV fluids to correct dehydration, increase tissue perfusion, and promote diuresis.

NURSING CARE

• Goals—prevent absorption; increase excretion; prevent metabolism. • Induction of vomiting and gastric lavage with activated charcoal not recommended unless can be performed in first 30 minutes following ingestion due to rapid absorption of EG. • IV fluids—correct dehydration, increase tissue perfusion, and promote diuresis; accompanied by bicarbonate given slowly IV to correct metabolic acidosis. • Monitor serial plasma bicarbonate concentrations—0.5 × body weight (kg) × (24 – plasma bicarbonate) = sodium bicarbonate needed (mEq).
• Monitor urine pH in response to therapy.
• Azotemia and oliguric renal failure (dogs)—most of the EG has been metabolized; little benefit from inhibition of alcohol dehydrogenase (ADH); correct fluid, electrolyte, and acid-base disorders; establish diuresis; diuretics (particularly mannitol) may help; hemodialysis or peritoneal dialysis may be useful; may need extended treatment (several weeks) before renal function reestablished.

SURGICAL CONSIDERATIONS

Kidney transplantation—successfully employed in cats with EG-induced renal failure.

MEDICATIONS

DRUG(S) OF CHOICE

Dogs

Fomepizole (4-methyl pyrazole, available from Kacey Diagnostics)—effective and nontoxic liver ADH inhibitor; much more expensive than ethanol but less intensive care required; 5% (50 mg/mL) at 20 mg/kg IV initially; then 15 mg/kg IV at 12 and 24 hours; then 5 mg/kg IV at 36 hours.

Cats

• Fomepizole—cats must be given a higher dose of fomepizole than dogs; 125 mg/kg IV initially, then 31.25 mg/kg at 12, 24, and 36 hours.
• Ethanol—use if fomepizole not available; 20% at 5mL/kg diluted in fluids and given in an IV drip over 6 hours for 5 treatments; then over 8 hours for 4 more treatments.

CONTRAINDICATIONS

Avoid drugs that cause CNS depression, including ethanol.

PRECAUTIONS

• Competitive substrates (alcohols, such as ethanol) contribute to CNS depression; monitor respiration. • Cats may become hypothermic; require heat. • Other pyrazoles—may be toxic to the marrow and liver; do not substitute for fomepizole.

POSSIBLE INTERACTIONS

• Fomepizole—contributes slightly to CNS depression in cats; none in dogs. • Ethanol—contributes to CNS depression; further increases serum osmolality.

ALTERNATIVE DRUG(S)

• Ethanol, propylene glycol, and 1,3-butanediol—have higher affinity for ADH than does EG; effectively inhibit EG metabolism; may cause CNS depression and increase serum osmolality; constant serum ethanol concentrations of 100 mg/dL will inhibit most EG metabolism.
• Ethanol treatment requires hospitalization, constant IV infusion (ethanol and fluids); continuous monitoring for respiratory and acid-base status.

FOLLOW-UP

PATIENT MONITORING

BUN, creatinine, acid-base status, and urine output—monitored daily.

PREVENTION/AVOIDANCE

• Increasing client awareness of toxicity—helps prevent exposure; earlier treatment of patients. • Use of antifreeze products (e.g., Sierra®, Prestone LowTox®) that contain propylene glycol, which is much less toxic.

POSSIBLE COMPLICATIONS

• Without azotemia—usually no complications. • Urine concentrating ability—may be impaired with azotemia; may recover.

EXPECTED COURSE AND PROGNOSIS

• Untreated—oliguric renal failure (dogs: 36–72 hours; cats: 12–24 hours); anuria by 72–96 hours post ingestion. • Dogs treated <5 hours post ingestion—prognosis excellent with fomepizole treatment. • Dogs treated up to 8 hours post ingestion—most recover.
• Dogs treated up to 36 hours post ingestion—may be of benefit to prevent metabolism of any remaining EG. • Cats treated within 3 hours post ingestion—prognosis good. • If a large quantity of EG is ingested, prognosis is poor, unless treated within 4 hours of ingestion.
• Patients with azotemia and oliguric renal failure—prognosis poor; almost all of the EG will have been metabolized.

MISCELLANEOUS

AGE-RELATED FACTORS

Patients <6 months of age with oliguric renal failure sometimes fully recover.

SYNONYMS

Antifreeze poisoning.

SEE ALSO

Hyperosmolarity

ABBREVIATIONS

• ADH = alcohol dehydrogenase. • BUN = blood urea nitrogen. • EG = ethylene glycol.
• PCO_2 = partial pressure of carbon dioxide.
• PCV = packed cell volume. • RBC = red blood cell. • WBC = white blood cell.

EXCESSIVE VOCALIZATION AND WAKING AT NIGHT—DOGS AND CATS

BASICS

DEFINITION
• Vocalization that is uncontrollable, excessive, at inappropriate times of day or night, or that disrupts owners, neighbors, or other animals.
• In night-time waking, the pet wakes during the night, does not fall asleep at bedtime, or awakens early, leading to disruption of owner's sleep.

PATHOPHYSIOLOGY
• Varies with cause.
• Barking may be normal canine communication (social, threat, warning, care-soliciting) but unacceptable to owners.
• Owner responses may reinforce or increase anxiety (punishment).
• Cats are crepuscular, so early morning waking may be normal.
• May be due to medical conditions that cause anxiety, discomfort, irritability, or altered sleep–wake cycles.
• Hearing decline may be associated with increased vocalization.
• Cognitive dysfunction syndrome (CDS) can lead to sleep disturbances, anxiety, and excessive vocalization.
• Night waking may be due to a change in schedule, environment, or activity, especially in senior pets that are more sensitive to change.

SYSTEMS AFFECTED
• Behavioral.
• Diseases of other systems may cause or contribute to signs.

GENETICS
N/A

INCIDENCE/PREVALENCE
Unknown

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Asian breeds of cats may be prone to excess vocalization.
• Working and hunting breeds may be more prone to barking.

Mean Age and Range
• Puppies may not be able to sleep through the night without waking to eliminate.
• Senior pets may be more prone to vocalization and night waking due to underlying medical conditions.

Predominant Sex
Intact females during estrus and mating.

SIGNS

Historical Findings
• Vocalization at times or in intensity that disturbs owners or neighbors.
• Sleeping pattern altered—does not fall asleep at bedtime, awakens during the night, or sleeps more during the day.
• Signs reported vary with how disruptive they are to the family, neighbors, and the pet's quality of life.
• Pets with CDS may pace, wander aimlessly, have decreased interest in social interactions, be less responsive to stimuli and increasingly anxious.
• Additional signs related to medical causes.

Physical Examination Findings
Signs associated with underlying medical issues.

CAUSES
• Vocalization and night waking—medical: gastrointestinal, metabolic (renal, hepatic), urogenital, CNS disorders, CDS, hypertension, hyperadrenocorticism or hypothyroidism (dog), hyperthyroidism (cat), pain, sensory decline.
• Vocalization:
  ◦ Anxiety or conflict.
  ◦ Normal for individual or breed.
  ◦ Alarm barking—response to novel stimuli.
  ◦ Territorial—warning or guarding.
  ◦ Owner inadvertently reinforces.
  ◦ Also reinforced each time stimulus retreats.
  ◦ Distress vocalization, e.g., howl or whine may be related to separation from social group.
  ◦ Growl—associated with agonistic displays.
  ◦ Stereotypic behaviors—dog.
  ◦ Mating/sexual—cat.
• Night waking:
  ◦ Normal crepuscular rhythm—cat.
  ◦ Changes in routine and/or environment—insufficient enrichment/scheduling.
  ◦ Owner inadvertently reinforces.
  ◦ Hyperactivity/hyperkinesis—dog.
  ◦ Mating/sexual—cat.

RISK FACTORS
• Increasing age.
• Changes in schedule or environment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Sleep disorders.

CBC/BIOCHEMISTRY/URINALYSIS
To determine if underlying medical cause.

OTHER LABORATORY TESTS
• T_4 and blood pressure—senior cats.
• Rule out hypothyroidism and hyperadrenocorticism in dogs.

IMAGING
To rule out medical/neurologic if indicated.

DIAGNOSTIC PROCEDURES
• Behavioral diagnosis based on history; observation of pet, owner, and their interactions; video if available.
• Intraocular pressure.
• Brainstem auditory evoked response (BAER) if indicated to rule out auditory decline.
• Endoscopy and biopsy if gastrointestinal cause suspected.

PATHOLOGIC FINDINGS
N/A

TREATMENT

APPROPRIATE HEALTH CARE
If any medical issues.

NURSING CARE
If any medical issues.

ACTIVITY
Insure behavioral needs (e.g., social interactions, exercise, elimination, routine, and mental stimulation) are adequately met each day.

DIET
• Feed from toys to encourage normal hunting and scavenging behaviors.
• Timed feeders and multiple small meals.

CLIENT EDUCATION
Individualize for the pet, home, and problem.

Behavior Modification
• Identify and minimize or avoid exposure to inciting stimuli.
• Provide a quiet and calm environment for security, rest, and sleep.
• Structure all interactions (i.e., calm sit or down and quiet behavior for all rewards).
• Reward-based training to teach calm/settle on cue ("Sit," "Down," "Mat").
• Response substitution—use settle commands to train alternative acceptable behavior.
• Head halter may provide more immediate control to quiet and calm.
• Eliminate any owner reinforcement.
• Owner anxiety, verbal reprimands, and punishment may increase anxiety and potentiate barking.
• Desensitize and countercondition—expose the pet to the inciting stimulus at a low level (under the response threshold) and pair a favored reward (e.g., food treat) with each exposure to change the emotional response. Gradually progress to more intense stimulus.
• Interrupting vocalization by directing into an alternative behavior may help to achieve

(CONTINUED) EXCESSIVE VOCALIZATION AND WAKING AT NIGHT—DOGS AND CATS

quiet, which can then be reinforced; however, aversive techniques may increase anxiety.

Environmental Modification

Modify environment to avoid or minimize exposure to stimuli that incite vocalization or wake the pet, e.g., covered crate, quiet room, thunder cap, classical music, white noise or fan.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUG(S) OF CHOICE

- Short term or as needed for situations of anxiety or for inducing sleep.
- Benzodiazepines—dog: clonazepam 0.05–0.25 mg/kg, diazepam 0.5–2.2 mg/kg; cat: oxazepam 0.2–0.5 mg/kg, alprazolam 0.125–0.25 mg/cat, clonazepam 0.02–0.2 mg/kg.
- Trazodone—dog: 5–10 mg/kg; cat: 25–50 mg/cat.
- Gabapentin—dog: 20–30 mg/kg; cat: 50–100 mg/cat.
- Melatonin—dog and cat: 3–6 mg (1.5–12 mg).
- For ongoing therapy for chronic anxiety or compulsive disorders—clomipramine (tricyclic antidepressant [TCA]): dog: 1–3 mg/kg PO q12h, cat: 0.5–1 mg/kg PO q24h; fluoxetine or paroxetine (selective serotonin reuptake inhibitors [SSRIs]): dog: 1–2 mg/kg PO q24h, cat: 0.5–1.5 mg/kg PO q24h.
- Natural products that might be used adjunctively for anxiety—Adaptil®, Feliway®, l-theanine, alpha-casozepine, Harmonease®, S-adenosyl-L-methionine-tosylate disulfate (SAMe), or aromatherapy (lavender).
- For CDS—selegiline and cognitive supplements (see Cognitive Dysfunction Syndrome).

CONTRAINDICATIONS

Review contraindications and side effects for each drug used.

PRECAUTIONS

- Caution with drugs that might sedate in elderly pets.
- Monitor for undesirable behavioral effects.
- Avoid anticholinergic drugs in pets with CDS.

POSSIBLE INTERACTIONS

Do not use SSRIs and TCAs together with monoamine oxide (MAO) inhibitors such as selegiline and amitraz, and use cautiously or avoid with buspirone and tramadol.

ALTERNATIVE DRUG(S)

- Concurrent sedation with acepromazine 0.5–2.2 mg/kg might be considered, but it is not anxiolytic and may increase noise sensitivity and vocalization.
- For a less sedating anxiolytic consider buspirone at 0.5–1 mg/kg (dogs: q8–12h; cats: q12h).
- Analgesics for pain control.

FOLLOW-UP

PATIENT MONITORING

Modify the program based on response to therapy.

PREVENTION/AVOIDANCE

- Train calm and settle on cue (sit, down, go to mat).
- Predictable interactions, e.g., insure calm sit or down and quiet before any reward given.
- Reward desirable, do not punish undesirable behavior.
- Socialize and habituate pet when young to a wide range of people, pets, stimuli, and environments.
- Provide enrichment to meet needs including food puzzles and multiple small meals for cats.

POSSIBLE COMPLICATIONS

- Night-time waking can lead to fatigue, increased irritability, and possibly aggression.
- Both night waking and vocalization can be particularly distressing to the pet owner's health and wellbeing and greatly weaken the bond.

EXPECTED COURSE AND PROGNOSIS

- Variable—based on diagnosis, environment, pet, and owner expectations.
- Most can be improved over time, but might not be eliminated.

MISCELLANEOUS

ASSOCIATED CONDITIONS

CDS

AGE-RELATED FACTORS

Increased anxiety and night waking more common in senior pets.

ZOONOTIC POTENTIAL

None, but sleep disruption and anxiety in pets can contribute to sleep disruption and anxiety in owners.

PREGNANCY/FERTILITY/BREEDING

N/A

SYNONYMS

Sleep disturbances.

SEE ALSO

- Cognitive Dysfunction Syndrome.
- Compulsive Disorders—Cats.
- Compulsive Disorders—Dogs.
- Separation Anxiety Syndrome.

ABBREVIATIONS

- BAER = brainstem auditory evoked response.
- CDS = cognitive dysfunction syndrome.
- MAO = monoamine oxide.
- SAMe = S-adenosyl-L-methionine-tosylate disulfate.
- SSRI = selective serotonin reuptake inhibitor.
- TCA = tricyclic antidepressant.

Consulting Editor Gary M. Landsberg

EXERCISE-INDUCED WEAKNESS/COLLAPSE IN LABRADOR RETRIEVERS

BASICS

DEFINITION
Inherited nervous system disorder causing weakness and collapse during intensive exercise in otherwise normal Labrador retrievers and a few other breeds.

SIGNALMENT
- Labrador retrievers—approximately 6% of all pet, show, and field Labrador retrievers are affected.
- Also occurs in Chesapeake Bay retrievers, curly-coated retrievers, and Boykin spaniels, and rarely in Old English sheepdogs, German wirehaired pointers, Bouvier des Flandres, Pembroke Welsh corgis, and cocker spaniels.
- No sex or color predilection.

SIGNS

General Comments
- No systemic signs.
- Episodes of collapse first occur between 5 months and 3 years of age.
- Collapse episodes occur only with extremes of exciting exercise.
- Dogs can engage normally in hiking, swimming, jogging, and other activities.

Physical Examination Findings
Between weakness/collapse episodes, physical and neurologic examinations are normal.

Features of Weakness/Collapse Episodes
- Weakness occurs after 5–20 minutes of intense exercise with excitement or stress.
- Rear limbs become weak and unable to support weight.
- Rear limb muscles are flaccid during collapse and there is a loss of patellar reflexes.
- Dogs may continue to run, dragging their rear limbs in a crouched posture.
- During a severe episode, all four limbs can be affected; rarely the dog may become recumbent and unable to move its limbs or raise its head.
- Dogs remain conscious and fully alert during episodes.
- There is no apparent pain or discomfort on palpation or manipulation of the muscles, joints, or spine during or after collapse.
- Complete recovery occurs within 5–30 minutes.
- Rectal temperature is elevated (mean >107 °F; >41.6 °C), but not different from Labradors without exercise-induced collapse doing similar exercise.
- A few dogs with exercise-induced collapse (EIC) have died during collapse—death is usually preceded by a short generalized seizure. The cause of death is uncertain, but weakness of the respiratory muscles and extreme hyperthermia are suspected.

CAUSES
- Genetic disorder—inherited as an autosomal recessive trait.
- Symptomatic dogs are homozygous for a mutation in the dynamin 1 gene. Dynamin 1 (*DNM1*) is a protein important in neurotransmission in the brain and spinal cord during high-level neuronal activity. There is evidence that the *DNM1* mutation associated with EIC has its most profound effect on *DNM1* function when body temperature is elevated, as normally occurs with exercise.

RISK FACTORS
- Genetically affected dogs are at risk for collapse when participating in high-intensity exercise with concurrent excitement or stress.
- Trigger activities most likely to induce collapse include repetitive fun or training retrieves, upland bird hunting, intense play with other dogs, and running alongside an all-terrain vehicle.
- Increased ambient temperature and humidity increase the risk of collapse in affected dogs.
- Most genetically affected dogs (>80%) will have at least one episode of collapse before they reach 3 years of age, but affected dogs with a sedentary lifestyle or calm temperament may never exhibit weakness or collapse.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- The episodic nature of the collapse, association with exercise and excitement, typical features of collapse including rear limb weakness and normal mentation, progression of weakness during an episode, and rapid complete recovery should lead to a presumptive diagnosis of EIC in an otherwise healthy Labrador retriever. Physical and neurologic examinations are normal; further evaluation should be performed to eliminate other causes of weakness and collapse. Genetic testing is required to confirm the diagnosis of EIC.
- The disorder most often confused with EIC is a focal seizure/movement disorder characterized by brief episodes of abnormal crouched gait, disequilibrium, head-bobbing, or incoordination. Episodes are often induced by exercise/excitement, leading to confusion with EIC. The onset of signs is peracute, the episodes are short (usually less than 5 minutes), all limbs are involved, and recovery is immediate, helping to distinguish this disorder from the more progressive gait disturbance caused by EIC. Diagnosis can only be made by ruling out other disorders (including EIC) with testing.
- Dogs with metabolic myopathies, polymyositis, and myasthenia gravis are typically much more exercise intolerant than dogs with EIC and they collapse with mild exercise of short duration.
- Centronuclear myopathy—inherited muscle disorder in Labrador retrievers that causes generalized muscle atrophy, constant weakness that worsens with exercise, and absent patellar reflexes at rest. Diagnosis of this disorder is by muscle biopsy or DNA testing (http://labradorcnm.vet-alfort.fr/pages/site/Overview_history.html).
- Cardiac arrhythmia—as a cause of exercise intolerance can be ruled out by cardiac auscultation, palpation of femoral pulses, and performing an ECG at rest and during collapse. Holter monitor or an ECG event recorder may be required to rule out intermittent cardiac arrhythmia.
- Pulmonary hypertension—can cause exercise intolerance and syncopal episodes as exercise and excitement increase systolic pressure in an already overloaded right ventricle and pulmonary arteries, resulting in reflex bradycardia, vasodilation, and hypotension.
- Hypoglycemia—ruled out by measuring blood glucose during an episode.
- Hypo- or hyperkalemia—ruled out by measuring potassium during collapse.
- Hypoadrenocorticism (Addison's disease)—can cause exercise-induced hypoglycemic collapse or seizures; should be ruled out with adrenocorticotropin hormone (ACTH) stimulation test.
- Cataplexy—peracute, nonprogressive, brief episodes of flaccid paralysis.
- Heat stroke—collapse due to heat stroke is usually associated with bleeding, shock, and abnormal mentation. Acute renal failure, disseminated intravascular coagulation (DIC), and death are common. Recovery, if it does occur, is prolonged.
- Malignant hyperthermia—hypermetabolic state triggered by certain anesthetics, extreme heat, intense activity, or psychologic stress in genetically susceptible dogs. Hyperthermia, generalized skeletal muscle contraction, rhabdomyolysis, and DIC occur and many dogs die. Recovery, if it does occur, is prolonged. In vitro contracture tests on muscle biopsies or identification of the causative genetic mutation of the ryanodine receptor (*RYR1*) is required for diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS
Normal at rest and during collapse.

OTHER LABORATORY TESTS
- Arterial blood gas—normal at rest, respiratory alkalosis and metabolic acidosis during collapse identical to intensively exercising Labradors without EIC.
- Lactate and pyruvate—normal at rest, not different during collapse from exercising Labradors without EIC.
- Thyroid evaluation—normal.
- ACTH stimulation test—normal.

(CONTINUED) EXERCISE-INDUCED WEAKNESS/COLLAPSE IN LABRADOR RETRIEVERS

• Analysis for mutation in *RYR1* causing malignant hyperthermia—negative.
• Testing for acetylcholine receptor antibodies causing acquired myasthenia gravis— negative.

IMAGING
Thoracic and abdominal radiographs, abdominal ultrasound, echocardiography—normal.

DIAGNOSTIC PROCEDURES
ECG findings at rest and during collapse—normal.

DNA Testing
• Definitive diagnosis requires demonstration that a dog has two copies of the causative *DNM1* mutation.
• Testing can be performed on blood, cheek swabs, puppy dewclaws, or semen.
• Approximately 6% of all tested Labrador retrievers have two copies of the *DNM1* mutation (affected); >35% of all tested Labrador retrievers have one copy of the *DNM1* mutation (carrier).
• Finding two copies of the *DNM1* mutation confirms that a dog is EIC affected and susceptible to collapse, but does not rule out other causes of exercise intolerance or collapse. It is important to do the necessary tests to rule out other causes of collapse that may be potentially more treatable.

PATHOLOGIC FINDINGS
• Muscle histology—normal.
• Complete postmortem examinations of dogs dying during collapse due to EIC—normal.

TREATMENT

ACTIVITY
Most affected dogs can live normal active lives if specific trigger activities are avoided or done in moderation.

CLIENT EDUCATION
• Signs commonly worsen in the 3–5 minutes after exercise is terminated; some (<5%) affected dogs die during collapse.
• All activity should be halted at the first sign of weakness or incoordination.
• Consider offering cool water orally, spraying with water, or immersing in water to lower body temperature.

MEDICATIONS

DRUG(S) OF CHOICE
There is no recommended drug therapy for this disorder.

FOLLOW-UP
Most affected dogs can be managed effectively by avoiding trigger activities and carefully observing for the first signs of weakness.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Dogs with EIC do not develop other associated medical conditions as they age.

AGE-RELATED FACTORS
Episodes of collapse may become less frequent as dogs age, perhaps because of less excitement associated with trigger activities.

PREGNANCY/FERTILITY/BREEDING
• Animals should be tested to establish their EIC status prior to breeding.
• Affected dogs (with two copies of the *DNM1* mutation) should not be bred or should be bred only to known noncarriers to avoid producing affected offspring.
• Carrier dogs (with one copy of the *DNM1* mutation) should only be bred to known noncarriers to avoid producing affected offspring.

ABBREVIATIONS
• ACTH = adrenocorticotropin hormone.
• DIC = disseminated intravascular coagulation.
• EIC = exercise-induced collapse.

EXOCRINE PANCREATIC INSUFFICIENCY

BASICS

DEFINITION
Syndrome that is caused by inadequate amounts of pancreatic digestive enzymes in the small intestinal lumen.

PATHOPHYSIOLOGY
• Most commonly caused by insufficient synthesis and secretion of pancreatic enzymes by the exocrine pancreas. • In rare cases can be caused by an obstruction of the pancreatic duct or isolated lipase deficiency.
• Insufficient synthesis of pancreatic digestive enzymes can be due to destruction of acinar cells resulting from chronic pancreatitis (approximately 50% of cases in dogs and almost all cases in cats) or can be due to idiopathic pancreatic acinar atrophy (PAA; most common cause of exocrine pancreatic insufficiency in German shepherd dogs).
• Deficient exocrine pancreatic secretion results in maldigestion and nutrient malabsorption, leading to weight loss and loose stools with steatorrhea. • Malabsorption contributes to small intestinal dysbiosis.

SYSTEMS AFFECTED
Nutritional—protein-calorie malnourishment.

GENETICS
Assumed to be hereditary in the German shepherd dog and probably transmitted by a complex trait (early studies have suggested an autosomal recessive trait, but this is no longer believed to be the case).

INCIDENCE/PREVALENCE
• PAA is very commonly seen in the German shepherd dog; it is less commonly seen in rough-coated collies and Eurasians. • Other causes of exocrine pancreatic insufficiency (EPI) may be seen in all dog and cat breeds.
• Less common in cats than in dogs.

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT

Species
Dog and cat.

Breed Predilections
German shepherd dogs, rough-coated collies, and Eurasians.

Mean Age and Range
• PAA in young adult dogs. • Chronic pancreatitis in dogs and cats of any age.

Predominant Sex
No sex predilection.

SIGNS

General Comments
• Consider in young adult (age range approximately 1–4 years) German shepherd dogs with weight loss and loose stools.
• Severity—varies depending on time until diagnosis and therapy.

Historical Findings
• Weight loss with normal to increased appetite. • Chronically loose stools or diarrhea. • Fecal volumes are larger than normal and may be associated with steatorrhea. • Flatulence and borborygmus are commonly reported, especially in dogs.
• May show coprophagia and/or pica. • May be accompanied by polyuria/polydipsia with diabetes mellitus as a sequel to chronic pancreatitis.

Physical Examination Findings
• Thin body condition. • Decreased muscle mass. • Poor-quality hair coat. • Cats with steatorrhea may have greasy "soiling" of the hair coat in the perineal area, but this is seen in the minority of cases.

CAUSES
• PAA. • Chronic pancreatitis. • Pancreatic adenocarcinoma or other abdominal tumor leading to pancreatic duct obstruction

RISK FACTORS
• Breed—German shepherd dogs, rough-coated collies, and Eurasians. • Any condition predisposing dogs or cats to chronic pancreatitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Secondary causes of chronic diarrhea and weight loss (e.g., hepatic failure, renal failure, hypoadrenocorticism, and hyperthyroidism in cats). • Primary gastrointestinal disease (e.g., infectious, inflammatory, neoplastic, mechanical, or toxic).

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS

Direct/Indirect Fecal Examinations
Negative for parasites.

Exocrine Pancreatic Function Tests—Trypsin-Like Immunoreactivity (TLI)
• Diagnostic test of choice in both dogs and cats. • Principle of test—serum TLI can be measured by an assay that detects trypsinogen and trypsin that is directly released into the blood from pancreatic acinar cells; serum TLI is detected in the serum of all normal dogs and cats with a functional exocrine pancreatic mass.
• Serum TLI concentrations are dramatically reduced with EPI—dogs: cTLI ≤2.5 µg/L; cats: fTLI ≤8.0 µg/L. • The TLI tests are species specific. • Advantages—simple; quick; single serum specimen (fasted); highly sensitive and specific for EPI in both species.

Other Exocrine Pancreatic Function Tests
• Assays of fecal proteolytic activity using casein-based substrates have been used to diagnose EPI in both dogs and cats; however, fecal proteolytic activity is associated with false-positive and false-negative test results and should only be used in exotic species for which a serum TLI test is not available. • An assay for the measurement of fecal elastase has been validated for the dog; however, this test is associated with a high rate of false-positive test results; therefore a positive test result, suggesting EPI, must be verified by measurement of a serum cTLI concentration.

Screening Tests for Malassimilation
Microscopic examination of feces for undigested food, assessment of fecal proteolytic activity, and the plasma turbidity test are unreliable and *not* recommended.

Cobalamin and Folate
• Often run as a panel with TLI. • Used to assess for concurrent small intestinal dysbiosis or concurrent small intestinal disease (such as inflammatory bowel disease [IBD]). • Cobalamin (vitamin B_{12}) is frequently deficient in both dogs and cats with EPI and can lead to treatment failure or complications if not addressed.

IMAGING
Abdominal radiography and ultrasonography are unremarkable unless the patient has concurrent conditions.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Chronic pancreatitis—microscopically, acini and possibly islets are depleted and replaced by fibrous tissue; there may also be an active inflammatory infiltration. • PAA—marked atrophy/absence of pancreatic acinar tissue on gross and histopathologic inspection in dogs with PAA.

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient medical management.
• Patients with concurrent diabetes mellitus may initially require hospitalization if ill (e.g., diabetic ketoacidosis).

NURSING CARE
N/A

ACTIVITY
No restriction.

DIET
• Type of diet does not play a role in the management of EPI in dogs and cats.
• However, low-fat and high-fiber diets should be avoided.

(CONTINUED) # EXOCRINE PANCREATIC INSUFFICIENCY

CLIENT EDUCATION
• Discuss hereditary nature in German shepherd dogs. • Discuss expense of pancreatic enzyme supplementation and need for lifelong therapy. • Discuss the possibility of diabetes mellitus in patients with chronic pancreatitis.

SURGICAL CONSIDERATIONS
Mesenteric torsion has been reported in German shepherd dogs with EPI in Finland, but not North America.

MEDICATIONS

DRUG(S) OF CHOICE
• Powdered pancreatic enzymes are the treatment of choice (as a reference these products should contain at least 70,000 USP of lipase per teaspoon). • In Europe, microencapsulated products are available; because the lipase is protected from gastric inactivation a much smaller amount is needed for treatment. • Initially—mix enzyme powder in food at a dosage of 1 teaspoon/10 kg body weight with each meal; feed at least two meals daily to promote weight gain. • Preincubation of enzymes with food does *not* improve the effectiveness of oral enzyme therapy, but may negatively impact owner compliance. • Approximately 85% of all dogs with EPI and virtually all cats with EPI are cobalamin deficient and require parenteral or oral cobalamin supplementation (see Cobalamin Deficiency for dosing). • Administration of a proton pump inhibitor (e.g., omeprazole at 0.7–1.0 mg/kg q12h) may improve the condition in nonresponsive patients. • Most dogs and cats respond to therapy within 5–7 days; after a complete response has been achieved, the amount of pancreatic enzyme supplement may be gradually reduced to a dose that prevents return of clinical signs. • Oral antibiotic therapy (tylosin: 25 mg/kg PO q12h) may be required for 4–6 weeks in patients with concurrent dysbiosis, but in most patients dysbiosis resolves spontaneously upon commencement of enzyme replacement therapy. • Severely malnourished dogs may also require supplementation with tocopherol; body stores of other fat-soluble vitamins are probably also decreased in dogs and cats with EPI, but supplementation does not appear to be crucial.

CONTRAINDICATIONS
Avoid tablets and capsules, as mixing of enzymes and chyme is unpredictable.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
• The cost of pancreatic enzyme replacement is very high; also, some cats refuse to consume the pancreatic enzyme supplement; these patients can often be successfully managed by addition of fish oil to the enzyme supplement or administration of raw beef, pork, or game pancreas. • Each teaspoon of pancreatic enzyme supplement needs to be replaced with 1–3 ounces (approximately 30–90 g) of raw chopped pancreas. • Raw pancreas can be kept frozen for months without losing enzymatic activity.

FOLLOW-UP

PATIENT MONITORING
• Weekly for first month of therapy. • Diarrhea improves markedly—fecal consistency typically normalizes within 1 week. • Gain in bodyweight. • Patients that fail to respond after 2 weeks of enzyme therapy and cobalamin supplemenation should be treated for secondary intestinal dysbiosis. • Once bodyweight and condition normalize, gradually reduce daily dosage of enzyme supplements to a level that maintains normal fecal quality and bodyweight.

PREVENTION/AVOIDANCE
Do not breed patients that belong to a breed predisposed to PAA.

POSSIBLE COMPLICATIONS
• Approximately 20% of dogs fail to respond to pancreatic enzymes and need further evaluation and therapy. • Most patients with EPI have cobalamin deficiency and need to be managed accordingly. • Some dogs and cats treated with pancreatic enzyme supplements develop oral ulcerations; in most of these patients the dose of pancreatic enzyme supplements can be decreased, while maintaining therapeutic response; in a few patients, the dose of the pancreatic enzyme supplement needs to be adjusted frequently to avoid treatment failure and oral ulceration. • Two cats with EPI and vitamin K–responsive coagulopathy have been reported; thus, patients that present with a bleeding diathesis should be further evaluated and possibly treated with parenteral vitamin K supplementation.

EXPECTED COURSE AND PROGNOSIS
• Most causes are irreversible, and lifelong therapy is required. • Patients with EPI alone have a good prognosis with appropriate enzyme supplementation and supportive management. • Prognosis is more guarded in patients with EPI and concurrent diabetes mellitus.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Dysbiosis. • Cobalamin deficiency. • IBD. • Diabetes mellitus. • Associated vitamin K–responsive coagulopathy.

AGE-RELATED FACTORS
Consider EPI in young adult German shepherd dogs with weight loss and loose stools.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Do not breed animals with EPI suspected to be due to PAA.

SYNONYMS
None

SEE ALSO
• Cobalamin Deficiency.
• Diarrhea, Chronic—Cats.
• Diarrhea, Chronic—Dogs.
• Pancreatitis—Cats.
• Small Intestinal Dysbiosis.

ABBREVIATIONS
• cTLI = canine trypsin-like immunoreactivity.
• EPI = exocrine pancreatic insufficiency.
• fTLI = feline trypsin-like immunoreactivity.
• IBD = inflammatory bowel disease.
• PAA = pancreatic acinar atrophy.
• TLI = trypsin-like immunoreactivity.

EYELASH DISORDERS (TRICHIASIS/DISTICHIASIS/ECTOPIC CILIA)

BASICS

OVERVIEW

• Trichiasis—normal hair from the skin contacting corneal or conjunctival surface. • Distichiasis—abnormal hairs that emerge from the meibomian glands along the eyelid margin; may contact corneal or conjunctival surface. • Ectopic cilia—abnormal hairs that emerge through the palpebral conjunctiva several millimeters from the lid margin; contact the corneal surface.

SIGNALMENT

• *Trichiasis*: ○ Facial fold trichiasis—brachycephalic dogs with prominent facial folds or a shallow orbit and prominent globe (e.g., Pekingese, pug, English bulldog). ○ Entropion—rolling in of eyelid margin; conformational (primary) entropion common in young dogs in predisposed breeds (shar pei, retrievers, chow chow, English bulldog, among others); secondary (acquired) entropion may occur in dogs and cats of any breed or age. ○ Eyelid agenesis (eyelid coloboma)—congenital in cats; sporadic occurrence. • *Distichiasis*— common in young dogs; rare in cats; some predisposed breeds include spaniels, English bulldog, flat-coated retriever, and dachshund. • *Ectopic cilia*—common in young dogs, rare in cats; predisposed breeds include Pekingese, shih tzu, and English bulldog.

SIGNS

Facial-Fold Trichiasis

• Commonly bilateral. • Epiphora. • Pigmentary keratitis (especially nasally). • Often associated with lagophthalmos (incomplete blink). • Blepharospasm if ulcerative keratitis present.

Trichiasis Associated with Entropion

• Bilateral if primary. • Blepharospasm. • Epiphora. • Conjunctivitis. • Keratitis (vascularization, pigmentation, possibly ulcerative).

Eyelid Agenesis

• Typically bilateral. • Absent portion of dorsal-lateral eyelid margin. • Other intraocular congenital abnormalities are common. • Conjunctivitis. • Keratitis (vascularization, pigmentation; possibly ulcerative). • Lagophthalmos. • Blepharospasm.

Distichiasis

• Involves upper and/or lower eyelid margin; unilateral or bilateral. • Soft hairs and those directed away from the cornea: asymptomatic. • Stiff, stout cilia contacting the cornea: blepharospasm, epiphora, conjunctivitis, and keratitis (vascularization, pigmentation; possibly ulcerative).

Ectopic Cilia

• Unilateral or bilateral; typically central/upper eyelid. • Hair may be pigmented or nonpigmented. • Severe blepharospasm. • Epiphora. • Conjunctivitis. • Recurrent superficial corneal ulcers.

CAUSES & RISK FACTORS

• Trichiasis—often related to conformation. • Secondary (acquired) entropion may be associated with pain (spastic entropion), scarring (cicatricial entropion), or enophthalmos; occasionally seen in cats. • Distichiasis—considered to be inherited; many predisposed breeds. • Eyelid agenesis (eyelid coloboma)—may be hereditable or due to in utero viral infection. • Ectopic cilia—multiple breeds predisposed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other adnexal abnormalities. • Keratoconjunctivitis sicca. • Conjunctival foreign body. • Infectious or inflammatory conjunctivitis. • Diagnosis based on observation of abnormal cilia and lid/facial conformation.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Ocular examination with magnification.

TREATMENT

Trichiasis

• Conservative management—topical lubricating ointments. • Clipping hair on facial folds may cause hairs to become stiffer and more irritating. • Surgical correction of adnexal abnormalities (primary entropion, eyelid agenesis). • Reduce/remove facial folds in contact with ocular surface. • Medial canthoplasty—for nasal trichiasis; reduces lagophthalmos and medial entropion. • Treat underlying cause (e.g., spastic entropion, enophthalmia); temporary eyelid tacking may be indicated.

Distichiasis

• If asymptomatic, no treatment is required. • Symptomatic—mechanical removal (periodic manual epilation) or surgical destruction of hair follicles by cryoepilation, electroepilation, or transconjunctival electrocautery. • Avoid lid-splitting and partial tarsal plate excision techniques; may predispose to cicatricial entropion and impaired lid function.

Ectopic Cilia

• Surgical treatment—en bloc resection of the cilia and associated meibomian gland. • Cryotherapy—may be used as sole treatment or adjunct after resection. • May develop ectopic cilia at other locations. • Recheck if clinical signs recur.

MEDICATIONS

DRUG(S) OF CHOICE

• Rarely indicated. • Lubricant ointments—lessen irritation before surgical correction. • Soft contact lens—temporary relief of clinical signs before surgical correction. • Topical antibiotics—for ulcerative keratitis, prophylactic following surgical eyelid procedures.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

• Trichiasis—good prognosis; some corneal changes may occur; destructive procedures must be done conservatively to minimize lid damage. • Ectopic cilia—good prognosis; regrowth may occur.

FACIAL NERVE PARESIS AND PARALYSIS

BASICS

DEFINITION
Dysfunction of the facial nerve (cranial nerve [CN] VII) causing paresis (weakness) or paralysis of the muscles of facial expression, which include the ears, eyelids, lips, and nostrils.

PATHOPHYSIOLOGY
- Central—impairment of the facial nucleus within the rostral medulla (brainstem).
- Peripheral—impairment of the facial nerve anywhere along its length or at the neuromuscular junction.

SYSTEMS AFFECTED
- Nervous—facial nerve peripherally or its nucleus centrally.
- Ophthalmic—if parasympathetic preganglionic neurons that supply the lacrimal gland and gland of the third eyelid that course with the facial nerve proximally are affected, keratoconjunctivitis sicca (KCS) develops due to lack of tear secretion.

GENETICS
N/A

INCIDENCE/PREVALENCE
More common in dogs than cats.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Idiopathic paralysis—cocker spaniel, beagle, Pembroke Welsh corgi, boxer, English setter, golden retriever, and domestic longhair cats.

Mean Age and Range
Adults

Predominant Sex
N/A

SIGNS

General Comments
- Assess strength of palpebral closure—there should be full eyelid closure when a finger is gently passed over the eyelids.
- Idiopathic—unaffected side may become affected within a few weeks to months; may rarely occur bilaterally at first presentation; can have concurrent idiopathic vestibular neuropathy.
- Most patients with bilateral nerve involvement have polyneuropathy-associated systemic disease—look for other nerve deficits.
- May accompany other clinical signs and/or neurologic deficits—always perform a full neurologic examination.
- Ear droop is not always evident in cats and dogs with erect ears.

Historical Findings
- Messy eating; food left around mouth.
- Excessive drooling on affected side.
- Facial asymmetry.
- Eye—inability to close eyelids, rubbing, ocular discharge, ulceration.

Physical Examination Findings
- Facial asymmetry—lip and ear droop, wide palpebral fissure, collapse of nostril.
- Decreased or absent palpebral reflex.
- Decreased or absent menace response (may see eye retraction rather than lid closure).
- Inability to close eyelids.
- Excessive drooling or food falling from mouth on affected side.
- Chronically, patients may have facial muscle contraction toward the affected side due to muscle fibrosis subsequent to paralysis and denervation.
- Decreased Schirmer tear test, mucopurulent discharge from affected eye, and exposure conjunctivitis or keratitis with concurrent KCS.
- Altered mentation (e.g., somnolence or stupor) and/or other cranial nerve abnormalities and gait disturbances may be noted when secondary to intracranial (brainstem) disease.
- Hemifacial spasms (facial nerve tetanus) may be infrequently observed in lesions affecting the facial nerve such as neuritis or otitis media. These patients have sustained contraction of the facial muscles, giving a "grinning" appearance to the affected side of the face. This is a dynamic process and at times the face will appear normal, only to begin the "grinning" appearance once again. If one notices this clinical presentation, middle ear disease should be investigated thoroughly.
- Intermittent facial paresis can be observed in patients with a contralateral thalamocortical lesion when patient is relaxed—due to "release" of upper motor neuron influence on lower motor neuron (CN VII).
- Concurrent heat tilt on ipsilateral side with concurrent otitis interna.
- Concurrent head tilt on ipsilateral side with concurrent idiopathic vestibular neuropathy.
- Abnormal tympanum (bulging, opaque, rupture) on otoscopic examination. Obvious external ear disease may not be present with otitis media.

CAUSES

Unilateral Peripheral
- Idiopathic.
- Metabolic—hypothyroidism.
- Infectious—otitis media–interna (dogs and cats).
- Inflammatory—nasopharyngeal polyps (cats), neuritis.
- Iatrogenic—secondary to surgical ablation of external ear canal or bulla osteotomy; secondary to exuberant ear cleaning; idiosyncratic reaction to potentiated sulfonamides (dogs).
- Neoplastic—aural cholesteatoma, squamous cell carcinoma.
- Trauma—fracture of petrous temporal bone, direct injury to facial nerve by laceration, or compression by hematoma or other mass.
- Toxic—tick bite paralysis (*Dermacentor* spp. (humans), *Ixodes holocyclus*).

Bilateral Peripheral
- Idiopathic.
- Immune-mediated—polyradiculoneuritis (coonhound paralysis), polyneuropathy, myasthenia gravis.
- Metabolic—paraneoplastic polyneuropathy (e.g., insulinoma), hypothyroidism.
- Toxic—botulism.

CNS
- Most unilateral.
- Infectious—viral, bacterial, fungal, rickettsial, protozoal encephalitis.
- Inflammatory—meningoencephalitis of unknown etiology (MUE).
- Neoplastic—primary such as meningioma, choroid plexus tumor, lymphoma; metastatic tumor such as hemangiosarcoma, carcinoma.

RISK FACTORS
Chronic otitis externa and otitis media.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Differentiate unilateral from bilateral involvement.
- Look for other neurologic deficits—behavior change, gait disturbance, other CN deficits.
- Idiopathic—diagnosis of exclusion; no historical or physical signs of ear disease and no other neurologic deficits.
- Hypothyroidism—with clinical evidence (e.g., lethargy, poor hair coat, weight gain, anemia, hypercholesterolemia, ↓FT4, ↑canine thyroid-stimulating hormone [cTSH]).
- Otitis media–interna—Horner's syndrome, head tilt, and KCS may be simultaneously present.
- CNS disease—if there is somnolence, gait disturbances, or other CN deficits.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal in idiopathic facial paralysis.
- Fasting hypercholesterolemia, normocytic/normochromic nonregenerative anemia may be observed with hypothyroidism-associated facial paralysis.
- Hypoglycemia with insulinoma.

OTHER LABORATORY TESTS
- Indicated for patients with suspected underlying disease
- Insulin : glucose ratio to detect insulinoma.
- Acetylcholine receptor antibodies to diagnose myasthenia gravis.

FACIAL NERVE PARESIS AND PARALYSIS (CONTINUED)

• Free T_4 (ideally by equilibrium dialysis) and cTSH to diagnose hypothyroidism.

IMAGING
• CT—sensitive to evaluate middle–inner ear diseases, preferred modality to evaluate bony structures in middle ear.
• MRI—superior to CT for intracranial imaging, preferable for CNS disease; contrast enhancement of facial nerve in dogs with idiopathic facial nerve paralysis; the greater the extent of enhancement, the poorer the prognosis for return to function.
• Bullae radiographs—four views; two obliques, 30° open mouth, dorso-ventral; not sensitive for middle–inner ear diseases.

DIAGNOSTIC PROCEDURES
• Schirmer test—evaluate tear production (normal >15 mm in 60 seconds), should always be performed when evaluating a patient with facial paresis/paralysis.
• Fluorescein test—evaluate for presence of corneal ulceration secondary to KCS.
• Otoscopic examination—evaluate integrity of tympanic membrane and for evidence of otitis media.
• Cerebrospinal fluid (CSF)—evaluate for evidence of intracranial disease; not sensitive if used alone, should be combined with diagnostic imaging (e.g., MRI).
• Facial muscle electromyography—evaluate for denervation and neuromuscular disease.
• Facial and trigeminal nerve reflex electrodiagnostic testing—evaluate peripheral nerve integrity, distinguish between peripheral and central lesions.

PATHOLOGIC FINDINGS
Idiopathic—may see degeneration of large and small myelinated fibers without evidence of inflammation.

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient—idiopathic facial paralysis.
• Inpatient—initial medical workup and management of systemic or CNS disease if present.

DIET
No change required.

CLIENT EDUCATION
• Clinical signs may be permanent; however, as muscle fibrosis develops, there is a natural "tuck up" of the affected side that reduces asymmetry; drooling usually stops within 2–4 weeks.
• Inform client that other side can become affected.
• Discuss eye care—cornea on affected side may need lubrication; extra care may be needed if animal is a breed with natural exophthalmia; client must regularly check eyes for redness, discharge, or pain that may indicate corneal ulcer.
• Inform client that most animals tolerate this nerve deficit well; there is no significant impact on quality of life.

SURGICAL CONSIDERATIONS
Bulla osteotomy may be indicated for patients with disorders of middle ear.

MEDICATIONS

DRUG(S) OF CHOICE
• Treat specific disease if possible (e.g., thyroxine for hypothyroidism).
• Idiopathic disease—no treatment required; efficacy of corticosteroids unknown and used commonly in humans to treat Bell's palsy, however are not recommended in veterinary medicine at this time.
• Tear replacement if Schirmer test value low (<15 mm), in patients with KCS or with exophthalmic globes.

CONTRAINDICATIONS
If middle ear disease is suspected, and tympanic membrane may be ruptured, do not use topical ear cleaning solutions due to risk of ototoxicity.

PRECAUTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
• Reevaluate early for evidence of corneal ulcers.
• Reassess monthly (for 2–3 months) for menace responses, palpebral reflexes, and lip and ear movements to evaluate return of function, condition of affected eye, and development of other neurologic deficits that would indicate progressive disease.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
• KCS.
• Corneal ulcers.
• Permanent facial asymmetry (aesthetic only).

EXPECTED COURSE AND PROGNOSIS
• Depends on underlying cause if one is present.
• Idiopathic disease—prognosis guarded for full recovery.
• Improvement may take weeks or months or may never occur.
• Lip contracture sometimes develops.
• Corneal ulcers may perforate and require enucleation.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Otitis

FALSE PREGNANCY

BASICS

DEFINITION
• Physical and behavioral changes resulting from normal hormonal changes during diestrus and early anestrus in the nonpregnant bitch. The term false pregnancy is a misnomer, since the pattern of hormonal changes is normal.
• Physical, hormonal, and behavioral changes following a nonfertile mating or spontaneous ovulation in the queen.

PATHOPHYSIOLOGY
• Hormone profile of pregnant and nonpregnant bitch very similar following ovulation.
• All cycling bitches undergo a lengthy (2+ months) diestrus following ovulation.
• Mammary development and behavioral changes occur under the influence of progesterone and prolactin in late diestrus.
• Galactorrhea (excessive production and inappropriate excretion of milk) is seen following a rise in serum prolactin at the end of diestrus, and also in dogs with severe hypothyroidism due to resulting hyperprolactinemia.
• False pregnancies in the bitch are thought to occur as a holdover from a period in evolution when females of a pack would cycle at the same time, but only dominant individuals would become pregnant. Nonpregnant pack members were available to nurse puppies of the more dominant females.
• Any event that results in an abrupt drop in serum progesterone and rise in prolactin can lead to a clinically overt false pregnancy. Signs are frequently created iatrogenically when ovariectomy (OVE) or ovariohysterectomy (OHE) is performed during mid to late diestrus.
• Queens that ovulate spontaneously or ovulate following mating but do not become pregnant experience a 6–7-week period of diestrus due to elevated progesterone concentrations; some queens develop a clinically overt false pregnancy during this time.

SYSTEMS AFFECTED
• Reproductive.
• Behavioral.
• Endocrine.

GENETICS
N/A

INCIDENCE/PREVALENCE
• False pregnancies occur in 100% of bitches following ovulation.
• >60% of cycling bitches exhibit signs of false pregnancy.
• Spontaneous ovulation occurs frequently in the queen (35–85%) depending on presence of other queens and tom. False pregnancy occurs after every nonpregnant ovulation in the queen, but overt symptoms are uncommon.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
Any age.

Predominant Sex
Female only.

SIGNS

General Comments
• Although all cycling bitches have similar progesterone and prolactin hormone profiles during late diestrus and early anestrus, they vary in the magnitude of clinical symptoms associated with the false pregnancy. This may be due in part to individual sensitivities to prolactin.
• Some bitches experience repeated overt false pregnancies, while others have covert false pregnancies.
• The magnitude of symptoms can vary during individual false pregnancies for the same bitch.
• Overt symptoms are uncommon in queens.

Historical Findings
• Estrus—bitch: ~6–12 weeks previously; queen: ~40 days previously.
• OVE or OHE during diestrus, 3–14 days prior to presentation.
• Mammary gland development.
• Galactorrhea.
• Weight gain.
• Behavior change including nesting, maternal behavior, aggression, lethargy.
• Inappetence.
• Abdominal distension (rare).

Physical Examination Findings
• Mammary gland hypertrophy.
• Galactorrhea—fluid can be clear to milky to brown in color.

CAUSES
• Decline in serum progesterone concentration and rise in serum prolactin concentration.
• Decline in serum progesterone concentrations due to OVE or OHE during diestrus.
• Hyperprolactinemia—can be due to severe hypothyroidism.

RISK FACTORS
• OHE or OVE during diestrus.
• Does not impact future fertility.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Pregnancy.
• Mastitis.
• Mammary neoplasia.
• Mammary hyperplasia (queens).
• Pyometra.
• Other causes of abdominal distension (organomegaly, ascites).
• Hypothyroidism.
• Pituitary tumor causing hyperprolactinemia (rare).

CBC/BIOCHEMISTRY/URINALYSIS
• Normocytic, normochromic anemia—17–21% decrease in hematocrit during late diestrus.
• Hypercholesterolemia—75–94% increase during diestrus.

OTHER LABORATORY TESTS
Serum progesterone concentrations elevated if tested during diestrus.

IMAGING
• Ultrasonography—uterine enlargement; performed after 25 days from mating; can be used to evaluate for pregnancy and uterine fluid accumulation.
• Radiography—normal; performed after 54 days from mating; can be used to detect presence of fetal skeletons and uterine fluid accumulation.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
N/A

TREATMENT

APPROPRIATE HEALTH CARE
• Usually no treatment needed.
• Outpatient treatment for medical management of severe clinical signs of false pregnancy.

NURSING CARE
• Prevent mammary gland stimulation from self-nursing with Elizabethan collar or body suit.
• Owners can cold pack mammary glands to reduce mammary gland activity.

ACTIVITY
Increase activity in sedentary dogs and cats to increase caloric expenditure and decrease calories available for lactation.

DIET
Decrease caloric intake for several days to reduce energy available for lactation.

CLIENT EDUCATION
• False pregnancies are normal in bitches and do not impact future fertility.
• Advise cat owners that pyometra can develop following spontaneous ovulations.

SURGICAL CONSIDERATIONS
• OVE or OHE if bitch or queen is not intended for use in a breeding program.
• Perform OVE or OHE during anestrus or early diestrus when possible.

FALSE PREGNANCY (CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE
- Dopamine agonists—reduce milk production and some maternal behaviors by inhibiting prolactin release.
- Cabergoline 5 µg/kg PO q24h for 5–7 days.
- Bromocriptine 10 µg/kg PO q8h for 5–7 days.

CONTRAINDICATIONS
Dopamine agonists can cause abortion if given to a pregnant bitch or queen, as prolactin is luteotrophic. Drugs that suppress prolactin will terminate pregnancy by reducing progesterone and can cause premature parturition (abortion).

PRECAUTIONS
- Incidence of vomiting with bromocriptine administration reduced if given with food; cabergoline has fewer side effects and higher efficacy, but is more costly.
- Coat color changes in dogs possible with prolonged dopamine agonist treatment (uncommon).

POSSIBLE INTERACTIONS
Avoid acepromazine and metoclopramide; both can promote lactation and reduce efficacy of dopamine agonists.

ALTERNATIVE DRUG(S)
- Short-term therapy with diazepam can be useful for bitches with extreme behavioral signs.
- Mibolerone 16 µg/kg PO q24h for 5–7 days to reduce symptoms of false pregnancy. Can also be used at 2.6 µg/kg/day PO starting at least 1 month prior to the next heat cycle to suppress estrus in bitches, which will prevent recurrence. Side effect and risks of treatment should be explained and owners should give informed consent prior to treatment. Do not give to cats.

FOLLOW-UP

PATIENT MONITORING
Have owners monitor mammary glands for inflammation and discoloration that could indicate mastitis.

PREVENTION/AVOIDANCE
- Perform OVE or OHE during anestrus or early diestrus when possible.
- Estrus suppression.

POSSIBLE COMPLICATIONS
Mastitis with significant mammary gland hypertrophy, galactostasis, and ascending infection.

EXPECTED COURSE AND PROGNOSIS
- Typically resolves in 4–6 weeks without treatment.
- Resolution in 10–14 days with dopamine agonist or mibolerone.
- May recur after any ovulation.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
- The tendency to display overt false pregnancies has no impact on fertility.
- Bitches and queens should be evaluated for possible pregnancy before treating for false pregnancy.

SYNONYMS
- Pseudopregnancy.
- Pseudocyesis.
- Pseudogestation.
- Phantom pregnancy.
- False whelping.

ABBREVIATIONS
- OHE = ovariohysterectomy.
- OVE = ovariectomy.

FAMILIAL SHAR-PEI FEVER

BASICS

DEFINITION
A hereditary autoinflammatory disease in the Chinese Shar-Pei dog characterized by episodic fever and progressive systemic amyloidosis.

PATHOPHYSIOLOGY
- Multifactorial disorder caused by genetic defects that induce chronic inflammation and reactive amyloidosis. Environmental factors and gene modifiers play a role.
- Associated with the thick skin phenotype, resulting from an excessive dermal deposition of hyaluronic acid (HA) by increased expression of hyaluronic acid synthase 2 (HAS2).
- Overabundant HA is degraded into low molecular weight HA, triggering release of inflammatory interleukins.
- Elevated inflammatory cytokines increase serum amyloid A (SAA) concentration. SAA is deposited extracellularly throughout the tissues.
- Amyloid deposition may cause organ failure, particularly in kidneys and liver.

SYSTEMS AFFECTED
- Musculoskeletal—nonerosive polyarthropathy, frequently affecting the tibiotarsal joints.
- Skin—periarticular edema, especially around the tibiotarsal region, swollen muzzle, icterus, skin sloughing.
- Renal/urologic—amyloid deposition in renal medulla, glomerular amyloidosis, renal failure, proteinuria.
- Hepatobiliary—impaired hepatic function; hepatomegaly; friable liver, hepatic rupture and hemoabdomen (rare).
- Hemic/lymphatic/immune—inflammatory response; anemia; coagulation defects; hypercoagulability; hyperglobulinemia; occasionally decreased immunoglobulin (Ig) A or IgG levels.
- Gastrointestinal (GI)—submucosal amyloid deposition; GI ulceration due to renal or hepatic failure.
- Cardiovascular—venous thrombosis; systemic hypertension.
- Nervous—vascular accident; hepatic encephalopathy.
- Ophthalmic—retinal detachment.
- Respiratory—pleural effusion; pulmonary thromboembolism.

GENETICS
- Autosomal recessive inherited disorder. Different modes of inheritance proposed.
- A greater number of mutations in the "meatmouth" (or heavily wrinkled) shar-pei phenotype increases risk.

INCIDENCE/PREVALENCE
- Estimated 23–28% of shar-pei dogs.
- Estimated 53% of shar-pei dogs with fever.

SIGNALMENT
- Mean age—4 years.
- Range—19 weeks–9 years.
- Sex predisposition—female (female : male, 2.5 : 1).

SIGNS

General Comments
Findings vary depending on distribution and severity of amyloidosis.

Historical Findings
- Episodic anorexia, lethargy, stiffness, swollen hocks and/or muzzle—self-limiting (12–36 hours) or responsive to nonsteroidal anti-inflammatory drugs (NSAIDs).
- Intermittent abdominal pain, vomiting, and/or diarrhea.
- Polyuria and polydipsia.
- Weight loss.

Physical Examination Findings
- Marked fever 39.4–41.7 °C (103–107 °F) of 12–36-hour duration.
- Lethargy and dehydration.
- Edematous periarticular soft tissue swellings.
- Joint effusion.
- Swollen muzzle.
- Abdominal pain.
- Reluctance to move/hunched posture.
- Tachypnea or dyspnea.
- Hepatomegaly, ascites, and icterus.
- Pale mucous membranes secondary to chronic anemia or rarely hemoperitoneum.

CAUSES
Dysregulation of inflammatory processes in the shar-pei dog induces reactive amyloidosis.

RISK FACTORS
Stress may trigger a fever episode.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Infectious or immune-mediated causes of polyarthritis (see Polyarthritis, Nonerosive, Immune-Mediated, Dogs).
- Infectious or immune-mediated causes of fever (see Fever).

CBC/BIOCHEMISTRY/URINALYSIS
- Nonregenerative anemia.
- Neutrophilia with or without left shift.
- Acute kidney injury (e.g., azotemia, hyperphosphatemia, metabolic acidosis, isosthenuria).
- Hypoalbuminemia—secondary to proteinuria or liver failure.
- Hypercholesterolemia—consistent with nephrotic syndrome.
- Elevations in serum alkaline phosphatase (ALP) and alanine aminotransferase (ALT) activities and bilirubin concentration.
- Proteinuria—in cases of glomerular amyloidosis.
- Bilirubinuria—secondary to cholestasis or hepatic failure.

OTHER LABORATORY TESTS
- Genetic tests are available for HAS2 and MDM2 binding protein (MTBP) defects.
- Coombs' test, antinuclear antibody test, and rheumatoid factor identify concurrent underlying immune-mediated disease.
- Prothrombin time (PT) and partial thromboplastin time (PTT)—can be prolonged with liver failure and disseminated intravascular coagulation (DIC); DIC may result in increased D-dimer concentration.
- Antithrombin activity—may be low (urinary loss).
- Thromboelastography/elastometry—hypercoagulability.
- IgA or IgG levels—may be low.
- Urine protein : creatinine ratio (UPC)—severely elevated with glomerular deposition of amyloid.

IMAGING
- Abdominal radiography—hepatomegaly or decreased detail due to peritoneal effusion.
- Thoracic radiography—pleural effusion.
- Joint radiography—periarticular swelling of the soft tissues without bony involvement.
- Abdominal ultrasonography—diffusely hypoechoic liver with rounded edges; kidneys may appear hyperechoic with loss of corticomedullary distinction.

DIAGNOSTIC PROCEDURES
- Synovial fluid analysis—may reveal acute synovitis.
- Kidney and/or liver fine-needle aspiration or biopsy (pending coagulation testing, biopsy preferred)—amyloid deposition, confirmed by Congo red staining and polarized light.

PATHOLOGIC FINDINGS
Deposition of amyloid in multiple organs, associated primarily with vessels or within the parenchyma.

TREATMENT

APPROPRIATE HEALTH CARE
- Minor episodes of pain and fever—outpatient care.
- Inpatient care required for severe fever, anorexia, dehydration, lameness or nonspecific pain, vomiting and/or diarrhea.
- Intensive care may be required to treat organ failure or sequelae of thromboembolism.

FAMILIAL SHAR-PEI FEVER (CONTINUED)

NURSING CARE
• IV isotonic crystalloid fluids—for dehydration, anorexia, vomiting and/or diarrhea.
• Oxygen—to treat hypoxemia.
• Abdominocentesis/thoracocentesis—if effusion causes respiratory compromise or elevated intra-abdominal pressure.
• Blood transfusions—to treat anemia.
• Fresh frozen plasma—consider for coagulopathies, DIC.

DIET
• Protein and phosphorus restriction in accordance with IRIS renal staging.
• Dogs with hepatic encephalopathy should be fed protein-restricted diet.
• Omega-3 fatty acids may be beneficial for glomerular disease.

CLIENT EDUCATION
• There is no cure; therapy is palliative and lifelong.
• Early therapy may decrease further deposition of amyloid.
• Diagnostics should be performed to ensure there is no underlying or concurrent disorder.
• Affected dogs should not be bred; genetic testing available.

MEDICATIONS

DRUG(S) OF CHOICE
• Colchicine 0.03 mg/kg PO q24h; advised early in course of disease to delay amyloid deposition; unknown if beneficial once amyloid has been deposited.
• Corticosteroids—if concurrent immune-mediated disease is present.
• Clopidogrel (1–2 mg/kg PO q24h) if concerned about hypercoagulability.
• Angiotensin-converting enzyme (ACE) inhibitor (e.g., enalapril or benazepril 0.25–0.5 mg/kg PO q12–24h) or angiotensin receptor blocker (ARB; e.g., telmisartan 1 mg/kg PO q24h) for proteinuria (may cause transient worsening of azotemia).
• Anti-hypertensive therapy if indicated.
• Antibiotics—for concurrent infection or sepsis.
• NSAIDs/analgesics for fever and pain, unless corticosteroids have been given.
• Gastroprotectants—if gastric ulcer suspected.

CONTRAINDICATIONS
• NSAIDs contraindicated in patients with renal disease, GI upset, and in combination with corticosteroid therapy.
• ACE inhibitors/ARBs contraindicated in dehydrated or hypovolemic patients.

PRECAUTIONS
Colchicine can cause GI upset; chronic use can be associated with bone marrow suppression.

POSSIBLE INTERACTIONS
Concurrent use of colchicine and cyclosporine increases risk of colchicine toxicity.

FOLLOW-UP

PATIENT MONITORING
• Body temperature.
• Blood pressure measurement and fundic examination—monitor for hypertension.
• Urinalysis and UPC.
• Biochemistry panel—renal and hepatic parameters, including albumin.
• CBC—to assess anemia and inflammation.

PREVENTION/AVOIDANCE
Avoid puppies from lines that have a history of shar-pei fever.

POSSIBLE COMPLICATIONS
• Death—due to hepatic rupture or pulmonary thromboembolism (PTE).
• Neutrophilic vasculitis causing severe skin sloughing; streptococcal toxic shock syndrome causing localized necrotizing fasciitis and/or concurrent shock and multiorgan failure.

EXPECTED COURSE AND PROGNOSIS
• Waxing and waning, progressive disorder with a fair to poor prognosis, depending on timing of diagnosis.
• Inevitably fatal due to chronic kidney disease or hepatic failure.
• Time course may be weeks to more than 10 years.

MISCELLANEOUS

AGE-RELATED FACTORS
Most severe in cases diagnosed at an early age.

PREGNANCY/FERTILITY/BREEDING
Do not breed affected dogs.

SYNONYMS
• Swollen hock syndrome.
• Shar-pei autoinflammatory disorder.

SEE ALSO
• Hepatic Encephalopathy.
• Icterus.
• Nephrotic Syndrome.
• Proteinuria.

ABBREVIATIONS
• ACE = angiotensin-converting enzyme.
• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• ARB = angiotensin receptor blocker.
• DIC = disseminated intravascular coagulation.
• GI = gastrointestinal.
• HA = hyaluronic acid.
• HAS2 =hyaluronic acid synthase 2.
• Ig = immunoglobulin.
• MTBP = MDM2 binding protein.
• NSAID = nonsteroidal anti-inflammatory drug.
• PT = prothrombin time.
• PTE = pulmonary thromboembolism.
• PTT = partial thromboplastin time.
• SAA = serum amyloid A.
• UPC = urine protein : creatinine ratio.

FANCONI SYNDROME

BASICS

OVERVIEW
Defective proximal renal tubular reabsorption of glucose, electrolytes, and amino acids.

SIGNALMENT

Species
Dogs and rarely cats.

Breed Predilections
Sporadically reported in several breeds, idiopathic Fanconi syndrome primarily affects the basenji breed (approximately 75% of cases). In America, 10–30% of basenjis are affected. It is presumed to be inherited in this breed, but the mode of inheritance is unknown.

Mean Age and Range
Age at diagnosis: 10 weeks–11 years. Affected basenjis usually are >2 years of age; most develop clinical signs from 4 to 7 years.

Predominant Sex
None

SIGNS
- Depends on the severity of specific solute losses and residual renal function.
- Loss of amino acids and glucose—usually not associated with clinical signs other than polyuria and polydipsia.
- Weight loss.
- Uremia, lethargy, decreased appetite.
- Abnormal growth (rickets) may occur in young animals.

CAUSES & RISK FACTORS
- Inherited in basenjis and possibly Irish wolfhounds.
- Acquired Fanconi syndrome has been reported in dogs given gentamicin, streptozotocin, maleic acid, amoxicillin, chlorambucil (cats), and chicken or duck jerky treats, many of which have originated from China; also reported secondary to primary hypoparathyroidism, copper associated hepatopathy, and lead toxicity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Primary renal glucosuria causes glucosuria despite normoglycemia; documentation of aminoaciduria, mild proteinuria, or a hyperchloremic normal anion gap metabolic acidosis suggests Fanconi syndrome.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC usually normal.
- Hypokalemia.
- Hyperchloremic metabolic acidosis.
- Azotemia if renal failure develops.
- Hypophosphatemia and hypocalcemia may occur in affected young, growing animals.
- Urine specific gravity usually low (1.005–1.018); mild proteinuria common; ketonuria may be present.
- Granular or lipid casts and bacteria were seen in 27–40% of dogs.

OTHER LABORATORY TESTS
Hyperchloremic normal anion gap metabolic acidosis due to bicarbonaturia with urine pH <5.5. Urine pH >6.0 in distal renal tubular acidosis, which is key diagnostic difference to proximal renal tubular acidosis (Fanconi syndrome).

IMAGING
Radiography—young growing dogs may have rickets and angular limb deformities; adults may have decreased bone density.

DIAGNOSTIC PROCEDURES
Urinary clearance studies to document excessive excretion of glucose, amino acids, and electrolytes needed for confirmation. Do not test animals <8 weeks of age because false-positive results may occur. Urine can be evaluated at PennGen for aminoaciduria. Fractional reabsorption of amino acids in affected dogs ranges from 50% to 96% (normal 97–100%).

PATHOLOGIC FINDINGS
Renal papillary necrosis may occur in late disease.

TREATMENT
- Discontinue any drug or treats that may cause Fanconi syndrome or treat for specific intoxication.
- No treatment reverses transport defects in dogs with inherited or idiopathic disease.
- Because magnitude of transport defects varies among affected animals, treatment must be individualized.
- Treat for metabolic acidosis if blood bicarbonate concentration <12 mEq/L. Large doses of alkalinizing agents may be required because decreased proximal tubular resorptive capacity results in marked bicarbonaturia. Goal of alkali therapy to maintain blood bicarbonate concentration 12–18 mEq/L.
- Young, growing dogs may require vitamin D, calcium, and phosphorus supplementation.

MEDICATIONS

DRUG(S) OF CHOICE
Use potassium citrate or sodium bicarbonate (start with low dosage) as dictated by blood gas and electrolyte data.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Avoid drugs that are nephrotoxic or have potential to cause Fanconi syndrome (see Causes & Risk Factors).
- Avoid potassium chloride if hyperchloremic.

FOLLOW-UP
- Monitor serum biochemistry at 14-day intervals to assess treatment response; monitor serum potassium concentration regularly as bicarbonate therapy may aggravate renal potassium loss; once stable, monitor biochemistry at 3-month intervals.
- Clinical course varies; some dogs remain stable for years, others develop rapidly progressive renal failure over a few months; cause of death usually acute kidney injury with severe metabolic acidosis.
- Some dogs (18% in one study) developed seizures or other neurologic signs several years after diagnosis.

MISCELLANEOUS

SEE ALSO
- Acute Kidney Injury.
- Chronic Kidney Disease.

FEAR AND AGGRESSION IN VETERINARY VISITS—CATS

BASICS

DEFINITION
• Fear—involuntary, negative emotional state caused by anticipation/awareness of danger. • Aggression—warning/intent to cause harm/increase distance to perceived threat.

PATHOPHYSIOLOGY
See Causes and Risk Factors.

SYSTEMS AFFECTED
• Behavioral—neurochemical input between limbic system and forebrain. • Sympathetic nervous system arousal.

GENETICS
Fearful/fractious temperaments are heritable.

INCIDENCE/PREVALENCE
Up to 85% of cats stressed at physical exam.

GEOGRAPHIC DISTRIBUTION
None

SIGNALMENT
Species
Cat

Breed Predilections
Any

Mean Age and Range
Any

Predominant Sex
Any

SIGNS
Fearful body language—dilated pupils, ears back, crouching, hissing, growling, tail thrashing, swatting.

CAUSES
• Previous frightening/painful experience.
• Fearful temperament.

RISK FACTORS
History of fearful/fractious behavior to handling, unfamiliar people, travel, or at previous visits.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Pain. • Irritability from illness. • Forebrain lesion. • Cognitive dysfunction syndrome.

CBC/BIOCHEMISTRY/URINALYSIS
Stress leukogram; hyperglycemia; glucosuria.

IMAGING
If indicated to rule out medical conditions, e.g., pain.

DIAGNOSTIC PROCEDURES
If indicated to rule out medical conditions.

PATHOLOGIC FINDINGS
Stress related increase in blood pressure, heart rate, temperature, respiratory rate.

TREATMENT

APPROPRIATE HEALTH CARE
Prior to Handling
Assess environment, patient, and veterinary personnel. What cats see, smell, feel, taste, and hear affects emotional state and can lower aggression threshold.

Assess Environment: Make Cat Comfortable
• Reduce carrier/transport stress. • Eliminate/avoid triggers. • Modify environmental stimuli—light, noises, sound level (stress at ≥80 DB), movement, touch, temperature (30–36 °C).
• Comfortable exam site (no slippery, shiny, cold surfaces). • Allow cats to hide, feel secure.

Assess Animal: Anxiety/Fear/Arousal Fuel Aggression
• Body language interpretation is critical.
• Track willingness to approach, interact with environment and people. • Intervene early.
• Change in location (examination vs. treatment area), interaction, procedure, personnel can affect patient.

Assess Yourself: Avoid Perceived Threats, Track Body Postures and Behavior
• Avoid direct eye contact or putting face near fearful cat. • Avoid petting top of head, grabbing body, or reaching into carrier.
• Remove carrier tops—do not pull or dump cat. • Allow time to sniff your hand; gently scratch under chin and side of head if postures indicate safety; avoid petting beyond shoulder—often overarousing. • Start exam at head or middle and move back; save socially invasive (head, feet, rear, belly) or painful areas for last.
• Talk softly; work quietly; avoid sudden movements. • Often narrow window of opportunity before fear/arousal escalates. • Not approaching indicates use of social distance to cope; anticipate approach may lead to aggressive response—make a plan. • Fear or frustration by handler increases cat fear. • Use language that is scientifically accurate and promotes patient empathy—fearful, painful, confused; avoid labels that result in poor handling and offend clients—evil, spiteful, mean, bad, stupid.
• Strictly avoid punishment (verbal or physical).

Make Handling Plan
• Handling plans unique to individual cats, environment, and procedures and require adjustments based on patient response. • Make plan for safety, decreased handling time, patient welfare, client satisfaction. • Maintain record of likes and dislikes to plan future visits.

Patient Handling Plan Guidelines
• Determine cat's preferred food/treat for distraction and counter-conditioning (CC).
• Select restraint for individual cat/procedures.
• Select handling tools that increase safety and decrease patient fear/arousal. • Critically consider procedures—must it be done today? Consider rescheduling to add oral sedative/anxiolytics and/or divide treatment into shorter visits with fewer procedures. • Place required procedures in order of most important to least in case not all are tolerated. • Place procedures in order of least to most aversive so early procedures do not inhibit completion of later ones. • Consider pain, invasiveness, number of procedures, how patient is coping. • Use chemical restraint immediately, prior to any necessary procedures in which fear may escalate above mild. • Have chemical restraint prepared for at-risk patients—use before arousal to promote efficacy, safety, reduce future fear.

CC
• Learning where cat's negative emotional response (fear) to stimulus (veterinary setting) is changed to positive one (pleasure). • Food is easiest/most powerful way to create this shift.
• Palatability must be high (e.g., meat baby food, squeeze cheese, canned food) to maximize cat's interest/increase positive emotional response.
• Offer food while cat relaxed/feels safe, then just before/during/after any (aversive) procedure.
• Stressed cats may need food for duration of handling to prevent escalation of fear/arousal.
• Barometer—stressed cats often reject food.

Guidelines for Restraint
• Create safe handling plan for each procedure; use least restraint required. • Avoid over-restraint—causes more stress than procedure itself. • If greater restraint needed, use balanced pressure with global support. • Prevent flailing—control head/rear. • Avoid scruffing—use only for cats comfortable with technique.
• Avoid stretching—use lateral recumbency only if procedure requires. • Avoid multiple bouts of restraint; adjust position by sliding hands along body instead of release/regrab. • Struggling 2 seconds—stop, reposition, try again; wait for cat to relax to resume. • Second attempt—if not relaxed and/or starts to get fractious, stop; is procedure essential? • If essential—use chemical restraint. • If nonessential—send home with handling plan and medication if indicated for return visit. • Owner presence—can provide secure base and reduce stress.

Handling Tools
Expedite procedures by reducing patient fear, minimizing manual restraint, and increasing safety.

Pheromones: F3 Cheek Gland (Feliway® Classic)
• Diffusers—reception, exam rooms, wards.
• Spray/wipes—travel, examination, cages.

Muzzles
Toweling preferred.

Towels
• Towel/thick bedding for immobilization—protects cat from flailing, handler from bites/scratches. • Provides head/body control, avoids visual stimuli, firm global pressure—can modify to gain head/jugular or front/back leg access.
• Allows auscultation, abdominal palpation.
• Safe restraint of fleeing/fearful cats, removal from carrier/cage, chemical restraint injection.

(CONTINUED) # FEAR AND AGGRESSION IN VETERINARY VISITS—CATS

Music
Classical music and cat-specific music may mask stressful external sounds, relax patients, have potential calming effects on clients and staff.

Cat Carrier
• Positively condition/train cats to carrier prior to travel. • Select carrier that allows cat to easily exit or remain in lower portion for exam (removable top). • Provides familiar area, prevents fleeing, promotes hiding. • Soft-sided/mesh panels—can press mesh against cat's body for safe IM injection. • Place carrier in cage of hospitalized cat—offers familiarity, encourages faster return to eating.

Restraint Nets (EZ Nabber)
• Provides safe option for catch/restraint for prompt administration of IM injections. • Very effective for cats housed in wall unit cages. • Cover with towel once cat inside—reduces visual stimulation, protects handler.

NURSING CARE
N/A

ACTIVITY
N/A

DIET
N/A

CLIENT EDUCATION
• Preventive counseling (start at first visit)—positive carrier training, travel, handling, feline communication, reward training, avoid use of punishment. • Provide kitten classes in veterinary clinic. See Internet Resources.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE

Chemical Restraint
• Allows safe handling, effective completion of procedures. • Blocks/prevents fear, discomfort, pain, further distress, and fear escalation. • Minimal or no physical restraint. • Injectable sedation (IM) most effective for safe handling of fractious/highly fearful patients. • Base protocol on age, temperament, health. • Pre-travel oral anxiolytics/sedatives reduce fear, facilitate gentle handling, promote safety for injection, reduce injectable doses.

Oral Sedative/Anxiolytics
• Administer 60–90 min prior to travel for mild/moderate fear, or to facilitate administering chemical restraint. • May give first dose 12h in advance. • Also may be required for inpatients. • Gabapentin—10–20 mg/kg PO (50–150 mg/cat). • Trazodone—25–50 mg/cat PO. • Lorazepam—0.05–0.25 mg/kg PO (0.125–0.25 mg/cat). • Buprenorphine—0.01–0.03 mg/kg oral transmucosal (OTM). • For additional sedation can add acepromazine—0.5–2.2 mg/kg PO.

Injectable Sedation/Chemical Restraint
• *Young/healthy*—dexmedetomidine 10–20 µg/kg *or* acepromazine 0.1 mg/kg + opioid; for additional sedation can add ketamine 3–5 mg/kg IM. • *Alternative*—tiletamine/zolazepam 5–10 mg/kg IM. • *Geriatric/ill*—acepromazine 0.01–0.05 mg/kg *or* dexmedetomidine 5–10 µg/kg + opioid: for greater sedation add ketamine 3–5 mg/kg IM; hydromorphone 0.05 mg/kg + midazolam 0.1–0.2 mg/kg ± ketamine 3–5 mg/kg ± acepromazine 0.01–0.05 mg/kg; alfaxalone 1–2 mg/kg + midazolam 0.2 mg/kg ± opioid ± acepromazine 0.01–0.05 mg/kg. • Can reverse dexmedetomidine—½ volume atipamezole to volume of dexmedetomidine administered IM. • Dexmedetomidine/ketamine protocols—to avoid dysphoria wait 45–60 min to reverse. • Opioid choices (full Mu agonist superior for pain control)—butorphanol 0.2 mg/kg; buprenorphine 0.01–0.03 mg/kg; morphine 0.2 mg/kg; hydromorphone 0.05–0.1 mg/kg; oxymorphone 0.1 mg/kg.

CONTRAINDICATIONS
Reports of acute hepatic necrosis with oral diazepam.

PRECAUTIONS
• Have client perform drug trial at home to determine response/ideal dose. • Agitation, gastrointestinal upset, sedation, appetite changes possible with above oral medications. • Benzodiazepines—disinhibition of aggression uncommon but possible. • Gabapentin—caution with chronic renal disease.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
Natural products including pheromones and supplements containing l-theanine or alpha-casozepine.

FOLLOW-UP

PATIENT MONITORING
• Evaluate physiologic/behavioral parameters. • Evaluate and record response to handling, location, personnel, products, drugs.

PREVENTION/AVOIDANCE
• Prevention—more effective, safer, less expense, improves healthcare compliance, avoids fear sensitization. • Low Stress handling and CC during all kitten and adult visits recommended.

POSSIBLE COMPLICATIONS
Fearful and/or aggressive behavior negatively impacts frequency and level of veterinary care.

EXPECTED COURSE AND PROGNOSIS
Effective implementation of Fear Free, Low Stress, and Cat Friendly visits reduces fear, anxiety, and stress and improves frequency and quality of veterinary care.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Fearful/fractious cats in veterinary setting often have comorbid behavioral problems at home, such as aggression to owners or strangers, undesirable elimination, and anxiety disorders.

AGE-RELATED FACTORS
• Socialization period (2–7 weeks)—time where positive early exposure minimizes fear. • Regular, gentle, brief exposure to handling paired with positive experience (food) leads to less fear/improved future handling.

ZOONOTIC POTENTIAL
Bite wounds and associated infections.

PREGNANCY/FERTILITY/BREEDING
Fearful/aggressive temperaments are heritable.

SYNONYMS
• Fear aggression. • Defensive aggression. • Phobic behavior.

SEE ALSO
• Car Ride Anxiety—Dogs and Cats. • Fears, Phobias, and Anxieties—Cats. • Kitten Socialization and Kitten Classes.

ABBREVIATIONS
• CC = counter-conditioning. • OTM = oral transmucosal.

F

FEAR AND AGGRESSION IN VETERINARY VISITS—DOGS

BASICS

DEFINITION
• Fear—involuntary, negative emotional state caused by anticipation/awareness of danger. • Aggression—warning/intent to cause harm/increase distance in response to perceived threat.

PATHOPHYSIOLOGY
See Causes and Risk Factors.

SYSTEMS AFFECTED
• Behavioral—neurochemical input between limbic system and forebrain. • Activation of hypothalamic pituitary axis (HPA) and sympathetic nervous system.

GENETICS
Fearful temperament may be heritable.

INCIDENCE/PREVALENCE
Over 75% fearful when examined.

SIGNALMENT
Species
Dog

Breed Predilections
Any

Mean Age and Range
Any

Predominant Sex
Any

SIGNS
Fearful body language—ears back, gaze avoidance, crouching, tail tucked, yawning, panting, lip licking, scanning.

CAUSES
• Previous frightening/painful experiences. • Fearful temperament (genetics, peri/postnatal experience, socialization).

RISK FACTORS
History of fearful behavior to handling, unfamiliar people, noises, environments, or previous visits.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Pain. • Irritability from illness. • Forebrain lesion. • Cognitive dysfunction syndrome.

CBC/BIOCHEMISTRY/URINALYSIS
Stress leukogram; glucosuria.

OTHER LABORATORY TESTS
As indicated to rule out medical conditions.

DIAGNOSTIC PROCEDURES
As indicated to rule out medical conditions.

PATHOLOGIC FINDINGS
Stress-induced increase in blood pressure, heart rate, temperature, panting.

TREATMENT

APPROPRIATE HEALTH CARE
Prior to Handling
Assess environment, dog, and veterinary personnel. What dogs see, smell, feel, taste, and hear affects emotional state and lowers aggression threshold.

Assess Environment: Make Dog Comfortable
• Eliminate known triggers. • Modify environmental stimuli including light, noises, sound level (stress at ≥80 DB), movement, touch, temperature (15–30 °C). • Owner presence—can provide secure base, reduce stress. • Comfortable exam site (no slippery, shiny, cold surfaces). • Allow fearful dogs to hide, feel secure.

Assess Dog
• Anxiety/fear/arousal leading to aggression. • Body language interpretation critical. • Track willingness to approach, interact with environment/people. • Intervene early. • Change in location (examination vs. treatment area), interaction, procedure, personnel can affect patients.

Assess Yourself: Avoid Perceived Threats, Track Body Postures and Behavior
• Avoid direct eye contact, bending over, putting face near fearful dog, loud talking, sudden movements. • Bend at knee, turn to side, squat (when safe). • Avoid reaching out, petting top of head, grabbing collar. • Encourage patients to approach or have handler they trust move them to you. ○ Hand at your side, pat your leg gently, soft verbal encouragement. ○ Palm open with valued treats. ○ Allow dog to sniff/investigate. ○ Gently pet under chin/neck. ○ Test acceptance—stop petting, does dog reengage. ○ If no: stop, make a plan. ○ If yes: pet again, slowly move to desired exam position. ○ Start exam in middle, slowly work to rear, back to center, to head. ○ Monitor/be prepared for any fear- or pain-evoking handling. • Not approaching indicates use of social distance to cope; approach may lead to aggressive response—make a plan. • Avoid front-facing interactions or cover dog's head; work at side, just behind point of shoulder, facing same direction as dog. • Often narrow window of opportunity before fear/arousal escalates. • Fear or frustration by handler or veterinary personnel increases pet fear; use scientifically accurate language that promotes patient empathy—fearful, painful, confused; avoid labels that result in poor handling/offend clients—mean, bad, spiteful, dominant. • Strictly avoid punishment (verbal or physical).

Make Handling Plan
• Handling plans unique to individual dogs, environment, and procedure and require adjustments based on dog's response. • Make plan for safety, decreased handling time, patient welfare, and client satisfaction. • Maintain record of likes and dislikes to plan further visits.

Patient Handling Plan Guidelines
• Determine most motivating food/treats for distraction and counter-conditioning (CC). • Select restraint for individual dog/procedures. • Select handling tools that increase safety and decrease patient fear/arousal. • Critically consider procedures—must it be done today? Consider rescheduling to add oral sedative/anxiolytics and/or divide treatment into shorter visits with fewer procedures. • Place required procedures in order of most important to least in case not all are tolerated. • Place procedures in order of least to most aversive, so early procedures do not inhibit completion of later ones. • Consider pain, invasiveness, number of procedures, how dog is coping. • Use chemical restraint immediately for any necessary procedures in which fear escalates beyond mild; use before arousal to promote efficacy, safety, escalation, learning.

CC
• Learning where dog's negative emotional response (fear) to stimulus (veterinary setting) is changed to positive one (pleasure). • Food easiest/most powerful way to create shift. • Palatability must be high (meat baby food, squeeze cheese, canned food) to maximize dog's interest/increase positive emotional response. • Offer food while dog relaxed/feels safe, then just before/during/after any (aversive) procedure. • Stressed dogs may need food for duration of handling to distract and prevent escalation of fear/arousal. • Barometer—stressed dogs often reject food.

Restraint
• Create safe handling plan for each procedure. • Use least restraint required—increased restraint increases stress. • If greater restraint needed, use gentle, balanced pressure with global support. • Prevent flailing by controlling head/rear. • Avoid lateral recumbency—only if procedure requires. • Avoid multiple bouts of restraint—adjust positioning by sliding hands along body. • Struggling 3 seconds—stop, reposition, try again; wait for dog to relax to begin. • Second attempt—if fear increases or starts to get fractious, stop; is procedure essential? • Essential—use chemical restraint. • Nonessential:—send home with handling plan and pre-visit meds if indicated for return visit.

Handling Tools
Expedite procedures by reducing dog fear, minimizing manual restraint, and increasing safety.

Music
Music and sources of white noise may mask stressful external sounds. Classical music may relax dogs and have calming effects on clients and staff.

Dog-Appeasing Pheromone (Adaptil®)
• Diffusers—reception, exam rooms, wards. • Spray/wipes—travel, examination, cages.

(CONTINUED) # FEAR AND AGGRESSION IN VETERINARY VISITS—DOGS

Muzzles
• For safety, assessment/evaluation, avoid human fear response, injectable sedation. • Home desensitization (DS)/CC—enters wearing comfortably. • Basket muzzle preferred—allows panting: safer for longer procedures/kenneling; allows CC: inserted food or smeared along inside. • Nylon sleeve—short procedures or facilitate essential injection.

Elizabethan Collar
Muzzle alternative for avoiding/reducing visual stimuli.

Towels
• Towels/thick bedding can help immobilize—especially small dogs: head/body control, reduced visual stimuli, global pressure. • Roll towels (cervical collar)—head control.

Eye Covers (e.g., ThunderCap®)
Reduce visual stimuli/triggers for fear and anxiety during travel, exam, injections.

Compression Garments (e.g., ThunderShirt®)
Swaddles—may relax patients with balanced body pressure.

NURSING CARE
N/A

ACTIVITY
N/A

DIET
N/A

CLIENT EDUCATION
Preventive counseling at first puppy visit ± puppy classes in clinic to review positive travel, handling, communication, reward training, and avoiding punishment. See Internet Resources.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE

Chemical Restraint
• Allows safe, effective, minimal handling and successful completion of procedures. • Blocks or prevents distress, discomfort, pain, escalation, and fear sensitization. • Injectable sedation (IM)—most effective for safe handling fractious/fearful dogs. • Base protocol on age, temperament, health. • Pre-travel oral sedative/anxiolytics reduce fear, facilitate gentle handling, safety for injection, reduce injectable doses.

Oral Sedative/Anxiolytics
• Administer 1.5–2 hours pre-travel for mild/moderate fear or to facilitate restraint injection; may give first dose 12 hours in advance; repeat dosing as needed if patient is hospitalized. • Trazodone—4.0–10 mg/kg (up to 18 mg/kg); maximum 300 mg per dose. • Clonidine—0.01–0.05 mg/kg. • Dexmedetomidine oromucosal gel—125 µg/m^2. • Gabapentin—20–50 mg/kg. • Lorazepam—0.05–0.5 mg/kg. • Diazepam—0.5–2.2 mg/kg. • Alprazolam—0.01–0.1 mg/kg. • For additional sedation can add acepromazine—0.55–2.2 mg/kg. • Can combine trazodone, clonidine, gabapentin, benzodiazepines. • Avoid acepromazine as sole agent—ineffective anxiolysis

Injectable Restraint
• *Young/healthy*—dexmedetomidine 10–20 µg/kg + opioid: for additional sedation can add ketamine 3–5 mg/kg IM. • *Alternative*—tiletamine/zolazepam 5–10 mg/kg IM (not practical for dogs >20 kg due to volume). • *Geriatric/ill*—acepromazine 0.01–0.05 mg/kg *or* dexmedetomidine 5–10 µg/kg + opioid: for additional sedation add ketamine 2–5 mg/kg IM; alfaxalone 1–2 mg/kg (not practical for dogs >10 kg due to volume) + midazolam 0.2 mg/kg ± opioid ± acepromazine 0.01–0.05 mg/kg. • Can reverse dexmedetomidine—equivolume atipamezole to volume of dexmedetomidine IM. • Dexmedetomidine/ketamine protocols—to avoid dysphoria wait 45–60 min to reverse; opioid choices (full Mu agonist superior for pain control): butorphanol 0.2–0.4 mg/kg; morphine 0.2–0.4 mg/kg; hydromorphone 0.05–0.2 mg/kg; methadone 0.3–0.5 mg/kg.

Oral Transmucosal (OTM)
• *Young/healthy*—dexmedetomidine 10–40 µg/kg ± opioid (e.g., morphine 10 mg/kg or butorphanol 0.2 mg/kg) OTM; can reverse dexmedetomidine with atipamezole (½ volume of dexmedetomidine). • DS/CC to syringe in buccal pouch. • Up to 1h to effect. • Mucosal contact time improves absorption—mix with syrup.

CONTRAINDICATIONS
Avoid clonidine with cardiovascular output issues.

PRECAUTIONS
• Have client perform oral medication trial at home to determine dose/response. • Agitation, gastrointestinal upset, sedation, appetite changes possible. • Benzodiazepines—disinhibition of aggression possible. • Gabapentin—caution with chronic renal disease.

POSSIBLE INTERACTIONS
Avoid combining oral acepromazine with clonidine—potential blood pressure fluctuation.

ALTERNATIVE DRUG(S)
Natural products including pheromones, supplements containing l-theanine or alpha-casozepine and calming probiotic.

FOLLOW-UP

PATIENT MONITORING
• Evaluate and monitor physiologic/behavioral parameters. • Maintain record of response to handling, location, personnel, products, and drugs.

PREVENTION/AVOIDANCE
• Prevention—more effective, safer, less expense, improved healthcare compliance, and avoids fear sensitization. • Also see Client Education.

POSSIBLE COMPLICATIONS
Dogs with fearful and/or aggressive behavior may not receive adequate veterinary care including wellness care, diagnostics, and treatment.

EXPECTED COURSE AND PROGNOSIS
Effective implementation of Fear Free, Low Stress care prevents and reduces fear, anxiety, and stress and improves frequency and quality of veterinary care.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Dogs with fearful/fractious behavior in veterinary setting often have comorbid behavioral problems, including aggression to owners or strangers, leash reactivity, resource guarding, anxiety disorders.

AGE-RELATED FACTORS
• Socialization period (3–12 weeks)—sensitive period where positive exposure minimizes fear; gentle, brief handling paired with positive experience (food) leads to less fear and improved handling. • Fear period (8–10 weeks of age and between 4 and 11 months)—susceptible to single-event learning, highly sensitive to negative experiences. • Social maturity (1–3 years)—fearful puppies/adolescents may begin to show fear and aggression at this time; prompt recognition and intervention essential at first signs of fear to establish handling plan.

ZOONOTIC POTENTIAL
Bite wounds and associated infections.

PREGNANCY/FERTILITY/BREEDING
Fearful/aggressive temperaments heritable.

SYNONYMS
• Fear aggression. • Defensive aggression. • Phobic behavior.

SEE ALSO
• Car Ride Anxiety—Dogs and Cats. • Fears, Phobias, and Anxieties—Dogs. • Puppy Socialization and Puppy Classes.

ABBREVIATIONS
• CC = counter-conditioning. • DS = desensitization. • HPA = hypothalamic pituitary axis. • OTM = oral transmucosal.

FEARS, PHOBIAS, AND ANXIETIES—CATS

BASICS

DEFINITION
• Fear is the feeling of apprehension resulting from the nearness of some situation or object presenting an external threat. The response of the autonomic nervous system prepares the body for "freeze, fight, or flight." As such, it is a normal behavior, essential for adaptation and survival.
• Anxiety is the anticipation of dangers from unknown or imagined origins that results in physiologic reactions associated with fear. Anxiety may occur in the aftermath of a fear-producing event or as a result of unrelated environmental changes that are unpredictable.
• A phobia is a persistent and excessive fear of a specific stimulus, such as a thunderstorm or separation from an attachment figure.

PATHOPHYSIOLOGY
• Stress responses become problematic when the individual is not able to control the stressful situation by their actions or escape from it through appropriate behavioral responses.
• Chronic anxiety or fear can lead to secondary behavior problems, such as overgrooming, spraying, or intercat aggression, or predispose the cat to health problems owing to a compromised immune system.

SYSTEMS AFFECTED
• Behavioral—hypervigilance, avoidance behaviors, possible aggression.
• Cardiovascular—increased heart rate and blood flow to internal organs during fear-evoking incidents.
• Endocrine/metabolic—glucose release into bloodstream, release of glucocorticoids.
• Gastrointestinal (GI)—decreased appetite.
• Hemic/lymphatic/immune—chronic stress effects on immune function.
• Musculoskeletal—weight loss in response to chronic stress effects on appetite, decreased food intake due to hiding behavior.
• Neuromuscular—decrease in activity due to avoidance and hiding; fearful/anxious reaction may also include pacing, trembling, repetitive activity.
• Ophthalmic—dilated pupils in response to autonomic nervous system stimulation.
• Respiratory—increased respiratory rate when anxious or frightened.
• Skin/exocrine—overgrooming in response to stressors.

GENETICS
• Genetic component possible.
• Breed/coat color and paternal personality have been linked to individual personality traits in cats.

SIGNALMENT
Any age, sex, or breed.

SIGNS
General Comments
• Signs of fear or anxiety can vary between individuals and with different stimuli that may be specific (a particular individual, sound, etc.) or more generalized.
• In mild cases of anxiety or fear the cat may become tense and more reactive to environmental stimuli. Some individuals may retreat to perceived safe hiding places or show little movement.
• Cats in panic can become very aggressive or destructive in an attempt to retreat from the fearful stimulus.

Historical Findings
• Clear description of the cat's body language, behavior, and events or situations that consistently trigger anxiety or fear is helpful in setting up behavioral modification and environmental management program.
• Body postures associated with fearful behavior include ears flattened to back or side of head, crouched body posture when resting or moving, lowered head, tail tucked alongside body or held low, piloerection, dilated pupils, shaking, panting, drooling, "Halloween cat" silhouette.
• If fear is intense, cat may lose bladder and bowel control and express its anal sacs.
• Vocalizations are usually minimal, unless cat is showing defensive behavior in response to perceived threat.
• Cat may pace, vocalize, and solicit attention from owner.
• Urine spraying and destructive scratching may be seen in anxious cats.

Physical Examination Findings
Usually unremarkable unless cat has injured itself trying to escape or while seeking shelter.

CAUSES & RISK FACTORS
Fearful behavior in cats can be related to genetic influences on temperament; lack of positive early experience and socialization, observational learning from fearful mother, other adult cats; learning from negative experiences; social stress, population pressure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Thorough medical history and physical examination will help differentiate fearful behavior from withdrawal due to illness.

CBC/BIOCHEMISTRY/URINALYSIS
As indicated to rule out medical conditions and as baseline prior to medication use and as premedication screen.

OTHER LABORATORY TESTS
As indicated, including T4 in middle age and older.

IMAGING
As indicated.

TREATMENT

ACTIVITY
Normal social interactions and play should be encouraged, but contact should not be forced.

DIET
Placement of food, water, and litter box may need to be altered if anxious or fearful behavior is limiting access.

CLIENT EDUCATION
General Comments
• Educate owners to read and understand cat communication language for early recognition of signs.
• Discuss behavioral expectations. Owner expectations in regard to social interactions with humans or other cats may be contributing to the problem and could affect prognosis.
• Treatment plan involving case-tailored behavioral modification, environmental adjustments, and support material will help owner better understand situation and implement treatment.

Behavioral Therapy
• Identify and avoid exposure to fear-evoking stimuli and situations. Provide ways for cat to manage situation by creating "safe places" for cat to go to avoid the stimulus.
• If cat must be handled while fearful, caution and gentle physical restraint aids (cat muzzles, head covers, towel wraps, etc.) should be used to prevent injury and decrease stress.
• Desensitization and counter-conditioning to help decrease reactivity to fear-producing stimulus. Systematic desensitization is program of slowly increasing exposure to fearful stimulus or situation. Counter-conditioning consists of enhancing internal and external environment with food rewards or other pleasurable stimuli such as playing with toys.
• Address secondary problems such as strained social interactions subsequent to defensive aggression directed toward humans or other cats, or elimination problems that may be result of fears or anxieties.

MEDICATIONS

DRUG(S) OF CHOICE
• Medication can be helpful adjunct to behavioral modification, if animal's fearful or

anxious behavior is so intense that it interferes with quality of life.
• No drug is approved by FDA for use in cats for fearful behavior; therefore, clients must be advised that information concerning efficacy, contraindications, and side effects is limited.
• If there are questions or concerns about a specific patient or medication, consultation with a veterinary behaviorist may be helpful.
• Selective serotonin reuptake inhibitors (SSRIs)—fluoxetine or paroxetine 0.5–1 mg/kg PO q24h. Side effects—decreased appetite and irritability; paroxetine has anticholinergic effects.
• Tricyclic antidepressants (TCAs)—clomipramine 0.5 mg/kg PO q24h (2.5–5 mg/cat). Side effects—sedation, anticholinergic effects, possible cardiac conduction disturbances in predisposed animals.
• Buspirone—0.5–1.0 mg/kg q8–24h. Side effects—GI upset, mild sedation.
• Benzodiazepines—oxazepam 0.2–0.5 mg/kg q12–24h; alprazolam 0.125–0.25 mg/cat q12h or as needed prior to event; lorazepam 0.025–0.05 mg/kg (or 0.125–0.5 mg/cat) q12h or as needed prior to event. Side effects—sedation, increased appetite, agitation.
• Buspirone and benzodiazepines might reduce fear and build confidence in fearful cat that does not retaliate or fight back.

CONTRAINDICATIONS
• Cats with renal or hepatic disease.
• Caution with TCAs and SSRIs in diabetics.
• TCAs in patients with cardiac abnormalities.

PRECAUTIONS
• Laboratory screening tests suggested before placing animal on psychotropic medication for health assessment and baseline for comparison.
• Compounding medications in more palatable form can ease administration and improve compliance.
• Assess all medications and natural supplements being administered for potential contraindications.

POSSIBLE INTERACTIONS
• TCAs and SSRIs should not be used together.
• Mirtazapine should be used cautiously in combination with TCA or SSRI.
• Practitioner should verify safety when combining psychoactive drugs with other medications.

ALTERNATIVE DRUG(S)
• Natural products that might aid in reducing anxiety alone or in conjunction with drugs—S-adenosylmethionine (SAMe) 100 mg PO q24h; alpha-casozepine 75 mg (15 mg/kg or greater) PO q24h; l-theanine 25 mg PO daily.
• Cat-appeasing pheromone (Feliway® Multicat or Friends); F3 cheek gland pheromone (Feliway).
• Calming and stress diets containing alpha-casozepine and l-tryptophan.

FOLLOW-UP

PATIENT MONITORING
Frequent follow-up either in person or by telephone is necessary, especially during first few months of treatment, to motivate client and monitor effectiveness of any adjunct drug treatment.

PREVENTION/AVOIDANCE
• Early socialization to people, places, and things up to 7 weeks of age, and ongoing positive exposure during first year, may help prevent some later problems with fearful behavior.
• Calm interactions and positive associations with fear-producing stimuli may help keep fear-based reactions to minimum.

POSSIBLE COMPLICATIONS
Secondary behavior problems may arise or persist after fearful or anxious behavior has diminished and will need specific treatment.

EXPECTED COURSE AND PROGNOSIS
• Realistic "end point" depends on animal's background (socialization history, genetic and individual differences in personality), home situation, and other confounding factors such as frequency of natural exposure to fear-producing stimuli.
• Medication may improve but not totally ameliorate signs.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Stereotypic or compulsive disorders.
• Urine marking, inappropriate elimination.
• Defensive aggression directed toward humans, other animals; may also make cat target for aggression from other cats.

ZOONOTIC POTENTIAL
N/A except for bite and scratch wounds.

PREGNANCY/FERTILITY/BREEDING
Drug use in pregnant animals should be avoided.

SEE ALSO
• Aggression, Overview—Cats.
• Compulsive Disorders—Cats.
• Fear and Aggression in Veterinary Visits—Cats.
• Housesoiling—Cats.
• Marking, Roaming, and Mounting Behavior—Cats.

ABBREVIATIONS
• GI = gastrointestinal.
• SAMe = S-adenosylmethionine.
• SSRI = selective serotonin reuptake inhibitor.
• TCA = tricyclic antidepressant.

FEARS, PHOBIAS, AND ANXIETIES—DOGS

BASICS

DEFINITION

• *Fear*—an emotion consisting of a physiologic stress response (PSR) and a psychologic response to the presence of a stimulus perceived as dangerous (e.g., person, animal, situation, sound, object, scent) inducing an adaptive, avoidance reaction. • *Phobia*—marked, irrational, and excessive fear of a stimulus (e.g., animal, situation, person, sound, object, scent) consisting of a PSR and psychologic response resulting in a maladaptive reaction. • *Anxiety*—reaction consisting of a PSR and psychologic response triggered by anticipation of future or memory of past dangers.

PATHOPHYSIOLOGY

• Information about a fear-inducing stimulus is perceived by sensory organs and transmitted to the central nucleus of the amygdala; the central nucleus sends output to the central grey matter (musculoskeletal response), lateral hypothalamus (autonomic nervous system [ANS] response), and stria terminalis (hormonal response) causing a PSR. • The PSR is graded based on the animal's perceived level of control, coping strategy, and level of difficulty. • Any neutral stimulus in the environment can be paired with the PSR through classical conditioning triggering a PSR to the conditioned stimulus. • Hormones and neurotransmitters released during the PSR enhance learning, memory consolidation, and retrieval. • There is evidence that while frightening memories can be significantly reduced, they cannot be "erased."

SYSTEMS AFFECTED

• Psychologic—immobility, restlessness, pacing, circling, hyperattachment, escape, avoidance, approach/retreat, destructiveness, vocalization, aggression. • Cardiovascular—tachycardia, hypertension. • Endocrine/metabolic—alterations in hypothalamic pituitary–adrenal axis, increased blood glucose. • Gastrointestinal—inappetence, hypersalivation, vomiting, diarrhea, defecation. • Hemic/lymphatic/immune—stress leukogram. • Musculoskeletal—self-injury. • Neurologic—increased motor activity, trembling, decreased pain perception, catatonia, partial seizure. • Ophthalmic—episcleral injection, mydriasis. • Renal/urologic—urination. • Respiratory—tachypnea. • Skin/exocrine—traumatic injury, acral lick dermatitis (ALD).

GENETICS

Heredity influences development of fears and phobias, although unclear at this time to what extent specific fears (e.g., noise) are heritable.

INCIDENCE/PREVALENCE

• Separation anxiety—13–40%. • Sound aversion, fear, and phobia—up to 50%. • General fearfulness—26%. • Reactivity to people—7%. • Fear of veterinarian—up to 78.5%.

SIGNALMENT

No age, breed, or sex overrepresented.

SIGNS

General Comments

Hypervigilance, ANS arousal, catatonia, increased motor activity, elimination, destruction, vocalization, hypersalivation, panting, hiding, trembling, escape behaviors, fearful body language.

Historical Findings

Traumatic experience, inadequate socialization, fearful/anxious dam or sire, history of inability to escape stimulus (e.g., locked in crate).

Physical Examination Findings

May be unremarkable; self-induced injuries possible.

CAUSES

• Inadequate socialization, traumatic event, hereditary, cognitive dysfunction syndrome (CDS), previous learning. • Illness or pain may contribute to development of fears, phobias, and anxieties.

RISK FACTORS

General—existing fears, anxieties, and phobias; inadequate socialization, rehoming, anxious/fearful/physically ill dam, traumatic event.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Psychologic—CDS; incomplete housetraining; urine/fecal marking; territorial aggression; separation-related disorders; attention-seeking; storm, noise, or environmental phobias; generalized anxiety; neophobia; fear-induced aggression. • Medical—neoplasia (e.g., intracranial), endocrinopathy (e.g., Cushing's, hypothyroidism), cystitis, pyelonephritis, diabetes, gastrointestinal disease (e.g., inflammatory bowel disease), neurologic disease (e.g., seizures), dermatologic (e.g., ALD, atopy, food allergies), toxicity (e.g., lead, recreational drugs).

CBC/BIOCHEMISTRY/URINALYSIS

Perform before initiating drug treatment.

OTHER LABORATORY TESTS

• Thyroid status. • Adrenal tests if indicated by history, signalment, physical examination, and laboratory tests.

IMAGING

CT or MRI if indicated to rule out CNS disorder. Other imaging if indicated (e.g., pain).

DIAGNOSTIC PROCEDURES

• Thorough behavioral history and observation of patient (video of behavior is helpful). • Exposure to stimulus if safe.

TREATMENT

APPROPRIATE HEALTH CARE

• Typically outpatient. • Inpatient (dayboarding/daycare)—if fear-/anxiety-/phobia-inducing stimulus unavoidable, patient causing self-injury, medication not yet effective, hospitalization to stabilize patient on medication. • Treatment includes owner education, safety, behavior modification to change emotional state of patient, environmental modification to avoid triggers and distract patient during episodes, reduction of anxiety. • Diagnose and treat any conditions that may cause pain, discomfort, or changes in mood as well as any injuries.

Safety

• Owner—should not push, pull, grab, or reach for dog showing clinical signs, as this can result in owner-directed aggression; instead, use food or toy to move patient. • Patient—if intense escape attempts or self-injury are present, avoid crating and limit dog's access to windows, doors, electrical wiring, and water lines; consider dayboarding. • Public—avoid situations where stimulus is present until treatment is complete.

Behavior Modification

• Avoid stimulus for 2–8 weeks depending on severity of reaction while teaching coping skills to patient (e.g., sit, watch, look at that, leave it, relaxation) and setting up safe spot. • Structured interactions with owner (e.g., sit for all interactions). • Independence exercises—down/stay with food toy. • Punishment (e.g., shock/choke collar correction, yelling, hitting) contraindicated. • Client should distract dog and redirect to play or food toy when frightened or anxious. • Desensitization and counter-conditioning (DS/CC)—can begin after coping tools have been taught; can be attempted with supervision of highly qualified positive reinforcement trainer or veterinary behavior technician; DS/CC can sensitize animal to stimulus, causing behavior disorder to worsen.

Environmental Modification

• Create safe spot/safe haven where exposure to fear-producing stimulus can be limited. • Consider dayboarding/daycare. • Limit use of crate until dog uses readily and does not panic when confined. • Environmental enrichment (e.g., rotate toys, food toys, exercise).

(CONTINUED) # FEARS, PHOBIAS, AND ANXIETIES—DOGS

NURSING CARE
Behavior treatment appointments can be scheduled with veterinary technicians. Consider short-term or day boarding for regulation of medications or avoidance of stimulus.

ACTIVITY
• Increased exercise will act as environmental enrichment for patient but will not significantly lower anxiety/fear disorders. • Exercise should avoid any exposure to fear-inducing stimulus.

CLIENT EDUCATION
• Advise owners that patient is not spiteful or guilty; may be long course of treatment; will most likely be managed, not cured. • Help client understand subtlety of signs involved and learn to recognize signs associated with fear, anxiety, and stress.

MEDICATIONS

DRUG(S) OF CHOICE
• Should always be prescribed with complete treatment plan in order to be compliant with standard of care. • Most treatment will be long term, possibly years; minimum treatment generally 6 months with concurrent behavior modification; if dog has significantly improved in 6 months, try slow weaning by reducing dose by 25–50% every 14 days. • Situational, mild PRN drug indicated, e.g., benzodiazepine, serotonin reuptake inhibitor/antagonist (SARI) either alone if stimulus is occasional and predictable, or more commonly concurrent with selective serotonin reuptake inhibitor (SSRI) or tricyclic antidepressant (TCA) prior to event.
◦ Best administered before any signs of anxiety, fear, or panic; minimally 60–90 min before anticipated provocative stimulus.
◦ Benzodiazepines—diazepam 0.50–2 mg/kg PO up to q8h; clorazepate 0.50–2 mg/kg PO up to q6h; alprazolam 0.01–0.1 mg/kg PO up to q4h. ◦ SARI: trazodone 3.0–10 mg/kg PO up to q8h (up to 15 mg/kg). ◦ Alpha-2 agonist—clonidine 0.01–0.05 mg/kg PO up to q8h.
• Dexmedetomidine oromucosal gel—125 µg/m^2 onto oral mucosa 30–60 min prior to fear-evoking event. • Generalized, stimulus unavoidable or severe—daily administered drug indicated. ◦ Both TCAs and SSRIs can take up to 6 weeks to take effect; start at low end of dosing range and then slowly increase in 2–4-week increments based on response to avoid side effects. ◦ TCA—clomipramine 1.0–3.0 mg/kg PO q12h. ◦ SSRI—sertraline 1.0–3.0 mg/kg PO q24h; fluoxetine or paroxetine 0.5–2.0 mg/kg PO q24h.

PRECAUTIONS
• All listed medications are extra-label except clomipramine and fluoxetine for treatment of separation anxiety and dexmedetomidine oro-mucosal gel for noise aversion in dogs in the United States—follow Health and Human Services recommendations. • Cardiac conduction anomalies—use caution and monitoring when giving TCAs. • Use caution when prescribing drugs to geriatric patients or patients with hepatic or renal compromise—review metabolism and elimination of medication before prescribing. • Clients should receive drug information handouts with potential side effects listed. • Mood-altering medications have potential to increase agitation, fear, and aggression.

POSSIBLE INTERACTIONS
• Use caution when prescribing multiple medications concurrently that have same mode of action; review drug monographs for each drug before prescribing. • Do not use SARIs, SSRIs, or TCAs with monoamine oxidase inhibitor (MAOIs), including but not limited to selegiline and amitraz. • Do not use SSRIs and TCAs together—possible risk of serotonin syndrome, which can be fatal.

ALTERNATIVE DRUG(S)
Buspirone (daily)—0.5–1.0 mg/kg BID–TID.

Supplements
Natural products that may aid in reducing anxiety—dog-appeasing pheromone (Adaptil®); alpha-casosopene (Zykene®) alone or in diet together with l-tryptophan (Royal Canin Calm® diet); l-theanine alone (Anxitane®) or in combination product containing whey protein, *Phellodendron amurense*, and *Magnolia officinalis* (Solliquin®); melatonin; S-adenosylmethionine (SAMe); Souroubea and Plantanus (Zentrol®), or a probiotic supplement (Calming Care®).

FOLLOW-UP

PATIENT MONITORING
• Clients should contact veterinary healthcare team with updates at 2-week intervals for first 6–8 weeks of treatment; typically, treatment plan will have to be altered. • CBC, biochemistry, urinalysis, T_4, fT_4, q12 months for animals <8 years on daily administered medications; senior dogs may require more frequent reassessment based on age and health.

PREVENTION/AVOIDANCE
• Proper socialization—8–12 weeks, including puppy classes starting at 8 weeks. • Structured relationship with owner (e.g., sit for all interactions). • Basic obedience. • Treat traumatic experiences immediately.

POSSIBLE COMPLICATIONS
If left untreated or treated with medication only, worsening clinical signs likely.

EXPECTED COURSE AND PROGNOSIS
• Depends on response to medication, suitability of environment, and client's ability to perform behavior modification. • Treatment duration varies from 2 to 12 months depending on severity and number of problems; only dogs who respond well to behavior modification and environmental management can be expected to be weaned off medication. • Typically, treatment will continue to some extent throughout dog's life.

MISCELLANEOUS

AGE-RELATED FACTORS
CDS can present as nonspecific fear.

PREGNANCY/FERTILITY/BREEDING
Most listed medications are not evaluated in or contraindicated in pregnant animals.

SYNONYMS
• Generalized anxiety. • Neophobia.

SEE ALSO
• Aggression – Overview Dogs.
• Fear and Aggression – Veterinary Visits Dogs.
• Separation Anxiety Syndrome.
• Thunderstorm and Noise Phobias – Dogs.

ABBREVIATIONS
• ALD = acral lick dermatitis.
• ANS = autonomic nervous system.
• CDS = cognitive dysfunction syndrome.
• DS/CC = desensitization and counter-conditioning.
• MAOI = monoamine oxidase inhibitor.
• PSR = physiologic stress response.
• SAMe = S-adenosylmethionine.
• SARI = serotonin reuptake inhibitor/antagonist.
• SSRI = selective serotonin reuptake inhibitor.
• TCA = tricyclic antidepressant.

FELINE ALVEOLAR OSTEITIS

OVERVIEW

Thickening of bone over the jugum of tooth roots due to inflammation. Alveolar osteitis most commonly occurs over the maxillary canine tooth roots of middle-aged and older cats (sometimes also called buttressing). This process appears to be secondary to periodontal inflammation. Tooth resorption and extrusion (supereruption) may also be seen in affected teeth. Feline alveolar osteitis should be distinguished from benign alveolar bone expansion (also called buccal bone expansion), which is devoid of inflammation.

SIGNALMENT

Although alveolar osteitis can occur in dogs, it is far more common in cats. There are no established breed or sex predilections, and no established genetic basis. Middle-aged and older cats are most commonly affected.

SIGNS

History

- Owner may report thickening or bulging over the maxillary canine teeth roots, usually bilateral, but can be unilateral.
- Evidence of oral pain is not often noted by pet owners.
  - Discomfort may occur with mobile teeth.
  - Discomfort may occur when extruded maxillary canine teeth contact the lower lip or the opposing canine, resulting in an acquired malocclusion.

Clinical Findings

- Bulging of alveolar bone on the buccal surface of the root; variable degree of gingival inflammation.
- Patient may have abnormal periodontal pocket depths on probing (normal sulcus depth for cats is 0–1 mm); patients often exhibit vertical bone loss with infrabony pockets.
- Patients may exhibit extrusion (supereruption) of one or more teeth; extended tooth length may cause trauma to lower lip or malocclusion with opposing mandibular canine tooth.
- May progress to tooth mobility and acquired dental malocclusion due to contact between maxillary and mandibular canine teeth.

CAUSES & RISK FACTORS

Cause is unknown, but buttressing in humans is considered to be an attempt by the body to stabilize a diseased tooth. Cats that are prone to periodontal disease may be at a higher risk for developing alveolar osteitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Alveolar bone expansion, also known as buccal bone expansion, is an enlargement of alveolar bone that looks similar to alveolar osteitis. However, when biopsied, alveolar bone expansion may show no signs of inflammation.

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities seen related to alveolar osteitis.

IMAGING

Intraoral dental radiographs typically show evidence of vertical periodontal bone loss along the long axis of the root on the palatal and buccal surface of the root. The expanded bone may be less dense than normal adjacent alveolar bone.

DIAGNOSTIC PROCEDURES

- Appropriate preanesthetic diagnostics when indicated prior to procedure.
- Complete oral examination with periodontal probing—assess for periodontal pockets, gingival bleeding or tooth mobility; pay particular attention to probing depth of palatal surface of maxillary canine teeth.
- Intraoral radiographs under anesthesia—assess extent of osseous changes; assess root stability, attachment loss, and evidence of tooth resorption.
- Consider biopsy if bone changes are unilateral or if aggressive osseous changes are seen on dental radiographs.

TREATMENT

- If mild periodontal changes are present (moderate pocket depth, no tooth mobility, minimal extrusion, no oronasal fistulation), a professional ultrasonic dental cleaning with root planing and subgingival curettage ± placement of periodontal pocket antimicrobial treatment ± osseous surgery.
- If extensive periodontal disease is present (deep periodontal pocket, tooth mobility, extensive extrusion, patient discomfort, oronasal fistula), consider extraction. Buccal attached gingiva may be very thin, making it difficult to elevate a gingival flap. Ostectomy/osteoplasty of buccal alveolar bulge is necessary after raising the gingival flap and prior to closure. Biopsy of buccal alveolar bone can be accomplished with rongeurs once a mucogingival flap has been elevated. Gently elevate palatal mucosal edge to facilitate closure.

MEDICATIONS

DRUG(S) OF CHOICE

Appropriate antimicrobials and pain medications when indicated.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Recheck patient at 2 weeks postoperatively, with regular reevaluations depending on what treatment was chosen.

PREVENTION/AVOIDANCE

No known methods of prevention.

POSSIBLE COMPLICATIONS

Complications include those that may occur when extracting teeth (perforation of mucogingival flap, dehiscence, iatrogenic oronasal fistula, etc.).

EXPECTED COURSE AND PROGNOSIS

Good with appropriate treatment, unless neoplasia is diagnosed with biopsy.

Author John R. Lewis
Consulting Editor Heidi B. Lobprise

FELINE CALICIVIRUS INFECTION

BASICS

DEFINITION
A common viral respiratory disease of domestic and exotic cats characterized by upper respiratory disease and oral ulceration, occasionally pneumonia or arthritis, and rarely a highly fatal systemic hemorrhagic disease (FCV–VSD).

PATHOPHYSIOLOGY
- Spread through ocular, nasal, and oral secretions.
- Transmission typically occurs through direct contact or fomite exposure; droplet transmission possible within 4–5 feet; replication takes place primarily in respiratory and oral tissues.
- Rapid cytolysis of infected cells results in tissue pathology and clinical disease.

SYSTEMS AFFECTED
- Gastrointestinal—ulceration of the tongue common; occasional ulceration of the hard palate and lips.
- Hemic/lymphatic/immune—hemorrhage; splenic necrosis (FCV–VSD).
- Hepatobiliary—hepatic necrosis (FCV–VSD).
- Musculoskeletal—acute arthritis.
- Ophthalmic—acute serous conjunctivitis without keratitis or corneal ulcers.
- Respiratory—rhinitis; interstitial pneumonia; ulceration of nose tip.
- Skin/exocrine—subcutaneous edema; ulcerations of pinnae or pawpads; pancreatic necrosis (FCV–VSD).

GENETICS
None

INCIDENCE/PREVALENCE
- Persistent infection common, resulting in virus-shedding carriers.
- Clinical disease—common in multicat facilities, shelters, breeding catteries.
- Routine vaccination—reduces incidence and severity of clinical disease; has not decreased prevalence of the virus.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Cat

Breed Predilections
None

Mean Age and Range
- Young kittens >6 weeks old—most common.
- Cats of any age may show clinical disease.

Predominant Sex
None

SIGNS

General Comments
Severity of disease is dependent on host immune status, virulence of infecting strain, and presence of co-infections. Most common manifestation involves self-limiting upper respiratory tract disease and oral ulceration.

Historical Findings
- Sudden onset.
- Anorexia.
- Serous ocular or nasal discharge, usually with little or no sneezing.
- Ulcers on tongue, hard palate, lips, tip of nose, or around claws.
- Dyspnea from pneumonia.
- Acute, painful lameness.

Physical Examination Findings
- Ranging from generally alert and in good condition to lethargy and decreased mentation.
- Fever.
- Ulcers of tongue/mouth may occur without other signs.
- Hypersalivation.
- Upper to lower respiratory tract disease—nasal discharge, or stertor; wheezes, crackles, or increased bronchovesicular sounds on pulmonary auscultation,
- Epistaxis or hematochezia with systemic hemorrhage (FCV–VSD).
- Facial and limb edema with crusting/ulcerations of face, pinnae, and feet due to vasculitis (FCV–VSD).
- Icterus (FCV–VSD).

CAUSES
- A small, nonenveloped single-stranded RNA virus, feline calicivirus (FCV).
- Numerous strains exist in nature, with varying degrees of antigenic cross-reactivity.
- More than one serotype.
- Relatively stable and resistant to many disinfectants.

RISK FACTORS
- Lack of vaccination or improper vaccination.
- Multicat facilities.
- Concurrent infections with other pathogens, e.g., feline herpesvirus (FHV), feline panleukopenia virus (FPV), feline immunodeficiency virus (FIV), feline leukemia virus (FeLV).
- Poor ventilation.
- Stress.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- FHV.
- Chlamydiosis.
- *Bordetella bronchiseptica*.

CBC/BIOCHEMISTRY/URINALYSIS
No characteristic or consistent findings.

OTHER LABORATORY TESTS
Often diagnosed on clinical signs.

IMAGING
Radiographs of lungs—consolidated lung tissue in cats with pneumonia.

DIAGNOSTIC PROCEDURES
- PCR—oropharyngeal swabs most likely to detect virus; positive result does not prove that FCV is causative agent for disease due to persistently shedding cats.
- Cell cultures to isolate virus—oral pharynx; lung tissue; feces; blood; secretions from nose and conjunctiva.
- Immunofluorescent assays of lung tissue—viral antigen.
- Serologic testing on paired serum samples—detect rise in neutralizing antibody titers against virus; vaccination interferes with results from serum neutralization testing.

PATHOLOGIC FINDINGS
- Gross—upper respiratory infection; ocular and nasal discharge; pneumonia with consolidation of large portions of individual lung lobes; possible ulcerations on tongue, lips, and hard palate; systemic hemorrhages.
- Histopathologic—interstitial pneumonia of large portions of individual lung lobes; ulcerations on epithelium of tongue, lips, and hard palate; mild inflammatory reactions in nose and conjunctiva; systemic hemorrhages, vasculitis, or necrosis.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient, unless severe pneumonia, hemorrhage, or severe systemic disease.

NURSING CARE
- Clean eyes and nose as indicated with warm water or saline.
- Provide access to steam, such as in a bathroom, to clear secretions.
- Provide palatable, soft foods.
- Oxygen—with severe pneumonia.

ACTIVITY
Patients should be restricted from contact with other cats to prevent transmission of causative virus.

DIET
- No restrictions.
- Special diets—to entice anorectic cats to resume eating.
- Soft foods—if ulcerations restrict eating.

CLIENT EDUCATION
Discuss need for proper vaccination and to modify vaccination protocol in breeding catteries to include kittens before they

FELINE CALICIVIRUS INFECTION (CONTINUED)

become infected (often at 6–8 weeks of age) from a carrier queen.

SURGICAL CONSIDERATIONS
None

MEDICATIONS

DRUG(S) OF CHOICE
- No specific antiviral drugs are clearly indicated.
- Broad-spectrum antibiotics—indicated for treatment of secondary bacterial infections (e.g., amoxicillin or amoxicillin–clavulanate at 22 mg/kg PO q12h; doxycycline at 5 mg/kg PO q12h).
- Secondary bacterial infections of affected cats not nearly as important as with FHV-1 infections.
- Antibiotic eye ointments—to reduce secondary bacterial infections of conjunctiva.
- Pain medication—as indicated for arthritis pain or significant ulceration.

CONTRAINDICATIONS
None

PRECAUTIONS
None

POSSIBLE INTERACTIONS
None

ALTERNATIVE DRUG(S)
None

FOLLOW-UP

PATIENT MONITORING
- Monitor for sudden development of dyspnea associated with pneumonia.
- No specific laboratory tests.

PREVENTION/AVOIDANCE
- American Association of Feline Practitioners—classifies FHV, FPV, and FCV as core vaccines; vaccinate all cats with either a modified live virus (MLV) or inactivated core vaccine on initial visit (as early as 6 weeks of age), repeat every 3–4 weeks until 16 weeks of age, and booster 1 year after last kitten vaccine; revaccinate every 3 years.
- Breeding catteries—respiratory disease is a problem; vaccinate kittens at earlier age, either with additional vaccination at 4–5 weeks or with intranasal vaccine at 10–14 days; follow-up vaccinations every 3–4 weeks until 16 weeks of age.
- Vaccination will not prevent virus infection in subsequent exposure, but can prevent serious clinical disease caused by most strains; FCV–VSD can occur in vaccinated cats.
- Environmental management—decrease housing density; isolate affected cats by >4 ft; beware of hygiene and fomites; disinfect with dilute (1 : 30) bleach.

POSSIBLE COMPLICATIONS
- Interstitial pneumonia—most serious complication; can be life-threatening.
- Secondary bacterial infections of lungs or upper airways.

EXPECTED COURSE AND PROGNOSIS
- Clinical disease—usually appears 3–4 days after exposure.
- With supportive care, infection usually self-limiting and cats with upper respiratory signs respond favorably within 7–10 days.
- Oral ulcerations typically improve in 2–3 weeks.
- Lameness usually resolves in 1–2 days.
- Prognosis excellent, unless severe pneumonia or systemic hemorrhagic disease develops.
- FCV–VSD may be severe and fatal.
- Recovered cats—persistently infected for long periods; will shed small quantities of virus in oral secretions continuously.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Affected cats may also be concurrently infected with FHV-1, especially in multicat and breeding facilities. FCV has been implicated in development of feline chronic gingivostomatitis.

AGE-RELATED FACTORS
Usually occurs in young kittens whose maternally derived immunity has waned.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Generally no problem, because most cats have been exposed or vaccinated before becoming pregnant.

SYNONYMS
- Feline picornavirus infection—FCV originally classified as a picornavirus; older literature refers to the infection by this name; no known picornavirus infects cats.
- Limping kitten syndrome.
- Hemorrhagic calicivirus.

SEE ALSO
- Chlamydiosis—Cats.
- Feline Herpesvirus Infection.
- Feline (Upper) Respiratory Infections.
- Rhinitis and Sinusitis.
- Stomatitis and Oral Ulceration.

ABBREVIATIONS
- FCV = feline calicivirus.
- FCV–VSD = feline calicivirus–virulent systemic disease.
- FeLV = feline leukemia virus.
- FHV = feline herpesvirus.
- FIV = feline immunodeficiency virus.
- FPV = feline panleukopenia virus.
- MLV = modified live virus.

FELINE HERPESVIRUS INFECTION

BASICS

DEFINITION
An acute disease in cats characterized by sneezing, fever, rhinitis, conjunctivitis, and ulcerative keratitis.

PATHOPHYSIOLOGY
Feline herpesvirus-1 (FHV-1) causes acute cytolytic infection of respiratory or ocular epithelium after oral, intranasal, or conjunctival exposure. The intracellular virus travels from cell to cell and does not stimulate a strong immune response from the host.

SYSTEMS AFFECTED
- Integumentary—herpes dermatitis near the nares.
- Ophthalmic—conjunctivitis with serous or purulent ocular discharge; ulcerative keratitis or panophthalmitis.
- Reproductive—in utero infection (infected pregnant queen) may result in severe neonatal herpetic infection.
- Respiratory—rhinitis with sneezing and serous to purulent nasal discharge; chronic sinusitis may result; tracheitis possible.
- Neurologic—latent virus found in optic nerve, ciliary ganglion, brainstem, cerebellum, and olfactory bulb.

GENETICS
N/A

INCIDENCE/PREVALENCE
- Common, especially in multicat households or facilities housing large numbers of cats; catteries and shelters are source of most infections.
- Perpetuated by latent carriers that harbor virus in nerve (especially trigeminal) ganglia.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
All domestic and many exotic cats.

Breed Predilections
- None.
- Brachycephalic breeds have more severe corneal disease and are more likely to have corneal sequestra.

Mean Age and Range
- All ages.
- Kittens most susceptible.

Predominant Sex
N/A

SIGNS

Historical Findings
- Acute onset of paroxysmal sneezing.
- Blepharospasm and ocular discharge.
- Anorexia (from high fever, general malaise, or inability to smell).
- Recurrent signs—carriers.
- Abortion.

Physical Examination Findings
- Fever—up to 106 °F (41 °C).
- Rhinitis—serous, mucopurulent, or purulent discharge.
- Conjunctivitis—serous, mucopurulent, or purulent discharge.
- Chronic rhinitis/sinusitis—chronic purulent nasal discharge.
- Keratitis—ulceration, descemetocele, panophthalmitis.

CAUSES
FHV-1

RISK FACTORS
- Lack of vaccination for FHV-1, although vaccines do not bestow sterilizing immunity.
- Multicat facilities with overcrowding, poor ventilation, poor sanitation, poor nutrition, or physical or psychologic stress.
- Pregnancy and lactation.
- Concomitant disease, especially owing to immunosuppressive organisms or other respiratory organisms.
- Kittens born to carrier queens—infected ~5 weeks of age.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Feline calicivirus infection—less sneezing than FHV-1, conjunctivitis, ulcerative keratitis; may cause ulcerative stomatitis, pneumonia.
- Feline *Chlamydophila* infection—more chronic conjunctivitis, which may be unilateral; pneumonitis; intracytoplasmic inclusions in conjunctival scrapings; responds to tetracyclines or chloramphenicol.
- Bacterial infection (*Bordetella*, *Haemophilus*, or *Pasteurella*)—less nasal and ocular involvement; often respond to antibiotics.

CBC/BIOCHEMISTRY/URINALYSIS
- Nonspecific.
- Transient leukopenia followed by leukocytosis may occur.

OTHER LABORATORY TESTS
- PCR testing from pharyngeal and conjunctival swabs will identify presence of virus; more sensitive than other diagnostic modalities; may be transiently positive following vaccination with modified live virus (MLV) vaccine for FHV-1.
- Immunofluorescent assay—nasal or conjunctival scrapings; viral detection.
- Viral isolation—pharyngeal swab sample.
- Stained conjunctival smears—detect intranuclear inclusion bodies.

IMAGING
- Radiography—open-mouth ventrodorsal and rostrocaudal (skyline) views of skull reveal presence of chronic disease in nasal cavity and frontal sinuses; infection cannot be reliably distinguished from neoplasia and inflammatory polyps; no abnormal radiographic findings with acute disease.
- CT provides more accurate assessment of disease in nasal cavity and frontal sinus compared to radiographs; CT may differentiate neoplasia from inflammation based on amount of bony destruction.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
- Gross—ocular and nasal discharge, mucosal edema of upper airway epithelium, tracheitis, sinusitis, ulcerative keratitis, panophthalmitis.
- Microscopic—submucosal edema, inflammatory cell infiltrates of upper respiratory and conjunctival tissues, chronic sinusitis, intranuclear inclusion bodies in epithelial cells.

TREATMENT

APPROPRIATE HEALTH CARE
- Inpatient—nutritional and fluid support to anorectic cats.
- Outpatient—if eating and afebrile.

NURSING CARE
- Outpatient—keep patient indoors to prevent environmentally induced stress, which may lengthen disease course.
- Fluids—IV or SC; to correct and prevent dehydration; to keep nasal secretions thin.
- Appetite stimulant as needed (mirtazapine—1.8 mg/cat PO q24–48h).

ACTIVITY
Isolate affected cats during acute phase because they are contagious.

DIET
- Outpatient—encourage food consumption to avoid anorexia; offer foods with appealing tastes and smells; warming food may enhance smell.
- Inpatient—forced enteral feeding for anorectic cats; remove nasal secretions (so nasal breathing can occur) before starting orogastric or esophagostomy tube feeding; avoid nasoesophageal tubes because of rhinitis.

CLIENT EDUCATION
- Inform client of contagious nature of disease.
- Discuss proper vaccination protocols and early vaccination of cats in multicat facilities and households.

FELINE HERPESVIRUS INFECTION (CONTINUED)

• Inform client that early weaning and isolation from all other cats except littermates may prevent infections.

SURGICAL CONSIDERATIONS
Surgically implanted feeding tubes (esophagostomy tube, gastrostomy tube) may be needed to manage prolonged anorexia.

MEDICATIONS

DRUG(S) OF CHOICE
• Antibiotics not recommended if nasal discharge is serous and lacks purulent or mucopurulent component; antibiotics recommended only if fever, lethargy, or anorexia present concurrently with mucopurulent nasal discharge.
• Doxycycline (10 mg/kg PO q24h) recommended; amoxicillin (22 mg/kg PO/IM/SC q8–12h) or ampicillin (10–20 mg/kg IV/IM/SC q6–8h) for secondary bacterial infections.
• Famciclovir (40–90 mg/kg PO 12h) may shorten course and severity of disease.
• Ophthalmic antibiotics—for keratitis.
• Ophthalmic antivirals for herpetic ulcers in order of efficacy—trifluridine, cidofovir, idoxuridine, ganciclovir, aciclovir; must be instilled q2h for significant effect, except for cidofovir which can be given q12h, making it ophthalmic drug of choice, although it must be compounded.
• Some evidence that administration of intranasal vaccine 2–6 days prior to exposure will result in lessening of clinical signs; may be helpful in outbreak in multicat setting.

CONTRAINDICATIONS
• Idoxuridine ophthalmic—may be painful; discontinue medication.
• Cidofovir ophthalmic—scarring of nasolacrimal duct reported in humans, rabbits.
• Trifluridine, idoxuridine, acyclovir—toxic if given systemically.
• Systemic corticosteroids—may induce relapse in chronically infected cats.
• Ophthalmic corticosteroids—may predispose to ulcerative keratitis
• Nasal decongestant drops—0.25% oxymetazoline HCl; decrease nasal discharge; contraindicated because some cats object and some experience rebound rhinorrhea.

PRECAUTIONS
• Oral doxycycline tablets can cause esophageal ulceration.
• Death usually result of inadequate nutritional and fluid support or immunosuppression due to feline leukemia virus (FeLV) or feline immunodeficiency virus (FIV).

ALTERNATIVE DRUG(S)
• Lysine (500 mg PO q12h) might reduce viral shedding, clinical signs.
• Lysine-lactoferrin (500 mg PO q12h) more effective than lysine alone for treatment.
• Penciclovir—effectively inhibits FHV-1, doses unknown at this time.

FOLLOW-UP

PATIENT MONITORING
Monitor appetite closely; hospitalize for fluids and tube feeding if anorexia develops.

PREVENTION/AVOIDANCE
Can survive in environment for several hours; drying and most disinfectants effectively kill the virus.

Vaccines
• Routine vaccination with MLV or inactivated virus vaccine—prevents development of severe disease; does not prevent infection and local viral replication with mild clinical disease and virus shedding.
• Vaccinate at 8–10 weeks, 12–14 weeks, and 16–18 weeks of age and with annual boosters for reasonable protection, especially in high-risk populations.
• Endemic multicat facilities or households—vaccinate kittens with dose of intranasal vaccine at 10–14 days of age, then parenterally at 6, 10, and 14 weeks of age; isolate litter from *all* other cats at 3–5 weeks of age; then use kitten vaccination protocol to prevent early infections.

POSSIBLE COMPLICATIONS
• Chronic rhinitis or rhinosinusitis with long-term sneezing and nasal discharge.
• Herpetic ulcerative keratitis.
• Corneal sequestrum that must be removed surgically.
• Permanent closure of nasolacrimal duct with chronic ocular discharge.

EXPECTED COURSE AND PROGNOSIS
• 7–10 days followed by spontaneous remission, if secondary bacterial infections do not occur.
• Prognosis generally good, if fluid and nutritional therapy are adequate.
• Correlation between severity of acute signs and degree of latent infection.
• May become chronically affected and exhibit respiratory signs long term.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Simultaneous viral or bacterial respiratory diseases.

AGE-RELATED FACTORS
More severe in young kittens.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Pregnant cats with FHV infection may transmit FHV-1 to kittens in utero, resulting in abortion or neonatal disease.

SYNONYMS
• Coryza.
• Feline rhinotracheitis.
• Rhino.

SEE ALSO
Feline Calicivirus Infection.

ABBREVIATIONS
• FeLV = feline leukemia virus.
• FHV-1 = feline herpesvirus type 1.
• FIV = feline immunodeficiency virus.
• MLV = modified live virus.

FELINE HYPERESTHESIA SYNDROME

BASICS

OVERVIEW

• Idiopathic disorder of cats characterized by paroxysmal agitation, focal epaxial muscle spasms, vocalization, and intense biting or licking of the back, tail, and pelvic limbs. • Also known as atypical neurodermatitis, rolling skin disease, apparent neuritis, and twitchy cat disease. • Pathophysiology unknown. • Organ systems affected—behavioral, nervous, neuromuscular, skin/exocrine.

SIGNALMENT

Species

Cat

Breed Predilections

Can be seen in any breed; Siamese, Abyssinian, Burmese, and Himalayan may be predisposed.

Mean Age and Range

Most common at 1–7 years of age.

SIGNS

• Episodes of twitching of skin over lumbar area, violent swishing of tail, vocalizing, and biting or licking of flank, pelvic region, or tail. • Pupils often dilate, and cats can become aggressive or appear agitated and run wildly about the environment. • Episodes are several seconds to several minutes in length; cats are typically normal between episodes, but may be intolerant of being stroked along the back. • General physical examination often reveals no abnormalities aside from possible alopecia and broken hair over lumbar area from self-mutilation; many cats resent palpation of thoracolumbar musculature, and manipulation of area may elicit an episode; no neurologic deficits present.

CAUSES & RISK FACTORS

• Not known whether this syndrome is manifestation of underlying behavioral problem, dermatopathy, focal seizure disorder, or abnormal sensory state causing neuropathic pain or itch; speculated that cause is multifactorial, or that syndrome is not distinct entity with single cause, but rather can develop from variety of different factors. • Cats that tend to be nervous or hyperexcitable may be at increased risk; environmental stressors can serve as trigger.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Dermatologic conditions causing pruritus—parasitic (e.g., flea, *Notoedres*, *Cheyletiella*), fungal (e.g., dermatophytosis), or allergic (e.g., parasitic, inhalant, dietary); evaluate for underlying dermatitis; skin scrapings and fungal cultures can help confirm diagnosis. • Diseases of spinal cord, nerve roots, epaxial muscles, or vertebral column causing pain—degenerative (intervertebral disc disease), inflammatory (discospondylitis, meningitis, myositis), neoplastic, or traumatic; spinal radiographs helpful in evaluating for abnormalities; further diagnostics (e.g., advanced imaging, serology for infectious agents, cerebrospinal fluid [CSF] analysis) may be necessary. • Forebrain disease causing behavioral changes and/or seizures—metabolic (hepatic encephalopathy), infectious/inflammatory (feline leukemia virus, feline immunodeficiency virus, feline infectious peritonitis, cryptococcosis, toxoplasmosis), neoplastic, vascular; complete diagnostic evaluation including bile acid tolerance, testing for infectious causes, CSF analysis, and brain imaging may be indicated. • Behavioral condition—compulsive disorder; exclusion diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS

Frequently normal.

IMAGING

None required aside from that necessary to exclude differential diagnoses.

DIAGNOSTIC PROCEDURES

• Diagnosis based on characteristic history and clinical findings, and by excluding other diseases that can cause similar signs. • No test or group of tests support definitive diagnosis. • Electromyography (EMG)—evidence of abnormal spontaneous activity in thoracolumbar epaxial muscles in one study of affected cats. • Muscle biopsy—if EMG changes; isolated report of vacuoles within epaxial muscles, with antibody labeling characteristics similar to those described with inclusion body myositis/myopathy in humans.

TREATMENT

• Outpatient. • Eliminate environmental changes that can precipitate episodes. • Behavioral modification has been successful in reducing clinical manifestations in some cats. • In severe cases of self-mutilation, Elizabethan collar or tail bandaging may be necessary.

MEDICATIONS

DRUG(S) OF CHOICE

• Several pharmacologic agents recommended, based on suspected underlying cause. • Prednisolone indicated if pruritic dermatitis suspected. • Antiepileptic drugs often utilized; phenobarbital (1–2 mg/kg PO q12h) effective in some cats; gabapentin (5–10 mg/kg PO q12h) can be used for both antiepileptic and analgesic properties; topiramate (5 mg/kg PO q12h) is antiepileptic that has also been used to treat self-mutilation in cats. • Selective serotonin reuptake inhibitors (fluoxetine 0.5–2.0 mg/kg PO q24h), tricyclic antidepressants (clomipramine 0.5–1.0 mg/kg PO q24h), or benzodiazepines (lorazepam 0.125–0.50 mg per cat PO q8–24h) recommended when primary behavioral disorder suspected. • Combination therapy often required. • Treatment response variable; in cats that respond, therapy often lifelong as episodes tend to resume after medication discontinued.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Fluoxetine inhibits the cytochrome P450 system and should be used cautiously with other drugs that undergo extensive hepatic metabolism, including phenobarbital, benzodiazepines, and tricyclic antidepressants.

FOLLOW-UP

PATIENT MONITORING

Cats administered phenobarbital—check serum drug concentrations in 2–3 weeks and adjust dosage as needed to maintain levels of 20–30 µg/mL (85–130 µmol/L); CBC and biochemistry profile at 6–12-month intervals to monitor for adverse effects.

EXPECTED COURSE AND PROGNOSIS

Prognosis depends on whether underlying cause is identified, response to medication, and frequency and severity of episodes.

MISCELLANEOUS

ABBREVIATIONS

• CSF = cerebrospinal fluid. • EMG = electromyography.

FELINE IDIOPATHIC LOWER URINARY TRACT DISEASE

BASICS

DEFINITION
Idiopathic lower urinary tract disease, commonly referred to as feline idiopathic cystitis (FIC), is a nonmalignant, sterile, inflammatory disease of the urinary bladder and urethra. It is the most common urinary disorder of young to middle-aged cats and is characterized by dysuria, pollakiuria, hematuria, periuria, and in some cases urinary obstruction. Clinical observations suggest that FIC is associated with different clinical phenotypes (acute self-limiting, chronic, nonobstructive, and obstructive forms) and pathologic phenotypes (ulcerative, inflammatory, hyperplastic, nonulcerative, and noninflammatory forms). Regardless of form, the terms idiopathic lower urinary tract disease and FIC represent an exclusionary diagnosis established only after known causes have been eliminated.

PATHOPHYSIOLOGY
- Etiopathogenesis is uncertain.
- Urinary bladder abnormalities include alterations in urothelial barrier structure and function, differentiation and repair, signaling, eicosanoid biosynthesis, and innate immune and inflammatory responses.
- Association of FIC with stress (environmental, psychologic, physiologic, or comorbid pathologic stressors) and identification of multiple abnormalities of nervous and endocrine systems have led to hypothesis that systemic psychoneuroendocrine factors may have a role in the pathogenesis.
- Clinical and morphologic features of chronic forms of FIC are similar to those of an idiopathic cystopathy of humans called interstitial cystitis/painful bladder syndrome (IC/PBS). However, the extent to which the feline and human forms share pathogenic mechanisms has not yet been fully defined.

SYSTEMS AFFECTED
- Renal/urologic—lower urinary tract.
- Persistent urethral outflow obstruction results in postrenal azotemia.

INCIDENCE/PREVALENCE
- Incidence of hematuria, dysuria, and/or urethral obstruction (UO) in domestic cats has been previously reported to be ~0.5–1% per year.
- Hospital morbidity rate for FIC in cats with lower urinary tract signs is ~65%; it is the single most common cause of lower urinary tract signs in cats.

SIGNALMENT
Species
Cat

Mean Age and Range
- May occur at any age, but most commonly recognized in young to middle-aged adults (mean 3.5 years, range: 2–7 years).
- Uncommon in cats <1 and >10 years old.

SIGNS
Historical Findings
- Dysuria.
- Hematuria.
- Pollakiuria.
- Periuria.
- Urge incontinence.
- Outflow obstruction.

Physical Examination Findings
Thickened, firm, contracted bladder wall.

CAUSES
See Pathophysiology.

RISK FACTORS
- Male, middle-aged, and overweight cats, as well as cats housed indoors or living in a home with other cats, are at increased risk.
- Feeding dry food has not been consistently recognized as a risk factor.
- Stress may play a role in precipitating or exacerbating signs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Metabolic disorders including various types of uroliths/urethral plugs.
- Urinary tract infection (UTI) from bacteria, mycoplasma/ureaplasma, fungal agents, and parasites.
- Trauma.
- Neurogenic disorders including reflex dyssynergia, urethral spasm, and hypotonic or atonic bladder.
- Iatrogenic disease including reverse flushing solutions, indwelling and postsurgical urethral catheters, and urethrostomy complications.
- Anatomic abnormalities including urachal anomalies and acquired urethral strictures.
- Neoplasia.
- Clinical signs may be confused with constipation.

CBC/BIOCHEMISTRY/URINALYSIS
- Hematuria and proteinuria without significant pyuria or bacteriuria—usually present.
- If UO persists, serum chemistry profiles reveal azotemia, hyperphosphatemia, hyperkalemia, and acidosis.

OTHER LABORATORY TESTS
- Absence of bacteriuria—verify by quantitative urine culture; collect urine specimens by cystocentesis to avoid contamination.
- Transmission electron microscopy has revealed calicivirus-like particles in some urethral plugs.

IMAGING
- Survey radiography may exclude radiopaque uroliths or urethral plugs.
- Ultrasonography may exclude uroliths and thickening of bladder wall due to inflammation or neoplasia.
- Contrast cystography may exclude small or radiolucent uroliths, blood clots, urethral stricture, vesicourachal diverticula, and thickening of bladder wall due to inflammation or neoplasia.

DIAGNOSTIC PROCEDURES
- Cystoscopy may exclude uroliths and diverticula.
- Biopsies of urinary bladder wall may permit morphologic characterization of inflammatory or neoplastic lesions.

PATHOLOGIC FINDINGS
- Cystoscopy may reveal petechial hemorrhages (glomerulations) of urinary bladder mucosa.
- Mucosal ulceration or hyperplasia, submucosal edema, hemorrhage, neovascularization, fibrosis, and mononuclear inflammatory cell infiltrates are prominent features of chronic FIC.

TREATMENT

APPROPRIATE HEALTH CARE
- Patients with nonobstructive lower urinary tract diseases—typically managed as outpatients; diagnostic evaluation may require brief hospitalization.
- Patients with obstructive lower urinary tract diseases—usually hospitalized for diagnosis and management.

DIET
- Results of prospective, randomized, double-masked, controlled clinical trial provided evidence that feeding specific multipurpose therapeutic urinary food (Hill's c/d Multicare) enriched with omega-3 fatty acids (EPA and DHA) and antioxidants significantly reduced rate of recurrent episodes of FIC signs.
- Low-grade evidence that recurrence of signs may be minimized by feeding moist foods.
- Appropriate dietary management for persistent crystalluria associated with matrix-crystalline urethral plugs.

CLIENT EDUCATION
- Hematuria, dysuria, and pollakiuria—often self-limiting within 4–7 days in most cats. Signs may recur unpredictably; up to 65% of cats experience ≥1 episodes within 1–2 years.
- A lack of controlled studies demonstrating efficacy of most drugs used to treat this disorder symptomatically.
- Reduce environmental stress by minimizing impact of changes in the home and maintaining a constant diet. Environmental enrichment for indoor-housed cats consists of provision of necessary resources (food, water, litter boxes, space, play), providing a safe place to hide, refinement of cat–owner interactions, and management of conflict.

(CONTINUED) # FELINE IDIOPATHIC LOWER URINARY TRACT DISEASE

• Provide proper litter box hygiene.
• Males should be monitored for signs of UO.

SURGICAL CONSIDERATIONS
Do not perform perineal urethrostomy to minimize recurrent UO without localizing obstructive disease to penile urethra by contrast urethrography.

MEDICATIONS

DRUG(S) OF CHOICE
• Amitriptyline—empirically advocated to treat cats with severe recurrent or persistent signs; suggested dosage is 5–10 mg/cat q24h given at night; not recommended for treatment of acute, self-limiting episodes of FIC.
• Butorphanol, buprenorphine, and fentanyl—have been empirically recommended for short-term analgesia in cats with FIC; there have been no reports of controlled studies to evaluate their safety or efficacy.
• Prazosin—may be used to minimize reflex dyssynergia and functional urethral outflow obstruction; suggested dosage is 0.25–0.5 mg/cat PO q12–24h.
• Tolteridine may be considered as an anticholinergic and antispasmodic to minimize hyperactivity of bladder detrusor muscle and urge incontinence; suggested dose is 0.05 mg/kg PO q12h; there have been no controlled studies to evaluate its safety or efficacy.
• Glycosaminoglycans—empirically recommended to help repair glycosaminoglycan coating of urothelium; results of controlled clinical studies have not demonstrated any beneficial effects on reducing severity or frequency of clinical signs in cats with FIC.
• Feline facial pheromone—empirically recommended to decrease signs of stress in cats with FIC; results of controlled clinical studies have not demonstrated any beneficial effects in management of FIC.
• Corticosteroids—no detectable effect on remission of acute clinical signs demonstrated; predispose to bacterial UTIs, especially in cats with indwelling transurethral catheters.
• Nonsteroidal anti-inflammatory drugs (NSAIDs)—empirically recommended by some because of their anti-inflammatory and analgesic properties; the safety of NSAIDs in the treatment of FIC has not been evaluated by controlled clinical trials.
• Antibiotics—no detectable effect on remission of clinical signs in cats demonstrated.

CONTRAINDICATIONS
• Phenazopyridine—may result in methemoglobinemia and irreversible oxidative changes in hemoglobin resulting in formation of Heinz bodies and anemia.
• Methylene blue—may cause Heinz bodies and severe anemia.
• Bethanechol—do not use in patients with UO.

PRECAUTIONS
• Cats with UO and postrenal azotemia are at increased risk for adverse drug events, especially with drugs and anesthetics that depend on renal elimination or metabolism.
• Indwelling transurethral catheters, especially when associated with fluid-induced diuresis, predispose patients to bacterial UTIs.

FOLLOW-UP

PATIENT MONITORING
Monitor hematuria by urinalysis; cystocentesis may cause iatrogenic hematuria, so naturally voided samples are preferred.

PREVENTION/AVOIDANCE
Best evidence suggests that multimodal approach to managing cats with acute nonobstructive FIC is advised, including multipurpose therapeutic urinary food proven to reduce rate of recurrent episodes of FIC signs (Hill's c/d Multicare); environmental enrichment; feeding moist food; and short-term administration of analgesics to control signs of pain.

POSSIBLE COMPLICATIONS
• Indwelling transurethral catheters—cause trauma; predispose to ascending bacterial UTIs.
• Perineal urethrostomies—predispose to bacterial UTIs and urethral strictures.

EXPECTED COURSE AND PROGNOSIS
Hematuria, dysuria, and pollakiuria often self-limiting within 4–7 days in most patients. These signs often recur unpredictably.

MISCELLANEOUS

AGE-RELATED FACTORS
Frequency of recurrence appears to decline with advancing age.

SYNONYMS
• Feline idiopathic cystitis.
• Feline interstitial cystitis.

SEE ALSO
• Dysuria, Pollakiuria, and Stranguria.
• Hematuria.
• Lower Urinary Tract Infection, Bacterial.
• Lower Urinary Tract Infection, Fungal.
• Urolithiasis, Struvite—Cats.

ABBREVIATIONS
• FIC = feline idiopathic cystitis.
• IC/PBS = interstitial cystitis/painful bladder syndrome.
• NSAID = nonsteroidal anti-inflammatory drug.
• UO = urethral obstruction.
• UTI = urinary tract infection.

FELINE IMMUNODEFICIENCY VIRUS (FIV) INFECTION

BASICS

DEFINITION
A complex retrovirus that causes immunodeficiency in domestic cats; same genus (*Lentivirus*) as human immunodeficiency virus (HIV).

PATHOPHYSIOLOGY
- Infection causes immune dysfunction due to cytokine alterations, nonspecific hyperactivation of B and T lymphocytes, and apoptosis of T cells.
- Strain or subtype influences pathogenicity; subtypes A and B are most common in the United States.
- Acute infection—virus spreads from site of entry to lymph tissues and thymus via dendritic cells, first infecting T lymphocytes, then macrophages.
- Primary receptor is feline CD134; uses chemokine receptor CXCR4 as co-receptor.
- CD4+ and CD8+ T cells can be infected; virus selectively and progressively decreases CD4+ (T-helper) cells; inversion of the CD4+ : CD8+ ratio (from ~2 : 1 to <1 : 1) develops slowly, with absolute decrease of CD4+ T cells after several months of infection.
- Early infection and activation of CD4+ CD25+ regulatory T cells may limit effective immune response to FIV infection.
- Cats clinically asymptomatic until cell-mediated immunity is disrupted; humoral immune function declines in advanced stages of infection.
- T cells and macrophages—main cellular reservoirs of virus in affected cats; lymphoid tissues are reservoirs throughout the body.
- Astrocyte and microglial cells in brain and megakaryocytes and mononuclear bone marrow cells may be infected; neuronal loss may occur.
- Co-infection with feline leukemia virus (FeLV) may increase expression of FIV in many tissues, including kidney, brain, and liver.

SYSTEMS AFFECTED
- Hemic/lymphatic/immune—loss of CD4+ T cells; lymphocytic/plasmocytic infiltrates in tissues (especially gingiva, lymphoid tissues); lymphomas, mast cell tumors.
- Gastrointestinal—panleukopenia-like syndrome.
- Nervous—alterations in astrocyte function and neurotransmitter expression.
- Ophthalmic—anterior uveitis.
- Renal/urologic—nephropathy.
- Reproductive—fetal death or perinatal infections.
- Cardiovascular—possible myocarditis.
- Other body systems—secondary infections.

GENETICS
No predisposition for infection, but may play role in progression and severity.

INCIDENCE/PREVALENCE
United States and Canada—1–3% prevalence in healthy cat populations; 9–15% in sick cats.

GEOGRAPHIC DISTRIBUTION
Worldwide; variable seroprevalence.

SIGNALMENT

Species
Cat

Mean Age and Range
- Prevalence of infection increases with age.
- Mean age—6 years at time of diagnosis.

Predominant Sex
Male—more aggressive; roaming.

SIGNS

General Comments
- Diverse due to immunosuppressive nature.
- Cannot be clinically distinguished from FeLV-associated immunodeficiency.

Historical Findings
Recurrent minor illnesses, especially upper respiratory and gastrointestinal.

Physical Examination Findings
- Opportunistic infections.
- Lymphadenomegaly—mild to moderate.
- Gingivitis, stomatitis, periodontitis (25–50% of cases).
- Rhinitis, conjunctivitis, keratitis (30% of cases); often associated with feline herpesvirus and calicivirus infections.
- Persistent diarrhea (10–20% of cases); bacterial or fungal overgrowth, parasite-induced inflammation; direct effect of FIV on gastrointestinal epithelium.
- Chronic, nonresponsive, or recurrent infections of external ear and skin—bacterial infections or dermatophytosis.
- Fever and wasting—especially in later stage.
- Ocular disease—anterior uveitis; pars planitis; glaucoma.
- Neurologic abnormalities—disruption of normal sleep patterns; behavioral changes (pacing and aggression); motor and neurocognitive deficits; peripheral neuropathies.

CAUSES
- Cat-to-cat transmission—usually by bite wounds.
- Occasional perinatal transmission.
- Sexual transmission uncommon, although FIV has been detected in semen.

RISK FACTORS
- Male.
- Free-roaming or feral.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Primary bacterial, parasitic, fungal, or viral infections, especially FeLV.
- Toxoplasmosis—neurologic and ocular manifestations may be the result of *Toxoplasma* infection, FIV infection, or both.
- Nonviral neoplastic diseases.
- Chronic kidney disease.

CBC/BIOCHEMISTRY/URINALYSIS
- Anemia, lymphopenia, or neutropenia—common; but neutrophilia may occur in response to secondary infections; may also be normal.
- Urinalysis and serum chemistry profile—hypergammaglobulinemia, azotemia with isosthenuria, proteinuria (immune-mediated glomerulonephritis).

OTHER LABORATORY TESTS

Serologic Testing
- Detects antibodies to FIV.
- ELISA—routine screening; point-of-care and diagnostic laboratory kits; confirm positive results with additional testing, especially in healthy, low-risk cats.
- Western blot (immunoblot)—confirmatory testing of ELISA-positive samples.
- Kittens—when <6 months old may test positive owing to passive transfer of antibodies from FIV-positive queen; positive test does not indicate infection; retest at 8–12 months to determine infection.
- Vaccinated cats may test positive for FIV antibodies.

Others
- Virus isolation and subtyping.
- Reverse transcriptase polymerase chain reaction (RT-PCR)—useful in vaccinated cats or kittens with maternal antibody.
- CD4+ : CD8+ evaluation—helps determine extent of immunosuppression.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
- Lymphadenopathy—initially, follicular hyperplasia and paracortical infiltration of plasmacytes; later, follicular hyperplasia with follicular depletion or involution; in terminal stages, lymphoid depletion.
- Lymphocytic and plasmacytic infiltrates—gingiva, lymph nodes and other lymphoid tissues, spleen, kidney, liver, and brain.
- Perivascular cuffing, gliosis, neuronal loss, white matter vacuolization, and occasional giant cells in the brain.

(CONTINUED) # FELINE IMMUNODEFICIENCY VIRUS (FIV) INFECTION

• Intestinal lesions similar to those seen with feline parvovirus infection.

TREATMENT

APPROPRIATE HEALTH CARE
• Outpatient sufficient for most patients.
• Inpatient—with severe secondary infections until stable.

NURSING CARE
• Primary consideration—manage secondary and opportunistic infections.
• Supportive therapy—parenteral fluids and nutrition, as required.

ACTIVITY
Normal

DIET
Normal, may alter as necessary for cats with diarrhea, kidney disease.

CLIENT EDUCATION
• Inform client that infection is slowly progressive and healthy antibody-positive cats may remain healthy for years.
• Advise client that cats with clinical signs will have recurrent or chronic health problems that require medical attention.
• Discuss importance of keeping cats indoors to protect them from exposure to secondary pathogens and to prevent spread of FIV.

SURGICAL CONSIDERATIONS
• Oral treatment or surgery—dental cleaning, tooth extraction, gingival biopsy as needed; gingivitis and stomatitis may be refractory to treatment.
• Biopsy or removal of neoplastic lesions.

MEDICATIONS

DRUG(S) OF CHOICE
• Zidovudine (Retrovir®) 5–10 mg/kg PO q12h—antiviral agent; most effective against acute infection; monitor for bone marrow toxicity.
• Immunomodulatory drugs—may alleviate some clinical signs:
  ◦ α-interferon (Roferon®-A)—diluted in saline at 30 units/day PO for 7 days, every other week; may increase survival rates and improve clinical status.
  ◦ Feline omega-interferon (Virbagen® Omega)—1 million units/kg/day SC q24h for 5 days at 3 intervals (d0–4, d14–18, d60–64); lower-dose oral protocols may be effective.
• Antibacterial or antimycotic drugs—as indicated; prolonged therapy or high dosages may be required.
• Corticosteroids or gold salts—judicious but aggressive use may help control immune-mediated inflammation.
• Topical corticosteroids—for anterior uveitis; long-term response may be incomplete or poor; pars planitis often regresses spontaneously and may recur.
• Glaucoma—standard treatment.
• Vaccinate for respiratory and enteric pathogens based on individual risk assessment. Rabies vaccination according to regulatory guidelines.

CONTRAINDICATIONS
• Griseofulvin—avoid or use with extreme caution in FIV-positive cats; may induce severe neutropenia; neutropenia is reversible if drug is withdrawn early enough, but secondary infections can be life-threatening.

PRECAUTIONS
Systemic corticosteroids—use with caution; may lead to further immunosuppression.

ALTERNATIVE DRUG(S)
• *Propionibacterium acnes* (ImmunoRegulin®)—0.5 mL/cat IV once or twice weekly.
• Acemannan (Carrisyn®)—100 mg/cat PO q24h.

FOLLOW-UP

PATIENT MONITORING
Varies according to secondary infections and other manifestations of disease.

PREVENTION/AVOIDANCE
• Prevent contact with FIV-positive cats.
• Quarantine and test incoming cats before introducing into multicat households.
• Vaccine no longer available in the U.S.

EXPECTED COURSE AND PROGNOSIS
• Approx. 20% of cats die within 2 years of diagnosis or 4.5–6 years after estimated time of infection, but >50% remain asymptomatic.
• In late stages of disease (wasting and frequent or severe opportunistic infections), life expectancy ≤1 year.
• Overall survival time and quality of life for many FIV-positive cats will be similar to uninfected cats.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Secondary bacterial, viral, fungal, and parasitic disease.
• Lymphoid tumors.
• Immune-mediated disease.

AGE-RELATED FACTORS
Kittens (up to 4–6 months old) may test positive because of passive antibody transfer.

ZOONOTIC POTENTIAL
• None known.
• Potential transmission of secondary pathogens (e.g., *Toxoplasma gondii*) to immunocompromised humans.

PREGNANCY/FERTILITY/BREEDING
FIV-positive queens—reported abortions and stillbirths; transmission to kittens infrequent if queen is antibody-positive before conception; rate of transmission may be subtype or strain-dependent (>90% for experimental infections with some strains).

SYNONYMS
Feline immunodeficiency syndrome.

SEE ALSO
• Feline Calicivirus Infection.
• Feline Herpesvirus Infection.
• Feline Leukemia Virus (FeLV) Infection.
• Feline Stomatitis—Feline Chronic Gingivostomatitis (FCGS).

F

FELINE INFECTIOUS DIARRHEA

BASICS

DEFINITION
• Diarrhea is defined as excess fecal water, increased quantity of fecal material, or increased frequency of bowel movements.
• Etiologies include viral, enteropathogenic bacterial, protozoal, fungal, or helminths; small bowel, large bowel, or mixed bowel diarrhea.
• Secondary systemic signs likely with infection by feline immunodeficiency virus (FIV), feline leukemia virus (FeLV), feline enteric coronavirus (FECV), feline parvovirus (FPV), histoplasmosis.
• Presence of organisms on diagnostic screening does not indicate causation; patient factors (clinical signs, age, environmental exposure) should be considered before treatment.
• Some cats will have self-resolution; diagnostic testing may be appropriate for more severely affected animals or if clinical signs are persistent despite supportive care and having ruled out other causes of acute or chronic diarrhea; kittens with acute diarrhea should be screened for FPV.

PATHOPHYSIOLOGY
• Typically, fecal–oral route of infection.
• Diarrhea may result from decreased intestinal absorption or increased intestinal secretion caused by enterotoxins, osmotic forces, or epithelial damage.
• Immune response to infectious organisms can contribute to development of diarrhea; activated white blood cells release inflammatory mediators that stimulate secretion and damage intestinal epithelium.

SYSTEMS AFFECTED
• Cardiovascular—fluid balance.
• Gastrointestinal (GI).

GENETICS
Feline infectious peritonitis (FIP) more likely in purebred cats.

INCIDENCE/PREVALENCE
• 84% of cats from shelters had enteropathogens—no difference with or without diarrhea.
• FECV more common in cats with diarrhea.

GEOGRAPHIC DISTRIBUTION
• Widespread.
• Prevalence of etiologies varies by region.
• Histoplasma more common in eastern United States, Latin America.

SIGNALMENT

Species
Cat

Breed Predilections
Purebred cats have higher prevalence of FIP.

Mean Age/Range
Young cats more likely to develop diarrhea from FECV, FPV, *Cryptosporidium*, helminths; FIP has bimodal distribution (young and old).

Predominant Sex
FIP more frequent in males.

SIGNS

General Comments
Range from mild to severe.

Historical Findings
• Acute or chronic, small or large bowel diarrhea.
• Possibly lethargy, vomiting, weakness, weight loss, hyporexia.
• Crowded environment.

Physical Examination Findings
• Dehydration.
• Poor body condition.
• Fluid/gas-filled intestinal loops.
• Signs of sepsis or systemic inflammatory response syndrome (SIRS) possible—tachycardia, hypotension, hyper/hypothermia, tachypnea, pale mucous membranes.
• Abdominal masses or enlarged lymph nodes may be palpable (histoplasmosis, FIP).
• With systemic infections may note chorioretinitis, icterus, neurologic deficits.

CAUSES
• Viral—FECV, FPV, astrovirus, calicivirus, FIV, FeLV, torovirus-like agent.
• Bacterial—*Campylobacter* spp., *Clostridium perfringens* enterotoxin A, *Clostridium difficile* toxins, *Salmonella* spp., *Escherichia coli, Yersinia spp.*
• Helminth—*Toxocara* spp., *Ancylostoma* spp., *Strongyloides* spp., *Toxascaris leonine, Spirometra* spp., *Trichuris vulpis.*
• Protozoal—*Giardia* spp., *Tritrichomonas foetus, Toxoplasma gondii.*
• Coccidial—*Cryptosporidium* spp., *Cystoisospora* spp.
• Fungal—*Histoplasma capsulatum.*

RISK FACTORS
• Pediatric, young adult cats more commonly affected, particularly with helminths, viral, and coccidial disease.
• Crowding, poor sanitation increase risk of transmission.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Acute diarrhea—dietary indiscretion, foreign body, GI neoplasia; non-GI diseases: hyperthyroidism, iatrogenic, hepatotoxicity, renal disease, and other systemic diseases (frequently have hyporexia, vomiting, icterus).
• Chronic diarrhea—chronic enteropathy (dietary responsive, antibiotic responsive, dysbiosis, or inflammatory bowel disease), primary GI neoplasia, pancreatic insufficiency, and hepatic or renal disease.

CBC/BIOCHEMISTRY/URINALYSIS
• Eosinophilia with intestinal parasitism or histoplasmosis.
• Leukopenia with FPV, sepsis from salmonellosis or translocation, bone marrow involvement with histoplasmosis or FeLV.
• Anemia and microcytosis suggest GI hemorrhage or iron deficiency, particularly with high worm burden.
• Elevated liver enzyme activities or creatine kinase with toxoplasmosis.
• Hyperglobulinemia, elevated total bilirubin with FIP.
• Hemoconcentration, prerenal azotemia, electrolyte derangements with dehydration.
• Panhypoproteinemia if protein-losing enteropathy or GI blood loss.

IMAGING
• Abdominal radiographs if no response to symptomatic care to rule out other causes of diarrhea.
• Abdominal ultrasound recommended in nonpediatric patients with diarrhea nonresponsive to symptomatic care.
• Thoracic radiographs may show pulmonary disease or enlarged lymph nodes with histoplasmosis or toxoplasmosis.

DIAGNOSTIC PROCEDURES
• Fecal flotation—for intestinal parasitism; false negatives are possible as ova are intermittently shed; cats suspected to have intestinal parasitism should have multiple fecal flotations or be treated with anthelmintics.
• Fecal cytology—bacterial morphology (frequent spirochetes, spores) or presence of fungal or protozoal organisms.
• *Giardia* ELISA.
• Tritrichomonas PCR using "colonic flush" technique.
• Histoplasma enzyme immunoassay (EIA)—urine.
• Toxoplasmosis immunofluorescence antibody test (IFA) for immunoglobulin (Ig) G and IgM, rising titer between acute and convalescent samples.
• FIV antibody, FeLV antigen ELISA.
• Infectious diarrhea PCR panels assess for range of infectious causes of diarrhea; caution should be used in interpretation; positive results do not necessarily indicate causation and false-negative results possible.

PATHOLOGIC FINDINGS
• Gross examination of intestinal mucosa may demonstrate parasites attached to intestinal mucosa with multifocal hemorrhagic ulcerations, submucosal congestion or hemorrhage, intestinal wall thickening, lymphadenopathy.
• Histopathology of intestine may show eosinophilic, neutrophilic, pyogranulomatous, or lymphoplasmacytic enteritis with varying

degrees of hemorrhage and necrosis, depending on etiology; may visualize causative agent.

TREATMENT

APPROPRIATE HEALTH CARE
- Mildly affected cats treated as outpatients.
- Moderate to severely affected cats may require IV fluids for dehydration/electrolyte management.
- Dextrose should be supplemented parenterally for hypoglycemia,

ACTIVITY
N/A

DIET
- Diets high in easily digestible protein, including adequate taurine.
- In anorexic pediatric patients, nasogastric tube feeding of liquid diet recommended if anorexia >48 hours.

CLIENT EDUCATION
- For most infectious organisms, environmental decontamination prevents reinfection and transmission to other pets/humans; isolation during hospitalization may be warranted depending on cause.
- Appropriate vaccination and deworming schedules should be followed.
- Cats with identified infectious causes of diarrhea should be isolated from other cats until clinical signs resolve; *Histoplasma* not directly transmitted from cat to other hosts.

SURGICAL CONSIDERATIONS
Viral and parasitic enterocolitis can result in intussusceptions.

MEDICATIONS

DRUG(S) OF CHOICE
- Many cases self-resolve with supportive care and time.
- Empiric therapy, pending diagnostics if clinical signs persist—probiotics (Visbiome® 112.5 billion bacteria/cat/day), or metronidazole 10 mg/kg PO q12h, with fenbendazole 50 mg/kg PO q24h for 5 days.
- Anthelmintics—fenbendazole 50 mg/kg PO q24h for 5 days; pyrantel pamoate 10 g/kg PO q24h for 3 days.
- Coccidiostatic—sulfadimethoxine 50–60 mg/kg PO q24h for 5–10 days; ponazuril 50 mg/kg PO once.
- Campylobacteriosis with persistent clinical signs—erythromycin 10–15 mg/kg PO q8h; azithromycin 5–10 mg/kg PO q24h.
- Histoplasmosis—itraconazole 5–10 mg/kg PO q12–24h: do not use compounded formulations.
- Toxoplasmosis—clindamycin 10–17 mg/kg PO/IM/IV q8–12h for 4 weeks.
- Trichomoniasis—ronidazole 30 mg/kg PO q24h for 14 days.
- Patients with sepsis or leukopenia should be treated with broad-spectrum antibiotics.
- Cats with confirmed salmonella should *not* be treated with antibiotics unless systemically ill.

CONTRAINDICATIONS
N/A

PRECAUTIONS
- Metronidazole dose should be reduced in animals with hepatic insufficiency.
- Clindamycin should be given with food or water to prevent development of esophageal strictures.
- Ronidazole can cause neurotoxicity and should be discontinued if clinical signs including anorexia develop.

POSSIBLE INTERACTIONS
Dependent on drug used; itraconazole has many interactions.

FOLLOW-UP

PATIENT MONITORING
- Case-based, may include reassessment of anemia, leukopenia, or electrolyte derangements as appropriate.
- Persistent clinical signs after appropriate treatment suggest alternative cause of diarrhea.
- Patients with recurrent clinical signs should be retested, particularly if environmental reinfection possible (e.g., giardiasis, campylobacteriosis).

PREVENTION/AVOIDANCE
- Routine vaccination.
- Monthly flea and heartworm preventative with combination anthelmintic therapy.
- Maintain clean facilities and quarantine ill patients.
- Do not allow nonimmunocompetent patients to contact other animals until determined to be low risk.

POSSIBLE COMPLICATIONS
- Sepsis.
- Anemia.
- Dehydration, electrolyte, acid-base disturbances.

EXPECTED COURSE AND PROGNOSIS
- Usually good to excellent; underlying immunosuppressive conditions may increase susceptibility to infection and worsen prognosis.
- Infectious agents that cause systemic illness likely have worse prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Young animals more susceptible.

ZOONOTIC POTENTIAL
- Toxoplasmosis—human abortion.
- Giardiasis—low risk of transmission.
- Cryptosporidiosis.
- Salmonellosis.
- *Campylobacter jejuni*.
- *Toxocara* spp. (ascarids)—visceral larval migrans, most common in children.
- *Ancylostoma* (hookworms)—cutaneous larval migrans, most common in children.

PREGNANCY/FERTILITY/BREEDING
Patients exhibiting clinical signs of illness should not be bred. If illness develops while pregnant, take caution regarding drug choice.

FELINE INFECTIOUS PERITONITIS (FIP)

BASICS

DEFINITION
A systemic, immune-mediated, viral disease of cats characterized by insidious onset, persistent fever, pyogranulomatous tissue reaction, exudative effusions in body cavities, and high mortality.

PATHOPHYSIOLOGY
- The term feline coronavirus (FCoV) encompasses feline enteric coronavirus (FECV) and feline infectious peritonitis virus (FIPV).
- FECV is common and highly infectious; replicates locally in intestinal tract.
- FIPV infects monocytes/macrophages, which disseminate virus throughout body; localizes at vein wall and perivascular sites.
- FIP is an immune-mediated disease—perivascular accumulation of virus-infected macrophages and inflammatory cells produces pyogranulomatous inflammation in various organs.

SYSTEMS AFFECTED
- Multisystemic—pyogranulomatous or granulomatous lesions on omentum, serosal surface of abdominal organs, within abdominal lymph nodes, and submucosa of intestinal tract.
- Nervous—vascular lesions throughout CNS, especially in meninges.
- Ophthalmic—uveitis, chorioretinitis, and iritis.
- Respiratory—lesions on lung surfaces, pleural effusion.

INCIDENCE/PREVALENCE
- Prevalence of antibodies against FCoV—high, due to widespread presence of FECV, especially in multicat facilities.
- Incidence of FIP—low in most populations, especially in single-cat households.
- Because of difficulty in diagnosis, control, and prevention, outbreaks within breeding catteries may be catastrophic; in endemic catteries, risk of FCoV antibody–positive cat eventually developing FIP is usually <10%.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Species
Cats—domestic and exotic.

Breed Predilections
Some bloodlines or breeds of cats may be more susceptible.

Mean Age and Range
Highest incidence in kittens 3 months–2 years of age.

SIGNS
General Comments
- Variable, depending on effectiveness of cell-mediated immune response, and organ system(s) affected.
- Two classic forms—wet (effusive) and dry (noneffusive); depends on presence of effusion in body cavities; dry form may become wet form with disease progression.

Historical Findings
- Insidious onset.
- Gradual weight loss and inappetence.
- Stunted growth in kittens.
- Gradual increase in size of abdomen due to effusion.
- Persistent fever—fluctuating, antibiotic unresponsive.

Physical Examination Findings
- Depression.
- Fever.
- Poor condition.
- Stunted growth.
- Dull, rough hair coat.
- Icterus.
- Abdominal and/or pleural effusion.
- Palpable abdominal masses (granulomas or pyogranulomas).
- Ocular—anterior uveitis, keratic precipitates, iris color change, irregularly shaped pupil.
- Neurologic—seizure, ataxia, paresis/paralysis, abnormal behavior, cranial nerve deficits.

CAUSES
- Prevailing theory is that FECV mutates to FIPV during FECV infection in individual cats; weak cell-mediated immunity plays a role in development of FIP.
- FCoV has two genomic types (FCoV type 1 and 2) and two biotypes (FECV and FIPV).
- FCoV type 1 is predominant (>85%); both types 1 and 2 can cause FIP.
- FECV—enteritis; highly transmissible among cats.
- FIPV—systemic, fatal disease (FIP); cat-to-cat transmission unlikely.

RISK FACTORS
- Contact with FECV-shedding cat; >30% of cats are chronic shedders.
- Breeding catteries or multicat facilities.
- Less than 2 years of age.
- Feline leukemia virus (FeLV) or feline immunodeficiency virus (FIV) infection.
- Certain cat breeds have higher incidence of FIP, especially dry form; some breeding pairs are prone to producing litters that develop FIP.

DIAGNOSIS
- Wet form—straightforward clinical diagnosis.
- Dry form—difficult to diagnose.
- Reverse-transcription polymerase chain reaction (RT-PCR) or immunohistochemistry on effusion or affected tissue confirmatory.
- No single diagnostic laboratory test.

DIFFERENTIAL DIAGNOSIS
- Fever of unknown origin—infection, inflammation.
- Pleural effusion—cardiac disease; cardiac effusion has low specific gravity and cell count.
- Neoplasia—lymphoma, other causing abdominal organ enlargement/effusion.
- CNS signs—neoplasia, toxoplasmosis.
- Anemia and icterus—blood parasites causing hemolysis.
- Pansteatitis (yellow fat disease)—classic feel and appearance of fat within abdominal cavity; pain on abdominal palpation; often a fish-only diet.
- Leukopenia, enteritis—panleukopenia (see Feline Panleukopenia).

CBC/BIOCHEMISTRY/URINALYSIS
- Leukocytosis with neutrophilia and lymphopenia.
- Mild to severe anemia.
- High total plasma protein, specifically globulin fraction (serum albumin : globulin typically <0.8).
- Hyperbilirubinemia and hyperbilirubinuria.

OTHER LABORATORY TESTS
- Serum antibody tests—detect antibodies against FCoV; positive tests not diagnostic of FIP (indicate only previous FECV infection); likelihood of FIP increases with titers ≥1 : 3200, but low titers do not exclude FIP.
- RT-PCR—detect viral genome; positive tests on blood or stool not diagnostic of FIP; positive tests on effusion or tissues confirm FIP.
- Immunohistochemistry—detect virus in biopsy or tissue samples; excellent for confirming cause of specific lesions, especially abdominal disease, which often is not diagnosed as FIP.

IMAGING
- May confirm abdominal and pleural effusions.
- May detect granulomatous lesions.

DIAGNOSTIC PROCEDURES
- Thoracocentesis and/or abdominocentesis—fluid pale to straw colored, viscous with flecks of fibrin, specific gravity 1.017–1.047; fluid may be used for RT-PCR or immunohistochemistry.
- Laparoscopy—to observe specific lesions of peritoneal cavity and obtain biopsy samples.
- Exploratory laparotomy—may be indicated for difficult-to-diagnose patients.

PATHOLOGIC FINDINGS
Gross
- Variable, patient generally emaciated, with rough hair coat.

(CONTINUED) FELINE INFECTIOUS PERITONITIS (FIP)

• Abdomen and/or thoracic cavity—may contain thick, viscous exudates.
• White, rough, pyogranulomatous plaques or granulomas—may be on serosal surface of abdominal organs and omentum; fibrous strands may extend between organs.
• Discolored iris with anterior uveitis—may see keratic precipitates.
• Lesions in brain and/or spinal cord possible

Histopathologic

• Granulomas or pyogranulomas in any affected tissue.
• Lesions—perivascular; increase in size, involving large portions of tissue; microscopic appearance suggests diagnosis.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient or outpatient, depending on severity of disease and owner's willingness and ability to provide good supportive care.

NURSING CARE

• Therapeutic paracentesis—to relieve pressure/dyspnea from ascites or pleural effusions.
• Encourage cat to eat.

ACTIVITY

FIP transmission to other cats unlikely; no or low levels of FIPV shedding.

DIET

Any food that will entice patient to eat.

CLIENT EDUCATION

• Discuss various aspects of disease, including grave prognosis; once clinical FIP is confirmed, nearly 100% of cats will die of disease.
• Inform client of high prevalence of FECV infection but low incidence of FIP; <10% of FCoV antibody–positive cats <2 years of age eventually develop clinical disease.

SURGICAL CONSIDERATIONS

• Generally none.
• Rarely, inflammatory abdominal disease from FIP may cause intestinal obstruction.

MEDICATIONS

DRUG(S) OF CHOICE

• No cure; only symptomatic treatment is available.
• Immunosuppressive drugs (e.g., oral prednisolone)—may alleviate some symptoms.
• Feline omega interferon—unclear effectiveness in symptomatic management.
• Antibiotics—generally not necessary.

ALTERNATIVE DRUG(S)

Direct-acting antiviral drugs for FIP have shown effectiveness in treatment and are under development.

FOLLOW-UP

PATIENT MONITORING

Monitor for development of pleural effusion or neurologic disease.

PREVENTION/AVOIDANCE

• Modified live intranasal vaccine—against FIPV; low efficacy; cannot rely on vaccination alone for control; will produce antibody-positive cats, complicating monitoring in catteries or colonies; not generally recommended.
• Mother/offspring—main method of transmission appears to be from asymptomatic carrier queens to their kittens at 4–7 weeks of age, after maternal immunity wanes; break cycle of transmission by early weaning at 4–5 weeks of age and isolating litter from direct contact with other cats, including queen.
• Routine disinfection to reduce FECV transmission—premises, cages, and water/food dishes; common disinfectants readily inactivate virus.
• Introduce only FCoV antibody–negative cats to catteries or colonies that are free of virus.
• Avoid breeding pairs that are prone to producing litters that develop FIP.

POSSIBLE COMPLICATIONS

Pleural effusion may require thoracocentesis; supportive care for other clinical signs.

EXPECTED COURSE AND PROGNOSIS

• Clinical course—a few days to several months until euthanasia is warranted.
• Prognosis grave once clinical signs occur; mortality nearly 100%.

MISCELLANEOUS

ASSOCIATED CONDITIONS

FeLV or FIV-positive cats—more prone to developing FIP.

PREGNANCY/FERTILITY/BREEDING

FIPV transmission from mother to offspring during pregnancy is presumed rare.

SYNONYMS

• Feline coronaviral polyserositis.
• Feline coronaviral vasculitis.
• Systemic feline coronavirus infection.

ABBREVIATIONS

• FCoV = feline coronavirus.
• FECV = feline enteric coronavirus.
• FeLV = feline leukemia virus.
• FIP = feline infectious peritonitis.
• FIPV = feline infectious peritonitis virus.
• FIV = feline immunodeficiency virus.
• RT-PCR = reverse-transcription polymerase chain reaction.

FELINE ISCHEMIC ENCEPHALOPATHY

BASICS

DEFINITION
• Seasonal neurologic disease that occurs in outdoor cats or those with access to outdoors in North America during late spring, summer, and early fall; usually results in sudden onset of seizures, circling, altered mentation, and/or blindness; however, any neurologic abnormalities can be found in these cats.
• Aberrant migration of *Cuterebra* larva in the brain of a cat that often causes thrombosis or vasospasm of middle cerebral artery with ensuing ischemic necrosis; degeneration of superficial layers of cerebral cortex and parenchymal destruction associated with physical migration of larva in brain parenchyma.
• Must be differentiated from other causes of vascular diseases affecting brains of cats as well as other neurologic diseases of cats.

PATHOPHYSIOLOGY
• In feline ischemic encephalopathy (FIE), *Cuterebra* larva enters nasal passage of cat, migrates through cribriform plate into olfactory bulb of the brain, then along olfactory peduncle and sometimes continues in parenchyma of brain, or alternatively in subarachnoid space; parasite then, if still alive, migrates caudally, where it may compromise the middle cerebral artery (MCA) physically through spines on the larvae's body, or possibly via chemical agent secreted by parasite causing vasospasm to vessel; or vasospasm may be secondary to hemorrhage caused by parasite; parasite may then die in subarachnoid space (SAS) or within parenchyma.
• Adult botfly lays eggs by entrance of rodent's den; eggs hatch into L1 stage of larva, which attaches to hair of mouse or rabbit and enters body through a normal orifice (mouth, nose, eye, or anus) and migrates into associated tissues (nasopharynx, trachea, thoracic cavity, diaphragm, abdominal cavity); then larva continues its migration to reach subcutaneous site in inguinal or thoracic region where it matures first to L2 stage and then within warble to L3 larval stage, emerges through skin, drops off host, pupates in soil over winter, and then emerges in spring as an adult botfly. Adult lays eggs near entrance of rodent's den; eggs hatch to form L1 larvae… When cat hunts near rodent's den, L1 larva attaches to cat's hair and gains access to nasal passage of cat and begins catastrophic pathway of FIE.
• Occasionally larva does not migrate through cribriform plate but embeds in nasal passage or respiratory tract of cat, causing focal respiratory signs; larva has also been found in the eye and oropharyngeal region.

SYSTEMS AFFECTED
• Brain and less commonly spinal cord.
• Larvae can also be found in skin, nasal passage, pharynx, larynx, eye, trachea, and thorax of cats.

GENETICS
None

INCIDENCE/PREVALENCE
Not known.

GEOGRAPHIC DISTRIBUTION
• North America only.
• Same distribution as *Cuterebra* botfly.
• Disease not recognized in locations that do not have *Cuterebra* botfly, such as Australia and Japan.

SIGNALMENT

Breed Predilections
None

Mean Age and Range
• Median age—2 years old.
• Range—1–7 years old.

Predominant Sex
None

SIGNS
• Sudden onset of neurologic signs.
• Often preceded by upper respiratory signs 1–3 weeks prior to neurologic signs (due to migration of the parasite in the nasal passage).
• Often prosencephalic signs.
• Most commonly—seizures, circling, altered mentation, blindness.
• Sometimes multifocal neurologic signs.
• Rarely spinal cord signs.
• May stop meowing/develop aphasia.

CAUSES
Cuterebra larvae.

RISK FACTORS
• Outdoor cats; access to outdoors.
• Not reported in indoor only cats.
• July, August, and September in northeast United States and southeast Canada; can be found in May and June in southeast United States.
• Hunting cats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other causes of vascular accidents in brain such as renal disease and hyperthyroidism with hypertension.
• External trauma.
• Tumors—usually progressive rather than sudden in onset.
• Infectious/inflammatory diseases—such as those caused by *Cryptococcus* sp., *Toxoplasma gondii*, feline infectious peritonitis (FIP) virus, and feline immunodeficiency virus (FIV).

CBC/BIOCHEMISTRY/URINALYSIS
• Usually normal.
• CBC—occasionally neutrophilia, leukocytosis, or eosinophilia.
• Chemistry—occasionally elevated globulins or hyperglycemia.

OTHER LABORATORY TESTS
• Serology for feline leukemia virus (FeLV), FIV, FIP—negative.
• Cryptococcal antigen titers—negative.
• Toxoplasma immunoglobulin (Ig) G and IgM—negative.

IMAGING
• MRI—diagnostic modality of choice; detect track lesion extending from cribriform plate into olfactory bulb and frontal, parietal, and temporal lobes best recognized on dorsal sequences; may see abnormalities in ipsilateral nasal passage; may also see area of ischemic infarction in brain; if performed soon after onset of signs, increased signal intensity on T2 weighted, proton density weighted, and fluid attenuated inversion recovery (FLAIR) images associated with ischemia of superficial layers of cerebral cortex, or the area supplied by MCA; scant parenchymal enhancement in area of infarction after administration of contrast. If MRI is done more then 2–3 weeks after onset of signs, may find loss of overlying gray matter in region supplied by MCA and associated hydrocephalus ex vacuo. Magnetic resonance angiography (MRA; time of flight or postcontrast) may be of some utility in some cases.
• CT—limited value.

DIAGNOSTIC PROCEDURES
Cerebrospinal fluid—normal or nonsuppurative inflammation with macrophages, lymphocytes, or eosinophils.

PATHOLOGIC FINDINGS
• Local areas of malacia and hemorrhage involving olfactory bulbs and peduncles on brain transverse sections. Thorough examination of nasal passage, cribriform plate, olfactory bulbs, and peduncles, as well as remaining parenchyma, meninges, and overlying calvaria, may reveal the larva, which is approximately 5–10 mm in length (stage 2 larva), tan, and with concentric rings of spines along length of body.
• Histopathologic features may include necrosis and hemorrhage of parasitic track, or less specific findings such as superficial laminar cerebrocortical necrosis, cerebral infarction, subependymal rarefaction, and astrogliosis and subpial astrogliosis.

TREATMENT

NURSING CARE
• Padded cage may be necessary if cat is having seizures.
• Swivel IV line can be used if patient exhibits propulsive/compulsive circling or loss of balance.

(CONTINUED) # FELINE ISCHEMIC ENCEPHALOPATHY

CLIENT EDUCATION
- Only occurs in outdoor cats and those with access to outdoors; strictly indoor cats do not develop FIE.
- Only occurs in summer months, with majority of patients seen during July, August, and September in the northeast United States and southeast Canada.
- May not occur in major metropolitan areas that do not have normal appropriate hosts such as cottontail rabbit.

SURGICAL CONSIDERATIONS
Successful removal of parasite from the brain/spinal cord has not been reported in cats, but may be possible if neuroimaging is available early after onset of clinical signs.

MEDICATIONS

DRUG(S) OF CHOICE
- Supportive care including antiepileptic drugs and appropriate fluid supplementation, which may include thiamine administration and additional potassium IV depending on nutritional status of patient; typically phenobarbital is used at maintenance dose of 7.5–15 mg PO/IM/IV q12h/cat; in addition phenobarbital can be loaded at a total loading dose of 16 mg/kg IV/PO/IM; this dose is usually divided over 24–48h (e.g., 4 mg/kg q12h for 2 days); then maintenance dose is started; diazepam can be used at 2.5–5 mg IV to stop cluster seizures or status epilepticus; other anticonvulsants, such as levetiracetam, may also be utilized.
- Cocktail treatment has been proposed for recently affected cats—diphenhydramine IM at 4 mg/kg 1–2h before giving ivermectin SC at 200–500 µg/kg and prednisolone sodium succinate at 30 mg/kg IV; treatment is repeated at 24h and 48h after first injection of ivermectin; in addition patients receive prednisone at 5 mg/cat q12h PO for 14 days and enrofloxacin at 22.7 mg PO q12h for 14 days. Because of concerns of blindness in some cats with administration of enrofloxacin, pradofloxacin or other antibiotics with broad-spectrum utility can be considered; ivermectin is not approved for use against *Cuterebra* larva so appropriate client permission must be obtained prior to administration; this cocktail treatment is not for patients with clinical signs >1 week as parasite is likely already dead.

CONTRAINDICATIONS
Do not use ivermectin in cats with known sensitivity.

PRECAUTIONS
No adverse effects from ivermectin have been noted; however, anaphylactic or allergic reaction could occur if *Cuterebra* larva suddenly dies and releases possible foreign antigens.

ALTERNATIVE DRUG(S)
Can use dexamethasone instead of prednisone.

FOLLOW-UP

PATIENT MONITORING
Sequential neurologic evaluations.

PREVENTION/AVOIDANCE
- Keep cat indoors.
- Use of monthly fipronil, imidacloprid, selamectin, or ivermectin has been suggested to prevent infections with *Cuterebra* parasite in outdoor cats.

POSSIBLE COMPLICATIONS
- May continue to have uncontrolled seizures.
- May continue to circle compulsively/propulsively.
- May have behavioral changes such as aggression, especially in cats with damage to piriform lobe.
- May stop meowing/develop aphasia in some cats.

EXPECTED COURSE AND PROGNOSIS
After initial onset, many patients improve and become acceptable pets; there may be persistent deficits, seizures, circling, and undesirable behavior such as aggression; may develop aphasia; persistent clinical signs depend on damage caused by infarction and parasitic migration.

MISCELLANEOUS

ASSOCIATED CONDITIONS
None

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
None; however, aberrant *Cuterebra* larva migration has been reported in humans, most commonly as ocular form in children.

SYNONYMS
CNS cuterebriasis.

FELINE LEUKEMIA VIRUS (FeLV) INFECTION

BASICS

DEFINITION
A simple retrovirus (*Gammaretrovirus* genus) that causes immunodeficiency and neoplastic disease in domestic cats.

PATHOPHYSIOLOGY
- Four subgroups of feline leukemia virus (FeLV)—A, B, C, and T; FeLV-A most transmissible and present in all isolates; FeLV-B arises from recombination of FeLV-A *env* gene with endogenous retroviral sequences (50% of isolates); FeLV-C (1% of isolates) arises from mutation in *env* gene sequences; FeLV-T infects only T cells.
- Early infection (five stages)—(1) viral replication in tonsils and pharyngeal lymph nodes; (2) infection of circulating B lymphocytes and macrophages that disseminate virus; (3) replication in lymphoid tissues, intestinal crypt epithelial cells, bone marrow precursor cells; (4) release of infected neutrophils and platelets from bone marrow; and (5) infection of epithelial and glandular tissues, subsequent shedding of virus into saliva, urine.
- *Abortive infection*—if virus replication terminated at stage 1; no viremia.
- *Regressive or nonproductive infection*—immune response stops progression at stage 2 or 3 (4–8 weeks after exposure) and forces virus into latency after transient viremia; may be reactivated with immune suppression or other viral infections.
- *Progressive or productive infection*—immune response not effective, persistent viremia (stages 4 and 5) from 4–12 weeks after infection.
- Tumor induction—DNA provirus integrates into cat chromosomal DNA in critical regions near oncogenes (e.g., *c-myc* or genes influencing *c-myc* expression); thymic lymphosarcoma results.
- Feline sarcoma viruses—FeLV mutants; arise by recombination between FeLV and host genes; virus–host fusion proteins responsible for induction of fibrosarcomas.
- Pathogenesis influenced by presence of other viruses (e.g., feline foamy virus, feline coronavirus, feline immunodeficiency virus [FIV]) or endogenous retroviruses.

SYSTEMS AFFECTED
- Hemic/lymphatic/immune—bone marrow dyscrasia, neoplasia, immunosuppression.
- Nervous—degenerative myelopathy, neoplasia.
- Other body systems—immunosuppression with secondary infections or neoplasia.

GENETICS
N/A

INCIDENCE/PREVALENCE
- In United States, 2–3% in healthy cat population; worldwide infection rate 1–8% in healthy cats; 3–4 times greater in clinically ill cats.
- Decline in US prevalence since 1980s.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Species
Cat

Mean Age and Range
- Prevalence highest between 1 and 6 years of age.
- Mean—3 years.

Predominant Sex
Male : female ratio—1.7 : 1.

SIGNS
General Comments
- Onset of FeLV-associated disease—months to years after infection.
- Associated diseases—non-neoplastic or neoplastic; most non-neoplastic or degenerative diseases result from immunosuppression.
- Regressive infections may be associated with cardiomyopathies, lymphomas, leukemias, anemia, other infections.
- Clinical signs of FeLV-induced immunodeficiency cannot be distinguished from FIV-induced immunodeficiency.

Historical Findings
- Outdoor cat.
- Multicat household.

Physical Examination Findings
- Depend on type of disease (neoplastic or non-neoplastic) and secondary infections.
- Lymphadenomegaly—mild to severe.
- Fever, wasting.
- Upper respiratory tract—rhinitis, conjunctivitis, keratitis.
- Persistent diarrhea—bacterial or fungal overgrowth, parasite-induced inflammation, direct effect on crypt cells.
- Gingivitis, stomatitis, periodontitis.
- Nonresponsive or recurrent infections of external ear and skin.
- Lymphoma—risk increased 62-fold in FeLV-infected cats; thymic and multicentric; extranodal lymphoma can affect eye, nervous system.
- Erythroid and myelomonocytic leukemias.
- Fibrosarcomas—coinfection with mutated sarcoma virus; frequently young cats.
- Peripheral neuropathies; progressive ataxia.

CAUSES
- Cat-to-cat transmission—close casual contact (grooming), shared dishes or litter pans, bites.
- Perinatal transmission—transplacental and transmammary transmission in ≥20% of surviving kittens from infected queens.

RISK FACTORS
- Age—kittens more susceptible than adults.
- Male—result of behavior.
- Free-roaming.
- Multicat household.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- FIV.
- Other infections—bacterial, parasitic, viral, or fungal.
- Nonviral neoplastic diseases.

CBC/BIOCHEMISTRY/URINALYSIS
- Anemia—often severe, often nonregenerative; regenerative anemias usually associated with *Mycoplasma haemofelis* or *M. haemominutum* coinfections.
- Lymphopenia or lymphocytosis.
- Neutropenia—sometimes cyclic; may be response to secondary infections or immune-mediated disease.
- Thrombocytopenia and immune-mediated hemolytic anemia.
- Biochemistry/urinalysis abnormalities depend on affected organs.

OTHER LABORATORY TESTS
- Immunochromatography (lateral flow) and ELISA—point-of-care screening, detect antigen in plasma, serum, saliva, tears; more sensitive than immunofluorescent antibody (IFA) for early or transient infection; single positive test does not predict persistent viremia (retest in 12 weeks); confirm positive tests with another method.
- IFA—identify FeLV antigen in leukocytes and platelets in fixed smears of whole blood or buffy coat; positive result indicates productive bone marrow infection; 97% of IFA-positive cats persistently infected and viremic for life; antigen usually detected by 4 weeks after infection, but may be up to 12 weeks; for leukopenic cats, use buffy coat smears rather than whole blood smears; confirm positive tests.
- FeLV vaccination does not interfere with antigen testing.
- PCR for proviral DNA in blood or tissue—denotes exposure, confirm with antigen test; proviral DNA detectable 1–2 weeks after infection; proviral loads can differentiate cats with regressive versus progressive infections.
- Reverse transcription PCR (RT-PCR) for viral RNA (virus circulating or replicating within cells) in saliva or blood—denotes viremia and FeLV shedding; first test to become positive as early as 1 week after infection.
- Multiple tests over several months may be needed to clarify FeLV status and whether infection progressive or regressive; a few cats have persistently discordant ELISA-positive and IFA-negative tests or test positive only sporadically.

IMAGING
Thymic atrophy (fading kittens); mediastinal mass and pleural effusion with thymic lymphoma.

(CONTINUED)

FELINE LEUKEMIA VIRUS (FeLV) INFECTION

DIAGNOSTIC PROCEDURES
Bone marrow aspiration or biopsy—arrest in erythroid differentiation; true aplastic anemia with hypocellular bone marrow may be seen; some cases of anemia result from myelopthesis.

PATHOLOGIC FINDINGS
- Bone marrow hypercellularity with neoplastic disease.
- Lymphocytic and plasmacytic infiltrates of gingiva, lymph nodes, other lymphoid tissues, spleen, kidney, liver.
- Intestinal lesions—feline panleukopenia-like syndrome.

TREATMENT

APPROPRIATE HEALTH CARE
- Outpatient for most cats.
- Inpatient—may be required with severe secondary infections, anemia, cachexia.
- Blood transfusions—emergency support; may need multiple transfusions; passive antibody transfer (if vaccinated donor) reduces level of FeLV antigenemia in some.
- Management of secondary and opportunistic infections.

NURSING CARE
Supportive therapy (e.g., parenteral fluids, nutritional supplements) as indicated.

ACTIVITY
Normal

DIET
Normal, may alter as necessary for cats with diarrhea, kidney disease.

CLIENT EDUCATION
- Keep cats indoors and separated from FeLV-negative cats to protect from secondary pathogens and prevent spread of FeLV.
- Discuss good nutrition, routine husbandry to control secondary infections.

SURGICAL CONSIDERATIONS
- Biopsy or removal of tumors.
- Oral treatment or surgery—dental cleaning, tooth extraction, gingival biopsy.

MEDICATIONS

DRUG(S) OF CHOICE
- Antiretroviral therapy not routinely indicated due to inconsistent evidence of efficacy and potential adverse effects; immune modulator therapy also unproven.
  - Zidovudine (Retrovir® 5–10 mg/kg PO q12h)—clinical improvement, does not clear virus.
  - α-interferon (Roferon®-A in saline 30 U/day PO for 7 days every other week).
  - Feline recombinant interferon omega (Virbagen® Omega 1 million U/kg SC for 5 days starting days 0, 14, 60)—may increase survival rates and improve clinical status.
- *Mycoplasma haemofelis* infection—see Mycoplasmosis for recommended treatment.
- Lymphoma—management with standard chemotherapy protocols; remission periods average 3–4 months.
- Myeloproliferative disease, leukemias—more refractory to treatment.
- Vaccinate for respiratory and enteric pathogens based on individual risk assessment. Rabies vaccination according to regulatory guidelines.

CONTRAINDICATIONS
Modified live vaccines—potential for disease in severely immunosuppressed cats.

PRECAUTIONS
Systemic corticosteroids—potential for further immunosuppression.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
Immunomodulatory drugs—*Propionibacterium acnes* (ImmunoRegulin® 0.5 mL/cat IV once or twice weekly); acemannan (Carrisyn® 100 mg/cat/day PO).

FOLLOW-UP

PATIENT MONITORING
Varies according to clinical manifestations.

PREVENTION/AVOIDANCE
- Prevent contact with FeLV-positive cats.
- Quarantine and test incoming cats before introduction to multicat households.
- Screen blood donor cats for FeLV-regressive infections using PCR for proviral DNA.

Vaccines
- Most commercial vaccines induce virus-neutralizing antibodies, reported efficacy ranges from <20% to almost 100%, depending on methodology; canarypox–FeLV recombinant vaccine does not contain adjuvant.
- Test cats for FeLV before initial vaccination.
- Vaccinate kittens at 8–9 and 12 weeks of age; boost at 1 year of age; revaccinate every 2–3 years if cat is in low risk environment; annually if high risk..

EXPECTED COURSE AND PROGNOSIS
Persistently viremic cats: >50% succumb to related diseases within 2–3 years after infection.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Secondary infections.
- Neoplasia (lymphoid, fibrosarcoma).
- Immune-mediated disease.

AGE-RELATED FACTORS
- Neonatal kittens—most (70–100%) susceptible to infection.
- Older kittens—<30% susceptible to infection by 16 weeks of age; may develop regressive infections.

ZOONOTIC POTENTIAL
Probably low, but controversial.

PREGNANCY/FERTILITY/BREEDING
- Abortions, stillbirths, and fetal resorptions occur in about 80% of FeLV-positive queens.
- Transmission from queen to kittens—in at least 20% of live births.

SEE ALSO
- Anemia, Nonregenerative.
- Feline Immunodeficiency Virus (FIV) Infection.
- Feline Stomatitis—Feline Chronic Gingivostomatitis (FCGS).
- Lymphoma—Cats.
- Myeloproliferative Disorders.

ABBREVIATIONS
- FeLV = feline leukemia virus.
- FIV = feline immunodeficiency virus.
- IFA = immunofluorescent antibody.
- RT-PCR = reverse transcription polymerase chain reaction.

FELINE PANLEUKOPENIA

BASICS

DEFINITION
A viral infection of cats characterized by sudden onset, vomiting and diarrhea, severe dehydration, and high mortality.

PATHOPHYSIOLOGY
Feline parvovirus (FPV) infects and causes acute death of rapidly dividing cells.

SYSTEMS AFFECTED
- Gastrointestinal—crypt cells of jejunum and ileum are destroyed causing blunted villi; malabsorption of nutrients; acute vomiting and diarrhea; dehydration; and secondary bacteremia.
- Hemic/lymphatic/immune—severe panleukopenia; atrophy of thymus.
- Nervous and ophthalmic—in neonates, rapidly dividing granular cells of cerebellum and retinal cells of eye destroyed; cerebellar hypoplasia with ataxia and retinal dysplasia result.
- Reproductive—in utero infection in nonimmune queens leads to fetal death or neurologic abnormalities.

GENETICS
N/A

INCIDENCE/PREVALENCE
- Unvaccinated populations—most severe and important feline infectious disease.
- Routine vaccination—almost total control of disease.
- Extremely contagious.
- Extremely stable virus, survives for years on contaminated premises.

GEOGRAPHIC DISTRIBUTION
Worldwide in unvaccinated populations.

SIGNALMENT

Species
- Felidae—all, domestic and exotic.
- Canidae—susceptible to canine parvovirus; some exotic canids may be susceptible to FPV.
- Mustelidae—especially mink; may be susceptible.
- Procyonidae—raccoon and coatimundi; susceptible.

Breed Predilections
None

Mean Age and Range
- Unvaccinated and previously unexposed cats of any age can become infected once maternal immunity has been lost.
- Kittens 2–6 months of age—most susceptible to develop severe disease.
- Adults—often mild or subclinical infection.

Predominant Sex
N/A

SIGNS

Historical Findings
- History of recent exposure (e.g., from shelter population).
- Newly acquired kitten.
- Kitten 2–4 months old from premises with history of feline panleukopenia (FP).
- No vaccination history or last vaccinated when <16 weeks of age.
- Sudden onset, with vomiting, diarrhea, depression, complete anorexia.

Physical Examination Findings
- Mental dullness/lethargy.
- Typical "panleukopenia posture"—sternum and chin resting on floor, feet tucked under body, top of scapulae elevated above the back.
- Dehydration—appears rapidly; may be severe.
- Vomiting, diarrhea.
- Body temperature—usually mild to moderately increased or decreased in early stages; becomes severely low as patients become moribund.
- Abdominal pain.
- Small intestine—either turgid or flaccid.
- Subclinical or mild infections common, especially in adults.
- Ataxia from cerebellar hypoplasia—kittens infected in utero or neonatally; evident at 10–14 days of age and persist for life: hypermetria; dysmetria; base-wide stance; alert, afebrile, and otherwise normal; retinal dysplasia sometimes seen.

CAUSES

FPV
- Small, single-stranded DNA virus.
- Single antigenic serotype.
- Antigenic cross-reactivity with canine parvovirus (CPV) type 2 and mink enteritis virus.
- Extremely stable against environmental factors, temperature, and most disinfectants.
- Requires a mitotic cell for replication.

CPV Types 2a, 2b, and 2c
- CPV-2a, CPV-2b, and CPV-2c can produce FP in domestic and/or exotic cats.
- Properties of CPV similar to FPV.

RISK FACTORS
- Factors that increase mitotic activity of small intestinal crypt cells such as intestinal parasites or pathogenic bacteria.
- Secondary or coinfections—viral upper respiratory infections.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Panleukopenia-like syndrome of feline leukemia virus (FeLV) infection—chronic enteritis and panleukopenia, frequently anemia; patient positive for FeLV antigen.
- Salmonellosis—can cause severe gastroenteritis; white blood cell (WBC) count usually high.
- Acute poisoning—similar to acute disease; depression; subnormal temperature; WBC count normal.
- Many diseases cause mild clinical signs hard to differentiate from mild FP; total WBC count always low during acute infection with FPV, even in subclinical infections.

CBC/BIOCHEMISTRY/URINALYSIS
- Panleukopenia—most consistent finding; WBC counts usually between 500 and 3,000 cells/μL during acute disease.
- Biochemical findings usually nonspecific—hypoproteinemia, hypoalbuminemia, hypocholesterolemia possible.

OTHER LABORATORY TESTS
- CPV antigen fecal immunoassay (Cite Canine Parvovirus Test Kit, IDEXX Labs)—not licensed for FP; detects FPV antigen in feces.
- Chromatographic test strip—feces for FPV and CPV.
- Serologic testing—paired serum samples detect rising antibody titer.
- PCR testing–confirms FPV in blood, feces, or tissue; positive result with recent modified live virus (MLV) vaccination.

DIAGNOSTIC PROCEDURES
- Viral isolation from feces or affected tissues (e.g., thymus, small intestine, spleen).
- Electron microscopy of feces—detects parvovirus, presumably FPV.

PATHOLOGIC FINDINGS

Gross
- Rough hair coat, weight loss.
- Severe dehydration.
- Evidence of vomiting and diarrhea.
- Edematous, turgid small intestine.
- Petechial or ecchymotic hemorrhages in jejunum and ileum.
- Thymic atrophy.
- Gelatinous or liquid bone marrow.
- In utero or neonatal infection—gross hypoplasia of cerebellum.

Microscopic
- Dilated small intestinal crypts with sloughing of epithelial cells.
- Shortened and blunt intestinal villi.
- Lymphocytic depletion of follicles of lymph nodes, Peyer's patches, spleen.
- Neonatal and fetal infection—disorientation and depletion of granular and Purkinje cells of cerebellum.
- Eosinophilic intranuclear inclusions in affected tissues during early infection.

(CONTINUED)

FELINE PANLEUKOPENIA

TREATMENT

APPROPRIATE HEALTH CARE
- Main principles of treatment—rehydration; antibiotic therapy; supportive care (antiemetics and analgesics as needed).
- Inpatient—severe cases.
- Outpatient—mild cases.

NURSING CARE
- IV fluid therapy—essential in severe cases: correct dehydration and provide electrolytes; add dextrose if patient is hypoglycemic.
- SC fluids—mild cases without dehydration or shock.
- Antiemetic therapy should be considered in vomiting patients.
- Whole blood, packed red blood cells, or fresh frozen plasma transfusions—if clinical signs of anemia are present or serum albumin <2 g/dL.

ACTIVITY
Keep patient indoors during acute disease.

DIET
Temporarily withhold food until vomiting is controlled.

CLIENT EDUCATION
- Inform client that current and future cats in household must be vaccinated for FPV before exposure.
- Inform client that virus will remain infectious for years unless environment can be adequately disinfected with dilute bleach.

SURGICAL CONSIDERATIONS
None

MEDICATIONS

DRUG(S) OF CHOICE
Broad-spectrum antibiotics (e.g., ampicillin or ampicillin–sulbactam IV, amoxicillin or amoxicillin–clavulanate PO)—counter secondary bacteremia from intestinal bacterial translocation.

CONTRAINDICATIONS
Oral medications until vomiting/gastroenteritis has been controlled.

ALTERNATIVE DRUG(S)
None

FOLLOW-UP

PATIENT MONITORING
- Monitor hydration and electrolyte balance closely.
- Monitor CBC every 24–48h until recovery.

PREVENTION/AVOIDANCE
- Contaminated environments (e.g., cages, floors, food and water dishes) should be disinfected with 1 : 32 dilution of bleach.
- FPV resistant to most commercial disinfectants.

Vaccines
- FP vaccines are core vaccines—to be given to all cats.
- FP is preventable by routine vaccination of kittens.
- MLV vaccines are available for parenteral injection or intranasal administration; MLV vaccine is preferred, with exceptions, as it may provide better protection.
- Inactivated vaccine is available for parenteral injection.
- Do not use MLV vaccines in pregnant cats or kittens younger than 4 weeks old.
- Immunity—long duration, perhaps even for life.
- Kittens—vaccinate as early as 6 weeks of age, then every 3–4 weeks until 16–20 weeks of age; American Association of Feline Practitioners vaccination guidelines now recommend the last vaccine to be given when kitten is at least 16 weeks old, instead of 12 weeks, because maternal antibodies may not have waned until 16 weeks of age.
- Boosters—1 year after last kitten vaccine; then repeat every 3 years.

POSSIBLE COMPLICATIONS
- Shock, sepsis—severe dehydration, hypoglycemia, hypoproteinemia bacterial translocation, electrolyte imbalance.
- Chronic enteritis—fungal or other cause.
- Teratogenic effects (cerebellar hypoplasia resulting in ataxia for life)—virus infection of fetus.
- Concurrent infection with intestinal parasites.

EXPECTED COURSE AND PROGNOSIS
- Most cases acute, lasting only 5–7 days.
- Guarded prognosis during acute disease, especially if WBC count <2,000 cells/μL.
- Approximately 50% mortality has been reported.
- If patient survives acute disease, recovery usually rapid and uncomplicated.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Viral upper respiratory diseases—feline viral rhinotracheitis and feline calicivirus infection.

AGE-RELATED FACTORS
- Clinical—typically in kittens.
- Subclinical—usually adults.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
- Unvaccinated pregnant cats at great risk of infection.
- Fetuses almost always become infected with fatal or teratogenic effects, even when dam has subclinical infection.
- Fetal resorption, abortion, fetal mummification, stillbirth, or birth of weak, fading kittens.
- Kittens may have cerebellar hypoplasia.

SYNONYMS
- Feline distemper.
- Feline parvovirus infection.
- Feline viral enteritis.

ABBREVIATIONS
- CPV = canine parvovirus.
- FeLV = feline leukemia virus.
- FP = feline panleukopenia.
- FPV = feline parvovirus.
- MLV = modified live virus.
- WBC = white blood cell.

FELINE PARANEOPLASTIC ALOPECIA

BASICS

OVERVIEW
- Rare condition characterized by cutaneous lesions that serve as markers of internal neoplasia.
- Most affected cats have pancreatic adenocarcinoma with metastases to liver, lungs, pleura, and/or peritoneum; reports of other neoplasias.
- Link between internal malignancies and cutaneous lesions is unknown; may involve cytokines producing atrophy of hair follicles.

SIGNALMENT
- Domestic shorthair cats only reported cases. Median age—13 years; range: 7–16 years.

SIGNS
- Decrease in appetite followed by rapid weight loss and excessive shedding.
- Pruritus—variable; sometimes with excessive grooming.
- Hairs epilate easily leading to severe alopecia on ventral neck, abdomen, medial thighs; rapidly progressive.
- Stratum corneum may "peel," leading to glistening appearance to skin.
- Alopecic skin is shiny, inelastic, and thin, but not fragile.
- Gray lentigines may develop in alopecic areas.
- Footpads may be fissured and/or scaly; often painful.

CAUSES & RISK FACTORS
- Majority of cases are associated with underlying pancreatic adenocarcinoma.
- Other associated tumor types include cholangiocarcinoma, hepatocellular carcinoma, intestinal carcinoma, neuroendocrine pancreatic neoplasia, and hepatosplenic plasma cell tumor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Hyperadrenocorticism—polyuria, polydipsia, and skin fragility.
- Hyperthyroidism—polyphagia.
- Feline symmetrical alopecia—hair loss self-induced; not associated with easy epilation.
- Thymoma—skin is thick, scaly, and fissured; lymphocytic interface dermatitis; radiographs reveal thoracic mass.
- Demodicosis—mites not associated with paraneoplastic alopecia.
- Dermatophytosis—hair loss often associated with breakage, not spontaneous shedding; inappetence and weight loss rare.
- Alopecia areata—rarely involves entire ventral surface; inappetence and weight loss rare.
- Telogen effluvium—not associated with miniaturization of hair follicles.
- Skin fragility syndrome—markedly thin skin with lacerations; not always associated with exfoliation.
- Superficial necrolytic dermatitis—not associated with marked exfoliation and miniaturization of hair follicles.

CBC/BIOCHEMISTRY/URINALYSIS
No consistent abnormalities; may be helpful in ruling out other differentials.

OTHER LABORATORY TESTS
- Endocrine (thyroid profiles and dexamethasone suppression test)—endocrine disease.
- Skin scrapings—demodicosis.
- KOH examination of hairs and/or fungal culture—dermatophytosis.
- Skin cytology—possible secondary *Malassezia* infection (causing pruritus).

IMAGING
- Ultrasonography—pancreatic mass and/or nodular lesions in liver, intestines, or peritoneal cavity; failure to demonstrate nodules does not exclude the diagnosis, neoplasia may be too small for detection.
- Thoracic radiographs—metastatic lesions in lungs or pleural cavity.

DIAGNOSTIC PROCEDURES
- Skin biopsy.
- Laparoscopy or exploratory laparotomy—identify primary and metastatic tumors.

PATHOLOGIC FINDINGS
- Skin—nonscarring alopecia; severe atrophy of hair follicles and adnexa; miniaturization of hair bulbs; mild to severe acanthosis; variable absence of stratum corneum; variable mixed superficial perivascular infiltrates of neutrophils, eosinophils, and mononuclear cells; some have secondary *Malassezia* infections.
- Primary tumor—usually pancreatic adenocarcinoma, rarely primary bile duct cholangiocarcinoma, hepatocellular or intestinal carcinomas, other pancreatic tumors (neuroendocrine), and hepatosplenic plasma cell tumor. • Metastatic nodules—common in liver, lungs, pleura, and peritoneum.

TREATMENT
- Removal of tumor via surgery may be curative; prognosis guarded, as majority of cases have metastatic disease.
- Chemotherapy or other medications—no reported response.
- Affected animals rapidly deteriorate; euthanasia should be suggested.
- Supportive care—only if owners refuse to consider euthanasia; feed highly palatable, nutrient-dense foods and/or tube feed.

MEDICATIONS

DRUG(S) OF CHOICE
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- Progressive deterioration.
- Supportive care—ultrasonography and thoracic radiographs may demonstrate progression of metastatic disease.
- Death most often occurs within 2–20 weeks after onset of skin lesions.

MISCELLANEOUS

SEE ALSO
Adenocarcinoma, Pancreas.

FELINE STOMATITIS—FELINE CHRONIC GINGIVOSTOMATITIS (FCGS)

BASICS

OVERVIEW

- Inflammatory response affecting the oral cavity in cats.
- FCGS oropharyngeal inflammation is classified by location as:
  - Alveolar mucositis (alveolar stomatitis)—inflammation of alveolar mucosa (i.e., mucosa overlying the alveolar process and extending from the mucogingival junction without obvious demarcation to the vestibular sulcus and to the floor of the mouth).
  - Caudal mucositis—inflammation of mucosa of the caudal oral cavity, bordered medially by the palatoglossal folds and fauces, dorsally by the hard and soft palate, and rostrally by alveolar and buccal mucosa.
  - Glossitis—inflammation of mucosa of the dorsal and/or ventral surface of the tongue.
  - Stomatitis—inflammation of the mucous lining of any of the structures in the mouth; in clinical use the term should be reserved to describe widespread oral inflammation (beyond gingivitis and periodontitis) that may also extend into submucosal tissues.

SIGNALMENT

- Cats.
- Purebred breeds predisposed—Abyssinian, Persian, Himalayan, Burmese, Siamese, and Somali.

SIGNS

- Ptyalism.
- Halitosis.
- Dysphagia.
- Anorexia—and/or prefers soft food.
- Weight loss.
- Scruffy hair coat from lack of grooming.
- Erythematous, ulcerative, proliferative lesions affecting gingiva, glossopalatine arches, tongue, lips, buccal mucosa, and/or hard palate.
- Gingival inflammation commonly completely surrounds the tooth, compared with gingivitis, which usually occurs on buccal and labial surfaces.
- May extend to glossopharyngeal arches as well as palate.

CAUSES & RISK FACTORS

- Cause unknown; bacterial, viral, and immunologic etiologies suspected.
- Significant findings of feline calicivirus; however, calicivirus load does not correlate with degree of inflammation or prognosis of positive therapy.
- Immunosuppression from feline leukemia virus (FeLV) or feline immunodeficiency virus (FIV) can also lead to poorly responsive infections; most affected cats are negative for FeLV. Concomitant FIV infection is not uncommon.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Periodontal disease.
- Oral malignancy.
- Eosinophilic granuloma complex.

CBC/BIOCHEMISTRY/URINALYSIS

- Elevated globulin—polyclonal gammopathy secondary to antibody production following bacterial invasion into periodontal tissues.
- Leukocytosis and eosinophilia may be present.

IMAGING

Intraoral radiographs to evaluate periodontal disease and tooth resorption.

DIAGNOSTIC PROCEDURES

- Biopsy (especially unilateral lesions) to rule out neoplasia—primarily squamous cell carcinoma.
- Calicivirus, *Bartonella*, and oral bacterial culture and sensitivity testing not recommended.

TREATMENT

- Prognosis for cats whose lesions do not include caudal oral mucosa is better than those affected by caudal stomatitis.
- Initial therapy for early cases of alveolar mucositis involves dental scaling above and below gingiva and treatment (extraction) for teeth affected with grades 3 and 4 periodontal disease and/or tooth resorption.
- For cases of focal vestibular and alveolar mucositis, extraction of locally affected teeth in proximity to lesions usually results in resolution.
- For cases of moderate to marked caudal stomatitis, extraction of all maxillary and mandibular teeth (including root fragments) or those distal to canines (if no clinical evidence of disease affecting canines and incisors) resulted in resolution of inflammation in ~60% of cases without further need for medication, with ~20% of cases requiring control with medication, and ~20% refractory.
- To aid extractions—create a gingival flap in all quadrants for exposure; after completely elevating all roots, use high-speed drill with water spray to create trough of bone where roots were, removing most of keratinized gingiva, periodontal ligament, and periradicular alveolar bone; before suturing, "smooth down" alveolar margin to remove sharp edges with round or football-shaped diamond bur.
- CO_2 laser has been effective as treatment adjunct during initial care, especially in cases of moderate to marked caudal stomatitis; laser helps to remove some of inflamed tissue and bacterial load; laser is set to 4 W of continuous energy; after shielding airway from laser energy with moistened gauze, inflamed areas can be rastered; relasering recommended monthly for 3 months if inflammation persists.
- If patients do not respond to extraction of teeth distal to canines, consider trial of prednisolone 2 mg/kg every other day to control the inflammation, or remove all teeth; when extracting teeth, pay meticulous attention to removing all dental hard tissue; take intraoral radiographs before and after surgery; postoperative application of fluocinonide 0.05% (Lidex Gel) to gingival margin may help healing.
- Refractory cases with extensive proliferative lesion in caudal oral cavity and pharynx warrant more guarded prognosis.

MEDICATIONS

DRUG(S) OF CHOICE

- Medication and other therapies have been used with limited long-term success; lack of permanent response to conventional oral hygiene, antibiotics, anti-inflammatory drugs, and immunosuppressive drugs is typical; medications should not be regarded as primary method to control oropharyngeal inflammation.
- Antibiotics—clindamycin 5 mg/kg q12h, metronidazole, amoxicillin, ampicillin, enrofloxacin, tetracycline.
- Corticosteroids—prednisone 2 mg/kg initially daily, followed by every other day; methylprednisolone acetate 2 mg/kg q7–30 days may also help control inflammation.
- Gold salts—Solganal 1 mg/kg IM weekly until improvement (up to 4 months), then every 14–35 days.
- Chlorambucil—2 mg/m^2 PO every other day or 20 mg/m^2 every other week.
- Bovine lactoferrin—40 mg/kg applied to oral mucous membranes.
- Interferon—alpha or omega 30 IU/day 7 days on, 7 days off, indefinitely.
- CO_2 laser to decrease inflamed tissue.
- Cyclosporine—2 mg/kg BID.

FOLLOW-UP

PATIENT MONITORING

- Recommend 2- and 4-week postoperative examinations to determine success of surgical procedure.
- Soft diet should be encouraged for 2 weeks postoperatively, though some cats may not accept any dietary changes well.

FELINE STOMATITIS—FELINE CHRONIC GINGIVOSTOMATITIS (FCGS) (CONTINUED)

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Wound dehiscence; inappetence, refractory caudal inflammation.

F

EXPECTED COURSE AND PROGNOSIS
- Caudal mouth extractions have been shown to greatly improve large percentage of patients; full-mouth extractions sometimes warranted.
- Refractory cases with extensive proliferative lesion in caudal oral cavity and pharynx warrant more guarded prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Lymphocytic plasmacytic stomatitis.
- Stomatitis.

ABBREVIATIONS
- FeLV = feline leukemia virus.
- FIV = feline immunodeficiency virus.

FELINE SYMMETRICAL ALOPECIA

BASICS

OVERVIEW
- Alopecia in a symmetrical pattern with no gross changes in the skin.
- Common clinical presentation in cats.
- Similar manifestation for many different underlying disorders.

SIGNALMENT
No age, breed, or sex predilection reported.

SIGNS
- Total to partial hair loss; most often symmetrical but can occur in a patchy distribution.
- Areas of the body commonly affected—ventrum, caudal dorsum, and lateral and caudal thighs.
- Affected areas are often those accessible for grooming.
- Patchy areas of hair loss (unsymmetrical) on distal extremities or body.

CAUSES & RISK FACTORS
- Cutaneous hypersensitivity—flea allergic dermatitis, food, atopy.
- Ectoparasites—flea bite dermatitis, Cheyletiellosis, *Otodectes cynotis*.
- Infection—dermatophytosis.
- Neurologic or behavioral—"psychogenic alopecia" (uncommon as primary cause of symptoms).
- Stress or metabolic—telogen effluvium.
- Neoplasia—pancreatic neoplasia (paraneoplastic alopecia).
- Hyperadrenocorticism.
- Alopecia areata.
- Hyperthyroidism (early sign).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
See Causes & Risk Factors.

CBC/BIOCHEMISTRY/URINALYSIS
Eosinophilia may occur with hypersensitivities.

OTHER LABORATORY TESTS
Serum thyroxine—hyperthyroidism.

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- Flea combing—identify fleas, flea excrement, or both.
- Microscopic examination of hair—self-induced hair loss results in broken blunt shafts; endogenous hair loss results in tapered ends (telogen hairs).
- Fecal examination—excess hair, mites, and ova (*Cheyletiella*), tapeworm, or fleas.
- Food elimination diet trial—adverse reactions to food.
- Intradermal allergy testing—atopy.
- Skin biopsy—confirm/exclude presence of underlying cause (e.g., hypersensitivity dermatitis vs. psychogenic, or rarely systemic disease).
- Cytology of papules or crusts, if present, may have large numbers of eosinophils.
- Microscopic examination of skin scrapings—ectoparasites.
- Hair plucks (trichogram)—dermatophyte arthrospores or *Demodex* mites adjacent to hair shafts.

PATHOLOGIC FINDINGS
- Histopathologic findings—vary depending on cause.
- Feline psychogenic alopecia—hair follicles and skin normal.
- High numbers of mast cells, eosinophils, lymphocytes, or macrophages suggest allergic dermatitis.
- Alopecia areata—lymphocytic inflammation that encircles bulb portions of hair follicles; rare.

TREATMENT
- Management of underlying cause.
- Inform the owner of the diagnostic plan and the time it could take to see a response (hair coat regrowth).
- Environmental enrichment in cases of true psychogenic cause.

MEDICATIONS

DRUG(S) OF CHOICE
- Antihistamines—e.g., chlorpheniramine 0.5 mg/kg PO q8h; cetirizine 5 mg/cat q12–24h.
- Glucocorticosteroid—prednisolone 0.5 mg/kg PO, tapering/alternate-day therapy.
- Amitriptyline—1–2 mg/kg PO daily.
- Clomipramine hydrochloride—0.5 mg/kg q24h.
- Cyclosporine, modified—5–7 mg/kg PO daily; tapering therapy.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Glucocorticosteroids—can cause alopecia, diabetes mellitus, polydipsia, polyuria, polyphagia, and weight gain; can suppress pruritus, making it difficult to determine underlying cause.
- Withdraw antipruritic medications (including glucocorticosteroids) as diagnostic tests near completion (e.g., restricted-ingredient food trials).

FOLLOW-UP
- Frequent examinations are essential in confirming differential diagnoses.
- Successful identification of underlying cause offers best prognosis, if cause can be controlled (e.g., flea bites or food hypersensitivity).

FELINE TOOTH RESORPTION (ODONTOCLASTIC RESORPTION)

BASICS

DEFINITION
Tooth resorption (TR) is resorption of dental hard tissues (cementum, dentin, and in late stages also enamel).

PATHOPHYSIOLOGY
- Odontoclasts deriving from hematopoietic stem cells migrate to the external root surface, where they start resorption of cementum and dentin.
- TR is often preceded by dentoalveolar ankylosis (fusion between alveolar bone and the root with disappearance of the periodontal ligament space). The alveolar bone (already in a state of constant resorption and apposition) will then include the tooth in its normal remodeling process, which results in noninflammatory replacement resorption. If TR progresses coronally and emerges at the gingival margin, an inflammatory component through contact with oral bacteria joins the initially noninflammatory process, and inflamed granulation tissue may form to cover defects in the crown of the tooth (inflammatory resorption).
- TR in cats most commonly starts anywhere on the external root (not crown) surface and not just close to the cementoenamel junction.

SYSTEMS AFFECTED
Gastrointestinal—oral cavity.

INCIDENCE/PREVALENCE
At least one-third of cats may develop TR during life, with the risk of developing TR increasing with age. Reported prevalence (25–75%) greatly depends on the population of animals investigated (general practice versus dental specialist practice) and the diagnostic methods applied (observation only, tactile exploration with an instrument, and/or use of dental radiography).

SIGNALMENT

Species
Cats

Breed Predilections
Persian longhaired cats reported to have TR at a younger age compared with other breeds.

Mean Age and Range
Rarely seen in cats less than 2 years of age; first teeth usually affected at 4–6 years of age.

SIGNS

Historical Findings
Most affected cats do not show clinical signs, in particular when teeth are affected by replacement resorption only (which is asymptomatic) and the TR is located apical to the gingival attachment (not yet exposed to oral bacteria); some show dropping of food while eating, reluctance to eat hard food, and repetitive lower jaw motions ("chattering").

Physical Examination Findings
- Dental deposits, hyperplastic gingiva, and granulation tissue often cover a clinically evident TR emerging at the gingival margin. A dental explorer can be used under general anesthesia to detect irregularities at the tooth surface near the gingival margin.
- TR occurs more often on the labial and buccal aspects of premolar and molar teeth, and less commonly on canine and incisor teeth. The mandibular third premolar teeth are usually the first teeth affected by TR.
- Canine teeth (in particular maxillary) often appear to extrude excessively (abnormal tooth extrusion), leading to exposure of the root surface. Thickening of alveolar bone with local osteomyelitis (alveolar bone expansion) is often associated with this phenomenon.

Classification of Tooth Resorption
- American Veterinary Dental College (AVDC) currently suggests classification based on the severity (stages 1–5) and radiographic appearance of the resorption (types 1–3):
  - Stage 1 (TR1)—mild dental hard tissue loss (cementum or cementum and enamel).
  - Stage 2 (TR2)—moderate dental hard tissue loss (cementum or cementum and enamel with loss of dentin that does not extend to the pulp cavity).
  - Stage 3 (TR3)—deep dental hard tissue loss (cementum or cementum and enamel with loss of dentin that extends to the pulp cavity) with most of the tooth still retaining its integrity.
  - Stage 4 (TR4)—extensive dental hard tissue loss (cementum or cementum and enamel with loss of dentin that extends to the pulp cavity) with most of the tooth having lost its integrity; there are substages TR4a (crown and root equally affected), TR4b (crown more severely affected than root, and TR4c (root more severely affected than crown).
  - Stage 5 (TR5)—remnants of dental hard tissue are visible only as irregular radiopacities with complete gingival covering.
- See Imaging for additional classification scheme (types 1–3).

CAUSES
- Etiology is unknown; possibly multifactorial (e.g., nutritional, inflammatory, and hereditary).
- One hypothesis is that chronic dietary intake of excess vitamin D would lead to periodontal ligament degeneration, hypercementosis, hyperosteoidosis, narrowing of the periodontal ligament space, dentoalveolar ankylosis, and replacement resorption. If such a process occurred close to the gingival attachment, an inflammatory component would join the initially noninflammatory disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Periodontal disease, stomatitis.

IMAGING
- Without dental radiography, TR below the gingival attachment (and thus the vast majority of TR) will not be detectable.
- On a radiograph of a tooth with type 1 resorption, a focal or multifocal radiolucency is present in the tooth with otherwise normal radiopacity and normal-appearing periodontal ligament space. On a radiograph of a tooth with type 2 resorption, there is narrowing or disappearance of the periodontal ligament space in at least some areas and decreased radiopacity of part of the tooth. On a radiograph of a tooth with type 3 resorption, features of both type 1 and type 2 resorptions are present in the same tooth; the affected tooth shows areas of normal and narrow or lost periodontal ligament space, and there is focal or multifocal radiolucency in the tooth and decreased radiopacity in other areas of the tooth.
- For example, a clinically evident TR emerging at the gingival margin (inflammatory resorption) will generally be visible as a notched radiolucency in the tooth with sharp or scalloped margins (type 1 resorption). The periodontal ligament space may be of normal width apical to the TR, but there will be horizontal or vertical loss of alveolar bone adjacent to the TR. Lesions on mesial and distal tooth surfaces or in the furcation area usually are more obvious on radiographs than those on labial/buccal and lingual/palatal tooth surfaces.
- Fusion of the root and alveolar bone (dentoalveolar ankylosis) results in focalized or generalized disappearance of the periodontal ligament space and lamina dura on radiographs. Resorbed dental tissue will gradually be replaced by bone (replacement resorption). The root will take on a striated or moth-eaten appearance ("ghost roots"), and the periodontal ligament space and lamina dura will disappear on radiographs (type 2 resorption). Unlike inflammatory resorption, adjacent bone usually is not resorbed.

TREATMENT

DIET
Add water to hard kibble to soften it.

CLIENT EDUCATION
Daily tooth brushing or other means of home oral hygiene may help control plaque and allow for earlier detection of teeth affected by TR.

(CONTINUED) FELINE TOOTH RESORPTION (ODONTOCLASTIC RESORPTION)

SURGICAL CONSIDERATIONS

• The treatment of choice for teeth with TR is complete extraction. Multirooted teeth are sectioned after creation of a flap and removal of alveolar bone on labial and buccal aspects of the roots so that each single-rooted crown–root segment can be elevated and removed. Resorbing root remnants under noninflamed and intact gingiva (often appearing as a small gingival bulge) and without periapical pathology on dental radiographs may be left where they are. However, root remnants underneath inflamed gingiva with sinus tracts must be extracted.

• Teeth with dentoalveolar ankylosis and replacement resorption can be treated by means of crown amputation and intentional retention of resorbing root tissue. A flap is made, the crown is removed with a water-cooled round bur to, or slightly below, the level of the alveolar margin, and the wound is rinsed and closed by suturing. Contraindications include periodontitis, endodontic and periapical disease, and stomatitis.

• Canine teeth exhibiting moderate to severe abnormal extrusion and alveolar bone expansion should be treated with an open extraction so that a flap can be used to close the wound.

MEDICATIONS

Topical chlorhexidine or zinc ascorbate gel applied to the mouth once a day.

FOLLOW-UP

PATIENT MONITORING

• Recommend 2-week postoperative examination to determine success of surgical procedure.

• Soft diet should be encouraged for 2 weeks postoperatively, though some cats may not accept any dietary changes well.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Wound dehiscence.

EXPECTED COURSE AND PROGNOSIS

Additional teeth may develop TR in the future, so monitoring with dental radiographs is warranted.

MISCELLANEOUS

SYNONYMS

Feline odontoclastic resorptive lesion (FORL).

ABBREVIATIONS

• TR = Tooth resorption.

FELINE (UPPER) RESPIRATORY INFECTIONS

BASICS

DEFINITION
- Viral, bacterial, fungal etiologies.
- Most cats harbor viral causes and become clinical with stress.
- Viral upper respiratory infection (URI) very common, secondary bacterial infections common; primary bacterial rhinitis uncommon.
- Most organisms spread through direct contact, air (droplets from coughing, sneezing, or discharge), and contaminated surfaces (e.g., shared bowls, cages).
- Illness typified by rhinosinusitis, conjunctivitis, lacrimation, salivation, oral ulcerations.

PATHOPHYSIOLOGY
- Feline herpesvirus (FHV) induces marked rhinitis, sneezing, and conjunctivitis, and may lead to chronic signs; cats are infected for life, with latent virus sequestered in trigeminal nerve ganglion.
- FHV infects epithelial cells of respiratory tract, conjunctiva, and/or cornea; during primary infection or recrudescence, direct effect is cytolysis of infected cells and necrosis of affected tissues; inflammatory disease can occur via immune-mediated response to infection; turbinate lysis can occur.
- Feline calicivirus (FCV) has predilection for epithelial cells of oral cavity and upper respiratory tract; causes rhinitis, stomatitis, oral ulceration: ulcers start as vesicles; some strains infect lungs and can cause focal alveolitis and interstitial pneumonia; other strains cause "limping syndrome."
- FCV–virulent systemic disease (VSD) caused by hypervirulent strains that can infect endothelium of liver, lungs, and pancreas, leading to severe systemic illness characterized by vasculitis; results in edema, alopecia, ulcers, and can cause multiple organ dysfunction syndrome (MODS), systemic inflammatory response syndrome (SIRS), disseminated intravascular coagulation, death.
- *Chlamydophila felis* predominantly infects conjunctiva and causes conjunctivitis; has also been associated with URI.
- Bacterial infection—often secondary to viral disease, trauma, allergic rhinitis.
- *Cryptococcus* affects rostral nasal cavity resulting in rhinitis and turbinate lysis; granulomatous protuberances can occur; destruction of adjacent facial bones facilitates spread of infection to contiguous regions, such as bridge and side of nose, nasal planum, or hard palate, resulting in facial distortion; infection can spread through cribriform plate, resulting in meningoencephalitis, cryptococcal optic neuritis, secondary retinitis.

SYSTEMS AFFECTED
- Respiratory—nasal and upper airway, including sinuses, lower airway.
- Ophthalmologic—conjunctiva.
- Musculoskeletal—FCV.
- Integument/mucous membranes—FHV, *Cryptococcus*.
- Neurologic—*Cryptococcus*, lymph.
- VSD can affect many organ systems.

GENETICS
N/A

INCIDENCE/PREVALENCE
- FHV and FCV most common causes of URI.
- Over 90% of cats are seropositive for FHV.
- Conjunctivitis is most common disease caused by FHV, most common feline ophthalmic disease.
- Carrier states exist for FHV, FCV (10–75%).
- *C. felis*—1–5% for cats without signs of respiratory tract disease, 10–30% for cats with conjunctivitis or URI.
- *Bordetella bronchiseptica*—seroprevalence of 24–79%, isolation rates up to 47% reported.

GEOGRAPHIC DISTRIBUTION
- Ubiquitous.
- *Cryptococcus*—worldwide, associated with pigeon guano.

SIGNALMENT
- Species—cat.
- Breed predilection—N/A.
- Mean age/range—more common in younger cats, though viral flare-ups can occur through life.
- Predominant sex—N/A.

SIGNS

Historical Findings
- Exposure to other cats common; stress, steroids, immunosuppression may precipitate clinical signs for viral causes.
- Caretakers may report upper respiratory signs, weight loss, anorexia, gagging, halitosis, depression.

Physical Examination Findings
- Depend on organism.
- Frequently—sneezing, nasal discharge, stertor, halitosis, ocular discharge, inappetence.
- FHV—fever, sneezing, nasal discharge, conjunctivitis, ulcerative stomatitis, ulcerative keratitis, blepharospasm, salivation, depression, anorexia.
- FCV—fever, salivation and ulceration of tongue, hard palate, or nostrils, stomatitis, gingivitis, rhinitis, conjunctivitis, coughing, dyspnea, lameness.
- With VSD—peripheral edema, dermal ulcers, icterus possible.
- *B. bronchiseptica*—fever, sneezing, ocular discharge, nasal discharge, lymphadenopathy, coughing, dyspnea, cyanosis.
- *Cryptococcus*—sneezing, nasal discharge, ocular discharge, gagging, dysphagia, stertor, upper airway obstruction, facial deformity, lymphadenopathy, neurologic abnormalities, optic neuritis, chorioretinitis.
- *C. felis*—conjunctivitis, occasional sneeze, fever.
- *Mycoplasma* spp.—conjunctivitis, ocular and nasal discharge, dyspnea.

CAUSES
- Viral—FHV, FCV, influenza.
- Primary bacterial—*B. bronchiseptica*, *C. felis*, *Streptococcus canis*, *Mycoplasma* spp.
- Secondary bacterial invaders—*Corynebacterium* spp., *Escherichia coli*, *Pasturella multocida*, *Pseudomonas aeruginosa*, *Streptococcus* spp., *Staphylococcus* spp.
- Fungal—*Cryptococcus neoformans*, *Sporothrix schenckii*, *Aspergillus* spp., *Penicillium* spp.

RISK FACTORS
- Stress/steroids.
- Decreased immune function, feline immunodeficiency virus (FIV)/feline leukemia virus (FeLV) infection.
- Multicat households, shelters, young cats.

DIAGNOSIS
- Direct fluorescent staining of conjunctival scraping—FHV.
- PCR for *B. bronchiseptica* (controversial if positive), *Chlamydophila felis*, FCV, FHV, H7N2 influenza virus, influenza A virus (including H7N2, H3N2, H1N1, H3N8), *Mycoplasma felis*.
- Viral isolation.
- Mycoplasma culture.
- *Cryptococcus*—direct microscopic visualization of organisms in nasal discharge or tissue: cytology or histopathology, culture, serology; latex agglutination to identify antigen.

DIFFERENTIAL DIAGNOSIS
- Nasopharyngeal polyps.
- Nasopharyngeal stenosis.
- Foreign body.
- Neoplasia.
- Dental disease—tooth root abscess.
- Anatomic defects.
- Trauma.
- Burn—caustic agent or electrical.

CBC/BIOCHEMISTRY/URINALYSIS
Generally normal with most etiologies—with virulent systemic FCV may see inflammatory leukogram, thrombocytopenia, elevated liver enzymes/total bilirubin.

OTHER LABORATORY TESTS
- Culture of upper airways.
- Lymph node cytology.
- Nasal biopsies.

IMAGING
- Skull radiographs generally not helpful.
- Thoracic radiography—generally normal, may see pulmonary involvement if fungal disease or pneumonia.

(CONTINUED) # FELINE (UPPER) RESPIRATORY INFECTIONS

• CT of head—may show mass, turbinate lysis, increased soft tissue within nasal passages, lymphadenopathy.

DIAGNOSTIC PROCEDURES
• Conjunctival scraping may identify FHV.
• Rhinoscopy—in cats with *Cryptococcus*.
• Upper airway exam.
• Bronchoalveolar lavage if pneumonia suspected.
• FIV antibody, FeLV antigen testing.

PATHOLOGIC FINDINGS
Histopathology—lymphoplasmacytic stomatitis: FCV; vasculitis: FCV–VSD; bacterial rhinitis, suppurative inflammation; *Cryptococcus* organisms on nasal or lymph node biopsy.

TREATMENT

APPROPRIATE HEALTH CARE
• Most cats managed as outpatient; isolate if hospitalized, as many organisms highly contagious and airborne.
• Moderate to severely affected cats may require IV fluids for hydration.
• May require supplemental oxygen.

ACTIVITY
N/A

DIET
• Enteral feeding recommended if anorexia persists >48 hours.
• Nasogastric feeding may not be appropriate if there is severe nasal discharge.
• Cats with severe oral ulceration may need enteric feeding while ulcers heal.

CLIENT EDUCATION
Most agents are contagious.

SURGICAL CONSIDERATIONS
Corneal ulcers can be deep, may require surgical intervention.

MEDICATIONS

DRUG(S) OF CHOICE
• Many cases will self-resolve.
• Antibiotics not recommended for cats with only serous discharge; observation without antibiotics recommended for up to 10 days for acute-onset mucopurulent/purulent discharge without systemic signs (fever, lethargy, anorexia) or specific etiology identified by exam or history; susceptibility profiles of organism may be helpful for chronic cases.
  ◦ First choices—doxycycline 10 mg/kg PO q24h, usually effective for *B. bronchiseptica*, *C. felis*, *Mycoplasma* spp.; amoxicillin 22 mg/kg, PO, q12h.
  ◦ Other options—amoxicillin–clavulanate 15–20 mg/kg PO q12h, azithromycin 5–15 mg/kg PO q24h, marbofloxacin 2.5–5 mg/kg PO q24h, pradofloxacin 5–10 mg/kg PO q24h.
• Antifungals—fluconazole 50 mg/cat PO q12–24h, itraconazole 10 mg/kg PO q24h; compounded formulations not recommended.
• Antivirals—famciclovir 62.5 mg/cat PO q12h, cidofovir topical 0.5% 1 drop OU q12h.

CONTRAINDICATIONS
Use azole drugs with caution in patients with liver disease.

PRECAUTIONS
Doxycycline can cause esophagitis and esophageal strictures—follow with food and/or water.

POSSIBLE INTERACTIONS
Azole antifungals have many drug interactions.

FOLLOW-UP

PATIENT MONITORING
• Viral—most cases improve within 1 week; could take up to 6 weeks to resolve.
• Persistent clinical signs after appropriate treatment suggest alternative cause.

PREVENTION/AVOIDANCE
• Vaccination.
• FCV, FHV—core vaccines; modified live and inactivated virus vaccines give reasonable protection, mild clinical signs may be seen; vaccines do not prevent infection or viral latency, although shedding post challenge may be reduced.
• Vaccination against *C. felis* and *B. bronchiseptica* is noncore.
• Do not allow non-immunocompetent patients to contact other animals until determined to be low risk.
• Bleach diluted 1 : 30 with water mixed with detergent is effective at eliminating most respiratory pathogens from environment.

POSSIBLE COMPLICATIONS
• Pneumonia.
• Septicemia (rare).

EXPECTED COURSE AND PROGNOSIS
• Good to excellent; underlying immunosuppression may increase susceptibility to infection, worsen prognosis.
• FHV—generally, mortality low and prognosis good, except for young kittens and aged cats.
• FCV–VSD—poor, mortality >50%.

MISCELLANEOUS

AGE-RELATED FACTORS
Young animals more susceptible.

ZOONOTIC POTENTIAL
• *B. bronchiseptica* rare cause of zoonotic infections.
• Human conjunctivitis caused by feline chlamydia has been reported.

PREGNANCY/FERTILITY/BREEDING
Animals who are actively ill should not be bred. FHV can cause abortions.

SEE ALSO
• Chlamydiosis—Cats.
• Cryptococcosis.
• Feline Calicivirus Infection.
• Feline Herpesvirus Infection.
• Mycoplasmosis.
• Rhinitis and Sinusitis.

ABBREVIATIONS
• FCV = feline calicivirus.
• FeLV = feline leukemia virus.
• FHV = feline herpesvirus-1.
• FIV = feline immunodeficiency virus.
• MODS = multiple organ dysfunction syndrome.
• SIRS = systemic inflammatory response syndrome.
• VSD = virulent systemic disease.
• URI = upper respiratory infection.

Author Genna Atiee
Consulting Editor Amie Koenig

FEVER

BASICS

DEFINITION
Higher than normal body temperature because of changed thermoregulatory set point in hypothalamus; normal body temperature in dogs and cats 100.2–102.8 °F (37.8–39.3 °C). Fever of unknown origin (FUO)—at least 103.5 °F (39.7 °C) on at least four occasions over 14-day period and illness of 14 days' duration without obvious cause.

PATHOPHYSIOLOGY
Exogenous or endogenous pyrogens reset thermoregulatory center to higher temperature, activating physiologic responses to raise body temperature. Physiologic consequences include increased metabolic demands, muscle catabolism, bone marrow suppression, heightened fluid and caloric requirements, and possibly disseminated intravascular coagulation (DIC) and shock.

SYSTEMS AFFECTED
- Cardiovascular—tachycardia.
- Hemic/lymphatic/immune—bone marrow depression, DIC.
- Nervous—cerebral edema, depression.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Some breed-associated conditions may result in FUO (e.g., shar-pei fever).

SIGNS

General Comments
- Fever lowers bacterial division and increases immune competence.
- Prolonged fever >105 °F (>40.5 °C) leads to dehydration and anorexia.
- Fevers >106 °F (>41.1 °C) may lead to cerebral edema, bone marrow depression, arrhythmia, electrolyte disorders, multiorgan damage, DIC.

Historical Findings
- Clinical history (e.g., contact with infectious agents, lifestyle, travel, recent vaccination, drug administration, insect bites, previous illness, allergies) and physical examination (including retinal examination) may help identify underlying disease condition.
- Fever patterns (e.g., sustained, intermittent) rarely helpful.

Physical Examination Findings
- Hyperthermia.
- Lethargy.
- Inappetence.
- Tachycardia.
- Tachypnea.
- Hyperemic mucous membranes.
- Dehydration.
- Shock.

CAUSES

Infectious Agents
- Viruses—feline leukemia virus (FeLV), feline immunodeficiency virus (FIV), parvo, distemper, herpes, calici.
- Bacteria—endotoxins, *Mycoplasma*, *Bartonella*, *Leptospira*, *Borrelia burgdorferi*, others.
- Systemic fungi—*Histoplasma*, *Blastomyces*, *Coccidioidomyces*, *Cryptococcus*.
- Vector borne—*Rickettsia*, *Borrellia*, *Ehrlichia*, *Anaplasma*, *Neorickettsia*.
- Parasites and protozoa—*Babesia*, *Toxoplasma*, aberrant larva migrans, *Dirofilaria* thromboemboli, *Leishmania*, *Cytauxzoon*, *Hepatozoon*, *Neospora*.

Immune-Mediated Processes
Systemic lupus erythematosus, immune-mediated hemolytic anemia, immune-mediated thrombocytopenia, pemphigus, polyarthritis, polymyositis, rheumatoid arthritis, vasculitis, hypersensitivity reaction, transfusion reaction, infection secondary to inherited or acquired immune defects.

Endocrine and Metabolic
Hyperthyroidism, hypoadrenocorticism (rare), pheochromocytoma, hyperlipidemia, hypernatremia.

Neoplasia
Lymphoma, myeloproliferative disease, plasma cell neoplasm, mast cell tumor, malignant histiocytosis, metastatic disease, necrotic tumor, and solid tumor, particularly in liver, kidney, bone, lung, lymph nodes.

Other Inflammatory Conditions
Cholangiohepatitis, hepatic lipidosis, toxic hepatopathy, cirrhosis, inflammatory bowel disease, pancreatitis, peritonitis, pleuritis, granulomatous diseases, portosystemic shunting, thrombophlebitis, infarctions, pansteatitis, panosteitis panniculitis, hypertrophic osteodystrophy, blunt trauma, cyclic neutropenia, intracranial lesions, pulmonary thromboembolism.

Drugs and Toxins
Tetracycline, sulfonamide, penicillins, nitrofurantoin, amphotericin B, barbiturates, iodine, atropine, cimetidine, salicylates, antihistamines, procainamide, heavy metals.

FUO—Dogs
- Infection (28%)—discospondylitis, fungal infections, endocarditis, abscesses, bacteremia, septic arthritis, septic meningitis, pyothorax, pulmonary foreign body/abscess, stump pyometra, pneumonia, osteomyelitis, peritonitis, prostatitis, pancreatitis, pyelonephritis, sepsis secondary to immunodeficiency, leptospirosis, leishmaniasis, toxoplasmosis, Lyme disease, infection with *Ehrlichia*, *Anaplasma*, *Bartonella*, others.
- Immune-mediated disease (27%)—polyarthritis, meningitis, vasculitis, others.
- Bone marrow disease, including neoplasia (16%).
- Neoplasia (7%).
- Miscellaneous (10%)—hypertrophic osteodystrophy, lymphadenitis, panosteitis, portosystemic shunting, shar-pei fever.
- Undiagnosed (12%).

FUO—Cats
- Most virally mediated (e.g., FeLV, FIV, feline infectious peritonitis [FIP], less commonly parvo, herpes, calici).
- Occult bacterial infection with atypical bacteria, sometimes secondary to bite wounds (e.g., *Yersinia*, *Mycobacteria*, *Nocardia*, *Actinomyces*, *Brucella*).
- Pyothorax.
- Additional causes—pyelonephritis, blunt trauma, penetrating intestinal lesion, dental abscess, systemic fungal disease, lymphoma, solid tumors.
- Immune disorders, endometritis, discospondylitis, pneumonia, endocarditis rare.

RISK FACTORS
- Recent travel.
- Exposure to biologic agents.
- Immunosuppression.
- Very young or old animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Differentiate fever from hyperthermia. Temperatures up to 103 °F (39.4 °C) may be caused by stress or illness. Temperatures >104 °F (>40 °C) almost always important. Temperatures >107 °F (>41.7 °C) usually not fever, more likely to be primary hyperthermia.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC and blood smear—leukopenia or leukocytosis, left shift, monocytosis, lymphocytosis, thrombocytopenia or thrombocytosis, spherocytes, organisms.
- Biochemistry profile and urinalysis vary with organ system involved.

OTHER LABORATORY TESTS
- If infectious disease suspected, attempt to culture an organism—urine culture, blood cultures (i.e., three anaerobic/aerobic cultures, taken 20 min apart; try to use as much volume as possible to increase diagnostic yield; use special blood culture bottles), fungal and cerebrospinal fluid cultures, synovial and prostatic fluid, biopsy specimens.

(CONTINUED) FEVER

• FeLV and FIV test, Snap 4DX test, serologic tests or PCR for *Toxoplasma*, *Borrelia*, *Mycoplasma*, *Bartonella*, *Anaplasma*, *Ehrlichia*, *Rickettsia*, FIP, systemic mycoses.
• Fecal examination.
• Tracheal wash or bronchoalveolar lavage.
• If immune disorders suspected—cytologic examination of synovial fluid; Coombs' test, rheumatoid factor, antinuclear antibodies.
• Pancreatic lipase immunoreactivity.
• T_4 in cats.

IMAGING

Radiography

• Abdominal radiographs—tumors and effusion.
• Thoracic radiographs—pneumonia, neoplasia, pyothorax.
• Survey skeletal radiographs—bone tumors, multiple myeloma, osteomyelitis, discospondylitis, panosteitis, hypertrophic osteopathy, hypertrophic osteodystrophy.
• Dental/skull radiographs—tooth root abscess, sinus infections, foreign bodies, neoplasia.
• Contrast radiography (e.g., gastrointestinal and excretory urography).

Ultrasonography

• Abdominal (plus directed aspirate or biopsy)—abdominal neoplasia, abscess or other site of infection (e.g., pyelonephritis, pancreatitis, pyometra).
• Echocardiography if endocarditis suspected.

Nuclear Imaging

• Radionuclide scanning procedures to evaluate for bone tumors, osteomyelitis, pulmonary embolism.
• CT, MRI, or positron emission tomography scan if indicated.

DIAGNOSTIC PROCEDURES

• Arthrocentesis (culture and cytology).
• Bone marrow aspirate and biopsy if malignancy or myelodysplasia suspected.
• Lymph node, skin, or muscle biopsy if clinically indicated.
• Fine-needle aspirate or biopsy of any mass or abnormal organ.
• Central spinal fluid tap if neurologic signs.
• Endoscopy and biopsy if gastrointestinal signs.
• Exploratory laparotomy—last resort if all other diagnostic tests fail to determine cause and patient not improving.

TREATMENT

APPROPRIATE HEALTH CARE

Goals of treatment—reset thermoregulatory set point to lower level; remove underlying cause.

NURSING CARE

• Fluid administration (IV) often lowers body temperature.
• Topical cooling if fever is severe (convection cooling with fans, evaporative cooling with alcohol on foot pads, axilla, and groin).
• Only use antipyretic treatment when fever is prolonged and life-threatening (>106 °F, >41.1 °C) and topical cooling is unsuccessful. Impaired patients (e.g., with heart failure, seizures, or respiratory disease) require antipyretic treatment earlier. Antipyretic treatment may preclude elucidation of cause, delay correct treatment, and complicate patient monitoring (e.g., reduction of fever is important indication of response to treatment).

DIET

Febrile patients in hypercatabolic state require high caloric intake.

CLIENT EDUCATION

Work-up of patients with FUO often extensive, expensive, and invasive, and may not result in definitive diagnosis.

SURGICAL CONSIDERATIONS

Surgery may be necessary in some animals (e.g., pyometra, peritonitis, pyothorax, liver abscess, neoplasms).

MEDICATIONS

DRUG(S) OF CHOICE

Do not use broad-spectrum (i.e., "shotgun") treatment in place of thorough diagnostic workup unless patient's status is critical and deteriorating rapidly.

Antibiotics

• Based on results of bacterial culture or serology.
• In emergency situations, combination antibiotic therapy can be started after culture specimens obtained (e.g., cephalothin 20 mg/kg IV q6–8h; combined with enrofloxacin 10 mg/kg IV q24h). Additional antimicrobials depend on main clinical suspicion based on preliminary laboratory and clinical evidence.
• Do not give antibiotics longer than 1–2 weeks if ineffective.

Antipyretics

• Aspirin—dogs: 10 mg/kg PO q12h; cats: 6 mg/kg PO q48h.
• Deracoxib—dogs: 1–2 mg/kg/day.
• Carprofen—dogs: 2 mg/kg q12h.
• Meloxicam—0.1 mg/kg/day.
• Dipyrone—dogs: 25 mg/kg IV.
• Flunixin meglumine—dogs: 0.25 mg/kg SC once (give IV fluids).

Glucocorticoids

• Do not use unless infectious causes have been ruled out.
• May mask clinical signs, may lead to immunosuppression, and not recommended for use as antipyretics; administration of corticosteroids to cats with intractable FUO after ruling out infectious diseases may promote favorable response.
• Primarily indicated for fever associated with immune-mediated disease and certain steroid-responsive tumors (e.g., lymphoma).

PRECAUTIONS

Side effects of antipyretics include emesis, diarrhea, gastrointestinal ulceration, renal damage, hemolysis, hepatotoxicity.

POSSIBLE INTERACTIONS

Combination of nonsteroidal anti-inflammatory drugs and steroids raises risk of gastrointestinal hemorrhage.

FOLLOW-UP

PATIENT MONITORING

• Body temperature at least q12h.
• If cause of fever not found, repeat history and physical exam along with screening laboratory tests.
• If fever develops or worsens during hospitalization, consider nosocomial infection or superinfection.

EXPECTED COURSE AND PROGNOSIS

Vary with cause; in some patients (more commonly cats), underlying cause cannot be determined.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Young animals—infectious disease more common; prognosis better.
• Old animals—neoplasia and intra-abdominal infection more common; signs tend to be more nonspecific; prognosis often guarded.

SYNONYMS

Pyrexia

SEE ALSO

Heat Stroke and Hyperthermia.

ABBREVIATIONS

• DIC = disseminated intravascular coagulation.
• FeLV = feline leukemia virus.
• FIP = feline infectious peritonitis.
• FIV = feline immunodeficiency virus.
• FUO = fever of unknown origin.

Authors Maria Vianna and Jörg Bucheler
Consulting Editor Michael Aherne

FIBER-RESPONSIVE LARGE BOWEL DIARRHEA

BASICS

OVERVIEW

- A form of chronic idiopathic large bowel diarrhea that occurs in dogs and usually responds favorably to dietary soluble fiber supplementation.
- At the author's institution, chronic idiopathic large bowel diarrhea is diagnosed in approximately 25% of dogs referred for evaluation of chronic large bowel diarrhea.
- Exclusion diagnosis that requires eliminating known causes of chronic large bowel diarrhea and clinical response to dietary fiber supplementation.
- No pathophysiologic studies have been performed.
- Only 3 reports in dogs comprising 83 cases.
- May overlap with a stress-associated poorly defined syndrome that has been called irritable bowel syndrome, also referred to as nervous colitis, spastic colon, or mucus colitis. Some dogs with irritable bowel syndrome respond to dietary fiber supplementation, while others require stress alleviation, antispasmodic medications, and/or anti-anxiety drugs.

SIGNALMENT

- Dogs of all ages (0.5–14 years); median 6 years.
- Many breeds, including mixed breeds; common breeds include German shepherd dog, miniature schnauzer, cocker spaniel, and miniature or toy poodle.

SIGNS

- Chronic diarrhea (soft to liquid) with classic large bowel characteristics; tenesmus, excess fecal mucus, hematochezia, increased frequency (median 3.5 times/day), and urgency.
- Diarrhea usually episodic alternating with periods of normal stool; diarrhea may be continuous in approximately 25% of dogs.
- Less common signs include occasional vomiting, decreased appetite during episodes of diarrhea, abdominal pain, and anal pruritus.
- Weight loss rare.
- Stress factors or abnormal personality traits in approximately 35% of dogs; household visitation, travel, moving, construction, instillation of an invisible fence; recent adoption or considered nervous, high-strung, sensitive, or aggressive; or possess noise phobia, anxiety, or depressive disorders.
- Physical examination reveals no significant findings related to gastrointestinal tract.
- Digital rectal examination is usually normal. Feces may be normal due to episodic nature of the disease. Loose stool may be present and it may contain hematochezia (red blood) or excess mucus.

CAUSES & RISK FACTORS

- Unknown; stress or abnormal personality traits may play a role in some.
- Clinical response to dietary soluble fiber supplementation suggests abnormal colonic motility and/or dysbiosis. Dysbiosis is defined as a microbial imbalance within the gastrointestinal tract. Soluble dietary fiber is a prebiotic, fermented by colonic bacteria resulting in altered composition or activity of bacteria. Prebiotics are not digested by mammalian digestive enzymes and "feed" colonic bacteria, potentially correcting dysbiosis. Soluble fibers also adsorb water, improving stool quality. Fermentation of soluble fiber by colonic bacteria produces volatile fatty acids, which are energy source for colonic epithelial cells.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dietary indiscretion.
- Highly digestible diet-responsive diarrhea.
- Hypoallergenic diet-responsive diarrhea.
- Whipworms.
- *Clostridium perfringens*–associated diarrhea.
- Lymphocytic plasmacytic colitis.
- Eosinophilic colitis.
- Miscellaneous types of colitis.
- Irritable bowel syndrome.
- Colonic neoplasia (adenocarcinoma, lymphoma, and adenoma are most common).
- Cecal inversion.

CBC/BIOCHEMISTRY/URINALYSIS

No consistent or specific abnormalities, although can recognize peripheral eosinophilia occasionally in dogs with colonic whipworms, eosinophilic colitis, and food allergy.

OTHER LABORATORY TESTS

Multiple fecal flotations by zinc sulfate; negative for whipworms and other parasites.

IMAGING

- Abdominal radiographs within normal limits.
- Abdominal ultrasound within normal limits.

DIAGNOSTIC PROCEDURES

- *Clostridium perfringens* enterotoxin fecal ELISA; negative.
- Therapeutic deworming for whipworms (fenbendazole 50 mg/kg PO q24h for 5 days); no improvement.
- Highly digestible diet trial for 2–3 weeks; no improvement in stool quality. During the food trial the dog must not receive any other nutrients. These diets are highly digestible, low in fiber, and restricted in fat. If the dog's stool becomes normal during this diet trial, no further diagnostic tests are indicated. The highly digestible diet can be fed for another 2–4 weeks and then the original diet can be slowly introduced. Some dogs develop diarrhea again, others can be maintained on their original diet.
- Hypoallergenic diet trial for 2–3 weeks; no improvement in stool quality. During the food trial the dog must not receive any other nutrients, including flavored heartworm preventatives, vitamins, or any other supplements. For this diet trial the author recommends using a hydrolyzed diet. The hydrolyzed protein in these diets is hypoallergenic. If the dog's stool becomes normal during this diet trial a diagnosis of dietary hypersensitivity or inflammatory bowel disease can be made. These hydrolyzed diets are also highly digestible, low in fiber, and restricted in fat. Some clinicians skip the highly digestible diet trial and go directly to the hydrolyzed diet trial. Without performing a highly digestible diet trial first, response to the hydrolyzed diet trial could also be due to digestibility, fat, and fiber content and not due to dietary hypersensitivity. Many dogs that respond to a hypoallergenic food trial can be slowly switched back to their original diet after 12–14 weeks.
- Colonoscopy; usually within normal limits or only mild nonspecific findings such as slight increases in mucosal granularity or friability.

PATHOLOGIC FINDINGS

- Histopathologic evaluation of colonic biopsy samples; within normal limits.
- Multiple biopsy samples should be evaluated from throughout the colon from the cecum to the rectum. Usually at least 5–6 locations are sampled.

TREATMENT

- Health care can be provided on an outpatient basis and consists of dietary fiber supplementation.
- Activity level does not have to be modified.
- A highly digestible "GI" diet should initially be supplemented with 1–3 tbsp daily of psyllium hydrophobic mucilloid (Metamucil 10.2 g psyllium/tbsp).
- Psyllium is a soluble fiber that adsorbs water, improving fecal consistency, and acts as a prebiotic promoting bacterial fermentation and production of volatile fatty acids, which are an energy source for colonic epithelial cells. Psyllium comes from the seeds or husks of the plant ispaghul and consists of approximately 90% soluble fiber. Psyllium has been shown to be an effective treatment in some children with chronic nonspecific diarrhea and in other people with several diarrheal disorders.
- Median dose is 2 tbsp/day, or 0.13 tbsp/kg/day, or 1.3 g psyllium/kg/day.

(CONTINUED)

FIBER-RESPONSIVE LARGE BOWEL DIARRHEA

• Initial response to lower amounts of fiber supplementation or use of other types of fiber is not as successful.
• After 2–3 months without diarrhea, the amount of fiber can be slowly reduced successfully in approximately 50% of dogs.
• After resolution of diarrhea with psyllium supplementation, owners may attempt to switch to a commercial high-fiber (insoluble fiber) diet that may be more convenient to feed; however diarrhea may return in 50% of dogs. Insoluble dietary fiber helps to distend the colonic lumen; distention is necessary for normal fecal storage and colonic motility.
• After resolution of diarrhea with psyllium supplementation, owners may be able to switch from the highly digestible "GI" diet to a high-quality maintenance dog food.
• Lack of initial response to fiber supplementation suggests that chronic idiopathic large bowel diarrhea may be due to irritable bowel syndrome, and pharmacologic management of that disorder should be instituted.

MEDICATIONS

None indicated.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

No known interactions of fiber supplementation with commonly used drugs.

FOLLOW-UP

• Patient monitoring requires periodic assessment of stool quality, performed during recheck office examinations or via telephone interviews.
• If stresses were initially identified, stress reduction should be attempted.
• If abnormal personality traits were initially identified, they should be modified.
• Dietary soluble fiber supplementation can occasionally produce excessive flatulence, which can be managed by reduction in fiber dosage.
• Prognosis is very favorable, as approximately 85% of dogs have excellent or very good long-term response to fiber supplementation.

MISCELLANEOUS

• There are no known associated conditions.
• Age does not play a role in diagnosis or treatment.
• There is no known zoonotic potential.
• There are no special considerations regarding pregnancy, fertility, or breeding.

FIBROCARTILAGINOUS EMBOLIC MYELOPATHY

BASICS

DEFINITION
Acute ischemic necrosis of the spinal cord caused when fibrocartilaginous emboli become lodged in the spinal vasculature.

PATHOPHYSIOLOGY
- Emboli—found in spinal cord vasculature; histologically and histochemically identical to nucleus pulposus of the intervertebral disc.
- Exact mechanism of entry into the spinal vasculature unknown.

SYSTEMS AFFECTED
Nervous

GENETICS
N/A

INCIDENCE/PREVALENCE
- Common cause of spinal cord disease in nonchondrodystrophic breeds of dogs.
- Rarely reported in chondrodystrophic breeds.
- Uncommon in cats.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
- Giant- and large-breed dogs most common, but seen in small breeds as well.
- Miniature schnauzers overrepresented.

Mean Age and Range
- Median age 5 years.
- Range: 8 weeks–14.5 years.

Predominant Sex
Males overrepresented.

SIGNS

Historical Findings
- May be associated with trauma or physical activity at or immediately before onset of signs.
- Sudden onset, generally nonprogressive and nonpainful.
- Discomfort occasionally noted at onset but resolves rapidly (minutes to hours).
- Signs of paresis or paralysis develop over a matter of seconds, minutes, or hours.
- Condition typically stabilizes within 24 hours.

Physical Examination Findings
N/A

Neurologic Examination Findings
- Localization—any spinal cord segment can be affected; T3–L3 and L4–S3 most common; multifocal lesions may rarely be seen; may see spinal shock with T3–L3 lesions, which can give the appearance of a multifocal spinal cord lesion.
- Deficits—commonly lateralized (due to spinal vascular anatomy) but can be symmetric; contralateral side may be mildly affected or normal.
- Severity of deficits—related to severity of infarction. Most display nonambulatory paresis, or plegia with intact nociception; fewer patients display ambulatory paresis, or plegia with absent nociception.
- Spinal pain—may be present briefly at onset of signs (owner report) and generally resolves by the time patient is examined.

CAUSES
Unknown

RISK FACTORS
- Trauma/physical activity may precede the incident.
- Hyperlipoproteinemia may be a comorbidity in miniature schnauzers and Shetland sheepdogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Acute noncompressive nucleus pulposus extrusion (ANNPE)—most important clinical difference may be persistent spinal pain beyond 24 hours; differentiate with cross-sectional imaging; may be indistinguishable but treated the same.
- Thrombi/emboli from other sources can cause similar ischemic injury to the spinal cord—consider underlying predisposing conditions (cardiomyopathy, hypothyroidism, hyperthyroidism, hyperadrenocorticism, chronic kidney disease, hypertension, hyperlipidemia; especially in cats).
- Intervertebral disc disease; discospondylitis; neoplasia; fracture and luxation—typically painful with symmetric deficits; survey radiography, MRI, CT, and/or myelography help confirm the diagnosis.
- Intra- and extramedullary hemorrhage secondary to coagulopathy (e.g., anticoagulant rodenticide ingestion, thrombocytopenia, or disseminated intravascular coagulation)—rule out by examining for underlying causes of hemorrhage, performing platelet count, and determining blood clotting times.
- Infectious/immune-mediated focal myelitis—differentiate on progressive history and cerebrospinal fluid (CSF) analysis.
- Acute, nonprogressive, asymmetric, and nonpainful spinal cord disease—presence of these characteristics greatly helps in diagnosis of fibrocartilaginous embolic myelopathy (FCE).

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

IMAGING
- Survey spinal radiograph—usually normal, used to rule out other causes of myelopathy such as fracture, neoplasia, or discospondylitis.
- Myelography and CT myelography—in acute stage often demonstrates focal intramedullary swelling at embolic site; later, often normal or shows area of cord atrophy.
- MRI—preferred imaging modality for antemortem diagnosis: may see increased T2 signal intensity within spinal cord at site of lesion; may see mild contrast enhancement.

DIAGNOSTIC PROCEDURES

CSF Analysis
- Normal or nonspecific changes (mild pleocytosis/elevated protein concentration). Profound elevations in cell count can occasionally be observed with severe necrosis.
- Results depend on location (lumbar vs. cerebellomedullary cistern) and time of collection in relation to onset of clinical signs.

PATHOLOGIC FINDINGS
- Gross—focal spinal cord swelling ± hemorrhage.
- Microscopic—emboli of fibrocartilage in arteries and/or veins of spinal cord within or near area of focal spinal cord swelling; gray matter generally more affected than white matter.
- Histologic examination required for definitive diagnosis. Presumptive antemortem diagnosis is based on typical presentation and exclusion of other causes of acute myelopathy.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient—for immediate medical treatment and diagnostic procedures.

NURSING CARE
- Keep recumbent patients on padded surface; turn frequently to prevent pressure sores.
- Assist and encourage patients to ambulate as soon as possible.
- Assist bladder emptying (catheterize or express) several times daily if needed.
- Physical rehabilitation therapy may improve recovery and reduce residual neurologic deficits.
- Sling or harness support for assisted walking at home.

ACTIVITY
- Restrict until diagnosis is made in case of vertebral column instability from other causes such as intervertebral disc herniation or fracture/luxation.
- Once FCE is confirmed, activity should be encouraged, not restricted.

DIET
Normal unless other general health comorbidities are present.

CLIENT EDUCATION
- Gradual recovery from paresis or paralysis; most will recover ambulation, but residual neurologic deficits are common. Patients who

(CONTINUED) FIBROCARTILAGINOUS EMBOLIC MYELOPATHY

are paraplegic with absent nociception have a more guarded prognosis for return of function.
• Most patients need considerable home care during recovery, including bladder management.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
No specific medications are indicated for the treatment of FCE. Use of steroids such as methylprednisolone sodium succinate is controversial and unlikely to be of benefit.

CONTRAINDICATIONS
Nonsteroidal analgesics should not be administered with methylprednisolone sodium succinate.

PRECAUTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
• Sequential neurologic evaluations—during first 12–24 hours after initial examination.
• Neurologic status—at 2, 3, and 4 weeks after onset of clinical signs.
• Urinary incontinence—manually express bladder in patients who are not voluntarily urinating. Urinalysis and culture/sensitivity to detect urinary tract infection.

PREVENTION/AVOIDANCE
• Recurrence highly unlikely but possible.
• No known method of prevention in most cases.

POSSIBLE COMPLICATIONS
• Fecal and urinary incontinence.
• Urinary tract infection.
• Urine scalding and pressure sores.

EXPECTED COURSE AND PROGNOSIS
• Generally good prognosis for recovery of ambulation.
• Most patients (85%) recover ambulation within 3 weeks (range: 3 days–12 weeks).
• Most patients retain some permanent neurologic deficits despite recovering ambulation.
• Paraplegia with loss of pain perception at presentation implies more guarded prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Disorders that lead to compromise in circulatory function may predispose or mimic FCE—hyperadrenocorticism; hypothyroidism; high systemic blood pressure; hyperviscosity syndrome; hyperlipidemia; bleeding diathesis; bacterial endocarditis.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
High-dose corticosteroid administration—may cause premature delivery.

ABBREVIATIONS
• ANNPE = acute noncompressive nucleus pulposus extrusion.
• FCE = fibrocartilaginous embolic myelopathy.
• CSF = cerebrospinal fluid.

FIBROSARCOMA, BONE

BASICS

OVERVIEW
• Primary bone fibrosarcoma (FSA) arises from stromal elements within the marrow cavity and is characterized by malignant spindle cells that produce varying amounts of collagen but not any osteoid or cartilage.
• In dogs, FSA accounts for <8% of all primary bone tumors, with 60% occurring in the axial skeleton and 40% arising in the appendicular skeleton.
• Bone tumors are rare in cats. FSA is the second most common bone tumor in cats and can involve the maxilla, mandible, humerus, scapula, carpus, digits, ribs, and sacrum.

SIGNALMENT
• Dog and cat; no obvious breed or gender predilections in either species.
• Mean age of dogs 9.7 years (range: 2–15 years).
• Affected cats tended to be older, but have been reported as young as 1.5 years old.

SIGNS

Historical Findings

Appendicular FSA
• Lameness, usually progressive, but occasionally acute if there is a pathologic fracture.
• A palpable swelling may be present.

Axial FSA
• Localized swelling with or without pain is common; however, anatomic site dependent.
• Tumors arising from the mandible or maxilla can be associated with halitosis, dysphagia, pain on opening the mouth, or nasal discharge.
• Vertebral tumors may induce neurologic deficits secondary to spinal cord compression.
• Rib tumors are rarely associated with respiratory signs unless large and causing space-occupying effects. Rib tumors can grow asymmetrically, with majority of growth occurring within the intrathoracic space.

Physical Examination Findings
• For appendicular FSA, lameness and a palpable swelling may be present.
• Physical examination findings may be variable for FSA for the axial skeleton depending on the size and location of the tumor; a mass may be visible or palpable.

CAUSES & RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other primary bone tumors (osteosarcoma, chondrosarcoma, hemangiosarcoma, histiocytic sarcoma, etc.).
• Metastatic bone tumors (transitional cell, prostatic, mammary, thyroid, apocrine gland anal sac carcinomas).
• Tumors that locally invade adjacent bone (nasal carcinoma; oral squamous cell carcinoma, melanoma, fibrosarcoma, ameloblastoma; synovial sarcoma; histiocytic sarcoma; digital squamous cell carcinoma, melanoma).
• Hematopoietic tumors (myeloma, lymphoma).
• Bacterial or fungal osteomyelitis.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

IMAGING
• Radiographs of the primary lesion show features of an aggressive bone lesion (bone lysis, cortical destruction, nonhomogenous bone formation, ill-defined zone of transition).
• Thoracic radiographs are recommended to screen for pulmonary metastasis (uncommon).
• CT is recommended for axial tumors to plan for surgery and/or radiation therapy.

DIAGNOSTIC PROCEDURES
• Histopathology is needed for a definitive diagnosis.
• Primary bone FSA has been reported to metastasize to a variety of locations—lungs, regional lymph nodes, other bones, skin, kidneys, pericardium, and myocardium. Consider additional diagnostic evaluation as indicated to rule out metastasis to these or other locations.

TREATMENT
• Amputation is recommended for appendicular tumors.
• For axial tumors, wide surgical excision is recommended whenever possible. If surgical excision is incomplete, adjuvant radiation therapy might help improve local control.
• Palliative analgesic therapy is recommended for patients with nonresectable local disease or gross metastasis, or when definitive therapy is declined.
• The benefit of adjuvant chemotherapy is unknown, but it may be considered for high-grade tumors; consult a veterinary oncologist for current recommendations.

MEDICATIONS

DRUG(S) OF CHOICE
• Nonsteroidal anti-inflammatory drugs (NSAIDs).
• Tramadol (2–5 mg/kg PO q6–12h).
• Gabapentin (3–10 mg/kg PO q8–24h).
• Intravenous aminobisphosphonates (pamidronate, zoledronate) might alleviate bone pain and attenuate bone resorption.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Use NSAIDs cautiously in all cats and in dogs with renal insufficiency.
• Do not combine NSAIDs with corticosteroids.

FOLLOW-UP

PATIENT MONITORING
Physical examination and thoracic radiographs every 2–3 months.

EXPECTED COURSE AND PROGNOSIS
• There is limited information regarding long-term prognosis.
• Complete excision of the primary tumor can potentially provide long-term control.
• Patients with high-grade primary bone FSA may be more likely to develop metastasis.

MISCELLANEOUS

SEE ALSO
• Chondrosarcoma, Bone.
• Osteosarcoma.

ABBREVIATIONS
• FSA = fibrosarcoma.
• NSAID = nonsteroidal anti-inflammatory drug.

Suggested Reading

FIBROSARCOMA, GINGIVA

BASICS

OVERVIEW

- Fibrosarcoma (FSA) is a malignant tumor of spindle cells that produce varying amounts of collagenous (fibrous) extracellular matrix and associated stroma.
- Oral FSA arises most commonly in the gingiva; occasionally involves lips and rarely tongue; invasion into bone is common.
- In dogs, FSA is third most common oral malignancy (20% of all oral tumors).
- In cats, FSA is second most common oral malignancy (5–15% of all oral tumors).

SIGNALMENT

- Dogs—overall, large-breed dogs are predisposed; median age 9 years (range: 1–13 years).
- Golden retrievers are overrepresented specifically for histologically low-grade but biologically high-grade FSA variant (see Pathologic Findings).
- Cats—no breed predilections; median age 8–10 years (range: 1–21 years).

SIGNS

Historical Findings

- Visible mass arising within oral cavity or causing facial deformity.
- Halitosis, hypersalivation, dysphagia, and/or bloody oral discharge.
- Oral pain—head-shy behavior and/or decreased food intake despite showing interest in food; change in food preference (favor soft vs. hard foods).

Physical Examination Findings

- Firm, smooth oral mass with intact overlying mucosa is commonly observed.
- Halitosis, hypersalivation, and/or oral bleeding.
- Difficulty or pain when opening mouth and/or facial deformity.
- Ipsilateral mandibular lymphadenopathy.
- Nasal discharge, epistaxis, or decreased nasal air flow (maxillary tumors) can be identified.

CAUSES & RISK FACTORS

None identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other malignant oral tumors, including melanoma, squamous cell carcinoma, or osteosarcoma.
- Benign tumors such as acanthomatous ameloblastoma, peripheral odontogenic fibroma (epulis), or osteoma.
- Tooth root abscess or osteomyelitis.
- Dentigerous cyst.
- Craniomandibular osteopathy (lion's jaw).

IMAGING

- Skull radiographs recommended to evaluate for bone involvement (present in 60–70%).
- Thoracic radiographs to screen for pulmonary metastasis (uncommon).
- CT imaging can more accurately determine extent of local disease and useful for planning surgery and/or radiation therapy.

DIAGNOSTIC PROCEDURES

- Histopathology required for definitive diagnosis.
- Cytology or histopathology of ipsilateral mandibular lymph node recommended to screen for metastasis.

PATHOLOGIC FINDINGS

Histologically low-grade yet biologically high-grade tumors are a distinct subset of oral FSA that tend to occur in large pure-breed dogs, particularly golden retrievers. These tumors classified as benign lesions (nodular fasciitis, chronic inflammatory nodules, granulation tissue) or low-grade FSA on histopathology. However, aggressive biologic behavior, including rapid tumor growth, bone destruction (75%), lymph node metastasis (20%), and pulmonary metastasis (12%), observed in affected dogs.

TREATMENT

- Surgical excision—removal of mass and adjacent bone (maxillectomy or mandibulectomy) with margin of at least 2–3 cm recommended whenever anatomically possible.
- If tumor margins observed to be incomplete or narrow on histopathology, adjuvant radiation therapy recommended to improve local control.
- Radiation therapy can be considered as sole local treatment modality when surgery not possible or declined; however, treatment intent might not be curative in nature.
- Palliative care focuses on pain control.

MEDICATIONS

DRUG(S) OF CHOICE

- Nonsteroidal anti-inflammatory drugs (NSAIDs).
- Tramadol (2–5 mg/kg PO q6–12h).
- Gabapentin (3–10 mg/kg PO q8–24h).
- Empiric antibiotic therapy can be considered for secondary bacterial infections.
- IV aminobisphosphonates might alleviate bone pain for dogs treated palliatively.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Use NSAIDs cautiously in all cats and in dogs with renal insufficiency.

FOLLOW-UP

PATIENT MONITORING

Physical examination every 2–3 months and thoracic radiographs every 3–4 months.

EXPECTED COURSE AND PROGNOSIS

- Most patients die or are euthanized due to progression or recurrence of local disease.
- Overall metastatic rate is 25% (regional lymph nodes and lungs).
- Prognosis with surgery alone depends on tumor size and location, with reported median survival times 9–24 months; long-term control is possible with complete excision.
- Combining surgery with radiation therapy, median survival is 18 months.
- With radiation therapy alone, median progression-free survival is 45 months for tumors <2 cm, 31 months for tumors 2–4 cm, and 7 months for tumors >4 cm.

MISCELLANEOUS

ABBREVIATIONS

- FSA = fibrosarcoma.
- NSAID = nonsteroidal anti-inflammatory drug.

FIBROSARCOMA, NASAL AND PARANASAL SINUS

BASICS

OVERVIEW
- Fibrosarcoma (FSA) is a malignant tumor of spindle cells that produce varying amounts of collagenous (fibrous) extracellular matrix and associated stroma.
- In dogs, FSA accounts for up to 5% of all canine sinonasal tumors.
- Nasal FSA uncommon in cats.

SIGNALMENT
- In dogs, no breed or gender predilections identified. Median age 9 years (range: 1–16 years).
- Uncommon in cats—no identified predilections.

SIGNS

Historical Findings
- Intermittent unilateral epistaxis and/or mucopurulent discharge, may progress to bilateral involvement.
- Sneezing, stertorous breathing, and/or facial deformity.
- Decreased appetite and/or halitosis secondary to oral cavity invasion.
- Seizures, behavior changes, and/or obtundation secondary to cranial invasion (uncommon).

Physical Examination Findings
- Epistaxis and/or nasal discharge, initially unilateral but can progress to bilateral.
- Decreased nasal air flow (unilateral or bilateral).
- Pain on nasal or paranasal sinus palpation or percussion.
- Facial deformity decreased ocular retropulsion, exophthalmia, or epiphora.
- Visible mass effect protruding through palate into oral cavity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other nasal tumors—adenocarcinoma, squamous cell carcinoma, chondrosarcoma, osteosarcoma, lymphoma, transmissible venereal tumor (dogs), nasopharyngeal polyp (cats).
- Fungal rhinitis—aspergillosis and penicilliosis (dogs), *Cryptococcus* (cats), sporotrichosis (both).
- Rhinosporidiosis (dogs).
- Foreign body.
- Thrombocytopenia or other coagulopathy.
- Tooth root abscess or oronasal fistula.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal—evaluate for thrombocytopenia if signs of epistaxis.

OTHER LABORATORY TESTS
- Nasal flush for cytology and culture—rarely helpful.
- Coagulation profile.
- Buccal mucosal bleeding time.

IMAGING
- Thoracic radiographs to screen for pulmonary metastasis (distant metastases uncommon).
- CT for detecting soft tissue opacity within nasal cavity and surrounding sinuses, bony destruction, extension through cribriform plate into brain.
- If CT scan not accessible, skull radiographs can be performed to assess for soft tissue opacity in nasal cavity and/or frontal sinuses.

DIAGNOSTIC PROCEDURES
- Blood pressure measurement to rule out systemic hypertension as cause for epistaxis.
- Mandibular lymph node cytology to screen for possible regional metastasis (uncommon).
- Rhinoscopy helpful for visualization of mass or fungal plaque and guiding subsequent tissue biopsy.
- Tissue biopsy and histopathology needed for definitive diagnosis; biopsy instrument should not pass the level of the medial canthus of the eye to avoid penetrating the cribriform plate.
- Intranasal approach to obtaining tissue biopsy preferable if treatment with radiation therapy planned.

TREATMENT
- Radiation therapy is treatment of choice.
- Conventional linear accelerator is used most commonly; however, if available, stereotactic radiation therapy can reduce number of radiation treatments and reduce adverse effects while maintaining treatment efficacy.
- Palliative radiation protocols (fewer treatments and lower total radiation dose) might be preferable for dogs with very advanced disease or if intent of treatment is primarily symptomatic.
- Surgery alone is ineffective.

MEDICATIONS

DRUG(S) OF CHOICE
- Nonsteroidal anti-inflammatory drugs (NSAIDs) for pain control.
- Prednisone (0.5–1 mg/kg PO q24h) to help relieve nasal congestion.
- Phenylephrine nasal spray can be used intermittently to help with epistaxis.
- Empiric antibiotic therapy can be considered for secondary bacterial infections.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Use NSAIDs cautiously in all cats and in dogs with renal insufficiency.
- Do not combine NSAIDs with corticosteroids.

FOLLOW-UP

PATIENT MONITORING
- Physical examinations every 2–3 months and thoracic radiographs every 3–4 months.
- CT of nasal cavity can be considered to monitor disease regression or if clinical signs recur or worsen.

EXPECTED COURSE AND PROGNOSIS
- Overall metastatic rate <20% (usually involve regional lymph nodes and/or lungs).
- Median survival with palliative care alone 3 months.
- With definitive radiation therapy, 1-year relapse-free survival rate around 50% and 2-year relapse-free survival rate around 30%.
- Recurrence/progression of tumor and recurrence of clinical signs is generally life-limiting event for nasal/paranasal FSA.
- Brain involvement is poor prognostic factor.
- Unilateral versus bilateral involvement is not a significant prognostic factor.

MISCELLANEOUS

SEE ALSO
- Adenocarcinoma, Nasal.
- Chondrosarcoma, Nasal and Paranasal Sinus.
- Epistaxis.

ABBREVIATIONS
- FSA = fibrosarcoma.
- NSAID = nonsteroidal anti-inflammatory drug.

FIPRONIL TOXICOSIS

BASICS

OVERVIEW

- Phenylpyrazole compound with selective toxicity against insects.
- Discovered in 1987, registered as a pesticide in the United States in 1996; used worldwide today.
- Blocks chloride passage through γ-aminobutyric acid (GABA) and glutamate gated chloride channels.
- Except for rabbits, low mammalian toxicity—GABA receptors less sensitive and lack mammals lack glutamate gated chloride channels.
- Uses:
  - Topical flea and tick spot-on products ("plus" versions include S-methoprene).
  - Roach and ant-bait stations. Flea and tick sprays for pets.
  - Granular turf products.
  - Soil treatment.
  - Crop pest control.

SIGNALMENT

Dogs

- Accidental ingestion and/or licking of topical spot-on products.
- Chewing ant and roach-bait stations or licking gel products.
- Ingesting liquid from bottles or granules from bags containing product.

Cats

Accidental ingestion of topical spot-on product from grooming.

Rabbits

- Inappropriate application of spot on products to rabbits.

SIGNS

- Dermal—skin irritation, alopecia, or dermal hypersensitivity reaction.
- Oral—hypersalivation, nausea, vomiting, diarrhea.
- Ingestion of large doses—CNS: hyperexcitability, tremors, convulsions, seizures, death.

Rabbits

Dermal and oral exposure (any amount) can cause anorexia, hypersalivation, ataxia, tremors, seizures and death.

CAUSES & RISK FACTORS

- Ingestion by dogs, especially young dogs, occurs more frequently due to behavioral factors.
- With chronic studies in dogs, severe neurotoxic signs were observed at a dose of 20 mg/kg.
- Wide availability and frequent access to products.
- Biggest concern is exposure to concentrated products frequently found on farms and ranches or used by pesticide control applicators.

DIAGNOSIS

- History of exposure.
- Detected in blood, tissue, hair with gas chromatography/mass spectrometry (GC/MS).
- Differential diagnosis—dogs and cats: exposure to agents that can cause dermal hypersensitivity or CNS signs.

TREATMENT

- Baseline CBC, chemistry profile, and urinalysis should be performed to rule out preexisting organ dysfunction, which could increase the risk for toxicosis.
- For dermal reaction, bathe with liquid dishwashing detergent and rinse thoroughly.
- Antihistamine or steroids for dermal hypersensitivity reaction.
- With ingestion of a large dose, one dose of activated charcoal with sorbitol may be beneficial.
- Methocarbamol for tremors.
- Anticonvulsants for seizures.
- IV fluids (balanced crystalloid) at twice maintenance if CNS signs occur.

MEDICATIONS

- Activated charcoal 1–2 g/kg PO and an osmotic cathartic (sorbitol) × 1 dose for large ingestions.
- Methocarbamol for tremors—55–220 mg/kg IV; titrate as needed; max daily dose 330 mg/kg/day (cats and dogs).
- Anticonvulsants for seizures—diazepam 0.5–1 mg/kg IV (dogs and cats); phenobarbital 2–6 mg/kg IV (dogs and cats).
- Diphenhydramine 2–4 mg/kg q8–12h PO; 0.5–2 mg/kg q8–12h IM/SC/IV.
- Dexamethasone 0.5–1 mg/kg IV/IM (dogs); 0.125–0.5 mg/kg IV/IM (cats).

FOLLOW-UP

Patients usually recover well with symptomatic and supportive care; no long-term organ damage is expected to occur.

MISCELLANEOUS

- Puppies/young dogs are less discriminating and more likely to chew up product containers.
- Young and geriatric animals may have lower detoxification capabilities.

PREGNANCY/FERTILITY/BREEDING

Fipronil was administered to rats (route of exposure not included) to determine reproductive effects. No reproductive effects were noted at 30 ppm (2.54 mg/kg/day in males and 2.74 mg/kg/day in females). The lowest dosage at which reproductive effects were observed was 300 ppm (26.0 mg/kg/day in males and 28.4 mg/kg/day in females) based on unspecified clinical signs in the offspring, reduced litter size, decreased bodyweights, decreased mating, reduced fertility, reduced postimplantation and offspring survival, and delay in physical development.

ABBREVIATIONS

- GABA = γ-aminobutyric acid.
- GC/MS = gas chromatography/mass spectrometry.

FLATULENCE

BASICS

DEFINITION
The act of expelling gases formed in the gastrointestinal (GI) tract through the anus. "Flatus" refers to gas formed in the GI tract.

PATHOPHYSIOLOGY
- Passing flatus is a normal physiologic function in the dog and cat. Variations in the volume, odor, and frequency of the pet's flatus may cause the owner to perceive the act of flatulence as a problem.
- Swallowed air (aerophagia), bacterial fermentation of nutrients, the interaction of gastric acid and pancreatic/salivary bicarbonate, and diffusion of gases from blood are the main sources of GI gas.
- Odorless gases comprise more than 99% of GI gases; these include nitrogen, oxygen, hydrogen, carbon dioxide, and methane.
- Malodorous gases containing volatile sulfur compounds comprise less than 1% of GI gases; these include ammonia, hydrogen sulfide, methanethiol, dimethylsulfide, indole, skatole, volatile amines, and short-chain fatty acids.
- Dogs and cats lack digestive enzymes to cleave oligosaccharides (commonly of vegetable source) into absorbable monosaccharides. Diets high in oligosaccharides provide substrate for colonic microbiota fermentation and lead to excessive gas formation.
- Foods containing fermentable fibers (including pectins, gums, and carrageenan) contribute to flatus directly by fermentation of the fiber by colonic microbiota.
- Dogs and cats are lactose intolerant; a dietary concentration of 1.5 g/kg/day (there is 11 g lactose in 1 cup of milk) may produce flatulence and diarrhea.
- Hypersensitivity or intolerance to certain proteins or carbohydrates is often responsible for increased volume or odor of flatus.
- Disease states causing malassimilation of nutrients (such as protein-losing enteropathies [PLEs] and exocrine pancreatic insufficiency), making them available for colonic fermentation, can cause increased flatulence.
- Infection with certain enteropathogenic organisms, such as *Giardia* sp., can cause increased flatulence.
- Antibiotics that alter the colonic microbiota may cause increased flatulence.

SYSTEMS AFFECTED
GI

GENETICS
No known genetic basis, although brachycephalic breeds are overrepresented.

INCIDENCE/PREVALENCE
Excessive flatulence was reported in 10% of dogs in the United States, with 1 out of 4 experiencing daily episodes.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog (common); cat (rare).

Breed Predilections
Excessive aerophagia is seen in brachycephalic breeds, sporting dogs, and those with gluttonous/competitive eating behavior.

Mean Age and Range
Any age.

Predominant Sex
None

SIGNS

Historical Findings
- "He who smelt it dealt it"—a pet who turns around frequently to sniff or look at its rear end.
- Increased frequency, volume, or objectionable odor of flatus reported by the pet owner.
- When excessive flatulence is due to pancreatic or GI disease, concurrent GI signs such as diarrhea, vomiting, borborygmus, changes in appetite, and weight loss may be present.

Physical Examination Findings
- May be normal.
- Abdominal discomfort due to GI gas distention.
- Increased borborygmus on abdominal auscultation or decreased gut sounds suggesting ileus.
- Low body condition score may indicate underlying pancreatic insufficiency or GI disease.
- Obesity may suggest a sedentary lifestyle or gluttonous eating habits.
- When excessive flatulence is due to aerophagia, concurrent respiratory signs such as excessive panting, increased upper- or lower-airway sounds, dyspnea, and tachypnea may be present.

CAUSES

Aerophagia
- Gluttony or competitive eating.
- Respiratory disease or any cause of increased respiratory rate or effort.
- Brachycephalic breeds.

Diet-Related
- Diets high in nonabsorbable oligosaccharides—soybeans, peas, beans.
- Diets high in fermentable fiber—pectin, gums, carrageenan, inulin, psyllium, oat bran.
- Spoiled foods.
- Dairy products.
- Abrupt changes in diet.

Disease Conditions
- Acute and chronic intestinal disease—including protein-losing enteropathies; intestinal dysbiosis; neoplasia; irritable bowel syndrome; parasitism; bacterial, protozoal, or viral enteritis; and food allergy or intolerance.
- Exocrine pancreatic insufficiency.

RISK FACTORS
- Nervous, gluttonous, or competitive eating.
- Eating soon after exercise.
- Brachycephalic breeds.
- Large-breed dogs.
- Abrupt dietary changes.
- Inappropriate (table food that is likely to be fermented) or spoiled foods.
- Lack of regular exercise.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Differential diagnoses include excessive aerophagia, dietary factors, motility disorders, malabsorption, and changes in the colonic microbiota.
- Distinguish dietary and behavioral causes of flatus from GI disease by thorough evaluation of the patient history; this allows the clinician to ascertain the type of diet, amount fed, frequency of feeding, frequency of dietary changes or additions, the environment in which the patient is fed, and frequency of exercise.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal unless significant pancreatic or GI disease is present (e.g., hypoalbuminemia in PLE).

OTHER LABORATORY TESTS
- Rectal cytology to evaluate presence of neoplasia, parasites, protozoa, or fungal organisms.
- Zinc sulfate flotation tests and fecal PCR, ELISA, or culture to detect *Giardia* sp., *Tritrichomonas* (cats), and other parasitic, bacterial, viral, and protozoal infections.
- Serum trypsin-like immunoreactivity to diagnose exocrine pancreatic insufficiency.
- Serum cobalamin and folate concentrations to investigate small intestinal malabsorptive disease.

IMAGING
- Thoracic and abdominal radiographs can show the distribution of gas in the alimentary tract, as well as reveal specific reasons such as gastric dilatation volvulus, pulmonary infiltrates, and megaesophagus.
- Abdominal ultrasonography to evaluate GI thickness and rule out masses.
- Contrast studies may be needed in some cases to detect an obstructive pattern and provide insight into GI transit time.
- Assessment of gut motility using motility capsules and scintigraphic markers may be available in certain referral hospitals.

DIAGNOSTIC PROCEDURES
GI biopsy specimens obtained at surgery or via endoscopy to detect infiltrative GI disease.

PATHOLOGIC FINDINGS
N/A

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient—treat any underlying pancreatic or GI disease.

NURSING CARE
None

ACTIVITY
Encourage an active lifestyle—exercise increases GI motility, which will help decrease gas retention and increase regularity of defecation.

DIET
- Feed smaller meals more frequently in an isolated, quiet environment.
- Provide interactive/modified feeding containers to slow the rate of food intake.
- Change diet to one that is highly digestible, with low fermentable fiber and fat content. If food intolerance is suspected, consider a trial of hydrolyzed protein diet or novel protein diet.
- Limit vegetables, which are generally high in fermentable fibers, in pet's diet.

CLIENT EDUCATION
- Encourage a consistent diet.
- Encourage routine exercise.
- Prevent coprophagia by leash-walking and cleaning up fecal waste daily.

SURGICAL CONSIDERATIONS
None

MEDICATIONS

DRUG(S) OF CHOICE
- Carminatives are medications or remedies that relieve flatulence; there are few studies to show safety or benefit of these drugs in dogs or cats.
- Zinc acetate and bismuth are divalent cations that bind sulfhydryl compounds (e.g., hydrogen sulfide) and can decrease odor of flatulence.
- *Yucca schidigera* decreases odor by binding ammonia and by decreasing the production and release of hydrogen sulfide in the intestinal tract.
- Dry activated charcoal adsorbs virtually all odiferous gases due to its large surface area.
- Inclusion of activated charcoal (0.32 g/5 kg), *Y. schidigera* (2.45 mg/5 kg), and zinc acetate (17 mg/5 kg) in a treat reduced the frequency of highly odiferous episodes in dogs.
- Bismuth subsalicylate (dogs: 1 mL/kg/day PO, in divided doses) adsorbs hydrogen sulfide and has antibacterial properties. Do not use in cats due to potential for salicylate toxicity.
- Simethicone (25–200 mg PO q6h) is an antifoaming agent that reduces the surface tension of gas bubbles, allowing easier coalescence and release of intestinal gas; its effectiveness in controlling flatulence in animals is unknown.
- Pancreatic enzyme supplements reduce flatulence in patients with exocrine pancreatic insufficiency.
- Probiotics, specifically *Enterococcus faecium* SF 68, the probiotic in Purina Veterinary Diets® FortiFlora® Canine Nutritional Supplement, has been shown to help nutritionally manage dogs with flatulence by promoting greater beneficial intestinal microflora.
- Nonabsorbed antibacterials such as neomycin and rifaximin may have a role in normalizing gut microbiota and decreasing flatulence.

CONTRAINDICATIONS
Avoid bismuth subsalicylate in cats and in dogs with gastroduodenal ulceration and bleeding disorders.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
More than 30 herbal and botanical carminatives are available; however, the dosage, safety, and efficacy are unknown.

FOLLOW-UP

PATIENT MONITORING
Response to therapy.

PREVENTION/AVOIDANCE
- Avoid diets high in nonabsorbable oligosaccharides and high in fermentable or nonfermentable fibers.
- Avoid milk products, spoiled diets, and abrupt changes in diet.
- Do not feed shortly after exercise.

POSSIBLE COMPLICATIONS
None

F

FLEA BITE HYPERSENSITIVITY AND FLEA CONTROL

BASICS

DEFINITION
Flea bite hypersensitivity (FBH)—allergic reaction to antigens in flea saliva.

Flea Life Cycle
• *Ctenocephalides felis* (cat flea)—not host specific: parasitizes cats, dogs, wildlife. • Adult fleas mate on host and within 24 hours females lay up to 50 eggs per day. • Eggs fall off pets into the environment and hatch. • Larvae have negative phototropism and infest carpets, upholstery, and under furniture. • Eggs from wildlife and feral cats survive in moist, protected areas. • Larvae undergo molts until they pupate; the cocoon enhances survival. • Adults emerge when environmental conditions and host availability are favorable. • Less than 5% of the total flea burden is found as adults on the pet. • The majority of the biomass is found as immature stages in the home and in peridomestic areas.

PATHOPHYSIOLOGY
• Antigens in flea saliva cause FBH. • Major allergen—*Ctef1*, an 18-kD protein. • Flea saliva—contains histamine-like compounds that irritate skin. • Both immunoglobulin (Ig) E and IgG anti-flea antibodies reported. • Immediate and delayed hypersensitivity reactions reported. • Mast cell degranulation follows antigen exposure. • FBH is associated with a T_H2 response.

SYSTEMS AFFECTED
Skin

GENETICS
No known inheritance pattern.

INCIDENCE/PREVALENCE
• Varies with climatic conditions and flea population.
• In areas where fleas are prevalent, FBH is considered the most common skin disease.

GEOGRAPHIC DISTRIBUTION
May occur anywhere; nonseasonal in climates that are warm and humid.

SIGNALMENT

Species
Dogs and cats.

Breed Predilections
None

Mean Age and Range
Typically signs by 5 years of age, but may be seen at any age.

SIGNS

Historical Findings
• Pruritus. • Lack of consistent or effective flea control.

Physical Examination Findings
• Determined by the severity of the reaction. • Finding fleas and flea dirt is supportive but not essential for diagnosis. • Sensitive animals require a low exposure and tend to overgroom, removing evidence of infestation. • Dogs—lesions concentrated in the caudal-dorsal lumbosacral region; caudal-lateral aspect of the thighs, lower abdomen, and inguinal region; primary lesions are papules; secondary lesions (hyperpigmentation, lichenification, alopecia, and scaling) and pyotraumatic dermatitis ("hotspots") are common. Erythema and papules around the umbilicus are highly suggestive ("peri-umbilical rush")
• Cats—head and neck pruritic papular dermatitis and/or a generalized distribution including dorsal lumbosacral area, caudomedial thighs, and abdomen. Also common clinical signs are self-induced symmetrical alopecia and lesions of the eosinophilic granuloma complex.

CAUSES
See Pathophysiology.

RISK FACTORS
Exposure to fleas; atopy may predispose dogs to FBH.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Food allergy. • Atopy. • Ectoparasitism. • Dermatophytosis. • Pyoderma. • Any pruritic skin disease.

CBC/BIOCHEMISTRY/URINALYSIS
• Usually normal. • Cats—occasional eosinophilia.

OTHER LABORATORY TESTS
• Skin scrapings—negative. • Flea combings—may find fleas or flea dirt. • Intradermal allergen testing (IDT), radioallergosorbent test (RAST), and ELISA—variable accuracy; both false-positive and false-negative results reported.

DIAGNOSTIC PROCEDURES
• Diagnosis based on historical information, clinical signs, and response to anti-flea treatment. • Fleas or flea dirt is supportive but not mandatory. • Identification of *Dipylidium caninum* segments in stool is supportive. • The only way to confirm FBH is by response to treatment.

PATHOLOGIC FINDINGS
• Superficial perivascular to interstitial dermatitis. • Eosinophils often the predominant cell type.• Eosinophilic intra-epidermal microabscesses may be visible. • In cats—superficial or deep perivascular to interstitial dermatitis with numerous eosinophils and mast calls. • Histopathologic evaluation—does not differentiate FBH from other hypersensitivities.

TREATMENT

APPROPRIATE HEALTH CARE
Outpatient therapy.

NURSING CARE
N/A

DIET
N/A

CLIENT EDUCATION
• Inform owners that there is no cure for FBH; flea-allergic animals often become more sensitive to flea bites as they age. • Hyposensitization is not effective. • Medications that stop itching are meant to bring relief while flea control is instituted.

MEDICATIONS

DRUG(S) OF CHOICE

Itch Relief

Corticosteroids
• Anti-inflammatory dosages for symptomatic relief while instituting adequate flea control. Use only as much as is needed and for the shortest duration to achieve the desired effect. • Oral—prednisolone: cats, 1–2 mg/kg PO q24h for 5–7 days then taper; dogs, 0.5–1 mg/kg PO q24h for 7 days then taper, or for 4 days without tapering.

Oclacitinib
• Anti-itch, mild to moderate anti-inflammatory properties approved for allergic itch relief in dogs only. Usually a 7–10-day period is enough to control the itch while the anti-flea treatment is enhanced. • Oral: 0.4–0.6 mg/kg q12h for 14 days, then reduce frequency to q24h.

Antihistamines
Little to no effect.

Flea Control
The most important therapy is the immediate reduction or elimination of adult fleas on the host. In a highly infested environment, it is recommended to treat the surroundings as well.

Pet-Targeted Flea Control
• Oral: ○ Nitenpyram—adulticide; has the fastest onset, but short acting; for dogs q24h, for cats q48h. ○ Spinosad—monthly oral treatment for dogs and cats. ○ Isoxazolines—very effective antiparasitic drugs, lotilaner, and sarolaner monthly and fluralaner trimonthly. • Topical/spot-on: ○ Dinotefuran/pyriproxyfen—rapid-acting spot-on product for dogs and cats; a second canine product

(CONTINUED) # FLEA BITE HYPERSENSITIVITY AND FLEA CONTROL

contains high-dose permethrin and should not be used on cats. ○ Fipronil plus insect growth regulator (IGR)—spot-on treatment for cats and dogs (spray treatment for dogs). ○ Imidacloprid plus IGR—monthly spot-on treatment for cats and dogs; a second canine product contains permethrin and should not be used on cats; also available as a collar. ○ Indoxycarb—monthly spot-on, dogs only, activated by flea digestive enzymes, contains permethrin, should not be used on cats. ○ Selamectin—for dogs and cats, monthly spot-on; also has insect development inhibitor (IDI) action. ○ Selamectin plus sarolaner spot-on for cats—monthly spot-on. ○ Fluralaner spot-on for dogs and cats—tri-monthly treatment. • Sprays—usually contain pyrethrins and pyrethroids with IGR.

IGRs

S-methoprene and pyriproxyfen are analogues of insect juvenile hormone that bind to immature stages and prevent maturation.

IDIs

Lufenuron and selamectin inhibit chitin synthesis in egg shell, immature stages, and adults.

Premises-Targeted Flea Control

• Indoor treatment: ○ Vacuuming significantly reduces the flea burden: removing eggs, larvae, and adult fleas; particularly carpets, furniture and the floor under furniture. ○ "Foggers/bombs" and premises sprays—contain organophosphates, pyrethrins, and/or IGRs. Etofenprox plus IGR and permethrin/pyrethrin plus IGR, available in inverted aerosol sprays; apply according to manufacturer's directions; treat all areas of the house; can be applied by the owner. ○ Foggers/bombs do not effectively penetrate all areas commonly inhabited by fleas such as under furniture; handheld sprays are highly effective against biomass, may be directed where flea populations reside, and have long residual activity. • Professional exterminator—discuss products with representative.

Environment-Targeted Flea Control

• Outdoor treatment—concentrate in shaded areas; sprays usually contain pyrethroids or organophosphates and an IGR; owners should be educated on areas of application based on likelihood of reinfestation from feral cats and wildlife. • Nematode (*Steinerma carpocapsae*)—may kill *C. felis* larvae and pupae, but efficacy is unknown; no knowledge of the effects these worms might have on beneficial insects, mammals, or humans.

CONTRAINDICATIONS

N/A

PRECAUTIONS

• Label instructions—must be strictly followed. • Spinosad can potentiate neurologic side effects of high-dose ivermectin—but is safe when combined with heartworm preventive dose. • Isoxazolines should be used with caution in animals with preexisting epilepsy. • Pyrethrin/pyrethroid-type flea products—adverse reactions include depression, hypersalivation, muscle tremors, vomiting, ataxia, dyspnea, and anorexia: do not use in cats. • Organophosphates—inappropriate given the current alternatives.

ALTERNATIVE DRUG(S)

• Powders and dips—adverse reactions and toxicity make their use inappropriate given the current alternatives. Shampoos containing D-limonene on cats can cause acute necrotizing dermatitis and septicemia. • Over-the-counter products often contain the same ingredient(s), but the absence of proper education frequently leads to failure in flea control.

FOLLOW-UP

PATIENT MONITORING

• Pruritus—a decrease means the FBH is being controlled. • Fleas and flea dirt—absence is not always a reliable indicator of successful treatment.

PREVENTION/AVOIDANCE

• Warm climates and infested premises require year-round flea control. • Seasonally warm climates—begin flea control when temperatures consistently remain above freezing.

POSSIBLE COMPLICATIONS

• Secondary bacterial folliculitis. • Acute moist dermatitis. • Acral lick dermatitis.

EXPECTED COURSE AND PROGNOSIS

Prognosis is excellent if strict flea control is instituted.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Anemia—could result from heavy flea burden, especially in puppies or kittens. • *Dipylidium caninum* due to ingestion of the flea.

AGE-RELATED FACTORS

Package should be consulted for the minimum approved age for application.

ZOONOTIC POTENTIAL

• Humans can be bitten by fleas; the resulting papular rash can be mild to extensive, depending on numbers of fleas and individual hypersensitivity reactions. • *C. felis* can transmit zoonotic agents, including *B. henselae* (cat scratch disease), *R. felis* (murine typhus, flea-borne typhus), and *D. caninum* (tapeworms).

PREGNANCY/FERTILITY/BREEDING

• Corticosteroids and organophosphates—do not use in pregnant bitches and queens. • The safe use of sarolaner and afoxolaner has not been evaluated in breeding, pregnant, or lactating dogs.

SYNONYMS

• Flea bite allergy. • Flea allergy dermatitis.

ABBREVIATIONS

• ELISA = enzyme-linked immunosorbent assay. • FBH = flea bite hypersensitivity. • IDI = insect development inhibitor. • IDT = intradermal allergen testing. • Ig = immunoglobulin. • IGR = insect growth regulator. • RAST = radioallergosorbent test.

FOOD REACTIONS, DERMATOLOGIC

BASICS

DEFINITION
• Adverse reactions to food affecting the skin. • Associated with ingestion of one or more substances. • Reaction may be immunologic or idiosyncratic.

PATHOPHYSIOLOGY
• Pathogenesis not completely understood. • Food hypersensitivity—immediate and delayed reactions to specific ingredients documented; immediate reactions presumed to be type I hypersensitivity reactions; delayed presumed to be type III or IV. • Failure or prevention of the development of oral tolerance to food allergens may encourage sensitization. • Food intolerance—nonimmunologic, idiosyncratic reaction; involves metabolic, toxic, or pharmacologic effects of offending ingredients. • Adverse food reaction is the most common term used, and does not distinguish between immunologic and idiosyncratic reactions. • Adverse food reactions patients associated with an increased predisposition to atopy. • Cutaneous adverse food reactions can trigger flares of atopic dermatitis.

SYSTEMS AFFECTED
• Skin/exocrine. • Gastrointestinal. • Nervous.

GENETICS
N/A

INCIDENCE/PREVALENCE
• Approximately 5% of all dermatitis and 10–15% of allergic dermatitis in dogs and cats are caused by adverse reactions to food. • 13–30% of food allergic dogs have concurrent atopy or flea bite hypersensitivity. • Third most common pruritic skin disease in the dog; second most common in the cat. • Percentages vary greatly with clinicians and geographic location.

SIGNALMENT
Species
Dogs and cats.

Breed Predilections
• Dogs—none reported; breeds associated with atopic dermatitis overrepresented. • Cats—Siamese.

Mean Age and Range
• Any age—dogs: possibly increased development (over other allergic dermatoses) in patients <12 months or >7 years of age; 40% of cases develop at <12 months of age in one study; cats: patients <2 years or >5 years of age. • Most adult patients have been fed the offending allergen for over 2 years prior to becoming symptomatic.

Predominant Sex
None reported.

SIGNS
General Comments
• Symptoms similar to other hypersensitivity reactions. • Pruritus is the main dermatologic sign.

Historical Findings
• Pruritus of any bodily location. • Usually nonseasonal. • Poor response to anti-inflammatory doses of glucocorticosteroids, or oclacitinib or lokivetmab. • Recurrent bacterial folliculitis with or without pruritus. • Persistent otitis externa. • Concurrent gastrointestinal symptoms in a minority of cases—vomiting and/or diarrhea, excessive borborygmus, flatulence, and frequent bowel movements. • Very rare association of neurologic signs (seizures) with food hypersensitivity. • Respiratory signs have been reported in dogs.

Physical Examination Findings
• Dogs—rump, perineum, axillae, groin, face, and interdigital areas frequently affected. • Cats—face, neck, and ears frequently affected. • Cats—lesions of the eosinophilic granuloma complex. • Otitis externa. • Malassezia dermatitis. • Secondary bacterial folliculitis. • Plaques. • Pustules. • Erythema. • Crusts. • Scale. • Self-induced alopecia. • Excoriation. • Lichenification. • Hyperpigmentation. • Urticaria. • Angioedema. • Pyotraumatic dermatitis. • Acral lick dermatitis.

CAUSES
• Immune-mediated reactions (food hypersensitivity)—result from the ingestion and subsequent presentation to the immune system of one or more glycoproteins (allergens) either before or after digestion; sensitization may occur at the gastrointestinal mucosa, after the substance is absorbed, or both; cross-reactivity between various food allergens, and between food and pollen allergens, has been demonstrated. • Non-immune-mediated reactions (food intolerance)—result of ingestion of foods with high levels of histamine or substances that induce histamine either directly or through histamine-releasing factors.

RISK FACTORS
• Unknown. • Intestinal parasites, infection, or inflammation may damage the intestinal mucosa, resulting in the abnormal absorption of allergens and subsequent sensitization.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Flea bite hypersensitivity—usually confined to the caudal half of the body; often seasonal. • Atopy—similar clinical symptoms, but typically develop between 1 and 3 years of age; 20–30% of dogs with adverse reactions to food also have atopic dermatitis. • Drug reactions—history of drug administration before the development of signs and improvement after withdrawal of the suspected drug. • Scabies mites—pruritus usually specific to the ears, elbows, and hocks (dogs) and head, ears, and neck (cats); mites in skin scrapings and/or response to specific therapy.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
In vitro (serum, hair, saliva) allergy tests; poor correlation between test results and food exposure; poor correlation between diet trial and test results; neither sensitive or specific; significant discrepancy between labs; currently no standard to enable comparisons between techniques; not recommended either as a diagnostic test for food allergy or for choosing appropriate ingredients for food trials.

DIAGNOSTIC PROCEDURES
Diagnosis requires response to dietary exclusion in the form of restricted-ingredient food trials followed by challenge and redevelopment of symptoms.

Food Elimination Diet
• Definitive test for adverse food reactions. • Tailored to the individual patient. • Diet must be restricted to one novel protein and one novel carbohydrate—veterinary prescription novel protein or hydrolyzed diets strongly recommended over over-the-counter novel protein diets; multiple studies report contamination of over-the-counter diets with proteins not listed on the label. • Most patients will improve within 6–8 weeks. • Food trials should be continued up to 10 weeks unless improvement occurs earlier. • Home-cooked food trials remove possible sources of antigen due to processing, storage, and cross-contamination from other ingredients.

Challenge and Provocation Diet Trials
• Used if the patient improves on the elimination diet. • Challenge—feed the patient the original diet; a return of the signs confirms that the original diet contains an inciting ingredient; the challenge period should last until the signs return, but no longer than 10 days. • Provoke (provocation diet trial)—if the challenge confirmed the presence of an adverse food reaction, add single ingredients to the elimination diet; test ingredients include a full range of meats (beef, chicken, fish, pork, lamb), a full range of carbohydrates (corn, wheat, soybean, rice), eggs, and dairy products; the provocation period for each ingredient should last up to 10 days or less if signs develop sooner; results

guide the selection of commercial foods that do not contain the offending substance(s).

PATHOLOGIC FINDINGS

• Skin biopsy—not diagnostic; may be helpful to confirm or eliminate other differential diagnoses. • Histopathologic findings—variable; common findings suggest hypersensitivity; secondary bacterial folliculitis or Malassezia dermatitis may be present.

TREATMENT

Avoidance of the offending food substance(s).

APPROPRIATE HEALTH CARE

Outpatient management.

DIET

Avoid any food substances that caused the clinical signs to return during the provocation phase of the diagnosis.

CLIENT EDUCATION

• Explain the principles involved in each phase of the diagnostic test diets. • Instruct client to eliminate treats, chewable toys, vitamins, medication wraps, and flavored medications (e.g., parasiticides), as these may contain previously fed ingredients. • If a home-cooked diet is needed, the website www.balanceit.com is useful to create a diet with adequate supplementation. • Outdoor pets must be confined to prevent foraging and hunting. • Advise all family members to adhere to the restricted-ingredient diet trial protocol.

MEDICATIONS

DRUG(S) OF CHOICE

• Systemic antipruritic drugs—may be useful during the first 2–3 weeks of diet trial to control self-mutilation. • Antibiotics or antifungal medications—useful for secondary bacterial folliculitis or Malassezia dermatitis.

CONTRAINDICATIONS

• Antibiotics that are known to have anti-inflammatory effects (e.g., tetracycline, doxycycline, erythromycin, and trimethoprim-potentiated sulfas) may confuse response to dietary trials. • Chewable medications may contain a food protein such as chicken or beef to which the animal is allergic. • Glucocorticosteroids and antihistamines should be discontinued for at least 10–14 days while on the diet trial to allow correct assessment of the animal's response.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUG(S)

None

FOLLOW-UP

PATIENT MONITORING

Examine patient and evaluate and document the pruritus and clinical signs every 3–4 weeks.

PREVENTION/AVOIDANCE

Avoid intake of any of the ingredients included in the previous diet, including treats and chewable vitamins and toys.

POSSIBLE COMPLICATIONS

Other causes of pruritus, such as bacterial or yeast infections, as well as parasites such as fleas or mites, must be eliminated or controlled to permit accurate assessment of the effect of dietary antigens on clinical signs.

EXPECTED COURSE AND PROGNOSIS

• Prognosis is good if food ingredients are the only cause of pruritus and offending ingredients are avoided. • Rarely a dog or cat may develop hypersensitivity to new substances, requiring a new elimination diet trial. • A partial response to a food elimination diet trial suggests a combined food reaction with atopy or with another cause of pruritus.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Superficial bacterial folliculitis. • Malassezia dermatitis. • Otitis externa. • Atopic dermatitis.

AGE-RELATED FACTORS

None, except age ranges during which symptoms of food allergy most often develop.

ZOONOTIC POTENTIAL

None

PREGNANCY/FERTILITY/BREEDING

N/A

SYNONYMS

• Adverse reactions to food. • Food allergy. • Food hypersensitivity. • Food intolerance.

F

FOOD REACTIONS (GASTROINTESTINAL), ADVERSE

BASICS

DEFINITION
• Adverse food reactions encompass disorders with an immunologic (food allergy), non-immunologic (food intolerance), and toxic basis (food intoxication). • Food allergy, food intolerance, and food intoxication may have similar signs, diagnostics, and treatments and may not be easily distinguishable.

PATHOPHYSIOLOGY
• The pathogenesis of food allergy involves complex immunologic events—a leaky intestinal mucosal barrier, dysregulated immune responses, and loss of oral tolerance. Most food allergies are due to type 1 hypersensitivity reactions. Major food allergens include milk, eggs, beef, chicken, and plant proteins from corn, wheat, and soybeans. • Food intolerance may be due to idiosyncratic reactions to dietary ingredients or additives, pharmacologic reactions to compounds in the diet, defects or deficiencies in the metabolic pathways needed to use the food, or a toxicity reaction to food ingredients or spoiled foodstuffs. Unlike food allergy, food intolerance requires no previous exposure to the food product. • Toxic reactions to food may occur when a foodstuff is ingested in large amounts (e.g., onion poisoning). • Toxicity reactions occur when food contains toxins (e.g., aflatoxin, a hepatotoxin produced by *Aspergillus* spp.) or has spoiled or been contaminated by bacterial growth.

SYSTEMS AFFECTED
• Gastrointestinal (GI)—small intestine, colon, and/or stomach can be affected by adverse food reactions. • Skin/exocrine—food allergy can manifest with concurrent dermatologic signs or exclusive dermatologic signs.

GENETICS
Gluten sensitivity in Irish setters has a genetic basis.

INCIDENCE/PREVALENCE
Up to 50% of dogs and cats with chronic GI signs respond to an elimination diet.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Soft-coated wheaten terriers affected with the syndrome of protein-losing enteropathy (PLE) and/or protein-losing nephropathy (PLN) have been shown to be affected by food allergies, which may play a role in the development of PLE/PLN. • Gluten-sensitive enteropathy is an autosomal recessive trait seen in some Irish setters.

Mean Age and Range
• Dogs affected with diet-responsive chronic enteropathy tend to be young (median age 3.4 years in one study). • Cats of all ages have been reported to be affected (median age 5 years).

Predominant Sex
None

SIGNS

General Comments
• Food intolerance commonly produces diarrhea (small or large bowel), vomiting, flatulence, anorexia, and abdominal discomfort. • Food allergy may cause cutaneous signs, such as pruritus and hair loss, which may be associated with GI signs.

Historical Findings
• Acute food intolerance may accompany feeding a novel foodstuff, a new food source, or dietary change. • Clients may report cessation of clinical signs in the fasted state or within days of an elimination diet trial.

Physical Examination Findings
The physical examination is generally nonspecific, but may show abdominal discomfort, flatulence, bloating, or patchy areas of alopecia along the pinnae of the ears and periorbital regions, especially in cats.

CAUSES
• Idiosyncratic reactions to food additives—colorings, preservatives (butylated hydroxyanisole, monosodium glutamate, sodium nitrate, sulfur dioxide, etc.), spices, propylene glycol, etc. • Pharmacologic reactions—vasoactive substances (i.e., histamine), psychoactive agents, stimulants (i.e., theobromine, caffeine), etc. • Metabolic defects or deficiencies—brush border enzyme defects (i.e., lactase deficiency), inborn errors of metabolism, aminopeptidase N (in gluten-sensitive enteropathy). • Toxic reactions to foods or spoiled foods—spices, oxalate toxicity, lectin toxicity, *N*-propyl disulfide aflatoxicosis, ergotism, botulism, dietary indiscretion, etc. • Genetic mutations in innate immunity genes regulating host responses to dietary constituents.

RISK FACTORS
• Young Irish setters susceptible to gluten-sensitive enteropathy may be at greater risk of developing the disease if exposed to gluten at an early age. • Host genetic susceptibility is suspected in wheaten terriers and German shepherd dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Infectious diseases—intestinal nematodes, *Giardia*, histoplasmosis, salmonellosis, toxoplasmosis (cats), feline infectious peritonitis. • Infiltrative GI diseases—inflammatory bowel disease, histiocytic ulcerative colitis (boxers, French bulldogs). • Endocrine diseases—hypoadrenocorticism, hyperthyroidism (cats). • Exocrine pancreatic insufficiency. • Lymphangiectasia. • GI motility disorders. • Pancreatitis. • Metabolic diseases (renal disease, liver disease).

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal; animals with food allergy may occasionally have eosinophilia.

OTHER LABORATORY TESTS
• Few diagnostic tests are specific to adverse food reactions, but the following are helpful to rule out differential diagnoses and to identify complicating factors. • Serum cobalamin and folate—can help determine involvement of proximal and distal small intestine as well as identify possible need for supplementation. • Trypsin-like immunoreactivity—for exocrine pancreatic insufficiency. • Baseline cortisol or adrenocorticotropic hormone stimulation test—to rule out hypoadrenocorticism if clinically suspected. • Total T_4 (cats)—to evaluate for hyperthyroidism if clinically suspected. • Fecal alpha-1 proteinase inhibitor—this test can be performed if there is a suspicion of PLE, but other lab results are equivocal, or there is complicating proteinuria. • Perinuclear antineutrophilic cytoplasmic autoantibodies—this test is currently limited to use in a research setting, but has shown promise in early detection of PLE and PLN, believed to be due to underlying food allergy, in soft-coated wheaten terriers. Additionally, it may help to differentiate between dogs with diet-responsive enteropathies and enteropathies requiring treatment with glucocorticoids. • Fecal flotation and fecal smear—perform 2–3 tests over several days to increase sensitivity. • Empiric deworming with a broad-spectrum anthelminthic may be considered to address possible undetected parasitism.

IMAGING
• Abdominal radiographs or ultrasound may be useful in eliminating differential diagnoses. • Doppler evaluation (ultrasound) may detect alterations in blood flow through the celiac and cranial mesenteric arteries of dogs.

DIAGNOSTIC PROCEDURES
• Perform an elimination diet trial of 2 weeks in cats and 3 weeks in dogs with GI signs. • Following improvement on an elimination diet, use challenge exposure to sequential single ingredients to specifically identify the incriminating dietary ingredient. While technically the gold standard, this is generally impractical in a clinical setting.

(CONTINUED) # FOOD REACTIONS (GASTROINTESTINAL), ADVERSE

• Exclusive feeding with a hydrolyzed or novel protein source indefinitely is generally required to prevent clinical relapse. • Perform urinalysis and urine protein : creatinine ratio (if indicated) in diet-responsive wheaten terriers to screen for concurrent glomerular injury with urinary protein loss.

PATHOLOGIC FINDINGS
Villous atrophy and mild lymphoplasmacytic enteritis may be seen with food allergy.

TREATMENT

APPROPRIATE HEALTH CARE
Generally treat on an outpatient basis.

NURSING CARE
If an adverse food reaction is severe, IV fluid therapy, administration of antiemetics, and nutritional support via enteral-assisted feeding may be temporarily required.

ACTIVITY
No restrictions.

DIET
• Lifelong dietary management is essential for animals with food intolerance and food allergy. • Diets that can be chosen for an elimination diet trial include veterinary prescription hydrolyzed protein diets, commercial novel protein diets (available as veterinary prescription diets or over-the-counter products), or a home-cooked novel protein diet. • Novel protein diets are foods containing only protein sources to which the animal has not been previously exposed and are selected based on a careful dietary history. • Over-the-counter novel protein diets have been found to contain proteins other than those listed on the label, which may be due to contamination during processing; veterinary prescription products are prepared specifically for animals with food allergy and should be chosen when possible. • Home-prepared novel protein diets can uncommonly result in a beneficial response in animals who did not respond to a commercial diet containing the same protein. Considerations for home-prepared novel protein diets are that many are not suitable for long-term feeding (unless the diet is complete and balanced with the help of a veterinary nutritionist) and create inconvenience for the owner, which may limit compliance. • Hydrolyzed protein diets are created by enzymatic hydrolysis of the intact protein into peptides small enough to reduce the potential of the protein to induce an allergic response. • Hydrolyzed diets are ideal when an animal has been exposed to many different protein sources or when a reliable dietary history cannot be obtained. • Hydrolyzed protein diets can retain some antigenicity and, if possible, the parent protein of the hydrolyzed diet should be a protein to which the animal does not have a known sensitivity. • Hydrolyzed protein diets may also benefit animals without true food allergy due to the improved digestibility of the diet.

CLIENT EDUCATION
• Owners should be aware of possible sources of food antigen during an elimination trial that may make the animal's response difficult to interpret, including table scraps, flavored medications and toothpastes, and coprophagy. • Counsel clients on the necessity of lifelong avoidance of ingredients to which their animal is sensitive.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS
N/A

FOLLOW-UP

PATIENT MONITORING
• Assess efficacy of elimination diet trial by observing improvement in GI signs. • Failure to improve in 2–3 weeks may warrant a subsequent trial with another diet if adverse food reaction is strongly suspected, or continued work-up for other causes of GI signs, including endoscopy with biopsies.

PREVENTION AND AVOIDANCE
Avoid foods, treats, and flavored medications outside of the elimination diet.

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
The prognosis is excellent as long as the offending dietary components are successfully identified and avoided.

MISCELLANEOUS

ASSOCIATED CONDITIONS

F

GALLBLADDER MUCOCELE

BASICS

OVERVIEW

• Gallbladder (GB) accumulation of tenacious, thick, mucin-rich, inspissated bile conglomerate (sludge) impairing GB reservoir capacity and GB contraction, thereby thwarting periprandial bile expulsion; often associated with episodic abdominal pain. • Organized sludge expands GB lumen, flattens/thins GB wall; when severe, provokes necrotizing cholecystitis and occasional GB rupture. • Canine syndrome, rare in cats. • Initiated by GB dysmotility.

SIGNALMENT

• Dog. • Shetland sheepdogs, miniature schnauzers, cocker spaniels, bichon frisé, shih tzu overrepresented in one study of 219 dogs. • Middle-aged to older adults. • No sex predilection. • Associated with endocrinopathies—adrenal hyperplasia (typical or sex hormone atypical form), hypothyroidism, diabetes mellitus, and administration of glucocorticoids; these likely associated with GB dysmotility, hypertriglyceridemia, or hypercholesterolemia that may impart negative influence on GB contraction. • Notably associated with hypertriglyceridemic syndromes.

SIGNS

General Comments

• Symptomatic or asymptomatic—depending on stage at diagnosis: mature vs. immature gall bladder mucocele (GBM). • Asymptomatic GBM—often serendipitously discovered on abdominal US.

Historical Findings: Symptomatic

• Episodic periprandial abdominal discomfort. • Anorexia. • Vomiting. • Lethargy. • ± Polyuria/polydipsia—reflects underlying endocrinopathy. • Collapse—vasovagal episode or bile peritonitis.

Physical Examination Findings

• May demonstrate no physical signs if immature GBM. • ± Lethargy. • ± Cranial abdominal discomfort—GB dysmotility and maturing GBM. • Jaundice late in syndrome. • ± Dehydration. • ± Fever—secondary infection.

CAUSES & RISK FACTORS

• Inborn errors of lipid metabolism (hypertriglyceridemia)—miniature schnauzer, Shetland sheepdogs, beagles, others. • Medical/dietary conditions provoking hypercholesterolemia or dyslipidemia—endocrinopathies, recurrent pancreatitis, feeding high-fat diet to dog with predisposing disorder or dyslipidemia. • GB dysmotility. • Cystic mucosal hyperplasia—common in older dogs; may be aggravated by sex hormones (e.g., progestins).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Conditions causing GB bile stasis—GB dysmotility; or other causes of incomplete GB emptying such as cystic duct or GB wall neoplasia, pedunculated adenomatous mucosal lesions, ball-valve cholelith obstructions.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

• Inflammatory leukogram—variable, depends on GB wall viability and hepatic impact of GBM. • Stress leukogram—if underlying hyperadrenocorticism. • Nonregenerative anemia—if chronic inflammation or hypothyroidism.

Biochemistry

• High liver enzymes—may be noted on acute presentation for GBM or serendipitously discovered on routine health assessments; alkaline phosphatase (ALP), γ-glutamyl-transferase (GGT), alanine aminotransferase (ALT), ± aspartate aminotransferase (AST) variably affected; ALP activity predominant. • High ALP—often associates with glycogen-type vacuolar hepatopathy (VH), may reflect adrenal endocrinopathy or glucocorticoid therapy. • Variable hyperbilirubinemia; depends on GBM maturation and common bile duct patency. • Low albumin—if ruptured biliary tree and bile peritonitis. • Prerenal azotemia—if ruptured GB, sepsis, or dehydration from vomiting. • Electrolyte abnormalities with fluid and acid-base disturbances—due to bile peritonitis or persistent vomiting.

Urinalysis

No specific features.

OTHER LABORATORY TESTS

• Triglyceride concentrations. • Coagulation tests—normal unless chronic extrahepatic bile duct obstruction (EHBDO), GB rupture, bile peritonitis, sepsis, or disseminated intravascular coagulation (DIC).

IMAGING

• Abdominal radiography—normal or large liver; loss of detail in cranial abdomen if focal peritonitis with GB rupture or concurrent pancreatitis; rarely intrahepatic gas. • Abdominal US—liver may be large, with rounded margins, or normal sized; diffuse to multifocal hyperechoic hepatic parenchyma (associated with glycogen-type VH); may have hypoechoic nodular appearance if severe VH; typical GBM US image: lumen filled with amorphous echogenic "organizing" nongravitational debris with stellate or finely striated pattern resembling sliced kiwi fruit ("kiwi sign"); distended GB (>1.2 mL/kg bodyweight) and sometimes distended common bile duct ± cystic duct if EHBDO; pericholecystic edema may enhance GB wall imaging; pericholecystic or generalized effusion with hyperechogenicity of surrounding tissues may indicate focal peritonitis and bile leakage (even if GB wall not ruptured); diffusely thick GB wall with segmental hyperechogenicity and double-rimmed or laminated appearance associates with necrotizing cholecystitis; GB rupture associated with discontinuous GB wall or difficult-to-image GB; ruptured GBM may have inspissated congealed biliary material released into abdominal cavity where discrete free-floating "mass" may be discovered; intrahepatic bile ducts may be difficult to visualize or appear prominent or distended. • GB motility study—indicated if suspected developing GBM serendipitously recognized if GB volume ≥1.2 mL/kg bodyweight; sequential GB volume measurements determined after meal ingestion (100 g food; may include 0.5 mg/kg erythromycin as motilin agonist provoking GB contraction if no response with food alone). Normal GB contraction results in ≥25% decline of initial or baseline GB volume on one or more recorded postprandial images. Procedure: image GB at 0, 15, 30, 45, 60, 90, 120 min relative to feeding. • GB volume in mL = [length (cm) × width (cm) × height (cm)] × 0.52.

DIAGNOSTIC PROCEDURES

• Aspiration sampling—fluid adjacent to biliary structures or free in abdominal cavity; clarifies GB rupture and/or infection; *caution*: do *not* perform cholecystocentesis on suspected GBM as this may cause bile peritonitis. • Laparotomy—for diagnosis, cholecystectomy, perhaps cholecystenterostomy. • Laparoscopy—*not* advised as CBD should be flushed to patency. • Liver biopsy—collect biopsy distant to GB; biopsy from GB area often interpreted as severely fibrotic or as cholangitis. • Bacterial culture/sensitivity—any effusion; GB wall, mucinous debris clinging to GB wall (scrape GB wall for best sample), liver (single inoculum); request aerobic and anaerobic bacterial culture. Positive ranging from 17% to 33% in different studies; histologic identification of bacteria unreliable. • Cytology—impression smears of GB wall mucinous debris and liver assist prompt recognition of suppurative septic inflammation or rarely neoplasia.

PATHOLOGIC FINDINGS

• Gross—mature GBM: GB distended, wall may appear normal, erythematous, or hemorrhagic ± focal areas of necrosis; may be evidence of focal peritonitis with adhesions; liver and extrahepatic biliary structures usually appear normal but EHBDO possible; GB contents: dark green-black, tenacious, firm, or organized as solid light green-yellow rubbery conglomerate. Slender long proliferative mucosal projections or cystic mucosal hyperplasia on GB mucosa are common. Immature GBM: normal to distended GB with thick dark black green bile with black particulate calcium bilirubinate debris.

• Microscopic—mature GBM demonstrates mural thinning with elongate mucosal fronds ± cystic mucosal hyperplasia and laminated dehydrated mucin; occasional particulate bilirubinate conglomerates in GB sections; mixed inflammatory infiltrates and fibrosis in chronic GBM; focal areas of necrosis usually caused by arterial thrombosis; Gram stain and modified Steiner's stains should be used to detect intraluminal bacteria as not all cultures recover infectious organisms. If GB not sectioned before fixation, mucosa may not fix and will appear necrotic. Liver biopsy collected distant to GB often discloses glycogen-type VH with no evidence of mechanical bile stasis if immature GBM and underling endocrinopathy; ascending suppurative cholangitis and cholangiohepatitis may be secondary complications.

TREATMENT

• Outpatient management—ursodeoxycholic acid and *S*-adenosylmethionine (SAMe) induce bile acid and non-bile acid mediated choleresis and provide hepatoprotection—*but* medical therapy is *not* advised to resolve GBM. While medical management has occasionally resolved immature GBM in some dogs, these patients remain at risk for GBM recurrence. Naïve unmonitored treatment with choleretics may eventuate in ruptured GB. • Inpatient—depends on whether patient presents with severe acute necrotizing cholecystitis, suppurative cholecystitis, intact nonurgent mature GBM, or incidentally discovered immature GBM. • If patient hyperlipidemic, investigate cause, restrict dietary fat, avoid glucocorticoids. • Symptomatic patients require exploratory surgery for cholecystectomy and evaluation/treatment for potential bile peritonitis. • Cholecystotomy and mucocele removal with GB retention *not* advised; high risk for recurrent GBM and potential bile peritonitis. • Fluid therapy—balanced polyionic solutions to correct hydration and electrolyte status. • Be prepared for blood component therapy. • Abdominal lavage—at surgery if bile peritonitis encountered.

DRUG(S) OF CHOICE

Antimicrobials

Initiate combined broad-spectrum antimicrobials *before* surgery; continue treatment 4–8 weeks if septic complications; adjust drugs based on culture and sensitivity test reports and biochemical appraisals. If no histologic or culture evidence of infection and postoperative recovery unremarkable, discontinue antimicrobials 7–10 days after surgery.

Vitamin K1

0.5–1.5 mg/kg IM/SC q12h for three doses—*if jaundiced*; oral route ineffective if EHBDO.

Antiemetics/Antacids/Gastroprotectants

• Antiemetics—may be needed during preoperative interval. Maropitant citrate (Cerenia®), NK-1 antagonist—2 mg/kg PO or 1 mg SC q24h up to 5 days. Ondansetron—0.1–0.3 mg/kg PO 30 min before feeding, maximum q8h, or 0.1–0.2 mg/kg slow IV push q6–12h if vomiting. • Antacids—preoperative interval, proton pump inhibitors preferred: omeprazole 0.7–1.0 mg/kg PO/IV q24h or pantoprazole 0.7–1.0 mg/kg IV q24h. • Gastric prokinetics—if postoperative gastric atony: metoclopramide 0.2–0.5 mg/kg PO/IV/SC q6–8h or 1–2 mg/kg/day CRI. • Gastroprotectant—if suspected gastritis, esophagitis, or upper gastrointestinal bleeding: sucralfate—0.5–1.0 g PO q8–12h.

Choleretics

• Maintain hydration status to optimize choleresis. • Ursodeoxycholic acid—choleretic, hepatoprotectant, anti-inflammatory, anti-endotoxic effects: 10–15 mg/kg PO divided BID daily with food for best bioavailability; treat until complete biochemical recovery or chronically if suspect persistent cholangitis. • SAMe—choleretic, antioxidant, and metabolic benefits; choleretic dose (40 mg/kg PO q24h on empty stomach) higher than antioxidant dose.

Antioxidants

• Vitamin E—α-tocopherol 10 IU/kg/day PO with food: antioxidant, anti-inflammatory, antifibrotic influence. • SAMe—20 mg/kg PO daily 2h before feeding: give until liver enzymes normalize or indefinitely if chronic hepatitis or cholangitis.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

• Repeat sequential hematology, biochemistry, and imaging to monitor surgical recovery; if GBM caused clinicopathologic abnormalities, all changes should resolve within weeks. • Persistent clinicopathologic abnormalities implicate underlying endocrinopathy, intrahepatic cholangiopathy, or other liver disease. • At-risk dogs should have US assessment of GB as part of routine health appraisal when middle-aged to geriatric.

POSSIBLE COMPLICATIONS

• Suppurative cholangitis or cholangiohepatitis. • Bile peritonitis. • EHBDO.

EXPECTED COURSE AND PROGNOSIS

• Good with successful surgery, chronic choleretic therapy, correction/management of comorbid conditions, dietary and/or medical management of hypertriglyceridemia. • Anticipate protracted clinical course if ruptured biliary tract or peritonitis—dogs with ruptured GBM 2–3 times more likely to succumb to GBM-related illness. • Recrudescence may occur if mucocele contents removed and GB retained, with or without chronic medical therapy. • Chronic postoperative jaundice may reflect iatrogenic stricture at site of cholecystectomy.

MISCELLANEOUS

SEE ALSO

• Bile Peritonitis.
• Cholecystitis and Choledochitis.
• Cholelithiasis.
• Glycogen-Type Vacuolar Hepatopathy.
• Hepatitis, Chronic.

ABBREVIATIONS

• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• AST = aspartate aminotransferase.
• DIC = disseminated intravascular coagulation.
• EHBDO = extrahepatic bile duct obstruction.
• GB = gallbladder.
• GBM = gallbladder mucocele.
• GGT = γ–glutamyltransferase.
• SAMe = *S*-adenosylmethionine.
• VH = vacuolar hepatopathy.

GASTRIC DILATION AND VOLVULUS SYNDROME

DEFINITION

Gastric dilation and volvulus syndrome (GDV) is a disease in which the stomach rotates around its short axis, with or without distention of the stomach.

PATHOPHYSIOLOGY

The mechanism and etiology are poorly understood. Many risk factors have been evaluated. Rotation of the stomach can occur in any direction, but the majority occur in clockwise rotation. The pylorus, pyloric antrum, and proximal duodenum move from dorsal to ventral, from right to left of the patient, continuing from the ventral abdomen to the left, and eventually are located in the left dorsal quadrant of the peritoneal cavity. With distention of the stomach, intra-abdominal pressure increases. Collapse of the compliant abdominal venous network leads to decreased venous return to the heart and portal hypertension. As the disease progresses, hypovolemic shock and decreased organ perfusion lead to local and systemic inflammatory response, visceral and myocardial ischemia, disseminated intravascular coagulation (DIC), and eventually cardiovascular collapse and death.

SYSTEMS AFFECTED

• Gastrointestinal (GI)—rotation of the stomach causes venous congestion of the stomach, spleen, pancreas, and proximal small intestine and arterial compromise of the stomach. • Hemic/lymphatic/immune—splenic engorgement, vascular compromise, ischemia, and thrombosis are common. • Cardiovascular—both distributive and obstructive hypovolemic shock may be seen; cardiac arrhythmias are common. • Renal/urologic—acute kidney injury (AKI) may occur secondary to shock and renal vascular compression. • Endocrine/metabolic—nephrogenic diabetes insipidus has been reported, likely secondary to AKI, endotoxemia, and systemic inflammatory responses.

GENETICS

• Having a first-order relative with a history of GDV markedly increases the risk of developing GDV. • While the genetic basis is unknown, it is likely to be a complex, multifactorial (or polygenic) disorder.

INCIDENCE/PREVALENCE

One study indicated that likelihood of a purebred large- or giant-breed dog developing GDV during its lifetime is approximately 24% and 21.6%, respectively.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Dog (common) and cat (rare).

Breed Predilections

• German shepherd dog. • Great Dane. • Standard poodle. • Labrador retriever. • Akita. • Golden retriever. • Saint Bernard. • Doberman pinscher. • Chow chow. • Collie. • Rottweiler. • Mastiff. • Weimaraner. • Bloodhound. • Basset hound. • Belgian shepherd. • Great Pyrenees. • Boxer. • Husky. • German shorthaired pointer. • Samoyed. • Newfoundland. • Bernese mountain dog. • Smaller breeds are reported, including dachshund, corgi, and Pekingese.

Mean Age and Range

Any age. Risk increases with age in large- and giant-breed dogs.

Predominant Sex

Male > female.

SIGNS

Historical Findings

• Restlessness. • Anxiety. • Vomiting progressing to nonproductive retching or nonproductive retching alone. • Abdominal distension and/or pain. • Ptyalism. • Lethargy. • Collapse.

Physical Examination Findings

• Distended abdomen; may not be noted in deep-chested dogs. • Tachycardia. • Tachypnea or dyspnea. • Weak pulses. • Pale or hyperemic mucus membranes and prolonged or rapid capillary refill time.

CAUSES

• Multifactorial. • Genetic. • Conformational. • Environmental. • Secondary to gastric, hepatic, or splenic neoplasia. • Any cause of aerophagia. • Massive food consumption or other cause of gas or liquid gastric distention. • Pyloric outflow obstruction.

RISK FACTORS

• Direct relative with a history of GDV. • Large- or giant-breed dog. • Deep-chested body conformation. • History of splenic torsion, colonic torsion, or mesenteric volvulus. • Gastric motility disorder. • Rapid consumption of large amounts of food and water with or without excessive postprandial activity. • Altered microbiome. • Trauma. • Anxious temperament.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Gastric dilation without volvulus. • Abdominal effusion. • Any cause of abdominal pain. • Gastric or intestinal obstruction. • Urinary tract obstruction. • Pyometra. • Splenic torsion. • Mesenteric volvulus. • Colonic torsion. • Hepatic, gastric, or splenic mass.

CBC/BIOCHEMISTRY/URINALYSIS

• Stress leukogram; hemoconcentration; thrombocytopenia from consumption if DIC is present or if significant intra-abdominal hemorrhage has occurred. • Electrolyte abnormalities; increased liver enzymes; azotemia, either prerenal or due to AKI. • Increased specific gravity with dehydration; isosthenuria with AKI.

OTHER LABORATORY TESTS

• Plasma lactate—initial lactate and trends are useful in predicting gastric necrosis and prognosis. ◦ Dogs with initial lactate >9 mmol/L had reduced survival (13/24 = 54%) compared to those with initial lactate ≤9 mmol/L (36/40 = 90%). ◦ Dogs with initial lactate >9 mmol/L that did not decrease by ≥4 mmol/L had 10% survival rate, while those whose lactate decreased by ≥4 mmol/L with presurgical stabilization had 90% survival rate. ◦ Decrease in plasma lactate by ≥50% within 12 hours is associated with a good outcome. • Coagulation testing—may show evidence for DIC.

IMAGING

• Abdominal radiography—right lateral abdominal radiograph is imaging modality of choice. ◦ In a normal patient, the pylorus would be filled with fluid. ◦ In a patient with GDV, the pylorus, which is now on the left side of the peritoneal cavity, is filled with gas and visualized as such, showing the classic compartmentalization of the stomach, which is considered to be pathognomonic. ◦ Gas bubbles within the gastric wall indicate gastric necrosis. ◦ Pneumoperitoneum may be evident. • Thoracic radiographs—three views to screen for aspiration pneumonia and metastatic disease; may also see evidence of hypovolemia (microcardia, small-caliber vessels). • Abdominal ultrasound—may show fluid due to small volume hemoabdomen, serosanguinous effusion, or gastric perforation.

DIAGNOSTIC PROCEDURES

ECG to detect presence of cardiac arrhythmias.

PATHOLOGIC FINDINGS

• Splenic engorgement, ischemia, malposition, and/or venous thrombosis. • Gastric wall may appear edematous and thickened, or areas may be extremely thinned.

TREATMENT

APPROPRIATE HEALTH CARE

• GDV is a medical and surgical emergency. • Aggressive emergency medical stabilization is initiated. • Subsequent to cardiovascular stabilization, gastric decompression should be performed, ideally via orogastric intubation; the patient should be intubated with a cuffed endotracheal tube prior to performing orogastric intubation and decompression to minimize the risk of aspiration pneumonia. • If orogastric intubation is unsuccessful,

(CONTINUED) # GASTRIC DILATION AND VOLVULUS SYNDROME

percutaneous gastrocentesis may be performed for decompression by locating the point of maximal tympany, which typically corresponds to an area of the stomach that is gas filled. ○ The largest-diameter needle or catheter that the clinician is comfortable using is passed into the stomach at this area. ○ Considerable time is necessary to achieve gastric decompression using this technique.
• Recent studies suggest that when comparing orogastric decompression and percutaneous decompression, there is no difference in complication rates or outcome. Therefore, clinicians should select the technique that they are most familiar and comfortable with.
• Surgical management occurs once the patient is stable.

NURSING CARE
• IV fluid therapy is initiated and type, rate, and duration are based on individual patient needs and personal preference. ○ Avoid use of saphenous veins for emergency resuscitation, as venous return from the caudal half of the body is compromised. ○ Crystalloids, colloids, or a combination can be used; initial fluid resuscitation efforts may require crystalloid boluses at 15–30 mL/kg increments, up to 90 mL/kg total; colloid boluses up to 5–10 mL/kg total may be required. • Physical therapy may be necessary, as many patients will be recumbent for several days in the postoperative period.

ACTIVITY
Restriction of activity for 2 weeks postoperatively is recommended.

DIET
• Enteral nutrition is recommended as soon as adequate recovery from anesthesia has been achieved to stimulate GI mucosal healing and motility. • Optimal diet is unknown; consider fat-restricted diets to improve gastric emptying.

CLIENT EDUCATION
• Clients should be aware of the critical nature of GDV. • Patients can still experience gastric dilation after gastropexy, as many have gastric motility disorders.

SURGICAL CONSIDERATIONS
• Surgery is required after medical stabilization. • Goals of surgery are: ○ Continue decompression. ○ Assess stomach and spleen for evidence of devitalization and necrosis that necessitates partial gastrectomy or splenectomy. ○ Reposition stomach and spleen. ○ Perform systematic and thorough exploratory laparotomy. ○ Perform gastropexy to prevent recurrence of GDV—should always be performed; decreases risk of recurrent GDV from 80% to <5%; incorporating gastropexy and gastrocolopexy are associated with higher rates of recurrence of GDV and should not be performed.

MEDICATIONS

DRUG(S) OF CHOICE
• Lidocaine beginning with a 2 mg/kg IV bolus, followed by a CRI (0.05 mg/kg/min for 24h) in perioperative period improves morbidity but not mortality. ○ Fewer cardiac arrhythmias. ○ Lower incidence of AKI. ○ Shorter hospitalization.
• Perioperative antibiotics are indicated. ○ For patients with moderate to severe disease in which there is a risk of visceral perforation or hematogenous bacterial translocation from the GI tract, cefoxitin sodium (30 mg/kg IV q6–8h) may be an appropriate choice. ○ For patients in which no entry into the GI tract has occurred, cefazolin sodium (22 mg/kg IVq2h intra-operatively) is sufficient. • Treatment for esophagitis and gastritis or gastric ulceration is indicated. ○ Pantoprazole (1 mg/kg IV q12h) or omeprazole (1 mg/kg PO q12h) for acid suppression. ○ Metoclopramide (2 mg/kg/day IV as CRI) or cisapride (0.5–1 mg/kg PO q8–12h) as a prokinetic. ○ Sucralfate 0.25–1 g PO as a slurry q6–8h if gastric ulceration is present. • Pain management based on patient needs postoperatively.

CONTRAINDICATIONS
Synthetic colloids should be used cautiously in patients with DIC or AKI.

PRECAUTIONS
Patients may decompensate at any time, particularly under anesthetic intervention. Emergency drug dosages should be calculated for the patient before anesthesia and be readily available.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
There is conflicting evidence to support the use of physiologic corticosteroids in patients with GDV. Use is not currently recommended.

FOLLOW-UP

PATIENT MONITORING
• Intermittent or continuous ECG postoperatively to monitor for arrhythmias.
• Monitor urine production and renal function postoperatively.

PREVENTION/AVOIDANCE
While not proven, the following have been suggested to decrease risk of GDV: elevation of food bowl; avoiding exercise after eating or drinking; slowing rate of consumption of meals; feeding multiple smaller meals.

POSSIBLE COMPLICATIONS
• Gastric dilation without volvulus may recur, even after a gastropexy is performed, because of a possible underlying motility disorder.
• Failure to resect all necrotic or devitalized gastric tissue may result in eventual stomach perforation and septic peritonitis. • Cardiac arrhythmias, DIC, esophagitis, AKI, and gastric ulceration may also occur.

EXPECTED COURSE AND PROGNOSIS
• Prognosis in dogs treated appropriately that do not have gastric necrosis is excellent, with a reported survival rate of 98%. • Dogs with gastric necrosis have a more guarded prognosis, with a reported survival rate of 66%. • Potential negative prognostic indicators include hypotension, DIC, peritonitis, and the need to perform both a splenectomy and a partial gastrectomy.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
More common in middle-aged to older dogs.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Affected dogs should not be bred due to potential genetic predisposition.

SYNONYMS
• Bloat. • Gastric torsion. • Gastric volvulus.

ABBREVIATIONS
• AKI = acute kidney injury. • DIC = disseminated intravascular coagulation.
• GDV = gastric dilation and volvulus syndrome. • GI = gastrointestinal.

GASTRIC MOTILITY DISORDERS

BASICS

DEFINITION
Gastric motility disorders result from conditions that disrupt normal peristalsis and, consequently, gastric emptying. This abnormal gastric retention may, in turn, cause gastric distention, and subsequent signs of anorexia, nausea, bloating, and vomiting.

PATHOPHYSIOLOGY
The stomach has two distinct motor regions. The proximal stomach (fundus and body) relaxes to accommodate ingested food and regulates the expulsion of liquids. Intrinsic slow contractions of this region push liquids toward the pylorus. The distal stomach (antrum) mechanically breaks down solids through strong peristaltic contractions and ultimately expels them. The gastric pacemaker, an area of intrinsic electrical activity located in the greater curvature of the stomach, regulates distal gastric motility and emptying. Gastric electrical activity, dietary composition, and extrinsic factors (e.g., vagal and sympathetic innervation) all influence emptying. During fasting, indigestible solids are expelled from the stomach by migrating myoelectric complexes (MMCs). These produce strong "digestive housekeeper" contractions that, in the fasted state, sweep through the stomach and small intestine to mid-jejunum every 2 hours, preparing the gastrointestinal (GI) tract for the next meal. MMCs are regulated by the hormone motilin. Dysrhythmias in normal gastric electrical activity may be fundamental in the pathophysiology of disorders affecting gastric motility, but may also be secondary to gastric inflammation, neoplasia, and overdistension.

SYSTEMS AFFECTED
GI

GENETICS
N/A

INCIDENCE/PREVALENCE
Unknown. Many factors can alter gastric emptying, although they may not result in clinical disease or may only partially contribute to signs.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Unknown

Mean Age and Range
Signs occur at any age, though it is uncommon to observe primary motility disorders in young animals.

Predominant Sex
N/A

SIGNS

General Comments
Clinical signs are often secondary to the primary etiology causing the gastric motility disorder.

Historical Findings
• Major clinical sign is chronic postprandial vomiting of food; stomach should normally be empty after average-sized meal in approx 6–8 hours in dogs and 4–6 hours in cats (note: normal emptying times vary greatly from animal to animal and are influenced by meal volume, caloric density, fiber content, and environmental factors, e.g., stress); vomiting of undigested food >12 hours following meal suggests abnormal gastric motility or outflow obstruction; vomiting can occur, however, any time after eating. • Gastric distention, nausea, anorexia, belching, bloating, pica, and weight loss may occur. • Distal esophageal sphincter may be incompetent with gastric hypomotility and signs associated with reflux esophagitis may occur.

Physical Examination Findings
• Normal or findings associated with underlying cause. • Palpation of large, distended stomach. • Decreased gastric sounds on abdominal auscultation.

CAUSES
• Rarely, idiopathic gastric motility disorders arise from primary defects in normal myoelectric activity, e.g., myenteric ganglionitis, intestinal leiomyositis; most motility disorders occur secondary to other conditions. • Metabolic disorders include hypokalemia, uremia, hepatic encephalopathy, and hypothyroidism. • Nervous inhibition as result of stress, fear, pain, or trauma. • Drugs such as anticholinergics, beta-adrenergic agonists, narcotics, and chemotherapeutics. • Primary gastric disease such as outflow obstructions, gastritis, gastric ulcers, parvovirus, and gastric surgery. • Gastric dilatation and volvulus syndrome (GDV) is suspected to be, in part, result of abnormal gastric motility associated with changes in myoelectric and mechanical activity, although whether primary or secondary to overstretching of gastric wall is unknown; some dogs with GDV may continue to have signs of gastric hypomotility following surgical gastropexy. • Gastroesophageal reflux and enterogastric reflux (see Bilious Vomiting Syndrome) may result from primary gastric hypomotility. • Dysautonomia may affect GI tract and result in abnormal esophageal, gastric, and intestinal motility.

RISK FACTORS
Any gastric disease may result in secondary hypomotility.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Differential diagnosis is extensive and should consider any gastric condition causing vomiting, including gastritis, gastric ulcers, neoplasia, gastric surgery, and GDV. Gastric outflow obstruction as cause of delayed gastric emptying must always be ruled out.

CBC/BIOCHEMISTRY/URINALYSIS
Abnormalities may result from underlying cause of gastric hypomotility. Continued vomiting may result in changes indicative of dehydration, electrolyte abnormalities, or acid-base imbalance.

OTHER LABORATORY TESTS
Specialized testing may be required to determine specific cause of gastric hypomotility, and is individualized for each patient.

IMAGING

Survey Radiographs
Abdominal radiographs may reveal gas-, fluid-, or ingesta-distended stomach. (Note: important to determine when patient was last fed in relationship to when radiographs were taken.)

Barium Contrast Study
May be evidence of delayed gastric emptying and decreased gastric contractions if evaluated using fluoroscopy. Some cases may have normal emptying of liquids but abnormal emptying of solids. Normal dogs should empty stomachs by approx. 6–8 hours. (Note: stress of radiographs may decrease gastric emptying even in normal animal.)

Ultrasonography
Ultrasound can evaluate antral and pyloric motility.

Tests Available in Specialized Practices
Radionuclide Emission Scintigraphy
Radionuclide markers mixed with a meal give most clinically accurate measurement of emptying. Gastric emptying times (time for standard meal to leave stomach) range from 4 to 8 hours.

Stable Isotope Breath Tests
C-14-labeled foods are fed and time to onset of $^{14}CO_2$ emission in breath is marker of gastric emptying.

Smartpill
This is noninvasive wireless sensor capsule that is given orally and transmits data on pressures, transit time, luminal pH, and temperature as it passes through stomach and small and large bowel. Has been validated for use in healthy dog but, as yet, limited reports evaluating clinical conditions.

DIAGNOSTIC PROCEDURES

Endoscopy
Endoscopic findings frequently normal in primary gastric motility disorders. Food may be found in stomach when it should be empty following 12-hour pre-endoscopic fast. Endoscopy will detect obstructive or inflammatory/ulcerative diseases of stomach.

PATHOLOGIC FINDINGS
• Idiopathic conditions have normal gastric mucosa; special staining may reveal disruption of enteric nervous system. • Gastric histology

may identify inflammatory or neoplastic causes of gastric hypomotility.

TREATMENT

APPROPRIATE HEALTH CARE
• Most treated as outpatients. • With severe vomiting or dehydration and electrolyte imbalance, hospitalization, fluid support, and specific therapy required.

NURSING CARE
Dehydration with fluid and electrolyte imbalance requires appropriate fluid replacement. Drugs that inhibit gastric motility (e.g., opioids) should be withdrawn.

ACTIVITY
Dependent on underlying disease.

DIET
• Dietary manipulation important in management of primary gastric motility disorders in order to speed gastric emptying. • Optimal diets liquid or semi-liquid consistency and low in fat and fiber content. • Small-volume meals with frequent feeding should be given. • Occasionally dietary manipulation alone is successful.

CLIENT EDUCATION
Discuss possible underlying etiologies and that response to therapy varies with individual cases.

SURGICAL CONSIDERATIONS
• Large-breed dogs with chronic GDV syndrome and gastric retention should have surgical gastropexy. • Following gastric surgery generally takes several days but up to 14 days for return of normal motility. • Mechanical gastric outflow obstructions require surgical correction.

MEDICATIONS

DRUG(S) OF CHOICE

Gastric Prokinetic Agents
• Metoclopramide increases amplitude of antral contractions, inhibits fundic receptive relaxation, and coordinates duodenal and gastric motility; dopamine receptor antagonism in proximal GI tract results in increased release of acetylcholine from enteric neurons; at higher concentrations it has serotonin ($5HT_4$) agonist effects; also has antiemetic effects, blocking chemoreceptor trigger zone in dogs, but not in cats. ○ Oral dosage 0.2–0.5 mg/kg q8h given 30 min before meals (use lower dose in cats) or as CRI at 1–2 mg/kg q24h. ○ Metoclopramide generally considered to be weak prokinetic agent in dogs and recent studies suggest it has little effect at increasing lower esophageal sphincter pressure. • Cisapride works directly by cholinergic neurotransmission ($5HT_4$ agonist) of GI smooth muscle, stimulating motility; proposed mechanism of action is enhancement of release of acetylcholine at myenteric plexus; increases lower esophageal sphincter pressure, improves gastric emptying, and promotes motility of small and large intestine. ○ Oral dosage 0.2–0.5 mg/kg PO q8–12h given before meals. ○ Cisapride currently available through compounding pharmacies—human product has been removed from market because of associated cardiac arrhythmias not yet noted to occur in dogs or cats. ○ Mosapride (0.5–2 mg/kg PO q12–24h) and prucalopride (0.02–0.6 mg/kg PO q12–24h) are also $5HT_4$ agonist prokinetic agents. • Macrolide antibiotics, such as erythromycin, are motilin receptor agonists and increase GI motility; motilin is hormone that promotes MMC-associated motility. ○ Erythromycin given at low (submicrobiologic) doses binds motilin receptors promoting acetylcholine release, which speeds gastric emptying; dose of erythromycin for specific motility effects is 0.5–1 mg/kg PO q8–12h, given 30 min before meals. ○ Chronic use of submicrobiologic doses of antibiotics not recommended. • H_2 receptor antagonists ranitidine (1–2 mg/kg q8h) and nizatidine (2.5–5 mg/kg q24h) have reported prokinetic effects on gastric motility due to acetylcholinesterase inhibition; are considered poor prokinetic drugs and recent studies question ranitidine's prokinetic activity in dogs; neither cimetidine nor famotidine affects gastric emptying.

CONTRAINDICATIONS
Gastric prokinetic agents are contraindicated in patients with gastric outflow obstruction.

PRECAUTIONS
• Metoclopramide may cause nervousness, anxiety, or depression. • Cisapride may cause depression, vomiting, diarrhea, or abdominal cramping. • Erythromycin may cause vomiting.

POSSIBLE INTERACTIONS
Metoclopramide contraindicated with concurrent phenothiazine and narcotic administration or in animals with epilepsy.

ALTERNATIVE DRUG(S)
• Domperidone is peripheral dopamine receptor antagonist that regulates motility of gastric and small intestinal smooth muscle similar to metoclopramide. • Mirtazapine is noradrenergic and specific serotonergic antidepressant and has reported gastric prokinetic effects in dogs. • Acotiamide is acetylcholine esterase inhibitor that facilitates muscarinic activity and has been shown to stimulate postprandial gastroduodenal activity in dogs at dose of 30 mg/kg, but only available in Asia.

FOLLOW-UP

PATIENT MONITORING
• Response to therapy varies with underlying cause. • Clinical signs are primary indicator of response.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
GDV

EXPECTED COURSE AND PROGNOSIS
Length of treatment depends on ability to resolve underlying cause.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Gastric hypomotility may be associated with reflux esophagitis and reflux gastritis (see Bilious Vomiting Syndrome).

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
Avoid gastric prokinetic agents in pregnant animals.

GASTRITIS, CHRONIC

BASICS

DEFINITION
Inflammation of the stomach leading to clinical signs of >3 weeks' duration.

PATHOPHYSIOLOGY
• Inflammation may be secondary to drugs, infection, neoplasia, toxins/irritants, foreign material, food antigens or bacterial antigens; may be primary as a form of inflammatory bowel disease (IBD). • Visceral receptors stimulated by inflammation, distension, etc. send signals via vagal and sympathetic nerves to vomiting center (medulla oblangata).

SYSTEMS AFFECTED
• Gastrointestinal (GI). • Musculoskeletal—weight loss, muscle wasting, weakness. • Integument—hair coat changes. • Respiratory—aspiration pneumonia.

GENETICS
N/A

INCIDENCE/PREVALENCE
Common

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Norwegian lundehund—chronic atrophic gastritis with IBD (lymphoplasmacytic); can progress to adenocarcinoma. • Basenji and Drentse patrijshond—chronic hypertrophic gastritis.

Mean Age and Range
Any age.

Predominant Sex
None

SIGNS

Historical Findings
• Vomiting is most common—digested or undigested food, bile, frank blood, digested blood ("coffee grounds"); variable frequency. • Hyporexia to anorexia. • Melena. • Polydipsia. • Diarrhea with concurrent intestinal disease. • Retching. • Burping. • Weight loss.

Physical Examination Findings
• Abdominal distension ± pain. • Ptyalism. • Muscle wasting, weight loss, coat changes. • Pallor if bleeding ulcer. • Dehydration or hypovolemia.

CAUSES
• Food sensitivity. • IBD. • Toxins, e.g., heavy metals, environmental irritants (cleaners, herbicides). • Metabolic/endocrine disease—renal disease, liver disease, hypoadrenocorticism, pancreatitis, hyperthyroidism. • Neoplasia—large or small cell lymphoma, adenocarcinoma, polyp, gastrinoma, leiomyosarcoma, plasma cell tumor, mast cell tumor. • Foreign material. • Drugs—nonsteroidal anti-inflammatory drugs (NSAIDs), antibiotics, chemotherapeutics. • Parasitism—*Toxocara* spp., *Physaloptera* spp. (dogs and cats), *Ollulanus tricuspis* (cats). • *Helicobacter* spp. • Pythiosis. • Canine distemper virus. • Hypergastrinemia—gastrinoma, achlorhydria, Basenji gastroenteropathy, hepatic or renal disease. • Miscellaneous—stress, emphysematous gastritis (gas-forming organisms/severe signs), benign gastric emphysema (milder disease/air trapping), eosinophilic sclerosing fibroplasia.

RISK FACTORS
• Drugs (e.g., NSAIDs). • Unsupervised/free-roaming pets—exposure to toxin.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Any cause of GI signs. • Esophageal disease—differentiate vomiting from regurgitation. • Hypertrophic pyloric gastropathy. • Bilious vomiting syndrome.

CBC/BIOCHEMISTRY/URINALYSIS
• Hemoconcentration if dehydrated. • Anemia—if blood loss (regenerative anemia if acute blood loss such as ulceration; microcytic, hypochromic with chronic blood loss. • Thrombocytosis with chronic blood loss leading to iron deficiency. • Eosinophilia with parasitism, neoplasia, or eosinophilic gastritis. • Biochemistry—prerenal or renal azotemia; increased blood urea nitrogen (BUN) : creatinine ratio with GI bleeding; hyperkalemia and hyponatremia with hypoadrenocorticism; hypochloremic metabolic alkalosis with gastric outflow obstruction. • Urinalysis—unremarkable.

OTHER LABORATORY TESTS
• Gastrin levels—elevated with gastrinoma; may be elevated with azotemia or use of antacids. • T_4. • Fecal float. • Baseline cortisol ± adrenocorticotropic hormone (ACTH) stimulation test. • Pythium ELISA. • Iron panel (iron deficiency with bleeding).

IMAGING
• Abdominal radiographs—radiopaque foreign material, thickened gastric wall, gastric distension. • Contrast radiography—radiolucent foreign material, outflow obstruction, delayed emptying, wall defects or thickening. • Ultrasonography—wall thickening, layering loss, ulcer, foreign object, mass.

DIAGNOSTIC PROCEDURES
• Upper GI endoscopy—visualize gastric mucosa, identify ulcer or mass, retrieve foreign object, biopsy (even when grossly normal), removal of small mass lesions (cautery), evaluate duodenum. • Exploratory laparotomy—perforated ulcer, full-thickness biopsy, partial gastrectomy, mass removal. • Wireless capsule endoscopy—identify mass or ulcer.

PATHOLOGIC FINDINGS
• IBD—variable inflammatory infiltrate: lymphoplasmacytic, eosinophilic, neutrophilic, granulomatous/histiocytic gastritis (investigate for infectious cause). • *Helicobacter* spp. do not always convey pathology—significant populations deep in gastric glands may warrant treatment. • Special stains—further evaluation of potential neoplasia and infectious organisms.

TREATMENT

APPROPRIATE HEALTH CARE
• Many treated as outpatients pending diagnostic testing or treatment trials (i.e., diet, drugs). • Inpatient management warranted if significant dehydration or hypovolemia present.

NURSING CARE
• IV fluids based on patient status; *caution* for fluid overload with hypoproteinemia. • Enteral nutrition (nasoesophageal, nasogastric, or esophageal tubes) with persistent anorexia. • Severe hypoalbuminemia—consider albumin, plasma, or colloids.

ACTIVITY
Restrict postoperatively if surgery performed.

DIET
• Novel protein or hydrolyzed diet when allergy or IBD suspected; initial response expected within 2 weeks; worsening warrants diet change or other intervention; if improvement noted, continue beneficial diet for several months before reintroducing other foods to assess tolerance. • Challenge with original diet can prove food hypersensitivity; rarely pursued. • Low-fat diet if hyperacidity or gastric ulcer. • Frequent, small meals (q4–6h) may provide benefit. • Small late-night meal may decrease bilious vomiting. • Calorie requirement/diet guideline increases compliance. • Unflavored or topical flea, tick, and heartworm preventatives. • Treats limited to prescription diet. • If commercial diet declined, consider home-cooked diet formulated by veterinary nutritionist.

CLIENT EDUCATION
• Review multiple etiologies. • Least invasive testing first when patient status allows; biopsy for definitive diagnosis if extra-intestinal causes ruled out and patient fails diet and drug trial (i.e.. anthelminthic).

(CONTINUED) GASTRITIS, CHRONIC

SURGICAL CONSIDERATIONS

• Obstructive lesion or material. • Perforated ulcer. • Removal of foreign objects if endoscopy unsuccessful or not available. • Full-thickness biopsy. • Mass resection and biopsy.

MEDICATIONS

DRUG(S) OF CHOICE

• Anthelminthic—fenbendazole (50 mg/kg PO q24h for 5 days), pyrantel pamoate + febantel. • Gastroprotectants—proton pump inhibitor (PPI), i.e., omeprazole (1 mg/kg PO q12h 30–60 min before meal); also consider sucralfate, H2 receptor antagonist, and others per ACVIM consensus (see Suggested Reading). • Antiemetics—maropitant (1 mg/kg SC or IV q24h; 2 mg/kg PO q24h), ondansetron, metoclopramide, mirtazapine. • Prokinetics—metoclopramide (0.2–0.4 mg/kg PO q8h; CRI 1–2 mg/kg/day), cisapride, ranitidine, low-dose erythromycin. • IBD suspected/confirmed—glucocorticoid (i.e., prednisone 2 mg/kg PO q24h or divided q12h; prednisolone for cat) when no clinical response to other therapeutic trials or in advanced disease; taper by 20–25% increments over time to lowest effective dose; discontinue when possible; total dose not >60 mg per day (dog); use with diet. • If glucocorticoid not tolerated and/or relapse, consider second drug; see Alternative Drug(s). • *Helicobacter* gastritis—several protocols have been described (e.g., metronidazole, amoxicillin, clarithromycin); see Suggested Reading.

CONTRAINDICATIONS

• Do not use prokinetics if GI obstruction possible. • Do not use antacids or PPIs with atrophic gastritis and achlorhydria.

PRECAUTIONS

• Immune modulation predisposes to secondary infections. • Steroids can cause GI ulceration, diabetes mellitus. or fluid overload (especially cat: congestive heart failure); patient monitoring and client education are vital to success. • Prolonged use of antacids or PPIs can lead to overgrowth of bacteria.

POSSIBLE INTERACTIONS

• Sucralfate will decrease absorption of other medications; separate by 2 hours from other medications. • Omeprazole affects clearance of many drugs. • Never use NSAIDs with glucocorticoids; high risk for GI erosion or ulcer.

ALTERNATIVE DRUG(S)

• IBD—if steroid and diet alone do not achieve disease remission, if patient relapses, and/or if steroid side effects are undesirable, second agent may be considered; options: cyclosporine, mycophenolate, chlorambucil, azathioprine (never in cats); find lowest effective dose. • Monitoring—exam, labwork (CBC, chemistry) for myelosuppression and other concerns (i.e., hepatic toxicity with cyclosporine, chlorambucil, and azathioprine). • Budesonide (steroid; 1–3 mg/patient depending on size) may have fewer systemic side effects; adrenal pituitary axis is affected.

FOLLOW-UP

PATIENT MONITORING

• Depends on patient severity and medication chosen; minimum—physical exam within 2 weeks of starting treatment. • Recheck abnormal labwork (i.e., electrolytes, proteins) and monitor for medication side effects (i.e., hyperglycemia, anemia, myelosuppression, heptaopathy, etc. based on specific drugs selected). • Recurrence warrants repeat diagnostics; repeat biopsy may be indicated (i.e., patients previously in remission of IBD can progress to lymphoma). • Lack of response—change in medical management (i.e., alternative diet or drug); repeat biopsy (primary disease may have been missed) and labwork (CBC, chemistry, fecal, T_4) for emerging comorbidity.

PREVENTION/AVOIDANCE

• Avoid drugs with high incidence of GI upset (i.e., doxycycline, NSAIDs). • Avoid rapid diet change. • Prevent free-roaming and potential for dietary indiscretion—may need basket muzzle in dogs.

POSSIBLE COMPLICATIONS

• Gastroesophageal reflux. • Delayed gastric emptying/motility disorders. • Erosions/ulcers. • Aspiration pneumonia. • Electrolyte or acid-base imbalances. • Progression from superficial to atrophic gastritis. • Debilitation/death in refractory cases. • Steroids—diabetes mellitus, heart failure, calcinosis cutis, muscle weakness, ulcers. • Other immune-modulating drugs—bone marrow suppression, pancreatitis, hepatitis, GI upset.

EXPECTED COURSE AND PROGNOSIS

• Varies with cause. • Medication tapered to lowest effective dose ± stopped with diet.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

• Foreign objects—more common in young animals. • Food-responsive enteropathy—often younger animals. • IBD—often middle-aged to older. • Neoplasia—middle-aged to older animals more common.

ZOONOTIC POTENTIAL

Potential/uncommon concern secondary to parasites (i.e., *Toxocara spp*.—larval migrans).

PREGNANCY/FERTILITY/BREEDING

• Prednisone—abortion, teratogenic, can induce parturition. • Azathioprine—fetal harm; decrease sperm production. • Cyclosporine—fetal toxicity.

SEE ALSO

• Bilious Vomiting Syndrome.
• Gastroduodenal Ulceration/Erosion.
• Gastroenteritis, Eosinophilic.
• *Helicobacter* spp.
• Hypertrophic Pyloric Gastropathy, Chronic.

ABBREVIATIONS

• ACTH = adrenocorticotropic hormone.
• GI = gastrointestinal.
• IBD = inflammatory bowel disease.
• NSAID = nonsteroidal anti-inflammatory drug.
• PPI = proton pump inhibitor.

G

GASTRODUODENAL ULCERATION/EROSION

BASICS

DEFINITION
Ulcers are defects that extend completely through the mucosa; erosions extend part way through the mucosa.

PATHOPHYSIOLOGY
• Gastroduodenal ulceration/erosion (GUE) results from factors that damage or overwhelm normal gastric mucosal defense and repair mechanisms. • Factors protecting the stomach from GUE include the mucus/bicarbonate layer, gastric epithelial cell turnover, gastric mucosal blood flow, and local prostaglandins.

SYSTEMS AFFECTED
• Gastrointestinal (GI)—ulcers and erosion are most common in stomach, followed by proximal duodenum; however, neoplasia and some drugs (e.g., flunixin meglumine) can cause ulceration anywhere in GI tract. • Cardiovascular—hemorrhage may cause anemia, tachycardia, systolic heart murmur, and/or hypotension. • Peritoneal cavity—perforation may cause peritonitis/sepsis/systemic inflammatory response syndrome (SIRS).

INCIDENCE/PREVALENCE
• 40–60% in racing Alaskan sled dogs.
• Fairly common in dogs receiving nonsteroidal anti-inflammatory drugs (NSAIDs) or dexamethasone.

SIGNALMENT

Species
Dogs; rare in cats.

Breed Predilections
Chow chows, rough-coated collies, Staffordshire bull terriers, and Belgian shepherd dogs have increased incidence of gastric carcinoma.

Mean Age and Range
Any age.

Predominant Sex
Male dogs are predisposed to gastric carcinoma.

SIGNS

General Comments
Severity of clinical signs is not necessarily proportional to size/number of GUEs.

Historical Findings
• Some animals are asymptomatic (e.g., patients taking NSAIDs or dexamethasone, dogs working in extreme environments).
• Hyporexia is the most common clinical sign. • Vomiting, hematemesis, and/or melena may be seen (in decreasing order of frequency). • Cranial abdominal pain ("praying position") is rarely seen.
• Weakness, pallor, lethargy, and/or collapse if severe anemia or SIRS develops.

Physical Examination Findings
• Often normal. • Melena is rare. • Pale mucous membranes and weakness if severely anemic. • Tachycardia, hypotension, and prolonged capillary refill time if hypovolemic shock or perforation/SIRS.

CAUSES

Drugs
• NSAIDs—cyclooxygenase (COX)-2 selective NSAIDs are usually safer than nonselective NSAIDs; however, GUE and perforation can occur with all NSAIDs. Coadministration of glucocorticoids (either systemic or local) enhances ulcerogenic potential of NSAIDs. Some NSAIDs are renowned for being extremely ulcerogenic (flunixin meglumine, naproxen, indomethacin). • Glucocorticoids—dexamethasone is most ulcerogenic. Prednisolone less likely to cause clinically significant GUE unless there are additional stress factors (e.g., hypoxemia, hypoperfusion).

GI Diseases
• GI neoplasia—carcinomas are most common cause of neoplastic ulceration, but leiomyomas/leiomyosarcomas may cause severe hemorrhage. • Foreign bodies can be associated with GUE, but not a common cause. Intestinal foreign bodies (especially linear foreign bodies) commonly cause intestinal ulceration/perforation. • Gastric hyperacidity.

Infectious Diseases
Pythiosis can cause severe GUE. It is regionally important and is becoming increasingly widespread in North America.

Metabolic Diseases
• Hepatic disease. • Hypoadrenocorticism.

Toxicity
Heavy metal poisoning (arsenic, zinc, thallium, iron, and lead are rare causes).

Neoplasia
• GI neoplasia (carcinoma, lymphoma, leiomyoma, GI stromal tumor). • Paraneoplastic hyperacidity (mastocytosis, gastrinoma).

Stress/Major Medical Illness
• Shock/severe hypotension (e.g., secondary to trauma or surgery). • SIRS (heat stroke, sepsis). • Burns. • Sustained strenuous exercise (especially in extreme environments, either cold or hot).

RISK FACTORS
• Ulcerogenic drugs (NSAIDs, dexamethasone). • Hypovolemic shock/SIRS. • Extreme exercise.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Esophageal disease (neoplasia, esophagitis, foreign body)—diagnose with radiography and/or esophagoscopy. • Coagulopathies (thrombocytopenia, anticoagulant poisoning)—diagnose with platelet count, coagulation testing. • Bronchopulmonary disease causing hemoptysis—diagnose with radiography and/or bronchoscopy. • Regurgitation or vomiting blood (hematemesis) swallowed from respiratory tract or swallowed with food.
• Pepto-Bismol and activated charcoal cause stool to resemble melena.

CBC/BIOCHEMISTRY/URINALYSIS
• Acute blood loss (≤3–5 days)—nonregenerative anemia/hypoproteinemia. • Blood loss >7 days—regenerative anemia/hypoproteinemia. • Chronic blood loss—iron deficiency anemia (i.e., low mean corpuscular volume [MCV], high red cell distribution width [RDW], hypochromic, variable reticulocytosis) and hypoproteinemia. • Blood urea nitrogen (BUN) : creatinine ratio may be elevated with acute, severe GI hemorrhage, but this is hard to evaluate without recent pre-bleed laboratory values.

OTHER LABORATORY TESTS
• Fecal flotation (parasitism). • Bile acids (hepatic insufficiency). • Resting serum cortisol (screen for hypoadrenocorticism). • Serum gastrin concentrations (gastrinoma is rare).

IMAGING
• Abdominal radiography (GI foreign body, abdominal mass, pneumoperitoneum, effusion, hepatic disease). • Barium contrast radiography very insensitive for GUE.
• Ultrasonography specific but poorly sensitive for GI lesions (e.g., infiltrates, altered layering, ulcer); cannot detect erosions.

DIAGNOSTIC PROCEDURES
• Endoscopy most sensitive test for GUE. Allows biopsy of the lesion; best to biopsy normal-appearing tissue around GUE plus periphery of ulcer. Be careful biopsying center of ulcers as this rarely causes perforation. • Capsule endoscopy less expensive and does not require anesthesia, but not as sensitive as regular gastroscopy and does not allow for biopsy.
• Fine-needle aspirates or biopsies of infiltrative lesions in GI tract. • Abdominocentesis may reveal septic peritonitis if ulcer perforates.
• Exploratory surgery can be done to look for GUE, but easy to miss mucosal lesions from serosal surface. Can easily look into stomach through gastrostomy incision and miss lesions.

PATHOLOGIC FINDINGS
• GUEs are grossly visible. • Gastric body and antrum most common sites of GUE (especially from NSAIDs and steroids), but GUE can occur anywhere in stomach.
• Proximal duodenal ulceration classic but not diagnostic for excessive gastric acid secretion (mast cell tumor, gastrinoma).
• Microscopically can see inflammation, neoplasia, or fungal organisms.

(CONTINUED) # GASTRODUODENAL ULCERATION/EROSION

TREATMENT

APPROPRIATE HEALTH CARE
Very important: remove underlying cause if possible (e.g., drugs, toxins, poor perfusion). Many GUEs resolve spontaneously if cause is removed.

NURSING CARE
• IV fluids if needed to maintain hydration, gastric mucosal perfusion, and/or treat shock. • Transfusions if patient is severely anemic or has vigorous GI hemorrhage.

ACTIVITY
Based upon patient's condition.

DIET
• Discontinue oral intake if vomiting. • When feeding resumed, feed small amounts of low-fat/low-fiber diet.

CLIENT EDUCATION
• Dogs are especially prone to NSAID-induced GUE because these drugs have a longer half-life in dogs than in humans. • Never administer NSAID (especially if sold for human use) unless specifically prescribed by veterinarian (e.g., low dose of aspirin [0.5 mg/kg q24h] is safe when used to prevent thromboembolic disease in dogs being treated with steroids). • NSAID-associated GUE reduced by giving drug with food. • Proton pump inhibitors (PPIs) as effective as misoprostol in preventing NSAID-induced GUE. • No drug shown to be effective in preventing steroid-induced GUE.

SURGICAL CONSIDERATIONS
• If GI blood loss potentially life threatening, perform gastroduodenoscopy to identify sites of hemorrhage; then either surgically resect lesions or cauterize sites endoscopically (electrically or chemically). • Surgical excision of ulcers indicated if medical treatment shows no evidence of benefit after 5–7 days. • May need intraoperative endoscopy to locate lesions that cannot be found at surgery. • Rarely need surgeon to telescope intestines over tip of endoscope to thoroughly examine entire duodenal and jejunal mucosa.

MEDICATIONS

DRUG(S) OF CHOICE
• PPIs most potent inhibitors of gastric acid secretion. Require 3–5 days to achieve maximum efficacy. Used as prophylactic drugs and as first-line therapy for existing GUE; primary therapy for gastrinomas. Omeprazole (1–2 mg/kg PO q12h) administered orally; pantoprazole (1 mg/kg IV q12h) can be administered parenterally. • Histamine (H2) receptor antagonists also inhibit gastric acid secretion. Famotidine (0.5–1 mg/kg PO/IV q12–24h) most potent, but all of these drugs inferior to PPIs. • Sucralfate (0.5–1 g PO q6–8h) protects ulcerated tissue by binding to it and stimulating prostaglandin synthesis (use suspension instead of tablets). No benefit in combining with PPIs. • Misoprostol (2–5 µg/kg PO q12h) effective, but has many side effects. • Antiemetics if vomiting frequent or nausea severe. Maropitant (1 mg/kg SC q24h; 2 mg/kg PO q24h); ondansetron (0.2–0.5 mg/kg PO/IV q8–12h). • Oral antacids (e.g., calcium carbonate) poorly effective and not recommended.

POSSIBLE INTERACTIONS
• Sucralfate may slow absorption of other drugs. • Antacids may slow absorption of other drugs. • H2 receptor antagonists decrease effectiveness of PPIs. • Do not use misoprostol in pregnant patients.

FOLLOW-UP

PATIENT MONITORING
Effective medical therapy should result in clinical improvement within 5–7 days.

PREVENTION/AVOIDANCE
• Administer NSAIDs with food. • PPIs generally as effective as misoprostol at preventing NSAID-induced GUE. • COX-2 selective or dual lipoxygenase (LOX)/COX inhibitors less likely to cause GUE than nonselective NSAIDs, but can still cause GUE and perforation/peritonitis.

POSSIBLE COMPLICATIONS
Hemorrhage, perforation, septic peritonitis.

EXPECTED COURSE AND PROGNOSIS
• Varies with underlying causes. • GUE not due to local malignancy can usually be treated successfully medically (especially if one can remove cause). However, if perforation has occurred, surgery is necessary.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Anemia

AGE-RELATED FACTORS
Neoplasia more common in older animals.

SEE ALSO
• Hematemesis.
• Melena.

ABBREVIATIONS
• ACTH = adrenocorticotropic hormone.
• BUN = blood urea nitrogen.
• COX = cyclooxygenase.
• DIC = disseminated intravascular coagulation.

GASTROENTERITIS, ACUTE HEMORRHAGIC DIARRHEA SYNDROME

BASICS

DEFINITION
A peracute hemorrhagic enteritis of dogs characterized by a sudden onset of severe bloody diarrhea that is often explosive, with vomiting (typically the first clinical sign observed by the owner), hypovolemia, and usually marked hemoconcentration due to a dramatic loss of fluid into the intestinal lumen.

PATHOPHYSIOLOGY
• Many conditions result in hemorrhagic diarrhea, but the acute hemorrhagic diarrhea syndrome (AHDS) of dogs appears to have unique clinical features that distinguish it from other conditions. • AHDS results in a peracute loss of intestinal mucosal integrity with the rapid movement of fluid and electrolytes into the gut lumen. Dehydration and hypovolemic shock occur quickly. In proportion to fluid loss, blood loss is usually minor. This has to be differentiated from true gastrointestinal (GI) bleeding, in which anemia is usually observed. Protein loss can be substantial in some cases, resulting in severe hypoalbuminemia. Translocation of bacteria or toxins through the damaged intestinal mucosa can usually be compensated. In a few cases the immune defense mechanisms can be overwhelmed, resulting in septicemia/septic shock.

SYSTEMS AFFECTED
• GI. • Cardiovascular.

GENETICS
Unknown; small or toy breeds appear to be overrepresented.

INCIDENCE/PREVALENCE
Unknown; appears to be common.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog

Breed Predilections
• Any breed can be affected; incidence is greater in small and toy breeds. • Breeds most represented include Yorkshire terrier, miniature pinscher, miniature schnauzer, miniature poodle, and Maltese.

Mean Age and Range
Usually in adult dogs with a mean age of 5 years.

Predominant Sex
N/A

SIGNS

General Comments
• Mucosal lesions are restricted to the intestines and cannot be detected in the stomach histologically; therefore, it is suggested to replace the term hemorrhagic gastroenteritis (HGE), implicating gastric inflammation, with AHDS. • Most animals affected are previously healthy with no historical environmental changes; some dogs have a history of chronic intermittent GI disease. • Clinical findings are variable in both the course and severity of the disease; the disease is usually acute to peracute; with adequate fluid and symptomatic treatment, rapid clinical improvement is typically observed in the first 48 hours.

Historical Findings
• Acute vomiting, anorexia, and lethargy, followed by watery diarrhea quickly changing to bloody diarrhea. • Signs progress rapidly and become severe within a period of <12 hours as a result of hypovolemic shock and hemoconcentration.

Physical Examination Findings
• Evidence of hypovolemia; lethargy, weakness, tachycardia, prolonged capillary refill time, and weak pulse pressure. • Skin turgor as a reflection of dehydration may appear normal owing to the peracute nature of the disease and the lag time in compartmental fluid shifts. • Abdominal pain and fluid-filled bowel can be detected. • Rectal examination identifies bloody diarrhea, and later in the course of disease a "raspberry jam" characteristic stool develops. • Often normo- or hypothermia; fever is unusual and represents an important feature differentiating uncomplicated AHDS cases from dogs with infection and systemic reaction to an enteropathogen or septicemia following bacterial translocation.

CAUSES
• There is increasing evidence to suggest that *Clostridium perfringens* type A is involved, as these bacteria have been identified on necrotic mucosal surfaces closely associated with epithelial lesions. • A novel pore-forming toxin designated NetF was detected in *C. perfringens* type A strains, which were involved in AHDS; compared to healthy control dogs (prevalence: 0–10%), the prevalence of *C. perfringens* encoding the *netF* gene is significantly higher in dogs with AHDS (50–55%). • Other undetected clostridial toxins might be involved in the disease process; it is also possible that different etiologies are responsible for this syndrome in different patients.

RISK FACTORS
• Unknown. • Some dogs have a history of chronic intermittent diarrhea.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Drugs/toxins causing mucosal irritation (e.g., nonsteroidal anti-inflammatory drugs, high-dose corticosteroids, doxycycline). • Parvovirus. • Circovirus. • Acute GI ulceration. • Bacterial enteritis such as salmonellosis or campylobacteriosis. • Conditions resulting in endotoxic or hypovolemic shock. • Intestinal obstruction or intussusception. • Hypoadrenocorticism. • Heat stroke. • Pancreatitis. • Coagulopathy.

CBC/BIOCHEMISTRY/URINALYSIS
• Marked hemoconcentration with packed cell volume (PCV) usually >60%, with discordant plasma proteins that are normal to decreased due to protein loss into the GI tract; some dogs show significant hypoalbuminemia after rehydration; usually a stress leukogram. • Biochemistry profile may reveal secondary hepatic enzyme elevations and high blood urea nitrogen (BUN) due to prerenal causes.

OTHER LABORATORY TESTS

Fecal Tests
• Stool is negative for parasites. • ELISA and PCR for parvovirus are negative. • Fecal cytology shows many red blood cells (RBCs) and occasional white blood cells (WBCs). • *Clostridium* spp. may be cultured from healthy dogs and should not be used as a diagnostic test for AHDS. Fecal ELISA test for detection of *C. perfringens* enterotoxin is often positive. A culture for other enteric pathogens is not diagnostic, since many enteropathogens can be found in feces of healthy dogs. Fecal PCR for detection of *C. perfringens* alpha toxin gene alone is not sufficient to diagnose this disorder. A positive PCR for *netF* encoding *C. perfringens* strains is suggestive for AHDS.

Coagulogram
Usually normal, but rarely secondary disseminated intravascular coagulation (DIC) is a complication.

IMAGING
Abdominal radiographs or ultrasound show fluid- and gas-filled small and large intestine. Ultrasonography often reveals fluid-filled intestinal loops without peristaltic movements due to the presence of a paralytic ileus.

DIAGNOSTIC PROCEDURES

Endoscopy
• Rarely indicated. • Stomach may appear normal, but small and large intestine will show diffuse mucosal hemorrhage, and hyperemia.

PATHOLOGIC FINDINGS
• Gross findings include intestinal congestion. • Histological examination of the intestinal tract shows superficial mucosal hemorrhagic necrosis without significant inflammation. • Frequently, layers of rod-shaped bacteria (e.g., *C. perfringens*) can be detected on the surface of the intestinal mucosa. • Gastric mucosa is spared.

TREATMENT

APPROPRIATE HEALTH CARE
Patients suspected of having AHDS should be hospitalized and treated aggressively, because clinical deterioration is often rapid and can be fatal.

(CONTINUED) GASTROENTERITIS, ACUTE HEMORRHAGIC DIARRHEA SYNDROME

NURSING CARE
• Rapid volume replacement through a large-bore IV catheter is required in all cases. • Balanced electrolyte solutions are given up to the rate of 40–60 mL/kg/hour IV until PCV <50%. • Shock fluids can also be given as fast as 30 mL/kg in 10 min; this bolus can be repeated up to three times if needed. • A moderate rate of maintenance fluids is given to maintain circulatory function and correct any potassium or other electrolyte deficits during the recovery period. • Continued GI fluid losses should be estimated and that volume added to the fluid requirements. • Hypoproteinemic animals may require colloids, plasma, or albumin solutions (canine preferred over human, if available).

ACTIVITY
Restricted

DIET
• NPO during acute phase as long as dogs are vomiting. • Trickle feeding with oral glutamine solution or low-fat (liquid) diet as long as the dog is not eating. • During recovery period a bland, low-fat, low-fiber GI diet should be fed for several days before returning to normal diet. • Consider increased dietary fiber to alter the intestinal microbiota to reduce the likelihood of recurrence of *C. perfringens*–associated diarrhea.

CLIENT EDUCATION
• Discuss the need for immediate and aggressive medical management; with appropriate therapy, mortality is usually low. • Recurrence is reported in about 10% of cases.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE
• Antibiotics should be restricted to dogs with signs of systemic infection, immunosuppression, and reduced liver function, as well as to dogs inadequately responding to symptomatic therapy; amoxicillin/sulbactam (50 mg/kg q8h IV) is suggested prophylactically in dogs that cannot be monitored closely. • An antiemetic such as maropitant (1 mg/kg q24h IV) is suggested to control nausea and vomiting. • Analgesics (e.g., buprenorphine 0.01 mg/kg q6–8h IV) should be administered at the clinician's discretion. • Excessive blood loss may require blood transfusion (very rare).

CONTRAINDICATIONS
N/A

PRECAUTIONS
Septic and or hypovolemic shock can occur quickly and consequently the animal should be monitored closely.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
• Oral antibiotics and intestinal protectants are of little benefit and generally not administered. • Administration of mucosal protectants such as sucralfate is of questionable value. • Antidiarrheal drugs are contraindicated. • High-dose, multistrain probiotic therapy might help to displace *C. perfringens* strains from the GI tract, though clinical efficacy has not been evaluated. • Long-term administration of probiotics could theoretically alter the intestinal microbiota to reduce the likelihood of recurrence of *C. perfringens*–associated diarrhea, though clinical efficacy has not been evaluated.

FOLLOW-UP

PATIENT MONITORING
• Check response to fluid therapy by assessing heart rate, capillary refill time, pulse pressure, as well as mental status and urine production every hour until considering the dog stable. • Monitor PCV and total solids frequently (at least every 4–6 hours). • Modify fluid replacement based on patient status. • If there is failure of clinical improvement in 24–48 hours, reevaluate the patient, as other causes of hemorrhagic diarrhea are probable.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
• Occasionally DIC may develop. • Neurologic signs or seizures secondary to hemoconcentration may occur. • Cardiac arrhythmias occur from suspected myocardial reperfusion injury.

EXPECTED COURSE AND PROGNOSIS
• Most dogs recover; mortality rate can be high in untreated dogs; fewer than 10% of treated dogs die, and 10–15% have repeated occurrences. • The course of the disease is generally short, lasting from 24 to 72 hours. • About 50% of dogs still have soft feces on day 5. • Time to complete normalization of stool consistency can be up to 7–10 days.

MISCELLANEOUS

ASSOCIATED CONDITIONS

G

GASTROENTERITIS, EOSINOPHILIC

BASICS

DEFINITION
• Disease of gastrointestinal (GI) tract caused by primary infiltrate of eosinophils. • When other causes of eosinophilic infiltrates are ruled out, this is considered a form of inflammatory bowel disease (IBD).

PATHOPHYSIOLOGY
• Eosinophils involved in innate, acquired, and adaptive immunity; antigenic stimulation causes eosinophilic recruitment to GI tract. • Stimulation from food hypersensitivity, parasitic infection, neoplasia (i.e., mast cell, lymphoma), fungi, viruses, bacteria, disease affecting mast cells, or idiopathic. • Small and large eosinophil granules release substances cytoxic to microorganisms and recruit other immune defenses; also damaging to self tissues. • Eosinophils activate mast cells directly causing continued tissue destruction.

SYSTEMS AFFECTED
• GI—primarily stomach and small intestine; large intestine less commonly affected; esophagus rarely affected. • Hemic/lymphatic/immune—hypereosinophilic syndrome (HES) and certain neoplasms affect spleen and lymph nodes. • Hepatobiliary—HES may affect liver. • Respiratory—aspiration pneumonia secondary to vomiting. • Musculoskeletal—weight loss, muscle wasting, weakness. • Integument—hair coat changes with nutritional deficiencies.

GENETICS
Unknown

INCIDENCE/PREVALENCE
• Unknown. • Second most common form of IBD.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Species
Dog and cat.

Breed Predilections
German shepherd, boxer, Rottweiler, Doberman pinscher, and shar-pei.

Mean Age and Range
• Any age. • Dogs—commonly young (<5 years). • Cats—commonly middle-aged.

Predominant Sex
None

SIGNS
General Comments
Signs vary with severity of illness and sites affected.

Historical Findings
• Vomiting, small bowel diarrhea > large bowel diarrhea. • Abdominal pain. • Anorexia/hyporexia. • Weight loss. • Occasional melena.

Physical Examination Findings
• Cats > dogs—thickened bowel loops on abdominal palpation. • HES—skin lesions, enlarged peripheral lymph nodes, hepatosplenomegaly. • Abdominal pain. • Muscle wasting, weight loss, ± coat changes. • Pale mucous membranes with bleeding ulcer. • Dehydration, hypovolemia. • Palpable abdominal mass lesion.

CAUSES
• IBD. • Parasites—e.g., *Physaloptera* spp., *Ollulanus tricuspis*, *Spirocerca* spp. • Fungal, viral, bacterial infection. • Loss of tolerance to normal intestinal flora. • Systemic mastocytosis. • HES. • Neoplasia—mast cell tumor, lymphoma.

RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Any cause of GI signs. • Feline GI eosinophilic sclerosing fibroplasia (ulcerated intramural mass at pyloric sphincter or ileocecocolic junction most common).

CBC/BIOCHEMISTRY/URINALYSIS
• Hemogram—unremarkable, mild to marked peripheral eosinophilia (cats > dogs). • Biochemistry—blood urea nitrogen (BUN) elevation alone or disproportionally higher than creatinine suggests GI bleeding; hypoproteinemia and hypocholesterolemia common with significant disease; increased liver enzyme activity and/or azotemia may be seen with HES; prerenal azotemia with dehydration. • Urinalysis—usually unremarkable.

OTHER LABORATORY TESTS
• Buffy-coat smear—evaluate for systemic mastocytosis. • Serum cobalamin and folate—screen for evidence of intestinal malabsorption. • Fecal float, multiple. • Baseline cortisol ± adrenocorticotropic hormone (ACTH) stimulation test. • Based on location or travel history, testing for fungal organisms (i.e., histoplasmosis). • Expanded infectious disease testing depending on patient risk and exposure.

IMAGING
• Abdominal radiography—rules out other disease causing clinical signs; does not diagnose this condition; hepatosplenomegaly may be seen with HES. • Barium contrast radiography may demonstrate thick intestinal walls and mucosal irregularities, but does not provide etiology. • Ultrasonography—assess stomach and intestinal wall thickness; assess for mass lesions, ulcer, and obstruction; rule out other diseases; examine liver, spleen, and mesenteric lymph nodes with suspected HES or metastatic disease.

DIAGNOSTIC PROCEDURES
• Upper and lower GI endoscopy—visualize mucosa; identify ulcer or mass; biopsy (even when grossly normal); thickened rugal folds, increased mucosal friability, villous blunting, edema, and erythema are commonly visualized; intestinal parasites may be seen. • Fine-needle aspirate and cytology of enlarged liver, spleen, and/or lymph nodes. • Bone marrow aspirate cytology—when systemic mastocytosis or severe peripheral eosinophilia is present. • Exploratory laparotomy—perforated ulcer; full-thickness biopsy; removal of obstructive lesion and/or biopsy of other affected organs (lymph node, spleen, liver).

PATHOLOGIC FINDINGS
• Eosinophilic infiltrates can be patchy in intestine; multiple biopsies always recommended. • Histopathology reveals diffuse mucosal infiltrate of eosinophils; submucosa and muscularis are less commonly involved in the dog (more common in the cat); infiltrate of muscularis layer associated with obstructive eosinophilic lesions; eosinophilic inflammation within fibroplasia seen in feline GI eosinophilic sclerosing fibroplasia; WSAVA guidelines from international GI Standardization Group should be followed for interpretation of normal vs. pathologic numbers of eosinophils.

TREATMENT

APPROPRIATE HEALTH CARE
• Many treated as outpatients (minimal dehydration) after obstruction excluded, pending diagnostic testing or treatment trials (i.e., diet trial, drugs). • Inpatient medical management if significant dehydration or intractable vomiting.

NURSING CARE
• IV fluids to restore volume and correct dehydration when indicated; *caution* for fluid overload with hypoproteinemia. • Enteral nutrition (nasoesophageal, nasogastric, or esophageal tubes) with persistent anorexia. • Severe hypoalbuminemia—consider albumin, plasma, or colloids.

ACTIVITY
Restrict postoperatively if surgery performed.

DIET
• Novel protein or hydrolyzed diet when allergy or IBD suspected; initial response expected within 2 weeks; worsening warrants diet change or other intervention; if improvement noted, continue diet for several months before reintroducing other foods to assess tolerance. • Challenge with original diet can prove food hypersensitivity; rarely pursued. • Calorie requirement/diet guideline increases compliance. • Unflavored or topical flea, tick, and heartworm preventatives. • Treats limited to prescription diet. • If commercial diet declined, consider home-cooked diet formulated by veterinary nutritionist.

(CONTINUED) # GASTROENTERITIS, EOSINOPHILIC

CLIENT EDUCATION
• Review multiple etiologies. • Least invasive testing first when patient status allows; biopsy for definitive diagnosis if extra-intestinal causes ruled out and patient fails diet and drug trial (i.e., anthelminthic, antimicrobial). • Potential for waxing and waning nature; necessity for lifelong vigilance regarding inciting factors; potential for long-term therapy.

SURGICAL CONSIDERATIONS
• Obstructive lesion. • Perforated ulcer.
• Full-thickness biopsy.

MEDICATIONS

DRUG(S) OF CHOICE
• Gastroprotectants and antiemetics often needed to control clinical symptoms initially.
• Gastroprotectants—proton pump inhibitor (PPI), i.e., omeprazole 1 mg/kg PO q12h 30–60 min before meal; also consider sucralfate, H2 receptor antagonist, and others per ACVIM consensus (see Suggested Reading). • Antiemetics—maropitant (1 mg/kg SC/IV q24h; 2 mg/kg PO q24h); ondansetron, metoclopramide, mirtazapine.
• Prokinetics—metoclopramide (0.2–0.4 mg/kg PO q8h; CRI 1–2 mg/kg/day), cisapride, ranitidine, low-dose erythromycin.
•Anthelminthic—fenbendazole (50 mg/kg PO q24h for 5 days), pyrantel pamoate + febantel. • Antimicrobial—metronidazole (10 mg/kg PO q12h for 2–4 weeks), tylosin (11–20 mg/kg PO q12h for 2–4 weeks).
• IBD suspected/confirmed—glucocorticoid (i.e., prednisone 2 mg/kg PO q24h or divided q12h; prednisolone for cat) when no clinical response to other therapeutic trials or in advanced disease; taper by 20–25% increments over time to lowest effective dose; discontinue when possible; total dose not >60 mg per day (dog); use with diet. • If glucocorticoid not tolerated and/or relapse, consider second drug; see Alternative Drug(s).

CONTRAINDICATIONS
Do not use prokinetics if GI obstruction possible.

PRECAUTIONS
• Immune modulation predisposes to secondary infections. • Steroids can cause GI ulceration, diabetes mellitus, or fluid overload (especially cat: congestive heart failure); patient monitoring and client education are vital to success. • Prolonged use of antacids or PPIs can lead to overgrowth of bacteria.

POSSIBLE INTERACTIONS
• Sucralfate will decrease absorption of other medications; separate by 2 hours from other medications. • Omeprazole affects clearance of many drugs. • Never use nonsteroidal anti-inflammatory drugs (NSAIDs) with glucocorticoid; high risk of GI erosion/ulcer.

ALTERNATIVE DRUG(S)
• IBD—if steroid and diet alone do not achieve disease remission, if patient relapses, and/or if steroid side effects undesirable, second agent may be considered; options: cyclosporine, mycophenolate, chlorambucil, and azathioprine (never in cats); find lowest effective dose. • Monitoring—exam, labwork (CBC, chemistry) for myelosuppression and other concerns (i.e., hepatic toxicity with cyclosporine, chlorambucil, and azathioprine).
• Leukotriene receptor blockers (i.e., montelukast) have been successful in humans.
• Budesonide (steroid; 1–3 mg/patient depending on size) may have fewer systemic side effects; adrenal pituitary axis affected.

FOLLOW-UP

PATIENT MONITORING
• Depends on patient severity and medication chosen; minimum: physical exam within 2 weeks of starting treatment.
• Monitoring peripheral eosinophil count if initially elevated. • Recheck abnormal labwork (i.e., electrolytes, proteins) and monitor for medication side effects (i.e., hyperglycemia, anemia, myelosuppression, heptaopathy, etc. based on specific drugs selected). • Recurrence warrants repeat diagnostics; repeat biopsy may be indicated (i.e., patients previously in remission of IBD can progress to lymphoma). • Lack of response—change in medical management (i.e., alternative diet or drug); repeat biopsy (primary disease may have been missed) and labwork (CBC, chemistry, fecal, T_4) for emerging comorbidity.

PREVENTION/AVOIDANCE
• Avoid rapid diet change. • Prevent free-roaming and potential for dietary indiscretion—may need basket muzzle in dogs.

POSSIBLE COMPLICATIONS
• Gastroesophageal reflux disease (GERD).
• Delayed gastric emptying/motility disorders.
• Erosions/ulcers. • Aspiration pneumonia.
• Electrolyte, acid-base imbalances.
• Debilitation/death in refractory cases.
• Steroid—diabetes mellitus, heart failure, calcinosis cutis, muscle weakness, ulcers. • Other immune-modulating drugs—bone marrow suppression, pancreatitis, hepatitis, GI upset.

EXPECTED COURSE AND PROGNOSIS
• Vary with cause. • Medication tapered to lowest effective dose ± stopped with diet.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
• Food-responsive enteropathy—often younger. • IBD—often middle-aged to older.
• Neoplasia—middle-aged to older animals more common.

ZOONOTIC POTENTIAL
Potential/uncommon concern secondary to parasites (i.e., *Toxocara* spp.—larval migrans).

PREGNANCY/FERTILITY/BREEDING
• Prednisone—abortion, teratogenic, can induce parturition. • Azathioprine—fetal harm; decreases sperm production.
• Cyclosporine—fetal toxicity.

SEE ALSO
• Gastroduodenal Ulceration/Erosion.
• Inflammatory Bowel Disease.

ABBREVIATIONS
• ACTH = adrenocorticotropic hormone.
• BUN = blood urea nitrogen. • GERD = gastroesophageal reflux disease. • GI = gastrointestinal. • HES = hypereosinophilic syndrome. • IBD = inflammatory bowel disease.
• NSAID = nonsteroidal anti-inflammatory drug. • PPI = proton pump inhibitor.

GASTROESOPHAGEAL REFLUX

BASICS

OVERVIEW
- Reflux of gastric or intestinal fluid into the esophageal lumen.
- Incidence unknown; probably more common than clinically recognized.
- Transient relaxation of the lower esophageal sphincter (LES) or chronic vomiting may permit reflux of gastrointestinal juices into the esophageal lumen. Reflux is common in dogs with sliding hiatal hernias. A small amount of gastroesophageal reflux (GER) is a normal phenomenon in dogs and cats.
- Gastric acid, pepsin, trypsin, bicarbonate, and bile salts are all injurious to the esophageal mucosa with prolonged or repetitive contact.
- Sequelae of GER may vary from mild inflammation of the superficial mucosa to severe ulceration involving the submucosa and muscularis.
- Systems affected include gastrointestinal (regurgitation) and respiratory (aspiration pneumonia).

SIGNALMENT
- Dog and cats; male or female.
- No breed predilections reported.
- May be associated with congenital hiatal hernia seen in Chinese Shar-Pei dogs and brachycephalic breeds.
- Occurs at any age; younger animals may be at increased risk because of developmental immaturity of the gastroesophageal sphincter.

SIGNS
- Regurgitation.
- Hypersalivation.
- Painful swallowing (odynophagia).
- Anorexia.

CAUSES & RISK FACTORS
- General anesthesia.
- Retained gastric contents.
- Acquired or congenital hiatal hernia.
- Chronic vomiting with secondary esophagitis.
- Brachycephalic airway syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Oral or pharyngeal disease.
- Ingestion of caustic agent.
- Esophageal foreign body.
- Esophageal tumor.
- Megaesophagus.
- Hiatal hernia.
- Gastroesophageal intussusception.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

OTHER LABORATORY TESTS
N/A

IMAGING
- Survey thoracic radiography—usually unremarkable; may be air or fluid in the distal esophagus (nonspecific finding).
- Barium contrast radiography—reveals GER in some, but not all, animals; videofluoroscopy is superior to esophagram; aspiration pneumonia may be evident in the dependent portions of the lung.

DIAGNOSTIC PROCEDURES
Esophagoscopy—the best means of confirming esophagitis: irregular mucosal surface with hyperemia or active bleeding often present in the distal esophagus. Refluxed gastroduodenal secretions may be seen pooling in the distal esophagus near the LES, which may or may not be open.

TREATMENT
- Generally managed as outpatient.
- Not necessary to restrict activity.
- Moderate to severe cases—may withhold food for 24 hours to promote esophageal rest and to minimize further GER; thereafter, feed low-fat, low-protein meals in small, frequent feedings; dietary fat decreases gastroesophageal sphincter pressure and delays gastric emptying; protein stimulates gastric acid secretion and may precipitate GER.

MEDICATIONS

DRUG(S) OF CHOICE
- Drug therapy is recommended if significant mucosal injury is present.
- Oral sucralfate slurry (0.5–1 g PO q8h).
- Proton pump inhibitors (omeprazole: 0.7–1.5 mg/kg PO q12h or pantoprazole: 1 mg/kg IV q12–24h) for robust suppression of gastric acid production.
- Prokinetic agents—cisapride (0.5 mg/kg PO q8–12h) or metoclopramide (0.5 mg/kg PO q6–8h or 1–2 mg/kg q24h as CRI).
- Gastrostomy tube placement for enteral nutrition in animals with severe mucosal trauma.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Sucralfate may interfere with the absorption of other drugs.

FOLLOW-UP

PATIENT MONITORING
- It is appropriate in most patients to monitor clinical signs.
- Consider endoscopy for patients that do not respond to empirical medical therapies. Severe mucosal damage (esophagitis) may progress to stricture.

PREVENTION/AVOIDANCE
Clients should avoid feeding high-fat foods; they promote gastric retention and might exacerbate GER.

POSSIBLE COMPLICATIONS
Esophagitis and stricture formation.

EXPECTED COURSE AND PROGNOSIS
Most animals respond well to medical management and have a good prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Hiatal hernia.

AGE-RELATED FACTORS
May be worse in younger animals because of developmental immaturity of the gastroesophageal sphincter mechanism.

ZOONOTIC POTENTIAL
N/A

PREGNANCY/FERTILITY/BREEDING
N/A

SEE ALSO
- Esophageal stricture.
- Esophagitis.

ABBREVIATIONS

GASTROINTESTINAL OBSTRUCTION

BASICS

DEFINITION
The partial or complete physical impedance to the flow of ingesta and/or secretions aborally through the pylorus into the duodenum (gastric outflow tract obstruction [GOTO]) or through the small intestine. Obstructions in the pharynx, esophagus, large intestine, and rectum, and motility disorders, are addressed in separate chapters.

PATHOPHYSIOLOGY
• Mechanical obstruction commonly results from indiscriminate ingestion of foreign material, the presence of a gastrointestinal (GI) mass, or intussusception. • The accumulation of ingesta and GI secretions orad to the obstruction causes local vascular compromise, resulting in intestinal wall edema, necrosis, and possible sepsis. • Decreased oral intake, vomiting, and sequestration of GI secretions result in acid-base and electrolyte imbalances.

SYSTEMS AFFECTED
• Cardiovascular—hypovolemic or septic shock can result from fluid loss or GI translocation of bacteria. • GI—GI obstructions cause pathology by distension and compression of the GI tract orad to the obstruction; this results in decreased blood flow to the area with subsequent edema, ulceration, and necrosis of the mucosa; direct physical damage to the GI mucosa by foreign bodies (especially linear foreign bodies) can result in ulceration and possible perforation of the intestinal wall. • Hemic/lymphatic/immune—sepsis secondary to necrosis and/or bacterial translocation.

GENETICS
Unknown

INCIDENCE/PREVALENCE
Common

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Gastric dilation and volvulus (GDV) is common in large- and giant-breed dogs (Great Dane, German shepherd).

Mean Age and Range
• Foreign bodies—more common in young animals, but can occur at any age. • Pyloric stenosis—occurs most often in young animals. • Chronic hypertrophic gastropathy (CHG)—more common in middle-aged and older animals. • Intussusceptions—most common in young animals.

Predominant Sex
None

SIGNS

Historical Findings
• Severity of clinical signs is influenced by location and completeness of obstruction. • Patients with GOTO tend to have acute onset of severe vomiting; some patients can present as acute abdomen (acute and severe abdominal pain, vomiting); partial obstructions can have more chronic and intermittent clinical signs. • Duration of clinical signs varies, but usually 2–3 days. • Patients may have vomiting, anorexia, and/or lethargy.

Physical Examination Findings
• Moderate to severe dehydration is common. • Careful oral examination is recommended as linear foreign bodies can often be lodged at the base of the tongue. • Abdominal palpation will often elicit a painful response; sometimes patients will vomit in response to palpation. • Abdominal mass may be palpated. • Cranial abdominal distension and tympany often seen with GDV.

CAUSES
• Benign pyloric outflow tract obstruction. • Foreign body. • Gastroenteritis (infectious, granulomatous). • GDV. • GI neoplasia. • Intussusception. • Mesenteric torsion/volvulus. • Pyloric stenosis. • Stricture.

RISK FACTORS
• Foreign bodies more commonly found in young dogs and cats (mean age 2–4 years) due to indiscriminate eating behavior. • Linear foreign bodies found more commonly in cats. • GI tumors more common in older cats and dogs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Metabolic disease (e.g., renal failure, hepatic disease, diabetic ketoacidosis, hypoadrenocorticism). • Infectious gastroenteritis (e.g., viral, bacterial, parasitic). • Nonspecific gastroenteritis. • Pancreatitis. • Peritonitis. • Gastroduodenal ulcer and erosion. • CNS disease.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC—will often reflect systemic consequences of obstruction; variable degrees of neutrophilia with left shift and possible toxic changes seen with cases of sepsis. • Biochemistry—often reveals changes secondary to dehydration (increased blood urea nitrogen [BUN] and creatinine) as well as electrolyte and acid-base disturbances; animals with GOTO classically have hypokalemic and hypochloremic metabolic alkalosis. • Urinalysis—urine specific gravity may be increased secondary to dehydration.

OTHER LABORATORY TESTS
Lactate—hypoperfusion results in hyperlactatemia (>2.5 mmol/L).

IMAGING
• Survey abdominal radiographs—radiopaque foreign material may be seen in GI lumen; presence of soft tissue opacity in the stomach in a patient with recent history of vomiting and anorexia is highly suspicious for GOTO; indirect signs of GI obstruction can include gastric or intestinal distension with fluid or gas; linear foreign bodies characteristically cause grouping of intestinal loops on right of midline with small luminal gas bubbles (apostrophe shaped); presence of free gas in abdomen is consistent with GI perforation and septic peritonitis. • Contrast abdominal radiographs—positive contrast agents (liquid barium) can be used to identify radiolucent material in GI lumen; retained contrast material in stomach 4–6 hours after administration is consistent with GOTO; use of barium contrast agents contraindicated if GI perforation is suspected; in these instances, use of iodinated contrast agents is recommended. • Abdominal ultrasound—ultrasound can be very effective at identifying GI foreign bodies and intraluminal masses as well as assessing for integrity of GI tract and presence of abdominal fluid/air; luminal foreign bodies will cause distal acoustic shadowing, while linear foreign bodies often appear as hyperechoic linear objects within intestinal lumen.

DIAGNOSTIC PROCEDURES
• In cases where intestinal neoplasia is suspected, advanced imaging techniques such as CT may provide additional information such as the nature of the mass and its degree of invasion. • GI endoscopy may be used for removal of gastric foreign bodies causing GOTO.

PATHOLOGIC FINDINGS
Histopathology of GI masses causing obstruction can reveal granulomatous inflammation, fungal infection (e.g., pythiosis), and neoplasia.

TREATMENT

APPROPRIATE HEALTH CARE
• *Emergency intervention is required to relieve the obstruction.*
• Prior to definitive treatment of the obstruction, stabilization of the patient and correction of dehydration as well as electrolyte and acid-base abnormalities are imperative. • Dogs with GDV should have gastric decompression first using orogastric intubation or percutaneous gastrocentesis in order to relieve gastric pressure.

GASTROINTESTINAL OBSTRUCTION (CONTINUED)

NURSING CARE

• Aggressive IV administration of isotonic crystalloids is recommended to correct dehydration and hypovolemia, if present; recommendation is to administer ¼ shock bolus of 20 mL/kg (dog) or 10 mL/kg (cat) over 15 min and reevaluate patient's status (heart rate, blood pressure, blood lactate); repeat 1–2 times if vital parameters fail to normalize; if crystalloid therapy not successful in stabilizing patient, colloid solutions such as hetastarch can be administered at 5 mL/kg (dog) and 2.5 mL/kg (cat), to max 20 mL/kg (dog) and 10 mL/kg (cat). • Colloids should be used with caution, especially in cases where sepsis is suspected, due to their association with acute kidney injury.

ACTIVITY

Restricted for first 10–14 days post surgery.

DIET

• Nothing by mouth until relief of obstruction and resolution of vomiting; then feed bland fat-restricted diet for 1–2 days, with gradual return to normal diet. • Enteral tube feeding or parenteral feeding may be required postoperatively.

CLIENT EDUCATION

Animals with a history of GI foreign bodies have a tendency to repeat this behavior; owners should be counseled on ways to minimize ingestion of these objects.

SURGICAL CONSIDERATIONS

• Surgical exploration of the abdomen allows for removal of the foreign body as well as resection of any nonviable tissue; if the obstruction is neoplastic, infectious, or inflammatory in nature, surgical intervention can be therapeutic as well as diagnostic as long as excised tissue is submitted for histopathology and culture. • When GI obstruction is caused by a gastric foreign body, endoscopic removal can be attempted; if unsuccessful, foreign material can be removed from the stomach by gastrotomy. • GOTO—GDV should be corrected and future volvulus prevented with a gastropexy. • Intestinal obstruction—the full length of the intestinal tract should be examined and palpated; enterotomy should be performed to remove any luminal foreign material; if nonviable or perforated sections are present, resection and anastomosis should be performed. • Although intussusceptions can be percutaneously reduced, recurrence is very common; surgical reduction and/or resection with or without enteropexy is recommended.

MEDICATIONS

DRUG(S) OF CHOICE

• Parenteral broad-spectrum IV antibiotic therapy (ampicillin–sulbactam 30 mg/kg IV q8h with enrofloxacin 10 mg/kg IV q24h) should be initiated as soon as possible in patients with suspected GI obstruction. • In cases where GI ulceration is suspected or confirmed, use of a proton pump inhibitor is recommended (omeprazole or pantoprazole 1 mg/kg q12h PO or IV, respectively). • Appropriate analgesia should be provided before, during, and after surgery; mu-agonist opioids (fentanyl 2–5 µg/kg/h IV as CRI or hydromorphone 0.1 mg/kg IV q4–6h) are recommended given their strong analgesic effect.

CONTRAINDICATIONS

Prokinetic agents (e.g., metoclopramide, cisapride) must be avoided until obstruction is resolved.

PRECAUTIONS

• Use of antiemetic medications is contraindicated in patients with suspected GI obstruction. • Nonsteroidal anti-inflammatory drugs should not be used in patients with GI obstructions due to their adverse effects on the GI mucosa and renal function in patients that are not hemodynamically stable.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

• Dehiscence of gastrotomy and enterotomy sites can occur 3–5 days postoperatively; patients should be watched closely during this period for signs of lethargy, recurrence of vomiting, and fever. • Ventricular arrhythmias are documented in approximately 40% of GDV patients; in these cases, electrolyte and acid-base disturbances should be identified and treated, if present.

PREVENTION/AVOIDANCE

Efforts to prevent repeat ingestion of foreign bodies.

POSSIBLE COMPLICATIONS

• Aspiration pneumonia. • Septic peritonitis. • Functional ileus.

EXPECTED COURSE AND PROGNOSIS

• With rapid surgical intervention of uncomplicated cases of GI foreign bodies, prognosis is good (>95%); however, prognosis associated with septic peritonitis is significantly lower (50%); negative prognostic factors that have been identified include longer duration of clinical signs, presence of linear foreign body, and multiple surgical procedures. • With intestinal neoplasia, prognosis remains guarded to poor, with the exception of small cell lymphoma in cats; with gastric carcinoma, complete surgical excision is rarely attainable and intestinal carcinoma has high rate of metastasis at time of diagnosis; large cell GI lymphoma has relatively poor response rate to commonly used chemotherapy protocols, and median survival times in cats and dogs are 4–6 months and 110 days, respectively.

GESTATIONAL DIABETES MELLITUS

OVERVIEW

Diabetes mellitus (DM), which occurs during mid to late gestation, most likely due to insulin resistance from increased progesterone and growth hormone production by the mammary glands.

SIGNALMENT

- Middle-aged intact female dogs.
- Mean age—6 years.
- Nordic spitz breeds are overrepresented.
- Not reported in cats.

SIGNS

- Polyuria.
- Polydipsia.
- Polyphagia.
- Weight loss.
- Lethargy.
- Vomiting.
- Ketosis.

CAUSES & RISK FACTORS

- Late-term pregnancy.
- Diestrus.
- Exogenous progesterone supplementation.
- Acromegaly.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acromegaly—affected bitches are listless and have increased abdominal size, increased interdental spaces, polyuria/polydipsia, weight gain, and excessive skin folds in the facial/neck areas.

CBC/Biochemistry/Urinalysis

- Hyperglycemia.
- Glucosuria.
- Metabolic acidosis if ketonemic or ketonuric.

Other Laboratory Tests

Urine culture—urinary tract infections can contribute to insulin resistance.

Imaging

- Ultrasonography—assess fetal viability; deceased puppies may affect treatment decisions.
- Radiographs—determine fetal size and relative risk for dystocia.

Diagnostic Procedures

N/A

TREATMENT

- Nonpharmacologic considerations—management of gestational DM requires intensive fluid and insulin therapy. Continued glucose toxicity can destroy the pancreatic beta cells' capacity to produce insulin, leading to permanent DM.
- Ovariohysterectomy is recommended. While the diabetes may resolve at the end of diestrus or after parturition, it will return on subsequent cycles and then has a greater potential to become permanent.

MEDICATIONS

DRUG(S) OF CHOICE

- Insulin—if ketosis not present, start at an insulin dose of 0.25 U/kg SC q12h of intermediate or long-acting insulin; will likely need to increase the dose to achieve glycemic control. If ketoacidosis is present, regular insulin (0.1–0.2 U/kg IM q4–6h) may be necessary to achieve initial glycemic control before switching to longer-acting insulin.
- Aglepristone—10 mg/kg SC days 1, 2, 9, and 17 from diagnosis. This medication is a progesterone receptor blocker, but does not affect progesterone levels. Treatment reserved for cases in which ovariohysterectomy is not possible or authorized by the owners.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

Care must be taken to avoid insulin overdose causing hypoglycemia during the immediate postpartum period (or the end of diestrus), because the speed at which insulin resistance resolves and exogenous insulin requirements decrease is unpredictable.

PREVENTION/AVOIDANCE

Ovariohysterectomy to remove source of progesterone.

POSSIBLE COMPLICATIONS

Lack of prompt resolution of hyperglycemia may result in diabetes mellitus becoming permanent.

EXPECTED COURSE AND PROGNOSIS

- Diabetes usually resolves at parturition or at the end of diestrus. More likely to be transient DM if pregnancy terminated, whereas insulin-treated bitches more likely to develop permanent DM.
- May abort the litter or have dystocia as a result of the effects of chronic hyperglycemia.
- Small, unthrifty puppies may result from an abnormal placental blood supply. Conversely, some fetuses in a hyperglycemic environment experience an abnormally increased growth rate (macrosomia). These puppies tend to be large, leading to dystocia.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Pregnancy

AGE-RELATED FACTORS

Older bitches are more likely to develop permanent DM.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

May abort the litter or have dystocia as a result of the effects of chronic hyperglycemia. There is thought to be a genetic component, due to a breed predisposition. It is not advised to continue to breed affected individuals.

SEE ALSO

Diabetes Mellitus without Complication—Dogs.

ABBREVIATIONS

- DM = diabetes mellitus.

Consulting Editor Erin E. Runcan

GIARDIASIS

BASICS

OVERVIEW
- Enteric infection of dogs and cats with protozoan parasite, *Giardia duodenalis*.
- Direct transmission by ingestion of cysts that are immediately infective when shed in feces.
- Trophozoites, motile (flagellated) organisms released from ingested cysts, attach to surface of enterocytes in small intestine with ventral sucking disc; move from site to site.
- Can cause small bowel diarrhea, but infection often asymptomatic.

SIGNALMENT
More common in dogs than cats.

SIGNS
- Clinical signs more common in young hosts; adults usually asymptomatic.
- Signs can be acute, transient, intermittent, or chronic.
- Malabsorption syndrome with soft, frothy, greasy, voluminous feces (diarrhea), usually with rancid odor.

CAUSES & RISK FACTORS
- Transmitted by ingestion of cysts from feces in/on food, water, environment, or fur.
- Indirect water-borne transmission most common; cool, moist conditions favor cyst survival.
- Higher risk of infection in puppies and kittens, in high-density populations, and in animals with compromised immunity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Infectious and noninfectious causes of small bowel diarrhea, maldigestion, and malabsorption syndromes, especially pancreatic exocrine insufficiency or inflammatory bowel disease.
- In cats, differentiate from infection with *Tritrichomonas foetus*.

CBC/BIOCHEMISTRY/URINALYSIS
Generally within normal limits.

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

DIAGNOSTIC PROCEDURES
- Detection of *Giardia* trophozoites, cysts, or antigen in feces.
- Trophozoites (15 × 8 µm) detectable in fresh feces (especially diarrheic feces) and in duodenal aspirates obtained by endoscopy; trophozoites identified on Diff-Quik® or Lugol's iodine-stained fecal smear by teardrop shape with two prominent nuclei. Trophozoites identified in wet mount diluted in saline by "falling leaf" motility; flotation media may lyse trophozoites, interfering with accurate identification.
- Cysts, ~12 µm long, oval with 2–4 nuclei, shed intermittently; centrifugal flotation of fresh feces in zinc sulfate (specific gravity 1.18) preferred method for identification of cysts. Three samples collected at 2–3-day intervals should be examined to detect >70% of infections; cysts become distorted (crescent-shaped) in sugar or other flotation solution with specific gravity >1.25; formalin–ethyl acetate sedimentation is useful in cases of steatorrhea.
- ELISA-based kits available for in-house detection of *Giardia* antigen in feces have high sensitivity; kits should be used to confirm suspicious cases rather than for screening healthy animals; if clinical signs resolve, continued antigen testing not recommended.
- PCR testing—commercial laboratories; studies have shown variable (usually poorer) sensitivity compared to other methods.

TREATMENT
- Outpatient, unless debilitated or dehydrated.
- Drug therapy should be combined with environmental cleaning and disinfection plus bathing of patient.
- *Giardia* vaccines commercially available; efficacy is poor and vaccine not widely used.

MEDICATIONS

DRUG(S) OF CHOICE
- All extra-label.
- Fenbendazole—50 mg/kg PO q24h for 3 days (dogs) or 5 days (cats); second course of treatment may be necessary.
- Metronidazole—20–22 mg/kg PO q12h for 5–8 days in dogs.
- Metronidazole benzoate—22–25 mg/kg PO q12h for 5–7 days in cats.
- Fenbendazole (50 mg/kg PO q24h) plus metronidazole (25 mg/kg PO q12h) for 5 days—may provide better resolution and reduction in cyst shedding.
- Combination febantel, pyrantel pamoate, and praziquantel product—use for 3 days at label dose for *Giardia*.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Metronidazole—efficacy reportedly 50–67% in dogs; bitter taste; can cause anorexia, vomiting, vestibular signs.
- Albendazole (25 mg/kg PO q12h for 2 days in dogs or 5 days in cats) is effective but not recommended because it can be teratogenic and cause anorexia, depression, vomiting, ataxia, diarrhea, abortion, and myelosuppression.

FOLLOW-UP
- Repeat fecal examinations to confirm efficacy of treatment and detect reinfection.
- Chronic infection can lead to debilitation.

MISCELLANEOUS

ZOONOTIC POTENTIAL
- In North America, *Giardia* is the most common intestinal parasite in humans. Dog and cat isolates are host specific, with little data to demonstrate transmission from pets to humans.
- Most *Giardia* infections in humans are anthroponotic or originate from livestock.
- Zoonotic transmission from pets to immunosuppressed humans may occur.

PREGNANCY/FERTILITY/BREEDING
Do not use albendazole in pregnant animals.

GINGIVAL ENLARGEMENT/HYPERPLASIA

BASICS

OVERVIEW
- Enlargement of gingival tissue due to proliferation of its elements (abnormal multiplication or increase in the normal number of cells in normal arrangement).
- Probable familial tendency—boxers.

SIGNALMENT
- Dogs and rarely cats.
- Breed predilections—boxers, Great Danes, collies, Doberman pinschers, Dalmatians.

SIGNS
- Thickening and increase in height of attached gingiva and gingival margin—sometimes completely covers tooth surface.
- Resultant formation of "pseudopockets"—increase in pocket depth due to increased gingival height; not due to loss of attachment, unless untreated and progresses to concurrent periodontal disease.
- Gingival margin may be thickened in a labial to lingual direction, especially at incisors.
- Locally affected areas possible (shelties), but typically more generalized pattern found.
- Focally affected areas, other than the marginal gingiva, may develop hyperplastic areas due to chronic irritation, such as the "gum chewer's lesion." These areas should be evaluated for therapeutic need (excision).
- May form as protuberant masses (grape cluster) at gingival margins—biopsy necessary to rule out neoplasia.

CAUSES
Chronic inflammatory response to presence of bacteria in plaque associated with periodontal disease.

RISK FACTORS
- Breed predilection (see Signalment).
- Chronic drug administration—diphenylhydantoin, cyclosporine, nitrendipine, nifedipine, amlodipine.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Presumptive diagnosis based on clinical appearance, especially if generalized and found in breed with high predilection.
- Oral neoplasia—e.g., peripheral odontogenic fibromas; usually not generalized; sometimes osseous changes present.
- Oral papillomatosis—papilloma usually on mucosal surfaces.
- Operculum—seen in young animals during eruption phase of teeth; incomplete loss and/or persistence of gingival tissue covering erupting tooth.
- Chronic sublingual or buccal trauma with proliferation—"gum chewer's lesion."

IMAGING
Intraoral radiography—to rule out any underlying osseous changes (more common with epulides or tumors).

DIAGNOSTIC PROCEDURES
- Biopsy—focal area or areas that do not respond to standard therapy.
- Histopathology—to rule out neoplasia and other causes; histologic evaluation is only way to confirm.

TREATMENT

Appropriate Health Care
Regular dental cleanings and homecare—to minimize effects of plaque and bacterial accumulation.

Client Education
- Chronic, recurring problem that often needs repeated therapy.
- Encourage the highest level of home care and regular professional cleaning.

Surgical Considerations
Gingivectomy (Excising Excess Tissue) and Gingivoplasty (Recontouring)
- To remove excess gingival tissue and return pocket depths to normal.
- Provide appropriate patient monitoring and support during anesthetic procedures.
- Regional and local anesthetic injections or topical gels.
- Periodontal probe—to determine depth of pseudopocket; can mark pocket depth on outside of pocket with end of probe to mark with a bleeding "dot."
- Excise excess tissue and reshape gingival margin.
- Cold steel—sharp, stout scissors (crown and collar scissors) or scalpel blade.
- Connect dots made by probe with blade to approximate normal gingival margin or use scissors, following pocket depth to remove bulk tissue.
- Twelve-fluted bur on high-speed handpiece—contour margin to feather angle; assists in hemostasis.
- Electrocautery or radiosurgery—use fully or partially rectified current; avoid damage to underlying bone or tissue.
- Laser—use appropriately and avoid damage to tooth and bone.
- Excessive thickness (incisor and canine region)—modified Widman technique; envelope flap to lift gingiva off tooth surfaces; excise tissue wedge to remove gingiva at inside of pocket to provide narrower width of attached gingiva; suture interdentally to secure gingiva; use digital pressure to reposition.
- Tincture of myrrh and benzoin—use dropper; coat cut margins and dry; 4–5 layers.
- Hemostatic solutions—to aid in hemorrhage control as needed.

MEDICATIONS

DRUG(S) OF CHOICE
- Oral antimicrobials—chlorhexidine; zinc ascorbate gel.
- Postoperative pain management.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Patients on chronic administration of amlodipine, diphenylhydantoin or cyclosporine may be predisposed to hyperplastic changes. Dose reduction may decrease extent of gingival enlargement.

FOLLOW-UP

PATIENT MONITORING
- Postoperative comfort—give pain medication as needed.
- Regular examinations and professional cleaning and treatment—to avoid recurrence, which is common.

PREVENTION/AVOIDANCE
Regular professional cleaning, meticulous home care.

POSSIBLE COMPLICATIONS
- Possible exacerbation of periodontal disease in pseudopockets if left untreated; deeper pockets are more susceptible to anaerobic bacterial infections.
- Excessive heat with electrosurgical treatment may result in damaged teeth (pulpitis, pulpal death) and alveolar bone.

EXPECTED COURSE AND PROGNOSIS
- Good prognosis with regular care.
- Recurrence common.

GLAUCOMA

BASICS

DEFINITION
• A group of diseases where elevated intraocular pressure (IOP) causes optic nerve and retinal degeneration with subsequent loss of vision.
• Diagnosis—IOP >20 mmHg (dogs) or >25 mmHg (cats) as determined by tonometry, with changes in vision or the appearance of the globe, optic nerve, and/or retina.

PATHOPHYSIOLOGY
• Multifactorial disease where obstruction of aqueous humor outflow leads to increased IOP and optic nerve degeneration.
• Elevated IOP induces mechanical changes (stretching of sclera in lamina cribosa damages optic nerve axons) and vascular changes (decreased ocular perfusion causes ischemic damage to retina), resulting in ganglion cell death and optic nerve atrophy.

SYSTEMS AFFECTED
• Ophthalmic.
• Nervous.

GENETICS
• Primary angle-closure glaucoma (PACG; dogs)—complex trait with multiple genetic risk factors and uncertain mode of inheritance.
• Primary open-angle glaucoma (POAG; dogs)—monogenic (*ADAMTS10*) and autosomal recessive.
• Primary congenital glaucoma (PCG; cats)—monogenic (*LTBP2*) and autosomal recessive.

INCIDENCE/PREVALENCE
• Dogs—prevalence depends on breed; primary and secondary glaucoma are each listed as approximately 0.8% of all hospital admissions in the North American Veterinary Medical Database (NAVMDB).
• Cats—relatively uncommon; less than 0.3% of diagnoses in NAVMDB.

SIGNALMENT

Species
• Dog—primary and secondary common.
• Cat—primary rare; secondary more common (due to intraocular neoplasia or chronic uveitis).

Breed Predilections
• PACG—Alaskan Malamute, American cocker spaniel, Australian cattle dog, basset hound, Boston terrier, bouvier des Flandres, bullmastiff, Chinese Shar-Pei, chow chow, Dalmatian, Dandie Dinmont terrier, English cocker spaniel, English springer spaniel, flat-coated retriever, golden retriever, Great Dane, Labrador retriever, Newfoundland, poodle, Samoyed, Shiba Inu, shih tzu, Siberian husky, Welsh springer spaniel.
• POAG—beagle, Norwegian elkhound, petit basset griffon Vendéen.
• PCG—Siamese cats.
• Other forms of primary glaucoma—Burmese, Persian, Siamese cats.

Mean Age and Range
• Primary (dogs)—any age; predominantly affects middle-aged (4–9 years).
• Secondary (cats)—usually affects older cats (>6 years).

Predominant Sex
Females suffer PACG compared to males at a ratio of 2 : 1.

SIGNS

General Comments
All well-equipped small animal hospitals should have a tonometer.

Historical Findings
• Dogs—owners may note pain (blepharospasm, tenderness about the head), serous to seromucoid ocular discharge, red or cloudy eye, dilated pupil, or altered vision; in chronic cases, globe enlargement may be apparent.
• Cats—signs are more subtle; eye may not appear painful, red, or cloudy; owners may note dilated pupil, vision changes, or enlarged globe.

Physical Examination Findings
Acute Primary
• High IOP (often >30 mmHg).
• Blepharospasm.
• Enophthalmos with elevated third eyelid.
• Episcleral injection.
• Diffuse corneal edema.
• Mydriasis.
• Vision loss—may be detected by lack of menace response, dazzle reflex, and/or direct or consensual pupillary light reflex.
• Optic nerve may be normal or swollen and hyperemic.

Chronic (End Stage)
• High or normal IOP.
• Buphthalmos.
• Descemet's streaks (Haab's striae).
• Subluxated lens with an aphakic crescent.
• Optic nerve head atrophy will appear dark and cupped.
• Retinal atrophy detected by peripapillary or generalized tapetal hyper-reflectivity.

Secondary
• High IOP.
• Episcleral injection.
• Corneal edema.
• Aqueous flare.
• Iris changes (miosis or mydriasis, posterior synechia, iris bombé).
• Hyphema.
• Anterior lens luxation.
• Intumescent cataracts.
• Intraocular mass.

CAUSES
• Congenital—severe dysgenesis/lack of formation of the iridocorneal angle.
• Primary—developmental iridocorneal angle anomalies that impede aqueous humor outflow.
• Secondary—obstruction of aqueous humor outflow by various mechanisms, e.g., uveitis (inflammatory cells or debris), anterior lens luxation (lens or attached vitreous), red blood cells, or neoplastic cells.

RISK FACTORS
• Age.
• Breed.
• Chronic uveitis.
• Goniodysgenesis—developmental defect of iridocorneal angle.
• Lens luxation.
• Hypermature or intumescent cataracts.
• Hyphema.
• Intraocular neoplasia.
• Topically applied mydriatics—may precipitate acute glaucoma in predisposed animals.
• Primary glaucoma is bilateral and often asymmetric; the unaffected fellow eye is at risk for developing glaucoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• See Red Eye.
• Conjunctivitis—normal IOP and pupil size with conjunctival hyperemia (diffuse, red discoloration) instead of episcleral vessel engorgement.
• Uveitis—initially low IOP with miotic pupil.

IMAGING
Ocular ultrasound—facilitates evaluation of eye with opaque ocular media; may identify cause of secondary glaucoma (lens luxation, intraocular tumor).

DIAGNOSTIC PROCEDURES
• Rebound or applanation tonometry—essential for diagnosis of glaucoma.
• Gonioscopy—referral procedure that allows for evaluation of iridocorneal angle and assists with diagnosis of primary vs. secondary glaucoma.
• Systemic workup may be indicated in cases of secondary glaucoma due to chronic uveitis, hyphema, or intraocular neoplasia.

PATHOLOGIC FINDINGS
• Histopathologic evaluation is required for all eyes enucleated due to intractable glaucoma.
• Iridocorneal angle morphology assists diagnosis of primary vs. secondary glaucoma.
• Loss of retinal ganglion cells.
• Gliosis and "cupping" of optic nerve head.

(CONTINUED) GLAUCOMA

TREATMENT

APPROPRIATE HEALTH CARE

- Acute—outpatient medical management vs. referral.
- Chronic—outpatient medical management vs. salvage surgical management.

CLIENT EDUCATION

- Warn client that primary glaucoma is a bilateral disease; more than 50% of dogs develop glaucoma in the other eye within 8 months without prophylactic therapy.
- Warn client that up to 50% of dogs will be blind in the affected eye within the first year regardless of therapy.

SURGICAL CONSIDERATIONS

- Acute, visual eyes (dogs)—referral surgical procedures aim to control IOP by decreasing aqueous humor production (transscleral or endoscopic cyclophotocoagulation), increasing outflow (gonioimplants), or both; medical treatment is still required long term to control IOP and inflammation.
- Blind, painful eyes (dogs and cats)—salvage procedures include enucleation, evisceration with intrascleral prosthesis (if no intraocular infection or neoplasia), and intravitreal gentamicin or cidofovir injection to minimize long-term medical therapy.

MEDICATIONS

DRUG(S) OF CHOICE

Use multiple agents to lower IOP into the normal range as quickly as possible in an attempt to salvage vision and maintain comfort. Topical hypotensive drugs have largely replaced systemic therapy due to higher efficacy and fewer side effects.

Acute Primary (Dogs)

- Prostaglandin analog—latanoprost 0.005% q12h. In emergency, apply one drop to affected eye, followed by another drop in 30 min. Recheck IOP in 1–2 hours.
- Carbonic anhydrase inhibitor—dorzolamide 2% q8h. Use in combination with latanoprost for long-term therapy.
- Topical corticosteroids—0.1% dexamethasone or 1% prednisolone acetate q12h. Use to control intraocular inflammation from initial hypertensive episode.
- ± Topical beta blocker—timolol maleate 0.5% q12h. Minimal effect on lowering IOP in companion animals. Use as auxiliary or prophylactic medication.
- ± Hyperosmotic agent—mannitol 1–2 g/kg IV over 20 min. In emergency, use to dehydrate vitreous humor and lower IOP if topical medications ineffective.

Secondary (Dogs and Cats)

- Identify and treat primary disease.
- Topical corticosteroids—to reduce inflammation if no ulcerative keratitis.
- Topical carbonic anhydrase inhibitors.
- ± Topical beta blockers.

CONTRAINDICATIONS

- Topical atropine—do not use with glaucoma.
- Prostaglandin analogs/miotic agents—do not use with primary anterior lens luxation or uveitis; mostly ineffective in cats.

PRECAUTIONS

- Systemic absorption of topical beta blockers may cause bronchoconstriction and bradycardia in small dogs and cats.
- Hyperosmotic agents may initiate acute pulmonary edema in patients with cardiovascular disease or hypervolemia.

POSSIBLE INTERACTIONS

Concurrent administration of latanoprost with a topical nonsteroidal anti-inflammatory drug such as flurbiprofen 0.03% may decrease its hypotensive effect.

ALTERNATIVE DRUG(S)

- Prostaglandin analogs—travoprost 0.004% q12h, bimatoprost 0.03% q12h.
- Carbonic anhydrase inhibitor—brinzolamide 1% q8h.
- Beta blockers—levobunalol 0.5% q12h, betaxolol 0.5% q12h.
- Osmotic agents—hypertonic hydroxyethyl starch 6–7.5% (4 mL/kg IV over 15–20 min).

FOLLOW-UP

PATIENT MONITORING

- IOP—monitored often (weekly to monthly) after starting initial therapy, then q3-4 months long term. Client's daily observation of comfort and vision is most important.
- Monitor for drug reactions.

PREVENTION/AVOIDANCE

- Primary—bilateral disease; recommend that a veterinary ophthalmologist examine the unaffected eye to determine its risk of developing glaucoma.
- Prophylactic therapy for the predisposed, unaffected eye delays onset of glaucoma—0.25% demecarium bromide (miotic) q12h, or 0.5% timolol maleate q12h, or 2% dorzolamide q8–12h.

POSSIBLE COMPLICATIONS

- Blindness.
- Chronic ocular pain.

EXPECTED COURSE AND PROGNOSIS

- Chronic disease that requires constant medical treatment (even with surgical intervention).
- With medical treatment only—most patients ultimately become blind.
- Referral surgical treatment—better chance of retaining vision longer; most patients do not remain visual for more than 2 years after initial diagnosis.
- Secondary to lens luxation—may carry fair prognosis with referral for successful removal of luxated lens and postoperative medical therapy.
- Secondary to anterior uveitis—may carry fair prognosis with control of uveitis.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

- All listed drugs may affect pregnancy.
- Primary and lens luxation cases—inherited; do not breed affected animals.

SEE ALSO

- Anterior Uveitis—Cats.
- Anterior Uveitis—Dogs.
- Lens Luxation.
- Red Eye.

ABBREVIATIONS

- IOP = intraocular pressure.
- PACG = Primary angle-closure glaucoma.
- POAG = Primary open-angle glaucoma.
- PCG = Primary congenital glaucoma.
- NAVMDB = North American Veterinary Medical Database.

GLOMERULONEPHRITIS

BASICS

DEFINITION
Glomerulonephritis (GN) is a term often used to describe proteinuria of glomerular origin; however, GN is immune-mediated inflammation within the glomerulus (immune complex glomerulonephritis [ICGN]). Because this can only be diagnosed from a renal biopsy, many noninflammatory conditions (glomerulosclerosis, amyloidosis, etc.) may be incorrectly labeled GN in patients who have not undergone evaluation via renal histology.

PATHOPHYSIOLOGY
- Circulating antigen–antibody complexes become entrapped or antibodies can attach in situ to glomerular antigens or soluble antigens entrapped within the glomerular basement membrane; complement component C3 and/or immunoglobulins (Ig) G, M, or A may be involved in complexes, which alter glomerular permeability and induce inflammation, causing proteinuria, nephron injury, fibrosis, and progressive loss of renal function.
- ICGN has several different morphologies depending on the location of immune-complex deposition as well as the glomerular response to injury; membranoproliferative, membranous nephropathy, proliferative, IgA nephropathy, and minimal change disease are recognized ICGN in small animals.
- Inflammation and altered glomerular permeability result in proteinuria; subsequent oxidative damage and tubular obstruction cause renal injury, progressive nephron loss, and decreased glomerular filtration; azotemia and uremia may ensue.
- Hypercoagulability, hypoalbuminemia, and hypertension (HTN) are common complications.

SYSTEMS AFFECTED
- Renal/urologic—proteinuria is the initial symptom; both acute kidney injury (AKI) and chronic kidney disease (CKD) may occur secondarily.
- Cardiovascular—HTN is common; ascites and edema occur in nephrotic syndrome (NS); hypercoagulability and thromboembolism (TE).
- Endocrine/metabolic—hypercholesterolemia in NS.

GENETICS
Many breeds have inheritable glomerular disease leading to protein-losing nephropathy (PLN). Most are non-ICGN; however, several breeds are more frequently affected by GN (see below).

INCIDENCE/PREVALENCE
Glomerular disease is present in most patients with kidney disease; however, not all are ICGN. Approximately 50% of dogs and cats that have undergone renal biopsy have ICGN. GN may be clinically silent and undiagnosed in many patients.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
- Species—dog and cat.
- Breed predilections—American foxhound, Bernese mountain dog, Doberman pinscher, German shepherd, golden retriever, greyhound, Labrador retriever, Shetland sheepdog, and soft-coated wheaten terrier.
- Mean age and range—middle age (4–8 years), although may occur at any time; cats often younger—mean 4 years.
- Predominant sex—dogs: none; cats: majority are male.

SIGNS
- Proteinuria caused by albuminuria is hallmark.
- Historical findings—nonspecific and include weight loss, muscle wasting, decreased appetite, lethargy, vomiting, and polyuria/polydipsia.
- Physical examination findings—may be normal; subcutaneous edema, peritoneal and/or pleural effusion seen in NS; acute dyspnea and hypoxia may be present in pulmonary TE.

CAUSES
- Most patients have ICGN secondary to systemic infection or inflammation; many patients will not have an obvious trigger identified. * Infectious causes include rickettsial infection (*Borrelia*, *Ehrlichia*, *Anaplasma*, Rocky Mountain spotted fever), babesiosis, bartonellosis, leishmaniasis, brucellosis, dirofilariasis, leptospirosis, systemic fungal infections, and hepatozoonosis.
- Inflammatory conditions include pancreatitis, polyarthritis, pyometra, and systemic lupus erythematosus; reactions to sulfonamides and vaccines is possible; paraneoplastic GN is uncommon.

RISK FACTORS
Lyme-associated GN is a severe and progressive form of ICGN found in dogs with positive *Borrelia* serology, but causation unknown. Labrador retrievers, golden retrievers, and several other breeds are more at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Proteinuria—commonly occurs for reasons other than GN (see Proteinuria).
- Hypoalbuminemia—may result from decreased hepatic synthesis or protein-losing enteropathy.
- Azotemia—can also be due to AKI or CKD, which may not be caused by ICGN.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC may reveal thrombocytopenia, uncommonly leukocytosis; usually unremarkable.
- Hypoalbuminemia with normal or increased serum globulins; hypercholesterolemia seen in NS; azotemia may be present.
- Persistent proteinuria; some patients may be azotemic with preservation of urine concentration.

OTHER LABORATORY TESTS
- Urine protein : creatinine ratio (UPC) is gold standard test for diagnosing, quantifying, and monitoring proteinuria.
- Testing for underlying systemic infectious/inflammatory causes should be performed as indicated.
- Urine electrophoresis can be performed to fraction proteins by molecular weight to discriminate glomerular and tubular causes of proteinuria.
- Blood pressure measurement should be performed.

IMAGING
Thoracic radiographs and abdominal ultrasound to evaluate for systemic disease.

DIAGNOSTIC PROCEDURES
- Renal biopsy is the only way to diagnose GN and determine the subtype; it characterizes fibrosis and chronicity, which may help predict recovery of renal function following treatment; percutaneous ultrasound-guided needle biopsy is commonly performed; small patients or those with congenital disease may benefit from a surgical wedge/punch biopsy; biopsy contraindications include uncontrolled hypertension, severe thrombocytopenia, and anticoagulant therapy.
- Histology using multiple stains, immunofluorescence, and electron microscopy is required for definitive diagnosis of ICGN; biopsies should be submitted to a veterinary nephropathologist.
- Some patients are too unstable to have renal biopsy performed (thrombocytopenic, rapidly progressing azotemia, etc.); empiric immunosuppression should be given when ICGN is suspected in the absence of biopsy.

PATHOLOGIC FINDINGS
- Definitive diagnosis of ICGN depends on ultrastructural findings of electron-dense immune within glomeruli; positive immunofluorescence.
- Secondary changes to glomerular basement membrane, hypercellularity, and sclerosis.

TREATMENT

APPROPRIATE HEALTH CARE
- Many require inpatient therapy to correct hypovolemia, nausea, and anorexia; once

stabilized, patients can be managed as outpatient.
• Patients with AKI may require dialysis to treat severe uremia.
• Therapeutic plasma exchange may be considered.

NURSING CARE
IV crystalloids should be used judiciously. Hypervolemia is a common complication of aggressive fluid therapy.

ACTIVITY
No specific need for activity restriction; patients often have limited endurance.

DIET
• Ideal diets are protein and sodium restricted; prescription "renal" diets are most appropriate; home-prepared diets may be used after consultation with a nutritionist.
• Feeding tubes allow for delivery of supplemental nutrition and medication.

CLIENT EDUCATION
• Prognosis is guarded for azotemic patients; however, complete recovery may occur.
• Dialysis and plasma exchange may allow for more rapid control of disease and promote renal recovery.

SURGICAL CONSIDERATIONS
• Avoid hypotension and renal hypoperfusion.
• Discontinue anticoagulant 1 week before biopsy.

MEDICATIONS

DRUG(S) OF CHOICE
• ICGN requires immunosuppression; mycophenolate (5–10 mg/kg q12h) is most commonly used; GI upset is most frequently observed side effect; peripheral edema is rare; short course of corticosteroids (prednisone 2 mg/kg/day) can be used as mycophenolate may require 2 weeks to take effect.
• Cyclophosphamide (50 mg/m^2 4 days/week); sterile hemorrhagic cystitis and bone marrow suppression are side effects.
• Anti-proteinuric therapy includes angiotensin-converting enzyme (ACE) inhibitors (enalapril/benazepril 0.5–1 mg/kg q12h) or angiotensin receptor blockers (ARB; telmisartan 1–3 mg/kg q24h); these have modest antihypertensive effects; begin at low doses and increase if response is inadequate; cautious use in severely azotemic patients.
• HTN treated with amlodipine (0.25–0.8 mg/kg q24h) or telmisartan (1–3 mg/kg q24h).
• Systemic anticoagulation to prevent TE—clopidogrel (1–4 mg/kg q24h) or aspirin (2–5 mg/kg q24h); newer direct factor X inhibitors may also be considered.

CONTRAINDICATIONS
• ACE inhibitors and ARBs should not be used if patient is dehydrated or hypovolemic.
• Anticoagulation should be avoided in thrombocytopenic patients until platelet count is normal.

PRECAUTIONS
• ACE inhibitors and ARBs should be used cautiously in patients with serum creatinine >3.5, as they may exacerbate uremia; 30% increase in serum creatinine is generally tolerated, if uremic symptoms do not occur; hyperkalemia may occur at higher doses.
• Hypoalbuminemic patients poorly tolerate parenteral fluids; enteral hydration via feeding tube may be better tolerated.
• Immunosuppression increases risk of opportunistic infections.

POSSIBLE INTERACTIONS
Dual therapy of ACE inhibitor and ARB increases risk of hyperkalemia.

ALTERNATIVE DRUG(S)
• Corticosteroids not used for long-term management, but may be considered if other therapies cannot be afforded.
• Patients who fail initial immunosuppressive therapy may benefit from alternative immunosuppression.

FOLLOW-UP

PATIENT MONITORING
• Renal values, electrolytes, blood pressure, and urinalysis with UPC should be checked 1–2 weeks after starting therapy; reduction in proteinuria may take 4–6 weeks; subsequent rechecks should occur every 1–4 months.
• Complete remission is obtaining UPC <0.5; partial remission is >50% reduction and therapeutic failure is <50% reduction in UPC.
• Normalization of serum creatinine expected with complete response to therapy; many patients will have partial remission with improved but not normal serum creatinine.
• Goal to obtain serum albumin >2.0 mg/dL.
• Repeat renal biopsy can document resolution of immune complexes and guide duration of immunosuppression.

PREVENTION/AVOIDANCE
Avoiding exposure to fleas and ticks may reduce risk of vector-borne infections causing ICGN; preventative therapies should be used.

POSSIBLE COMPLICATIONS
• AKI or CKD.
• HTN.
• NS.
• TE.

EXPECTED COURSE AND PROGNOSIS
Guarded prognosis. Short survival has been reported for azotemic proteinuric dogs. Disease may progress despite therapy. Complete resolution of disease may occur with immunosuppression.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• HTN.
• Hypoalbuminemia.
• Hypercoagulability.

AGE-RELATED FACTORS
None

ZOONOTIC POTENTIAL

GLUCAGONOMA

BASICS

OVERVIEW

• Glucagonoma is an uncommon pancreatic islet cell tumor originating from alpha cells, which secrete glucagon. They occasionally arise in extra-pancreatic locations (i.e., liver). Glucagonomas may secrete other hormones, such as gastrin, pancreatic polypeptide, and (rarely) insulin.
• Excess circulating glucagon activates glycogenolysis and gluconeogenesis and inhibits glycogenesis. This increases protein catabolism and lipolysis. Glucagon excess can inhibit erythropoiesis. The culmination of these biochemical changes results in hyperglycemia and occasionally diabetes mellitus (DM), hypoaminoacidemia, anemia, and weight loss. Glucagon can exert a secretory effect on the small intestine, leading to diarrhea.
• Glucagonomas may cause an overall decrease in plasma amino acid concentrations, with epidermal protein depletion in the skin, leading to the classic dermatopathy associated with glucagonoma (necrolytic migratory erythema [NME]).
• Glucagonomas can affect numerous organ systems, including musculoskeletal, integumentary, endocrine, gastrointestinal, nervous/behavioral, and hepatobiliary.

SIGNALMENT

• Dog—rare; older animals.
• Cat—rare.

SIGNS

• The hallmark sign is NME, although this may be caused by glucagonoma or hepatocutaneous syndrome. NME has also been described in veterinary medicine as metabolic epidermal necrosis and superficial necrolytic dermatitis.
• Skin lesions include erythema, erosions, and crusting, generally located around mucocutaneous junctions (perineum, face, and genitalia), distal extremities, and footpads. Lesions are often pruritic with hyperkeratotic and painful footpads. In many cases, footpads are the only affected area.
• Other systemic signs include lethargy, polyuria, polydipsia, diarrhea, secondary pyoderma or yeast infection, anorexia, and weight loss.

CAUSES & RISK FACTORS

Component of the multiple endocrine neoplasia syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other diseases that produce skin lesions consistent with NME are nonspecific liver disease, hypoaminoacidemia, DM, and pancreatic tumors.
• Other similar dermatopathies include pemphigus foliaceus, systemic lupus erythematosus, vasculitis, food dermatoses, vitamin A responsive dermatosis, and zinc deficiency dermatopathy.
• Mild–moderate hyperglucagonemia can result from nonglucagonoma diseases such as liver disease, pancreatic disease, chronic kidney disease, starvation, bacteremia, diabetic ketoacidosis, and hyperadrenocorticism.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—may be normal or show a normocytic, normochromic anemia or mature neutrophilia.
• Biochemistry—may be normal or show mild elevations in liver enzyme activity or total bilirubin concentration, with mild hyperglycemia and hypoalbuminemia.
• Liver function tests (e.g., bile acid concentrations) are generally normal.
• Urinalysis—decreased urine specific gravity, glucosuria with DM.

OTHER LABORATORY TESTS

• Plasma glucagon levels are generally extremely elevated (>1,000 pg/mL); however, normal to mild elevation does not rule out glucagonoma.
• Plasma amino acid concentrations are generally severely reduced and are thought to be associated with the development of NME.
• Plasma zinc concentration is generally reduced and also thought to be associated with the development of NME.
• Serum fructosamine may be elevated in patients with DM.

IMAGING

• Ultrasonography—to detect pancreatic glucagonomas, peripancreatic metastases, and hepatic metastases; however, ultrasound was normal in 4/9 dogs with glucagonoma. A honeycomb pattern has been described in the liver of patients with NME.
• CT, MRI, PET scans, selective visceral angiography, and somatostatin receptor scintigraphy (octreoscan and radioiodinated MIBG) are used to detect glucagonoma in humans.

DIAGNOSTIC PROCEDURES

• Increased serum glucagon and clinical signs consistent with NME are indicative of glucagonoma, but the definitive diagnosis can only be made by biopsy, histopathologic examination, and immunohistochemical documentation of glucagon expression.
• Immunohistochemical assays for other pancreatic and gastrointestinal hormones may also be performed.

PATHOLOGIC FINDINGS

• Skin biopsies taken from glucagon-associated NME lesions typically exhibit severe superficial to mid-epidermal edema, diffuse parakeratotic hyperkeratosis, and irregular epidermal hyperplasia.
• Biopsies taken from the primary glucagonoma (and/or metastases) typically exhibit pleomorphic islet cells with fine cytoplasmic granules and occasional mitoses with immunohistochemical glucagon (and often other secretory hormone) expression.

TREATMENT

• Surgical excision of nonmetastatic primary pancreatic glucagonoma is the best chance for cure. There is a high rate of postoperative morbidity and mortality in dogs, often secondary to pancreatitis. Glucagonoma syndrome reported in people is associated with thromboembolic disease.
• Combined debulking (primary tumor and/or metastases) and octreotide therapy can temporarily resolve skin lesions and provide relief of clinical signs.
• If surgery and/or octreotide therapy are not possible, symptomatic palliative therapies may be beneficial and include high-protein diet with egg whites (approximately two to four egg whites/day for a 25 kg dog), zinc supplementation (beneficial even in the face of normal serum zinc concentration), and fatty acid supplementation.
• IV amino acid therapy may be beneficial in patients with NME.
• Secondary bacterial and/or yeast skin infections are common and should be appropriately treated.
• Concurrent DM should be treated.

MEDICATIONS

DRUG(S) OF CHOICE

• Octreotide—somatostatin analogue that inhibits conversion of preproglucagon to glucagon; may be beneficial in patients with unresectable or metastatic glucagonoma. Side effects reported in humans include injection site pain, vomiting, diarrhea, and cholestasis. A safe and effective dosage has not been reported in dogs; however, 10–20 µg/dog SC q8–12h has been used, and a one-time dose of 50 µg/dog SC is reported to be safe in healthy dogs. Octreotide can be difficult to obtain.
• Chemotherapeutics in humans with glucagonoma include doxorubicin and streptozotocin, although efficacy may be limited. The use of streptozotocin as an islet-cell lytic agent has been reported in a small number of dogs with insulinoma, but not in dogs with glucagonoma.

- Glucocorticoids may improve the pruritis of NME skin lesions, but are not recommended for use in glucagonomas as they are likely to exacerbate hyperglycemia associated with secondary DM.
- IV amino acids (500 mL of essential amino acids added to saline or lactated Ringer's solution over 12h, or 10% amino acid solution 24 mL/kg over 8–12h) have resulted in variable improvement in NME skin lesions in dogs. Treatments may be repeated every 1–2 weeks if effective until clinical signs abate or resolve.
- Sulfur/salicylic acid–based shampoos or very mild shampoos may help remove crusts, soften skin, and improve pain and pruritus associated with footpad or skin lesions.
- Oral zinc sulfate (10 mg/kg/day PO), zinc methionine (2 mg/kg/day PO), or zinc gluconate (3 mg/kg/day PO) may be considered.
- Supplementation with oral fatty acids (80 mg/kg PO) may also be of benefit.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Glucocorticoids may exacerbate hyperglycemia if DM is present.

FOLLOW-UP

PATIENT MONITORING

- Serial blood work should be performed postoperatively to confirm that hyperglucagonemia (and any other abnormalities) is resolving.
- Strong considerations should be given to serial ultrasounds and chest radiographs to monitor for regrowth or metastasis.

POSSIBLE COMPLICATIONS

- Pancreatitis.
- Thromboembolic disease.
- DM.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is considered poor in dogs.
- Transient improvement in skin lesions and clinical signs may be noted in patients treated with octreotride and amino acids.
- One cat had a survival time of 11 months following surgery.

MISCELLANEOUS

SEE ALSO

- Glycogen-Type Vacuolar Hepatopathy.
- Superficial Necrolytic Dermatitis.

GLUCOSURIA

BASICS

DEFINITION
Glucosuria is detected via routine laboratory testing, most commonly with reagent test strips. Persistent glucosuria is an abnormal finding.

PATHOPHYSIOLOGY
• Glucose is a small molecule that is freely filtered through the glomerulus into the ultrafiltrate. • Glucose is actively reabsorbed in the proximal renal tubule by a sodium–glucose co-transport system. Physiologic levels of filtered glucose are mostly reabsorbed, leaving excreted levels too low to detect using screening tests.

Hyperglycemic Glucosuria
• Glucosuria will be present when blood glucose concentration exceeds renal tubular epithelial transport maximum. This varies by species, with dogs typically above 180 mg/dL and cats typically above 280 mg/dL. • If hyperglycemia is present, determine whether glucosuria transient or persistent.

Transient
• Physiologic—usually transient and associated with release of endogenous "stress" hormones (catecholamines, glucagon, corticosteroids); especially common in cats. Serum may be normoglycemic or hyperglycemic at urine collection because different concentrations of glucose excreted in urine over time equilibrate in bladder.
• Pharmacologic—may occur following administration of glucose-containing solutions (e.g., dextrose); administration of drugs (glucocorticoids, growth hormone, thiazide diuretics, morphine, epinephrine) may also result in hyperglycemia and glucosuria. • Toxic—ethylene glycol.
• Pathologic—possible with acute pancreatitis.

Persistent
Pathologic conditions that can result in persistent glucosuria (due to hyperglycemia) include diabetes mellitus, hyperadrenocorticism, acromegaly, extreme stress, hyperthyroidism in cats.

Normoglycemic Glucosuria
Impaired renal proximal tubular epithelial cell reabsorptive capacity.

Congenital
Primary glucosuria—Scottish terriers; Fanconi syndrome: basenji dogs; also sporadic in Norwegian elkhounds, Shetland sheepdogs, miniature schnauzers, Labrador retrievers, border terriers, whippets, Yorkshire terriers, and mixed-breed dogs; decreased reabsorption of glucose, amino acids, and phosphorus plus decreased secretion of hydrogen ions.

Acquired
• Fanconi syndrome due to toxicity such as heavy metal poisoning (e.g., lead, mercury, copper, copper associated hepatitis) or dried chicken treats made in China, drugs (e.g., gentamicin, cephalosporins, outdated tetracycline, cisplatin, streptozotocin), chemicals (Lysol, maleic acid), other miscellaneous causes. • Acute renal failure with significant tubular lesions.

SYSTEMS AFFECTED
• Renal—normoglycemic patients have abnormal renal tubular epithelial cell function; dogs with Fanconi syndrome may develop metabolic acidosis and chronic kidney disease (CKD) with secondary multisystem involvement; glucosuria predisposes to bacterial urinary tract infection. • Endocrine—hyperglycemic patients may have diabetes mellitus and/or hyperadrenocorticism. • Liver—copper associated hepatitis; centrilobular hepatitis with copper accumulation.

SIGNALMENT
• Adult dogs and cats develop persistent hyperglycemic glucosuria due to adult-onset diabetes mellitus. • Dogs with congenital Fanconi syndrome typically develop clinical disease due to defective reabsorption of glucose and amino acids at 4–5 years of age; no sex predilection. • Familial renal tubular disorders have been reported (see Pathophysiology). • Primary renal glucosuria (Scottish terriers) may be recognized at early age as incidental finding. • Copper associated hepatitis with acquired Fanconi syndrome (Labrador retrievers). • Dogs (any breed or age) fed dried chicken treats made in China.

SIGNS
Clinical signs variable depending upon primary cause.

Historical Findings
• Persistent glucosuria results in polyuria (osmotic diuresis), leading to compensatory polydipsia. • Glucosuria predisposes to urinary tract infections; clinical signs associated with upper and/or lower urinary tract infection. • Breed and therapeutic history (see Pathophysiology) are important.

Physical Examination Findings
• Patients with hyperglycemic glucosuria may exhibit systemic signs; see diabetes mellitus chapters. • Patients with normoglycemic glucosuria may have normal body functions.
• Dogs with Fanconi syndrome may develop signs of metabolic acidosis, electrolyte abnormalities, and CKD.

CAUSES

Hyperglycemic Glucosuria Transient
• Physiologic—stress; common in cats.
• Pharmacologic—see Pathophysiology.

Persistent
• Diabetes mellitus; insulin deficiency or resistance. • Hyperadrenocorticism; insulin resistance. • Acute pancreatitis; insulin deficiency or resistance. • Less common causes include pheochromocytoma, acromegaly, hyperglucagonemia, hyperpituitarism, hyperthyroidism, and chronic liver failure (due to failure to metabolize glucagon).

Normoglycemic Glucosuria
Congenital
• Primary renal glucosuria (Scottish terrier).
• Fanconi syndrome. • Congenital diseases may be associated with renal dysfunction (Norwegian elkhound).

Acquired
• Acute kidney injury associated with proximal tubular dysfunction. • Fanconi syndrome. • CKD (rare).

RISK FACTORS
Vary with underlying causes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Persistent hyperglycemic glucosuria in fasted patients is frequently associated with endocrinopathies (diabetes mellitus, hyperadrenocorticism). • Acute pancreatitis.
• Renal tubular reabsorptive dysfunctions cause normoglycemic glucosuria. • Stressed patients exhibit mild transient hyperglycemia and glucosuria.

LABORATORY FINDINGS

Screening Tests
Normally negative (urine glucose concentration below detection).

Glucose Oxidase Tests
• Reagent strips use glucose oxidase method that is specific for glucose; positive values occur with urine glucose concentrations greater than 100 mg/dL. • Methodology is a two-step enzymatic process—glucose oxidase catalyzes glucose and produces gluconic acid and hydrogen peroxide; peroxidase catalyzes reaction of hydrogen with chromagen to produce color change on reagent pad; the test is time dependent, which varies with manufacturer; pigmenturia can complicate color interpretation. • False negatives can be seen with ascorbic acid, exposure to formalin, ketonuria, marked bilirubinuria, highly concentrated urine, and refrigerated urine samples that have not been warmed to room temperature prior to performing the test.
• False positives can be seen with exposure to oxidizing agents such as hydrogen peroxide or chlorine bleach (most commonly with samples obtained from table top or floor).
• Specific for glucose; more sensitive

(CONTINUED) GLUCOSURIA

(~40–100 mg/dL) than copper reduction methods.

$$\text{Glucose} + O_2\,(\text{air}) + H_20 \xrightarrow[\text{oxidase}]{} \text{glucuronic acid} + H_20$$

$$H_20_2 \xrightarrow[\text{peroxidase}]{\text{horseradish}} H_20 + O\,(\text{nascent oxygen})$$

$$O + \text{color indicator} \longrightarrow \text{oxidized color change complex}$$

Copper Reduction Tests

• Not specific for glucose; less sensitive (250 mg/dL) and higher detection limit than glucose oxidase methods; more often used in human medicine, but can be used in veterinary medicine to verify questionable reagent strip result. • Testing method uses copper, which reacts with reducing substance (e.g., glucose, fructose, lactose, etc.) to produce cuprous oxide and cuprous hydroxide, which results in color change. • Results are semiquantitative and reported as negative, approximately 250 mg/dl, approximately 500 mg/dL, approximately 750 mg/dl, approximately 1000 mg/dL, or approximately 2000 mg/dL. • Less affected by pigmenturia; false positives can be seen with cephalosporins, formaldehyde, reactions with other sugars, and high concentrations of ascorbic acid.

$$\underset{\text{(blue)}}{\text{Cupric ions}} + \text{glucose} \xrightarrow{\text{alkali}} \underset{\text{(orange-red)}}{\text{cuprous ions}} + \text{oxidized glucose}$$

Confirmatory Tests

Hexokinase or glucokinase dehydrogenase tests using automated chemistry analyzer may be used to confirm presence or absence of glucose when unexpected results or pigmented urine encountered.

Drugs That May Alter Laboratory Results

See Screening Tests.

Disorders That May Alter Laboratory Results

See Screening Tests.

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

Hyperglycemic Glucosuria

• Hyperglycemia with glucosuria and ketonuria indicates diabetic ketoacidosis; persistent hyperglycemia and glucosuria with appropriate clinical signs support diabetes mellitus. • Dogs with pancreatitis may have leukocytosis, fever, abdominal pain and effusion, elevations in pancreatic specific enzymes, and characteristic ultrasonographic abnormalities. • Dogs with markedly increased serum alkaline phosphatase activity, hyperglycemia, glucosuria (also hypercholesterolemia, hypertriglyceridemia) should be evaluated for hyperadrenocorticism. • Mild glucosuria with transient hyperglycemia is likely physiologic in stressed patients.

OTHER LABORATORY TESTS

• Hyperglycemic glucosuria—conduct appropriate screening test if hyperadrenocorticism suspected. • Normoglycemic glucosuria—measurement of phosphorus, glucose, and amino acid concentrations in timed urine samples may help differentiate Fanconi syndrome and primary renal glucosuria; also evaluation of hepatic function for acquired Fanconi syndrome due to copper associated hepatitis.

IMAGING

Ultrasonography aids in diagnosis of hyperadrenocorticism and pancreatitis.

TREATMENT

• Discontinue any drugs associated with acquired renal tubular transport defects. • Treatment varies with cause; see chapters related to specific causes.

MEDICATIONS

DRUG(S) OF CHOICE

• Hyperglycemic glucosuria—treat diabetes mellitus with insulin. • Normoglycemic glucosuria—no treatment required for tubular transport disorders unless metabolic acidosis, electrolyte abnormalities, or hepatic abnormalities present (e.g., Fanconi syndrome).

CONTRAINDICATIONS

Patients with diabetes mellitus should not be given diabetogenic drugs such as corticosteroids or dextrose-containing fluids.

FOLLOW-UP

PATIENT MONITORING

Variable, depending upon underlying condition.

POSSIBLE COMPLICATIONS

• Persistent glucosuria predisposes to development of bacterial urinary tract infections (cystitis, ascending pyelonephritis). • Osmotic diuresis with obligatory polyuria results in polydipsia, necessitating access to water to prevent dehydration.

MISCELLANEOUS

Growth hormone–secreting pituitary tumors in older cats (especially male) may induce diabetes mellitus (insulin resistant).

ASSOCIATED CONDITIONS

• Urinary tract infections. • CKD. • Diabetic retinopathy or cataracts. • Copper associated hepatitis.

PREGNANCY/FERTILITY/BREEDING

Excess progesterone secretion in intact female dogs may induce diabetes mellitus (insulin resistant).

SEE ALSO

• Congenital and Developmental Renal Diseases.
• Diabetes Mellitus without Complication—Cats.
• Diabetes Mellitus without Complication—Dogs.
• Fanconi Syndrome.
• Hyperadrenocorticism (Cushing's Syndrome)—Cats.
• Hyperadrenocorticism (Cushing's Syndrome)—Dogs.

GLUTEN ENTEROPATHY IN IRISH SETTERS

BASICS

OVERVIEW
A rarely confirmed, inherited, intestinal disease in which sensitivity develops to dietary gluten (present in wheat) and similar proteins present in related grains (i.e., rye and barley). In affected dogs, the enteropathy is characterized by partial villous atrophy, reduced brush border enzyme expression, lymphocytic infiltration of the intestinal mucosa, and goblet cell hyperplasia; changes that are reversed by feeding a gluten-free diet.

SIGNALMENT
- Irish setter breed—the line of affected setters originally described in the UK has been bred out.
- Signs develop in young dogs, but are modulated by the age of first exposure to gluten.
- Genetic transmission of gluten sensitive enteropathy is likely under the control of a single major autosomal recessive locus.
- Gluten enteropathy has been suspected but not proven in other dog breeds and cats.

SIGNS
- Poor weight gain (or weight loss).
- Poor body condition.
- Mild small intestinal diarrhea that can be intermittent.

CAUSES & RISK FACTORS
The enteropathy and clinical signs are triggered by gluten-containing diets. Abnormal mucosal permeability precedes the development of signs, implying there is abnormal entry of gluten across the mucosal barrier. Gluten is then either directly toxic to the intestinal mucosa or induces an immune-mediated reaction. An analogous condition in humans (celiac disease) is characterized by the presence of antibodies cross-reacting to gluten and tissue transglutaminase, but they have not been tested for in affected setters. These antibodies have been demonstrated in Border terriers with gluten-sensitive dyskinesia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Canine chronic enteropathy—food-responsive enteropathy, inflammatory bowel disease.
- Infectious diseases such as *Giardia*, hookworms, and roundworms.
- Metabolic abnormalities.
- Exocrine pancreatic insufficiency.

CBC/BIOCHEMISTRY/URINALYSIS
- Biochemistry can be unremarkable or may show panhypoproteinemia.
- CBC may show eosinophilia.

OTHER LABORATORY TESTS
- Serum folate concentrations are subnormal in some patients, reflecting malabsorption.
- Other tests are recommended to rule out other differentials, such as fecal flotation to rule out enteric parasites and serum trypsin-like immunoreactivity (TLI) to rule out exocrine pancreatic insufficiency.
- Serum TLI and cobalamin concentrations are usually unremarkable.

IMAGING
Only useful to rule out other conditions.

DIAGNOSTIC PROCEDURES
Intestinal biopsy specimens obtained via endoscopy or laparotomy may be helpful, but proof of gluten sensitivity requires histologic resolution in biopsies repeated following a clinically successful gluten-free diet trial.

PATHOLOGIC FINDINGS
- Histologic examination of jejunal biopsy specimens from affected dogs reared on a wheat-containing diet reveals partial villus atrophy and accumulation of intraepithelial lymphocytes.
- Jejunal abnormalities improve following gluten withdrawal, but recur with gluten challenge.

TREATMENT
Treatment is on an outpatient basis. Avoid diets containing gluten (wheat, rye, barley, triticale, brewer's yeast, and wheat starch) for the life of the animal.

MEDICATIONS

DRUG(S) OF CHOICE
Folate (0.5–2 mg PO q24h for 2–4 weeks) if serum folate concentration is markedly subnormal (<4 µg/L).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
Consider periodic assay of serum folate (q6–12 months) if initially decreased.

MISCELLANEOUS

ABBREVIATIONS
- TLI = trypsin-like immunoreactivity

GLYCOGEN STORAGE DISEASE

BASICS

OVERVIEW

• Also known as glycogenosis—rare inherited disorders of defective or deficient enzyme activity governing glycogen metabolism. • Tissue glycogen accumulation—leads to organ enlargement and dysfunction; may affect liver, heart, skeletal muscle, kidney, and CNS. • Impaired hepatic glycogenolysis—leads to symptomatic hypoglycemia (neuroglycopenia). • Classification—based on enzymatic defect and primary organ(s) involvement: more than 12 types in humans, 4 types in dogs (Ia, II, III, and VII), 1 type in cats (IV).

SIGNALMENT

• Clinical signs manifest in juveniles—may be days to months after birth. • Type Ia (von Gierke's disease)—Maltese puppies; autosomal recessive mutation of glucose-6-phosphatase gene (gene symbol: *G6PC*). • Type II (Pompe's disease)—Swedish Lapland, Finnish and Swedish Lapphund dogs; onset by 6 months of age; autosomal recessive, single mutation in acid α-glucosidase (gene symbol: *GAA*). • Type III (Cori's disease)—young female German shepherds, curly-coated retrievers; autosomal recessive mutation in glycogen debranching enzyme (gene symbol: *AGL*). • Type IV (Andersen disease)—Norwegian forest cats; may be stillborn or fade shortly after birth; may manifest signs at 5–7 months with progressive neurologic decline; autosomal recessive mutation in glycogen branching enzyme (complex rearrangement mutation; gene symbol *GBE1*). • Type VII (Tarui disease)—English springer, American cocker, whippets, mixed breeds; PFK (M-PFK) muscle isoform single missense mutation; different missense mutation in wachtelhunds; adult dogs, no sex predilection. • Autosomal recessive inheritance—Maltese, Lapland, Lapphund, English springer spaniels, Norwegian forest cats, other M-PFK affected breeds; also suspected in German shepherds.

SIGNS

• Depend on enzymatic defect. • Type Ia (Maltese puppies)—failure to thrive; mental depression; hypoglycemia; abdominal distention; hepatomegaly; death or euthanasia by 60 days of age. • Type II (Lapland dogs)—vomiting and regurgitation related to megaesophagus; progressive muscle weakness; cardiac changes; death before 2 years of age. • Type III (German shepherds, curly-coated retrievers)—depression; weakness; stunted; abdominal distention from hepatomegaly; mild hypoglycemia, high liver enzymes and creatine kinase. • Type IV (Norwegian forest cats)—perinatal death common; intermittent fever; generalized muscle tremors; muscle atrophy, weakness progressing to tetraplegia; sudden death from myocardial degeneration and terminal dysrhythmia; glucose administration can enable cats to survive to adulthood. • Type VII (English springer spaniels)—compensated hemolytic anemia; episodic weakness, exercise-induced with intravascular hemolysis; hemoglobinuria; one patient with a progressive myopathy at 11 years of age: no liver effect.

CAUSES & RISK FACTORS

Deficiencies

• Type Ia—glucose-6-phosphatase. • Type II—acid-α–glucosidase. • Type III—amylo-1,6-glucosidase. • Type IV—glycogen branching enzyme (α-1,4-d-glucan). • Type VII—phosphofructokinase.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• High index of suspicion for diagnosis. • Breed affiliation—familial history. • Differentiate other causes of juvenile hypoglycemia—malnutrition; endoparasitism; transient fasting hypoglycemia; portosystemic vascular anomaly. • Other causes of muscular weakness—infectious diseases; endocrinopathy; immune-mediated causes; hypokalemia; other neuromyopathies.

CBC/BIOCHEMISTRY/URINALYSIS

• Types I and III—hypoglycemia. • Type I—lactic acidemia, increased: cholesterol, triglycerides, uric acid. • Type VII—anemia; reticulocytosis; pigmenturia, no hepatic effects.

OTHER LABORATORY TESTS

Genetic testing—type I: in Maltese dogs, type II: in Lapland and Lapphund dogs, type III: in curly-coated retrievers, type IV: in Norwegian forest cats, type VII: in breeds listed previously and in vitro erythrocyte testing.

IMAGING

• Type II—thoracic radiography; cardiomegaly and megaesophagus. • Types Ia and III—abdominal radiography; hepatomegaly. • Abdominal ultrasonography—hepatomegaly, hyperechoic parenchyma consistent with hepatic glycogen accumulation. • Types II and IV—echocardiography may reveal cardiac changes.

DIAGNOSTIC PROCEDURES

• Tissue enzyme analysis and glycogen determination. • Electromyography—depends on disorder. • ECG—depends on disorder. • Genetic testing.

PATHOLOGIC FINDINGS

• Type Ia—emaciation; massive hepatomegaly due to hepatocyte glycogen and lipid vacuolation and similar change in renal tubular epithelium. • Type II—glycogen accumulation in skeletal, smooth, and cardiac muscle. • Type III—hepatomegaly due to hepatic glycogen accumulation; also in skeletal muscle. • Type IV—generalized muscle atrophy; glycogen accumulation: skeletal muscle, CNS, and peripheral nervous system. • Type VII—polysaccharide deposits in skeletal muscle.

TREATMENT

Nursing Care

• Supportive care. • Types I and III—may require IV/SC dextrose for management of hypoglycemic crisis; long-term management usually futile. • Gene therapy with adeno-associated virus vector experimentally for type 1a dogs resulted in survival.

Diet

Control hypoglycemia (types I and III) with frequent feedings of a high-carbohydrate diet until diagnosis is confirmed; glucose solutions usually used.

Client Education

• Advise that specimens be submitted for genetic/enzyme characterizations. • Discuss known mechanisms of inheritance to modify breeding programs.

MEDICATIONS

DRUG(S) OF CHOICE

N/A

FOLLOW-UP

• Monitor for hypoglycemia. • Cull parents from breeding programs. • Prognosis—poor; most patients with glycogen storage disorders causing hypoglycemia and hepatomegaly and stunted growth die or are euthanized owing to progressive deterioration.

MISCELLANEOUS

SEE ALSO

• Lysosomal Storage Diseases. • Mucopolysaccharidosis. • Portosystemic Vascular Anomaly, Congenital.

Author Sharon A. Center

Consulting Editor Kate Holan

GLYCOGEN-TYPE VACUOLAR HEPATOPATHY

BASICS

DEFINITION

- Glycogen-type vacuolar hepatopathy (VH)—reversible hepatocellular cytosolic vacuolation.
- Reflects many primary disorders including glucocorticoid treatment, hyperadrenocorticism, atypical adrenal hyperplasia (sex hormone hyperplasia), chronic systemic illnesses (inflammatory, neoplastic), and rarely congenital glycogen storage disorders.
- Typified by high alkaline phosphatase (ALP) activity—usually without hyperbilirubinemia or hepatic insufficiency.
- Similar but remarkably severe VH in hepatocutaneous disease; may reflect chronic phenobarbital administration.
- Glycogen VH may coexist with cytosolic lipid vacuolation—comparatively rare in dogs, but may associate with idiopathic hyperlipidemia, diabetes mellitus, hypothyroidism, and rare inborn errors of glycogen/lipid metabolism.

PATHOPHYSIOLOGY

- Glucocorticoids—induce reversible increase in hepatocyte glycogen within 2–3 days; injectable or reposital drug induces most severe VH compared to PO or topical (ocular, cutaneous, aural) routes.
- Cell expansion—causes hepatomegaly, ballooning degeneration leads to parenchymal collapse; when severe, nodularity grossly mistaken for cirrhosis.
- Variable response to glucocorticoids among dogs relates to drug type; route; dose; treatment duration; individual sensitivity—VH may follow low-dose, short-term oral treatment.
- VH may reflect stress response, cytokines, or acute-phase response initiated by nonhepatic systemic disorders or neoplasia (especially lymphoma), without exogenous glucocorticoid exposure or adrenal disease.
- VH common in dogs with gallbladder mucocele.

SYSTEMS AFFECTED

- Hepatobiliary—normal hepatic function usually; severe degenerative VH can lead to hepatic dysfunction, jaundice, ascites, liver failure.
- All systems affected by steroid hormones or primary systemic disease.

INCIDENCE/PREVALENCE

- Dogs—common, often accompanies primary necroinflammatory liver disorders.
- Cats—rare; liver vacuolation with triglyceride accumulation more common (see Hepatic Lipidosis).

SIGNALMENT

Species

Dog; rarely cat.

Breed Predilections

Breeds predisposed to hyperadrenocorticism develop glycogen VH (e.g., miniature poodles, dachshunds, boxers, Boston terriers), Scottish terriers (sex hormone adrenal hyperplasia, hyperlipidemia), and others with hyperlipidemia (miniature schnauzers, Shetland sheepdogs) may develop mixed glycogen/lipid VH.

Mean Age and Range

- Middle-aged to old dogs—spontaneous hyperadrenocorticism (>75% older than 9 years); chronic systemic inflammation or neoplasia.
- Dogs of any age—iatrogenic VH subsequent to glucocorticoid administration.
- Young dogs or cats—genetic glycogen storage disease.

SIGNS

General Comments

- Reflect glucocorticoids or underlying systemic illness.
- Rarely, signs of hepatic disease or failure; hepatic failure can develop with severe chronic VH.
- Hepatic encephalopathy observed in some dogs with hepatocutaneous syndrome.

Historical Findings

- Glucocorticoid excess—polyuria and polydipsia; polyphagia; endocrine alopecia; abdominal distention: weak muscles, loss of elasticity; skeletal muscle weakness; excessive panting; lethargy; friable skin; bruising tendencies; urinary tract infections, may be asymptomatic; corneal ulcer.
- Adrenal sex hormone hyperplasia—may display some signs of glucocorticoid excess but often fewer and less severe; endocrine alopecia may be only sign; some dogs remain asymptomatic except for chronic progressive marked ALP activity and degenerative VH.
- Other causes—depend on system affected; chronic phenobarbital may cause severe VH.
- Sex hormone hyperplasia causing VH may increase risk for dysplastic hepatic foci and hepatocellular carcinoma (e.g., Scottish terriers).

Physical Examination Findings

- Hepatomegaly.
- Relate to steroid hormone excess or underlying disease; depend on severity and duration.

CAUSES

- Glucocorticoid administration.
- Typical hyperadrenocorticism (spontaneous).
- Atypical adrenal hyperplasia—overproduction of cortisol precursor sex hormones (spontaneous).
- Systemic disease provoking acute-phase response or stress—e.g., severe dental disease, inflammatory bowel disease, chronic pancreatitis, systemic neoplasia (especially lymphoma), chronic infections (urinary tract, skin), hypothyroidism, many others.

RISK FACTORS

- Pharmacologic doses of glucocorticoids.
- Breeds at risk for hyperadrenocorticism.
- Breeds at risk for hyperlipidemia—often also demonstrate combined glycogen VH: miniature schnauzers, Shetland sheepdogs, beagles.
- Dogs receiving chronic phenobarbital.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

- Other diffuse hepatopathies (especially those causing hepatomegaly and increased ALP activity)—passive congestion; neoplasia (primary or metastatic to liver); necroinflammatory liver disease; anticonvulsant hepatopathy; hepatomegaly due to amyloid (rare).
- VH distinguishing features—most dogs have increase in ALP > alanine aminotransferase (ALT) or aspartate aminotransferase (AST); increased cholesterol, normal serum bilirubin; normal/mild increase in total serum bile acids (TSBA); heterogeneous or homogeneous hyperechoic hepatic parenchyma on ultrasonography (nodules or "Swiss cheese" pattern); characteristic cytology: hepatocytes engorged due to expanded "rarified" cytoplasm.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

- Depends on underlying disease.
- Nonregenerative anemia—anemia of chronic disease or hypothyroidism.
- Relative polycythemia—steroid excess.
- Stress leukogram—hyperadrenocorticism; glucocorticoid exposure; stress of illness.
- Thrombocytosis—neoplasia; hyperadrenocorticism; splenic disease.

Biochemistry

- ALP markedly increased; ALP glucocorticoid isoenzyme cannot differentiate cause of VH as other liver disorders also induce this isoenzyme; variable γ-glutamyltransferase (GGT), ALT, AST activity.
- Serum albumin and total bilirubin—usually normal; high bilirubin typically implicates another hepatobiliary or hemolytic process.
- Hypercholesterolemia—hyperadrenocorticism, sex hormone adrenal hyperplasia; breed-related hyperlipidemias; hypothyroidism; pancreatitis; nephrotic syndrome.

(CONTINUED)

GLYCOGEN-TYPE VACUOLAR HEPATOPATHY

OTHER LABORATORY TESTS

- ALP glucocorticoid isoenzyme—see above, lacks specificity and thus clinical utility.
- TSBA—may be modestly increased; ammonia tolerance test: usually normal.
- Pituitary adrenal axis—adrenocorticotropic hormone (ACTH) response test or low-dose ± high-dose dexamethasone suppression test (LDDST ± HDDST) and endogenous ACTH may help differentiate nonadrenal illness, adrenal or pituitary disorders.
- Urine cortisol : creatinine ratio—at-home urine collection helps rule out hyperadrenocorticism; high ratio may reflect stress or nonadrenal illness.
- Adrenal ultrasound imaging—nodules, adrenomegaly; consider dog size and age.
- If VH confirmed (liver biopsy) and underlying cause not evident, patient asymptomatic or symptomatic for adrenal disease—assess cortisol and sex hormone panel with ACTH response test.
- Thyroid testing—rules out hypothyroidism.
- Triglycerides (fasting)—hyperlipidemia.
- Canine pancreatic lipase immunoreactivity (cPLI)—may indicate "subclinical" pancreatic inflammation or inflammatory bowel disease.

IMAGING

- Abdominal radiography—reveals hepatomegaly or other underlying conditions.
- Thoracic radiography—may reveal lymphadenopathy, metastatic disease, cardiac or pulmonary disorders.
- Abdominal ultrasonography—discloses hepatomegaly, diffuse hyperechoic hepatic parenchyma or multifocal nodular "mottling"; multifocal lesions suggest nodules ("Swiss cheese pattern") formed by progressive hepatocellular ballooning degeneration; may disclose underlying primary visceral abnormalities (e.g., mesenteric lymphadenopathy, neoplasia) or adrenal disorders (size/shape): adrenals may be large with hyperadrenocorticism, sex hormone adrenal hyperplasia, chronic stress, or neoplasia.

DIAGNOSTIC PROCEDURES

- Hepatic fine-needle aspiration cytology—22 gauge, 2.5–3.75 cm (1–1.5 in) US-guided needle aspiration; target nodules and normal parenchyma.
- Cytology—glycogen vacuolation common in many primary liver disorders; used to rule out vacuolar change; cannot definitively confirm illness caused only by VH.
- Hepatic biopsy—verifies VH; excludes other primary hepatic disease; pursue if systemic disorder not discovered explaining high ALP and VH; use US-guided Tru-Cut® needle biopsy to confirm VH, but may miss primary hepatic disease, laparoscopy (recommended), or laparotomy (if visceral inspections and biopsies indicated).
- Cytologic features—hepatocellular cytosolic distention: "rarefication" or granular appearance with increased cell fragility; canalicular bile casts may be observed; primary VH not associated with inflammatory infiltrates; common association with extramedullary hematopoiesis (EMH) may be misinterpreted as suppurative inflammation.
- Tissue culture and sensitivity—if suppurative inflammation suspected, submit aerobic and anaerobic bacterial cultures.
- Coagulation assessments—prothrombin time (PT), activated partial thromboplastin time (APTT), fibrinogen, and mucosal bleeding time: usually normal; bench assessments have low predictive value in predicting iatrogenic hemorrhage; buccal mucosal bleeding time may be more relevant.

PATHOLOGIC FINDINGS

- Gross—variable; normal to moderate hepatomegaly; inconsistent surface irregularity; tan or pale color; confusion with cirrhosis if nodular severe degenerative VH.
- Microscopic—marked vacuolization and ballooning of hepatocytes; no consistent zonal distribution, foci of hepatic degeneration; focal aggregates of neutrophils due to EMH; severe degenerative VH leads to parenchymal collapse, forming nodules surrounded by a thin partition with minimal collagen deposition.

TREATMENT

DIET

- Hyperlipidemia or pancreatitis—restrict dietary fat and fatty supplements.
- Obesity—gradual energy restriction; treat predisposing disorders.

SURGICAL CONSIDERATIONS

- Depend on underlying conditions.
- Adrenal masses may be resected.
- Hypophyseal masses—resection only by experienced surgeons; pituitary mass lesions may respond to radiation therapy.

MEDICATIONS

DRUG(S) OF CHOICE

- Depend on underlying disease.
- Pituitary-dependent hyperadrenocorticism or adrenal hyperplasia syndrome (sex hormone)—usually treated medically: op'-DDD (mitotane or Lysodren®), trilostane, or ketoconazole; op'-DDD preferred for sex hormone adrenal hyperplasia, as trilostane augments sex hormone accumulation; l-deprenyl and melatonin ineffective.
- Manage primary inflammatory disorders necessitating immunosuppressive or anti-inflammatory medications—use polypharmacy to minimize glucocorticoid exposure if symptomatic or progressive VH; see Alternative Drug(s).
- Neoplasia—tumor resection, chemotherapy, or radiation, as appropriate.
- Dental disease—antibiotics and dentistry.
- Inflammatory bowel disease—hypoallergenic/hydrolyzed protein diets and immunomodulation (avoid glucocorticoids).
- Pyelonephritis, chronic dermatitis, or other infectious disorders—long-term antimicrobial treatment based on microbial culture and sensitivity tests; other appropriate medications.
- Hypothyroidism—supplemental thyroxine.

CONTRAINDICATIONS

- Avoid hepatotoxic drugs if severe VH.
- Beware of drug interactions if using ketoconazole for adrenal disease.
- Avoid drugs with hepatic ALP induction effects.

PRECAUTIONS

Glucocorticoids—caution in VH patients; use lowest effective dose regimen (e.g., alternate-day protocol if prednisone or prednisolone); special caution in hyperlipidemia: may worsen clinical signs of abdominal pain, vomiting, pancreatitis; increase insulin requirements in diabetes mellitus; may augment gallbladder mucocele formation; may provoke hepatic lipidosis in cats.

ALTERNATIVE DRUG(S)

Polypharmacy protocol—may reduce glucocorticoid usage in management of immune-mediated or inflammatory disorders; e.g., metronidazole, azathioprine, chlorambucil, cyclophosphamide, mycophenolate, or cyclosporine.

FOLLOW-UP

PATIENT MONITORING

- Hepatomegaly—abdominal palpation; imaging.
- Normalizing enzymes—biochemistry.
- Adrenal function—ACTH stimulation tests.
- Neoplasia—physical exams and imaging.
- Control of infection—repeat cultures.
- Hyperlipidemia—assess gross plasma lipemia; measure triglycerides and cholesterol.

PREVENTION/AVOIDANCE

- Limit glucocorticoid exposure.
- Use alternate-day therapy with prednisone/prednisolone; titrate to lowest effective dose; use alternative medications to control primary illness.

GLYCOGEN-TYPE VACUOLAR HEPATOPATHY (CONTINUED)

POSSIBLE COMPLICATIONS

Numerous—related to multisystemic effects of glucocorticoids and associated conditions.

EXPECTED COURSE AND PROGNOSIS

- Most patients are asymptomatic for VH despite high ALP; however, progressive degenerative hepatopathy leading to diffuse nodule formation and hepatic insufficiency may develop in chronic VH in dogs with high ALP activity.
- Laboratory and pathologic features reversible before degenerative parenchymal collapse.
- Dogs with sex hormone hyperplasia, VH, and dysplastic hepatocellular foci appear at risk for development of hepatocellular carcinoma.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Pulmonary thromboembolism and myopathy due to hyperadrenocorticism.
- Pancreatitis associated with hyperlipidemia.
- Gallbladder mucocele.

PREGNANCY/FERTILITY/BREEDING

Reproductive failure with glucocorticoid excess—testicular atrophy; abnormal estrus.

SYNONYMS

- Glucocorticoid hepatopathy.
- Steroid hepatopathy.
- Corticosteroid hepatopathy.
- Vacuolar change.

SEE ALSO

- Gallbladder Mucocele.
- Hyperadrenocorticism (Cushing's Disease)—Cats.
- Hyperadrenocorticism (Cushing's Disease)—Dogs.
- Hyperlipidemia.

ABBREVIATIONS

- ACTH = adrenocorticotropic hormone.
- ALP = alkaline phosphatase.
- ALT = alanine aminotransferase.
- APTT = activated partial thromboplastin time.
- AST = aspartate aminotransferase.
- cPLI = canine pancreatic lipase immunoreactivity.
- EMH = extramedullary hematopoiesis.
- GGT = γ-glutamyltransferase.
- HDDST = high-dose dexamethasone suppression test.
- LDDST = low-dose dexamethasone suppression test.
- PT = prothrombin time.
- TSBA = total serum bile acids.
- VH = vacuolar hepatopathy.

GRAPE AND RAISIN TOXICOSIS

BASICS

OVERVIEW
Syndrome resulting from ingestion of grapes, raisins, sultanas, or Zante currants (*Vitis vinifera*).

SIGNALMENT
- Dogs are the only species in which toxicosis has been well described.
- No breed, sex, or age predisposition noted.
- Anecdotal reports of toxicosis in cats and ferrets exist, but data are lacking to confirm.

SIGNS
- Vomiting within 24 hours of ingestion; vomitus frequently contains ingested fruit.
- Diarrhea, anorexia, lethargy, and abdominal pain may occur; stools may contain ingested fruit.
- Within 24 hours to several days, dehydration with oliguria or anuria occurs.
- Death due to anuric renal failure or euthanasia.

CAUSES & RISK FACTORS
- Although amounts of raisins and grapes reported to cause toxicosis lie in the range 2.8–9.6 g/kg and 11–31 g/kg, respectively, a minimum toxic dose has not been established. Additionally, not all exposures of dogs to *Vitis vinifera* have resulted in clinical evidence of renal injury.
- Ingestion of sultanas, Zante currants, and other varieties of *Vitis vinifera* has also been associated with renal injury in dogs, but amounts associated with toxicosis have not been reported.
- Mechanism of toxicity and toxic principle are unknown. Inconsistent development of clinical signs resulting from ingestion of *Vitis vinifera* may reflect idiosyncratic reactions of individual dogs or a toxic principle that is of variable presence in the fruit due to variances in growing conditions.
- Until further toxicity data are available, all exposures of dogs to *Vitis vinifera* should merit veterinary attention.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Other causes of acute renal failure—ethylene glycol, heavy metal toxicosis, nephrotoxic antibiotics (e.g., aminoglycosides), nonsteroidal anti-inflammatory drug toxicosis, hemoglobinuria, myoglobinuria, leptospirosis, borreliosis, and vitamin D toxicosis.

CBC/BIOCHEMISTRY/URINALYSIS
- Hypercalcemia, hyperphosphatemia, high creatinine and blood urea nitrogen (BUN) may develop within 24–48 hours of ingestion. Elevated creatinine and hyperphosphatemia tend to develop first, followed by elevation of BUN, with calcium elevation tending to increase 48–72 hours after exposure. Differentiate from vitamin D3 toxicosis, where calcium and phosphorus elevate first followed by elevations in BUN and creatinine as kidney injury develops. Not all cases develop hypercalcemia or hyperphosphatemia.
- Hyperkalemia, hyperamylasemia, hyperlipasemia, and elevated alanine aminotransferase (ALT) also occasionally occur.
- Isosthenuria, hyposthenuria, proteinuria, hematuria, and glucosuria have been reported.
- Granular casts may occur in the urine.

OTHER LABORATORY TESTS
Histopathology of kidneys reveals acute diffuse renal tubular degeneration and necrosis.

TREATMENT
- Gastrointestinal decontamination (induction of emesis, administration of activated charcoal) should follow ingestion of grapes or raisins by dogs.
- Fluid diuresis (2–3 times maintenance) for minimum of 48 hours is recommended, longer if renal failure develops. Fluid choice may vary with circumstance, but 0.9% NaCl is most commonly recommended.
- Monitor serum chemistry values, particularly renal values, for minimum of 72 hours, longer if renal failure develops.
- Correct fluid imbalances (e.g., dehydration).
- Monitor fluid in/out.
- Diuretics (e.g., furosemide, mannitol, dopamine) if oliguria or anuria develops.
- Hemodialysis or peritoneal dialysis may be required in anuric patients.

MEDICATIONS

DRUG(S) OF CHOICE
- Emetics—3% hydrogen peroxide 2.2 mL/kg up to a maximum of 45 mL/dog PO; may repeat once if first dose unsuccessful; *or* apomorphine crushed and diluted with sterile saline and instilled in conjunctival sac, rinse eye after emesis, or 0.03 mg/kg IV.
- Activated charcoal—1–3 g/kg PO.

Management of Oliguric or Anuric Renal Failure
- Mannitol 0.25–0.5 g/kg of 20–25% solution IV over 15–20 min, repeat q4–6h or administer as CRI of 8–10% solution for 12–24h.
- Furosemide 2 mg/kg IV, repeat at 4 mg/kg if no diuresis within 1h; use with dopamine for best results.
- Dopamine 0.5–3 µg/kg/min.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
N/A

FOLLOW-UP
- In dogs developing renal insufficiency, monitor renal values until they return to normal.
- Some dogs may develop irreversible renal injury requiring lifelong management.
- Evidence of pancreatitis developed in 3 of 43 dogs with acute renal injury following *Vitis vinifera* ingestion.

MISCELLANEOUS

ABBREVIATIONS
- ALT = alanine aminotransferase.
- BUN = blood urea nitrogen.

HAIR FOLLICLE TUMORS

BASICS

OVERVIEW

• Five types—trichoepithelioma and trichoblastoma are most common types, but uncommon types include infundibular keratinizing acanthoma, tricholemmoma, and pilomatricoma; these are differentiated based on their origin: trichoepithelioma, trichoblastoma, infundibular keratinizing acanthoma, and tricholemmoma, which arise from keratinocytes in the outer root sheath of the hair follicle (± hair matrix); and pilomatricoma, which arises from the hair matrix. • All types—generally benign; a few published reports of malignant trichoepitheliomas, trichoblastomas, and pilomatricomas. • Approximately 5% of all skin tumors in dogs and 1% of all skin tumors in cats.

SIGNALMENT

• Dog and cat. • Age—usually >5 years. • No sex predisposition. • Trichoepithelioma—common in dogs; rare in cats; golden retrievers, basset hounds, German shepherds, cocker spaniels, Irish setters, English springer spaniels, miniature schnauzers, and standard poodles may be predisposed; Persian and Siamese cats. • Trichoblastoma—common in dogs; common in cats; poodles and cocker spaniels may be predisposed; no known breed predisposition in cats. • Infundibular keratinizing acanthoma—uncommon in dogs and cats; Norwegian elkhound, keeshond, and German shepherd dog may be predisposed; no known breed predisposition in cats. • Tricholemmoma—uncommon in dogs and cats; Afghan hounds may be predisposed; no known breed predisposition in cats. • Pilomatricoma—uncommon in dogs and cats; Kerry blue terriers, Old English sheepdogs, and miniature poodles may be predisposed; no known breed predisposition in cats.

SIGNS

• Usually a solitary mass. • Trichoepithelioma—common on the lateral thorax and dorsal lumbar area (dogs) and head (cats). • Trichoblastoma—common on the head and neck, especially the base of the ear (dogs) and cranial half of the trunk (cats). • Infundibular keratinizing acanthoma—common on the back, neck, and limbs (dogs). • Tricholemmoma—common on the head and neck (dogs). • Pilomatricoma—common on the back, limbs, shoulders, flanks, and tail. • Firm, round, elevated, well-circumscribed, often hairless, or ulcerated dermoepithelial masses or nodules.

CAUSES & RISK FACTORS

Unknown, some genetic predisposition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Distinguish from other tumors, including basal cell tumor and squamous cell carcinoma, and from epidermal inclusion cysts.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

DIAGNOSTIC PROCEDURES

• Fine-needle aspiration and cytopathology. • Tissue biopsy and histopathology.

PATHOLOGIC FINDINGS

• Fine-needle aspiration cytology is very similar among all hair follicle tumors with basaloid and ghost cells; the exception to this rule is trichoblastomas, which have abundant pink matrix and scattered spindle cells. • Trichoepithelioma—varies in degree of differentiation and site of origin (root sheath or hair matrix); horn cysts, lack of desmosomes, and differentiation toward hair follicle-like structures and formation of hair common. • Trichoblastoma—four basic subtypes including ribbon, trabecular, granular, and clear cell; ribbon have basaloid cells in branding, winding, and radiating columns; trabecular have basaloid cells with prominent peripheral palisading; granular is identical to ribbon type but many of the cells are larger cells with granular or vacuolated cytoplasm; clear cell have basaloid cells in ribbon pattern with some cells having sebaceous differentiation. • Infundibular keratinizing acanthoma—characterized by keratin-filled crypt in the dermis that opens to the skin surface. • Tricholemmoma—characterized by nodular proliferation of keratinocytes, of which many are clear and surrounded by thickened basement membrane. • Pilomatricoma—characterized by a variable proliferation of basophilic cells resembling hair matrix cells and fully keratinized, faintly eosinophilic cells with a central unstained nucleus (shadow cells); calcification common; features of malignancy are present with the occasional malignant pilomatricoma.

TREATMENT

Complete excision, cryotherapy, or electrosurgery—curative with most cases.

MEDICATIONS

DRUG(S) OF CHOICE

• Isotretinoin (1 mg/kg q24h PO) was used to successfully control multiple pilomatricomas in one dog and multiple infundibular keratinizing acanthomas in some dogs. • Multimodal analgesia recommended for painful lesions.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

• Monitor for local recurrence. • Prognosis usually excellent; multiple reports of metastatic disease with the less common canine malignant pilomatricomas.

HALITOSIS

BASICS

DEFINITION
An offensive odor emanating from the oral cavity.

PATHOPHYSIOLOGY
- The sour milk odor accompanying periodontal disease may result from bacterial populations associated with plaque, calculus, unhealthy oral cavity tissues, decomposing food particles retained within the oral cavity, and tissue necrosis.
- Contrary to common belief, neither normal lung air nor stomach aroma contributes.
- The most common cause is periodontal diseases caused by plaque bacteria.
- A bacterial biofilm forms over a freshly cleaned and polished tooth as soon as the patient starts to salivate; bacteria attach to the pellicle within 6–8 hours; within days, the plaque becomes mineralized, producing calculus; as plaque ages gingival inflammation (gingivitis) may occur and progress into periodontitis (tooth support loss). Eventually the bacterial flora changes from a predominantly nonmotile Gram-positive aerobic coccoid flora to a more motile, Gram-negative anaerobic population including *Prophyromonas*, *Bacteroides*, *Fusobacterium*, and *Actinomyces* spp.
- The rough surface of calculus attracts more bacteria-laden biofilm, irritating the free gingiva; as the inflammation continues, the gingival sulcus is transformed into a periodontal pocket, which accumulates food debris and bacterial breakdown products, generating oral malodor (halitosis).
- The primary cause of malodor is Gram-negative anaerobic bacteria that generate volatile sulfur compounds (VSCs), such as hydrogen sulfide, methyl mercaptan, dimethyl sulfide, and volatile fatty acids.
- VSCs may also play a role in periodontal disease, affecting the integrity of the tissue barrier, allowing endotoxins to produce periodontal destruction, endotoxemia, and bacteremia.

SYSTEMS AFFECTED
Gastrointestinal—oral cavity.

SIGNALMENT
Species
Dogs and cats.

Breed Predilections
Small breeds and brachycephalic breeds are more prone to oral disease because the teeth are closer together, smaller animals live longer, and their owners tend to feed softer food.

Mean Age and Range
Older animals are predisposed.

SIGNS
- When oral malodor is secondary to oral disease, ptyalism (with or without blood), pawing at mouth, and anorexia may occur.
- In most cases, no clinical signs are present other than the odor.

CAUSES
- Eating malodorous food.
- Metabolic—diabetes, uremia.
- Respiratory—rhinitis, sinusitis, neoplasia.
- Gastrointestinal—megaesophagus, neoplasia, foreign body.
- Dermatologic—lip-fold pyoderma.
- Dietary—fetid foodstuffs, coprophagy.
- Oral disease—periodontal disease and ulceration, orthodontic, pharyngitis, tonsillitis, neoplasia, foreign bodies.
- Trauma—electric cord injury, open fractures, caustic agents damaging oral cavity.
- Infectious—bacterial, fungal, viral infections of oral cavity.
- Autoimmune diseases of oral cavity.
- Eosinophilic granuloma complex.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal. Might see changes consistent with diabetes mellitus or renal disease.

IMAGING
Intraoral radiographs are appropriate to help diagnose causes of halitosis.

DIAGNOSTIC PROCEDURES
- Hydrogen sulfide, mercaptans, and volatile fatty acids are the primary components of halitosis; an industrial sulfide monitor can be used to measure sulfide concentration in peak parts per billion.
- Additional diagnostic procedures to evaluate periodontal disease include intraoral radiography, probing pocket depths, attachment levels, and tooth mobility.

TREATMENT

APPROPRIATE HEALTH CARE
- Following appropriate tooth-by-tooth diagnostics (periodontal probing, intraoral imaging, mobility evaluation), under anesthesia all teeth should be ultrasonically scaled, and polished; a curette should be used to remove remaining plaque and calculus accessible subgingivally.
- Once the specific cause of halitosis is known, direct therapy at correcting existing pathology; often multiple teeth need to be extracted when advanced periodontal disease is the cause of halitosis.

CLIENT EDUCATION
- Halitosis is generally a sign of an unhealthy oral cavity and should prompt oral assessment under general anesthesia, treatment, and prevention.
- Initiate preventive measures to ensure good oral health (e.g., twice-daily brushing or wiping teeth, recommend accepted Veterinary Oral Heath Council products).

SURGICAL CONSIDERATIONS
Oral assessment performed under general anesthesia with intraoral radiographs and probing treatment including extraction of teeth with greater than 50% support loss.

MEDICATIONS

DRUG(S) OF CHOICE
- Antibiotics are not indicated to treat halitosis.
- Controlling periodontal pathogens helps control dental infections and accompanying malodor; when accompanied by follow-up home care, has been shown to decrease pocket depth.
- Weekly application of a plaque-retardant gel has been shown to decrease plaque in dogs and cats.
- The use of oral care products that contain metal ions, especially zinc, inhibits odor due to the affinity of the metal ion to sulfur; zinc complexes with hydrogen sulfide to form insoluble zinc sulfide; zinc interferes with microbial proliferation and calcification of microbial deposits (by interfering with the crystal development of calculus). Topical treatment with zinc ascorbate cysteine gel usually reduces halitosis within 30 minutes.

FOLLOW-UP

PATIENT MONITORING
Evaluate for recurrence of signs.

PREVENTION/AVOIDANCE
- Daily brushing or friction wipes to remove plaque and control dental disease and odor; periodic veterinary examinations to monitor care.
- Veterinary Oral Health Council (VOHC.org) was created to accept products that decrease the accumulation of plaque and/or tartar; additionally those products accepted are considered safe to use.

EXPECTED COURSE AND PROGNOSIS
Varies with underlying cause.

HALITOSIS (CONTINUED)

MISCELLANEOUS

SYNONYMS
- Bad breath.
- Fetor ex ore.
- Fetor oris.
- Foul breath.
- Malodor.

SEE ALSO
Periodontal Disease.

ABBREVIATIONS
- VSC = volatile sulfur compounds.

HEAD PRESSING

BASICS

DEFINITION
Compulsive pressing of the head against a wall or other object for no apparent reason.

PATHOPHYSIOLOGY
- Alterations in behavior—caused by lesions in the prosencephalon (i.e., cerebrum, limbic system, thalamus, and hypothalamus), particularly those affecting the limbic system and frontal and temporal cortices.
- Lesions may result in compulsive pacing; when an obstacle (e.g., a wall) is reached, the animal may press its head against it for long periods of time, apparently unable to turn and move away.
- Apparent inability to voluntarily move away—may reflect impaired integration of sensory information, leading to inappropriate behavior.

SYSTEMS AFFECTED
Nervous

GENETICS
N/A

INCIDENCE/PREVALENCE
N/A

SIGNALMENT
Dogs and cats of any age, breed, and sex.

SIGNS
- Head pressing—just one sign of prosencephalon disease.
- Compulsive pacing and circling toward the side of the lesion; circling can be toward either side if lesion is centrally located.
- Change in learned behavior, including loss of sleep cycles.
- Seizures.
- Contralateral postural reaction deficits.
- Contralateral visual deficits with normal pupillary light reflexes.
- Contralateral facial hypalgesia.

CAUSES & RISK FACTORS
- Anatomic—hydrocephalus, most commonly in young toy-breed dogs; lissencephaly (Lhasa apsos).
- Metabolic—hepatic encephalopathy as a result of a portosystemic shunt or severe hepatic disease; severe hyper- or hyponatremia.
- Nutritional—very unusual since most pets are fed compounded diets; thiamine deficiency can occur in cats fed a diet of raw fish, if thiamine supplementation in canned food is insufficient or in cats with severe malabsorptive syndromes; however, vestibular signs predominate.
- Neoplastic—primary (e.g., glioma, meningioma) or metastatic (e.g., hemangiosarcoma) tumors affecting the brain; more common in older animals (>6 years).
- Immune-mediated/inflammatory—granulomatous meningoencephalitis; necrotizing encephalitides (Maltese encephalitis, pug encephalitis); meningoencephalitis of unknown etiology.
- Infectious (dogs)—viral (rabies virus, canine distemper virus), rickettsial (*Ehrlichia canis*, Rocky Mountain spotted fever), protozoal (*Toxoplasma gondii*, *Neospora caninum*), or fungal (*Blastomyces*, *Cryptococcus*); rabies is of particular importance because neurons in the limbic system are frequently infected in carnivores.
- Infectious (cats)—viral (rabies, feline infectious peritonitis, feline leukemia virus: associated immunosuppression predisposes to other encephalitides and neoplasia; feline immunodeficiency virus: can cause encephalopathy primarily and can predispose to other encephalitides and neoplasia due to immunosuppression); *Bartonella henselae*; *Cuterebra* migration; toxoplasmosis; *Cryptococcus* and other fungal infections.
- Toxic—e.g., lead poisoning.
- Trauma.
- Vascular—intracranial hemorrhage as a result of hypertension (consider in older cats with hyperthyroidism, diabetes, or chronic renal insufficiency); bleeding disorder (either primary or secondary to rodenticide toxicity); ischemia (feline ischemic encephalopathy or secondary to systemic metabolic, inflammatory, or neoplastic disease).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
A newly blind animal might bump into objects, but rapidly recognizes its environment and acts visual; an animal with a prosencephalic lesion continues bumping into objects despite normal ocular exam.

CBC/BIOCHEMISTRY/URINALYSIS
- May reflect a metabolic or toxic cause.
- Hepatic encephalopathy—decreased serum albumin, blood urea nitrogen, cholesterol, and glucose concentrations, with or without elevated alanine phosphatase (ALP), alanine aminotransferase (ALT), and bilirubin concentrations; microcytic anemia may be present; ammonium biurate crystals may be present in the urine.
- Lead toxicity—basophilic stippling of erythrocytes; presence of reticulocytes and nucleated red blood cells (RBCs) in the absence of anemia.
- Encephalitis—findings often unremarkable, but may reflect an inflammatory process (e.g., with fungal infection).
- CNS lymphoma—may see evidence of bone marrow involvement.

OTHER LABORATORY TESTS
- Bile acid tolerance—to diagnose hepatic encephalopathy; blood ammonia concentrations may also be elevated.
- Acute and convalescent serologic titers—to diagnose rickettsial, protozoal, fungal, and viral diseases; for some infections (e.g., canine distemper virus, *Toxoplasma*, *Cryptococcus*) also measure cerebrospinal fluid (CSF) antibody or antigen (*Cryptococcus*) titers.
- PCR on CSF and serum—to diagnose rickettsial, bacterial, protozoal, fungal, and viral diseases; sensitive and specific if the infectious agent is present in CSF or serum.
- Blood lead concentration—to diagnose lead toxicity.

IMAGING
- Thoracic radiography—recommended for older patients to identify metastatic disease.
- Abdominal ultrasonography— recommended for older patients if intra-abdominal neoplasia is suspected; indicated if a portosystemic shunt or other hepatic disease is suspected.
- Rectal scintigraphy—may be used to definitively diagnose a portosystemic shunt.
- Brain CT or MRI—to identify intracranial masses, malformations, skull fractures, inflammation, and hemorrhage.
- Ultrasonography of the brain via persistent fontanels—may be used to diagnose hydrocephalus in young dogs.

DIAGNOSTIC PROCEDURES
- Fundic examination—to identify chorioretinitis (evidence of infectious/inflammatory disease) and vascular lesions.
- Blood pressure measurement to identify hypertension.
- CSF analysis—to diagnose encephalitis.

PATHOLOGIC FINDINGS
Findings at necropsy will reflect the etiology.

TREATMENT

APPROPRIATE HEALTH CARE
- Severe clinical signs—hospitalization for diagnostic workup and treatment.
- Suspected rabies—quarantine outdoor animal with no vaccination or unknown vaccination history when rapidly progressive neurologic signs are present and animal lives in a rabies-endemic area; minimize the number of people in contact with the animal, and maintain a contact log; if neurologic signs deteriorate rapidly, euthanize the animal and send it to a public health laboratory to be tested for rabies.

HEAD PRESSING (CONTINUED)

NURSING CARE
• When hospitalized, patients should be monitored closely for deterioration in mental status and for seizures.
• Maintenance IV fluids may be necessary for patients with severe prosencephalic syndrome.
• The cage may need to be padded to avoid self-trauma if constantly head pressing and pacing.
• Eyes should be monitored regularly for development of corneal ulcers due to self-induced trauma.
• Central IV catheters should be placed in the saphenous vein rather than the jugular vein if possible, to avoid increasing intracranial pressure by occlusion of the jugular veins.

ACTIVITY
N/A

DIET
• Suspected hepatic encephalopathy—appropriate low-protein diet.
• Hand-feeding may be necessary in severely encephalopathic patients; risk of aspiration if the patient fails to prehend and swallow correctly.

CLIENT EDUCATION
• Specific to the underlying condition.
• Clients should be warned about the possibility of seizures, be provided with a description of a seizure, and given instructions on what to do if a seizure occurs.
• Clients should be provided with a description of signs of acute decompensation due to brain herniation.

SURGICAL CONSIDERATIONS
• If signs are due to intracranial disease, elevated intracranial pressure is likely and therefore there is a risk of herniation during anesthesia, with induction and recovery from anesthesia posing the highest risk; patients should be ventilated carefully to ensure that their partial pressure of carbon dioxide (pCO_2) remains within normal limits (35–45 mmHg).
• Hydrocephalus can be treated by placement of a ventriculo-peritoneal shunt.
• Brain neoplasia, in particular extra-axial tumors such as meningiomas, can be treated surgically if tumor location accessible.

MEDICATIONS

DRUG(S) OF CHOICE
• Different causes require different treatment; do not initiate therapy until a diagnosis has been established.
• If patient's mental status deteriorates suggesting impending brain herniation, mannitol (0.25–1 g/kg IV over 10–30 min) or hypertonic saline (4 mL/kg of 7.5% or 5.3 mL/kg of 3%) can be used to transiently reduce intracranial pressure; treatment can be repeated, but recurrent use will simply result in dehydration.
• Furosemide (0.7 mg/kg IV) given prior to administration of mannitol can complement the use of mannitol and prolong its effect.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Sedatives should be used with caution in patients exhibiting head pressing, because they prevent assessment of mental status changes and might suppress respiratory drive, causing an increase in pCO_2 and thus causing an increase in intracranial pressure.

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
• Periodic repeat neurologic examinations to monitor progress.
• See specific diseases.

POSSIBLE COMPLICATIONS
N/A

EXPECTED COURSE AND PROGNOSIS
N/A

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
• Rabies should be considered in endemic areas.
• Fungal infections may be zoonotic if spores are released; most likely to occur if exudative skin lesions are present.

SEE ALSO
• Brain Injury.
• Encephalitis.
• Hepatic Encephalopathy.
• Hydrocephalus.

ABBREVIATIONS
• ALP = alanine phosphatase.
• ALT = alanine aminotransferase.
• CSF = cerebrospinal fluid.
• pCO_2 = partial pressure of carbon dioxide.
• RBC = red blood cell.

HEAD TILT

BASICS

DEFINITION
Tilting of the head away from its normal orientation with the trunk and limbs; usually associated with disorders of the vestibular system.

PATHOPHYSIOLOGY
- Vestibular system—coordinates position and movement of the head with that of the eyes, trunk, and limbs by detecting linear acceleration and rotational movements of the head; includes vestibular nuclei in the rostral medulla of the brainstem, vestibular portion of the vestibulocochlear nerve (cranial nerve [CN] VIII), and receptors in the semicircular canals of the inner ear.
- Head tilt—most consistent sign of diseases affecting the vestibular system and its projections to the cerebellum, spinal cord, cerebral cortex, reticular formation, and extraocular muscles (via medial longitudinal fasciculus); usually ipsilateral to the lesion.

SYSTEMS AFFECTED
Nervous—peripheral or CNS.

SIGNS
- Ensure that abnormal head posture is true head tilt and not a head turn; i.e., turning of the head and neck to the side as if to turn in a circle.
- Head tilt may not be present if disease is bilateral.

CAUSES

Peripheral Disease
- Anatomic—congenital head tilt.
- Metabolic—hypothyroidism; pituitary chromophobe adenoma; paraneoplastic disease.
- Neoplastic—nerve sheath tumor of CN VIII; neoplasia of the bone and surrounding tissue (e.g., osteosarcoma, fibrosarcoma, chondrosarcoma, and squamous cell carcinoma).
- Inflammatory—otitis media and interna; primarily bacterial but also parasitic (e.g., *Otodectes*), and fungal; foreign body; nasopharyngeal polyp(s).
- Idiopathic—canine geriatric vestibular disease; feline idiopathic vestibular disease.
- Immune-mediated—cranial nerve neuropathy.
- Toxic—aminoglycosides, lead, hexachlorophene.
- Traumatic—fracture of tympanic bulla or petrosal bone; ear flush.

Central Disease
- Degenerative—storage disease; demyelinating disease; vascular event.
- Anatomic—hydrocephalus.
- Neoplastic—glioma, choroid plexus papilloma, meningioma, lymphoma, nerve sheath tumor, medulloblastoma, skull tumor (e.g., osteosarcoma); metastasis (e.g., hemangiosarcoma, melanoma).
- Nutritional—thiamin deficiency.
- Inflammatory, infectious—viral (e.g., feline infectious peritonitis [FIP], canine distemper); protozoal (e.g., toxoplasmosis, neosporosis); fungal (e.g., cryptococcosis, blastomycosis, histoplasmosis, coccidioidomycosis, nocardiosis); bacterial (e.g., extension from otitis media and interna); parasitic (e.g., *Cuterebra* larvae); rickettsial (e.g., ehrlichiosis); algae (protothecosis).
- Inflammatory, noninfectious—granulomatous meningoencephalomyelitis (GME), meningoencephalitis of unknown etiology/origin (MUE/MUO), breed-specific meningoencephalitis (e.g., necrotizing encephalitis).
- Trauma—fracture petrosal bone with brainstem injury.
- Toxic—metronidazole.

RISK FACTORS
- Hypothyroidism.
- Administration of ototoxic drugs.
- Metronidazole treatment.
- Thiamin-deficient diet.
- Otitis externa, media, and interna.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Vestibular Disease
- Unilateral disease—head tilt usually toward side of lesion; usually accompanied by other vestibular signs, e.g., abnormal nystagmus (resting, positional) with fast phase usually in the direction opposite the tilt; ventral deviation of the eye (vestibular strabismus) ipsilateral to the tilt observed with elevation of the head; ataxia and disequilibrium with tendency to fall, lean, and/or circle toward the side of the tilt.
- Bilateral disease—head tilt may be absent or mild on the more severely affected side; abnormal nystagmus may be present; physiologic nystagmus (i.e., normal vestibular nystagmus) may be depressed or absent; may have wide side-to-side swaying movements of the head (especially evident in cats); may have wide-based stance or crouched posture with reluctance to move.
- Head tilt—localizes either to *peripheral* (e.g., vestibular portion of CN VIII or receptors in the inner ear) or *central* (e.g., vestibular nuclei and their neuronal pathways) nervous system.
- Peripheral deficits—horizontal or rotatory nystagmus with fast phase opposite the head tilt; possible concomitant ipsilateral facial nerve paresis or paralysis and/or Horner's syndrome, and/or decreased tear production because of the close association of CN VIII with CN VII and the sympathetic nervous system in the petrosal bone and tympanic bulla.
- Central deficits—vertical, horizontal, or rotatory nystagmus that can change direction with position of the head; altered mentation; ipsilateral paresis and/or proprioceptive deficits; central signs related to cerebellum, rostral medulla, and pons; in some patients, multiple CN involvement.
- Paradoxical vestibular syndrome—with lesions in the caudal cerebellar peduncles, or flocculonodular lobes of cerebellum; vestibular signs (e.g., head tilt, nystagmus) contralateral to the lesion, whereas the cerebellar signs and proprioceptive deficits are ipsilateral to the lesion.

Nonvestibular Head Tilt and Head Posture
- Uncommon.
- Unilateral midbrain lesions can cause severe rotation of the head (>90°) toward the side opposite the lesion; no other vestibular signs; tilt corrects when patient is blindfolded.
- Adversive syndrome—observed with rostral thalamic or frontoparietal lobe lesions; head turn, neck curvature, and/or compulsive circling can be misinterpreted as vestibular deficits; may have postural reaction, menace, and/or sensory deficits that are contralateral to the lesion; compulsive turning is usually in large circles and is without the disequilibrium and true head tilt of vestibular disease.

CBC/BIOCHEMISTRY/URINALYSIS
- Usually normal.
- Mild anemia—hypothyroidism.
- Leukocytosis with neutrophilia—otitis media and interna.
- Thrombocytopenia—ehrlichiosis.
- Hypercholesterolemia—hypothyroidism.
- High serum globulin concentration—FIP.

OTHER LABORATORY TESTS
- T_4, free T_4, free T_4 by equilibrium dialysis (FT_4 E_QD), and endogenous thyroid-stimulating hormone (TSH) levels—if hypothyroidism is suspected based on physical examination and associated unilateral or bilateral involvement of CN VIII and possibly VII.
- Bacterial culture and sensitivity—sample from myringotomy or surgical drainage of tympanic bulla if otitis media/interna is suspected.
- Microscopic examination of ear swab—parasites (e.g., *Otodectes*).
- Serologic testing—infectious causes (e.g., canine distemper; FIP; protozoal, fungal, rickettsial diseases).

IMAGING
- Radiographs of tympanic bullae and skull—normal radiographs do not rule out bulla disease.
- CT and MRI—valuable to confirm bulla lesions, CNS extension from peripheral

HEAD TILT (CONTINUED)

disease, localize tumor, granuloma, and document extent of inflammation.

DIAGNOSTIC PROCEDURES

- Cerebrospinal fluid (CSF)—from cerebellomedullary cistern; for evaluating central vestibular disease; detects inflammatory process; protein electrophoresis and titers to match with serologic testing if indicated; collection may put the patient at risk for herniation if elevated intracranial pressure.
- Brainstem auditory-evoked response (BAER)—assess cochlear portion of CN VIII and brainstem auditory pathways; particularly valuable for evaluating peripheral vestibular disease, because some diseases may cause ipsilateral deafness (e.g., otitis media/interna), whereas other diseases (e.g., canine geriatric and feline idiopathic vestibular diseases) affect only the vestibular portion of CN VIII.
- Biopsy—bone, tissue in tympanic bulla when a tumor, polyp, or osteomyelitis is suspected; brainstem mass (e.g., cerebellomedullary angle) difficult to approach and remove surgically.

TREATMENT

- Inpatient versus outpatient—depends on severity of signs (especially vestibular ataxia), size and age of patient, and need for supportive care.
- Supportive fluids—replacement or maintenance IV fluids may be required in acute phase when disorientation, nausea, and vomiting preclude oral intake; especially important in geriatric patients; maropitant—dog: 1 mg/kg SC q24h for up to 5 days or 2 mg/kg PO q24h for up to 5 days; cat: 1 mg/kg SC/PO for up to 5 days to help manage nausea (questionable benefit).
- Diet—as usual unless there is thiamin deficiency (e.g., exclusively fish diet without vitamin supplementation); restrict oral intake if nausea and vomiting; caution: aspiration secondary to abnormal body posture in patients with severe head tilt and disequilibrium or brainstem dysfunction.
- Discontinue drug if toxicity suspected.
- Sedative for severe disorientation and ataxia—e.g., dog: acepromazine 0.02–0.05 mg/kg IV/IM/SC to max 2 mg; dexmedetomidine 1–2 µg/kg IV; diazepam 2–10 mg/dog PO/IV q8h.
- Surgical treatment—to drain bulla with otitis media, remove nasopharyngeal polyp in cats, and resect tumor, if accessible.

MEDICATIONS

DRUG(S) OF CHOICE

- Otitis media and interna—broad-spectrum antibiotic (parenteral or oral) that penetrates bone while awaiting culture results; trimethoprim-sulfa (15 mg/kg PO q12h or 30 mg/kg PO q12–24h); first-generation cephalosporins, such as cephalexin (10–30 mg/kg PO q6–8h) or amoxicillin–clavulanic acid (Clavamox®—dogs: 12.5 mg/kg PO q12h; cats: 62.5 mg/cat PO q12h; Clavaseptin® 12.5 mg/kg PO q12h); treatment for 4–6 weeks.
- Hypothyroidism—T_4 replacement (dogs: levothyroxine 22 µg/kg PO q12h) should be introduced gradually in geriatric patients, especially with cardiac disease; response varies, partly depending on duration of signs (i.e., in some patients neuropathy is not reversible).
- Infectious CNS—specific treatment, if indicated; for bacterial diseases, antibiotic that penetrates the blood–brain barrier (e.g., trimethoprim-sulfa 15 mg/kg PO q12h; metronidazole 15 mg/kg q12h or 10 mg/kg q8h PO or slowly IV; third-generation cephalosporin, e.g., cefotaxime 25–50 mg/kg IV q8h); for protozoal diseases, clindamycin (12.5–25 mg/kg PO q12h); for fungal diseases, itraconazole (dogs: 2.5 mg/kg PO q12h or 5 mg/kg PO q24h; cats: 5 mg/kg PO q12h), fluconazole (dogs: 5–8 mg/kg PO q12h, 10–12 mg/kg PO q24h; cats: 50 mg/cat PO q12–24h); prognosis usually poor for protozoal, fungal, and viral diseases (e.g., FIP).
- GME/MUE/MUO—usually initially treated with steroids: dexamethasone (0.25 mg/kg PO, IM q12h for 3 days; followed by or starting with prednisone 2 mg/kg PO q24h for a minimum of 2 weeks; then decrease slowly); depending on progress, may need stronger immunosuppression, e.g., cytosine arabinoside 50 mg/m^2 q12h for four treatments repeated every 3 weeks (need to monitor CBC) or preferably starting with CRI of cytosine arabinoside at 200 mg/m^2 administered IV over 4h, then follow every 3 weeks with SC injections; also consider cyclosporine and/or leflunomide or radiation therapy.
- Trauma—supportive care (e.g., anti-inflammatory drugs, antibiotics, IV fluid administration); specific fracture repair or hematoma removal is potentially difficult considering the location.
- Canine geriatric and feline idiopathic vestibular disease—supportive care; maropitant—dog: 1 mg/kg SC q24h for up to 5 days or 2 mg/kg PO q24h for up to 5 days; cat: 1 mg/kg SC/PO for up to 5 days to help manage nausea (questionable benefit).
- Cranial nerve polyneuropathy—response to prednisone good if the patient has a primary immune disorder.
- Thiamin deficiency—diet modification and thiamin supplementation.

PRECAUTIONS

- Trimethoprim-sulfa administration—keratoconjunctivitis sicca (dry eye).
- Avoid administering drugs into external ear canal (especially oil-based) if tympanic membrane is ruptured.

FOLLOW-UP

PATIENT MONITORING

- Repeat the neurologic examination as dictated by underlying cause.
- Head tilt may persist.
- Hypothyroidism—measure T_4 concentration 4–6 hours after treatment 3–4 weeks after initiation of thyroid therapy or dosing change.
- Repeat CSF and brain imaging—with some central vestibular disorders.
- Monitor tear production (Schirmer tear test) with trimethoprim-sulfa administration.

EXPECTED COURSE AND PROGNOSIS

- Prognosis for central vestibular disorders usually poorer than peripheral vestibular disorders.
- Prognosis for canine geriatric and feline idiopathic vestibular syndromes is excellent.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Facial nerve paresis or paralysis.
- Horner's syndrome.

SEE ALSO

- Encephalitis.
- Otitis Media and Interna.
- Vestibular Disease, Geriatric—Dogs.
- Vestibular Disease, Idiopathic—Cats.

ABBREVIATIONS

- BAER = brainstem auditory-evoked response.
- CN = cranial nerve.
- CSF = cerebrospinal fluid.
- FIP = feline infectious peritonitis.
- FT_4E_QD = free T_4 by equilibrium dialysis.
- GME = granulomatous meningoencephalomyelitis.
- MUE/MUO = meningoencephalitis of unknown etiology/origin.
- TSH = thyroid-stimulating hormone.

HEAD TREMORS (BOBBING), IDIOPATHIC—DOGS

BASICS

OVERVIEW
- Common, very specific, benign, often self-limiting, head and neck tremors in dogs.
- Synonyms—head bobbing, wobbling, nodding, shaking, tremors; episodic head tremor syndrome; bobble head doll syndrome.
- A movement disorder (paroxysmal dyskinesia) was suspected, but the pathophysiology remains unknown and a recent electroencephalographic (EEG) study may support an epileptic syndrome.

SIGNALMENT
- All dog breeds can be affected.
- Not reported in cats.
- English bulldog (EB), French bulldog, boxer, Doberman pinscher (DP), and Labrador retriever are predisposed.
- Reported prevalence of 19–38% in EB.
- Reports that males are overrepresented in DP and EB.
- Generally starts early in life (<3 years old), but can start at any age.

SIGNS

Historical Findings
- Acute onset of head tremor episodes.
- Possible recent stressful event (heat, whelping with lactation, vaccination, illness, etc.).
- Littermates may be affected (familial form identified in DP ≤1 year old).

Physical Examination Findings
- None if not currently experiencing an episode.
- Typical vertical or horizontal rapid (4–8 Hertz or movements per second) head tremors—episodes last from a few seconds to a few hours.
- Variable tremor episode frequency, duration, and interepisode interval.
- Occasional reports of abnormal dystonic posture (subtle head tilt, stiffness, floppiness) during episodes, but not between episodes.
- Occasional reports of abnormal behavior (disorientation, sleepiness, agitation) immediately prior to episode.
- All dogs are reported to be responsive to their surroundings during the episode.
- Rare reports of associated generalized seizure.
- Episodes can often be interrupted by distraction or treats.
- Other neurologic abnormalities (ataxia, proprioceptive deficits, paresis) consistent with concurrent, unrelated neurologic disease (cervical spondylomyelopathy in DP, hemivertebrae in bulldogs) are often noted.

CAUSES & RISK FACTORS
- Unknown pathophysiology.
- Anatomic, neoplastic, and traumatic causes have been ruled out by different studies.
- Genetic basis suspected but unproven.
- May be triggered by a recent stressful event.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Tremorgenic toxin (mycotoxin, permethrins, etc.).
- Corticosteroid responsive shaker/tremor syndrome.
- Hypomyelinating/dysmyelinating congenital or degenerative disease.
- Cerebellar disease (intention tremor).
- Hypocalcemia.
- Hypoglycemia.
- Hypoadrenocorticism (electrolyte imbalance).
- Epilepsy (focal or generalized seizures) or reactive seizures.
- Stress.
- Muscle fatigue following exercise or associated with generalized weakness from myopathy, neuropathy, or neuromuscular disease.
- History, signalment, and viewing of a video helps greatly in identifying this typical head movement and differentiating it from other types of tremor.
- Variation from the above-described typical pattern should be video-filmed and reviewed.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

IMAGING
MRI might be considered if abnormalities other than typical head tremor noted.

DIAGNOSTIC PROCEDURES
Cerebrospinal fluid analysis and electrodiagnostic testing might be considered if abnormalities other than typical head bobbing episodes noted. Video-EEG may show seizure activity during an episode, but has been normal between episodes in one multicentric case series study.

PATHOLOGIC FINDINGS
Have not been studied.

TREATMENT
- No known effective treatment.
- Interrupting the episodes by distracting the dog should be tried by the client.
- If head bobbing episodes significantly impair crucial life functions such as eating or sleeping, consult a veterinary neurologist for further recommendations.

MEDICATIONS

DRUG(S) OF CHOICE
No known effective medication.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Commonly used antiepileptic drugs (phenobarbital, potassium bromide) have multiple significant side effects and have not been proven successful at treating head bobbing. Their use is not warranted with this condition.

FOLLOW-UP

PREVENTION/AVOIDANCE
N/A

EXPECTED COURSE AND PROGNOSIS
- Self-limiting in 49% of EB in one study.
- Benign head tremor episodes may continue lifelong at a variable frequency, usually decreasing over time.
- Prognosis is excellent as head bobbing is not associated with a life-threatening condition.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Concurrent epilepsy may be present.

PREGNANCY/FERTILITY/BREEDING
There is potential genetic transmission.

ABBREVIATIONS
- DP = Doberman pinschers.
- EB = English bulldog.
- EEG = Electroencephalography.

Client Education Handout available online

HEARTWORM DISEASE—CATS

BASICS

OVERVIEW

• Disease caused by infection with *Dirofilaria immitis*. • Microfilaremia uncommon (<20%) and usually transient if present. • Prevalence one-tenth that of unprotected dogs. • Low average worm burden. • Worms are physically smaller but recent evidence suggests lifespan is similar to that in the dog.

SIGNALMENT

• No age or breed predisposition. • Males more commonly infected naturally and easier to infect experimentally.

SIGNS

Historical Findings

• Coughing (this sign is relatively uncommon with heart failure). • Cough will commonly occur early in disease prior to established adult infection. • Heartworm-associated respiratory disease (HARD)—clinical signs and pulmonary pathology that occur 2–4 months post infection even when adult infection is never established. • Dyspnea. • Vomiting (undetermined cause). • Pulmonary thromboembolism (PTE) frequently results in acute respiratory failure and death. • Vomiting and respiratory signs predominate in chronic disease.

Physical Examination Findings

• Usually normal. • Increased bronchovesicular sounds. • Arrhythmia, murmur, or gallop rhythm should increase suspicion of primary cardiac disease.

CAUSES & RISK FACTORS

• Outdoor cats at increased risk (2 : 1). • Feline leukemia virus (FeLV) infection not predisposing factor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Asthma. • Cardiomyopathy. • Chylothorax. • *Aelurostrongylus abstrusus* infection. • *Paragonimus kellicotti* infection.

CBC/BIOCHEMISTRY/URINALYSIS

• Varies with stage of disease. • Mild nonregenerative anemia. • Eosinophilia inconsistent. • Concurrent basophilia should increase suspicion. • Hyperglobulinemia.

OTHER LABORATORY TESTS

Microfilaria Concentration Tests

Very low sensitivity, high specificity.

Heartworm Antigen Tests

• ELISA or immunochromatographic tests. • Tests that detect circulating adult heartworm antigen (HWAg) more specific than antibody tests. • Positive antigen test result is strong evidence of adult heartworm infection. • Low worm burdens (fewer than five worms) and single-sex infections commonly result in false-negative antigen tests. • Data suggest heat treatment of samples prior to testing may significantly increase test sensitivity; negative result does not rule out heartworm disease: more than 40% of cats with adult infection are antigen-negative; many cats are symptomatic (HARD) well before antigen test would become positive.

Heartworm Antibody Tests

• ELISA or immunochromatographic tests. • Tests that detect circulating antibodies to immature and adult heartworm antigen are most sensitive tests for feline heartworm disease. • Positive result does not confirm *adult* infection; usually becomes positive within 4 months of infection. • The more intense the antibody response, the more likely adult infection. • May become negative in adult infections perhaps associated with Ag;Ab complexing.

IMAGING

Radiography

• Enlarged (pulmonary artery, >1.6 times width of ninth rib). • Blunted, tortuous pulmonary arteries. • Patchy perivascular pulmonary infiltrates. • Pleural effusion may be present. • Chylothorax has been documented with spontaneously occurring and experimentally induced heartworm infections in cats.

Echocardiography

• Dilated main pulmonary artery. • Identification of worms in heart or main pulmonary artery; most commonly seen in right pulmonary artery but also in right ventricle and atrium (hyperechoic "=" sign). • Sensitive test in hands of experienced echocardiographer. • Excludes or confirms other primary cardiac diseases (cardiomyopathy).

TREATMENT

• Currently no approved or recommended medical adulticide therapy. • Surgical or catheter-based extraction may be most reasonable option. • Symptomatic cats should be stabilized (see below) prior to consideration of worm extraction. • Spontaneous "cure" probably more common in cats than dogs.

MEDICATIONS

DRUG(S) OF CHOICE

Initial Stabilization

• Supplemental oxygen. • Theophylline (sustained-release formulation) 15–25 mg/kg PO q24h in evening. • Prednisolone 1–2 mg/kg PO q12–24h for 10–14 days; then gradually taper and discontinue. • Doxycycline therapy 10 mg/kg PO q24h for 30 days (to eliminate endosymbiont *Wolbachia*) may hasten worm death and reduce severity of pulmonary inflammation secondary to worm embolization. • Cautious balanced fluid therapy if indicated. • Medical adulticide therapy not currently recommended. • Supportive care for PTE the same as initial stabilization (see above).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Aspirin therapy—no documented benefit. • Current information does not support use of melarsomine (Immiticide®) in cats.

FOLLOW-UP

PATIENT MONITORING

Serial evaluation of clinical response, thoracic radiographs, and heartworm antigen and antibody tests is most informative.

PREVENTION/AVOIDANCE

• Ivermectin 24 µg/kg PO q30 days. • Milbemycin oxime 0.5 mg/kg PO q30 days. • Selamectin 6.6–12 mg/kg cutaneously q30 days. • Moxidectin 1–2 mg/kg cutaneously q30 days. • Administration of these drugs in cats is not precluded by antibody or antigen seropositivity.

MISCELLANEOUS

ABBREVIATIONS

• FeLV = feline leukemia virus. • HARD = heartworm-associated respiratory disease. • HWAg = adult heartworm antigen. • PTE = pulmonary thromboembolism.

HEARTWORM DISEASE—DOGS

BASICS

DEFINITION
Disease caused by infestation with *Dirofilaria immitis*.

PATHOPHYSIOLOGY
• Severity directly related to worm number, duration of infestation, host response, and host activity level. • Endothelial damage leads to myointimal proliferation and inflammation predisposing to periarterial edema. • Lobar arterial enlargement, tortuosity, and obstruction cause impaired compliance, loss of collateral recruitment, pulmonary hypertension (PH), right-sided congestive heart failure (rCHF), thrombosis.
• Pulmonary damage exacerbated after death of adult worms and with exercise.

SYSTEMS AFFECTED
• Respiratory—PH, thromboembolism, allergic pneumonitis (some occult infections), eosinophilic granulomatosis (uncommon).
• Cardiovascular—severe PH causes right ventricular hypertrophy and, in some dogs, rCHF (ascites). • Hemic/lymphatic/immune—venous inflow to the heart can become obstructed by worms causing traumatic hemolytic anemia and cardiogenic shock (caval syndrome). • Renal/urologic—immune-complex glomerulonephritis.

INCIDENCE/PREVALENCE
Virtually 100% in unprotected dogs living in highly endemic regions.

GEOGRAPHIC DISTRIBUTION
• Most common in tropical and subtropical zones; endemic in North, Central, and South America, southern Europe, and Australia.
• Diagnosed in all 50 states of United States; common along Atlantic/Gulf coasts and Ohio/Mississippi river basins. • Ubiquitous mosquito vector in endemic areas.

SIGNALMENT

Breed Predilections
• Medium-to-large breed dogs > small dogs.
• Outdoor dogs > indoor dogs.

Mean Age and Range
Infestation can occur at any age; most affected dogs 3–8 years old.

Predominant Sex
Males > females.

SIGNS

Historical Findings
• Dogs often asymptomatic or exhibit minimal signs such as occasional coughing (mild infestation). • Coughing and exercise intolerance associated with moderate pulmonary damage (moderate infestation).
• Cachexia, exercise intolerance, syncope, and/or abdominal distention (rCHF) in severely affected dogs. • Cardiogenic shock, pigmenturia, abdominal distention (rCHF) in dogs with caval syndrome.

Physical Examination Findings
• No abnormalities—dogs with mild and some with moderate infestation. • Labored breathing and/or crackles—dogs with severe PH or pulmonary thromboembolism (PTE).
• Tachycardia, weight loss, exercise intolerance, syncope, coughing, pale or light pink mucous membranes, dyspnea. • Ascites, jugular vein distention/pulsation, hepatomegaly (rCHF).
• Hemoptysis—occasionally. • Pale mucous membranes, dyspnea, weak pulses.

RISK FACTORS
• Residence in endemic areas. • Outside habitat. • Lack of prophylaxis.
• Environmental temperature >57 °F (14 °C).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other causes of PH and thrombosis (e.g., hyperadrenocorticism, protein-losing nephropathy or enteropathy). • Chronic obstructive lung disease. • Pneumonia.
• Allergic lung disease. • Other causes of ascites (e.g., dilated cardiomyopathy).
• Other causes of hemolytic anemia (e.g., immune-mediated).

CBC/BIOCHEMISTRY/URINALYSIS
• Anemia—absent, mild, or moderate depending on chronicity, severity, thromboembolic complications. • Eosinophilia and basophilia—vary. • Inflammatory leukogram and thrombocytopenia associated with thromboembolism. • Hyperglobulinemia—inconsistent finding. • Hemoglobinemia—evident with caval syndrome and less often thromboembolism. • Proteinuria—common with severe and chronic infestation; due to immune-complex glomerulonephritis or amyloidosis. • Hemoglobinuria—caval syndrome or severe lysis with thromboembolism.

OTHER LABORATORY TESTS
• Highly specific, sensitive serologic tests identify adult female *D. immitis* antigen; test 7 months after end of previous transmission season; false positives possible with *Spirocerca* infestation; in author's experience, false negatives occur more commonly in shelter animals due to antigen-antibody complexes (antigen blocking); if infestation suspected with negative antigen test, consider heartworm heat treatment antigen ELISA testing.
• Antigenemia absent in absence of adult female worms. • Weak positive test verified by repeat testing using different test and/or microfilaria testing. • Strong reaction indicates relative high worm burden or recent worm death and highly predictive of thromboembolic complications post adulticide therapy.
• Microfilaria testing—mainly to confirm weak positive antigen tests, determine microfilarial status prior to using milbemycin preventatives, and identify microfilaria that may contribute to development of resistance when treated chronically with macrolide preventative.

IMAGING

Radiography
• Use DV projection. • Main pulmonary artery segment enlargement, lobar arterial enlargement, tortuosity/pruning vary from absent to severe; right caudal artery > left caudal artery > cranial arteries. • Parenchymal lung infiltrates of variable severity—surround lobar arteries; may extend into most or all of one or multiple lung lobes with thromboembolism and/or PH. • Diffuse, symmetric, alveolar, interstitial infiltrates occur secondary to allergic reaction to microfilaria (allergic pneumonitis) in about 10% of occult infestations.

Echocardiography
• Often unremarkable; may reflect right ventricular dilation and wall hypertrophy, tricuspid regurgitation, PH, small left heart due to underloading (pulmonary obstruction/hypertension). • Parallel, linear echodensities produced by heartworms may be detected in right ventricle, right atrium, pulmonary arteries.

DIAGNOSTIC PROCEDURES

ECG
• Usually normal. • May reflect right ventricular hypertrophy in dogs with severe infestation. • Heart rhythm disturbances—occasionally seen (atrial premature contractions and atrial fibrillation most common) in severe infestation.

PATHOLOGIC FINDINGS
• Large right heart. • Pulmonary arterial myointimal proliferation. • PTE.
• Pulmonary hemorrhage. • Hepatomegaly and congestion in dogs with rCHF.

TREATMENT

APPROPRIATE HEALTH CARE
• Most dogs hospitalized during adulticide administration. • Eliminate microfilaria with monthly prophylaxis and doxycycline/minocycline; milbemycin may cause rapid decrease in microfilaria numbers and should be used with caution in that scenario; dogs should be rendered microfilaria free 3-4 months post diagnosis. • Hospitalization recommended for dogs experiencing thromboembolic complications.

ACTIVITY
Severely restrict activity for 4–6 weeks after adulticide administration.

HEARTWORM DISEASE—DOGS (CONTINUED)

CLIENT EDUCATION

• Good prognosis for animals with mild to moderate disease. • Post-adulticide pulmonary complications likely in patients with moderate to severe pulmonary artery pathology and those with high worm burden. • Reinfestation can occur without appropriate prophylaxis.

SURGICAL CONSIDERATIONS

• Treatment of choice for caval syndrome. • Worm removal from right heart and pulmonary artery via jugular vein, by use of fluoroscopy and long, flexible alligator forceps or horsehair brush, highly effective for treating high worm burden when employed by experienced operator.

MEDICATIONS

DRUG(S) OF CHOICE

• Stabilize animals in rCHF with diuretics, angiotensin-converting enzyme (ACE) inhibitor, pimobendan, sildenafil, cage rest, and moderate sodium restriction before adulticide treatment. • Stabilize pulmonary failure with oxygen supplementation, antithrombotics (e.g., clopidogrel and heparin), and/or anti-inflammatory dosages of corticosteroid depending on clinical and radiographic findings. • Doxycycline/minocycline (5–10 mg/kg PO q12h) for 4 weeks followed by 1 month wait period is used prior to adulticide therapy to kill *Wolbachia*, a Gram-negative, endo-symbiotic, intrafilarial bacterium associated with inflammation of the lungs and kidneys; the author practices adulticide therapy after 4 weeks of treatment. • Adulticide—melarsomine dihydrochloride (2.5 mg/kg IM/dose): injections given into epaxial muscles using 22-gauge needles; apply pressure over injection site during and after needle withdrawal. • Graded-kill protocol recommended in most cases—administer one injection followed in 1 month by two injections (first injection on left or right epaxial muscles, followed by injection on opposite side 24h later). • For severe heartworm infestation with high worm burdens, administer one injection every 4–6 weeks for a total of three injections; maintain strictest patient confinement practical for 4–6 weeks; perform antigen test 6 months after third injection. • Allergic pneumonitis—administer prednisone or prednisolone (2 mg/kg PO q12–24h for several days) and then immediately administer melarsomine. • Rapid microfilaricidal therapy (e.g., milbemycin or high-dose ivermectin) not recommended—eliminate microfilaria with monthly prophylaxis and doxycycline/minocycline; confirm elimination of microfilaria by testing 3–4 months after initiating therapy.

PRECAUTIONS

• Adulticide treatment—not indicated in patients with renal failure, hepatic failure (icterus), or nephrotic syndrome. • Caval syndrome—remove worms surgically and stabilize patient with conservative management for at least 1 month prior to adulticide therapy.

ALTERNATIVE DRUG(S)

• Sodium heparin (75–100 units/kg SC q8h), clopidogrel (2–4 mg/kg PO q24h), or low molecular weight heparin (dalteparin: 100 units/kg SC q12–24h) for 1–3 weeks before, during, and for 3 weeks after adulticide administration are controversial recommendations for most severe cases; therapy is combined with strict, extended cage confinement. • Sodium heparin (200–500 units/kg SC q8h) recommended for dogs with PTE or hemoglobinuria with goal of prolonging activated partial thromboplastin time (APTT) 1.5–2 times baseline. • Soft or slow kill methods using any macrocyclic lactone alone are not recommended.

FOLLOW-UP

PATIENT MONITORING

• Perform antigen test 6 months after adulticide treatment; some dogs with persistent, low-grade antigenemia may not require retreatment. • Weak antigenemia indicates most worms killed, pulmonary pathology will improve, and ivermectin prophylaxis will likely eventually kill remaining worms.

PREVENTION/AVOIDANCE

• Heartworm prophylaxis should be provided for all dogs at risk—author recommends year-round prophylaxis; otherwise begin with mosquito season and continue for 1 month following first frost. • In highly endemic areas, consider combination of heartworm prophylaxis, insect repellents, and ectoparasiticides. • Antigen test 7 months after end of previous season. • Ivermectin (Heartgard®, Iverhart®, Tri-Heart®)—highly effective, monthly preventative; safe for microfilaremic dogs. • Milbemycin oxime (Interceptor®, Sentinel®, Trifexis®)—highly effective, monthly prophylaxis; acute reactions may occur when given to microfilaremic dogs. • Moxidectin (Advantage® Multi, ProHeart® 6)—topical solution administered monthly; slow-release injectable formulation (ProHeart® SR12) available in some countries. • Selamectin (Revolution®)—highly effective monthly topical preparation. • Administer to puppies as soon after 8 weeks of age as dictated by seasonal risk. • All prophylactic drugs can be administered safely to collies at labeled dosages. • For dogs infected with adult worms not already on prophylaxis, any of above drugs can be started immediately and should be started within 1 month of diagnosis; author recommends against using milbemycin in microfilaremic dogs. • All macrocyclic lactones combined with 1 month doxycycline/minocycline therapy should eliminate microfilaria in 1–3 months. • Due to recent increase in number of lack of efficacy reports and concern of possible heartworm resistance to current heartworm preventatives, dogs should be rendered microfilaria free 3–4 months post diagnosis.

POSSIBLE COMPLICATIONS

• Post-adulticide PTE—may occur up to 4–6 weeks after treatment; more likely in dogs with severe disease and those not properly confined. • Thrombocytopenia and disseminated intravascular coagulation. • Melarsomine adverse effects—PTE (usually 7–30 days post therapy); anorexia; injection site reaction: myositis; lethargy or depression; elevation of hepatic enzymes; paresis/paralysis/altered mentation; lack of efficacy.

EXPECTED COURSE AND PROGNOSIS

• Mild—usually uneventful with excellent prognosis. • Severe or caval syndrome—guarded prognosis with higher risk of complications.

MISCELLANEOUS

When anesthesia/surgery required, delay heartworm treatment until after procedure.

ASSOCIATED CONDITIONS

Wolbachia

PREGNANCY/FERTILITY/BREEDING

• Delay adulticide treatment. • Transplacental infestation by microfilaria can occur.

SEE ALSO

• Congestive Heart Failure, Right-Sided.
• Disseminated Intravascular Coagulation.
• Hypertension, Pulmonary.
• Nephrotic Syndrome.
• Pulmonary Thromboembolism.

ABBREVIATIONS

• ACE = angiotensin-converting enzyme.
• APTT = activated partial thromboplastin time.
• PH = pulmonary hypertension.
• PTE = pulmonary thromboembolism.
• rCHF = right-sided congestive heart failure.

HEAT STROKE AND HYPERTHERMIA

BASICS

DEFINITION

• Hyperthermia is defined as an elevation in body temperature above the normal range; although published normal values for dogs and cats vary slightly, it is generally accepted that body temperatures >103 °F (39.4 °C) are abnormal. • Hyperthermia can be categorized into pyrogenic hyperthermia (pyrexia or fever) and nonpyrogenic hyperthermia. • Heat stroke is a form of nonpyrogenic hyperthermia that occurs when heat-dissipating mechanisms of the body cannot accommodate excessive heat; this can lead to multisystem organ dysfunction; temperatures of ≥106 °F (41.1 °C) without signs of inflammation are suggestive of nonpyrogenic hyperthermia. • Malignant hyperthermia is an uncommon familial form of nonpyrogenic hyperthermia that can occur secondary to some anesthetic agents. • Other causes of nonpyrogenic hyperthermia include excessive exercise, thyrotoxicosis, and hypothalamic lesions.

PATHOPHYSIOLOGY

• The hypothalamic set point is changed with true fever; this is most likely mediated via the endogenous pyrogen interleukin-1. • Nonpyrogenic hyperthermia does not change the hypothalamic set point. • The critical temperature leading to multiple organ dysfunction is 109 °F (42.7 °C). • The primary pathophysiologic processes of heat stroke are related to thermal damage, which can lead to cellular necrosis, hypoxemia, and protein denaturalization. • Heat stroke and its sequelae can lead to systemic inflammatory response syndrome (SIRS).

SYSTEMS AFFECTED

• Cardiovascular—hypovolemia, cardiac arrhythmias, myocardial ischemia, necrosis. • Gastrointestinal—mucosal ischemia and ulceration, bacterial translocation and endotoxemia. • Hemic/lymphatic/immune—hemoconcentration, thrombocytopenia, disseminated intravascular coagulation (DIC). • Hepatobiliary—hepatocellular necrosis. • Musculoskeletal—rhabdomyolysis. • Nervous—neuronal damage, parenchymal hemorrhage, cerebral edema. • Renal/urologic—acute renal failure.

GEOGRAPHIC DISTRIBUTION

May occur in any climate but more common in warm and/or humid environments.

SIGNALMENT

Species

Dog and, uncommonly, cat.

Breed Predilections

• May occur in any breed. • Longhaired animals. • Brachycephalic breeds.

Mean Age and Range

• All ages but often age extremes. • Young dogs may tend to overexert. • Old dogs with preexisting disease.

SIGNS

Historical Findings

• Identifiable underlying cause—warm environmental conditions, locked in car or other confined area without adequate ventilation, grooming accident associated with drying cages, excessive exercise, restricted access to water. • Predisposing underlying disease—laryngeal paralysis, brachycephalic obstructive disease, cardiovascular disease, neuromuscular disease, previous history of heat-related disease.

Physical Examination Findings

• Panting. • Hypersalivation. • Hyperthermia. • Hyperemic mucous membranes. • Pale mucous membranes. • Cyanosis. • Tachycardia. • Cardiac dysrhythmias. • Shock. • Respiratory distress. • Hematemesis. • Hematochezia. • Melena. • Petechiation. • Changes in mentation. • Seizures. • Muscle tremors. • Ataxia. • Coma. • Oliguria/anuria. • Respiratory arrest. • Cardiopulmonary arrest.

CAUSES

• Excessive environmental heat and humidity (may be due to weather conditions or accidents such as enclosed in unventilated room, car, or grooming dryer cage). • Upper airway disease. • Exercise. • Toxicosis (some compounds that lead to seizures, i.e., strychnine and metaldehyde). • Anesthesia (malignant hyperthermia).

RISK FACTORS

• Previous history of heat-related disease. • Age extremes. • Heat intolerance due to poor acclimatization. • Obesity. • Poor cardiopulmonary conditioning. • Hyperthyroidism. • Underlying cardiopulmonary disease. • Brachycephalic breeds. • Thick hair coat. • Dehydration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• If temperature exceeds 106 °F (41.1 °C) without evidence of inflammation should consider heat stroke. • Panting and hypersalivation may not be seen with true fever as hypothalamic set point has been raised.

CBC/BIOCHEMISTRY/URINALYSIS

• May help identify underlying disease process and/or sequelae to hyperthermia. • CBC abnormalities may include stress leukogram, leukopenia, anemia, nucleated red blood cells, thrombocytopenia, or hemoconcentration. • Biochemistry profile may show azotemia, hyperalbuminemia, elevations in serum enzymes (alanine aminotransferase, aspartate aminotransferase, creatine kinase), hypernatremia, hyperchloremia, hyperglycemia, hypoglycemia, hyperphosphatemia, hyperkalemia, hypokalemia, hyperbilirubinemia. • Urinalysis may show hypersthenuria, proteinuria, cylindruria, hemoglobinuria, myoglobinuria.

OTHER LABORATORY TESTS

• Blood gas analysis may show mixed acid-base disorder, respiratory alkalosis, or metabolic acidosis. • Lactate concentrations may be elevated due to impaired perfusion. • Coagulation profile may indicate prolonged activated clotting time (ACT), prothrombin time (PT), or partial thromboplastin time (PTT); fibrin degradation products (FDP) or D-dimers may be positive; DIC may be present if PT and PTT are prolonged along with positive FDPs or D-dimers and thrombocytopenia; if available measurement of antithrombin may be valuable. • Thromboelastography may document hyper- or hypocoagulability.

IMAGING

• Thoracic/abdominal radiographs and/or ultrasound may help identify underlying cardiopulmonary disease or predisposing factors. • CT or MRI may help identify hypothalamic lesion.

DIAGNOSTIC PROCEDURES

Continuous temperature monitoring.

TREATMENT

• Early recognition is key. • Immediate correction of hyperthermia—spray with water or immerse in water prior to transport to veterinary facility; convection cooling with fans; evaporative cooling such as alcohol on foot pads, axilla, and groin. • Stop cooling procedures when temperature reaches 103 °F (39.4 °C) to avoid hypothermia. • Oxygen supplementation via oxygen cage, mask, or nasal catheter. • Airway management in cases of laryngeal paralysis or edema. • Ventilatory support if required. • Fluid support with shock doses of crystalloids or colloids. • Treat complications, seizures, DIC, renal injury, cerebral edema. • Treat underlying disease or correct predisposing factors.

APPROPRIATE HEALTH CARE

• Patients should be hospitalized until temperature is stabilized. • Most patients need intensive care for several days.

NURSING CARE

• External cooling—try to avoid ice as this may cause peripheral vasoconstriction and impede heat elimination; shivering response is also undesirable as this creates heat. • Fluid therapy—isotonic crystalloids can be administered at shock rates (dogs: 90 ml/kg/h; cats: 45–60 mL/kg/h) based on clinical assessment; synthetic colloids may also be

HEAT STROKE AND HYPERTHERMIA (CONTINUED)

used to treat shock (dogs: 20 mL/kg, 5 mL/kg IV boluses; cats: 5–10 mL/kg, 1–2 mL/kg boluses). • Oxygen supplementation—can be administered via mask, cage, or nasal cannula.

ACTIVITY
Restricted

DIET
Nil PO until animal is stable.

H

CLIENT EDUCATION
• Be aware of clinical signs. • Know how to cool off animals. • Seek veterinary care immediately. • An episode of heat stroke may predispose pets to additional episodes.

SURGICAL CONSIDERATIONS
Tracheostomy may be required if upper airway obstruction is underlying cause or contributing factor.

MEDICATIONS

DRUG(S) OF CHOICE
• No specific drugs for hyperthermia or heat stroke; therapy dependent on clinical presentation. • Prophylactic broad-spectrum antimicrobials may decrease incidence of bacterial translocation; first-generation cephalosporins or potentiated penicillins (clavulanate/amoxicillin, sulbactam/ampicillin) in combination with fluoroquinolones provide excellent four-quadrant coverage. • Acute renal failure—dopamine CRI (2–5 µg/kg/min), furosemide (2–4 mg/kg IV PRN), mannitol 0.5–1 g/kg as slow IV/CRI. • Cerebral edema—mannitol (1 g/kg IV over 15–30 min), furosemide (1 mg/kg IV) 30 min following mannitol infusion, corticosteroids: dexamethasone sodium phosphate (1–2 mg/kg IV), prednisone sodium succinate (10–20 mg/kg IV), methyl prednisolone (15 mg/kg IV); see Contraindications. • Ventricular arrhythmia—lidocaine bolus (2 mg/kg IV) followed by CRI (25–75 µg/kg/min); procainamide (6–8 mg/kg IV). • Metabolic acidosis—sodium bicarbonate (0.3 × BW [kg] × base excess) give ⅓ to ½ as IV bolus. • DIC—fresh frozen plasma (20 mL/kg); heparin doses vary widely (300–500 U/kg SC q 6–8h). • Thrombocytopenia—severe thrombocytopenia with active bleeding can be treated with fresh whole blood, platelet-rich plasma, lyophilized platelets, or frozen platelet concentrate. • Hematochezia or melena—broad-spectrum antibiotics, H2-antagonists, or proton pump inhibitors in combination with sucralfate. • Seizures—diazepam (0.5–1 mg/kg IV) or midazolam; phenobarbital (6 mg/kg IV PRN).

CONTRAINDICATIONS
• Nonsteroidal anti-inflammatory agents are not indicated in nonpyrogenic hyperthermia because the hypothalamic set point is not altered. • Corticosteroid use considered controversial in heat stroke due to possible adverse effects.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

PATIENT MONITORING
• Patients should be closely monitored during cooling-down period and for a minimum of 24 hours post episode; most animals must be monitored for several days depending on clinical presentation and clinical complications. • Thorough physical examination should be performed daily; in addition the following parameters should be given consideration: ○ Body temperature. ○ Body weight. ○ Blood pressure. ○ Central venous pressure. ○ ACT. ○ PT/PTT. ○ D-dimers. ○ ECG. ○ Thoracic auscultation. ○ Urinalysis and urine output. ○ Packed cell volume, total protein. ○ CBC, biochemical profile. ○ Venous blood gas analysis (electrolytes, lactate).

POSSIBLE COMPLICATIONS
• Cardiac dysrhythmias. • Organ failure. • Coma. • Seizures. • Acute renal failure. • DIC. • SIRS. • Sepsis/septic shock. • Pulmonary edema—acute respiratory distress syndrome (ARDS). • Rhabdomyolysis. • Hepatocellular necrosis. • Respiratory arrest. • Cardiopulmonary arrest.

EXPECTED COURSE AND PROGNOSIS
• Depends on underlying cause or disease process. • Prognosis may depend on time lag between event and hospital admission. • Prognosis is guarded—dependent on complications (renal failure and DIC) and duration of episode. • May predispose animal to further episodes due to damage to thermoregulatory center.

MISCELLANEOUS

SYNONYMS
• Heat exhaustion. • Heat prostration. • Heat-related disease. • Heat stroke.

SEE ALSO
Fever

ABBREVIATIONS
• ACT = activated clotting time. • ARDS = acute respiratory distress syndrome. • DIC = disseminated intravascular coagulation. • FDP = fibrin degradation products. • PT = prothrombin time. • PTT = partial thromboplastin time. • SIRS = systemic inflammatory response syndrome.

HELICOBACTER SPP.

BASICS

DEFINITION
Helicobacter spp. are microaerophilic, Gram-negative, urease-positive bacteria ranging in shape from coccoid to curved to spiral.

PATHOPHYSIOLOGY

Helicobacter *spp. in the Stomach*
• The association of *Helicobacter pylori* with gastritis, peptic ulceration, and gastric neoplasia fundamentally changed understanding of gastric disease in humans. • Putative mechanisms by which *H. pylori* alters gastric physiology in humans include disruption of gastric mucosal barrier and alteration of gastric secretory activity. • *H. pylori* in humans has been associated with increased secretion of proinflammatory cytokines and nitric oxide. • Several *Helicobacter* spp. other than *H. pylori* have been isolated from stomachs of dogs and cats; typically, multiple species are present. • A possible cause–effect relationship of *Helicobacter* spp. and gastric inflammation in cats and dogs remains unresolved; inflammation or glandular degeneration accompanies infection in some but not all. • Experiments to determine pathogenicity of *H. pylori* in specific pathogen free (SPF) cats and *H. pylori* and *H. felis* in gnotobiotic dogs demonstrated gastritis, lymphoid follicle proliferation, and humoral immune responses after infection.

Helicobacter *Spp. in the Liver and Intestines*
• Role in intestinal and hepatic disease is unclear. • Several *Helicobacter*-like organisms (HLOs) have been identified in large intestine and feces from normal and diarrheic dogs and cats. • *H. canis* has been isolated from liver of a dog with active, multifocal hepatitis.

SYSTEMS AFFECTED
Gastrointestinal (GI)—*Helicobacter* spp. may lead to gastritis in some dogs and cats, diarrhea in some dogs with *H. canis*, possible acute hepatitis.

GENETICS
N/A

INCIDENCE/PREVALENCE

Gastric Helicobacter *spp.*
• Gastric HLOs are prevalent in dogs and cats—86–90% of clinically healthy cats, 67–86% of clinically healthy pet dogs. • HLOs demonstrated in gastric biopsy specimens in 57–76% of cats and 61–82% of dogs presented for investigation of recurrent vomiting. • To date *H. pylori* has been identified only in a single colony of laboratory cats.

Enterohepatic Helicobacter *spp.*
• *H. canis* isolated in 4% of 1,000 dogs evaluated. • A single case of *H. canis*–associated hepatitis reported in 2-month-old puppy. • Prevalence of *H. fennelliae* and *H. cinaedi* undetermined.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
Dog and cat.

Mean Age and Range
Gastric infection acquired at a young age.

SIGNS

Historical Findings
• Asymptomatic presence of *Helicobacter* spp. common. • Vomiting, anorexia, abdominal pain, weight loss, and/or borborygmus have all been reported in dogs and cats with gastric *Helicobacter* spp. • *H. canis* in dogs may be associated with diarrhea. • Vomiting, weakness, and sudden death reported in puppy with hepatic *H. canis*.

Physical Examination Findings
• Usually unremarkable. • Dehydration due to vomiting or diarrhea.

CAUSES

Gastric Helicobacter *spp.*
• *H. felis*, *H. heilmannii*, and *H. baculiformis* have been identified in cats. • *H. felis*, *H. bizzozeronii*, *H. salomonis*, *H. heilmannii*, *H. bilis*, *H. cynogastricus*, and *Flexispira rappini* identified in dogs.

Enterohepatic Helicobacter *spp.*
• *H. bilis*, *H. canis*, *H. cinaedi*, and *Flexispira rappini* identified in feces from normal and diarrheic dogs. • *H. cinaedi* identified in one cat; its significance is unknown. • *H. canis* reported in one dog with acute hepatitis.

RISK FACTORS
Poor sanitary conditions and overcrowding may facilitate spread.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• High prevalence of *Helicobacter* spp. in dogs and cats. Therefore, exclusion of other causes of gastric disease and a positive identification of *Helicobacter* spp. are crucial before a diagnosis of GI disease due to *Helicobacter* spp. can be suspected. • Gastric helicobacteriosis—distinguish from other causes of vomiting. • Intestinal helicobacteriosis—distinguish from other causes of diarrhea. • Hepatic helicobacteriosis—distinguish from other causes of hepatobiliary disease.

CBC/BIOCHEMISTRY/URINALYSIS
• May reflect fluid and electrolyte abnormalities secondary to vomiting and/or diarrhea. • May indicate hepatic disease in patients with *H. canis*–associated hepatitis.

OTHER LABORATORY TESTS
• Examination of impression smears of gastric mucosa or gastric washings using May-Grünwald-Giemsa, Gram, or Diff-Quik® stain is sensitive for *Helicobacter* spp.; cannot distinguish between different HLOs. • Rapid urease test—requires gastric biopsy specimen. • ^{13}C-urea breath or blood test reliable in identifying infected dogs; not commercially available. • Bacterial culture requires special techniques and media and is impractical. • PCR of DNA extracted from biopsy specimens or from gastric juice. • Serologic tests (ELISA) measure circulating immunoglobulin (Ig) G in serum; cannot distinguish between HLOs. • Histopathology enables definitive diagnosis of infection, but cannot distinguish between different HLOs.

IMAGING
Abdominal radiography, ultrasonography usually normal.

DIAGNOSTIC PROCEDURES
• Gastric helicobacteriosis—in cases of *Helicobacter* spp.–associated gastritis, endoscopy may reveal superficial nodules that suggest hyperplasia of lymphoid follicles, diffuse gastric rugal thickening, punctate hemorrhages, erosions. • Hepatic helicobacteriosis—hepatic biopsy/histopathology (Warthin-Starry staining) and culture.

PATHOLOGIC FINDINGS
• Identification of HLOs requires special staining of tissue samples with Warthin-Starry or modified Steiner stain; routine H&E staining may reveal larger HLOs, but smaller organisms are often missed. • In cases of *Helicobacter* spp.–associated gastric disease—lymphocytic-plasmacytic gastritis and lymphoid follicle hyperplasia; rarely neutrophilic infiltrates; gastric ulcers have not been reported in dogs and cats. • In cases of *H. canis*–associated hepatitis—hepatocellular necrosis; infiltration of hepatic parenchyma with mononuclear cells, and spiral-shaped to curved bacteria predominantly in biliary canaliculi.

TREATMENT

APPROPRIATE HEALTH CARE
• Pathogenicity of *Helicobacter* spp. in dogs and cats is unclear; therefore, there are no generally accepted guidelines for treatment of HLO infections in dogs and cats. • Currently there is no indication for treating asymptomatic infected animals. • Eradication of gastric HLO should only be considered in infected dogs and cats that have compatible clinical signs that cannot be attributed to another disease process.

NURSING CARE
Fluid therapy in dehydrated patients.

HELICOBACTER SPP. (CONTINUED)

DIET
Easily digestible diets in patients with GI disease signs.

CLIENT EDUCATION
Explain difficulty of establishing a definitive diagnosis, high prevalence of infections with HLOs in normal dogs and cats, potential for recurrence, and zoonotic potential, though minimal, of these infections.

MEDICATIONS
• A triple therapy (combination of two antibiotics and one antisecretory drug) is effective in humans with *H. pylori* infection, with cure rates of approximately 90%. • Combination therapy may eliminate *Helicobacter* spp. infections in dogs and cats less effectively than in humans. • Treat for 2–3 weeks.

DRUG(S) OF CHOICE

Antibiotics (Two Antibiotics with One Antisecretory Agent)
• Clarithromycin (dogs: 5 mg/kg PO q12h; cats: 62.5 mg/cat PO q12h). • Metronidazole (dogs: 11–15 mg/kg PO q12h; cats: 12.5 mg/kg PO q12h). • Amoxicillin (22 mg/kg PO q12h). • Azithromycin (5 mg/kg PO q24h). • Tetracycline (20 mg/kg PO q8h). • Bismuth subsalicylate has mucosal protectant, anti-endotoxemic, and weak antibacterial properties; it remains unclear which property is responsible for its beneficial effects in HLO infections (0.22 mL/kg of 130 mg/15 mL solution of Pepto-Bismol PO q4–6h).

Antisecretory Agents (One with Two Antibiotics)
• Omeprazole (0.7–1 mg/kg PO q12h).
• Famotidine (0.5 mg/kg PO q12–24h).
• Ranitidine (1–2 mg/kg PO q12h).

Intestinal and Hepatic Helicobacter *spp. in Dogs*
Combination of amoxicillin and metronidazole may be effective.

CONTRAINDICATIONS
Hypersensitivity to drug therapy.

ALTERNATIVE DRUG(S)
Patients with HLO infections and gastritis that do not respond to antibiotic therapy usually are given immunosuppressive therapy for inflammatory bowel disease with gastric involvement.

FOLLOW-UP

PATIENT MONITORING
• Serologic tests not useful to confirm eradication of gastric HLOs—serum IgG titers may not decrease for up to 6 months after infection cleared. • If vomiting persists or recurs after cessation of combination therapy, endoscopic biopsy to determine whether infection has been successfully eradicated indicated.

PREVENTION/AVOIDANCE
Avoid overcrowding and poor sanitation.

EXPECTED COURSE AND PROGNOSIS
• Efficacy of therapeutic regimens currently employed in dogs and cats for eradicating *Helicobacter* spp. infections is questionable. • Metronidazole (20 mg/kg PO q12h), amoxicillin (20 mg/kg PO q12h), and famotidine (0.5 mg/kg PO q12h) for 14 days eradicated *Helicobacter* spp. in 6 of 8 dogs when evaluated 3 days post treatment; all dogs were recolonized by day 28 after treatment. • Clarithromycin (30 mg/cat PO q12h), metronidazole (30 mg/cat PO q12h), ranitidine (20 mg/cat PO q12h), and bismuth subsalicylate (40 mg PO q12h) for 4 days were effective in eradicating *H. heilmannii* in 11 of 11 cats by 10 days; 2 cats were reinfected 42 days post treatment. • Amoxicillin (20 mg/kg PO q8h), metronidazole (20 mg/kg PO q8h), and omeprazole (0.7 mg/kg PO q24h) for 21 days transiently eradicated *H. pylori* in 6 cats; all were reinfected 6 weeks post treatment. (*Note:* this dose of metronidazole has potential for toxicity.)

MISCELLANEOUS

ASSOCIATED CONDITIONS
Other gastric diseases.

AGE-RELATED FACTORS
Gastric HLOs appear to be acquired at a young age.

ZOONOTIC POTENTIAL
• High prevalence of *Helicobacter* spp. in dogs and cats raises the possibility that household pets may serve as a reservoir for transmission of *Helicobacter* spp. to human beings. • *H. pylori*, *H. heilmannii*, and *H. felis* have been isolated from humans with gastritis. • *H. fennelliae* and *H. cinaedi* have been isolated from immunocompromised humans with proctitis and colitis. • *H. cinaedi* and *H. canis* have been associated with septicemia in humans. • *H. pylori* has not been identified in pet dogs or cats.

PREGNANCY/FERTILITY/BREEDING
Avoid metronidazole and tetracycline in pregnant animals.

SYNONYMS
• Gastric spiral bacterial. • Gastrospirillum.

SEE ALSO
• Gastritis, Chronic.
• Vomiting, Chronic.

ABBREVIATIONS
• GI = gastrointestinal.
• HLO = *Helicobacter*-like organism.
• Ig = immunoglobulin.
• SPF = specific pathogen free.

Client Education Handout available online

HEMANGIOPERICYTOMA

BASICS

OVERVIEW

• A soft tissue sarcoma (STS) arising around blood vessels in subcutaneous tissue. • Also known as perivascular wall tumor. • Locally invasive—microscopic disease often extending beyond gross visible tumor margins.
• Metastasizes in less than 15% of patients with grade I/II (low/intermediate-grade) STS and less than 44% of patients with grade III (high-grade) STS.

SIGNALMENT

• Common in dogs, rare in cats. • More common in large-breed than small-breed dogs. • Middle-aged to older dogs and cats.

SIGNS

Historical Findings

• Typically, slow-growing, nonpainful, fluctuant to firm mass (weeks to months).
• Rapid growth uncommon unless high-grade or associated with hemorrhage. • Local tumor growth can interfere with limb function.

Physical Examination Findings

• Subcutaneous soft tissue mass, more frequently located on extremity than on trunk. • Soft, fluctuant, or firm.
• Nonpainful unless ulcerated or invading into deeper structures (muscle, nerve, bone).
• Generally adhered to underlying tissue.
• Regional lymph node metastasis uncommon.

CAUSES & RISK FACTORS

Large-breed dogs at increased risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other sarcomas such as fibrosarcoma, peripheral nerve sheath tumor, myxosarcoma, malignant fibrous histiocytoma, histiocytic sarcoma, hemangiosarcoma. • Lipoma and other subcutaneous tumors—benign and malignant.

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal.

IMAGING

• Thoracic radiographs recommended before treatment, although metastasis uncommonly identified. • Contrast-enhanced CT or MRI may be recommended to determine local extent of disease and optimize surgical treatment and radiation therapy planning.

DIAGNOSTIC PROCEDURES

• Fine-needle aspiration and cytology may provide tentative diagnosis, though cells do not exfoliate well given mesenchymal origin.
• Incisional biopsy and histopathology may be used to confirm diagnosis, determine grade of tumor, and plan treatment approach. • Immunohistochemistry evaluation of biopsy can aid in differentiation from other mesenchymal tumors. • Regional lymph node evaluation (cytology or histopathology) appropriate for high-grade tumors or if regional lymphadenomegaly detected.

TREATMENT

Surgical Considerations

• Early, aggressive, en bloc surgical excision is treatment of choice. • Microscopically, cancer cells extend beyond gross tumor borders.
• Pseudocapsule composed of compressed cancer cells is common. • Excise tumor en bloc; if peeled out, healthy bed of cancer cells (pseudocapsule) is left as residual disease.
• Submit entire sample to pathologist for surgical margin evaluation; applying ink to surgical borders is advised. • Limb amputation may be necessary with tumors affecting appendicular extremities that may be otherwise unresectable. • Rib resection or abdominal wall resection may be required for tumors of trunk.

Radiation Therapy Considerations

• Adjuvant radiation therapy should be considered following either planned marginal resection or unplanned incomplete resection. • Radiation therapy most effective when directed at microscopic disease—either preoperatively or as postoperative full-course fractionated protocol. • As single modality treatment for macroscopic disease, radiation therapy considered palliative—may be used to decrease pain and slow tumor growth.

MEDICATIONS

DRUG(S) OF CHOICE

• Doxorubicin-based chemotherapy not consistently reported as beneficial, but remains recommended after excision of high-grade (grade III) tumor. • Low-dose chemotherapy (metronomic) with piroxicam and cyclophosphamide may help delay local recurrence when sarcoma incompletely resected. • Novel therapeutic options may be available—contact veterinary oncologist for potential updated treatments. • Analgesic therapy should be administered as needed if pain or discomfort present.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

• If complete surgical resection achievable and tumor categorized as low-grade, tumor regrowth or metastases unlikely and continued patient monitoring may not be necessity. • If surgical resection incomplete or tumor categorized as high-grade, further treatment should be considered and patient should be monitored for local regrowth and distant metastases, with repeat physical exam and thoracic radiographs every 3 months.

EXPECTED COURSE AND PROGNOSIS

• Local recurrence, metastasis, and overall survival time greatly affected by surgical margin assessment and histological grade. • Cure from disease possible when surgery aggressive and surgical margins tumor-free, especially with grade I and II tumors—median survival approaches 2 years with low-grade (I) STSs of extremities treated with surgery alone. • Local recurrence considered inevitable if treatment not aggressive; increased risk for metastatic disease especially with high-grade (III) tumors. • Long-term tumor control with radiation therapy after surgically debulking tumor gives 1–5-year control rates of 60–85%. • Incomplete surgical excision should be managed with either second aggressive surgery or radiation therapy as soon as possible; low-dosage chemotherapy (metronomic) is another option.

MISCELLANEOUS

ABBREVIATIONS

• STS = soft tissue sarcoma.

HEMANGIOSARCOMA, BONE

BASICS

OVERVIEW

• A highly metastatic malignant tumor of endothelial cell precursors. • Primary bone hemangiosarcoma (HSA) is rare and accounts for <5% of all canine bone tumors. • Can arise from various appendicular and axial sites—hind limb more common (78% tibial origin); rib most common axial location.

SIGNALMENT

• Dogs, rarely cats. • Typically middle-aged to older dogs, older cats. • Predisposition for male dogs. • Golden retrievers, Labrador retrievers, and German shepherds predisposed.

SIGNS

• Appendicular: ○ Pain/lameness. ○ Soft tissue swelling/mass effect. ○ Pathologic fracture. ○ Axial: ○ Thoracic wall mass. ○ Hemothorax. ○ Spinal pain. ○ Myelopathy (from vertebral body collapse, spinal cord compression).

CAUSES & RISK FACTORS

• Dogs—genetic abnormalities including inactivation of the tumor suppressor gene *PTEN*; overexpression of growth and apoptosis-related proteins RB, cyclin D1, Bcl2, and survivin; and overexpression of angiogenic factors such as vascular endothelial growth factor (VEGF) and angiopoietins. • Cats—none identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• *Radiography*—lesions may appear similar to other primary or metastatic bone tumors or osteomyelitis (bacterial or fungal). • *Histopathology*—can be difficult to differentiate from telangiectatic subtype of osteosarcoma (OSA).

CBC/BIOCHEMISTRY/URINALYSIS

• Regenerative anemia. • Thrombocytopenia. • Neutrophilic leukocytosis.

IMAGING

• *Musculoskeletal radiography*—may reveal poorly marginated osteolytic lesion, often with minimal periosteal reaction; pathologic fractures possible; can be difficult to differentiate primary vs. metastatic lesions. • *Thoracic radiography*—used to screen for pulmonary metastasis, which typically appears as miliary to diffuse nodular pattern. • *Abdominal and cardiac ultrasonography*—used to screen for primary and metastatic visceral tumors (spleen, liver, heart). • *CT scan*—can better define extent of bone tumor for surgical excision (especially axial lesions), more sensitive screening for pulmonary metastasis.

DIAGNOSTIC PROCEDURES

• Excisional biopsy is preferred method for diagnosis. • Incisional biopsy may yield a diagnosis, but due to the vascular nature of the tumor, blood contamination within the specimen may preclude a diagnosis or prevent differentiation between HSA and telangiectatic OSA.

PATHOLOGIC FINDINGS

• *Gross findings*—a dark, friable mass often within the medullary cavity of the bone; metastasis can be multifocal, including lungs, spleen, liver, kidneys, muscle, peritoneum. • *Histopathology*—anaplastic mesenchymal cells arranged in chords forming vascular channels and spaces filled with red blood cells, thrombi, and necrotic debris.

TREATMENT

• Wide margin surgical excision is treatment of choice. • Amputation recommended for appendicular lesions. • Axial tumors may be more difficult to resect. • Palliative (hypofractionated) radiation therapy may be used to control pain and swelling. • Adjuvant doxorubicin chemotherapy is indicated due to high metastatic potential.

MEDICATIONS

DRUG(S) OF CHOICE

• Doxorubicin—dogs: 30 mg/m^2 IV >15 kg; 1 mg/kg IV <15 kg, q2–3 weeks for 5 cycles; cats: 1 mg/kg IV q3 weeks for 5 cycles. • Metronomic cyclophosphamide (12.5–15 mg/m^2 PO q24h) in combination with a nonsteroidal anti-inflammatory drugs (NSAID; e.g., piroxicam 0.3 mg/kg PO q24h) may be used concurrent to doxorubicin and/or as long-term maintenance therapy following doxorubicin. • Vincristine (0.5–0.7 mg/m^2) and cyclophosphamide (200–250 mg/m^2) q21 days can be used in rescue settings.

Alternative Drug(s)

• Bioactive extract (polysaccharide peptide) made from *Coriolus versicolor* mushroom may have benefit in dogs with HSA. • Chinese herbal remedy yunnan baiyao may have anti-bleeding and anti-neoplastic benefit for patients with has; however, was proven ineffective for HSA effusions.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Doxorubicin administration can lead to acute gastrointestinal, bone marrow, cardiac, renal, hypersensitivity, and extravasation toxicities. • Doxorubicin can lead to cumulative cardiotoxicity in dogs; dogs with preexisting cardiac disease or breeds at risk for dilated cardiomyopathy should be screened with echocardiogram/ECG before, during, and after treatment with doxorubicin. • Metronomic cyclophosphamide can lead to sterile hemorrhagic cystitis in ~22–58% of dogs, but risk can be significantly reduced (<10%) with use of concurrent furosemide. • NSAIDs can lead to gastrointestinal and liver/kidney toxicity.

FOLLOW-UP

PATIENT MONITORING

• Periodic physical examination, labwork, thoracic radiography, and abdominal ultrasonography during and after completion of therapy. • If treated with metronomic cyclophosphamide chemotherapy, monthly urinalysis recommended to screen for sterile hemorrhagic cystitis.

POSSIBLE COMPLICATIONS

• Pathologic fracture. • Bone lesions (esp. within rib) and visceral metastatic lesions may rupture, resulting in clinical signs related to effusion and/or anemia.

EXPECTED COURSE AND PROGNOSIS

• Aggressive disease with high risk for metastasis. • Less than 10% of patients survive 1 year following surgery alone. • Treatment with amputation and chemotherapy is associated with median overall survival of ~10 months (range: 4 months–2 years). • Younger age and more aggressive treatment are associated with longer survival.

MISCELLANEOUS

ABBREVIATIONS

• HSA = hemangiosarcoma. • NSAID = nonsteroidal anti-inflammatory drug. • OSA = osteosarcoma. • VEGF = vascular endothelial growth factor.

HEMANGIOSARCOMA, HEART

BASICS

OVERVIEW
• Highly metastatic malignant tumor of endothelial cell precursors • Most common cardiac tumor in dogs. • Can be primary or, less commonly, metastatic site. • Most tumors involve right atrium or right auricular appendage.

SIGNALMENT
• Dogs, rarely cats. • German shepherds, Labrador retrievers, golden retrievers predisposed. • Typically middle-aged to older animals. • Predisposition for male dogs.

SIGNS
• Signs most commonly related to pericardial effusion, cardiac tamponade, secondary right-sided congestive heart failure. • *Historical findings*—collapse, lethargy, weakness, exercise intolerance, anorexia, cough, dyspnea, vomiting. • *Physical examination findings*—muffled heart and lung sounds, arrhythmias, pulse deficits, pulsus paradoxus, pale mucous membranes, jugular vein distention, abdominal distension with effusion, hepatomegaly.

CAUSES & RISK FACTORS
Dogs—genetic abnormalities including inactivation of tumor suppressor gene *PTEN*; overexpression of growth and apoptosis-related proteins RB, cyclin D1, Bcl2, survivin; overexpression of angiogenic factors such as vascular endothelial growth factor (VEGF) and angiopoietins.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other cardiac neoplasia. • Idiopathic hemorrhagic pericardial effusion. • Other causes of right heart failure and arrhythmias.

CBC/BIOCHEMISTRY/URINALYSIS
• Regenerative anemia. • Thrombocytopenia. • Poikilocytosis—acanthocytes, schistocytes, spherocytes. • Neutrophilic leukocytosis.

OTHER LABORATORY TESTS
• Coagulation panel (prothrombin time [PT], partial thromboplastin time [PTT], D-dimers, fibrinogen)—criteria for disseminated intravascular coagulation (DIC) present in up to 50% of patients. • Plasma cardiac troponin (cTnI) levels elevated in dogs with pericardial effusion secondary to hemangiosarcoma (HSA) and can help differentiate from pericardial effusion not caused by HSA.

IMAGING
• *Thoracic radiography*—may reveal presence of globoid cardiac silhouette, pleural effusion, pulmonary metastasis, characterized by miliary to diffuse nodular pattern. • *Abdominal ultrasonography*—can screen for primary or metastatic hepatosplenic lesions, omental nodules, free abdominal fluid (hemoabdomen). • *Echocardiography*—useful for identifying and guiding removal of pericardial effusion and determining location and extent of tumor involvement (tumor better visualized when effusion present).

DIAGNOSTIC PROCEDURES
• Definitive diagnosis requires tissue biopsy. • Thoracoscopy can be used to perform pericardiectomy and obtain biopsies; thoracoscopic tumor resection also infrequently performed. • Cytologic evaluation of pericardial fluid rarely provides definitive diagnosis due to hemodilution and lack of tumor cell exfoliation. • ECG may reveal arrhythmias and electrical alternans.

PATHOLOGIC FINDINGS
• *Gross findings*—hemorrhagic friable mass in right side of heart; metastasis can be multifocal, including lungs, spleen, liver, kidneys, muscle, peritoneum. • *Histopathology findings*—anaplastic mesenchymal cells arranged in chords forming vascular channels and spaces filled with red blood cells, thrombi, necrotic debris.

TREATMENT

• Periodic pericardiocentesis can provide temporary symptomatic relief from cardiac tamponade. • Thoracoscopic pericardectomy (pericardial window) can be performed as palliative procedure to lower risk of life-threatening cardiac tamponade. • Surgical tumor excision provides best chance of long-term tumor control, but restricted to tumors on atrial appendage and/or small areas of right atrial wall. • Use of doxorubicin chemotherapy in measurable disease setting associated with >40% objective tumor response rate and provides clinical benefit in almost 70%.

MEDICATIONS

DRUG(S) OF CHOICE
• Doxorubicin (30 mg/m^2 IV for dogs >15 kg; 1 mg/kg IV for dogs <15 kg) q2–3 weeks for 5 cycles. • Metronomic cyclophosphamide (12.5–15 mg/m^2 PO q24h) in combination with nonsteroidal anti-inflammatory drug (NSAID; e.g., piroxicam 0.3 mg/kg PO q24h) may be used concurrent to or as alternative to doxorubicin.

Alternative Drug(s)
Bioactive extract (polysaccharide peptide) from *Coriolus versicolor* mushroom may have benefit in dogs with HSA.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
• Doxorubicin administration can lead to acute gastrointestinal, bone marrow, cardiac, renal, hypersensitivity, extravasation toxicities. • Doxorubicin can lead to cumulative cardiotoxicity in dogs; those with preexisting cardiac disease or at risk for dilated cardiomyopathy should be screened with echocardiogram/ECG before, during, and after treatment with doxorubicin. • Metronomic cyclophosphamide can lead to sterile hemorrhagic cystitis in ~22–58% of dogs, but risk can be significantly reduced (<10%) with use of concurrent furosemide. • NSAIDs can lead to gastrointestinal toxicity and liver/kidney toxicity.

FOLLOW-UP

PATIENT MONITORING
• Periodic physical examination, labwork, thoracic radiography, abdominal ultrasonography during and after completion of therapy. • If treated with metronomic cyclophosphamide chemotherapy, monthly urinalysis recommended to screen for sterile hemorrhagic cystitis.

EXPECTED COURSE AND PROGNOSIS
• Prognosis guarded to poor, high risk of acute death due to cardiac tamponade or fatal arrhythmias. • Median survival ~2 weeks without treatment, ~4 months with doxorubicin, possibly longer if tumor resection performed.

MISCELLANEOUS

ABBREVIATIONS
• cTnI = cardiac troponin. • DIC = disseminated intravascular coagulation. • HSA = hemangiosarcoma. • NSAID = nonsteroidal anti-inflammatory drug. • PT = prothrombin time. • PTT = partial thromboplastin time. • VEGF = vascular endothelial growth factor.

HEMANGIOSARCOMA, SKIN

BASICS

DEFINITION
- A highly metastatic malignant tumor of endothelial cell precursors.
- Primary tumor develops within dermal or subcutaneous/intramuscular tissues.
- Accounts for ~14% of all hemangiosarcomas (HSAs) in dogs.
- Metastatic risk dependent upon grade and location within the tissues (stage).
- Subcutaneous/intramuscular lesions may represent metastasis from a primary visceral tumor.

SIGNALMENT
- Dogs and cats.
- Pit bulls, boxers, and German shepherds.
- Dermal hemangiosarcoma—whippet, greyhound, and related breeds.
- Median age 9 years.

SIGNS

Dermal
- Firm, raised, dark nodules on the limbs, head, face, nasal planum, ears, ventral abdomen, and inguinal region.
- When caused by UV radiation, lesions often appear as multiple small blood blisters on the ventral abdomen/inguinal region.

Subcutaneous/Intramuscular
- Usually solitary lesions.
- Firm to fluctuant masses with associated discoloration and/or bruising from intratumoral bleeding.
- Pelvic limbs are commonly affected, but tumors may arise in any location.
- In cats—the flank, ventral abdomen, inguinal region, and cervical region are most commonly affected sites.

CAUSES & RISK FACTORS
- Dermal HSA is associated with UV radiation via induction of actinic keratosis, especially along the ventral abdomen/inguinal region in sparsely haired and lightly pigmented dogs that sunbathe.
- Subcutaneous HSA may be secondary to prior ionizing radiation therapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Trauma-induced subcutaneous hematoma.
- Other sarcomas.
- Mast cell tumor.

CBC/BIOCHEMISTRY/URINALYSIS
- Regenerative anemia.
- Thrombocytopenia.
- Neutrophilic leukocytosis.

OTHER LABORATORY TESTS
Coagulation panel (prothrombin time [PT], partial thromboplastin time [PTT], D-dimers, fibrinogen)—may see changes compatible with disseminated intravascular coagulation (DIC) if large, bleeding subcutaneous/intramuscular tumor.

IMAGING
- *Thoracic radiography*— used to screen for pulmonary metastasis, which typically appears as a miliary to diffuse nodular pattern.
- *Ultrasonography*—abdominal ultrasonography should be performed to screen for metastatic (or primary) hepatosplenic lesions, omental nodules, and free abdominal fluid (hemoabdomen); focal ultrasound of the mass may reveal cavitations.
- *Echocardiography*—can be used to identify right atrial masses.
- *Advanced imaging*—MRI/CT can be used for staging and surgical planning purposes, particularly for larger subcutaneous/intramuscular tumors.

DIAGNOSTIC PROCEDURES

Cytology
- Often unrewarding due to insufficient cell numbers and blood contamination.
- Neoplastic cells are spindle to stellate with anisocytosis and anisokaryosis, single round, oval, pleomorphic nuclei with prominent nucleoli, low nuclear cytoplasmic ratio, and moderate to abundant basophilic and usually vacuolated cytoplasm.

PATHOLOGIC FINDINGS
- *Gross findings*—well-circumscribed, blood blister–like lesions confined to the dermis or more invasive, poorly circumscribed hemorrhagic tumors within the subcutaneous and intramuscular space; metastasis can be multifocal including lungs, spleen, liver, kidneys, muscle, peritoneum.
- *Histopathologic findings*—anaplastic mesenchymal cells arranged in chords forming vascular channels and spaces filled with red blood cells, thrombi, and necrotic debris.
  - Allows differentiation between hemangioma and HSA and dermal versus subcutaneous/intramuscular origin.
  - Immunohistochemistry for von Willebrand factor (factor VIII–related antigen) or CD31/platelet endothelial cell adhesion molecule (PECAM) can be used to confirm endothelial cell origin.

Histologic Staging System
- Stage I—confined to dermis.
- Stage II—subcutaneous involvement.
- Stage III—intramuscular involvement.

TREATMENT
- Wide margin surgical excision is the treatment of choice.
- Definitive radiation therapy may be used for the control of microscopic residual disease (incomplete margins after resection of subcutaneous/intramuscular tumors).
- Palliative (hypofractionated) radiation may be used for treatment of nonresectable tumors and ~60% of patients will have a positive response for a median of 3 months.
- Doxorubicin chemotherapy has been associated with a moderate response rate (~40%) for a median of ~2 months, but in some cases may allow for complete tumor resection and longer remission/survival.
- Metronomic (daily low-dose) chemotherapy can be used to delay time to locoregional recurrence after surgery given its anti-angiogenic effect.

MEDICATIONS

DRUG(S) OF CHOICE
- Doxorubicin—dogs: 30 mg/m^2 IV >15 kg; 1 mg/kg IV <15 kg, q2–3 weeks for 5 cycles; cats: 1 mg/kg IV q3 weeks for 5 cycles.
- Metronomic cyclophosphamide (12.5–15 mg/m^2 PO q24h) in combination with a nonsteroidal anti-inflammatory drug (NSAID; e.g., piroxicam 0.3 mg/kg PO q24h) may be used concurrent to doxorubicin and/or as a long-term maintenance therapy following doxorubicin.
- Vincristine (0.5–0.7 mg/m^2) and cyclophosphamide (200–250 mg/m^2) q21 days can be used in rescue settings.

CONTRAINDICATIONS
- Doxorubicin administration can lead to acute gastrointestinal, bone marrow, cardiac, renal, hypersensitivity, and extravasation toxicities.
- Doxorubicin can lead to cumulative cardiotoxicity in dogs; dogs with preexisting cardiac disease or those breeds at risk for dilated cardiomyopathy should be screened with echocardiogram/ECG before, during, and after treatment with doxorubicin.
- Metronomic cyclophosphamide can lead to sterile hemorrhagic cystitis in ~22–58% of dogs, but the risk can be significantly reduced (<10%) with the use of concurrent furosemide.
- NSAIDs can lead to gastrointestinal and liver/kidney toxicity.

ALTERNATIVE DRUG(S)
- A bioactive extract (polysaccharide peptide) made from the *Coriolus versicolor* mushroom may have benefit in dogs with HSA.

• The Chinese herbal remedy yunnan baiyao may have anti-bleeding and anti-neoplastic benefit for patients with HSA; however, this was proven ineffective for HSA effusions.

FOLLOW-UP

PATIENT MONITORING

• Periodic physical examination, labwork, thoracic radiography, and abdominal ultrasonography during and after completion of therapy.
• If treated with metronomic cyclophosphamide chemotherapy, monthly urinalysis recommended to screen for sterile hemorrhagic cystitis.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Tumor hemorrhage.

EXPECTED COURSE AND PROGNOSIS

• Dermal HSA—prognosis very good with treatment; median survival time (MST) of 780–987 days for dogs undergoing surgery alone; disease-free interval >450 days for cats undergoing surgery alone.
• Higher risk of locoregional recurrence and distant metastasis with stage II (SC) and III (IM) HSA.
• Subcutaneous HSA—prognosis can be good with aggressive treatment; MST of 172 days for dogs undergoing surgery alone versus >1,100 days with surgery and adjuvant doxorubicin chemotherapy.
• Intramuscular HSA—MST of 272 days for dogs undergoing surgery and doxorubicin chemotherapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other UV-induced skin tumors such as squamous cell carcinoma.

PREGNANCY/FERTILITY/BREEDING

Chemotherapy drugs may be carcinogenic and mutagenic.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

Chemotherapy drugs may be carcinogenic and mutagenic.

ABBREVIATIONS

• DIC = disseminated intravascular coagulation.
• HSA = hemangiosarcoma.
• MST = median survival time.
• NSAIDs = nonsteroidal anti-inflammatory drugs.
• PECAM = platelet endothelial cell adhesion molecule.
• PT = prothrombin time.
• PTT = partial thromboplastin time.

HEMANGIOSARCOMA, SPLEEN AND LIVER

BASICS

DEFINITION
A highly metastatic malignant tumor of endothelial cell precursors.

PATHOPHYSIOLOGY
- Spleen is most common primary tumor location; liver is fourth most common location.
- Primary tumor rupture leads to acute hemorrhage, collapse, and often sudden death.
- Highly metastatic tumor that spreads early in the course of disease via hematogenous and intra-abdominal implantation routes.
- Metastasis can be to any organ including lungs, kidneys, muscle, peritoneum, omentum, lymph nodes, mesentery, adrenal glands, spinal cord, brain, subcutaneous tissue, and diaphragm.

SYSTEMS AFFECTED
- Cardiovascular.
- Hepatobiliary.
- Respiratory.
- Musculoskeletal.
- Nervous.
- Renal.

GENETICS
N/A

INCIDENCE/PREVALENCE
Accounts for 50–70% of all canine splenic tumors.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
- Dogs, rarely cats.
- German shepherd, Labrador retriever, golden retriever predisposed.
- Typically middle-aged to older animals.
- Possible slight predisposition for male dogs.

SIGNS
- *Historical findings*—can be variable and include weakness, lethargy, dyspnea, cough, inappetance, and weight loss.
- *Physical examination findings*—pale mucous membranes, arrhythmias, tachypnea, abdominal distension, and palpable cranial abdominal mass.

CAUSES
N/A

RISK FACTORS
- Dogs—genetic abnormalities including inactivation of the tumor suppressor gene *PTEN*; overexpression of growth and apoptosis-related proteins RB, cyclin D1, Bcl2, and survivin; and overexpression of angiogenic factors such as vascular endothelial growth factor (VEGF), endothlein-1, and angiopoietins.
- Cats—none identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Anticoagulant rodenticide ingestion.
- Other splenic and hepatic masses—hematoma, hemangioma, hepatoma, lymphoma, leiomyosarcoma, liposarcoma, splenic cyst, hepatocellular carcinoma, hepatic cyst, hepatic abscess.

CBC/BIOCHEMISTRY/URINALYSIS
- Regenerative anemia with nucleated red blood cells.
- Poikilocytosis—acanthocytes, schistocytes, spherocytes.
- Thrombocytopenia.
- Neutrophilic leukocytosis.
- Elevated liver enzymes.

OTHER LABORATORY TESTS
Coagulation panel (prothrombin time [PT], partial thromboplastin time [PTT], D-dimers, fibrinogen)—criteria for disseminated intravascular coagulation (DIC) present in up to 50% of patients.

IMAGING

Radiography
- Abdominal radiographs may identify a cranial abdominal mass and loss of serosal detail consistent with peritoneal effusion.
- Thoracic radiographs are used to screen for pulmonary metastasis, which typically appears as a miliary to diffuse nodular pattern.

Ultrasonography
- Abdominal ultrasonography is used for the detection of hepatosplenic lesions, omental nodules, and free abdominal fluid (hemoabdomen).
- Echocardiography is used to identify right atrial masses (better visualized when pericardial effusion is present).

Advanced Imaging
- MRI/CT provide high sensitivity and specificity in determining benign from malignant processes of the liver and spleen; more sensitive method of screening for metastasis.

DIAGNOSTIC PROCEDURES
- *Abdominocentesis*—usually a serosanguineous or hemorrhagic nonclotting effusion; can compare packed cell volume (PCV) of effusion to peripheral blood PCV to confirm hemorrhage.
- *Cytology*—often unrewarding due to insufficient cell numbers and blood contamination; neoplastic cells are spindle to stellate with anisocytosis and anisokaryosis, single round, oval, pleomorphic nuclei with prominent nucleoli, low nuclear cytoplasmic ratio, and moderate to abundant basophilic and usually vacuolated cytoplasm.

PATHOLOGIC FINDINGS
- *Gross findings*—solitary or multiple hemorrhagic, friable masses or nodules within the spleen and/or liver.
  - Stage I—tumor confined to one organ, no rupture.
  - Stage II—ruptured tumor.
  - Stage III—measurable metastatic disease.
- *Histopathology findings*— anaplastic mesenchymal cells arranged in chords forming vascular channels and spaces filled with red blood cells, thrombi, and necrotic debris; immunohistochemistry for von Willebrand factor (factor VIII–related antigen) or CD31/platelet endothelial cell adhesion molecule (PECAM) can be used to confirm endothelial cell origin.

TREATMENT

APPROPRIATE HEALTH CARE
- Balanced isotonic electrolyte solutions ± colloids to correct hypovolemic shock and reduced cardiac output.
- Fresh whole blood or packed red blood cell transfusions to replace reduced oxygen-carrying capacity lost by acute hemorrhage.
- Fresh frozen plasma if coagulopathy or signs of DIC present.

NURSING CARE
N/A

ACTIVITY
N/A

DIET
N/A

CLIENT EDUCATION
N/A

SURGICAL CONSIDERATIONS
- Splenectomy or liver lobectomy is the standard of care surgical procedure and initial treatment of choice; removes macroscopic tumor burden and lessens the ongoing risk of acute death from hemorrhage.
- The use of adjuvant doxorubicin-based chemotherapy has been consistently shown to improve remission duration and survival times.
- Adjuvant metronomic chemotherapy appears to prolong survival vs. surgery alone. Added benefit when given concurrent to or following doxorubicin chemotherapy remains unclear.

MEDICATIONS

DRUG(S) OF CHOICE
- Doxorubicin (30 mg/m^2 IV for dogs >15 kg, 1 mg/kg IV for dogs <15 kg, q2–3 weeks for 5 cycles) alone or as part of a

protocol with weekly vincristine (0.5–7 mg/m^2 IV) and cytoxan (250 mg/m^2 PO) or dacarbazine (200–250 mg/m^2 IV q24h for 5 days or 600–1000 mg/m^2 IV bolus q3 weeks)
• Metronomic cyclophosphamide (12.5–15 mg/m^2 PO q24h) in combination with a nonsteroidal anti-inflammatory drug (NSAID; e.g., piroxicam 0.3 mg/kg PO q24h) may be used concurrent to or as an alternative to doxorubicin.

CONTRAINDICATIONS
N/A

PRECAUTIONS
• Doxorubicin administration can lead to acute gastrointestinal, bone marrow, cardiac, renal, hypersensitivity, and extravasation toxicities.
• Doxorubicin can lead to cumulative cardiotoxicity in dogs; those with preexisting cardiac disease or breeds at risk for dilated cardiomyopathy should be screened with echocardiogram/ECG before, during, and after treatment with doxorubicin.
• Vincristine and dacarbazine administration can lead to acute gastrointestinal, bone marrow, and extravasation toxicities
• Metronomic cyclophosphamide can lead to sterile hemorrhagic cystitis in ~22–58% of dogs, but the risk can be significantly reduced (<10%) with the use of concurrent furosemide.
• NSAIDs can lead to gastrointestinal toxicity and liver/kidney toxicity.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
• A bioactive extract (polysaccharide peptide) made from the *Coriolus versicolor* mushroom may have benefit in dogs with hemangiosarcoma (HSA).
• The Chinese herbal remedy yunnan baiyao may have anti-bleeding and anti-neoplastic benefit for patients with HSA; however, this was proven ineffective for HSA effusions.

FOLLOW-UP

PATIENT MONITORING
• Periodic physical examination, labwork, thoracic radiography, and abdominal ultrasonography during and after the completion of therapy.
• If treated with metronomic chemotherapy, routine monthly urinalysis recommended to screen for sterile hemorrhagic cystitis.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Death due to acute hemorrhage or fatal tachyarrhythmias.

EXPECTED COURSE AND PROGNOSIS
• Prognosis poor to grave.
• Less than 10% of dogs will live 1 year or longer from diagnosis.
• Median survival time with surgery alone (dogs): 1–3 months.
• Median survival time with surgery plus chemotherapy (dogs): 4.5–8 months.

MISCELLANEOUS

HEMATEMESIS

BASICS

DEFINITION
Vomiting of blood.

PATHOPHYSIOLOGY
A disruption in the gastric or upper small intestinal mucosal barrier leading to inflammation and bleeding. Coagulopathies can also present with hematemesis. An animal may also vomit blood that originated in the oral cavity or respiratory system and was swallowed.

SYSTEMS AFFECTED
• Gastrointestinal (GI)—inflammation, trauma, ulceration, neoplasia, and/or foreign body in oral cavity, pharyngeal area, esophagus, stomach, and/or duodenum. • Cardiovascular—acute, severe hemorrhage may result in tachycardia and hypotension. • Hematologic—coagulopathy with GI hemorrhage can lead to hematemesis. • Respiratory—respiratory hemorrhage with ingestion can lead to hematemesis.

GENETICS
N/A

INCIDENCE/PREVALENCE
Unknown

SIGNALMENT

Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
Any age.

Predominant Sex
Male dogs have increased incidence of gastric carcinoma.

SIGNS

Historical Findings
• Vomiting with blood, which may appear as fresh blood, blood clots, or digested blood (looks like coffee grounds). • Melena. • Anorexia. • Abdominal pain.

Physical Examination Findings
• Abdominal pain. • Melena. • If patient is anemic—tachycardia, heart murmur, pallor, weakness.

CAUSES

Coagulopathies
• Thrombocytopenia. • Thrombocytopathia. • Von Willebrand's disease. • Hyperviscosity syndrome. • Disseminated intravascular coagulation. • Anticoagulant rodenticide toxicity. • Coagulation factor deficiency. • Liver failure.

Drugs
Nonsteroidal anti-inflammatory drugs (NSAIDs), glucocorticoids, toceranib phosphate.

GI Diseases
• Inflammatory bowel disease. • Gastric or duodenal neoplasia. • Gastric or duodenal foreign body. • Gastric or intestinal volvulus. • Hemorrhagic gastroenteritis. • Gastroduodenal ulcer. • Gastroesophageal intussusception.

Toxicity
• Heavy metal poisoning (arsenic, zinc, thallium, iron, or lead). • Plant intoxication (dieffenbachia, sago palm, mushroom, castor bean). • Chemical intoxication (phenol, ethylene glycol, corrosive agents, psoriasis creams—vitamin D analogues). • Pesticide/rodenticide toxicity (cholecalciferol). • Snake bite. • Aflatoxins. • Bee sting.

Infectious Diseases
• GI parasitism. • Pythiosis. • Viral, fungal, or bacterial gastroenteritis. • Virulent systemic feline calicivirus. • Rickettsial infections.

Metabolic Diseases
• Renal failure. • Liver disease. • Hypoadrenocorticism. • Pancreatitis.

Neoplasia
• Mastocytosis. • Gastrinoma. • Oral, nasal, respiratory, or GI tumors. • Amine precursor uptake decarboxylase cells (APUDomas).

Neurologic Diseases
• Head trauma. • Spinal cord disease.

Respiratory Diseases
• Nasal disease. • Pulmonary disease. • Mediastinal neoplasia.

Stress/Major Medical Illness
• Shock. • Severe illness. • Burns. • Heat stroke. • Major surgery. • Sustained strenuous exercise. • Trauma. • Systemic hypertension. • Thromboembolic disease. • Hypotension.

RISK FACTORS
• Administration of ulcerogenic drugs. • Critically ill patients. • Shock. • Thrombocytopenia. • Concurrent administration of NSAIDs and glucocorticoids.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Hemoptysis—thoracic radiographs may reveal presence of pulmonary disease. • Regurgitation or vomiting of swallowed blood from extra-GI diseases (e.g., oropharyngeal, nasopharyngeal, cutaneous). • Vomiting materials that look like fresh or digested blood (e.g., oral iron).

CBC/BIOCHEMISTRY/URINALYSIS
• If acute (3–5 days) blood loss—nonregenerative anemia. • If blood loss >5–7 days in duration—regenerative anemia. • If chronic blood loss—iron-deficiency anemia (microcytic, hypochromic, variable reticulocytosis, with or without thrombocytosis). • ± thrombocytopenia. • ± panhypoproteinemia. • ± mature neutrophilia or left-shift neutrophilia with sepsis and/or gastroduodenal ulcer perforation. • Blood urea nitrogen (BUN) : creatinine ratio may be elevated with GI hemorrhage.

OTHER LABORATORY TESTS
• Fecal occult blood test—often false positive if not on nonmeat diet for 3 days prior to test. • Fecal flotation—screen for GI parasitism. • Coagulation profile—if coagulopathy is suspected. • Bile acids—if liver disease is suspected. • Adrenocorticotropic hormone (ACTH) stimulation—if hypoadrenocorticism suspected.

IMAGING
• Abdominal radiographs may identify gastric or duodenal foreign body or mass, pneumoperitoneum, effusion, or changes consistent with kidney, pancreas, or liver disease. • Thoracic radiographs may reveal esophageal foreign body or mass, gastroesophageal intussusception, mediastinal mass, pulmonary disease, or pulmonary metastasis. • Abdominal ultrasonography may identify gastric or duodenal mass, gastric or duodenal wall thickening or altered layering, gastric ulcer, and/or abdominal lymphadenopathy. • Abdominal ultrasonography can also screen for abnormalities in pancreas, liver, kidneys, and other abdominal organs as source of hematemesis. • GI scintigraphy may be used to localize blood loss.

DIAGNOSTIC PROCEDURES
• Endoscopy to evaluate mucosal appearance of esophagus, stomach, and upper small intestinal tract once extra-GI causes ruled out. • Capsule endoscopy may be useful to identify sites of GI hemorrhage. • Biopsy mucosal lesions to determine nature of underlying GI disease. • Abdominocentesis may identify septic peritonitis. • Fine-needle aspirates or biopsy of organs or masses to identify neoplasia/disease.

PATHOLOGIC FINDINGS
• Gastroduodenal inflammation and hemorrhage. • Ulcers may have necrosis, microthrombi, and hemorrhage.

TREATMENT

APPROPRIATE HEALTH CARE
• Treat underlying cause. • Outpatient—those in which the cause is identified and removed, vomiting is not excessive, and gastroduodenal bleeding is minimal. • Inpatients—those with severe gastroduodenal bleeding, ulcer perforation, excessive vomiting, and/or shock.

(CONTINUED) HEMATEMESIS

NURSING CARE
• IV fluids to maintain volume and hydration. • Hypoproteinemic patients may require colloids and/or albumin to increase oncotic pressure. • Anemic or coagulopathic patients may require transfusion. • In severe cases—to stop the GI bleeding, ice water lavage (10–20 mL/kg remaining in stomach for 15–30 min) or lavage with norepinephrine (8 mg/500 mL) diluted in ice water can be attempted.

ACTIVITY
Restriction is indicated until resolution.

DIET
• Discontinue oral intake if vomiting. • When feeding is resumed, feed small, frequent meals.

CLIENT EDUCATION
• NSAIDs should be administered to pets only under the guidance of a veterinarian. • NSAIDs and glucocorticoids should not be administered together. • Adverse effects of NSAIDs can be reduced by giving drug with food and concurrent administration of a synthetic prostaglandin E_1 analogue (e.g., misoprostol).

SURGICAL CONSIDERATIONS
Surgery is indicated if medical treatment fails after 5–7 days, hemorrhage is uncontrolled, gastroduodenal ulcer perforates, and/or potentially resectable tumor is identified.

MEDICATIONS

DRUG(S) OF CHOICE
• Proton pump inhibitors (PPIs)—most potent inhibitors of gastric acid secretion and treatment of choice for gastroduodenal ulcer (dog and cat: omeprazole 1 mg/kg PO q12h; pantoprazole or esomeprazole 1 mg/kg IV q12h - esomeprazole may be superior for first 72 hours of therapy. • Histamine (H2) receptor antagonists also inhibit gastric acid secretion (dog and cat: famotidine 0.5–1 mg/kg PO/IV q12–24h); famotidine with a loading dose of 1 mg/kg followed by 8 mg/kg IV CRI daily for 3 consecutive days may be superior to pantoprazole. • H2 receptor antagonists are less potent than PPIs. • Sucralfate suspension (dog and cat: 0.25–1 g PO q6–8h) protects ulcerated tissue by binding to ulcer sites, adsorbing pepsin and bile salts, and stimulating prostaglandin synthesis; binding is greater in duodenal than gastric ulcers. • Antibiotic(s) with activity against enteric Gram-negative bacteria and anaerobes should be given parenterally if a break in GI mucosal barrier is suspected or aspiration pneumonia is present. • Antiemetics—dog and cat: chlorpromazine 0.5 mg/kg q6–8h SC/IM/IV, prochlorperazine 0.1–0.5 mg/kg q6–8h SC/IM, ondansetron 0.2–0.5 mg/kg IV q12h, maropitant 1 mg/kg SC/IV q24h; dog: metoclopramide 1–2 mg/kg/24h CRI, administered if vomiting occurs frequently or results in significant fluid losses.

CONTRAINDICATIONS
Avoid ulcerogenic drugs such as NSAIDs and corticosteroids.

PRECAUTIONS
Continued famotidine therapy can lead to tachyphylaxis.

POSSIBLE INTERACTIONS
• H2 blockers prevent uptake of omeprazole by oxyntic cells. • Sucralfate may alter absorption of other drugs and should be given 2 hours before or after other oral drugs. • Antacids may alter oral absorption and renal elimination of other drugs.

ALTERNATIVE DRUG(S)
Misoprostol, synthetic prostaglandin analogue (3 µg/kg PO q12h) with antisecretory and cytoprotective actions helps prevent NSAID-induced ulcers. There may be some efficacy in treating gastroduodenal ulcerations from other causes.

FOLLOW-UP

PATIENT MONITORING
• Improvement in some cases may be assessed on resolution of clinical signs; packed cell volume, total protein, fecal occult blood, and BUN may help detect continued blood loss. • Depending on the underlying cause of the hematemesis, specific laboratory or imaging tests may be necessary to monitor response to therapy.

PREVENTION/AVOIDANCE
• Avoid gastric irritants (e.g., NSAIDs, corticosteroids). • Concurrent use of misoprostol or PPI with NSAIDs; PPIs may be preferable because they are therapeutic as well. • Administer NSAIDs with food. • Cyclooxygenase (COX)-2 selective or dual lipoxygenase/COX inhibitors may have fewer adverse GI effects than nonselective NSAIDs.

POSSIBLE COMPLICATIONS
• Anemia. • Hypovolemia. • Ulcer perforation. • Sepsis.

EXPECTED COURSE AND PROGNOSIS
• Varies with underlying cause. • Patients with malignant gastric neoplasia, renal failure, liver failure, pythiosis, systemic mastocytosis, sepsis, and/or gastric perforation—guarded to poor prognosis. • Hematemesis secondary to NSAID administration, coagulopathies, inflammatory bowel disease, or hypoadrenocorticism—prognosis may be good to excellent, depending on severity of disease. • Hematemesis secondary to heat stroke, toxicities, and snake bites can have variable prognoses.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Anemia

PREGNANCY/FERTILITY/BREEDING
Synthetic prostaglandins (e.g., misoprostol) cause abortion.

SEE ALSO
• Gastroduodenal Ulceration/Erosion. • Gastroenteritis, Acute Hemorrhagic Diarrhea Syndrome. • Melena.

ABBREVIATIONS
• ACTH = adrenocorticotropic hormone. • APUDoma = amine precursor uptake decarboxylase cells. • BUN = blood urea nitrogen. • COX = cyclooxygenase. • GI = gastrointestinal. • NSAID = nonsteroidal anti-inflammatory drug. • PPI = proton pump inhibitor.

HEMATURIA

BASICS

DEFINITION
Blood in urine.

PATHOPHYSIOLOGY
Secondary to loss of endothelial integrity in urinary tract, clotting factor deficiency, or thrombocytopenia/cytopathia.

SYSTEMS AFFECTED
• Renal/urologic. • Reproductive. • Hemic/lymphatic/immune.

SIGNALMENT
• Dog and cat. • Familial hematuria in young animals; neoplasia in older animals. • Females at greater risk for urinary tract infection (UTI).

SIGNS

Historical Findings
Red-tinged urine with or without pollakiuria.

Physical Examination Findings
• Palpable mass in patients with neoplasia.
• Abdominal pain in some patients.
• Enlarged and/or painful prostate gland in males. • Petechiae or ecchymoses in patients with coagulopathy.

CAUSES

Systemic
• Coagulopathy. • Thrombocytopenia.
• Vasculitis.

Upper Urinary Tract
• Anatomic—cystic kidney disease and familial malformations. • Metabolic—nephrolithiasis. • Neoplastic—renal lymphoma, adenocarcinoma, and hemangiosarcoma. • Infectious—leptospirosis, feline infectious peritonitis (FIP), and bacterial or fungal UTI.
• Inflammatory—glomerulonephritis.
• Idiopathic renal hematuria. • Trauma.

Lower Urinary Tract
• Anatomic—bladder malformations.
• Metabolic—uroliths. • Neoplasia—transitional cell carcinoma and lymphosarcoma.
• Infectious—bacterial, fungal, and viral UTI. • Idiopathic—cats (idiopathic cystitis).
• Traumatic. • Cyclophosphamide-induced hemorrhagic cystitis.

Genitalia
• Metabolic—estrus, benign prostatic hyperplasia. • Neoplastic—transmissible venereal tumor (TVT), leiomyoma, and prostatic adenocarcinoma. • Infectious—bacterial and fungal disease. • Inflammatory—prostatitis. • Trauma.

RISK FACTORS
Breed predisposed to urolithiasis, coagulopathy, or neoplasia.

DIAGNOSIS

See Figure 1.

DIFFERENTIAL DIAGNOSIS
Other causes of discolored urine (myoglobinuria, hemoglobinuria, and bilirubinuria).

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results
Substantial doses of vitamin C (ascorbic acid) may cause false-negative reagent test strip results; newer generations of reagent strips are more resistant to interference by reducing substances such as ascorbic acid.

Disorders That May Alter Laboratory Results
• Common urine reagent strip tests for blood are designed to detect red blood cells, hemoglobin, or myoglobin. • Low urine specific gravity (polyuric syndromes) lyses red blood cells (RBCs). • Bacteriuria (bacterial peroxidase) causes false-positive reagent test strip results. • Formalin preservative causes false-negative reagent test strip results.

Valid if Run in a Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
• Thrombocytopenia and severe anemia in some patients. • Azotemia in some patients with bilateral renal disease. • RBCs (>5–10 RBC/hpf) and possibly infectious agents seen in urine sediment. • Crystalluria in some patients with urolithiasis.

OTHER LABORATORY TESTS
• Coagulation testing to rule out coagulopathy.
• Bacterial culture of urine to identify UTI.
• Examination of ejaculate to identify prostatic disease.

IMAGING
Ultrasonography, radiography, and possibly contrast radiography are useful in localizing the underlying cause. Cystoscopy often required to diagnose renal hematuria.

DIAGNOSTIC PROCEDURES
• Biopsy of mass lesion.
• Vaginourethrocystoscopy in females or urethrocystoscopy in males and females.

TREATMENT

• Hematuria may indicate a serious disease process. • Urolithiasis and renal failure may require diet modification. • UTI may be associated with another disease that also requires treatment—local (e.g., neoplasia and urolithiasis) or systemic (e.g., hyperadrenocorticism and diabetes mellitus). • Renal hematuria may be treated via endoscopic sclerotherapy; nephrectomy should not be performed.

MEDICATIONS

DRUG(S) OF CHOICE
• Blood transfusion if patient is severely anemic. • Antibiotics to treat UTI and septicemia. • Heparin for disseminated intravascular coagulation (DIC).

CONTRAINDICATIONS
Immunosuppressive drugs, except to treat immune-mediated disease.

POSSIBLE INTERACTIONS
Intravenous contrast media may cause acute kidney injury.

FOLLOW-UP

PATIENT MONITORING
Depends on primary or associated diseases.

POSSIBLE COMPLICATIONS
• Anemia. • Hypovolemia if severe hemorrhage. • Ureteral or urethral obstruction due to blood clots.

MISCELLANEOUS

AGE-RELATED FACTORS
• Neoplasia tends to occur in older animals.
• Immune-mediated diseases tend to occur in young adult animals.

ZOONOTIC POTENTIAL
Leptospirosis

SEE ALSO
• Coagulation Factor Deficiency. • Crystalluria.
• Cylindruria. • Dysuria, Pollakiuria, and Stranguria. • Feline Idiopathic Lower Urinary Tract Disease. • Glomerulonephritis.
• Hemoglobinuria and Myoglobinuria.
• Lower Urinary Tract Infection, Bacterial.
• Lower Urinary Tract Infection, Fungal.
• Nephrolithiasis. • Prostatitis and Prostatic Abscess. • Prostatomegaly. • Proteinuria.
• Pyelonephritis. • Thrombocytopenia.

ABBREVIATIONS
• DIC = disseminated intravascular coagulation.
• FIP = feline infectious peritonitis. • RBC = red blood cell. • TVT= transmissible venereal tumor. • UTI = urinary tract infection.

(CONTINUED) HEMATURIA

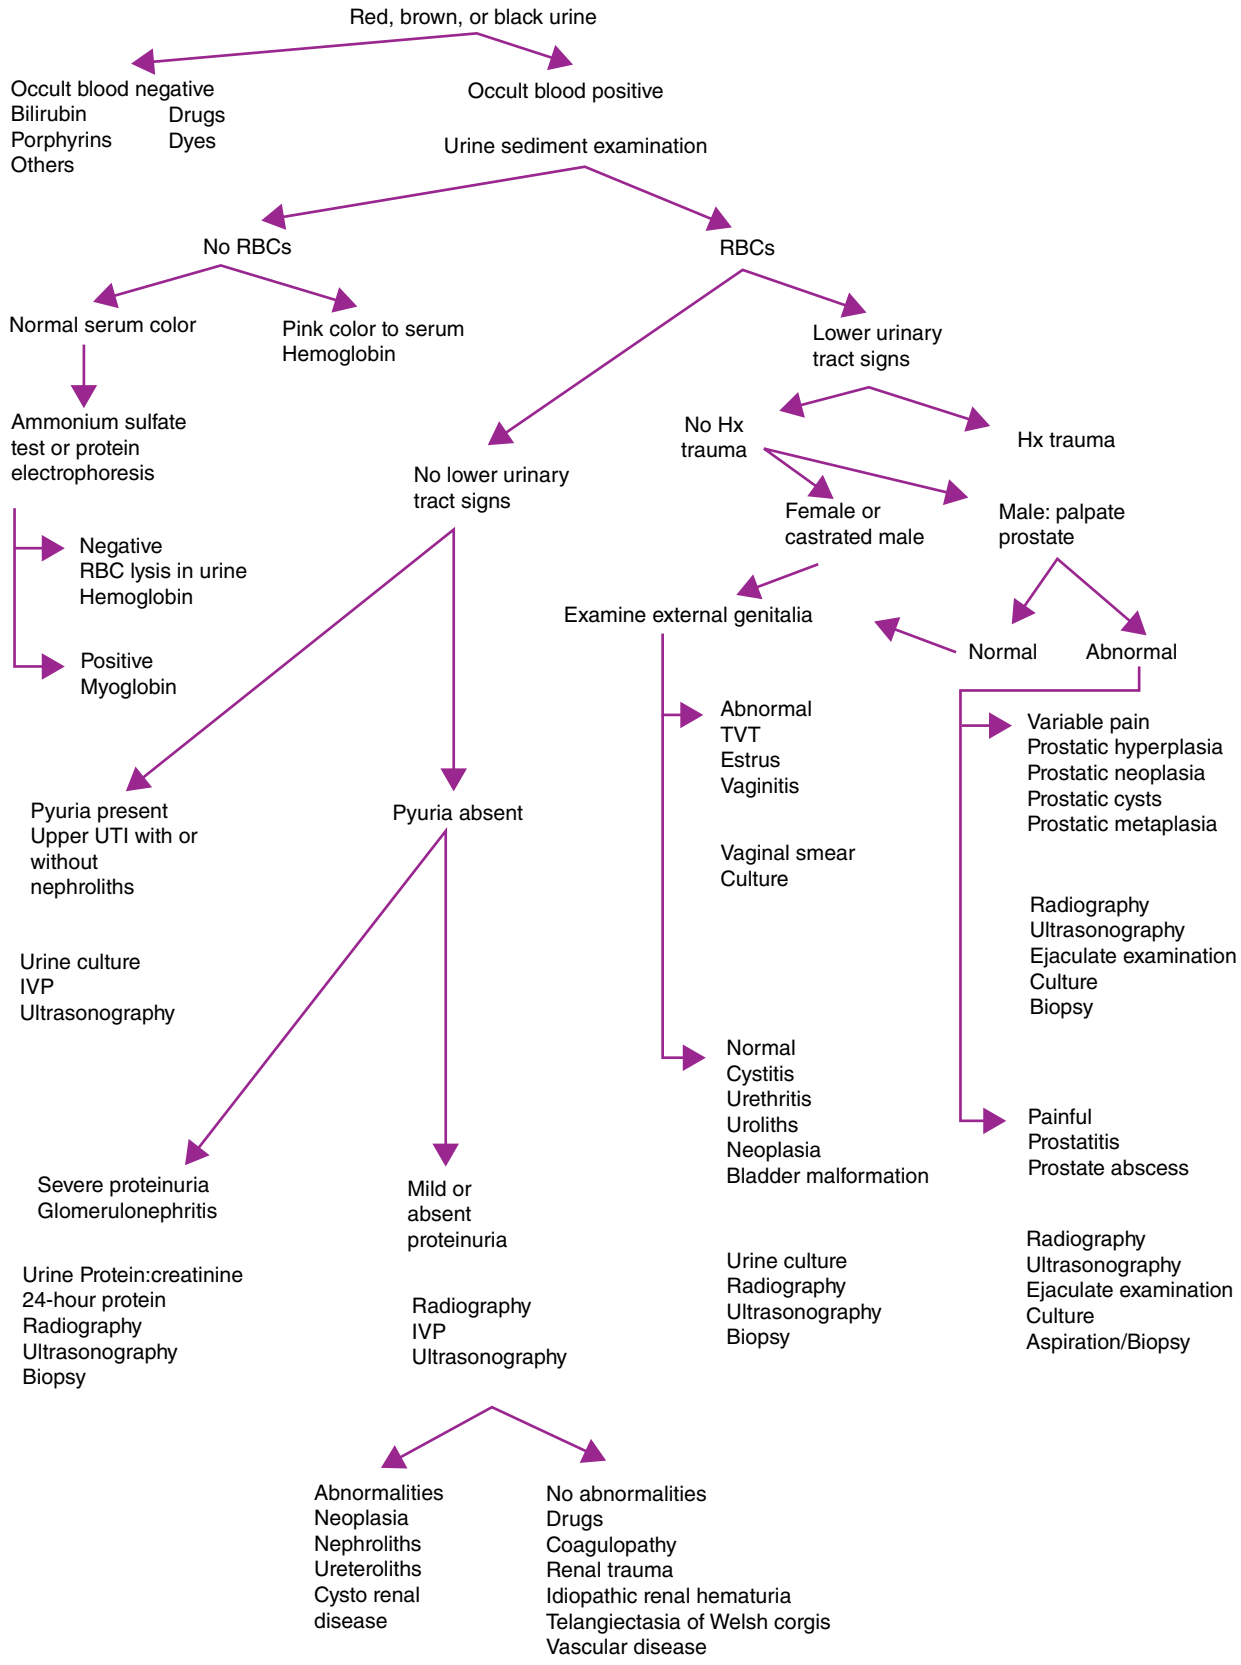

Figure 1.

Algorithm for the diagnosis of red, brown, or black urine.

HEMOGLOBINURIA AND MYOGLOBINURIA

BASICS

DEFINITION

Hemoglobinuria—presence of free hemoglobin (HGB) within urine secondary to intravascular hemolysis. Myoglobinuria—presence of myoglobin (MGB) within urine secondary to myocyte injury or death. Presence of either protein causes discoloration of urine (pigmenturia) as well as positive blood result during reagent test strip analysis of urine, a semiquantitative measurement of heme.

PATHOPHYSIOLOGY

• *Hemoglobinuria*—intravascular hemolysis or destruction of RBCs within vessels releases HGB from damaged red blood cells (RBCs). HGB, if free within plasma, can cause tissue injury. Haptoglobin, protein made by the liver, acts as HGB recovery system and binds free HGB. Resulting HGB–haptoglobin complexes too large to be cleared by glomerular filtration and so are removed primarily by splenic macrophages. Excessive intravascular hemolysis can saturate haptoglobin, resulting in free HGB in plasma, known as hemoglobinemia. Free HGB (4 heme-containing chains, 64,000 daltons) rapidly dissociates into unstable dimers (32,000 daltons) and passes freely through glomerular basement membrane leading to hemoglobinuria. Hemoglobinuria imparts pink, dark amber, red, or red-brown discoloration to urine. Methemoglobinemia causes analogous disease process.

• *Myoglobinuria*—MGB is single heme-containing chain (approximately 17,500 daltons). MGB able to carry oxygen without oxidation of ferrous (Fe^{2+}) to ferric (Fe^{3+}) iron due to interaction of heme with protein portion (globin). Myocyte injury and/or death releases MGB. Unlike free HGB, MGB is freely and rapidly cleared by glomerulus given its small size and absence of carrier protein, so plasma remains colorless even in face of significant myocyte death. Myoglobinuria causes brown or red-brown discoloration to urine.

• *Renal tubular injury*—presence of excess HGB or MGB in renal tubular fluid may result in kidney injury. Within tubules, acidic environment favors HGB or MGB precipitation, cast formation, and tubular obstruction. Both HGB and MGB are endocytosed by renal tubular epithelial cells. Globin, from HGB, is degraded within the cell, while free heme is catabolized by heme oxygenase, resulting in lipid peroxidation and Fe deposition. MGB also causes lipid peroxidation, but without release of free iron (via redox cycling of heme center). Alkaline conditions reported to prevent MGB-induced lipid peroxidation by stabilizing reactive ferryl MGB complex and also decreasing MGB precipitation in renal tubules. Free HGB also scavenges nitric oxide, leading to vasoconstriction of afferent renal arteriole and secondary hypoperfusion and ischemic injury.

SYSTEMS AFFECTED

Renal/urologic—HGB, methemoglobin, and MGB can result in tubular injury, especially with concurrent decreased renal perfusion and acidic conditions.

GENETICS

Some predispositions relating to breeds; see Signalment.

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Dog

• Hemoglobinuria secondary to phosphofructokinase (PFK) deficiency in affected English springer spaniel, American cocker spaniel, English cocker spaniel, cocker spaniel, wachtelhund, whippet.

• Hemoglobinuria uncommonly seen in Bedlington terriers with inherited copper toxicosis and copper release from hepatocytes causing hemolysis.

• Myoglobinuria secondary to exertional myopathy or rhabdomyolysis in racing sled dogs and greyhounds.

• Pigmenturia rarely reported secondary to exertional lactic acidosis in English sheepdog.

Cat

Hemoglobinuria secondary to neonatal isoerythrolysis in neonatal blood type A or AB kittens born to blood type B queens.

SIGNS

General Comments

Clinical signs diverse and related to specific causes; see Causes.

Historical Findings

Patient breed, exposure to certain drugs or foreign objects, and recent exertion particularly important; see Causes.

Physical Examination Findings

• Findings associated with hemolytic anemia may include pale mucous membranes, tachycardia, icterus.

• Findings associated with muscle damage may include muscle tenderness, swelling, bruising.

CAUSES

Hemoglobinuria

• Oxidative RBC injury—drugs (acetaminophen, benzocaine, vitamin K_3, new methylene blue, phenacetin, phenazopyridine, monensin); food (onions, garlic); heavy metals (copper, zinc in pennies minted before 1982 and zinc-containing sunscreens, diaper cream, hardware or toys).

• Physical RBC injury—severe burns, heat stroke, crush injury, electric shock, IV hypotonic fluid administration, shearing or microangiopathy due to disseminated intravascular coagulopathy, *D. immitis* caval syndrome.

• Toxin-induced RBC membrane damage—snake or spider venom; *Shiga* toxin in hemolytic uremic syndrome.

• Infection of RBCs—dogs: babesiosis; cats: *Mycoplasma hemofelis* infection, *Cytauxzoon felis*.

• Systemic infection—leptospirosis, *E. coli* or other *Shiga* toxin-producing bacteria causing hemolytic uremic syndrome, bacterial endocarditis.

• Immune-mediated RBC destruction—idiopathic or secondary immune-mediated hemolytic anemia, incompatible blood transfusions in dogs or cats, neonatal isoerythrolysis.

• Deficiencies—hypophosphatemia.

• Genetic associated—PFK deficiency, copper toxicity.

• Other—retroperitoneal hemorrhage, transfusion of inappropriately stored RBC units.

Myoglobinuria

• Exertional—extreme exercise.

• Myositis—infectious (e.g., toxoplasmosis, neosporosis), eosinophilic inflammatory (German shepherd dog, other breeds), immune mediated.

• Genetics-associated—X-linked muscular dystrophy; glycogenoses (storage diseases); mitochondrial abnormalities.

• Toxins (loss of membrane integrity)—snake or spider venom.

• Physical—ischemia, crush injury, compartment syndrome.

• Excessive body temperature (e.g., heat stroke, prolonged seizures).

RISK FACTORS

• Genetic predisposition (see Signalment).
• Exposure to specific drugs, toxins.
• Certain infectious agents.
• Extreme physical exertion.
• Heat stroke.
• Snake or spider venom.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Pigmenturia can result from hematuria, hemoglobinuria, methemoglobinuria, or myoglobinuria. Positive heme reaction of urine reagent test strip detects heme portion in intact RBCs, free HGB, and free MGB. Use of CBC, biochemical, and urinalysis results can aid in differentiation.

• Hematuria—supported by increased (>5/hpf) RBCs in urine sediment examination and clear plasma or serum.

• Hemoglobinuria—supported by <5/hpf RBCs in urine sediment, red or pink plasma or serum, indicating hemoglobinemia, anemia, RBC inclusions, or poikilocytes, supporting cause for hemolytic anemia,

(CONTINUED) HEMOGLOBINURIA AND MYOGLOBINURIA

hyperbilirubinemia, and bilirubinuria.
• Methemoglobinuria—supported by dark brown or chocolate-colored whole blood; often accompanies hemoglobinemia and hemoglobinuria.
• Myoglobinuria—supported by absence of RBCs in urine sediment, clear plasma or serum, increased creatine kinase (CK) and aspartate aminotransferase (AST), often normal packed cell volume (PCV), normal bilirubin.
• False-positive results.

LABORATORY FINDINGS

False-Positive Heme Urine Reagent Strip (Dipstick) Results

• Urine contact with bleach or hydrogen peroxide.
• Highly pigmented urine or marked bilirubinuria.
• Large amounts of bromide or iodide.
• Bacteriuria.

False-Negative Heme Urine Reagent Strip (Dipstick) Results

• Urine exposure to formalin.
• Patients taking captopril or ascorbic acid (Vitamin C).
• Failure to mix urine specimen prior to chemical/dipstick reagent testing or using supernatant for testing.

Disorders That May Alter Laboratory Results

Hyposthenuria or exposure of urine to extreme cold or heat in patients with hematuria may cause in vitro RBC lysis (no intact RBCs in sediment) with positive heme urine reagent dipstick reaction; could be misinterpreted as hemoglobinuria or myoglobinuria.

Valid if Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

• Intravascular hemolysis and hemoglobinuria:
  ◦ CBC support includes anemia, which may be preregenerative or regenerative depending on onset of hemolysis, RBC ghost cells, RBC inclusions (Heinz bodies to support oxidative injury, infectious agents), RBC poikilocytes (eccentrocytes and pyknocytes support oxidative injury, spherocytes support immune-mediated mechanisms, schistocytes support microangiopathic causes, some toxins), possibly increased mean cell HGB concentration (MCHC) or discrepant increase in HGB concentration from hemoglobinemia, red-colored plasma.
  ◦ Chemistry support includes red-colored serum or plasma, hyperbilirubinemia.
  ◦ Urinalysis support includes absence of hematuria, possible proteinuria.
• Rhabdomyolysis and myoglobinuria:
  ◦ CBC changes not expected.
  ◦ Chemistry findings include markedly increased (>4–5 × upper reference limit [URL]) CK with slower increases in AST; plasma and serum expected to be clear.
  ◦ Urinalysis findings include absence of hematuria, possible proteinuria.

OTHER LABORATORY TESTS

• Ammonium sulfate precipitation test unreliable and recommendation to use CBC and chemistry changes for differentiation.
• Incubation of whole blood with new methylene blue to detect Heinz bodies.
• Methemoglobin detection confirms toxin as oxidant.
• Increased serum copper or zinc concentration.
• DNA test for PFK deficiency.

IMAGING

Abdominal radiographs or ultrasound—metallic objects in gastrointestinal tract.

DIAGNOSTIC PROCEDURES

• Liver biopsy and copper quantification.
• Genetic testing for PFK.

TREATMENT

• IV fluid therapy to maintain renal perfusion.
• Avoid hyperventilation in PFK-deficient patients.
• See Causes for specific treatments.

MEDICATIONS

DRUG(S) OF CHOICE

Vary with underlying cause.

ALTERNATIVE DRUGS

HEMOTHORAX

BASICS

OVERVIEW

• Accumulation of blood in pleural space. • Can develop acutely due to trauma or a coagulopathy, or neoplasia; may also be chronic. • Cardiovascular and respiratory systems commonly affected.

SIGNALMENT

Any age, breed, or sex of dog and cat; younger dogs more commonly affected with anticoagulant rodenticide and trauma, older dogs more commonly affected with cancer.

SIGNS

• Peracute to acute onset—hypovolemic signs can occur before sufficient blood volume accumulates in the pleural space to impair respiration. • In chronic cases, larger volumes of blood may accumulate. • Respiratory distress, tachypnea; honking cough is possible in dogs with rodenticide poisoning; ecchymoses along ventral cervical and thoracic inlet areas. • Pale mucous membranes. • Weakness and collapse. • Weak, rapid pulse.

CAUSES & RISK FACTORS

• Trauma—bleeding artery or vein of the thoracic wall, mediastinum, or thoracic spine; damaged heart, lungs, thymus, or diaphragm; herniated abdominal viscera (liver or spleen). • Neoplasia—involving any structure adjacent to the pleural cavity; rib tumors are particularly common. • Coagulopathies—can be congenital or acquired; rodenticide ingestion common. • Lung lobe torsion. • Acute thymic hemorrhage in young animals. • *Dirofilaria immitis*, *Spirocerca lupi*, *Angiostrongylus vasorum*.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Nonhemorrhagic pleural effusions—chylothorax; pyothorax; modified transudates; transudates. • Congestive heart failure.

CBC/BIOCHEMISTRY/URINALYSIS

• PCV and hemoglobin—reflect blood loss after initial fluid compartment shifts have occurred. • Platelet count may be low (~100,000) with acute blood loss. • Very low platelet count (<20,000) consistent with spontaneous bleeding, although thrombocytopenia alone rarely represents in hemothorax.

OTHER LABORATORY TESTS

Fluid Analysis

• Hemorrhage-produced effusion—packed cell volume (PCV) and protein content similar to that of peripheral blood; platelets commonly seen on cytology. • Inflammation- or vascular-congestion related effusion—PCV <8%. • Neoplasia or lung lobe torsion—PCV can be low or mid-range. • Cytologic examination—often fails to identify malignant causes, but is recommended.

Coagulation Tests

• Prolonged prothrombin time (PT)/partial thromboplastin time (PTT) suggestive of coagulopathy. • Specific factor analysis—needed to diagnose congenital defect or acquired coagulopathy. • Buccal mucosal bleeding time—identifies platelet function defect or vasculitis.

IMAGING

• Radiology—reveals pleural effusion varying from diffuse increase in radiopacity to ventral leafing, interlobar fissures, and localized pleural densities. • Can see associated lesions (e.g., rib fractures or tumors, pneumothorax or pneumomediastinum, mediastinal hemorrhage, pulmonary contusions, diaphragmatic lesions, and masses). • Lobar consolidation with vesicular gas pattern suggestive of lung lobe torsion. • In stable patients without coagulopathy—evacuation of pleural space may allow better radiographic visualization of masses or other pathology.

DIAGNOSTIC PROCEDURES

• Thoracentesis (contraindicated if clotting abnormality). • CT to evaluate for neoplasia or lung lobe torsion.

TREATMENT

• Acute—judicious use of IV fluids; try to get systolic blood pressure above 90 mmHg using crystalloids and/or hypertonic saline to correct hypovolemia. • Coexisting pneumothorax—generally requires needle thoracentesis or tube thoracostomy. • Plasma, specific clotting factors, and/or blood transfusion can be needed to restore clotting factors or provide red blood cells (RBCs) for oxygen transport. • Pulmonary contusion—may require ventilator support. • Severe or recurrent thoracic hemorrhage—may require surgical exploration. • Oxygen therapy. • Most coagulopathic cases have respiratory difficulty associated with soft tissue bleeding rather than pleural hemorrhage and therefore rarely require evacuation of pleural fluid to resolve tachypnea. • Autotransfusion.

MEDICATIONS

DRUG(S) OF CHOICE

• Hypovolemia—see Shock, Hypovolemic. • Vitamin K_1—5 mg/kg SC loading dose (using small-gauge needle) followed by 1.5–2.5 mg/kg PO q12h for 21–30 days; takes 12 hours or more to carboxylate clotting factors and restore activity. • Analgesics—systemically or as nerve blocks for trauma. • Broad-spectrum antibiotics— when indicated.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Avoid aspirin and other nonsteroidal anti-inflammatory drugs (NSAIDs).

FOLLOW-UP

PATIENT MONITORING

• Clinical signs, respiratory rate and effort, heart rate. • Temperature. • Urine production. • Relief from pain. • Follow-up radiographs at 48-hour intervals until stable. • Coagulation panel in 48 hours if coagulopathy due to anticoagulant rodenticide toxicity diagnosed, and 48 hours after discontinuing vitamin K supplementation.

POSSIBLE COMPLICATIONS

• Pyothorax. • Sepsis. • Entrapment and constriction of lungs by scar tissue and fibrosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Peritonitis—with penetrating wounds (e.g., gunshot) into the abdomen. • Esophageal perforation.

SEE ALSO

• Disseminated Intravascular Coagulation. • Lung Lobe Torsion. • Pleural Effusion. • Pulmonary Contusions. • Rodenticide Toxicosis—Anticoagulants.

ABBREVIATIONS

• NSAID = nonsteroidal anti-inflammatory drug. • PCV = packed cell volume. • PT = prothrombin time. • PTT = partial thromboplastin time. • RBC = red blood cell.

HEMOTROPIC MYCOPLASMOSIS

BASICS

OVERVIEW

Red blood cell (RBC) destruction and anemia caused by bacterial attachment to the external surface of RBCs, nutrient scavenging by bacteria from RBC, and immune response by the host.

SIGNALMENT

- Dog and cat.
- Acute disease most common in young cats, chronic form most common in adults.
- More common in outdoor and male cats.
- Acute disease in splenectomized dogs, chronic disease in nonsplenectomized dogs.
- Kennel-raised beagles at increased risk for infection.
- No sex prevalence in dogs.

SIGNS

Cats

- For *Mycoplasma haemofelis* infection:
  - Variable disease severity ranging from inapparent infection (chronic disease) to marked anemia and death (acute disease).
  - Intermittent fever (50% of the time) during the acute phase, depression, weakness, anorexia, anemia, pale mucous membranes, splenomegaly, and (occasionally) icterus.
- For *Candidatus M. haemominutum* infection:
  - Usually results in inapparent infection.
  - Minimal or no decrease in hematocrit.
- For *Candidatus M. turicensis*:
  - Limited information regarding natural infection.
  - Mild anemia following experimental infection.

Dogs

- Mild or inapparent signs (e.g., pale mucous membranes and listlessness)—except when dogs have been splenectomized or splenic function is altered.
- High prevalence of chronic, inapparent infection in kennel-raised beagles, which may threaten validity of research results.

CAUSES & RISK FACTORS

- Caused by bacteria previously classified in the genus *Haemobartonella*, these organisms are now recognized to be mycoplasmas (hemotropic mycoplasmas or hemoplasmas) based on genetic determination,
- *M. haemofelis* (previously classified as large form of *H. felis*), *M. haemominutum* (previously classified as small form of *H. felis*), and *M. haemocanis* (previously classified as *H. canis*).
- *M. haemofelis* infection in cats generally causes more severe disease than *M. haemominutum* or *Candidatus M. turicensis* infection.
- Cats—anemia more severe if feline leukemia virus (FeLV) infected.
- Dogs—likelihood of severe anemia greatly increased if splenectomized or with pathologic changes in the spleen.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of hemolytic anemia, including immune-mediated hemolytic anemia (IMHA), babesiosis (not in cats in the United States), cytauxzoonosis (cats only), Heinz body hemolytic anemia (new methylene blue can be used to identify Heinz bodies), microangiopathic hemolytic anemia, pyruvate kinase deficiency, and phosphofructokinase deficiency (dogs only).
- Differentiated from IMHA only by recognition of parasites in blood (stained blood film or species-specific PCR-based assays); both disorders (IMHA and/or *M. haemofelis* infection) may be Coombs' test positive.
- *Babesia* and *Cytauxzoon* species are protozoal organisms that differ in morphology from mycoplasma.
- Enzyme assays or specialized DNA tests can be used to diagnose pyruvate kinase and phosphofructokinase deficiencies.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia most often present with reticulocytosis in animals with clinically important infections—may appear poorly regenerative if precipitous decrease in packed cell volume (PCV) has occurred early in the disease or if there are other concurrent disorders (e.g., FeLV or feline immunodeficiency virus [FIV] infection in cats).
- Autoagglutination may be seen in feline blood samples after they cool to below body temperature.
- Hyperbilirubinemia may be measured and/or seen clinically at times but is seldom severe.
- Substantial bilirubinuria seen in some dogs.
- Abnormalities related to anemic hypoxia may be shown by clinical chemistry profiles, but profile can be normal.
- Hypoglycemia possible in moribund cats or if slow to separate blood cells from plasma or serum.

OTHER LABORATORY TESTS

- Routine blood stains (e.g., Wright-Giemsa) to identify organisms in blood films.
- Organism may detach from RBCs in stored blood anticoagulated with EDTA.
- Reticulocyte stains cannot be used to identify *Mycoplasma* organisms because punctate reticulocytes in cats appear similar to the parasites.
- Organisms must be differentiated from precipitated stain, refractile drying, or fixation artifacts, poorly staining Howell-Jolly bodies, and basophilic stippling.
- Feline organisms—small blue-staining cocci, rings, or rods on RBCs, often many parasites for *M. haemofelis*; small rods or coccoid organisms in low numbers for *Candidatus M. haemominutum*; parasites not conclusively seen in blood for *Candidatus M. turicensis*.
- Canine organisms—commonly form chains of organisms that appear as filamentous structures on the surface of RBCs.
- Infection is cyclic and thus organisms are not always identifiable in blood (especially in cats).
- PCR-based assays can detect parasites in blood below the number required to make a diagnosis by a stained blood film.

DIAGNOSTIC PROCEDURES

- In patients with nonregenerative anemia, bone marrow biopsy should be performed to detect other disorders.
- PCR testing of blood donor cats and dogs is strongly recommended.

TREATMENT

- Without therapy, mortality with *M. haemofelis* infection may reach 30% in cats.
- Outpatient treatment unless severely anemic or moribund.
- Blood transfusions required when anemia is considered life-threatening.
- Shock should be treated with IV administration of isotonic crystalloid fluids, with or without glucose supplementation.

MEDICATIONS

DRUG(S) OF CHOICE

- Doxycycline (5 mg/kg PO q12h) should be given for minimum of 4 weeks.
- If PCR remains positive or bacteremia reoccurs after doxycycline therapy, antibiotic treatment should be switched to marbofloxacin (2 mg/kg PO q24h) for 2 weeks.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Esophageal strictures and gastrointestinal disease have been reported in cats following doxycycline administration.
- Fluroquinolones, including marbofloxacin, may cause arthropathy in young dogs and retinotoxicity in cats.

FOLLOW-UP

- Examine animal after 1 week of treatment to confirm that PCV has risen.
- Alert owners that cats may remain carriers even after completion of treatment, but seldom relapse with disease once PCV returns to normal.

HEMOTROPIC MYCOPLASMOSIS (CONTINUED)

• Cats have protective immunity against *M. haemofelis* reinfection for some period of time.

MISCELLANEOUS

SEE ALSO

- Anemia, Heinz Body.
- Anemia, Immune-Mediated.
- Anemia, Regenerative.
- Babesiosis.
- Cytauxzoonosis.
- Phosphofructokinase Deficiency.
- Pyruvate Kinase Deficiency.

ABBREVIATIONS

- FeLV = feline leukemia virus.
- FIV = feline immunodeficiency virus.
- IMHA = immune-mediated hemolytic anemia.
- PCV = packed cell volume.
- RBC = red blood cell.

HEPATIC AMYLOID

BASICS

OVERVIEW

• Amyloidosis—disorders of diverse etiology sharing common feature of deposition of extracellular insoluble fibrillar beta-pleated proteinaceous matrix with distinctive staining properties and fibrillar ultrastructure.
• Amyloid—derived from diverse primary proteins, sometimes an acute phase reactant.
• Serum amyloid A (SAA), an acute phase protein produced by hepatocytes, is produced during inflammation and is associated with the most commonly reported generalized form of amyloidosis in small animals.
• Amyloid AL, which is a monoclonal immunoglobulin G light chain and is associated with plasma cell dyscrasia, is not commonly reported in small animals and is not the form associated with hepatic amyloidosis.
• Amyloid may accumulate as a focal or systemic process secondary to inflammatory or lymphoproliferative disorders or as a familial genetic disorder.
• Liver and kidneys are most commonly affected.
• Familial amyloidosis—certain kindreds of purebred cats; certain breeds and kindreds of dogs; syndromic inflammatory disorders.
• Multiple organs commonly involved; clinical signs often reflect renal involvement.
• Liver amyloid accumulation—insidious; associated with variable liver enzymes, severe hepatomegaly, coagulopathies, liver rupture leading to hemoabdomen (cats), or liver failure.

SIGNALMENT

• Dogs—Chinese Shar-Pei, with cyclic "shar-pei fever syndrome"; Akita with cyclic fever and polyarthropathy; collie with "gray collie syndrome"; usually develop renal signs first, although some develop hepatic insufficiency.
• Cats—oriental shorthair, Siamese, Devon Rex, domestic shorthair cats; usually <5 years of age when first symptomatic (hepatic signs and coagulopathies predominate); familial in Abyssinians (renal signs predominate). Upper respiratory viral infection proposed to trigger amyloidosis in Siamese. Cats naturally infected with feline immunodeficiency virus (FIV) have been described to have systemic amyloid deposition, with kidneys, liver, and spleen most affected.

SIGNS

Historical Findings

• Episodic fever and swollen hocks—shar-pei.
• Episodic polyarthropathy, pain, and signs of meningitis—Akita.
• Acute lethargy, cyclic.
• Anorexia and vomiting, episodic.
• Polyuria and polydipsia.

Physical Examination Findings

• Pallor.
• Abdominal effusion—hemorrhage or ascites.
• Jaundice—unusual.
• Hepatomegaly with amyloid deposition.
• Edema—due to hypoalbuminemia secondary to pathologic proteinuria.
• Joint pain—Akita, shar-pei syndromes.
• Nonlocalized pain, meningeal pain, and abdominal discomfort—with different inflammatory disorders promoting amyloid.

CAUSES & RISK FACTORS

• Familial immunoregulatory disorders.
• Chronic infections—coccidioidomycosis; blastomycosis; tick-borne diseases; FIV.
• Cyclic neutropenia—gray collie syndrome.
• Bacterial endocarditis.
• Chronic inflammation (e.g., systemic lupus erythematosus [SLE]).
• Neoplasia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Chronic hepatic inflammation.
• Infiltrative hepatic neoplasia.
• Primary or rodenticide-induced coagulopathy.
• Glomerulonephritis.
• Pyelonephritis.
• SLE.
• Abdominal trauma.
• Peritonitis.
• Meningitis.
• Immune-mediated or infectious polyarthropathy.

CBC/BIOCHEMISTRY/URINALYSIS

• Anemia secondary to hepatic hemorrhage or liver lobe rupture or chronic inflammation.
• Leukocytosis with a left shift during febrile episodes in shar-pei and Akita.
• Normal or high—liver enzymes, total bilirubin, and serum bile acids; may be normal with severe hepatic amyloid deposition.
• Azotemia with severe renal infiltration—glomeruli targeted in dogs (proteinuria), renal interstitium targeted in cats (azotemia).
• Proteinuria—dogs: glomerular amyloid.
• Dilute urine—renal involvement or failure.
• Feline systemic amyloidosis—involves multiple organ systems: thyroid, cardiac, renal, intestine, pancreatic, bone marrow, lymph nodes, adrenals.

OTHER LABORATORY TESTS

• Coagulation tests—normal to prolonged clotting times, hyperfibrinogenemia.
• Synovial fluid—dogs with joint swelling or pain: suppurative nonseptic inflammation.
• Cerebrospinal fluid (CSF)—if meningeal pain, increased protein, and suppurative inflammation.
• Lyme disease testing—ELISA for C6 antibody presence in dogs with joint swelling/pain/fever.
• FIV—cats with hepatic, renal, or respiratory symptoms.

IMAGING

• Abdominal radiography—hepatomegaly; variable renal size; abdominal effusion.
• Abdominal ultrasonography—hepatomegaly: hypoechoic parenchyma (diffuse amyloid); variable renal size with normal or equivocally hypoechoic parenchyma (renal amyloid); inconsistent mesenteric lymphadenopathy; thickened gut wall (amyloid deposition); abdominal effusion.

DIAGNOSTIC PROCEDURES

• Fine-needle aspiration cytology—may disclose amorphous fibrillar material.
• Liver or other tissue biopsy.
• Abdominocentesis—hemorrhagic (esp. cats) or transudative effusion (diffuse hepatopathy).

PATHOLOGIC FINDINGS

Gross

Liver—normal to pale color; large, firm to friable; hemorrhages (subcapsular hematomas, capsular tears) to overt rupture.

Microscopic

• Liver—diffuse acellular amorphous material in the space of Disse, associated with hepatic cord atrophy; may primarily involve blood vessels in portal triads (Abyssinian cats).
• Cats with systemic amyloidosis may have amyloid deposited in many organs and endocrine tissue.
• Amyloid stains amorphous pink with routine hematoxylin and eosin; may stain turquoise blue with Masson's trichrome; Congo red staining with bright field: amyloid is salmon pink but with polarized light is birefringent (beta-pleated sheet structure refracts polarized light) and apple green.

TREATMENT

• Warn client that hepatic amyloidosis is difficult to treat; guarded to poor prognosis.
• Dictated by severity of clinical signs.
• No curative treatment; manage underlying disease; colchicine as described below may reduce organ amyloid deposition.
• Fluids—for dehydration.
• Blood transfusion—for acute blood loss; essential in cats with hepatic amyloid-induced liver lobe rupture.
• Diet—individually tailored to organ function.
• Liver failure—consider measures appropriate for hepatic encephalopathy as appropriate.
• Pathologic proteinuria—see Nephrotic Syndrome.

HEPATIC AMYLOID (CONTINUED)

• Surgical intervention—hepatic lobe resection as emergency measure for catastrophic bleeding from fractured liver lobe in cats; histologic features may describe centrilobular necrosis due to anemia-induced hypoxia; amyloid may be overlooked without special stains.

MEDICATIONS

DRUG(S) OF CHOICE

• Colchicine—dogs: 0.03 mg/kg PO q24h; may block amyloid deposition in early disease or control deposition in chronic disorders in dogs; modulates expression of adhesion molecules and chemotactic factors; causes microtubule polymerization by binding to tubulin blocking cell mitosis in cells such as neutrophils. Effects attenuate inflammatory response, triggering acute phase protein (amyloid precursor) production. Monitor CBC for bone marrow toxicity; observe patient for enteric side effects (vomiting, diarrhea [bloody]), beware of toxicity if coadministered with p450 blocking drugs (e.g., ketoconazole, omeprazole, cimetidine). Use colchicine without added probenecid. Limited experience in cats.
• Dimethyl sulfoxide (DMSO)—controversial treatment; use medical grade only; dogs: 80 mg/kg given as no more than a 33% solution in sterile water PO three times a week; may promote dissolution of amyloid fibrils or provide anti-inflammatory or anti-amyloid effect. Side effects: garlic odor and objectionable taste. Sterile solutions have also been prepared and administered SC. In humans this treatment given PO daily (3–20 g/patient) has benefit in polysystemic amyloidosis, but not renal amyloidosis associated with renal failure.
• Lactulose—dogs: 2.5–15 mL PO q8h; cats: 2.5–5.0 mL PO q8–12h; for patients with suspected hepatic encephalopathy. If oral administration is not tolerated this may be given as a retention enema.
• Nonsteroidal anti-inflammatory drugs (NSAIDs)—in dogs (shar-pei fever syndrome) to reduce pain and fever if present.
• Vitamin K_1—dogs and cats: initially at three doses of 0.5–1.5 mg/kg SC/IM. Subsequent dosing may be necessary, especially in cats. Monitor prothrombin time (PT); dosing interval should be determined by resolution of prolongation of PT.
• Medications as indicated for concurrent renal disease and/or proteinuria if present.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Colchicine combined with probenecid may cause vomiting, as probenecid prolongs residence time of colchicine.
• Colchicine toxicity if coadministered with p450 cytochrome inhibitor drugs.
• Colchicine may cause/enhance bone marrow suppression if administered with antineoplastics, immunosuppressive medications, chloramphenicol, or amphotericin B.

FOLLOW-UP

• Shar-pei—with hepatic amyloid may survive >2 years; most have episodes of fever and cholestasis; some resolve clinical signs and diminish hepatic amyloid with colchicine.
• Akitas with cyclic clinical signs—grave prognosis.
• Cats surviving liver hemorrhage eventually succumb to renal failure and other polysystemic effects of deposited amyloid.

MISCELLANEOUS

SEE ALSO

Amyloidosis

ABBREVIATIONS

• CSF = cerebrospinal fluid.
• DMSO = dimethyl sulfoxide.
• FIV = feline immunodeficiency virus.
• NSAID = nonsteroidal anti-inflammatory drug.
• PT = prothrombin time.
• SLE = systemic lupus erythematosus.

HEPATIC ENCEPHALOPATHY

BASICS

DEFINITION

• Hepatic encephalopathy (HE) defines broad spectrum of neurobehavioral signs caused by failure of liver to remove endogenous toxins, including ammonia, acquired from alimentary canal (predominantly from colon) into splanchnic portal venous circulation.
• Associated with acute liver failure; portosystemic shunting: congenital (portosystemic vascular anomaly [PSVA]) or multiple acquired portosystemic shunts (APSSs); or severe liver injury: critical loss of functional hepatic mass or cirrhosis where loss of functional mass combines with hepatic fibrosis, leading to portal hypertension and development of APSS.
• Metabolic/physiologic dysregulations causal to HE potentially reversible; pathologic changes in neural tissue may become permanent in chronic HE.
• Acute brain edema associated with high central spinal fluid pressure may lead to lethal brain herniation.

PATHOPHYSIOLOGY

• Neurobehavioral and neurocognitive abnormalities—largely attributed to gut-derived substances (bacterial and protein metabolites), with ammonia considered predominant toxin.
• Neurologic signs—reflect impact of neurotoxic molecules on cortical, basal ganglia, pontine, cerebellum, increased permeability of blood–brain barrier (BBB); astrocyte type II Alzheimer change, microglial activation, axonal demyelination, decreased cerebellar inhibition.
• Multifactorial process with numerous etiopathogenic mechanisms.
• Ammonia—best-studied toxin with neurotoxic impact on astrocytes; high ammonia associated with astrocyte swelling and brain oxidative stress.
• Complex multifactorial pathophysiology contributes to electrophysiologic derangements—energy failure (neuroglycopenia), altered cerebral pH (lactate accumulation), calcium ion flux, abnormalities involving glutamatergic, GABAergic and catecholaminergic neurotransmission; perturbed aromatic amino acid metabolism, increased cerebral concentrations of endogenous benzodiazepine-like substances and neurosteroids; local accumulation of inflammatory cytokines and bile acids, altered cerebral blood flow, and oxidative injury. Altered BBB permeability increases access of toxic factors to brain.

SYSTEMS AFFECTED

• Nervous—abnormal cerebral function predominates; decreased awareness and function progress to stereotypic pacing, somnolence, coma, or agitation progresses to seizures; aggression and seizures more likely in cats with PSVA.
• Gastrointestinal (GI)—vomiting, diarrhea, anorexia, or constipation.
• Renal/urologic—ammonium biurate urolithiasis involving bladder, renal pelvis; may cause urethral obstruction.

GENETICS

• PSVA—see Portosystemic Vascular Anomaly, Congenital.
• See Hepatitis, Chronic; Copper Associated Hepatopathy.

INCIDENCE/PREVALENCE

Uncommon disorder.

SIGNALMENT

Species

Dog and cat.

Breed Predilections

PSVA—usually purebred small dogs and mixes of these.

Mean Age and Range

• PSVA—usually young animals.
• Acquired liver disease with APSS—any age.

SIGNS

General Comments

• Neurologic—usually coordinate with meal ingestion (esp. high protein, e.g., red meat, fish, dogs consuming cat foods); systemic infection; dehydration; azotemia; constipation; any cause of catabolism; increased heme turnover: hemolysis, enteric bleeding, eruption of adult teeth in juveniles, blood transfusion; certain drugs.
• Temporary resolution of HE signs following dietary protein restriction, modification of enteric flora or enteric contents (e.g., certain oral antibiotics, administration of cathartics such as lactulose, or use of cleansing enema), ± resolution of provocative conditions.
• Prolonged recovery from sedation or anesthesia.
• Ammonium biurate obstructive uropathy.

Historical Findings

• Episodic neurobehavioral signs or neurocognitive impairment—slow onset and resolution.
• Learning disabilities (difficult to train).
• Lethargy/somnolence may progress to coma.
• Anorexia/vomiting.
• Ptyalism—especially cats.
• Polyuria/polydipsia (PU/PD).
• Disorientation—aimless wandering; compulsive pacing; head pressing.
• Amaurotic blindness.
• Focal or generalized seizures—neurologic signs of lethargy or somnolence as prodrome.
• Signs more frequent in cats—ptyalism, seizure, aggression disorientation; ataxic stupor.
• Signs more frequent in dogs—compulsive behavior, e.g., head pressing, circling, aimless wandering, vocalizing; GI signs: vomiting; diarrhea; PU/PD; signs associated with ammonium biurate urolithiasis: hematuria, pollakiuria, stranguria, dysuria males > females.

Physical Examination Findings

• PSVA—see Portosystemic Vascular Anomaly, Congenital.
• Ascites common in dogs with HE secondary to acquired liver disease; variable coagulopathies.
• May have distended bladder if obstructive uropathy; may pass small dark green uroliths.
• Neurologic signs.

CAUSES

• PSVA—congenital malformations.
• APSS—see Hypertension, Portal; Portosystemic Shunting, Acquired.
• See Hepatic Failure, Acute; Hepatotoxins.

RISK FACTORS

• Feeding high-protein foods to dogs; dogs consuming cat foods.
• Enteric bleeding—most common acute cause of HE.
• Disorders increasing heme turnover—enteric bleeding; hemolysis; oral bleeding: tooth eruption in juvenile with PSVA; blood transfusions: stored blood products may contain high concentrations of ammonia, incompatible blood transfusions.
• Alkalosis, hypokalemia, hypoglycemia.
• Certain anesthetics (alfaxalone), sedatives (benzodiazepines).
• Drugs, e.g., methionine, tetracycline, antihistamines.
• Constipation.
• Catabolism.
• Infections or severe inflammation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Lead toxicosis.
• Urinary tract infection, urolithiasis.
• Intestinal parasitism.
• Primary GI disease.
• Hypoglycemia.
• Toxoplasmosis.
• Congenital CNS disease or malformation—hydrocephalus; storage diseases.
• CNS neoplasia.
• Acute ethylene glycol, xylitol, other toxicoses.
• Infectious—rabies; canine distemper; neurologic dissemination of toxoplasmosis or other.
• Thiamin deficiency.
• Drug intoxications—human recreational drugs.

HEPATIC ENCEPHALOPATHY (CONTINUED)

CBC/BIOCHEMISTRY/URINALYSIS

CBC

PSVA and APSS—red blood cell microcytosis; variable mild nonregenerative anemia; poikilocytosis (cats); target cells (dogs); ± jaundiced plasma.

Biochemistry

- Variable low blood urea nitrogen and creatinine.
- Hypoglycemia.
- Low cholesterol.
- Liver enzymes—variable depending on cause.
- Bilirubin—normal to high depending on cause.
- Hypoalbuminemia.

Urinalysis

- Low concentration—common with PSVA; variable with APSS.
- Ammonium urate crystalluria—causing hematuria, pyuria, proteinuria; may also cause secondary infection; crystalluria imparts orange/brown color to urine.

OTHER LABORATORY TESTS

- Blood ammonia—sensitive but unreliable indicator of HE; fasting hyperammonemia unreliably associated with HE; lability of blood ammonia makes ammonia determinations less reliable than total serum bile acids (TSBA); ammonia tolerance testing—most reliable method of demonstrating ammonia intolerance (administer NH_4Cl PO or per rectum) but *caution*: may induce HE.
- TSBA—confirms hepatic insufficiency or shunting associated with HE; hepatobiliary jaundice renders TSBA testing superfluous.
- Coagulation tests—variable depending on underlying cause.
- Protein C—low activity in dogs with substantial shunting, liver failure, protein-losing enteropathy, disseminated intravascular coagulation.
- Abdominal effusion—effusions pure or modified transudates.

IMAGING

See Portosystemic Vascular Anomaly, Congenital; Portosystemic Shunting, Acquired.

DIAGNOSTIC PROCEDURES

- Hepatic aspiration—cannot differentiate disorders causing portosystemic shunting.
- Liver biopsy—open surgical wedge biopsy or laparoscopic sampling; essential to collect tissue from several liver lobes.
- Tru-Cut® needle biopsy—may inadequately sample tissue.

PATHOLOGIC FINDINGS

- Gross—liver appearance reflects underlying disorder; rare brain herniation in acute HE.
- Microscopic—liver lesions define causal hepatic disorder; CNS lesions: may include polymicrocavitation and Alzheimer type II astrocyte changes; inconsistent in dogs and cats.

TREATMENT

APPROPRIATE HEALTH CARE

- Depends on underlying cause.
- See Portosystemic Vascular Anomaly, Congenital.

NURSING CARE

- Avoid risk factors.
- Treatment depends on underlying condition(s); essential to eliminate factors provoking HE.
- Improve dietary protein tolerance by concurrent oral or rectal (enema) treatments (see Medications) and altering protein type and quantity (see Diet).
- If hepatic coma—discontinue oral medications; ensure euglycemia; provide fluid, electrolyte, and water-soluble vitamin support.
- Fluids—balanced crystalloids; avoid lactate if fulminant hepatic failure, if hypoglycemic supplement fluids with 2.5–5.0% dextrose; provide 20–30 mEq/L potassium chloride (not to exceed 0.5 mEq/kg/h) titrated to need; sodium-restricted fluids used in patients with ascites with APSS (esp. cirrhosis) and patients with marked hypoalbuminemia.
- B-soluble vitamins supplemented in fluids (2 mL/L); ensure adequate B_{12}.

ACTIVITY

- Keep patient warm, inactive, hydrated, euglycemic.
- Protect animal from environmental injury secondary to propulsive or aimless pacing, obtundation, amaurosis, generalized seizures.

DIET

- Adequate calories—avoid catabolism; important to maintain muscle mass.
- Dietary protein modification and restriction—cornerstone of medical management; use commercially formulated liver diets or diets for moderate renal insufficiency. Dog: use dairy and soy protein sources with initial 2.2–2.5 g protein/kg bodyweight per day allowance. Cat: pure carnivores must have meat-derived protein restricted to ~3.5 g protein/kg bodyweight per day.
- Dogs: after initial observed response to restricted protein allowance (1–2 weeks) gradually titrate allowance upward (0.25 g protein/kg bodyweight per day for 5–10-day observational increments) using dairy quality protein (e.g., shredded cheddar or mixed cheeses, often effective); increase up to 1.5 g protein /kg bodyweight per day depending on individual tolerance (no signs of HE, no ammonium biurate crystalluria).
- Good-quality vitamin supplements.
- Ensure thiamin repletion—50–100 mg daily for 3 days in cats and dogs, with water-soluble vitamins added in fluids; follow with dietary supplementation; *caution*: anaphylactoid reactions may occur with injectable (IM/SC) thiamin.
- *S*-adenosylmethionine—20 mg/kg PO/day on empty stomach.
- Partial parenteral nutrition—*only* for short-term inappetence.
- Total parenteral nutrition considered if >5 days inappetence and enteral route unavailable.
- No benefit shown for specific supplementation of oral branched-chain amino acids.
- No need to restrict fat.

CLIENT EDUCATION

- HE—usually episodic; relapse risk exists if underlying cause cannot be eliminated.
- Train owner to administer enemas to abate acute-onset HE and judiciously adjust medications used to control ammonia formation and absorption PRN.
- APSS—see Portosystemic Shunting, Acquired.
- PSVA—see Portosystemic Vascular Anomaly, Congenital.

SURGICAL CONSIDERATIONS

- PSVA—medically treat HE *before* anesthesia and surgery.
- APSS—do not ligate this vasculature.

MEDICATIONS

DRUG(S) OF CHOICE

- Treatment goals include increasing dietary protein tolerance; altering enteric environment and microbiome to modify generation of encephalogenic toxins (e.g., endotoxin and ammonia); reduce bioavailability or colonic dwell time of substances provoking HE.
- Antibiotics—first choice: systemic metronidazole (7.5 mg/kg q12h) or amoxicillin (esp. cats, 12.5–25 mg/kg PO q8–12h); *caution* if using neomycin (10–22 mg/kg PO q12h) chronically as enteric absorption may cause renal and otic toxicity.
- Local instillation of antimicrobials used in retention enemas—same dosages as oral but *do not* administer by both oral and rectal routes.
- In humans, rifaximin is as effective as single agent or combined lactulose and neomycin in management of HE and has favorable safety and tolerability profile; is expensive; no data regarding utility for management of HE in animals; suggested dose in dogs 5 mg/kg PO q24h or q12h.
- Nonabsorbable-fermentable carbohydrates—lactulose, lactitol, or lactose in milk products if patient is lactase deficient; lactulose most commonly used: start at 0.5 mL/kg q8–12h

(CONTINUED) HEPATIC ENCEPHALOPATHY

and titrate up to therapeutic goal of 2 or 3 soft stools/day; may also administer as enema for acute HE or patients in coma *after* cleansing enemas remove debris; *note*: concurrent use of neomycin may suppress bacterial fermentation of lactulose thereby diminishing its benefit.
• Probiotics combined with nonabsorbable-fermented carbohydrates may be advantageous for altering gut flora and provoking cathartic effect.
• Enemas—*cleansing enemas* (warmed polyionic fluids) mechanically cleanse the colon (10–15 mL/kg, until clear return); *retention enemas* deliver fermentable substrates, antimicrobials, or solution directly altering colonic pH: diluted lactulose, lactitol, or lactose (1 : 2 in water); antimicrobials mixed with water: metronidazole or neomycin but do not exceed PO dose, do not dose PO *and* rectally; diluted betadine (1 : 10 in water, *rinse well in 15 min*); diluted vinegar (1 : 10 in water) modifies colonic pH, alters colonic flora.
• Zinc supplementation—two urea cycle enzymes require zinc and portosystemic shunting may deplete body zinc reserves (shown in humans); measure baseline plasma zinc (dose 1–3 mg/kg elemental zinc PO using zinc acetate) then titrate dose using sequential plasma zinc measurements to avoid >800 µg/dL (causes hemolysis), but document an increase in baseline plasma zinc concentration inferring positive zinc balance; *note*: plasma zinc does not reflect liver zinc concentration.
• Cerebral edema—complicates acute HE; head-up posture (15–20° incline); mannitol (1 g/kg diluted in saline, over 30 min); nasal oxygen; *N*-acetylcysteine (140 mg/kg IV diluted 1 : 2 in saline given through nonpyrogenic filter unless sterile IV form used, then 70 mg/kg q8h); glucocorticoids controversial, may promote enteric bleeding but some evidence supports reduced astrocyte swelling.
• Salvage therapies for intractable HE (experimental)—L-ornithine-L-aspartate (humans, rats: 180–300 mg/kg/day divided into three doses); L-carnitine (100 mg/kg PO/IV) may attenuate HE-associated hyperammonemia.
• If epileptic seizure activity—Keppra® (levetiracetam; dose 20–60 mg/kg IV given 1 : 1 dilution over 15 min) is preferred anticonvulsant; secondary anticonvulsants include zonisamide (caution: rare idiopathic hepatotoxicity) or KBr (complicates fluid therapy) as preferred anticonvulsants to phenobarbital; avoid benzodiazepines in HE.

CONTRAINDICATIONS
• Avoid drugs metabolized by the liver or rapidly removed by first-pass extraction—or if used, judiciously reduce dose.
• Avoid alfaxalone.
• Avoid benzodiazepines.

PRECAUTIONS
• Consider altered drug pharmacokinetics—reduced first-pass extraction due to porto-systemic shunting; reduced protein binding if hypoalbuminemia, and compromised hepatic metabolism.
• Use anesthetics, sedatives, tranquilizers, potassium-wasting diuretics, analgesics, highly protein-bound drugs (if hypoalbuminemic) cautiously; reduce dose.
• If possible, avoid drugs predominantly reliant on hepatic metabolism, biotransformation, and excretion in patients with acquired chronic liver disease associated with APSS vs. those with PSVA or ductal plate malformation-associated APSS where metabolic or synthetic failure less likely.
• Avoid drugs or reduce dose if highly reliant on first-pass hepatic extraction if PSVA or APSS.

POSSIBLE INTERACTIONS
Drugs that influence p450 cytochrome hepatic metabolism, e.g., cimetidine, chloramphenicol, barbiturates, ketoconazole, may provoke adverse drug interactions.

FOLLOW-UP

PATIENT MONITORING
• Reevaluate patient at-home behavior and cognitive function, body condition, muscle mass, and weight; owner should record diary of progress and video abnormal behaviors.
• Monitor albumin and glucose.
• Adjust nutrition to optimize protein allowance and avoid sarcopenia.
• Monitor electrolytes—especially potassium if PU/PD or if diuretics prescribed.

PREVENTION/AVOIDANCE
Avoid provocative conditions—dehydration, azotemia, constipation, endoparasitism, enteric or oral bleeding, infusion of stored blood, hemolysis, meal-related ammonia challenge, urinary tract infections, hypokalemia, hypomagnesemia, alkalemia; and manage systemic infection or inflammation.

POSSIBLE COMPLICATIONS
Permanent neurologic damage may develop in chronic recurrent HE but uncommon; most often encountered in PSVA with acute severe HE.

EXPECTED COURSE AND PROGNOSIS
• Depends on underlying disorder.
• Acute or chronic hepatic failure—may be fully or partially reversible, or patient may die.

H

MISCELLANEOUS

AGE-RELATED FACTORS
PSVA—surgical outcome may be good in young and old patients.

SYNONYMS
• Hepatic coma.
• Portosystemic encephalopathy.

SEE ALSO
• Arteriovenous Malformation of the Liver.
• Ductal Plate Malformation (Congenital Hepatic Fibrosis).
• Hepatic Failure, Acute.
• Hepatitis, Chronic.
• Portosystemic Shunting, Acquired.
• Portosystemic Vascular Anomaly, Congenital.

ABBREVIATIONS
• APSS = acquired portosystemic shunt.
• BBB = blood–brain barrier.
• GI = gastrointestinal.
• HE = hepatic encephalopathy.
• PSVA = portosystemic vascular anomaly.
• PU/PD = polyuria/polydipsia.
• TSBA = total serum bile acids.

HEPATIC FAILURE, ACUTE

BASICS

DEFINITION
• Severe acute hepatic injury incapacitating ability to meet synthetic, metabolic, detoxification needs.
• Sudden loss of >75% of functional hepatic mass due to acute, massive hepatic necrosis.
• May lead to catastrophic multiorgan dysfunction/failure in previously healthy individual; may rapidly progress to death.

PATHOPHYSIOLOGY
• Necrosis—secondary to insufficient perfusion, hypoxia, hepatotoxins (drugs, other xenobiotics, toxins), heat excess, infectious agents.
• Severity of hepatic dysfunction depends on insult type and lobular (zonal) distribution.
• Reduced perfusion or hypoxia usually affects zone 3 (pericentral or centrilobular region).
• Ingested toxins—affect zone where toxin metabolized or toxic product formed, or where specific organelle tropism or propensity for oxidative injury (copper accumulation increases zone 3 vulnerability).
• Panlobular hepatic necrosis leading to acute liver failure uncommon; e.g., idiosyncratic drug toxicity: dogs—zonisamide, phenobarbital, primidone, diphenylhydantoin, nonsteroidal anti-inflammatory drugs (NSAIDs, e.g., carprofen), xylitol; cats—diazepam; dogs or cats—sulfa-antibiotics; primary toxins: dogs and cats—primary copper accumulation, acetaminophen; dogs—zonisamide, xylitol, cycad (sago palm), cheese tree (*Glochidion ferdinandi*) roots, blue-green algae, *Amanita* mushrooms, aflatoxin; infectious disease: dogs—leptospirosis, infectious canine hepatitis.
• Accompanied by enzyme leakage and markers of impaired liver function, hyperbilirubinemia, acute-onset splanchnic hypertension due to sinusoidal or centrilobular collapse.
• Lethal organ failure associated with coagulopathy, enteric hemorrhage, acute-onset hepatic encephalopathy (HE).
• Hepatic failure—associates with myriad metabolic derangements: altered glucose homeostasis, protein synthesis (albumin, transport proteins, procoagulants, anticoagulants), detoxification capabilities.

SYSTEMS AFFECTED
• Hepatobiliary—hepatocellular necrosis; hepatic failure, jaundice.
• Nervous—HE; cerebral edema.
• Gastrointestinal (GI)—vomiting; diarrhea; melena; hematochezia due to acute splanchnic hypertension ± coagulopathy.
• Hemic/lymphatic/immune—pro- and anticoagulant factor imbalances; disseminated intravascular coagulation (DIC).
• Renal/urologic—renal tubule damage from certain toxins or physiologic vasoconstriction; tubular injury: copper associated hepatopathy, leptospirosis, xylitol toxicity, NSAID toxicity.
• Hyperdynamic circulatory status—low systemic and pulmonary vascular resistance, increased cardiac output and metabolic rate, systemic hypotension; associates with endotoxemia, TNF-α, dehydration, and splanchnic hypertension.

INCIDENCE/PREVALENCE
Variable depending on preexistent liver disease: hepatocellular copper accumulation, chronic immune-mediated hepatitis, cholangitis.

SIGNALMENT
Species
More common in dog than cat.

Breed Predilections
Breeds with apparent predisposition to chronic hepatitis and copper associated hepatopathy (e.g., Labrador retriever, Doberman pinscher, Bedlington terrier) may have higher risk, e.g., Labrador retrievers and NSAID toxicity enhanced by copper associated hepatopathy.

SIGNS
• Acute-onset nonspecific clinical signs; lethargy, inappetence, GI disturbances (vomiting, small intestinal diarrhea may be bloody), polyuria/polydipsia (PU/PD).
• Tender hepatomegaly.
• Bleeding tendencies.
• Jaundice.
• HE.
• Seizures.

CAUSES
Drugs
• See Hepatotoxins.
• Drug-related toxicities *intrinsic* (direct) or *idiosyncratic* (unpredictable, unrelated to dose) consequent to immune-mediated hypersensitivity or metabolic injury.

Thermal Injury
• Heat stroke.
• Whole-body hyperthermia cancer treatment.

Hepatic Hypoxia
• Thromboembolic disease, shock, DIC.
• Acute circulatory failure from any cause.
• Acute centrilobular necrosis (zone 3).

RISK FACTORS
• Administration of potentially hepatotoxic substance or drug.
• Exposure to environmental toxins (e.g., *Amanita* mushroom, foodborne aflatoxin, cycad, cheese tree roots, blue-green algae), artificial sweetener—xylitol (gum, candy): dogs).
• Enzyme inducers (e.g., phenobarbital)—may increase risk for toxicities by enhancing xenobiotic toxin formation, e.g., acetaminophen toxicity greatly enhanced by phenobarbital.
• Indiscriminate substance ingestion—puppies; polyphagic animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Severe acute pancreatitis or gastroenteritis—differentiated via laboratory tests and imaging.
• Acutely decompensated chronic liver disease—distinguished by review of medical records, blood tests, abdominal US, liver biopsy.

CBC/BIOCHEMISTRY/URINALYSIS
• Anemia and panhypoproteinemia—bleeding, marrow toxicity, direct enteric toxicity.
• Thrombocytopenia—bleeding, DIC, portal hypertension.
• Liver enzyme activity—high acute alanine aminotransferase, and aspartate aminotransferase; smaller increases in alkaline phosphatase and γ-glutamyltransferase.
• Hypoglycemia—grave prognosis (esp. cats).
• Hypocholesterolemia—impaired synthesis or enteric loss with hemorrhage.
• Normal to low blood urea nitrogen concentration—reduced urea cycle function, PU/PD.
• Hyperbilirubinemia—initially absent.
• Bilirubinuria may precede hyperbilirubinemia—always abnormal in cats.
• Ammonium urate crystalluria signifies hyperammonemia, hepatic insufficiency, or portosystemic shunting.
• Acquired Fanconi syndrome—granular casts and renal glucosuria indicate proximal tubule injury (e.g., carprofen, copper, leptospirosis, other toxicities esp. in dogs).

OTHER LABORATORY TESTS
• Total serum bile acids (TSBA)—high values indicate hepatic dysfunction, cholestasis, or portosystemic shunting.
• Plasma ammonia concentration—high values coincide with high TSBA, confirm hepatic insufficiency; hyperammonemia inconsistent but reflected by ammonium biurate crystalluria; hyperammonemia may reflect concurrent myonecrosis.
• Coagulation tests—coagulation factor deficiencies, platelet dysfunction, low fibrinogen, low antithrombin or protein C activity, and DIC suggest severe liver failure, decompensated DIC, or enteric losses with hemorrhage.

IMAGING
• Abdominal radiography—may identify normal to slightly enlarged liver ± effusion.
• Abdominal US—may disclose nonhepatic disorders (e.g., pancreatitis), altered circulation (ratio hepatic vein : portal vein), altered liver echogenicity or surface contour reflecting chronic injury (e.g., remodeling

implicated by heterogeneous liver texture, nodularity, or hepatofugal portal blood flow); rule out biliary obstruction as source of hyperbilirubinemia.
• Brain MRI—may disclose early cerebral edema (not commonly done).

DIAGNOSTIC PROCEDURES
• Liver biopsy—confirms necrosis, characterizes lesion zonal distribution.
• Fine-needle liver aspirate may identify hepatocellular degeneration, copper accumulation, dysplastic hepatocytes observed with cycad or aflatoxin ingestion; canalicular cholestasis; many toxins lead to microvesicular hepatocellular lipid vacuolation.

PATHOLOGIC FINDINGS
• Gross—slightly enlarged, mottled liver.
• Microscopic—confirms necrosis; zonal involvement; may assist in determining underlying cause: hypoxia leading to zone 3 necrosis; certain toxins cause zone 1 or 3 necrosis; reticulin staining confirms zonal involvement, retention, or loss of reticulin substructure that orchestrates organized regeneration.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient—intensive care needed.

NURSING CARE
• *Caution*: delay inserting central catheters until bleeding diatheses controlled with vitamin K_1, fresh frozen plasma (FFP), or fresh whole blood; no advantage to prophylactic FFP administration as may contribute to onset of HE and cerebral edema.
• Fluids—non–lactate-containing; initially at resuscitation rate; monitor peripheral BP, pulse oximetry; mixed acid-base disturbances common.
• Colloid replacement—when low oncotic pressure from bleeding and protein loss; plasma always preferred; synthetic colloids second line; avoid dextran 70 and hetastarch (may promote bleeding) and human albumin (may induce fatal acute allergic reaction).
• Potassium, phosphate, glucose—supplement as appropriate; low phosphate, potassium, glucose aggravate HE and other clinical signs, complicating critical supportive care.
• Fluid regimen—adjust for maintenance needs after achieving euvolemia; typically provide ⅓ normal maintenance rate with polyionic crystalloids if concurrently giving slow CRI of synthetic colloid; avoid colloids if possible as leak from microvasculature (exacerbated with some toxicities that affect endothelium) and disturb signaling that triggers albumin and transporter protein synthesis.
• Supplemental oxygen—if pulse oximetry ≤94% saturation.
• If suspect cerebral edema—use 30° head-up elevation, consider mannitol, other interventions.
• Predisposition to infection from enteric bacterial translocation—cover with broad-spectrum antimicrobials; patient may not manifest fever or leukocytosis with infection; sepsis/systemic inflammatory response syndrome—major risks for cerebral edema.
• Early administration of *N*-acetylcysteine may improve microvascular perfusion, tissue oxygenation, and mitigate oxidative damage (see below).

ACTIVITY
Restricted activity—conserves energy and metabolites for healing and regeneration.

DIET
• Intractable vomiting—withhold PO food until controlled; antiemetics (see below).
• When enteric nutrition contraindicated (somnolent patient) use partial or total parenteral nutrition (TPN) until enteral feeding route established; <5 days advised.
• If enteric nutrition chronically compromised, establish TPN feeding catheter; use TPN formula with normal nitrogen content unless HE; branched-chain amino acids still controversial.
• Enteral feeding—small-volume, frequent meals; optimize digestion and assimilation, minimize enteric toxin formation contributing to HE.
• Diet composition—use normal protein (nitrogen) content in tolerant patients; moderate protein restriction if HE (2.5 g protein/kg bodyweight) but strive to maintain positive nitrogen balance for hepatic regeneration.
• Supplemental vitamins essential—water-soluble (twice normal); vitamin K_1 (0.5–1.5 mg/kg SC/IM, three doses at 12h intervals, then once to twice weekly); vitamin E (10 IU/kg PO or by injection q24h).
• Pro-/prebiotic yogurt—may protect against enteric bacterial translocation; tolerated dairy protein source if HE; controversial.

CLIENT EDUCATION
• Acute hepatic failure is serious condition.
• Some patients succumb despite optimal treatment.
• Cause of panlobular injury (e.g., exposure to drug or toxin) should be investigated but may remain unconfirmed.

MEDICATIONS

DRUG(S) OF CHOICE

Drugs for Vomiting
• Metoclopramide—1–2 mg/kg/day CRI for intermittent mild vomiting; contraindicated if spironolactone used for ascites mobilization.
• Ondansetron—0.5–1.0 mg/kg IV q12h.
• Maropitant—1.0 mg/kg IV/SC q24h (some suggest decreasing dose by 50% in patients with hepatic dysfunction due to hepatic metabolism).
• Omeprazole (0.5–1.0 mg/kg PO q12–24h) or pantoprazole (0.7–1.0 mg/kg IV q12h) may induce P450 cytochrome–associated drug interactions; 24–48h delay in onset of action; preferred over H2 blockers for gastric ulceration.
• Histamine H2 blocker—famotidine (0.5–1.0 mg/kg IM/SC q12–24h) if enteric bleeding; reserve cimetidine (0.5 mg/kg q8–12h) for purposeful P450 cytochrome inhibition.
• Chlorpromazine—0.5 mg/kg SC/IM/rectally q8–24h for severe vomiting; ensure volume expansion first as causes alpha blockade vasodilation.

Drugs for HE
• Lactulose—0.5–2.0 mL/kg PO q8h or rectally if PO hazardous; goal is soft feces.
• Probiotic yogurt (see above).
• Metronidazole—7.5 mg/kg PO q12h or rectally if PO hazardous.
• Ampicillin/amoxicillin (esp. cats) —12.5–25 mg/kg IV/PO q8–12h.
• Rifaximin—5–10 mg/kg PO or rectally q12h (nonabsorbed antibiotic alters enteric flora).
• Neomycin—22 mg/kg PO or rectally q12h; *caution*: may be ototoxic and renal toxic if increased absorption with reduced gut integrity.

Treatment of Cerebral Edema Associated with HE
• Mannitol—1 g/kg over 10–20 min, filtered; if brisk diuresis does not occur (~1h), check for excessive volume expansion (plasma osmolality, BP) and renal function.
• Furosemide—0.5–1.0 mg/kg IV q8–24h increases free water excretion and reduces cerebrospinal fluid (CSF) production; monitor hydration and serum potassium; avoid dehydration and hypokalemia that provoke or worsen HE.
• Vasopressin V_2 antagonists (aquaretics) *may* assist with management of diuretic resistant ascites; tolvaptan successful in dogs with experimentally induced (rapid pacing) congestive heart failure (see Hypertension, Portal).

Drugs for Coagulopathy
Fresh whole blood or FFP—if clinically significant bleeding.

Free Radical Scavengers and Antioxidants
• For ongoing damage (membrane injury), reperfusion injury, and hypoxia.
• Vitamin E—10 IU/kg PO q24h.
• *N*-acetylcysteine—140 mg/kg IV/PO loading dose; IV use 10% solution diluted 1 : 2 in saline, administer via 0.25 µm nonpyrogenic filter; follow with 70 mg/kg q6–12h.
• *S*-adenosylmethionine as glutathione (GSH) donor, use proven bioavailable product—

HEPATIC FAILURE, ACUTE (CONTINUED)

20 mg/kg PO q24h on empty stomach; multiple benefits: essential intermediary metabolites, GSH synthesis, promotes liver regeneration, antifibrotic, anti-inflammatory.

Hepatoprotectants

- Silybin (milk thistle), efficacy reported for *Amanita* toxicity and certain other toxins; use complexed with polyunsaturated phosphatidylcholine, 2–5 mg/kg PO q24h.
- Ursodeoxycholic acid—if chronic liver injury or high bile acids persist, 10–15 mg/kg PO q24h or divided q12h, best absorbed with food.

Blocking Enterohepatic Circulation

Cholestyramine—30–40 mg/kg mixed with water PO q24h; bile acid–binding resin that can absorb certain toxins in alimentary canal that undergo enterohepatic circulation, diminishing systemic availability, e.g., sago palm (cycad toxin).

CONTRAINDICATIONS

- Ideally avoid drugs biotransformed primarily in liver, altering liver perfusion, or metabolizing enzyme activity; may be difficult as many drugs metabolized in hepatic pathways or eliminated in bile.
- Vitamin C—100–500 mg q24h, *avoid* if high liver iron or copper concentrations; ascorbate may augment transition metal–associated oxidative injury; no substantiation for vitamin C administration in liver failure.

PRECAUTIONS

Administration of stored whole blood or packed red blood cells may precipitate or exacerbate HE in dogs with hepatic failure because of spontaneously generated ammonia during storage.

POSSIBLE INTERACTIONS

Compromised hepatic metabolism.

ALTERNATIVE DRUG(S)

Case-based considerations.

FOLLOW-UP

PATIENT MONITORING

- Temperature, pulse, respiration, mental status—q1–2h until stable.
- Maintain vigilance for infection, especially catheter-induced.
- Bodyweight—twice daily guides fluid therapy; bodyweight and condition used to assess nitrogen and energy allowances.
- Acid-base, electrolyte balances (especially potassium and phosphate), glucose—q12–24h for first 72h.
- Sequential measurements of liver enzymes, bilirubin, cholesterol, fibrinogen q2–3 days provide evidence of recovery.

PREVENTION/AVOIDANCE

- Vaccinate dogs against infectious canine hepatitis virus.
- Avoid indiscriminate ingestion of hepatotoxins and environmental exposure.
- Consider drugs as potential toxins.

POSSIBLE COMPLICATIONS

- Hypoglycemia.
- Uncontrolled GI bleeding and DIC.
- HE, cerebral edema, brain herniation.
- Chronic hepatic insufficiency, cirrhosis, fibrosis from postnecrotic scarring.
- Acute renal failure.
- Death.

EXPECTED COURSE AND PROGNOSIS

Prognosis—depends on extent of liver injury, etiopathogenesis, supportive nursing care.

MISCELLANEOUS

ASSOCIATED CONDITIONS

HEPATIC LIPIDOSIS

BASICS

DEFINITION
- Feline hepatic lipidosis (HL)—lipid vacuolation distends the cytosolic compartment in >80% of hepatocytes.
- Untreated—leads to progressive metabolic dysregulation, hepatic failure, and death.
- Develops secondary to a primary disease or condition causing anorexia or catabolism; idiopathic HL is uncommon: a cause is usually discoverable.

PATHOPHYSIOLOGY
- Cats have a unique propensity to accumulate triglyceride-filled hepatocellular vacuoles.
- Causal factors—negative energy and protein balance with increased peripheral fat mobilization.
- Cytosolic triglyceride vacuoles cause severe cholestasis and jaundice via canalicular compression and associated hepatic organelle dysfunction.
- Hepatic failure—with rare evidence of hepatic encephalopathy (HE).

SYSTEMS AFFECTED
- Hepatobiliary.
- Gastrointestinal—anorexia; vomiting.
- Musculoskeletal—peripheral muscle wasting (sarcopenia) and fat mobilization.
- Nervous—HE, ptyalism, moribund status.
- Hemic/lymphatic/immune—abnormal red blood cell (RBC) shapes (poikilocytes), Heinz body hemolysis.
- Renal/urologic—potassium wasting; renal tubule triglyceride accumulation.

INCIDENCE/PREVALENCE
Most common severe hepatopathy in North America causing jaundice in pet cats.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT

Species
Cats, rarely dogs (toy-breed failure-to-thrive puppies), juveniles with lysosomal or glycogen storage disease; may develop in small-breed puppies with portosystemic vascular anomaly (PSVA).

Breed Predilection
N/A

Mean Age and Range
Middle-aged adult cats—median age 8 (range: 1–16 years).

Predominant Sex
N/A

SIGNS

Historical Findings
- Anorexia or hyporexia, weight loss, sarcopenia.
- Vomiting, diarrhea or constipation, jaundice.
- Lethargy, with gradual onset of weakness progressing to collapse.
- Ptyalism.
- Neck ventriflexion—weakness, electrolyte depletions (potassium, phosphate), thiamine deficiency.
- Underlying disease or illness causing hyporexia/anorexia → hepatic lipidosis.

Physical Examination Findings
- Jaundice.
- Hepatomegaly.
- Dehydration.
- Weakness—neck ventriflexion, recumbency.
- Ptyalism.
- Collapse ←→ obtunded (signs of HE).
- Others, depending on underlying primary disease.

CAUSES

"Idiopathic" Hepatic Lipidosis
Idiopathic = uncommon; antecedent health problems discoverable in >85% of cases causing anorexia or malassimilation; remainder have food deprivation often attributable to adverse social interactions, environmental cause.

Secondary Hepatic Lipidosis
- Primary liver disease—PSVA; cholangitis/cholangiohepatitis syndrome (CCHS); extrahepatic bile duct obstruction (EHBDO); cholelithiasis; neoplasia.
- Gastrointestinal—obstruction; neoplasia; inflammatory bowel disease (IBD); pancreatitis.
- Urogenital disease—renal failure, chronic interstitial nephritis (CIN), lower urinary tract syndromes.
- Neurologic conditions—cannot eat.
- Infectious diseases—toxoplasmosis; feline infectious peritonitis (FIP); feline immunodeficiency virus (FIV)– or feline leukemia virus (FeLV)–related disorders.
- Hyperthyroidism.
- Vitamin B_{12} deficiency and deficiency of other water-soluble vitamins may predispose cats to HL as a result of disrupted metabolism as one factor.
- Many other systemic conditions or toxins can provoke anorexia and lead to HL.
- Rapid weight loss protocols or change to restricted-calorie diet the cat refuses to eat.

RISK FACTORS
- Obesity.
- Anorexia, negative nitrogen balance.
- Catabolism or rapid weight loss.
- Water-soluble vitamin deficiency.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Primary liver disease—CCHS, cholelithiasis, EHBDO, or neoplasia (esp. lymphosarcoma) differentiated by abdominal US, liver aspiration, and liver biopsy.
- PSVA—diagnosis by US or colorectal scintigraphy, lab testing.
- Hepatic toxoplasmosis or FIP—liver biopsy, serology, immunohistochemistry.
- Pancreatitis—differentiated by US, serum tests, pancreatic aspiration cytology, gross inspection, biopsy.
- Gastrointestinal disease—IBD differentiated by bowel biopsies; obstruction differentiated by abdominal survey or contrast radiography and US.
- Toxicities—suspected based on history (e.g., oral diazepam, acetaminophen, methimazole).
- Hyperthyroidism—serum thyroid panel, absence of jaundice.

CBC/BIOCHEMISTRY/URINALYSIS
- Hematology—poikilocytes common; nonregenerative anemia; hemolytic anemia (severe hypophosphatemia or Heinz bodies).
- Biochemistry—hyperbilirubinemia; high alkaline phosphatase (ALP), alanine aminotransferase (ALT), ± aspartate aminotransferase (AST) activity; normal or mild increase in γ-glutamyltransferase (GGT) if no primary necro-inflammatory ductal disorder (i.e., biliary, pancreatic); low blood urea nitrogen (BUN); normal creatinine; variable glucose (hypoglycemia rare); variable cholesterol, albumin, globulins; hypokalemia; hypophosphatemia, increased ketones (beta-hydroxybutyrate); lactic acidosis.
- Urinalysis—bilirubinuria, lipiduria, and unconcentrated urine common.

OTHER LABORATORY TESTS
- Prolonged coagulation times—prothrombin time (PT), activated partial thromboplastin time (APTT), activated clotting time (ACT); fibrinogen usually normal.
- Hyperammonemia—uncommon.
- Serum bile acids—high before hyperbilirubinemic; redundant test if hepatobiliary jaundice.
- B_{12} deficiency.

IMAGING

Survey Abdominal Radiography
- Hepatomegaly.
- May note features of underlying disorder.

Abdominal US
- Diffuse hyperechoic hepatic parenchyma, hepatomegaly.
- Look for primary disease causing HL.

DIAGNOSTIC PROCEDURES
- Fine-needle liver aspiration cytology—>80% hepatocytes display severe cytosolic lipid vacuolation; biopsy rarely needed to confirm HL.
- Definitive diagnosis HL—based on history, clinical features, high ALP, diffuse hyperechoic hepatic parenchyma, severe hepatocyte lipid

HEPATIC LIPIDOSIS (CONTINUED)

vacuolation on aspiration cytology; however, cannot rule out primary hepatic disorders (e.g., CCHS, EHBDO, PSVA) with these tests.
• Liver biopsy—definitive diagnosis of underlying "primary" liver disorders; *done only if poor response to therapy or high GGT*; *caution*: stabilize cat before anesthesia and liver biopsy.
• Vitamin K_1 (0.5–1.5 mg/kg SC/IM) three doses at 12h intervals, *before* aspiration sampling, liver biopsy, jugular vein catheterization, cystocentesis, or feeding appliance insertion.

PATHOLOGIC FINDINGS
• Gross—diffuse hepatomegaly, smooth surface, friable greasy consistency, yellow/pale color with reticulated appearance; sample floats in formalin.
• Microscopic—diffuse, severe hepatocellular lipid vacuolation; large (macrovesicular) or small (microvesicular) vacuolation; type of vacuolation lacks prognostic value.

TREATMENT

APPROPRIATE HEALTH CARE
• Inpatient—recumbent cats or those with neck ventriflexion and anorectic.
• Discharge for home care—see Patient Monitoring.
• Frequent reevaluations imperative.
• Outpatient—reduces stress and thereby facilitates recovery in some cats.

NURSING CARE
• Balanced polyionic fluids—*avoid* lactate and dextrose supplementation; 0.9% NaCl preferred.
• Potassium chloride supplementation essential (see Hypokalemia).
• Phosphate supplements usually needed (see Hypophosphatemia) at initial feeding; often started prophylactically, see below.
• Magnesium supplements rarely needed.

Correct Hypophosphatemia
• Serum phosphate <2.0 mg/dL reflects refeeding syndrome; may provoke anorexia, vomiting, weakness, myonecrosis, ileus, hemolysis, coagulopathy, neurologic signs confused with HE.
• Treatment—potassium phosphate initial dose 0.01–0.03 mmol/kg/h IV; monitor serum phosphate q6h; discontinue when stable phosphate >2 mg/dL; *caution*: judiciously reduce IV potassium chloride supplements concurrently given in fluids; monitor potassium.

Correct Hepatic and Circulating GSH Depletion
• Low liver glutathione (GSH) confirmed in HL; routine GSH measurements not available.
• Crisis intervention for low hepatic GSH or Heinz body anemia—*N*-acetylcysteine (NAC) 140 mg/kg IV, then 70 mg/kg IV, 10% solution diluted 1 : 2 in saline; administered over 20 min otherwise may provoke hyperammonemia.
• When enteral feeding established, change to *S*-adenosylmethionine (SAMe) 200 mg/cat PO q24h; need for dosing on empty stomach complicates use.

ACTIVITY
Physical activity (walking), when possible, may increase gastric motility when gastroparesis complicates feeding (chronic vomiting).

DIET
• Nutritional support—cornerstone of recovery.
• High-protein, high-calorie balanced feline diet essential.
• Energy—50–60 kcal/kg ideal weight/day; gradual transition to full energy requirement over 3–7 days; feed multiple small meals/day or trickle feed through esophageal feeding tube (E-tube).
• Forced alimentation usually required; *caution*: *oral* forced feeding may provoke food aversion syndrome.
• Correct hypokalemia and hydration before commencing feeding; associated gastroparesis may lead to vomiting and potential for aspiration pneumonia.
• Tube feeding—initially by nasogastric tube (first 1–2 days *after* electrolyte and vitamin deficiency improved), transition to E-tube after hydration and electrolyte status improves, and vitamin K_1 protocol administered.
• Avoid laparotomy for gastric feeding tube insertion; cats with HL have high risk for mortality with general anesthesia and surgery; E-tube preferable.
• Cautiously offer PO food daily to assess interest.
• Human stress formula enteral diets (not recommended)—require supplemental arginine (or citrulline), and taurine; use feline formulated liquified diet with vitamin supplements.

Supplements
• Supplements improve survival in severely affected cats.
• Water-soluble vitamins—in IV fluids; generally 2 mL/L.
• Thiamin—50–100 mg/day, give PO rather than SC/IM, also add via water-soluble vitamins mixed in IV fluids.
• Vitamin B_{12}—initially 0.25–1 mg IM/SC once): determine chronic vitamin B_{12} needs by sequential B_{12} values (weekly, q2 weeks, to monthly then quarterly intervals).
• Medical-grade L-carnitine (250–500 mg/day); over-the-counter carnitine supplements have wide variability in bioavailability; Carnitor® (liquid medical-grade carnitine) recommended.
• Taurine 250–500 mg/day PO.
• Vitamin E 10 IU/kg/day PO in food- use water-soluble form initially.
• Thiol donors IV NAC, PO SAMe—as above.
• Potassium gluconate (for hypokalemia) PO, reduce fluid potassium supplements.
• Marine oil in food 2000 mg q24h.

CLIENT EDUCATION
• Warn client—sequential biochemical assessments needed to monitor recovery.
• Educate client about feeding tube use/care and need for chronic use (up to 4–6 months).
• Advise client—recurrence unlikely; liver function will not be chronically compromised.

SURGICAL CONSIDERATIONS
• Avoid surgical interventions until normalization of hydration, electrolyte depletions, and supplements of vitamins provided, Heinz body anemia alleviated.
• Exploratory laparotomy and liver biopsy—*only* indicated if failure to improve on described interventions or marked increase in GGT activity to identify underlying disorders; biopsy liver, pancreas, stomach, and small bowel if explored; lymph nodes if enlarged.

MEDICATIONS

DRUG(S) OF CHOICE
• Vitamin K_1—recommended for all cats with suspected HL; see above, avoid overdosage.
• Drugs to ameliorate HE (see Hepatic Encephalopathy), rarely.
• Emesis control—metoclopramide: for vomiting, nausea, gastroparesis (0.2–0.5 mg/kg SC q8h 30 min before feeding, or as CRI IV drip at 0.01–0.02 mg/kg/h or 1–2 mg/kg/day); dolasetron or ondansetron; or maropitant (1 mg/kg IV/SC/PO q24h 5 days max); pantoprazole to avert esophageal damage secondary to vomiting (0.5–1.0 mg/kg q12–24h).
• Systemic antibiotics—as appropriate for suspected infection.

CONTRAINDICATIONS/PRECAUTIONS
• Downward adjust dosages of medications relying on hepatic metabolism or excretion.
• Avoid benzodiazepines and barbiturates—may provoke HE.
• Appetite stimulants do not provide dependable energy intake in cats with HL; some produce sedation; diazepam may cause rare fulminant hepatic failure.
• Avoid injectable medications with propylene glycol carrier; may lead to hemolysis in cats with low GSH.
• Ursodeoxycholic acid—likely not beneficial; may promote taurine deficiency.
• Dextrose supplements—may provoke hepatic triglyceride accumulation.

• Avoid tetracyclines or stanozolol—promote hepatocyte triglyceride vacuolation.
• Avoid recurrent or prolonged use of propofol—may provoke hemolysis (12h after infusion) esp. in cats with Heinz body anemia; HL cats may recover slowly; alternatively use gas anesthesia.

FOLLOW-UP

PATIENT MONITORING

• Bodyweight and condition, hydration, electrolytes; judicious adjustment of energy, fluid, electrolyte, and vitamin provisions essential.
• Serum bilirubin—predicts recovery.
• Reduced lactate and ketones reconcile with metabolic improvement.
• Liver enzyme activity—do not predict recovery.
• Discharge for home care—when vomiting controlled, gastroparesis resolved, bilirubin declining, patient ambulatory, and tube-feeding apparatus problem-free.
• Tube feeding—discontinued only after confirmed voluntary food consumption.

PREVENTION/AVOIDANCE

• Obesity—prevent; weight reduction must not exceed 2% bodyweight per week.
• Caution owner to verify food intake during weight loss regimens and at-home stress.

POSSIBLE COMPLICATIONS

• Feeding tube malfunction or obstruction—tube obstructions relieved with papaya juice, carbonated soft drink, or pancreatic enzyme slurry; 15 min dwell time, warm water flush.
• Rare HE after dietary support introduced.
• Unremitting HL can lead to lethal hepatic failure.
• Untreatable underlying causal disorder.

EXPECTED COURSE AND PROGNOSIS

• Optimal response to tube feeding and nutritional supplements—recovery in 3–6 weeks.
• Therapy as described—85% recovery in severely affected animals with controllable primary disease process that provoked HL.
• Underlying disease influences outcome.
• HL rarely recurs.
• HL does not cause chronic liver dysfunction, hepatitis, persistent remodeling.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Primary liver disorders.
• Pancreatitis.
• Malassimilation—various causes but IBD predominant.
• Diabetes mellitus—relatively uncommon.
• Neoplasia—hepatic and systemic.
• HE (rare).
• Systemic illness limiting food intake.

SYNONYMS

• Fatty liver syndrome.
• Hepatosteatosis.
• Feline hepatic vacuolation.
• Vacuolar hepatopathy.
• Vacuolar degeneration.

SEE ALSO

• Cholangitis/Cholangiohepatitis Syndrome.
• Hepatic Encephalopathy.

ABBREVIATIONS

• ACT = activated clotting time.
• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• APTT = activated partial thromboplastin time.
• AST = aspartate aminotransferase.
• BUN = blood urea nitrogen.
• CCHS = cholangitis/cholangiohepatitis syndrome.
• CIN = chronic interstitial nephritis.
• EHBDO = extrahepatic bile duct obstruction.
• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.
• GGT = gamma glutamyltransferase.
• GSH = glutathione.
• HE = hepatic encephalopathy.
• HL = hepatic lipidosis.
• IBD = inflammatory bowel disease.
• NAC = *N*-acetylcysteine.
• PSVA = portosystemic vascular anomaly.
• PT = prothrombin time.
• RBC = red blood cell.
• SAMe = *S*-adenosylmethionine.

HEPATIC NODULAR HYPERPLASIA AND DYSPLASTIC HYPERPLASIA

BASICS

OVERVIEW

Hepatic Nodular Hyperplasia (HNH)

- Benign parenchymal feature in middle-aged to older dogs; nonencapsulated, ≤2 cm (rarely up to 5 cm), expansile nodule of hepatocellular hyperplasia, maintaining a modified lobular architecture with recognizable central and portal elements that are irregularly spaced, organized hepatic cord structure 1 cell wide, without marginal parenchymal collapse or fibrosis (is not a regenerative nodule), smooth margins; hepatocyte phenotype may be similar to surrounding parenchyma but may contain glycogen of lipid vacuoles.
- May associate with increased liver enzymes in elderly dogs, especially alkaline phosphatase (ALP).
- Clinical concern derives from association with increased liver enzyme activity and US detection of hepatic nodules or hepatic nodularity during exploratory surgery.
- Variable US appearance.
- Biopsy specimens must include affected and unaffected liver for appropriate interpretation.
- Nodular hyperplasia may be mistaken for regeneration secondary to chronic hepatitis or hepatocellular neoplasia (adenoma) with needle core biopsies or when only nodular tissue without normal hepatic tissue is sampled.

Hepatocellular Dysplastic Hyperplasia (HDH)

- Potentially preneoplastic proliferative hepatocellular foci in dogs with glycogen-type vacuolar hepatopathy (VH); nonencapsulated, variably sized, reduced reticulin substructure, expansile nodules of nonvacuolated hepatocytes forming wide (2 cells wide, normal = 1 cell width) disorganized hepatic cords, an irregular (serrated) margin interfacing with adjacent "normal VH" affected hepatocytes, and lacking remodeled marginal lesions (fibrosis, parenchymal collapse).
- Associates with VH-related increased liver enzymes, dominated by increased ALP activity.
- Recognized as an antecedent hepatic lesion in dogs developing hepatocellular carcinoma (e.g., Scottish terriers, also other breeds) and is seemingly associated with increased sex hormone concentrations (androgens, progestins).
- Variable US appearance depending on size, number, distribution.
- May be mistaken for nodular regeneration without special stains to detail reticulin substructure and collagen fibril deposition.

SIGNALMENT

HNH

- Age-related lesion.
- Nodules develop by 6–8 years of age; one study documented lesions in all geriatric dogs >14 years of age.

HDH

- Associated with glycogen-type VH.
- Reflects adrenal hyperplasia syndromes.

SIGNS

Physical Examination Findings

- HNH does not cause clinical illness.
- Large nodules that rupture and bleed or nodules impairing hepatic sinusoidal perfusion likely represent misdiagnosed hepatic adenomas or well-differentiated hepatocellular carcinoma.
- HDH is associated with glycogen-type VH syndromes (see Glycogen-Type Vacuolar Hepatopathy).

CAUSES & RISK FACTORS

- HNH etiology—unknown; metabolic factors, prior injurious events. In humans associated with infarcts, but no evidence of this in dogs.
- HDH etiology—may represent hormonal influence promoting neoplastic transformation (sex hormone–related adrenal hyperplasia).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Necroinflammatory liver disease—regenerative nodular hyperplasia involves the entire liver; formation of irregular nodules of variable size that are segregated by parenchymal collapse, often marginated by fibrous connective tissue; demonstrate loss of lobular architecture, sinusoidal fibrosis, reduced reticulin substructure, and wide disorganized hepatic cords.
- Neoplasia—hepatic adenoma: mass lesions with margins reflecting expansile compression on normal adjacent liver, encapsulated, hepatic cords double wide, disorganized, reduced reticulin substructure, and minimal atypia. Hepatocellular carcinoma: single or multiple confluent or separate mass lesions, margins reflecting irregular expansile compression on normal adjacent liver, partially encapsulated, variable width of disorganized hepatic cords >2 cells, multiple phenotypes differing from adjacent normal tissue, variable atypia (may be well differentiated), may display pseudoglandular pattern associated with giant canaliculi, well-vascularized with arterial twigs; retention of some normal lobular elements possible (primarily at the periphery).

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—no association with HNH; for HDH see Glycogen-Type Vacuolar Hepatopathy.
- Biochemistry profile—increased serum ALP activity may be encountered with HNH and HDH; may range from 2.5- to 16-fold normal; higher with HDH and VH syndrome, see Glycogen-Type Vacuolar Hepatopathy; usually normal total protein, albumin, bilirubin, and cholesterol.
- Urinalysis—no consistent findings.

OTHER LABORATORY TESTS

Total serum bile acids (TSBA)—usually normal, unless lesions are diffuse and severe.

IMAGING

- Abdominal radiography—no abnormalities except hepatomegaly with HDH due to VH.
- Abdominal US—variable echogenicity relating to histologic features, nodule number and size, and associated VH. HNH often not noted until liver grossly inspected at surgery or laparoscopy.

DIAGNOSTIC PROCEDURES

- Aspiration cytology—may yield normal hepatocytes, hepatocytes with cytosolic rarefication and fragility consistent with VH (glycogen retention), or cells with discrete lipid (triglyceride) vacuoles (HNH); occasional binucleate hepatocytes may reflect cell proliferation or other concurrent disease (common in portosystemic vascular anomalies/microvascular dysplasia); hepatocytes may be small with size variation in HDH. Liver biopsy—collection of a needle biopsy specimen may not clearly differentiate HNH lesion because of small specimen size; definitive diagnosis requires targeted sampling of a large enough tissue specimen to include lesion and adjacent normal hepatic tissue. HDH may be recognized on needle samples.
- Recommended biopsy methods—laparoscopy, open-wedge biopsy during laparotomy, or multiple 14-G needle samples.
- Special stains—reticulin staining illustrates hepatocyte reticulin substructure, lobular collapse/remodeling, and changes associated with nodule margins. Masson's trichrome staining illustrates collagen deposition and remodeling typical of regenerative nodules secondary to chronic liver injury; periodic acid-Schiff staining with and without amylase predigestion confirms excess glycogen in vacuolated hepatocytes (see Glycogen-Type Vacuolar Hepatopathy).

PATHOLOGIC FINDINGS

- HNH gross—single or multiple mass lesions, rarely >2 cm in diameter; color similar to adjacent normal hepatic tissue or paler if vacuolated with glycogen or lipid.
- HDH gross—single or multiple lesions, usually small, may appear darker colored compared to adjacent tissue. Microscopic—see above.

(CONTINUED) HEPATIC NODULAR HYPERPLASIA AND DYSPLASTIC HYPERPLASIA

TREATMENT

• Usually none required; rupture of large nodules indicates hepatocellular carcinoma misdiagnosis; may necessitate blood transfusion and emergency mass excision. Palliate or alleviate underlying cause of VH.
• HDH—recommend biochemical assessments for rising ALP or alanine aminotransferase (ALT) that may indicate transformation of mass lesion to a neoplastic phenotype; US inspection of adrenal glands for adrenomegaly or nodules, US surveillance for expanding mass lesions that should be surgically removed; assess pituitary adrenal axis for typical or atypical hyperadrenocorticism; if increased sex hormones >2.5 × upper reference interval consider adrenal modulation with agent that does not increase sex hormones.

MEDICATIONS

DRUG(S) OF CHOICE

• HDH—if increased sex hormones, progressive VH, nodule formation, increasing ALP, or confirmed hepatocellular carcinoma (after mass resection), consider adrenal modulation with a drug that does not increase sex hormone concentrations (Lysodren® or mitotane); trilostane increases sex hormone concentrations and would be inappropriate.
• Scottish terrier syndrome does not respond to adrenal modulation; instead use surveillance to detect emerging hepatocellular carcinoma.

FOLLOW-UP

PATIENT MONITORING

• Quarterly biochemical profiles.
• Sequential abdominal US to evaluate progression of hepatic nodules.
• See Glycogen-Type Vacuolar Hepatopathy for related disorders.

POSSIBLE COMPLICATIONS

Distinction of HNH from neoplastic foci is not possible based only on clinical, laboratory, or imaging data, although lesions >2 cm are unlikely to be this diagnosis.

EXPECTED COURSE AND PROGNOSIS

More extensive numbers of nodules may develop in some dogs with HNH and HDH; HDH predicts risk for primary hepatocellular neoplasia, which requires surveillance and surgical treatment.

MISCELLANEOUS

SEE ALSO

• Cirrhosis and Fibrosis of the Liver.
• Glycogen-Type Vacuolar Hepatopathy.
• Hepatitis, Chronic.
• Hepatocellular Adenoma.
• Hepatocellular Carcinoma.

ABBREVIATIONS

• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• HDH = hepatic dysplastic hyperplasia.
• HNH = hepatic nodular hyperplasia.
• TSBA = total serum bile acids.
• VH = vacuolar hepatopathy.

HEPATITIS, CHRONIC

BASICS

DEFINITION
• Hepatic injury associated with active chronic necroinflammatory liver injury; "chronic active hepatitis" should not be used.
• Nonsuppurative inflammation—most common; lymphocytes, plasma cells, macrophages, occasional neutrophils.
• Chronicity—progressive remodeling, regenerative nodule formation, evolving sinusoidal fibrosis with location dependent on zonal tropism of inflammation; changes eventuate in cirrhosis.

PATHOPHYSIOLOGY
• A multitude of initiating events or agents cause hepatic injury; damage to cell and/or organelle membranes usually involves oxidative injury; activated cytokines and cell-mediated immune responses widen and perpetuate inflammation; hepatic neoepitopes may become targeted foci.
• Initial injury may include infectious agents, toxins, xenobiotics, or pathologic Cu accumulation; with exception of Cu-mediated injury, cause often remains undetermined.
• Inflammatory cells—predominantly lymphocytes, fewer Kupffer cells (resident hepatic sinusoidal macrophages), and variable neutrophils are initial effectors.
• Injury zone demarcates area of predominant necroinflammatory damage—zone 1 (periportal) common to idiopathic hepatitis or inflammation involving portal tract structures; zone 3 incriminates Cu, nonsteroidal anti-inflammatory drug (NSAID), other xenobiotic or toxin-mediated injury, or repeated ischemic/hypoxic insult; panlobular inflammation common.
• Lesion progression—variable, may include portal and periportal lymphoplasmacytic infiltrates with interface hepatitis (inflammation breaching limiting plate of portal tract), and otherwise variable lobular injury; chronic inflammation: leads to progressive fibrosis with bridging of involved zones.
• Bridging fibrosis and regenerative nodules distort lobular architecture; fibrosis, intrahepatic sinusoidal hypertension, neovascularization, and impaired hepatic function evolve into cirrhosis.
• Progressive cholestasis due to mechanical compression/distortion of bile ducts may occur.
• Cirrhosis and hepatic failure—late stage.
• Fibrosis—usually reflects chronic injury from sustained inflammation.
• Cirrhosis—associated with hepatic dysfunction, sinusoidal hypertension; intrahepatic shunting through collagenized sinusoids or neovascular pathways in fibrotic partitions that segregate regenerative nodules.
• Sinusoidal hypertension—leads to hepatofugal portal circulation (flow away from liver); mesenteric splanchnic hypertension; development of acquired portosystemic shunt(s) (APSS); episodic hepatic encephalopathy (HE); ascites; portal hypertensive enteric vasculopathy predisposes to enteric bleeding.

SYSTEMS AFFECTED
• Hepatobiliary—inflammation; necrosis; cholestasis; fibrosis.
• Gastrointestinal (GI)—emesis; diarrhea; anorexia, portal hypertension, ascites, and propensity for enteric bleeding.
• Neurologic—HE (advanced stage, associated with APSS).
• Hemic—red blood cell (RBC) microcytosis reflects APSS; bleeding or thrombotic tendencies: failed factor or anticoagulant synthesis or activation, thrombocytopenia or thrombopathia; coagulopathies typically observed with advanced injury or severe diffuse hepatic necrosis.
• Renal/urologic—polyuria/polydipsia (PU/PD); isosthenuria; ammonium biurate crystalluria (advanced stage with APSS and HE).
• Endocrine/metabolic—hypoglycemia if end-stage liver failure.
• Respiratory—tachypnea if tense ascites; bicavitary effusion or pulmonary edema.

GENETICS
• Breed or familial predisposition for chronic hepatitis—Doberman pinscher, Labrador retriever, West Highland white terrier, and Dalmatian may develop chronic hepatitis secondary to pathologic Cu accumulation; cocker spaniel hepatopathy, anecdotal in other breeds or breeding lines.
• Inherited Cu associated hepatopathy only proven in Bedlington terrier— autosomal recessive, genetic test available.

SIGNALMENT

Species
Dog

Breed Predilection
See Genetics.

Mean Age and Range
Average age 6–8 years (range: 2–14 years).

Predominant Gender
Inconsistent among reports for any breed.

SIGNS

General Comments
• Initially—vague and nonspecific, often includes lethargy and inappetence.
• Later—relate to complications of portal hypertension; impaired hepatic function including cholestasis.

Historical Findings
• May be no signs in early disease or mild lethargy.
• Anorexia, vomiting, weight loss, reduced body condition.
• PU/PD.
• Jaundice—later stage unless portal hepatitis involves bile duct injury.
• Ascites—late stage.
• HE—late stage, infers APSS with cirrhosis.

Physical Examination Findings
• May be no signs in early disease.
• Lethargy, poor coat, declining body condition.
• Variable jaundice.
• Liver size—normal to small, depends on chronicity.

Late-Stage Physical Findings
• Ascites.
• HE.
• Obstructive uropathy—ammonium biurates.
• Bleeding or thrombotic tendencies.

CAUSES
• Chronic necroinflammatory, oxidant, and immune-mediated liver injury has many causes.
• Infectious—canine hepatitis virus; leptospirosis, enteric-portal bacteremia or endotoxemia affiliated with inflammatory bowel disease; accidental parenteral administration of intranasal *Bordetella* vaccine.
• Immune-mediated—autoimmune with positive antinuclear antibody (ANA); acquired immune sensitization, nonsuppurative inflammation.
• Toxic—Cu associated hepatopathy; acute or chronic exposure to drugs—predictable or idiosyncratic toxicity: e.g., azole antifungals, trimethoprim-sulfa, zonisamide, phenobarbital, primidone, phenytoin, CCNU, NSAIDs (esp. carprofen); repeat exposure to environmental or food-borne toxins, e.g., dimethylnitrosamine, aflatoxin, cycad, cyanobacteria.

RISK FACTORS
• Immunostimulants (vaccinations?) and molecular mimicry of cell epitopes by infectious agents or infection of sinusoidal endothelium.
• Cu associated hepatopathy.
• Hepatic iron accumulation—from inappropriate supplementation.
• Xenobiotics (drugs, herbal, holistic, or Chinese remedies), inducers or inhibitors of microsomal enzymes, impaired hepatic antioxidant status; xenobiotic metabolites foster inflammation or augment direct initial liver injury.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Acute hepatitis—history, sequential biochemistry profiles or liver biopsy.
• Congenital portosystemic shunt (portosystemic vascular anomaly [PSVA]).

(CONTINUED) HEPATITIS, CHRONIC

- Primary hepatic neoplasia.
- Metastatic neoplasia or carcinomatosis.
- Chronic pancreatitis.
- Other causes of abdominal effusion—hypoalbuminemia; passive congestion; carcinomatosis; chemical peritonitis (bile, urine, pancreatitis), hepatic or nonhepatic causes of portal hypertension: see Hypertension, Portal.
- Jaundice—extrahepatic bile duct occlusion (EHBDO); bile peritonitis, cholangitis/cholangiohepatitis syndrome, ductopenia, hemolysis.

CBC/BIOCHEMISTRY/URINALYSIS

Hemogram

CBC—nonregenerative anemia; RBC microcytosis if APSS; variable leukogram, occasional thrombocytopenia; low total protein if chronic disease with synthetic failure and portal hypertension causing enteric protein loss.

Biochemistry

High liver enzymes; variable bilirubin, albumin, blood urea nitrogen (BUN), glucose, cholesterol; hepatic failure—suggested by low albumin, BUN, glucose, and cholesterol in absence of alternative causes.

Urinalysis

Variable urine concentration; escalated bilirubinuria; ammonium biurate crystalluria if APSS.

OTHER LABORATORY TESTS

- Total serum bile acids (TSBA)—variable; depends on extent of hepatic remodeling, sinusoidal hypertension, and cholestasis; *superfluous test if hepatic hyperbilirubinemia*.
- Ammonia intolerance—reflects APSS; insensitive to cholestasis, lability impairs accuracy.
- Coagulation tests—reflect panlobular injury, chronicity, vascular injury, impaired synthetic capacity or vitamin K adequacy; early disease: few abnormalities except possible high fibrinogen; advanced stage or severe panlobular injury: single or multiple abnormalities including prolonged prothrombin, activated partial thromboplastin time, low fibrinogen, increased D-dimers.
- Low protein C or antithrombin activity—may reflect PSVA, APSS, hepatic failure, or consumptive coagulopathy.
- Abdominal effusion—chronic liver disease portal hypertension: pure or modified transudate.
- Liver tissue zinc—low with chronic disease and APSS.
- Serologic or PCR tests—possible infectious agents, e.g., leptospirosis, rickettsial diseases, *Borrelia*, *Bartonella*, endemic fungal agents.
- ANA titer—if potential for autoimmune disease; *note*: low-level positive titers nonspecific and more common with advanced age.
- Immunohistochemical staining of liver biopsy—can confirm infectious agents or phenotype of infiltrating cells (inflammatory or neoplastic).

IMAGING

Abdominal Radiography

- Microhepatia—suggests late-stage disease or APSS causing lobular atrophy.
- Abdominal effusion—obscures image.
- Ammonium biurate calculi—radiolucent unless combined with radiodense minerals.

US

- Liver size depends on disease stage.
- Normal to variable parenchymal and biliary tract echogenicity; may note nodularity and irregular liver margins with chronicity due to regenerative nodules.
- APSS—tortuous vessels most commonly identified caudal to left kidney or near splenic vein.
- Abdominal effusion—US facilitates fluid sampling.
- Uroliths—renal pelvis or urinary bladder; may signify ammonium biurate urolithiasis but cannot differentiate mineral composition without stone analysis.
- Rule out—EHBDO; identify mass lesions; cholelithiasis; gallbladder mucocele (GBM); cholecystitis; choledochitis; cystic lesions (abscess or ductal plate malformation–related).
- Enables fine-needle aspiration—cytology and cholecystocentesis for bile collection.

Colorectal/Splenoportal Scintigraphy (CRS/SPS)

- ^{99M}Technicium pertechnetate isotope time activity curve displays chronologic isotope distribution: delivery to liver first = no shunting, delivery to heart first = shunting.
- CRS—sensitive, noninvasive; cannot differentiate PSVA from APSS.
- SPS—no diagnostic advantage, US-guided splenic injection, uses a lower isotope dose and therefore has faster discharge from hospital.

DIAGNOSTIC PROCEDURES

Aspiration Cytology

- Fine-needle aspiration cytology—*cannot define* fibrosis or nonsuppurative inflammation*; cannot* recommend therapy.
- Cannot definitively diagnose chronic hepatitis, hepatic fibrosis, or Cu associated hepatopathy.

Liver Biopsy

- Liver biopsy—needed for definitive diagnosis; acquire biopsies from multiple liver lobes.
- Tru-Cut® needle biopsy—use 14–16 G.
- Laparoscopy—best biopsy method; lower morbidity and faster recovery vs. exploratory laparotomy.

Bacterial Culture

Aerobic and anaerobic bacterial culture and sensitivity of liver and bile; use particulate biliary debris if possible.

Metal Analyses

- Measure Cu, iron, and zinc concentrations in liver (dry matter basis).
- Low hepatic zinc associated with portosystemic shunting requires supplementation.
- Iron commonly accumulates in necroinflammatory disorders; must be reconciled with distribution for relevance: e.g., Prussian blue staining defines distribution in macrophages (chronic inflammation) vs. predominantly in hepatocytes (hemochromatosis).
- Cu quantification and rhodanine staining—ascertains relevance to parenchymal injury.

PATHOLOGIC FINDINGS

- Gross—early: no gross change; late stage: irregular surface contours, microhepatica, ± tortuous APSS varices.
- Microscopic—nonsuppurative inflammation in zone(s) of necroinflammatory injury; variable cholestasis and biliary hyperplasia; interface hepatitis: invasion of limiting plate; late-stage disease: fibrotic bridging partitions between or within involved zones and marginating regenerative nodules, sinusoidal dissecting fibrosis; final transition to cirrhosis.

Histopathology

- Immune-mediated hepatitis—periportal, lobular, centrilobular, or panlobular with lymphoplasmacytic infiltrates, hepatic cord injury causing disorganization, sinusoidal fibrosis, biliary hyperplasia.
- Cu associated hepatopathy—initially centrilobular, may evolve panlobular immune-mediated hepatitis.
- Cirrhosis—diffuse, unresolvable; fibrosis, nodular regeneration distorting lobular architecture.

TREATMENT

APPROPRIATE HEALTH CARE

- Inpatient—for diagnostic testing, supportive care, treatment initiation in severe illness.
- Outpatient—if condition stable at diagnosis; slowly titrated onto medical therapy.

NURSING CARE

- Depends on underlying condition.
- Fluid therapy—balanced polyionic fluids supplemented to correct hydration, electrolyte aberrations, or hypoglycemia; restricted sodium if ascites, may require fresh frozen plasma, avoid synthetic colloids.
- Water-soluble vitamins—2 mL/L fluids.
- Ascites (see Cirrhosis and Fibrosis of the Liver).

ACTIVITY

Keep patient warm and hydrated; restricted activity may improve hepatic regeneration, euglycemia, and ascites mobilization.

HEPATITIS, CHRONIC (CONTINUED)

DIET

- Conserve body condition and muscle mass.
- Adequate calories and protein—to avoid negative nitrogen balance and catabolism.
- Dietary protein—restrict protein quantity *only* if signs of HE or observe ammonium biurate crystalluria; feed balanced species-specific diet; if HE, avoid fish and red meat source protein (dogs).
- Fat restriction rarely needed.
- If Cu associated liver injury, see Copper Associated Hepatopathy.
- Meal frequency—feed several small meals per day.
- Sodium restriction—with ascites or severe hypoalbuminemia: <100 mg/100 kcal or <0.2% dry matter basis formula.
- Balanced vitamin supplements (water soluble, fat soluble)— increased urinary water-soluble vitamin loss if PU/PD or diuretic therapy.
- Thiamin—ensure repletion to avoid metabolic complications and neurologic signs; 50–100 mg PO q24h; *caution*: anaphylactoid reactions may occur with injectable thiamin.
- Partial parenteral nutrition—may consider, insufficient to meet energy requirements.
- Total parenteral nutrition—if inappetence >7 days; branched-chain amino acids remain controversial in dogs with liver dysfunction.

CLIENT EDUCATION

- Control rather than cure is expected goal; medications usually required for life; chronic hepatitis is cyclic and will minimally require reevaluations q4–6 months after initial control.
- Antifibrotics—best control of fibrosis through control of inflammation and underlying primary process.
- Attenuate factors provoking HE—dehydration; azotemia, infection; catabolism; constipation; hypokalemia; alkalemia; high-protein meals; endoparasitism; enteric bleeding; certain drugs.

SURGICAL CONSIDERATIONS

- APSS—do not ligate APSS or band vena cava.
- Cirrhosis—high anesthetic risk; gas anesthesia preferred: isoflurane or sevoflurane.

MEDICATIONS

DRUG(S) OF CHOICE

- Treatments for specific etiologies.
- Withdraw plausible hepatotoxic drugs.
- No clinical trials prove efficacy of specific therapeutic regimens at this time.

Immunomodulation

- *Prednisolone/prednisone*—1–2 mg/kg daily PO; taper to lowest effective dose (0.25–0.5 mg/kg PO q48h); if ascites: use dexamethasone to avoid mineralocorticoid effects (divide prednisone dose by 7–10 for dexamethasone dose), SID q2–3 days.
- *Azathioprine*—dogs: 2 mg/kg (50 mg/m^2) PO q24h × 14 days *then* titrate to q48h; contraindicated in cats (toxic); dogs: combine with prednisone, antioxidants, antifibrotic polyunsaturated phosphatidylcholine (PPC); during chronic therapy, titrate by 25–50% dose reduction after 2–6 months based on sequential biochemistries showing improvements (e.g., normalization of total bilirubin and marked decline in liver enzyme activity); monitor CBC and biochemistry profile q7–14 days for first 2 months to ensure absence of hematopoietic, hepatic, or pancreatic toxicity; if acute hematopoietic toxicity, stop therapy, allow recovery, then reintroduce with 25% dose reduction; if insidious chronic hematopoietic toxicity (after months) or acute cholestatic liver or pancreatic injury, discontinue therapy and change to different drug (e.g., mycophenolate or cyclosporin); risk for neoplasia with chronic use.
- *Mycophenolate mofetil*—10–15 mg/kg PO q12h; doses ≥10 mg/kg PO BID may lead to diarrhea' start lower initial dose and/or divide total daily dose into 3–4 doses to reduce toxic effects; monitor as for azathioprine and adjust similarly; fewer bone marrow side effects than azathioprine but more GI toxicity; avoid dosing with food or after administration of proton pump inhibitor as these factors reduce drug bioavailability; if failure to respond to azathioprine go to cyclosporin vs. mycophenolate; if azathioprine toxicity go to mycophenolate.
- *Microemulsified cyclosporine* (Atopica®)—2.5–5 mg/kg PO q24h; use with glucocorticoids may increase drug efficacy and permit lower dose; side effects: gingival hyperplasia (managed with azithromycin), rare cholestatic liver injury, hyperlipidemia, hypercholesterolemia, worsening preexistent hypertension, risk for GB disease, risk for opportunistic infections; high dose can lead to nephrotoxicity; risk for neoplasia with chronic use; avoid concurrent use of p450 inhibitors unless cyclosporin dose substantially reduced.

Ursodeoxycholic Acid

Hepatomembranoprotectant, immunomodulatory, antifibrotic, choleretic, anti-endotoxic, and antioxidant effects; 10–15 mg/kg PO SID or divided q12h; administer with food for best bioavailability; may use as aqueous solution; no deleterious side effects; maintain indefinitely.

Antifibrotics

- Immunomodulators, *S*-adenosylmethionine (SAMe), vitamin E.
- *Polyunsaturated phosphatidylcholine* (PPC, dilinolylphosphatidylcholine [DLPC])—PPC containing DLPC antifibrotic, has immunomodulatory, antioxidant, hepatoprotectant effects, and improves membrane fluidity; 25–50 mg/kg/day PO with food; PhosChol® with preformed DLPC (52%) has benefit in some forms of liver disease (humans, animal models); may have corticosteroid-sparing effect (allows reduced glucocorticoid dosing); safely prescribed without liver biopsy.
- *Colchicine*—not recommended.
- *Silybin with PPC* (milk thistle)—experimental studies suggest potential hepatoprotectant (against numerous toxins), antifibrotic, antioxidant effects, and possibly promoting hepatocyte regeneration; low bioavailability of oral forms significantly limits biologic effect at traditional oral dosing: 2–5 mg/kg/day PO (PPC complexed form); only bioavailable form IV formulation (Legalon® SIL) used for *Amanita* death cap mushroom toxicity with high dose protocol; orphan drug.

Antioxidants

- Vitamin E—α-tocopherol, 10 IU/kg PO q24h with food.
- SAMe—20 mg/kg/day enteric-coated tablet PO, give on empty stomach for best bioavailability, 1–2h before feeding.
- Avoid vitamin C (ascorbate).
- Zinc (zinc acetate)—has antioxidant and antifibrotic benefits, supplementation may improve control of HE if low liver zinc concentration documented, unreliable for limiting enteric Cu uptake; elemental zinc 1.5–3 mg/kg PO daily as supplement if low liver zinc concentration (<120 µg/g dry weight liver); adjust dose using sequential plasma zinc concentrations that show increased concentrations; avoid plasma concentrations ≥800 µg/dL to prevent hemolysis; plasma zinc levels do not correlate with tissue levels.

Hepatoprotectants

- Ursodeoxycholate, vitamin E, SAMe, PPC—provide hepatoprotectant effects in addition to other benefits.
- Silybin—see above.

Bleeding Tendencies

See Coagulopathy of Liver Disease.

GI Signs/Vomiting/Hematemesis

- HCl pump inhibitors—omeprazole 0.5–1.0 mg/kg q12–24h PO or pantoprazole 0.7–1 mg/kg q12h IV, better long-term control vs. famotidine.
- Sucralfate—gastroprotectant dose 0.25–1.0 g/10 kg PO q8–12h; titrated to effect; beware of drug interactions as sucralfate may bind other medications, reducing bioavailability.
- Eliminate endoparasitism.

CONTRAINDICATIONS

- NSAIDs—avoid; may provoke enteric ulceration and bleeding; may worsen ascites; metabolites cause centrilobular hepatocyte injury.

• Avoid drugs requiring extensive hepatic metabolism or judiciously adjust dose if APSS, HE, jaundice, or hepatic failure evident.

PRECAUTIONS

• Diuretics—dehydration, hypokalemia, alkalosis, constipation: provoke or worsen HE.
• Glucocorticoids—increase susceptibility to infection, enteric bleeding, sodium and water retention (those with mineralocorticoid effects), PU/PD, protein catabolism, HE.
• Avoid drugs or reduce dose for those dependent on first-pass hepatic extraction if APSS or those requiring hepatic conjugation or biotransformation for detoxification, e.g., metronidazole—reduce conventional dose to 7.5 mg/kg PO q12h (often used for HE).
• Zinc overdose may cause hemolysis.

POSSIBLE INTERACTIONS

• Avoid medications altering hepatic p450 cytochrome biotransformation/elimination pathways (cimetidine, quinidine, ketoconazole).
• Avoid concurrent treatment with metoclopramide if spironolactone used for diuresis (causes aldosterone release).
• Adjust dose of immunomodulators if used in combination to avoid immunodeficiency.

ALTERNATIVE DRUG(S)

• Dexamethasone—if ascites, replace prednisone or prednisolone with this drug to avoid mineralocorticoid effect; divide dose by 7–10, administer q3 days.
• Mycophenolate—alternative if azathioprine intolerance, see above.

FOLLOW-UP

PATIENT MONITORING

• At-home behavior/cognitive function, bodyweight, body condition, and muscle mass scores monitored.
• CBC, biochemistry, urinalysis—depending on immunosuppressive medications (see above), initially q2 weeks for 2 months, then monthly or quarterly; depends on patient status and drugs administered; monitor for opportunistic infections.
• Serial monitoring of TSBA—usually does not add prognostic or diagnostic information.
• Abdominal girth—reflects ascites volume; important to standardize measurement site, method, and operator determining circumference.
• Azathioprine—monitor for possible bone marrow toxicity (serial CBCs q2 weeks for 2 months then quarterly); leukopenia may develop acutely or after chronic use; GI or pancreatic toxicity; hepatotoxicity (alanine aminotransferase activity), other effects and opportunistic infectious complications.
• Mycophenolate—monitor for GI toxicity, rare bone marrow toxicity, opportunistic infectious complications; diarrhea most common complication, manage by dividing daily drug dose into 3–4.
• Cyclosporine—renal function, infectious complications, avoid cytochrome p450 inhibitor drugs; remain aware of possible drug-provoked hyperlipidemia, hypercholesterolemia, related GB disease (dysmotility, GBM, cholelithiasis).

POSSIBLE COMPLICATIONS

HE, septicemia, bleeding—may be life-threatening; disseminated intravascular coagulation—may be terminal event.

EXPECTED COURSE AND PROGNOSIS

• Chronic hepatitis often cyclic; occasional flare-ups inconsistently associated with clinical illness, more consistently associated with vacillating liver enzymes or hyperbilirubinemia.
• Some dogs achieve solid long-term remission.
• Some dogs with Cu associated hepatopathy achieve permanent remission of apparent "immune-mediated" inflammation with Cu chelation and lifelong dietary Cu restriction.
• Development of ascites—severe liver injury, APSS, potential for HE, shorter survival.
• Severe disease—with APSS, HE, and ascites may require occasional hospitalizations to adjust nutritional and medical interventions.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Dogs with leptospirosis-associated chronic liver disease (rare) may shed organisms.
• *Bartonella* and rickettsial infections are sentinels for endemic vectors.

SEE ALSO

• Ascites.
• Cirrhosis and Fibrosis of the Liver.
• Copper Associated Hepatopathy.
• Glycogen-Type Vacuolar Hepatopathy.
• Hepatic Encephalopathy.
• Hepatic Failure, Acute.
• Hypertension, Portal.
• Portosystemic Shunting, Acquired.

ABBREVIATIONS

• ANA = antinuclear antibody.
• APSS = acquired portosystemic shunt.
• BUN = blood urea nitrogen.
• CRS = colorectal scintigraphy.
• DLPC = dilinolylphosphatidylcholine.
• EHBDO = extrahepatic bile duct occlusion.
• GBM = gallbladder mucocele.
• GI = gastrointestinal.
• HE = hepatic encephalopathy.
• NSAID = nonsteroidal anti-inflammatory drug.
• PPC = polyunsaturated phosphatidylcholine.
• PSVA = portosystemic vascular anomaly.
• PU/PD = polyuria/polydipsia.
• RBC = red blood cell.
• SAMe = S-adenosylmethionine.
• SPS = splenoportal scintigraphy.
• TSBA = total serum bile acids.

Client Education Handout available online

H

HEPATITIS, GRANULOMATOUS

BASICS

DEFINITION
- Uncommon necroinflammatory hepatitis.
- Characterized by histiocytes/macrophages, lymphocytes, plasma cells, and variable neutrophilic infiltrates forming granulomas that efface normal hepatic structure.
- May reflect infectious agents, immune-mediated or immunoregulatory disorders, or proliferative/neoplastic histiocytic syndrome.
- May localize to liver or be multisystemic (spleen, lymph nodes, bone marrow, lungs).
- Copper associated hepatopathy—involves unique small "copper granulomas" distinct from this syndrome.

PATHOPHYSIOLOGY
- Inflammatory process may be initiated by infection—bacteria (eubacterial, mycobacterial, chlamydial), viral, parasitic, protozoal, or fungal agents.
- May reflect immune-mediated or immunoregulatory disorders.
- May be initiated by adverse drug or xenobiotic interaction including herbal, holistic, or Chinese traditional remedies, or toxin exposure.
- May reflect proliferative histiocytic syndromes or histiocytic neoplasia.
- Hepatocyte necrosis—reflects insufficient regional perfusion and hypoxia, cytokine-mediated cytotoxic cell injury (histiocytes, lymphocytes), initial direct or indirect hepatotoxic injury.
- Severity of hepatic dysfunction—reflects density and lobular distribution of injury.
- Toxins—affect zone where bioactivated or metabolized as initial site of lesion distribution.
- Zone 3 copper accumulation—may augment zone 3 (centrilobular region) injury.
- Liver injury associated with enzyme leakage reflecting regional involvement; hyperbilirubinemia occurs with diffuse injury, canalicular damage, biliary tree involvement; sinusoidal injury leads to sinusoidal hypertension, splanchnic hypertension, ascites, acquired portosystemic shunt (APSS).
- Severe diffuse lobular involvement can lead to liver failure associated with complex coagulopathies; enteric hemorrhage may reflect acute splanchnic portal hypertension and lead to acute-onset hepatic encephalopathy (HE).
- Hepatic failure—associates numerous metabolic derangements and detoxification capabilities; may be lethal.

SIGNALMENT
- No breed, sex, or age predilection.
- More common in dogs than cats.

SIGNS

Historical Findings
- Nonspecific clinical signs, lethargy; abrupt or gradual onset of illness.
- Anorexia, vomiting, diarrhea, weight loss.
- Polyuria/polydipsia.

Physical Examination Findings
- Normal liver size or severe hepatomegaly.
- Abdominal pain—vague, due to hepatic capsule stretching.
- Distended abdomen—ascites; hepatomegaly.
- ± Splenomegaly—granulomatous process.
- ± Lymphadenopathy—granulomatous inflammation.
- ± Jaundice.
- ± Fever.
- ± Tachypnea—abdominal distention due to ascites or pulmonary involvement.
- Late stage—bleeding tendencies, ascites, HE.

CAUSES & RISK FACTORS
- Systemic fungal infection—histoplasmosis; blastomycosis; coccidioidomycosis; pythiosis.
- Bacterial infection—*Brucella*, *Nocardia*, *Borrelia*, *Propionibacterium acnes*, mycobacteria species; *Bartonella*, *Staphylococcus*, *Leptospirosis*, many other organisms.
- Rickettsial infections.
- Parasitism—visceral larval migrans; liver flukes, schistosomiasis; dirofilariasis.
- Virus—feline infectious peritonitis.
- Protozoal—*Toxoplasma*; visceral *Leishmania*.
- Neoplasia—histiocytic neoplasia, lymphoma.
- Hemophagocytic histiocytic sarcoma.
- Reactive or proliferative histiocytosis.
- Immune-mediated inflammation; may be autoimmune lupus like syndrome.
- Drug reactions (e.g., ketoconazole).
- Xenobiotics—holistic, herbal, Chinese traditional remedies.
- Toxins or infectious agents disseminated in treats or food products from countries with unregulated manufacturing processes.
- Idiopathic—no recognized cause after meticulous investigations; may be autoimmune.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Widely disparate features initiate pursuit of diagnostic considerations; drug history must be carefully reviewed; consideration of splenic and/or bone marrow involvement necessary to rule out histiocytic neoplasia if biopsy discloses mitotically active dysplastic-appearing histiocytes.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC—inflammatory or stress leukogram; nonregenerative anemia; spherocytes: microangiopathic shearing, immune-mediated anemia, or histiocytic hemophagocytic syndrome; monocytosis with chronic inflammation/infection.
- Biochemistry—high liver enzymes; variable: bilirubin, hypoglycemia; hypoalbuminemia, low blood urea nitrogen; high or low total proteins; high globulins; may note electrolyte abnormalities with fluid and acid-base disturbances, hypocholesterolemia with hemophagocytic histiocytic sarcoma.
- Urinalysis—may be normal or demonstrate: bilirubinuria, proteinuria, red blood cells, white blood cells, cellular and other casts.

OTHER LABORATORY TESTS
- Serum bile acid concentrations—often high with massive hepatic involvement or APSS.
- Coagulation assays—normal, except with end-stage liver failure.
- Acute-phase proteins may increase—certain globulins, fibrinogen, C-reactive protein, protein C, antithrombin.
- Serologic tests—evaluate titers with caution in regard to infectious agents; important to consider convalescent titers; increased immunoglobulin M titers to toxoplasmosis or leptospirosis support active infection, consider serology for *Bartonella*; test according to plausible exposures considering travel history and other variables (e.g., raw meat diet).
- Molecular diagnostic tests—PCR or fluorescent in situ hybridization (FISH) for eubacterial organisms or other infectious agents not visualized on microscopy of liver biopsy; mycobacterial PCR and *Bartonella* PCR may warrant investigation.
- Antinuclear antibody titer—positive with systemic lupus erythematosus but low positive titers nonspecific.
- Bacterial cultures—liver tissue, bile (use particulate debris), or blood; mycobacterial cultures grow slowly (months) thus mycobacteria may be more promptly detected using PCR and tissue staining (Ziehl-Neelsen, Fite Faraco); however, tissue staining with granulomatous inflammation and mycobacteria may be negative (as shown in humans).

IMAGING
- Abdominal radiography—may identify normal to large sized liver, abdominal mass(es), or ascites obscuring regional detail.
- Abdominal ultrasonography—discloses liver size and abnormal nodular parenchymal pattern, mass lesions, splenomegaly and lymphadenopathy; confirms abdominal effusion; enables diagnostic needle sampling of tissue for cytology or core liver biopsy.

DIAGNOSTIC PROCEDURES
- Aspiration sampling—hepatic parenchyma, spleen, bone marrow, and abdominal effusion.
- Liver biopsy—definitive diagnosis of granulomatous reaction but often does not define cause. Copper-specific stain and copper quantification in liver (dry weight basis) should be done to rule out, as copper granulomas misinterpreted as "pyogranulomatous" that

may lead to needless evaluations; copper concentration can be qualitatively estimated from liver stained with rhodanine; see Copper Associated Hepatopathy.
• Special staining for infectious agents—Gram stain, modified Steiner's, Ziehl-Neelsen and Fite Faraco (mycobacteria), periodic acid–Schiff (fungi, amoeba, protozoa), Grocott's methenamine silver (fungi, certain bacteria, e.g., *Norcardia*, *Actinomyces*).
• Consider bone marrow aspirate/core if histiocytic neoplasm or lymphoma suspected or to confirm certain infectious diseases (e.g., mycobacteria, brucellosis, toxoplasmosis).

PATHOLOGIC FINDINGS
• Gross—hepatomegaly; normal, finely irregular surface, indented circular or dimpled pale lesions; firm texture; may have blunted margins and abdominal effusion.
• Microscopic—pyogranulomatous reaction, random or variable zonal infiltrate distribution.

TREATMENT
• Inpatient vs. outpatient—dictated by severity of clinical signs.
• Fluid therapy—balanced polyionic solution for rehydration and maintenance needs, may require dextrose (2.5–5%) if hypoglycemic.
• Nutritional support essential; do not restrict protein if lacking signs of HE.
• Inform client that causes of this syndrome may be difficult to confirm and treat.
• If granulomatous response associates with copper, see Copper Associated Hepatopathy.

MEDICATIONS
DRUG(S) OF CHOICE
• Discontinue exposure to suspected causal xenobiotics, raw diets, rawhide products, jerky treats, or other consumables from foreign countries lacking enforced surveillance policies for pet care product manufacture.
• Depends on cause; see specific chapters for infectious disorders.
• Immunomodulation—if immune-mediated injury suspected with negative survey for infectious etiology; some injuries may transform to immune-mediated process.
• Idiopathic disease—glucocorticoids combined with azathioprine or mycophenolate or cyclosporin.
• Vomiting—antiemetics (e.g., metoclopramide 0.2–0.5 mg/kg PO/SC q6–8h; ondansetron 0.5–1.0 mg/kg 30 min before feeding q12–24h); or maropitant 1.0 mg/kg SC/PO.
• Gastrointestinal bleeding—omeprazole 1.0 mg/kg PO q12–24h or pantoprazole; sucralfate for gastroesophageal protection.

POSSIBLE INTERACTIONS
• Consider potential drug interactions because of broad spectrum of possible interventions.
• Consider adjusting drugs requiring hepatic activation, biotransformation, or elimination.
• Immunosuppression—may worsen clinical signs if cause is infectious disorder.

FOLLOW-UP
PATIENT MONITORING
• Routine monitoring of supportive care in hospital—fluids, acid-base and electrolyte balance, and general response to interventional medications.
• Sequential hematologic, biochemical, imaging, and relevant serologic titer/PCR evaluations.
• Sequential physical assessments and clinicopathologic monitoring especially important with immunomodulation because infectious causes may have been overlooked.

POSSIBLE COMPLICATIONS
• Chronic hepatitis, hepatic fibrosis, cirrhosis.
• Hepatic failure.
• Coagulopathy.
• Dissemination of undiagnosed infectious cause.

EXPECTED COURSE AND PROGNOSIS
Depend on primary cause.

MISCELLANEOUS
ZOONOTIC POTENTIAL
• Brucellosis, mycobacterial, leptospirosis infections—concern for zoonotic potential.
• Blastomycosis, coccidioidomycosis, bartonellosis, leishmaniosis, toxoplasmosis—not directly contagious but pet may serve as environmental exposure sentinel.

SEE ALSO
• Bartonellosis.
• Blastomycosis.
• Brucellosis.
• Coccidioidomycosis.
• Feline Infectious Peritonitis (FIP).
• Histoplasmosis.
• Leishmaniosis.
• Leptospirosis.
• Lupus Erythematosus, Systemic (SLE).
• Mycobacterial Infections.
• Pythiosis.

ABBREVIATIONS
• APSS = acquired portosystemic shunt.
• HE = hepatic encephalopathy.

HEPATITIS, INFECTIOUS (VIRAL) CANINE

BASICS

OVERVIEW

• Viral disease of dogs (*Canidae*) caused by canine adenovirus-1 (CAV-1). It is serologically homogeneous and antigenically distinct from respiratory CAV-2, the causative agent of canine infectious laryngotracheitis.
• CAV-1 has worldwide geographic distribution and it also causes disease in wolves, coyotes, skunks, and bears. It causes encephalitis in foxes.
• Virus is spread via direct dog-to-dog oronasal contact or via contact of contaminated fomites. Airborne transmission is not an important means of contracting the virus.
• Virus initially replicates in tonsils, then spreads to regional lymph nodes and bloodstream via lymphatics.
• Infection—targets parenchymal organs (especially liver), eyes, endothelium, lung, spleen, kidneys, and brain.
• Oronasal exposure—viremia (4–8 days); virus shed in saliva and feces; initial dispersal to hepatic macrophages (hepatic Kupffer cells) and endothelium; replicates in Kupffer cells; damages adjacent hepatocytes producing massive viremia when released.
• Adequate antibody response clears organs in 10–14 days; virus can persist in renal tubules, glomeruli, iris, ciliary body, and cornea. Virus can be shed in urine for 6–9 months.
• Chronic hepatitis—after infection in dogs with only partial neutralizing antibody response.
• Cytotoxic ocular injury—anterior uveitis; leads to classic "hepatitis blue eye" and can cause glaucoma. Develops in ~1% of dogs after modified live virus (MLV) vaccine.
• Glomerulonephritis can develop 1–2 weeks after acute signs resolve and produce proteinuria and interstitial nephritis; chronic renal failure has not been described.

SIGNALMENT

• Dogs and other *Canidae*.
• No breed or sex predilections.
• Most common in dogs <1 year of age.
• Any dog not vaccinated is susceptible.

SIGNS

• Depend on immunologic status of host and degree of initial cytotoxic injury.
• Peracute—fever; CNS signs; vascular collapse; disseminated intravascular coagulation (DIC); death within hours.
• Acute—fever; anorexia; lethargy; vomiting; diarrhea; hepatomegaly; abdominal pain; abdominal effusion; vasculitis (petechia, bruising); DIC; lymphadenopathy; rarely, nonsuppurative encephalitis.
• Uncomplicated—lethargy; anorexia; transient fever; tonsillitis; vomiting; diarrhea; lymphadenopathy; hepatomegaly; abdominal pain.
• Late—20% of cases develop anterior uveitis and corneal edema 4–6 days post infection; recover within 21 days; may progress to glaucoma and corneal ulceration. May be the only clinical feature of inapparent infection.

CAUSES & RISK FACTORS

• CAV-1.
• Unvaccinated dogs susceptible.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Canine herpesvirus (neonatal).
• Other infectious hepatopathies.
• Leptospirosis.
• Granulomatous hepatitis.
• Toxic hepatitis.
• Fulminant infectious disease—e.g., parvovirus, canine distemper.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—schistocytes; leukopenia during acute viremia, followed by leukocytosis with reactive lymphocytosis and nucleated red blood cells (RBCs); thrombocytopenia.
• Biochemistry—liver enzyme activity high initially, begins to decline within 14 days; low glucose and albumin reflect fulminant hepatic failure, vasculitis, and endotoxemia; low sodium and potassium levels reflect GI losses; hyperbilirubinemia if survive several days.
• Urinalysis—proteinuria (glomerular injury); granular casts (renal tubule damage); bilirubinuria consistent with jaundice.

OTHER LABORATORY TESTS

• Coagulation tests—reflect severity of liver injury and DIC.
• Serology for antibodies to CAV-1—fourfold rise in immunoglobulin IgM and IgG; recent vaccine-induced antibodies confuse interpretation.
• PCR—real-time PCR not currently available; conventional PCR is able to differentiate between virulent CAV-1 and vaccine virus, which is CAV-2 in all current vaccines. Nasal, rectal, or ocular swabs or blood can be submitted as well as tissue at necropsy; positive results from urine can be difficult to interpret due to potential shedding from asymptomatic dogs.
• Viral isolation—anterior segment of eye, kidney, tonsil, and urine; difficult in parenchymal organs (especially liver) unless first week of infection.

IMAGING

• Abdominal radiography—normal or large liver; poor detail due to effusion.
• Abdominal ultrasonography—may observe hepatomegaly, hypoechoic parenchyma (multifocal or diffuse pattern), and effusion.

DIAGNOSTIC PROCEDURES

• Liver cytology via aspiration or biopsy may identify intranuclear hepatocyte inclusions.
• Viral culture.
• Acute and convalescent serology.
• Necropsy.

PATHOLOGIC FINDINGS

• Acute—edema and hemorrhage of lymph nodes; serosal visceral hemorrhages; liver large, dark-mottled; edematous gallbladder; fibrinous exudate on liver, gallbladder, and other viscera; splenomegaly; renal infarcts; abdominal effusion. Perivascular necrosis in liver and other organs; widespread centrilobular to panlobular necrosis. Liver is discolored; abdominal effusion also observed in canine herpesvirus in neonates.
• Chronic—small, fibrotic or cirrhotic liver.

TREATMENT

• Usually inpatient.
• Fluid therapy—balanced polyionic fluids; avoid lactate if fulminant hepatic failure; carefully monitor fluids to avoid overhydration in context of increased vascular permeability.
• Judicious potassium (and other electrolyte) supplementation since electrolyte depletion may augment hepatic encephalopathy (HE).
• Avoid neuroglycopenia—supplement fluids with dextrose (2.5–5.0%) as necessary.
• Blood component therapy for coagulopathy; blood component preferred to synthetic colloids for support of colloidal osmotic pressure; widespread vasculitis and DIC allow rapid systemic third-space colloid dispersal.
• Overt DIC—fresh blood products and low molecular weight heparin, e.g., enoxaparin 100 U/kg (1 mg/kg) q24h. See Coagulopathy of Liver Disease.
• Nutritional support—frequent small meals as tolerated; optimize nitrogen intake; inappropriate protein restriction may impair tissue repair and regeneration; nitrogen restriction advised only if overt signs of HE. A feeding tube may be necessary initially.
• If oral feeding not tolerated, provide partial parenteral nutrition (maximum 5 days) or, preferably, total parenteral nutrition.

MEDICATIONS

DRUG(S) OF CHOICE

• Prophylactic antimicrobials—transmural passage of enteric bacteria and endotoxemia

with hepatic failure; e.g., ticarcillin (33–50 mg/kg q6–8h) combined with metronidazole (reduce conventional dose to 7.5 mg/kg IV q8–12h) and fluoroquinolone.
• Antiemetics—metoclopramide (0.2–0.5 mg/kg PO/SC q6–8h or CRI); ondansetron (0.5–1.0 mg/kg PO q12h); maropitant (1 mg/kg/day SC).
• Gastroprotection—proton pump inhibitors (omeprazole 0.5–1.0 mg/kg PO q12–24h, pantoprazole 0.7–1.0 mg/kg IV q12–24h); H2 receptor antagonists (e.g., famotidine 0.5 mg/kg PO/IV/SC q12–24h) and sucralfate (0.25–1.0 g PO q8–12h).
• Manage HE (see Hepatic Encephalopathy).
• Ursodeoxycholic acid—choleretic and hepatoprotectant (10–15 mg/kg daily in two divided doses, with food); give indefinitely if chronic hepatitis.
• Antioxidants—vitamin E (10 IU/kg/day PO), *N*-acetylcysteine IV (140 mg/kg load, then 70 mg/kg q8h) until PO route possible; transition to *S*-adenosylmethionine (20 mg/kg/day PO, dose on empty stomach) when patient can tolerate oral medications until liver enzymes normalize or indefinitely if chronic hepatitis.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Consider severity of liver injury, protein depletion, and age in calculating drug dosages.
• Sucralfate may impair oral absorption of certain medications (fluoroquinolones, tetracycline, doxycycline, and fat-soluble vitamins, e.g., vitamin E).

FOLLOW-UP

PATIENT MONITORING

• Monitor fluid, electrolyte, acid-base, and coagulation status to adjust supportive measures.
• Monitor for acute renal failure.

PREVENTION/AVOIDANCE

MLV vaccination—at 6–8 weeks of age; two boosters 3–4 weeks apart until 16 weeks of age; booster at 1 year; highly effective vaccine; boosters may not be needed.

POSSIBLE COMPLICATIONS

• Fulminant hepatic failure.
• HE.
• Septicemia.
• Acute renal failure.
• Glomerulonephritis.
• DIC.
• Glaucoma.
• Chronic hepatitis.

EXPECTED COURSE AND PROGNOSIS

• Peracute—poor prognosis; death within hours.
• Acute—variable: guarded to good prognosis.
• Poor antibody response (titer 1 : 16–1 : 50)— chronic hepatitis may develop.
• Good antibody response (titer >1 : 500 IgG)—complete recovery in 5–7 days possible.
• Recovered patients—may develop chronic liver or renal disease.

MISCELLANEOUS

AGE-RELATED FACTORS

• Maternal antibody—may protect some pups for first 8 weeks; depends on maternal antibody concentration and efficacy of passive transfer.
• Vaccination of pups with high levels of passively acquired antibodies—successful at 14–16 weeks of age.

SEE ALSO

• Acute Kidney Injury.
• Anterior Uveitis—Dogs.
• Disseminated Intravascular Coagulation.
• Hepatic Encephalopathy.
• Hepatic Failure, Acute.
• Hepatitis, Chronic.

ABBREVIATIONS

• CAV-1 = canine adenovirus-1.
• DIC = disseminated intravascular coagulation.
• HE = hepatic encephalopathy.
• Ig = immunoglobulin.
• MLV = modified live virus.
• RBC = red blood cells.

Consulting Editor Kate Holan
Acknowledgment The author and book editors acknowledge the prior contribution of Sharon A. Center.

HEPATITIS, SUPPURATIVE AND HEPATIC ABSCESS

BASICS

OVERVIEW

- Bacterial infection involving the hepatobiliary system.
- Distribution and lobular involvement—variable; multifocal microabscessation; diffuse suppurative cholangitis/cholangiohepatitis; cholecystitis; choledochitis, or discrete focal lesions; lesions associate with pyogenic bacteria.
- Large abscesses associated with hepatocellular carcinoma (HCA) in dogs.

SIGNALMENT

- Dog and cat.
- No breed predilection.
- Hepatic abscesses—most common: old dogs with HCA, or secondary to immunosuppression or diabetes mellitus; in neonates subsequent to omphalitis.
- Suppurative septic cholangitis/cholangiohepatitis—most common in young to middle-aged male cats.
- Cholestatic disorders predispose to enteric bacterial translocation and impair canalicular bacterial egress from the liver.

SIGNS

Historical Findings

- Anorexia.
- Lethargy.
- Gastrointestinal signs—vomiting, diarrhea.
- Weight loss.
- Polyuria and polydipsia.
- Trembling.
- Fever.
- May become jaundiced.

Physical Examination Findings

- Fever or hypothermia (cats).
- Abdominal pain—cranial abdomen.
- Dehydration.
- Hepatomegaly—focal, with large abscess or mass.
- Coagulopathy.
- Effusion—abdominal distention or fluid wave.
- May develop jaundice.
- Endotoxemia—tachycardia, tachypnea, hypotension, hypoglycemic collapse.

CAUSES & RISK FACTORS

- Hematogenous infection via the portal vein, hepatic artery, or umbilical vein.
- Biliary tree obstruction, preexisting hepatobiliary or pancreatic disease, and inflammatory bowel disease.
- Ascending biliary tract infection.
- Cholecystoenterostomy.
- HCA with necrotic foci.
- Compromised immune responses: diabetes mellitus, glucocorticoid administration, hyperadrenocorticism, hypothyroidism, chemotherapy, immune-mediated disorders managed with immunosuppressives.
- Recurrent urinary tract infections; pyelonephritis.
- Penetrating wounds.
- Complication of hepatic biopsy or other surgery.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious or necroinflammatory disease.
- Pancreatitis or pancreatic abscess.
- Hepatobiliary neoplasia.
- Hematoma.
- Metastatic neoplasia.
- Biliary cystadenoma.
- Gastrointestinal obstruction or perforation.
- Peritonitis, other intra-abdominal abscess.
- Cholecystitis, choledochitis, cholelithiasis.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—neutrophilic leukocytosis with left shift and toxic white blood cell (WBC) changes; monocytosis; thrombocytopenia; nonregenerative anemia, schistocytes (disseminated intravascular coagulation [DIC]).
- Biochemistry—variably increased alanine aminotransferase (ALT) > alkaline phosphatase (ALP) activity, increased aspartate aminotransferase (AST), hypoglobulinemia, hyperglobulinemia, inconsistent hyperbilirubinemia and hypoglycemia, inconsistent hypocalcemia (cats).
- Urinalysis—usually normal; bilirubinuria; proteinuria.

OTHER LABORATORY TESTS

- Serum bile acids—normal or high.
- Coagulation tests: changes consistent with DIC.
- Urine culture may or may not disclose hematogenously dispersed organisms.

IMAGING

Abdominal Radiography

- Hepatomegaly; irregular or rounded liver margins: diffuse or single lobe if isolated abscess.
- Hepatic mass effect.
- Reduced abdominal detail—effusion or peritonitis.
- Gas pattern in hepatic parenchyma or biliary tree.
- Thoracic radiographs—normal, or consistent with pneumonia or chronic bronchitis.

Ultrasonography

- Best noninvasive method of abscess detection (>0.5 cm lesions); solitary, variably echogenic, cavitated, hyperechoic rim.
- Dystrophic tissue mineralization or entrapped gas.
- Highly echogenic interface with cavitated mass—may be gas; combination with an abdominal effusion and hyperechoic perilesional effect supports an abscess.
- Multiple masses, may be complex.
- Miliary abscesses—cannot discern from other parenchymal hepatic disorders.
- Suppurative septic cholangitis/cholangiohepatitis syndrome (CCHS)—image not unique from nonsuppurative CCHS.
- Inconsistent regional lymphadenopathy.

DIAGNOSTIC PROCEDURES

Cytology

- Cytology is essential; histologic specimens may not reveal bacterial organisms.
- Samples—effusion; hepatic parenchyma, discrete lesions; cholecystocentesis: transhepatic approach, liquid bile and biliary debris.
- Stains—Wright-Giemsa for bacterial detection; Gram stain for morphology.
- Look for bacteria within biliary debris, in WBCs; primary or predisposing disease (e.g., neoplasia, VH reflecting adrenal disease or diabetes mellitus).

Culture and Sensitivity Testing

- If suppurative or pyogranulomatous—culture for aerobic, anaerobic bacteria, fungal organisms.
- Blood—aerobic and anaerobic culture.
- Polymicrobial infections ~30%.

TREATMENT

- Inpatient—if signs of sepsis.
- IV fluids and antibiotics—essential.
- Fluid support—correct dehydration; rectify acid-base and electrolyte disturbances.
- Abscess—drain via lobectomy during laparotomy or under ultrasound guidance before surgery; if endotoxic shock, ultrasound facilitated drainage is best; after drainage, monitor body temperature, liver enzymes, WBC count, and sequentially image with ultrasound (monitor abscess size, focal or diffuse peritonitis); judiciously repeat drainage (may require insertion of an indwelling catheter for short-term continuous drainage); consider alcoholization of abscess after drainage.
- In middle-aged/older dogs—lobectomy for abscess removal and possible wide-margin resection of an HCA.
- If extrahepatic bile duct obstruction (EHBDO)—see Bile Duct Obstruction (Extrahepatic).

MEDICATIONS

DRUG(S) OF CHOICE

- Antibiotics—initially based on cytology and Gram stain, then adjusted based on culture and sensitivity results; continue for 2–4 months, perhaps longer.
- Initial treatment—combine antimicrobials for possible polymicrobial infection; common effective empirical combination includes

(CONTINUED) # HEPATITIS, SUPPURATIVE AND HEPATIC ABSCESS

ticarcillin (25–50 mg/kg over 15 min CRI) or amoxicillin clavulanate (13.75–20 mg/kg PO q12h), enrofloxacin (5–10 mg/kg PO/IV/SC q12h in dogs or cats), and metronidazole (15 mg/kg IV q12h; reduce dose by 50% if hepatic dysfunction or severe cholestasis) or clindamycin (10–16 mg/kg SC per day; reduce dose if hepatic dysfunction or severe cholestasis to 5 mg/kg SC per day).
- Choleretics advised if biliary tree involved, but if EHBDO *not until* biliary decompression; see Bile Duct Obstruction (Extrahepatic); Cholangitis/Cholangiohepatitis Syndrome.
- Antioxidants advised (see Hepatitis, Chronic).

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Aminoglycosides—do not use until normal hydration.
- Avoid drugs metabolized or excreted by the liver or those known to be hepatotoxic if compromised liver function; adjust dosages or frequency of drugs if suspect reduced hepatic elimination, cholestasis, or hepatic dysfunction.

FOLLOW-UP

PATIENT MONITORING
- Assess vital signs, labwork abnormalities, and physical condition.
- Sequential ultrasound examinations—monitor for abscess recrudescence or suppurative peritonitis.
- If percutaneous drainage and alcoholization of an abscess—ultrasound monitoring at 24 and 48 hours post procedure and 15, 30, 60, and 120 days is recommended.

POSSIBLE COMPLICATIONS
- DIC.
- Septicemia/endotoxemia.
- Fulminant hepatic failure.
- Septic peritonitis.
- Acute renal failure.

EXPECTED COURSE AND PROGNOSIS
- Favorable prognosis—early detection and aggressive antimicrobial treatment, with judicious surgical intervention.
- Guarded prognosis—concurrent disorders, especially hepatic neoplasia.

MISCELLANEOUS

ABBREVIATIONS
- ALP = alkaline phosphatase.
- ALT = alanine aminotransferase.
- AST = aspartate aminotransferase.
- CCHS = cholangitis/cholangiohepatitis syndrome.
- DIC = disseminated intravascular coagulation.
- EHBDO = extrahepatic bile duct obstruction.
- HCA = hepatocellular carcinoma.
- WBC = white blood cell.

HEPATOCELLULAR ADENOMA

BASICS

OVERVIEW
- A benign liver tumor of epithelial origin.
- May be more common than primary malignant liver tumors.

SIGNALMENT
- Rare in dog and very rare in cat.
- Affected dogs commonly >10 years of age.
- Breed predispositions unknown.

SIGNS
- Usually asymptomatic; when clinical signs present, symptoms may be nonspecific; typically incidental finding.
- Acute tumor rupture may cause hemoperitoneum with resultant weakness and hypovolemic shock-like symptoms.
- Occasionally, large tumors may cause cranial abdominal pain, vomiting, and inappetance.

CAUSES & RISK FACTORS
Definitive cause or risk factors for tumor development are unknown.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Hepatocellular carcinoma.
- Hepatic nodular hyperplasia.
- Hepatic abscess.
- Abdominal mass.
- Splenomegaly.

CBC/BIOCHEMISTRY/URINALYSIS

CBC
- Usually unremarkable.
- Anemia—regenerative anemia if tumor is bleeding, or anemia of chronic disease.
- Leukocytosis with a left shift—large tumors with necrotic centers (rare).

Biochemistry
- Liver enzymes variable.
- Serum total bilirubin values—usually normal.

Urinalysis
Unremarkable

OTHER LABORATORY TESTS
- Serum bile acids are usually normal unless tumor growth compromises hepatic perfusion and biliary flow.
- Coagulation abnormalities consistent with disseminated intravascular coagulation (DIC) occur rarely with large necrotic or hemorrhagic tumors.

IMAGING

Radiography
- May demonstrate a single mass lesion or apparent asymmetry of hepatic silhouette.
- Rarely, gas in necrotic center of tumor.

Abdominal Ultrasonography
May identify discrete mass effect with variable echogenicity, ranging from normal liver echogenicity to mixed echogenicity, presence of multiple nodules, or cystic mass appearance.

Abdominal CT
- May allow for improved assessment regarding surgical feasibility, especially for large tumors, or tumors associated with critical structures, such as the gallbladder.
- May detect additional lesions, depending on the contrast enhancement protocol.

DIAGNOSTIC PROCEDURES
- Hepatic aspiration cytology with ultrasonographic guidance may allow the identification of normal hepatocytes or cells with mild atypia; this diagnostic will not be useful to differentiate between benign and low-grade malignant hepatic tumors, but will be useful to exclude other neoplastic diseases.
- Hepatic biopsy with Tru-Cut® needle—several core biopsies are necessary to provide enough tissue for histopathologic characterization; due to the overlap between the hepatocellular adenoma and the low-grade hepatocellular carcinoma, it may be difficult to obtain a definitive diagnosis.
- Abdominal exploratory surgery followed by mass resection (liver lobectomy) and histopathology is the best way to obtain a definitive diagnosis and treat the disease.

PATHOLOGIC FINDINGS

Gross Pathology
- Usually well-circumscribed single nodules <10 cm in diameter.
- May be yellow-brown.
- Often soft, highly vascular, and friable.
- Occasionally multiple.
- Occasionally very large (>20 cm).

Microscopic Findings
- May be difficult to distinguish from nodular hyperplasia, normal liver tissue, or low-grade hepatocellular carcinoma.
- Usually well-defined trabecular pattern; not necessarily encapsulated.
- Compression of adjacent hepatic parenchyma common.
- Mitotic figures infrequent.

TREATMENT
- Surgical resection for large tumors, or tumors that cause clinical signs or organ dysfunction.
- Bleeding tumor—requires immediate emergency care: hemodynamic stabilization, blood transfusion, and exploratory surgery.

Surgical Considerations
- Excision recommended for large, single-mass lesions.
- Between 60% and 70% of the liver can be resected if the patient is healthy, and appropriate postoperative supportive care is available.
- Biopsy of local lymph nodes, normal-appearing liver, and any abnormal tissue identified during the exploratory surgery is of paramount importance.

MEDICATIONS
None

FOLLOW-UP

PATIENT MONITORING
- Liver enzymes—serial evaluation, especially if they were elevated at the time of diagnosis.
- Abdominal ultrasonography— every 3–4 months for the first year; preferred method of reevaluation.

POSSIBLE COMPLICATIONS
Risk of tumor necrosis and massive abdominal hemorrhage if not resected.

EXPECTED COURSE AND PROGNOSIS
Excellent

MISCELLANEOUS

SYNONYMS
Hepatoma—should be avoided; refers to hepatocellular carcinoma in human medicine and hepatocellular adenoma in veterinary medicine.

HEPATOCELLULAR CARCINOMA

BASICS

OVERVIEW
• Malignant epithelial liver tumor.
• Accounts for about 50% of malignant hepatic tumors. • Metastasis to regional lymph nodes, lungs, and peritoneal cavity in dogs is associated with the nodular and diffuse forms of hepatocellular carcinoma.

SIGNALMENT
• Uncommon in dogs and rare in cats.
• Affected dogs commonly >10 years of age.
• No breed predispositions, although golden retrievers, miniature schnauzers, and male dogs are overrepresented in some studies.

SIGNS
• Typically absent until disease is advanced, unless it causes biliary obstruction. • Many times incidental finding. • Lethargy.
• Weakness. • Anorexia. • Weight loss.
• Polydipsia. • Diarrhea. • Vomiting.
• Hepatomegaly (asymmetric)—consistent; precedes development of overt clinical signs.
• Abdominal hemorrhage.

CAUSES & RISK FACTORS
• Unknown. • May be associated with chronic inflammation or hepatotoxicity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Hepatic adenoma. • Nodular hyperplasia.
• Biliary cystadenoma. • Bile duct adenoma/carcinoma. • Metastatic neoplasia. • Polycystic liver disease—less common form; fibrous stroma hyperplasia with anaplastic duct cells; few cysts. • Hepatic lymphoma, hemangiosarcoma, carcinoid.

CBC/BIOCHEMISTRY/URINALYSIS

CBC
• Usually unremarkable. • Anemia in >50% of cases with massive hepatocellular carcinoma in one study. • Anemia may be regenerative if tumor is bleeding. • Leukocytosis with a left shift—tumors with necrotic centers.

Biochemistry
• Liver enzymes variable. • Serum total bilirubin values—usually normal. • May note hypoalbuminemia, hypoglycemia, and hypocholesterolemia.

OTHER LABORATORY TESTS
• Serum bile acids—normal unless tumor impairs hepatic perfusion and biliary flow.
• Coagulation parameters— consistent with disseminated intravascular coagulation (DIC) in patients with massive or necrotic tumors, or intra-abdominal bleeding.

IMAGING

Radiography
• May demonstrate a single-mass lesion, apparent asymmetry of hepatic silhouette, or hepatomegaly. • Rarely, gas in necrotic center of tumor. • Loss of serosal detail in case of hemoabdomen.

Abdominal Ultrasonography
• Discrete mass lesion with variable echogenicity, depending on the presence of intratumoral necrosis, hemorrhage, gas, or cystic cavities. • Massive enlargement of a single liver lobe is occasionally observed.
• Mixed echogenic pattern—most common.
• Nodular pattern of lesions.

CT/MRI
CT is indicated for surgical planning (determine divisional or lobar origin), or when tumor involves/close proximity to critical anatomic structures, such as major vessels and the bile duct.

DIAGNOSTIC PROCEDURES
• Aspiration cytology—to exclude other types of neoplasia (lymphoma, sarcoma, etc.); aspirate cytology cannot reliably differentiate between hepatocellular carcinoma and benign hepatocellular proliferation (adenoma, hyperplasia). • Surgical hepatic biopsy for confirmation. • If tumor is not surgically resectable, ultrasound-guided needle biopsy may be useful in obtaining definitive diagnosis.

PATHOLOGIC FINDINGS
• Three clinical subtypes of this tumor are described—massive, nodular, and diffuse.
• Nodular forms account for 30% and diffuse types account for 10% of all reported hepatocellular carcinomas in dogs, and both types involve multiple liver lobes. • Massive form that is confined to one lobe accounts for about 60% of canine hepatocellular carcinoma cases. • Presence of necrotic areas.
• Diffusely infiltrated tumors may not be grossly apparent other than hepatomegaly.

TREATMENT

Surgical Considerations
• Complete excision (liver lobectomy) recommended when possible; excision with microscopically dirty margins can still afford durable tumor control and long survival times. • Massive form is often amenable to surgical resection. • Nodular and diffuse forms are often not amenable to surgery.
• Between 60% and 70% of the liver lobes can be resected if the patient is healthy and is given appropriate postoperative care.

MEDICATIONS

DRUG(S) OF CHOICE
While toceranib administration has resulted in short-term tumor control for some dogs, no medical treatment options have been successful in reducing tumor recurrence or risk for metastasis.

FOLLOW-UP

PATIENT MONITORING
• Abdominal ultrasonography—2 weeks postoperative for baseline and every 3–4 months for the first year. • Abdominal CT appears more sensitive than ultrasonography for detection of small, recurrent lesions.
• Monitor liver enzymes serially.

POSSIBLE COMPLICATIONS
Risk of tumor necrosis and massive abdominal hemorrhage if unresected.

EXPECTED COURSE AND PROGNOSIS
• Massive forms treated with surgery have a better prognosis than do the nodular or diffuse forms. • Median survival of dogs with massive form treated with surgery may be >1,460 days. • Local tumor recurrence or de novo tumor growth is not uncommon.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Polycystic liver disease in cats.

ABBREVIATIONS
• DIC = disseminated intravascular coagulation.

HEPATOCUTANEOUS SYNDROME

BASICS

OVERVIEW

• Liver lesion—severe degenerative vacuolar hepatopathy, hepatocyte degeneration leads to parenchymal collapse associated with marked proliferative hepatocyte response; this process leads to severe hepatic nodularity; hepatocutaneous syndrome (HCS) hepatopathy often associated with syndromic pressure point crusting, painful dermatosis, and diabetes mellitus (DM).
• Liver lesions—may precede cutaneous lesions and DM.
• Hepatopathy—recognized on abdominal US, pursued because of marked alkaline phosphatase (ALP) increase.
• Occasionally HCS hepatopathy develops in dogs treated chronically with phenobarbital.

SIGNALMENT

• Middle-aged to older dogs.
• Males may have a greater predilection.
• Familial syndrome in shih tzu dogs described.

SIGNS

Historical Findings

• Acute to subacute onset; may be few initial signs.
• Common signs— anorexia, weight loss, lethargy, polyuria/polydipsia, diarrhea, vomiting, ± jaundice, often with prominent cutaneous pressure point and painful foot pad lesions characterized as fissured crusted oozing wounds.

Physical Examination Findings

• Lethargy, poor body condition, with foot pad and elbow lesions causing pain in standing and recumbent postures, may be jaundiced.
• Cutaneous lesions—see Superficial Necrolytic Dermatitis.
• Normal, small to large hepatic size.
• Rare abdominal effusion—signifies late-stage HCS hepatopathy.

CAUSES & RISK FACTORS

• Etiology—associated with pathologic hypoaminoacidemia and aminoaciduria; low amino acid (AA) concentrations seemingly have causal association with cutaneous and liver lesions. Most significantly low AA affiliated with urea cycle and synthesis of glutathione and collagen.
• Hyperglucagonemia associated with glucagonoma—originally proposed as causal mechanism but that remains unproven; ~30–40% of tested dogs have increased plasma glucagon concentrations; glucagonoma confirmed in <15% of reported cases.
• Insulin-resistant DM—commonly associated with HCS; may reflect increased glucagon.
• Contributing role hypothesized for ill-defined deficiencies of zinc, fatty acids, or niacin.
• Similar cutaneous lesions described with primary hepatopathies caused by phenobarbital or rarely chronic mycotoxicosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Cirrhosis—unresolvable architectural remodeling with fibrosis, sinusoidal hypertension, and regenerative nodules.
• Chronic hepatitis—inflammatory infiltrates and individual hepatocyte necrosis.
• Copper associated hepatopathy—pathologic copper accumulation initially with zone 3 associated with oxidative necroinflammatory hepatocyte injury.
• Diffuse nodular hyperplasia—rare cause of hepatic nodularity of similar magnitude.
• Degenerative glycogen-type vacuolar hepatopathy (VH)—may evolve similar nodular hepatic US pattern.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—mild to moderate nonregenerative to mild regenerative anemia; red blood cell microcytosis; neutrophilic leukocytosis reflecting cutaneous lesion inflammation or infection.
• Biochemistry—high liver enzymes (especially ALP); variable hypoproteinemia with hypoalbuminemia, low cholesterol and blood urea nitrogen; euglycemic to fasting hyperglycemia.
• Urinalysis—ammonium biurate crystalluria reflects hepatic insufficiency in end-stage hepatopathy; occasionally develop acquired portosystemic shunts, with shunting contributing to hyperammonemia.

OTHER LABORATORY TESTS

• Total serum bile acids—normal or increased.
• Insulin—inappropriately increased before development of diabetes mellitus.
• Plasma glucagon—inconsistently increased.
• Plasma AA profile—30–50% reduction in AA concentrations of healthy dogs; dogs with cutaneous lesions have more severe AA deficiencies than dogs with only HCS hepatopathy.
• Urine AA profile—prodigious renal wasting of lysine and proline; profile of urine AA concentrations must be normalized with urine creatinine concentration for interpretation.

IMAGING

• Abdominal radiography—variable liver size (small, normal, to large); rare effusion.
• Abdominal US—may disclose irregular liver margin; characteristic nodular pattern: hypoechoic foci (proliferative nodules) with background hyperechoic parenchyma (glycogen-type VH and lipid-type VH) typified as "Swiss cheese pattern"; although suggested as pathognomonic, other causes of severe degenerative VH also may demonstrate this pattern; occasional diffuse nodularity cannot be imaged in HCS; pancreatic mass <15% of dogs.

DIAGNOSTIC PROCEDURES

• Aspiration sampling—hepatocytes display glycogen- and lipid-type vacuolation.
• Liver biopsy—needle biopsy may compromise definitive diagnosis due to limited sampling of distinctive proliferative hepatocyte foci between regions with massive degenerative VH; needle biopsy may be best option for dogs with extensive skin lesions; larger laparoscopic samples preferred; avoid laparotomy as dogs with cutaneous lesions may not promptly heal.
• Skin biopsy—see Superficial Necrolytic Dermatitis; usually diagnostic for HCS.
• AA profiles in plasma and urine with urine AA normalized using urine creatinine disclose profound reduction of plasma AA and severe aminoaciduria with prominent losses of lysine and proline.
• Glucagonomas often express somatostatin receptors; these might be identified using radioisotope somatostatin label; however, prohibitively expensive for most clients.
• If pancreatic mass discovered, should be resected, submitted for routine and special stains (request immunohistochemical stains for neuroendocrine neoplasia); like other islet cell tumors, glucagonomas may produce other hormones (see Suggested Reading). *Note*: positive immunohistochemical staining does not confirm pathologic hormone secretion.

TREATMENT

• Diet—use high-quality/high-quantity protein, energy-dense diets; enteral or parenteral feeding may be required for some dogs at initial diagnosis.
• If hepatic encephalopathy (HE) observed—improve nitrogen tolerance with lactulose and metronidazole (see Hepatic Encephalopathy) and use liver-specific diet as baseline formula.
• Supplemental AA therapy is cornerstone of treatment—IV route superior to oral route.
• Oral AA supplementation—historically done with egg yolk (3–6 yolks per day) but *not* very effective; dietary supplementation with anabolic whey protein powder increases protein intake, but alone *not* very effective; oral treatment may lack efficacy due to reduced enteral AA uptake.
• IV AA infusion with IV lipid infusion—*most* effective therapy (lesion resolution and survival).

(CONTINUED) HEPATOCUTANEOUS SYNDROME

• IV AA infusion—8.5–10% solution of crystalline AA (Aminosyn®); using 10% solution (100 mL delivers 10 g AA) dose: 25 mL/kg bodyweight over 6–8h through peripheral vein.
• IV 20% Intralipid® (or generic 20% IV fat emulsion)—dose: 7 ml/kg bodyweight over 6–8h; given concurrently with IV AA using Y-adaptor for combined infusions through one line; combined therapy achieves best response to date.
• IV infusion treatment interval—initially q7–10 days until evidence of improvement: skin easiest to appraise with photo documentation and evidence of foot pad pain resolution; hepatic lesions require US imaging for assessment: these take months to improve; liver enzymes may be used to infer improvement but do not normalize (remain vacillating). RBC microcytosis resolves with significant recovery. After initial strong response, frequency of IV AA and IV Intralipid determined based on dog's physical and lesional status and trends in hematologic and biochemical profiles. Chronically managed patients typically receive IV infusions at 6-week intervals, titrated frequency achieved by gradually lengthening intervals between infusions while monitoring for relapse.
• Essential fatty acid supplementation—omega-3 fatty acids; double normal dose.
• Metastatic pancreatic tumors secreting glucagon may be controlled with longacting somatostatin analogue (octreotide: 2–3.7 µg/kg q6–12h); prohibitively expensive.
• Manage DM with insulin and judicious dose titration to response.
• Other supplements—see Medications.

MEDICATIONS

DRUG(S) OF CHOICE

• Insulin for DM management; may demonstrate insulin resistance.
• AA infusion and lipid infusions and diet—see above.
• Cutaneous or nail bed infections—systemic antimicrobials or antifungals; germicidal baths.
• Ketoconazole—for secondary yeast infection; anti-inflammatory and antipruritic effects: monitor liver enzymes for drug-induced liver injury warranting drug discontinuation.
• Zinc supplementation—2–4 mg/kg elemental zinc q24h; avoid zinc methionine if HE.
• Niacinamide—250–300 mg/dog q12h (500 mg for dogs >10 kg); watch for toxic effects; avoid extended-release form.
• Topical glucocorticoids—if unresponsive inflammatory skin lesions, after infection managed (*caution*: systemic glucocorticoids may promote HE, enteric ulceration, infection, may complicate DM management).
• Ursodeoxycholic acid—10–15 mg/kg PO daily, divided dose given with food; hepatoprotectant against bile acid mediated membrane injury.
• Antioxidants—vitamin E (10 IU/kg daily PO with food); *S*-adenosylmethionine (20 mg/kg PO daily, empty stomach) provides additional metabolic and hepatoprotective influences.
• If associated with phenobarbital, discontinue this drug.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• HE induction—high-protein diet supplements and AA infusions.
• Toxic effects of ketoconazole and its interference with p450 drug metabolism.
• Toxic effects of niacinamide and zinc.

FOLLOW-UP

PATIENT MONITORING

• Weekly to monthly physical exam, CBC, biochemistry, and urinalysis to assess need for IV AA and lipid infusions and treatments for secondary infections.
• As needed for management of DM.

POSSIBLE COMPLICATIONS

• With HCS, IV infusions may cause thrombophlebitis and risk for thromboembolism.
• Ketoacidosis—uncommon.
• Hepatic encephalopathy.
• Sepsis—due to diabetes and skin lesions or IV catheter-related infections.
• Pain—from skin lesions may require analgesics.

EXPECTED COURSE AND PROGNOSIS

• Liver and skin lesions often improve with IV infusions.
• Some dogs achieve cutaneous remission ≥3 years with described therapies.
• Some dogs have unremitting HCS progression, necessitating euthanasia.

MISCELLANEOUS

SYNONYMS

• Superficial necrolytic dermatitis.
• Necrolytic migratory erythema.

HEPATOMEGALY

BASICS

DEFINITION
Large liver detected on physical examination, abdominal radiography, US, or direct visualization.

PATHOPHYSIOLOGY
• Liver size—influenced by hepatotropic factors produced by splanchnic viscera (insulin dominates); delivered in portal blood. • Enlargement may reflect sinusoidal capacitance (blood pooling), parenchymal or sinusoidal accumulation of cells or substrates, or storage products expanding hepatocytes.

Diffuse or Generalized
• Inflammatory—immune-mediated, infectious, pyogranulomatous hepatitis; classified by infiltrative cell type. • Lymphoreticular hyperplasia—response to antigens or accelerated erythrocyte destruction. • Congestion—impaired drainage through hepatic vein (cardiac, pericardial, thrombotic, neoplastic causes); sinusoidal occlusion syndrome or Budd Chiari syndrome. • Infiltration—cellular (neoplastic: primary hepatocellular, metastatic); excessive glycogen, lipid, or, rarely, metabolic products (genetic diseases) expanding hepatocytes or space of Disse (amyloid). • Cystic lesions as observed in ductal plate malformations (DPMs). • Cholestasis—most commonly with extrahepatic bile duct obstruction (EHBDO); rarely, intrahepatic cholestasis causing bile duct distention. • Extramedullary hematopoiesis (EMH)—diffuse, severe, or obstructing perfusion.

Nodular, Focal, or Asymmetric Hepatic Enlargement
• Neoplasia—hepatocellular carcinoma (HCA), hemangiosarcoma, lymphoma, metastatic carcinoma, other. • Hemorrhage. • Infection or inflammation. • Hepatic nodular hyperplasia (uncommon cause). • Nodular regeneration (uncommonly associated with hepatomegaly). • Arteriovenous malformation—involved lobe larger than other lobes; other lobes atrophied. • Asymmetric regeneration after large-volume resection or panlobular necrosis. • Biliary cystic lesions (DPM). • Other DPM malformations—large liver lobes usually with some atretic liver lobes or even atretic gallbladder; proliferative-like biliary epithelium with fibrotic bridging portal trabeculae (congenital hepatic fibrosis: DPM phenotype). • Liver lobe torsion—acute venous congestion.

SYSTEMS AFFECTED
• Gastrointestinal—gastric compression or displacement by large liver. • Peritoneal effusion—sinusoidal or postsinusoidal hepatic hypertension weeping lymph. • Pulmonary—reduced ventilatory space from diaphragmatic compression. • General/vague pain—stretching of liver capsule, compression of adjacent viscera.

SIGNALMENT
• Dog and cat. • Old animals more commonly; younger if DPM related.

SIGNS
Historical Findings
• Abdominal distention or palpable mass.
• Abdominal discomfort—vague location.
• Depends on underlying cause.

Physical Examination Findings
• Dogs—liver palpable beyond costal margin (normal liver palpable in some breeds).
• Cats—liver palpable >1.5 cm beyond costal margin (normal liver palpable in some cats). • May be undetected in obese animals.

CAUSES
Inflammation
• Infectious or chronic (early) hepatitis. • Acute toxic hepatopathy. • Feline cholangitis/cholangiohepatitis syndrome (CCHS). • EHBDO. • Lymphoreticular/pyogranulomatous—immune-mediated disease (hemolytic anemia, hemophagocytic syndrome, systemic lupus erythematosus, idiopathic), infectious disorders. • Venous outflow obstruction—sinusoidal occlusion syndrome or Budd Chiari syndrome.

Congestive Hepatopathy
• Increased central venous pressure—right-sided congestive heart failure: tricuspid valve disease; cardiomyopathy; congenital anomaly (cor triatriatum dexter); neoplasia; pericardial disease; heartworm disease; pulmonary hypertension; severe arrhythmias or bradycardia reducing cardiac output. • Vena caval or hepatic vein occlusion—thrombosis; tumor invasion or extramural caval occlusion; heartworm vena cava syndrome; vena caval stenosis or congenital kink (rare); diaphragmatic hernia; vena caval or large hepatic vein thrombosis (Budd Chiari syndrome); intrahepatic hepatic vein occlusion (thrombi, neoplasia, centrilobular parenchymal collapse causing sinusoidal occlusion syndrome). • Sinusoidal occlusion syndrome—collapsed centrilobular parenchyma and/or damage to hepatic venules impairing circulatory egress; causes include xenobiotic or herbal toxicity (e.g., pyrrolizidine alkaloids), severe nonsteroidal inflammatory drug–induced injury, severe copper hepatopathy. • Liver lobe torsion (acute).

Infiltration
• Neoplasia. • Metabolic abnormalities—amyloid; lipid (see Hepatic Lipidosis [cats]), glycogen (see Glycogen-Type Vacuolar Hepatopathy [dogs]); cats and dogs: diabetes mellitus (DM), hyperlipidemic syndromes; neonatal metabolic storage disorders. • Lymphohistiocytic/pyogranulomatous—infectious disease, immune response, antigen stimulation, neoplasia (histiocytic/dendritic cells: histiocytic sarcoma), hemophagocytic syndrome.

Extramedullary Hematopoiesis
Regenerative anemias—hemolytic (immune-mediated, congenital, metabolic, infectious); oxidant injury; erythroparasitism; severe blood loss, bone marrow failure; idiopathic.

Neoplasia
• Infiltrative, diffuse, or large focal tumors—primary or metastatic. • Primary hepatic—lymphoma; massive HCA; cholangiocarcinoma (bile duct carcinoma ± EHBDO); hemangiosarcoma. • Metastatic—lymphosarcoma, hemangiosarcoma, histiocytic sarcoma, fibrosarcoma, leiomyoma/sarcoma, neuroendocrine, osteosarcoma, others.

Major Bile Duct Obstruction
• Pancreatitis; pancreatic neoplasia. • Neoplasms in porta hepatis—bile duct carcinoma, lymphoma. • Granuloma/fibrosis of common bile duct. • Inspissated bile syndrome, choledochal cyst (DPM phenotype), or gallbladder mucocele. • Cholelithiasis. • Proximal duodenitis; duodenal foreign body. • Fluke migration (cats).

Cystic Lesions
• Primary single hepatic or biliary cysts. • Acquired cysts within neoplastic masses. • DPM—may associate with renal cysts (common in Persian cats). • Biliary cystadenoma (cats; DPM phenotype). • Hepatic abscesses (cystic cavitation); hepatocellular carcinoma housing abscess. • Parasitic—echinococcus (hydatid cyst).

Other
• Drugs—corticosteroids (see Glycogen-Type Vacuolar Hepatopathy), phenobarbital (dogs). • Hepatic nodular hyperplasia (rare cause). • Acromegaly—cats.

RISK FACTORS
• Cardiac disease. • Heartworm disease. • Neoplasia. • Primary hepatic disease—inflammatory, neoplastic, cystic, or other DPM phenotypes. • Corticosteroids—exogenous or endogenous. • Phenobarbital treatment. • Poorly controlled DM. • Anorexia in obese cats—hepatic lipidosis. • EHBDO. • Cystic malformations—DPM. • Certain anemias—diffuse hepatic EMH.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Similar Signs
Distinguish from other disorders causing visceromegaly (gastric, splenic), cranial abdominal masses, or effusions via radiography and US.

(CONTINUED) HEPATOMEGALY

Differential Causes

• Cardiac disorders—heart murmur, weak femoral pulses, hepatojugular reflex, jugular distention and jugular pulses, muffled heart sounds, arrhythmias, cough, dyspnea/tachypnea. • Symptomatic anemia—pallor ± jaundice; tachycardia; tachypnea; exercise intolerance; bounding pulses. • Parenchymal liver disease—lethargy, anorexia, vomiting, diarrhea, weight loss, variable liver enzymes ± jaundice, coagulopathies, polyuria/polydipsia (PU/PD), if advanced may see hepatic encephalopathy (HE) or ascites. • Glycogen-type vacuolar hepatopathy (VH; dog)—signs of hyperadrenocorticism or adrenal hyperplasia or other chronic disease imposing stress; DM—persistent hyperglycemia; PU/PD, signs of underlying endocrinopathy. • Hepatic lipidosis—jaundice in obese hyporexic cat, poorly controlled DM (dog or cat); failure-to-thrive puppies or kittens; congenital lysosomal or glycogen storage disorders.

CBC/BIOCHEMISTRY/URINALYSIS

CBC

• Identify anemia and cause; spherocytes (immune-mediated hemolytic anemia, microangiopathic anemia); schistocytes (vascular shearing-microangiopathic, vena cava syndrome, hemangiosarcoma, disseminated intravascular coagulation (DIC), Heinz bodies (oxidant injury); erythroparasitism (*Mycoplasma haemofelis* or *haemominutum*, *Babesia*). • Circulating blast cells—myeloproliferative or lymphoproliferative disorders. • Nucleated red cells—EMH, splenic disease, regenerative anemia. • Macrocytosis and nonregenerative anemia—feline immunodeficiency virus (FIV), feline leukemia virus (FeLV), myelophthisis. • Thrombocytopenia—increased consumption, destruction, or reduced platelet production. • Thrombocytosis—neoplasia; inflammation; hyperadrenocorticism; splenic disease.

Biochemistry

• Inflammatory hepatic disorders—usually high liver enzyme activity; variable hyperglobulinemia, bilirubin, and albumin concentrations. • Reticuloendothelial hyperplasia—variable liver enzyme activity. • Primary hepatic neoplasia—moderate to marked increases in liver enzyme activity (alkaline phosphatase [ALP] and γ-glutamyltransferase [GGT] usually predominate with HCA, variable alanine aminotransferase [ALT]. • Metastatic neoplasia—variable liver enzymes; occasional high calcium or globulin. • Infiltrative disorders—minor liver enzyme change; variable bilirubin concentration. • Glycogen-type VH (dogs)—markedly high ALP; high cholesterol ± triglycerides with increased glucocorticoids or sex steroids; DM—high ALP, cholesterol, hyperglycemia. • Hepatic lipidosis (cats)—high ALP, aspartate aminotransferase (AST), ALT; minor increase in GGT unless concurrent pancreatitis, CCHS, or EHBDO. • Storage diseases—may display few abnormalities. • EHBDO—markedly high ALP, GGT, other enzymes; high bilirubin and cholesterol. • Cystic lesions—normal, except with hepatic abscess (markedly high ALT and AST) or CCHS (high ALP, ALT, GGT, variable bilirubin); DPM often presents with suppurative CCHS. • Phenobarbital-associated—high liver enzymes (especially ALP in dogs). • Nodular hyperplasia—normal to moderately high ALP, elderly dogs: rare cause of hepatomegaly.

OTHER LABORATORY TESTS

• FeLV and FIV testing—cats. • Buffy coat—circulating blasts with neoplasia or uncommon cell type observed. • Coagulation panel—DIC common with hemangiosarcoma or diffuse lymphoma; prolonged coagulation times common with EHBDO >5 days esp. in cats. • Total serum bile acids (TSBA)—high in diffuse disorders or EHBDO; *redundant test if nonhemolytic jaundice*. • Pituitary-adrenal axis testing (dogs)—see Glycogen-Type Vacuolar Hepatopathy; Hyperadrenocorticism (Cushing's Syndrome)—Dogs. • Insulin-like growth factor-1 (IGF-1) in acromegalic cats; typically males with DM. • Heartworm testing—in endemic areas. • Fungal serology—in endemic areas. • Other serology—e.g., Rickettsial, *Bartonella*, *Leishmania*, *Toxoplasmosis*.

IMAGING

Abdominal Radiography

• Hepatomegaly—rounded margins extending beyond costal arch; caudal-dorsal gastric displacement; caudal displacement: cranial duodenal flexure, right kidney, transverse colon. • May suggest cause.

Thoracic Radiography

• Three views (lateral [right, left], dorsal-ventral)—metastasis, other disorders, cranial displacement of diaphragm, wide vena cava if passive congestion. • Cardiac, pulmonary, pericardial, and vena caval disorders usually need US imaging. • Sternal lymphadenopathy—reflects abdominal inflammation or neoplasia. • Puppies, kittens, deep inspiration, and certain canine breeds—spurious hepatomegaly.

Abdominal US

• Liver size and surface contour. • Diffuse enlargement with normal echogenicity—congestion; cellular infiltration (lymphoma); inflammation; EMH; reticuloendothelial hyperplasia, diffuse amyloid deposition expanding space of Disse. • Diffuse enlargement with hypoechoic parenchyma—normal variation; congestion, lymphoma, diffuse sarcoma; amyloidosis expanding space of Disse. • Diffuse enlargement with hyperechoic parenchymal (minor nodularity)—lipid or glycogen; inflammation; fibrosis; lymphoma; DPM fibrotic bridging portal trabeculae. • Diffuse enlargement with hypoechoic nodules—neoplasia; abscess; degenerative glycogen-type VH (dog); HCS, cystic lesions (DPM). • Identify EHBDO. • Identify concurrent abdominal diseases—kidneys; intestines; lymph nodes; effusion; interrogation of porta hepatis for obstructions and lymphadenopathy. • Identify portal or vena caval thrombi. • Identify abdominal effusion—distribution and echogenic patterns. • Cannot distinguish benign from malignant disease.

DIAGNOSTIC PROCEDURES

ECG/Echocardiography

Characterize cardiac rhythm, structure, function, pulmonary pressure gradient.

Fine-Needle Aspiration

• Procedure—22-G, 2.5–3.75 cm (1–1.5 in) needle; diffusely large liver directly aspirated without US; focal lesions aspirated under US guidance. • Cytology—may disclose infectious agents, vacuolar change, neoplasia, inflammation, or EMH; definitive diagnosis seldom confidently confirmed (false-positive and -negative results). • Hepatic biopsy—if US rules out EHBDO, cytology does not indicate septic inflammation or neoplasia, and no obvious diagnoses made; percutaneous ultrasound–guided Tru-Cut® needle biopsy for suspected neoplasia or amyloid (avoid if abscess or EHBDO possible); otherwise, best sampling with laparoscopic or surgical exploratory approaches. • Microbial culture—aerobic and anaerobic bacterial; fungal as appropriate. • Staining—H&E (routine); reticulin (architectural substructural remodeling, infiltration, compression), Masson's trichrome (collagen deposition, amyloid detection); rhodanine (copper); periodic acid–Schiff (glycogen ± amylase predigestion); acid-fast stain (mycobacteria if granulomatous inflammation); Congo red (amyloid); Oil Red O (lipid, requires frozen section), infectious disease stains (see Hepatitis, Granulomatous). • Coagulation testing—before liver sampling, consider measurement of prothrombin time, activated partial thromboplastin time, fibrinogen, buccal mucosal bleeding time (BMBT); prediction of iatrogenic hemorrhage poor with bench tests; BMBT may be more relevant. • Abdominal effusion—cytology; protein content; culture; evaluate before tissue sampling. • Pericardiocentesis—if pericardial tamponade. • Cyst aspiration sampling—if possible infectious cause when plausible treatment might be recommended; risk for abdominal contamination if hepatic abscess.

HEPATOMEGALY (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE

• Outpatient—except cardiac/pericardial causes or hepatic failure. • General supportive goals—eliminate or manage inciting cause; prevent complications; palliate derangements reflecting hepatic failure. • Important derangements—dehydration and hypovolemia; HE; hypoglycemia; acid-base and electrolyte abnormalities; coagulopathies; enteric hemorrhage; sepsis; endotoxemia.

NURSING CARE

• Heart failure or ascites—impose sodium restriction: fluids and food (<100 mg/100 kcal, <0.2% dry matter basis food), prescribe appropriate cardiac medications or diuretics. • Supplement potassium chloride if IV fluids—sliding scale (maintenance = 20 mEq/L fluid). • Supplement B-soluble vitamins in IV fluids. • If jaundiced—parenteral vitamin K before invasive procedures.

ACTIVITY

Restricted; initial cage rest in some disorders.

DIET

• Dietary protein—restrict only if evidence of HE. • Well-balanced, adequate energy, positive nitrogen balance essential; adequate vitamins and micronutrients for most disorders; fat restriction only if hypertriglyceridemia or steatorrhea. • May need feeding tube (e.g., esophagostomy tube) in cats with HL (see Hepatic Lipidosis). • Sodium—restrict if cardiac failure or ascites.

CLIENT EDUCATION

• Treatment depends on underlying cause. • Many causes life-threatening; some less serious and amenable to treatment. • Thorough diagnostic evaluations essential for determining definitive cause and interventions.

SURGICAL CONSIDERATIONS

• Resection of primary or focal hepatic mass lesions (neoplasia, abscess, compromising cyst)—biliary decompression if EHBDO. • Pericardiectomy (thoracoscopic procedure)—if effusion recurs after initial pericardiocentesis.

MEDICATIONS

DRUG(S) OF CHOICE

Vary with underlying cause.

CONTRAINDICATIONS

• Avoid hepatotoxic drugs. • Glycogen-type VH (dogs)—avoid glucocorticoids. • Hepatic lipidosis (cats)—avoid catabolism or drugs that promote it; avoid fasting.

FOLLOW-UP

PATIENT MONITORING

• Physical assessment and hepatic imaging—reassess liver size. • CBC, biochemistry, TSBA—serial assessments of lab abnormalities and liver function; packed cell volume and reticulocyte count with anemia. • Thoracic radiography, ECG, and echocardiography—reassess status. • Pituitary-adrenal axis—adrenal disorders. • Adjust drug dosages according to status of liver function, body condition, and weight.

POSSIBLE COMPLICATIONS

Many causes are life-threatening.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Certain infectious agents of concern.

SEE ALSO

• Amyloidosis.
• Anemia, Immune-Mediated.
• Bile Duct Obstruction (Extrahepatic).
• Cholangitis/Cholangiohepatitis Syndrome.
• Congestive Heart Failure, Right-Sided.
• Ductal Plate Malformation (Congenital Hepatic Fibrosis).
• Glycogen Storage Disease.
• Glycogen-Type Vacuolar Hepatopathy.
• Hepatic Lipidosis.
• Hepatitis, Granulomatous.
• Hepatitis, Suppurative and Hepatic Abscess.
• Hepatocellular Carcinoma.

ABBREVIATIONS

• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• AST = aspartate aminotransferase.
• BMBT = buccal mucosal bleeding time.
• CCHS = cholangitis/cholangiohepatitis syndrome.
• DIC = disseminated intravascular coagulation.
• DM = diabetes mellitus.
• DPM= ductal plate malformation.
• EHBDO = extrahepatic bile duct obstruction.
• EMH = extramedullary hematopoiesis.
• FeLV = feline leukemia virus.
• FIV = feline immunodeficiency virus.
• GGT = γ-glutamyltransferase.
• IGF-1 = Insulin-like growth factor-1.
• HCA = hepatocellular carcinoma.
• HE = hepatic encephalopathy.
• PU/PD= polyuria/polydipsia.
• TSBA = total serum bile acids.
• VH = vacuolar hepatopathy.

HEPATOPORTAL MICROVASCULAR DYSPLASIA

BASICS

DEFINITION
• Microvascular dysplasia (MVD) describes intrahepatic microscopic vascular malformations diminishing intrahepatic perfusion within tertiary portal vein branches; this is accompanied by a compensatory increase in hepatic arterial perfusion (hepatic arterial buffer response); MVD lacks macroscopic portosystemic shunting but genetically associates with congenital portosystemic vascular anomalies (PSVA, shunts) as an apparent complex polygenic autosomal syndrome.
• Occurs as an isolated malformation *or* associated with PSVA.
• Clinically distinct from severe intrahepatic portal vein atresia that causes formation of acquired portosystemic shunts (APSS).
• Histologic features—stereotypic histologic responses reflect portal venous hypoperfusion, of which MVD is one of many causes; often misdiagnosed as portal hypoplasia.
• Clinicopathologic hallmark—increased total serum bile acid (TSBA) concentrations in the absence of other abnormalities observed in PSVA or disorders associated with APSS.
• Coexistence of MVD with PSVA explains failure of TSBA to normalize after complete PSVA attenuation, and inability to fully attenuate PSVA (some dogs).

PATHOPHYSIOLOGY
• Malformations impairing intrahepatic portal venous perfusion reduce hepatocyte exposure to splanchnic-derived hepatotropic factors—this leads to lobular atrophy and impairs expedient hepatocyte extraction of bile acids from the enterohepatic circulation.
• Compensatory hepatic arterial buffer response maintains liver viability.
• Absence of macroscopic portosystemic shunting explains absence of clinical signs—there is no hepatic encephalopathy (HE) or ammonium biurate uroliths or crystalluria in dogs with MVD.

SYSTEMS AFFECTED
• Usually asymptomatic.
• May observe slow recovery from sedatives or anesthetics requiring first-pass hepatic extraction and apparent adverse drug reactions with other medications undergoing first-pass hepatic extraction or hepatic metabolism.
• If concurrent inflammatory bowel disease (IBD)—vacillating signs include vomiting, diarrhea, inappetence, increased liver enzymes (often alanine aminotransferase [ALT]).

GENETICS
• Compelling evidence supports inheritance of PSVA/MVD as a complex polygenic autosomal trait in many small pure-breed dogs.
• Unaffected parents may produce affected progeny due to polygenic inheritance.

INCIDENCE/PREVALENCE
• Prevalence of PSVA/MVD trait in small pure-breed dogs 30–80%—varies with breed.
• Genetic association of MVD and PSVA in kindreds of certain breeds confirms that MVD is most common—10–30 : 1 of MVD : PSVA.

GEOGRAPHIC DISTRIBUTION
Worldwide

SIGNALMENT
Species
Dog

Breed Predilections
• Small-breed dogs.
• Commonly affected breeds—Yorkshire terriers, Maltese, Cairn terriers, Tibetan spaniels, shih tzu, Havanese, miniature schnauzers, pugs, papillon, Norfolk terriers, bichon frisé, West Highland white terriers.
• Not identified in large-breed dogs.
• Not identified in cats.

Age and Range
MVD bile acid testing best done at 4–6 months of age; use paired TSBA tests (pre and 2h post meal); neonatal testing not advised.

SIGNS
Historical Findings
• Asymptomatic—unremarkable history; occasional delayed anesthetic recovery or drug intolerance reported.
• MVD often recognized serendipitously during routine screening tests or diagnostics for nonhepatic health problems, or during TSBA testing in breeds with high PSVA/MVD prevalence.
• Concurrent illnesses may complicate TSBA interpretation (e.g., gastrointestinal [GI] malabsorption or diarrhea may cause erroneously low TSBA values), cholestasis (causes high TSBA values).

Physical Examination Findings
Unremarkable.

CAUSES
Congenital inherited disorder.

RISK FACTORS
Purebred small-dog breeds and mixes of these breeds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• PSVA—suspected in symptomatic young dog with increased TSBA or HE; however, 20% of PSVA dogs are asymptomatic or minimally symptomatic.
• Other causes of increased ALT or high TSBA values (e.g., GI disease, cholestasis).

CBC/BIOCHEMISTRY/URINALYSIS
• CBC—normal.
• Biochemistry—generally unremarkable; hepatic enzyme activities normal (expect high alkaline phosphatase in young patients due to bone growth); vacillating ALT if coexistent IBD or degenerative/inflammatory centrilobular hepatic lesion (dogs with eosinophilic IBD); mild hypoglobulinemia or hypoalbuminemia noted in ~50% of young dogs.
• Urinalysis—normal.
• Hyperammonemia *not* documented in dogs with MVD without severe portal atresia, PSVA, severe ductal plate malformation congenital hepatic fibrosis phenotype, arteriovenous malformation (fistula), or some other acquired liver disorder.

OTHER LABORATORY TESTS
TSBA
• Paired pre- and post-meal TSBA—recommended diagnostic test; pre- and post-meal TSBA >25 µmol/L reflect abnormal liver function or perfusion in absence of cholestasis.
• No need to fast patient before meal-provoked enterohepatic bile acid challenge.
• Random single TSBA in normal reference range not reliable assessment.
• Paired samples essential to evaluate bile acid enterohepatic circulation.
• Important TSBA testing strategy—food-initiated enterohepatic bile acid challenge essential; verify meal consumption; feed typical size meal; feed dog's regular diet for testing.
• Approximately 15–20% of dogs and ~10% of cats have pre-meal TSBA > post-meal TSBA; this reflects individual differences in physiologic coordination of gallbladder contraction, and gastric and enteric transit rate relative to food intake; thus, *do not* apply fasting TSBA reference ranges.
• "Shunting pattern"—common: higher post-meal TSBA; post-meal TSBA concentration usually 0.5- to 3-fold > pre-meal TSBA.
• Best assessments—young small breed dogs at 6 months; avoids serendipitous discovery of high TSBA when dog later presents for nonhepatic illnesses, when inappropriate testing may be pursued chasing abnormal TSBA values.
• Magnitude of increased TSBA—typically lower for MVD vs. PSVA; but wide overlapping of values invalidates utility of TSBA as standalone test to distinguish MVD from PSVA; however, TSBA values ≥200 µM/L usually associate with PSVA or APSS.
• Quantitative abnormal TSBA values cannot discriminate severity of MVD between dogs; sequential testing demonstrates vacillating abnormal values (reflects physiologic variables).
• Avoid qualitative TSBA tests.

HEPATOPORTAL MICROVASCULAR DYSPLASIA (CONTINUED)

Protein C

• Protein C reflects severity of portosystemic shunting in dogs; not valid for this use in cats.
• Generalities—MVD: protein C *usually* ≥70%; symptomatic PSVA: protein C <70%; asymptomatic PSVA: protein C *may be* ≥70% more common in portoazygous PSVA.

IMAGING

• Abdominal radiography—normal.
• Abdominal US—no macroscopic shunting vessel; liver size subjectively normal or slightly small.
• Mesenteric portovenography—subtle abnormalities of blunted small portal vein branches, protracted contrast "blush" in liver lobes; *caution*: PSVA may be overlooked if radiographic portography only completed in single recumbent posture; CT angiograms lack definition to display MVD hypoperfusion.
• Colorectal (CRS) or splenoportal scintigraphy—normal or slightly increased shunt fraction in MVD; scintigraphy may reveal irregular distribution of isotope among liver lobes.

DIAGNOSTIC PROCEDURES

• Liver biopsy—sample several liver lobes (at least 3) as MVD does not uniformly affect liver lobes; *avoid* sampling caudate lobe as this lobe receives perfusion from first portal vein branch and is often best-perfused liver lobe in dogs with PSVA or MVD; surgical wedge or laparoscopic biopsies recommended.
• US-guided needle biopsy—may not sample enough tissue for definitive diagnosis.

PATHOLOGIC FINDINGS

Gross

• Normal appearance and liver size.
• Some liver lobes comparatively small, coordinating with histologic severity of MVD.

Microscopic

• *Cannot* discriminate MVD, PSVA, noncirrhotic portal hypertension (NCPH), or extrahepatic portal venous thromboembolism (TE)/occlusion without history, clinical findings, and imaging details; *cannot* conclude portal vein hypoplasia.
• Histologic evaluation—required for definitive diagnosis of portal venous hypoperfusion but must be considered in context of clinical, clinicopathologic, and imaging details; rules out most acquired hepatobiliary disorders causing increased TSBA except portal TE and NCPH; histopathologic features of all disorders causing portal venous hypoperfusion are similar; impossible to differentiate MVD from PSVA based only on liver biopsies in most cases.
• MVD diagnosis confused by inappropriate terminology, where "portal hypoplasia" has been used to characterize histologic features of portal venous hypoperfusion; "hypoplasia" defines lack of development—impossible to ascertain from liver biopsy without clinical features and vascular imaging details; MVD one of many causes of portal venous hypoperfusion.
• Stereotypic histologic features of portal venous hypoperfusion:
  ◦ Lobular atrophy—small hepatocytes, closely approximated portal tracts and centrilobular regions, increased appearance of miniaturized (or juvenile) portal tracts (tiny, too many, too close).
  ◦ Increased number of binucleated hepatocytes in portal regions reflecting focal proliferative response induced by restricted portal venous perfusion (proven in experimental models).
  ◦ Increased arteriolar profiles with thick muscular walls, occasional single orphaned arterioles in hepatic parenchyma—findings reflect physiologic compensatory hepatic arterial buffer response increasing perfusion to peribiliary arterial plexus (vasa vasorum for bile ducts and portal veins); serpiginous arteries reflect increased pressure and flow, angiogenic formation of new arterial twigs, and branching architecture of peribiliary arterial plexus.
  ◦ Small nonperfused or absent portal vein silhouettes or vascular silhouettes with malformative sacculated profiles (see below).
  ◦ Prominent perivenular smooth muscle "throttling apparatus" of hepatic veins/venules in dogs (influences transhepatic perfusion) hypothesized to reflect physiologic response to arterialized transhepatic perfusion.
  ◦ Distended lymphatics—in portal tracts, adjacent to hepatic veins, and variably beneath liver capsule reflect increased ultralymph formation from arterialized sinusoidal perfusion.
  ◦ Variable scattered lipogranulomas (coalesced foamy macrophages) inconsistently associate with hemosiderin-iron aggregates, represent foci of historic parenchymal injury.
  ◦ Some dogs display obscured hepatic vein profiles by perivenular aggregates of lipid engorged macrophages (lipogranulomas) ± variable nonsuppurative inflammation, obscuring, or shrouding of venular profiles coordinates; if concurrent PSVA these may be intolerant of complete ligation.
• MVD malformative features in small-breed dogs:
  ◦ Maldevelopment of tertiary portal vein branches—inconsistent identification of portal veins, portal vein silhouettes with dilated, thin-walled unusual-appearing vessels consistent with inlet veins (direct sinusoidal-portal tract interconnections).
  ◦ Malposition of hepatic venules adjacent to portal triads sharing supportive adventitia termed "fusion complexes."
  ◦ Randomly distributed, aberrant wide irregular hepatic sinusoids (microvascular malformation).
  ◦ Disorganized centrilobular hepatic cords with malformative web-like reticulin substructure (reticulin staining).
  ◦ Unusual longitudinal hepatic venule profiles—demonstrating prominent throttling muscle contraction in dog.
  ◦ Variation in histologic features among hepatic lobes.
• *Note*: animals ≤4 months of age demonstrate increased juvenile or small portal triads.

TREATMENT

APPROPRIATE HEALTH CARE

• Asymptomatic—requires no medical interventions except avoidance or dose reduction of drugs dependent on hepatic first-pass extraction.
• *Do not need* ursodeoxycholic acid, *S*-adenosylmethionine (SAMe; unless chronically increased liver enzymes implicating oxidative injury), silibinin extracts (milk thistle), or dietary protein restriction.
• Rarely, some dogs develop centrilobular (zone 3) hepatocyte degeneration that may lead to chronic progressive hepatopathy; diagnosis requires hepatic imaging *and* liver biopsy; may require management for hepatic insufficiency and ascites; more common in Maltese, shih tzu, bichon frisé, Yorkshire terriers; US imaging may disclose attenuated hepatic vein profiles.
• Confirmed MVD associated with nonsuppurative zone 3 inflammation (especially involving eosinophils) and IBD—usually managed with low-dose dexamethasone (0.05 mg/kg PO q48–72h) rather than prednisone to avoid mineralocorticoid supplementation that may provoke ascites, hypoallergenic or hydrolyzed diet (protein restriction only if HE; usually no protein restriction in MVD), or Vivonex® HN, and low-dose metronidazole 7.5 mg/kg PO q12h; if low protein C or increased D-dimers confirmed, add mini-dose aspirin 0.5 mg/kg PO q12–24h or clopidogrel; *must have liver biopsy* confirming need for glucocorticoid and anticoagulants.

DIET

Dogs with only MVD do not require protein-restricted diet.

CLIENT EDUCATION

• Parents with normal TSBA may produce progeny with MVD or PSVA; examination of TSBA in F1 and F2 progeny is only method of recognizing optimal breeding strategy.
• Counsel clients and breed enthusiasts that TSBA values *cannot* grade severity of MVD.
• TSBA testing should be used to identify MVD in juvenile dogs (6 months of age) to avoid future diagnostic confusion as might

(CONTINUED) HEPATOPORTAL MICROVASCULAR DYSPLASIA

occur in adult dogs with nonhepatic illnesses.
• Protein C—*should not be used* as screening test without TSBA to rule out PSVA.

MEDICATIONS

DRUG(S) OF CHOICE
SAMe when chronically elevated liver enzyme activity (esp. ALT) indicates oxidative injury.

PRECAUTIONS
Beware of adverse reactions to drugs reliant on hepatic first-pass extraction or metabolism.

FOLLOW-UP

PATIENT MONITORING
• Asymptomatic dogs—no specific treatment/long-term follow-up has confirmed normal lifespan, no chronic illness, no progressive hepatic degeneration with exception noted above.
• Repeated TSBA tests not advised as values remain abnormal and fluctuate.

PREVENTION/AVOIDANCE
Specific recommendations to eliminate MVD from a particular genetic line or breed possible at present. Based on information from large pedigrees of multiple dog breeds, simply breeding unaffected parents does not eliminate MVD from kindred. In high-incidence kindreds, important to remain vigilant for vaguely ill dogs that may have PSVA; surgical exploration can miss PSVA as can portovenography if only single recumbent position evaluated; rather, CT angiography considered imaging gold standard; CRS definitively detects hepatofugal circulation (portosystemic shunting) and provides quick yes/no test to detect portosystemic shunting; protein C activity assists in differentiating dogs with PSVA from MVD to advise further expensive imaging, but is *not* definitive as standalone test.

EXPECTED COURSE AND PROGNOSIS
• Most dogs with MVD remain asymptomatic and have normal lifespan.
• Progressive increase in magnitude of TSBA values with age (juvenile to adult) has been documented in MVD; this does not coordinate with ill health.
• Generally, TSBA tests in MVD dogs not quantitatively related to histologic severity.
• Dogs with zone 3 degenerative lesions (described above) may develop progressive hepatopathy leading to HE, portal hypertension, APSS, ascites, and rarely portal venous TE; *rare* syndrome.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Small-breed dogs with high incidence of PSVA affected.

AGE-RELATED FACTORS
TSBA can be used to screen young dogs (≥16 weeks of age) in breeds known to have high prevalence of PSVA/MVD.

PREGNANCY/FERTILITY/BREEDING
Bitches with MVD and even minimally symptomatic PSVA carry litters to term.

SYNONYMS
• Congenital portal hypoperfusion.
• Hepatic microvascular dysplasia.
• Microscopic portovascular dysplasia.
• Portal venous hypoplasia.

Confused Terminology
• Intrahepatic portal venous atresia not synonymous with MVD.
• Portal venous hypoplasia not interchangeable as histologic diagnostic term for MVD.

SEE ALSO
• Ductal Plate Malformation (Congenital Hepatic Fibrosis).
• Hepatic Encephalopathy.
• Portosystemic Shunting, Acquired.
• Portosystemic Vascular Anomaly, Congenital.

ABBREVIATIONS
• ALT = alanine aminotransferase.
• APSS = acquired portosystemic shunt.
• CRS = colorectal scintigraphy.
• GI = gastrointestinal.
• HE = hepatic encephalopathy.
• IBD = inflammatory bowel disease.
• MVD = microvascular dysplasia.
• NCPH = noncirrhotic portal hypertension.
• PSVA = portosystemic vascular anomaly.
• SAMe = *S*-adenosylmethionine.
• TE = thromboembolism.
• TSBA = total serum bile acids.

H

HEPATOSUPPORTIVE THERAPIES

BASICS

OVERVIEW

• Goals of treatment of hepatobiliary disease involve identifying and treating the underlying cause and attenuating pathophysiologic mechanisms common to many hepatobiliary diseases, including inflammation, oxidative damage, and fibrosis.
• Hepatosupportive agents, including prescription drugs and dietary supplements (vitamins, minerals, and nutraceuticals), have received much attention for their concomitant role in treatment of hepatic disease.
• These medications purportedly enhance natural defense mechanisms to inhibit inflammation and fibrosis, prevent hepatocyte apoptosis, and protect against oxidant injury.

DIAGNOSIS

N/A

TREATMENT

See Medications.

MEDICATIONS

DRUG(S) OF CHOICE

S-*adenosylmethionine (SAMe)*

• Endogenous molecule produced from the amino acid methionine and ATP by the enzyme methionine adenosyltransferase synthetase.
• Mechanisms of action—anti-apoptotic, stabilization of cell membranes, modulates cytokine expression, antioxidant activity through enhancement of glutathione levels.
• Indications—necroinflammatory, cholestatic, metabolic, toxic, and ischemic hepatopathies.
• Dosage—20 mg/kg/day PO (dogs and cats).
• Dosage information and comments—best administered in *fasted* state; enteric-coated tablets should not be broken or crushed; lack of bioavailability may be issue in over-the-counter human products.
• Adverse effects and precautions—side effects are rare; post-pill nausea and lack of appetite have been reported in dogs (typically transient); some cats may develop post-pill vomiting.
• Notes—despite lack of supporting evidence, SAMe is frequently prescribed for a variety of hepatobiliary disorders, as it is generally considered safe and has the potential for benefit.

N-*acetylcysteine (NAC)*

• Stable formulation of the amino acid L-cysteine.
• Mechanisms of action—blocks polymorphonuclear leukocyte (PMN)–endothelial cell adhesion, PMN activation, and cytokine release (anti-inflammatory); improves tissue oxygen delivery; antioxidant activity.
• Indications—acute liver failure, toxic hepatopathies (acetaminophen), and severe feline hepatic lipidosis.
• Dosage—140 mg/kg IV once, then 70 mg/kg IV q6h or 100 mg/kg/day CRI (dogs and cats).
• Dosage information and comments—administer through a nonpyrogenic filter using a 10% solution diluted 1 : 2 or more with saline.
• Adverse effects and precautions—vomiting if given orally (use oral SAMe instead).
• Notes—use of NAC should be considered in any veterinary patient fitting criteria for *acute* liver failure.

Ursodeoxycholic Acid

• Cytoprotective hydrophilic dihydroxylated bile acid.
• Mechanisms of action—replaces hepatotoxic bile acids, stabilization of mitochondrial function, immunomodulatory, anti-apoptotic, stimulation of choleresis.
• Indications—cholestatic, necroinflammatory, metabolic hepatopathies; asymptomatic or mildly symptomatic dogs with gallbladder mucocele.
• Dosage—15 mg/kg PO q24h (dogs and cats).
• Dosage information and comments—absorption enhanced *with food*; can increase to q12h dosing with severe cholestasis.
• Adverse effects and precautions—rare vomiting and diarrhea; avoid in cases of complete bile duct obstruction; may increase bioavailability of vitamin E and cyclosporine.

Silymarin

• Group of flavonoids of which silybin is the major active component.
• Mechanisms of action—antioxidant (reactive oxygen species scavenger), anti-inflammatory, modulates hepatocyte transport, increases hepatic protein synthesis, antifibrotic, choleretic.
• Indications—toxic (*Amanita* mushroom), cholestatic, and necroinflammatory hepatopathies.
• Dosage—silymarin: 20–50 mg/kg/day divided q6–8h PO (dogs and cats); Siliphos®: 3–6 mg/kg/day PO.
• Dosage information and comments—bioavailability is variable.
• Adverse effects and precautions—no side effects; silymarin may inhibit the activity of drug-metabolizing enzymes.

Vitamin E

• Nutritional antioxidant found in all cell membranes.
• Mechanisms of action—antioxidant, anti-inflammatory.
• Indications—cholestatic and necroinflammatory hepatopathies.
• Dosage—10–15 IU/kg/day PO of alpha-tocopherol acetate (dogs and cats).
• Dosage information and comments—may need higher doses with severe cholestasis; parental formulation available and should be considered in animals with severe cholestasis.
• Adverse effects and precautions—none.

FOLLOW-UP

N/A

MISCELLANEOUS

ABBREVIATIONS

• NAC = *N*-acetylcysteine.
• PMN = polymorphonuclear leukocyte.
• SAMe = *S*-adenosylmethionine,

HEPATOTOXINS

BASICS

DEFINITION
• Endogenous or exogenous substances (drugs, xenobiotics, toxins) that cause hepatic injury. • Direct—(dose dependent): causes predictable injury. • Idiosyncratic—(dose independent): unpredictable.

PATHOPHYSIOLOGY
• Liver highly susceptible because of location and central role in metabolism and detoxification; liver most commonly reported organ associated with true adverse drug reactions. • Mechanisms of damage are direct (active metabolic byproducts) or indirect (oxidative injury from free radical metabolites). • May cause hepatocellular or cytolytic injury (necrosis and apoptosis), cholestasis, immunologic (innocent bystander or hapten-mediated), or mixed histopathologic patterns of injury.

SYSTEMS AFFECTED
• Hepatobiliary. • Nervous—hepatic encephalopathy (HE). • Hemic/lymphatic/immune—disseminated intravascular coagulation (DIC). • Renal—proximal tubular necrosis or renal tubular acidosis/Fanconi syndrome; hepatorenal syndrome (rare).

GENETICS
See Breed Predilections.

INCIDENCE/PREVALENCE
Etiology dependent.

GEOGRAPHIC DISTRIBUTION
Etiology dependent.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Siamese cats—some kindreds have high risk (reduced glucuronide formation). • Dog breeds at risk for selected drug toxicity—Doberman, Samoyed: sulfonamide antibiotics; Doberman: amiodarone; Labrador retriever: nonsteroidal anti-inflammatory drugs (NSAIDs); cocker spaniel, German shepherd: phenobarbital; herding breeds: *ABCB1* substrates (ATP-binding cassette subfamily B member 1 gene, encodes for P-glycoprotein).

Mean Age and Range
Any age.

Predominant Sex
No sex predilection.

SIGNS

General Comments
• May reflect chronic long-term or single acute exposure. • Detailed history essential—environmental, drug, and past medical history.

Historical Findings
• Malaise to moribund state. • Hyporexia, vomiting, diarrhea, jaundice, neurologic signs.

Physical Examination Findings
• May be clinically normal if intoxication observed. • Variable body temperature (hypothermic to febrile), vomiting, diarrhea, weakness. • Icterus—overt or progressive (48–96 hours post exposure). • Ascites—rare (grave sign). • HE or coma. • Hemorrhage; petechia; ecchymosis (if DIC present).

CAUSES
Any drug, toxin, or xenobiotic may cause hepatotoxicity, variable severity, any individual.

Common Drugs
• Acetaminophen. • Amiodarone. • Azathioprine. • Azole antifungals. • Beta-lactam antibiotics. • Cyclosporine. • Diazepam (cat, oral only). • Glipizide (cat). • Glucocorticoids (dog). • Glucosamine-based joint supplements (dog). • Griseofulvin (cat). • Imidocarb. • Lomustine (dog). • Methimazole (cat). • Mitotane (dog). • NSAIDs (dog). • Phenobarbital (dog). • Sulfonamide antibiotics (dog). • Tetracyclines. • Toceranib (cat). • Zonisamide (dog).

Common Environmental Toxins
• *Amanita* mushrooms (amanitin-containing mushrooms). • Aflatoxins/mycotoxins. • Blue-green algae (*Cyanobacteria*). • Chlorinated compounds. • Cycad (sago palm nuts). • Heavy metals (Pb, Zn, Mn, Ar, Fe, Cu). • Phenolic chemicals (especially cats). • Gossypol from cottonseed.

Endotoxins
• Enteric organisms—*Clostridium perfringens*; Gram-negative organisms. • Food poisoning—*Staphylococcus*; *Escherichia coli*; *Salmonella*.

Nutritional/Herbal
• *Atractylis gummifera*. • Black cohosh. • *Callilepis laureola*. • Chaparral. • Chinese herbal medicines (certain constituents, contents difficult to characterize). • Comfrey extracts (pyrrolizidine alkaloids). • Germander. • Greater celandine. • Green tea extract. • Kava kava (dogs). • Licorice. • Lipoic acid (cats). • Mistletoe. • Pennyroyal. • Senna. • Usnic acid. • Valerian. • Xylitol (sugar substitute; dogs).

RISK FACTORS
• Medications influencing hepatic metabolism. • Antecedent hepatic disease. • Nutritional and antioxidant status. • Hepatic copper accumulation. • Prior exposure to hepatotoxic compounds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Infectious disorders affecting liver/biliary tract—leptospirosis, cholangitis/cholecystitis, feline infectious peritonitis, toxoplasmosis, rickettsial diseases, histoplasmosis. • Acute necrotizing pancreatitis. • Traumatic or hypoxic liver injury. • Chronic hepatitis. • Hepatic neoplasia. • Diagnosis of hepatotoxicity requires integration of history, environment, food, medications, and temporal relationship(s).

CBC/BIOCHEMISTRY/URINALYSIS
• PCV and total solids—often normal or high in acute hepatotoxicosis (shock or dehydration). • Alanine aminotransferase (ALT)—reflects cellular membrane damage and leakage; may be 10- to 100-fold normal; prognosis not correlated with magnitude of increase. Increased ALT may precede increases in bilirubin and alkaline phosphatase (ALP). Some toxins suppress hepatic enzyme synthesis, impairing clinical recognition of hepatic injury (e.g., blue-green algae, aflatoxin). • ALP—usually continues to rise for days/weeks while ALT falls. • Aspartate aminotransferase (AST)—may reflect more severe injury (mitochondrial) than ALT; use creatine kinase to differentiate hepatic damage from myonecrosis. • Bilirubin, albumin, blood urea nitrogen, cholesterol, glucose—variable.

OTHER LABORATORY TESTS
• Coagulation profile—monitor for DIC. • Pre- and post-prandial total serum bile acids—assess hepatic function in nonicteric patients. • Low protein C activity—biomarker for blocked protein transcription in aflatoxicosis.

IMAGING
• Abdominal radiography—acute toxicity: normal to large liver; chronic injury: variable liver size. • Abdominal US—variable echogenicity, hepatic size, margins; assess for presence of ascites.

DIAGNOSTIC PROCEDURES
• Hepatic biopsy—seldom indicated in acute toxicity; helpful in chronic hepatic injury without obvious cause; laparoscopy yields better samples than needle biopsies. • Fine-needle aspiration—helpful if neoplasia or infectious agents visualized; no pathognomonic findings for toxicity.

PATHOLOGIC FINDINGS
Variable; depends on toxin, mechanism of cell injury, acinar zone of metabolism or product accumulation, vascular injury, and chronicity.

HEPATOTOXINS (CONTINUED)

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient—critical care setting.

NURSING CARE
• Decontamination—if intoxication observed and animal presented promptly, decontamination with emetics, adsorbents, and cathartics can be beneficial. • Prevention/correction of shock imperative. • Crystalloid therapy—maintain hepatic perfusion to improve oxygenation and toxin removal; administer maintenance requirements; avoid lactate-containing fluids in fulminant hepatic failure; provide adequate potassium supplementation and monitor, hypokalemia potentiates clinical signs of HE. • Colloid administration—plasma initially preferred for delivery of clotting and anticoagulant factors followed by cautious use of synthetic colloid, if oncotic pressure low. • Coagulopathy—vitamin K_1 (0.5–1.5 mg/kg SC/IM q12–24h); fresh whole blood or fresh frozen plasma as needed (*caution*: stored blood products may have high ammonia concentration, causing HE). • Nasal oxygen—if compromised peripheral perfusion (hypotension) or pulmonary edema; may improve oxygen delivery to hepatic tissue. • Monitor urine output—diuretics as appropriate (see Acute Kidney Injury). • Hypoglycemia—administer dextrose as needed.

ACTIVITY
Restricted

DIET
• Protein—normal, unless overt HE. • Nutritional support—if normal body condition score and acute disease, can wait up to 48h for patient to voluntarily ingest food; then consider nasoesophageal/esophageal tube feeding. Parenteral only if unable to feed enterally; can cause severe complications. • Energy—begin with ~20–30% resting energy requirement (RER), then gradually increase to full RER over 3–5 days.

CLIENT EDUCATION
• Potential for 3–10 days of ICU. • Many recover but postnecrotic cirrhosis, acquired shunting, and chronic hepatitis can develop later.

SURGICAL CONSIDERATIONS
Surgical/laparoscopic liver biopsies—generally not indicated.

MEDICATIONS

DRUG(S) OF CHOICE
• *Discontinue* offending drug, if present. • See Hepatic Failure, Acute. • Antioxidant therapy—*N*-acetylcysteine (140 mg/kg IV load, followed by 70 mg/kg IV q6–8h, give over 20 min); *S*-adenosylmethionine (20 mg/kg enteric-coated tablet PO q24h, on empty stomach). • Silybin—active component of silymarin/milk thistle extract (2–5 mg/kg q24h PO); may augment liver regeneration; antioxidant, hepatoprotective, antifibrotic effects. • Ursodeoxycholic acid—primarily for chronic hepatopathies (15 mg/kg/day PO with food). • B-complex vitamins—parenteral; cofactors for hepatic metabolism. • Antiemetics—if indicated. • Antacids—if portal hypertension/gastric ulceration suspected. • Antibiotics—ampicillin/metronidazole, if HE or bacterial translocation suspected. • Lactulose—orally (0.5 mL/kg q8h) or retention enema (diluted 1 : 2 following cleansing enema) if HE suspected.

CONTRAINDICATIONS
Avoid known hepatotoxic drugs.

PRECAUTIONS
Caution when catheterizing large vessels or diagnostic needle aspirates/biopsies if coagulopathic.

POSSIBLE INTERACTIONS
Avoid drugs that require or inhibit hepatic metabolism.

ALTERNATIVE DRUG(S)
Alternative antioxidants—vitamin E (d-α-tocopherol acetate 10 IU/kg q24h PO); vitamin C (ascorbic acid 500–1000 mg/dog q24h PO, 125 mg/cat q12h PO).

FOLLOW-UP

PATIENT MONITORING
• Prevent hypothermia. • Blood glucose, electrolytes, packed cell volume—frequently; fluctuations occur rapidly in critically ill patients. • CBC, serum biochemical analyses, coagulation tests—monitor q48h or as warranted.

PREVENTION/AVOIDANCE
Close scrutiny of environment and future medications.

POSSIBLE COMPLICATIONS
• DIC, hemorrhage. • HE. • Progressive hepatic failure. • Postnecrotic cirrhosis with acquired shunting/ascites.

EXPECTED COURSE AND PROGNOSIS
• 2–5 days to estimate prognosis. • Negative indicators—intractable emesis, hematemesis, intolerance to supportive treatments, oliguria, DIC, HE, decline of ALT with increasing bilirubin and/or decreasing serum albumin/cholesterol. • Positive indicator—ALT declining by 20–30% or more every 48–72 hours, with other evidence of improvement. • Postnecrotic cirrhosis—possible in 2–6 months.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Hepatitis. • Fibrosis. • HE. • Hepatic lipidosis (cats). • Icterus. • Ascites. • Hypoglycemia. • Sepsis.

AGE-RELATED FACTORS
• Young animals may have greater exposure risk for toxin ingestion; <16 weeks of age: immature hepatic metabolic and excretory pathways. • Older animals may have diseases requiring drug therapies, increasing their risk.

ZOONOTIC POTENTIAL
None

SEE ALSO
• Acetaminophen (APAP) Toxicosis.

HEPATOZOONOSIS

BASICS

OVERVIEW
- Disease caused by infection with the protozoan *Hepatozoon americanum* or *Hepatozoon canis*; here the focus is on systemic infection with *Hepatozoon americanum*—the primary cause of American canine hepatozoonosis.
- *Hepatozoon canis* is less prevalent in the United States than *Hepatozoon americanum*; it is also less virulent and infections are typically subclinical.
- Infection typically involves muscle and bone.
- Dogs—more common in the southern and southeastern United States.
- Cats—uncommon in the United States.

SIGNALMENT
- Dogs and rarely cats.
- No age, breed, or sex predilections.

SIGNS
- Lameness and stiff gait.
- Waxing and waning fever.
- Mucopurulent ocular discharge.
- Hyperesthesia.
- Weight loss and cachexia.
- Polyuria and polydipsia in some cases if glomerulonephritis is present.

CAUSES & RISK FACTORS
- *Amblyomma maculatum*—tick ingestion.
- Ingestion of infected paratenic hosts (predation or scavenging).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Neoplasia.
- Endocarditis.
- Immune-mediated polyarthritis or polymyositis.
- Chagas disease.
- Leishmaniasis.
- Meningitis/meningoencephalitis.
- Hypertrophic osteopathy.
- Ehrlichiosis.
- Discospondylitis.
- Hepatic failure.

CBC/BIOCHEMISTRY/URINALYSIS
- Neutrophilic leukocytosis, usually profound (20,000–200,000 white blood cells [WBC]/μL), sometimes with a left shift.
- Anemia—mild to moderate, usually nonregenerative.
- Usually have a normal platelet count unless there is a coinfection.
- High serum alkaline phosphatase (ALP) activity.
- Decreased serum urea nitrogen concentration.
- Despite severe myositis, creatinine kinase concentrations are often within reference range.
- Hyperglobulinemia.
- Hypoalbuminemia.

OTHER LABORATORY TESTS
Blood smear—in rare cases identify organisms in circulating neutrophils and monocytes.

IMAGING
Radiographs—pelvis, lumbar vertebrae, and long bones; periosteal proliferation.

DIAGNOSTIC PROCEDURES
- Muscle biopsy.
- PCR on blood or muscle.

PATHOLOGIC FINDINGS
- Cachexia.
- Muscle atrophy—"onion-skin" meronts and pyogranulomatous myositis.
- Enlarged liver and spleen—may contain meront stages on histopathology.
- Periosteal proliferation of bone.

TREATMENT
- Inpatient—for severe pain; provide symptomatic relief.
- Pain management—as for any musculoskeletal disease.
- General activity level and appetite—depend on pain level.
- Most dogs will require lifelong treatment to maintain clinical remission.

MEDICATIONS

DRUG(S) OF CHOICE
- Mostly palliative, as no treatments have been shown to clear infection.
- Combination therapy (TCP) initially:
  - Trimethoprim/sulfadiazine—15 mg/kg PO q12h for 14 days.
  - Clindamycin—10 mg/kg PO q8h for 14 days.
  - Pyrimethamine—0.25 mg/kg PO q24h for 14 days.
- Followed with long-term therapy—decoquinate 10–20 mg/kg PO q12h for up to 33 months (possibly indefinite).
- Ponazuril 10 mg/mg PO q12h for 28 days has shown promise as an alternative initial treatment; long-term therapy with decoquinate is still necessary.
- Glucocorticoids—may give temporary relief, but are not routinely recommended.
- Nonsteroidal anti-inflammatory drugs (NSAIDs) may provide analgesia.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
None

FOLLOW-UP

PATIENT MONITORING
- Difficult to monitor organisms in chronically infected dogs.
- Best to monitor for clinical improvement.

PREVENTION/AVOIDANCE
- Control ticks within the household or kennel.
- Avoid predation and scavenging.

POSSIBLE COMPLICATIONS
- Glucocorticoids—may exacerbate clinical disease.
- Radiographic changes may never occur.

EXPECTED COURSE AND PROGNOSIS
- Treatment typically results in improvement of clinical signs and quality of life, but does not cure the infection.
- Treatment is likely to be needed for the remainder of the patient's life.
- If clinical relapse occurs, repeat of both initial and long-term treatments is recommended.

MISCELLANEOUS

ZOONOTIC POTENTIAL
No reported risk to humans.

ABBREVIATIONS
- ALP = alkaline phosphatase.
- NSAID = nonsteroidal anti-inflammatory drug.
- TCP = trimethoprim-sulfa, clindamycin, pyrimethamine.
- WBC = white blood count.

Author Adam J. Birkenheuer
Consulting Editor Amie Koenig

HIATAL HERNIA

BASICS

OVERVIEW

• Herniation of abdominal contents (most commonly the stomach) cranial to the diaphragm into the thorax through the esophageal hiatus. Four types have been described:
  ◦ Type I (sliding; most common).
  ◦ Type II (paraesophageal).
  ◦ Type III (includes elements of both types I and II).
  ◦ Type IV (herniation of organs other than the stomach).
• May be congenital or acquired—acquired most commonly associated with upper respiratory disease (brachycephalic syndrome, laryngeal paralysis).

SIGNALMENT

• Dogs > cats.
• Congenital reported in English and French bulldogs, shar-peis and chow chows; acquired common in brachycephalic breeds.

SIGNS

• Most signs secondary to gastroesophageal reflux (GER) and esophagitis.
• Regurgitation.
• Dysphagia.
• Hypersalivation.
• Lip smacking.
• Inability to gain weight.
• Vomiting.
• Respiratory distress.
• Anorexia.
• Weight loss.

CAUSES & RISK FACTORS

Congenital. Acquired— traumatic event ± severe upper respiratory disease; brachycephalic airway syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of weight loss or regurgitation such as megaesophagus, esophagitis, vascular ring anomaly, etc.

CBC/BIOCHEMISTRY/URINALYSIS

No specific abnormalities. May find inflammatory leukogram secondary to associated pneumonia.

OTHER LABORATORY TESTS

N/A

IMAGING

Thoracic Radiography

Cranial displacement of stomach. Soft tissue mass in caudal thorax adjacent to diaphragm. Gas-filled viscera in thorax. Infrequently diagnosed on survey thoracic radiographs alone.

Positive Contrast Esophagram

Preferably performed using videofluoroscopy. Helps to confirm diagnosis and differentiate between types I and II hernias. Can also diagnose associated GER and esophageal dysmotility. False-negative studies common due to highly intermittent and dynamic nature of hiatal herniation.

DIAGNOSTIC PROCEDURES

Upper gastrointestinal endoscopy can occasionally document herniation. However, effects of herniation such as esophagitis or stricture may be detectable if herniation does not occur during study.

TREATMENT

Not all dogs that have radiographic evidence require treatment. Conservative therapy can be successful in controlling clinical signs in dogs with mild hiatal herniation.

Medical Management

• Can often be managed as outpatient unless animal has severe aspiration pneumonia.
• Reduce gastric acid secretion (proton pump inhibitors are superior to H2 receptor antagonists).
• Increase rate of gastric emptying and increase lower esophageal sphincter (LES) tone (prokinetic agents such as cisapride).
• Provide esophageal mucosal protection (sucralfate).
• Feed a low-fat diet in an elevated position.
• 30-day trial of medical management before surgery often recommended; not all patients require surgery.

Surgical Management

• Patients nonresponsive to medical therapy.
• Treat with antacids and prokinetics prior to surgery.
• Surgical procedures (used alone or in combination)—phrenoplasty; esophagopexy; left-sided gastropexy.

MEDICATIONS

DRUG(S) OF CHOICE

• H2 receptor antagonists—increase gastric pH and reduce esophagitis secondary to GER:
  ◦ Famotidine 0.5–1 mg/kg PO/IV q12h.
  ◦ Ranitidine 1–2 mg/kg PO/IV q8–12h.
• Proton pump inhibitors—more potent than H2 receptor antagonists:
  ◦ Omeprazole 0.7–1.5 mg/kg PO q12h.
  ◦ Pantoprazole 0.7–1.5 mg/kg IV q12h.
• Prokinetics—increase gastric emptying:
  ◦ Metoclopramide 0.2–0.5 mg/kg PO q6–8h or 1–2 mg/kg/24h IV as CRI.
  ◦ Cisapride 0.2–0.5 mg/kg PO q8–12h.

FOLLOW-UP

PATIENT MONITORING

• Long-term medical therapy may be indicated in both surgically and conservatively managed patients.
• Postoperative—monitor for dyspnea, worsening regurgitation (may require second surgery), abdominal distension that could result from overtightening of hiatus resulting in inability to eructate.

POSSIBLE COMPLICATIONS

Continuation of clinical signs, bloat episodes.

EXPECTED COURSE AND PROGNOSIS

• Overall prognosis is good.
• When medical management fails, surgical intervention leads to positive outcome in majority of cases.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Often found in dogs with brachycephalic airway syndrome or other upper airway obstructive diseases. Hypothesized that decreases in intrathoracic pressures generated may pull the stomach into the thorax through the hiatus. Gastroesophageal reflux can worsen clinical signs of upper respiratory disease due to irritation of upper respiratory area or associated bronchospasm of the lower airway.

ABBREVIATIONS

• GER = Gastroesophageal reflux.
• LES = Lower esophageal sphincter.

HIP DYSPLASIA

BASICS

DEFINITION
A developmental syndrome characterized in growing animals by excessive laxity of the coxofemoral joint that results in secondary osteoarthritis (OA) of the coxofemoral joints in the adult animal.

PATHOPHYSIOLOGY
- Developmental defect initiated by genetic predisposition to subluxation of immature hip joint.
- Poor congruence between femoral head and acetabulum; creates abnormal forces across joint; interferes with normal development (leading to irregularly shaped acetabula and femoral heads); overloads articular cartilage (causing microfractures and OA).

SYSTEMS AFFECTED
Musculoskeletal

GENETICS
- Complicated, polygenetic transmission. Genetic markers for diagnosis and prevention are under development but are not standardized or routinely used.
- Expression is determined by interaction of genetic and environmental factors, the latter including overall excess caloric consumption and excess calcium during growth.
- Heritability index—depends on breed, but generally estimated at 0.3.

INCIDENCE/PREVALENCE
- One of most common skeletal diseases encountered clinically in dogs.
- Actual incidence unknown; depends on breed.
- Incidence in cats significantly lower than dogs.

SIGNALMENT

Species
Dog, rarely cat.

Breed Predilections
- Large-breed dogs—Saint Bernard, German shepherd, Labrador retriever, golden retriever, Rottweiler.
- Smaller-breed dogs—may be affected; in fact, incidence of disease in pugs is highest of all breeds, approaching 70%; small-breed dogs less likely to exhibit clinical signs.
- Cats—more commonly affects purebred cats; reportedly affects ~18% of Maine coon cats.

Mean Age and Range
- Onset of clinical signs varies with severity of hip laxity in immature dog and with worsening secondary OA in mature dog.
- Clinical signs—may develop after 4 months of age in dogs with severe laxity; may also develop at any age after onset of secondary OA.
- Clinical signs are biphasic in dogs; young dogs often exhibit most severe clinical signs between 6 and 12 months of age; clinical signs often diminish in animals 12–18 months of age, worsening again in older dogs in 4–8-year age period.

Predominant Sex
- Dogs—none.
- Cats—more common in female cats.

SIGNS

General Comments
- Severity of signs depends on degree of joint laxity, degree of OA, and chronicity of disease.
- Early—related to joint laxity.
- Later—related to severity of OA.

Historical Findings
- Decreased activity.
- Difficulty or slow rising.
- Reluctance to run, jump, or climb stairs.
- Intermittent or persistent hind limb lameness—often worse after exercise.
- Pelvic limb lameness may be unilateral or bilateral.
- Bunny-hopping or swaying gait.
- Narrow stance in hind limbs.

Physical Examination Findings
- Pain on palpation or manipulation of hip joint(s); particularly extension.
- Increased joint laxity (positive Ortolani sign)—characteristic of early disease; may not be finding in chronic cases owing to periarticular fibrosis.
- Crepitus during hip motion.
- Decreased range of motion in hip joints.
- Atrophy of thigh muscles.

CAUSES
- Genetic predisposition for hip laxity.
- Rapid weight gain may be associated with onset of clinical signs due to increased demands on joint.
- Nutritional influences, particularly excess caloric intake in young dog and calcium >1.6% in diet on dry-matter basis, increase phenotypic expression, development of hip dysplasia (HD), and progression of disease.
- Decreased gluteal and caudal thigh muscle mass—increase expression and progression.

RISK FACTORS
- Overweight puppies fed in excess of caloric requirements for normal growth at risk for increased incidence of HD.
- Additional calcium supplementation in diet of young large-breed dogs contraindicated and may predispose to development of HD.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Cranial cruciate ligament rupture—up to ⅓ of dogs referred for treatment of HD actually suffer from concurrent cranial cruciate rupture; cranial cruciate ligament rupture must remain alternative diagnosis for lameness in large-breed dogs until definitively eliminated from consideration.
- Degenerative myelopathy.
- Lumbosacral instability.
- Unilateral or bilateral stifle disease.
- Panosteitis.
- Polyarthropathies.

IMAGING
- Ventrodorsal hip-extended radiographs—commonly used for diagnosis; may need sedation or general anesthesia for accurate positioning.
- Early radiographic signs—subluxation of hip joint with poor congruence between femoral head and acetabulum; initially normally shaped acetabulum and femoral head; with disease progression, shallow acetabulum and flattened femoral head.
- Radiographic evidence of OA—flattening of femoral head; shallow acetabulum; periarticular osteophyte production; thickening of femoral neck; sclerosis of subchondral bone; periarticular soft tissue fibrosis. Remodeling of femoral neck is uncommon in cats.
- Distraction radiographs—quantify joint laxity; may accentuate laxity for more accurate diagnosis. Distraction radiographic procedures such as PennHip® have been standardized and allow better prediction of dogs likely to develop secondary hip OA and better selection of dogs for breeding potential.
- Dorsal acetabular rim view radiographs—evaluate acetabular rim; assess dorsal coverage of femoral head. Clinical efficacy of such views in diagnosis and treatment of HD has not been definitively established.

DIAGNOSTIC PROCEDURES
- Commercial genetic markers are under development but not in widespread use at this time.
- Arthroscopy of hip joint has been described in diagnosis of HD, but does not add useful clinical information regarding treatment.

PATHOLOGIC FINDINGS
- Early—normal conformation of femoral head and acetabulum; may note joint laxity and excess synovial fluid.
- With progression—malformed acetabulum and femoral head; synovitis; articular cartilage degeneration. Formation of periarticular osteophytes leads to radiographic formation of "Morgan's line," linear formation of enthesiophytes at origin of joint capsule on femoral neck.
- Chronic—may note full-thickness cartilage erosion.

TREATMENT

APPROPRIATE HEALTH CARE
- May treat with conservative medical therapy or surgery.

HIP DYSPLASIA (CONTINUED)

• Depends on patient's size, age, and intended function; severity of joint laxity; degree of OA; clinician's preference; financial considerations of owner.

NURSING CARE

• Physical therapy (passive joint motion)—decreases joint stiffness; helps maintain muscle integrity.
• Swimming (hydrotherapy)—excellent nonconcussive form of physical therapy; encourages joint and muscle activity without exacerbating joint injury.

ACTIVITY

• As tolerated.
• Swimming—recommended to maintain joint mobility while minimizing weight-bearing activities.

DIET

• Weight control—important and first goal of therapy; decrease load applied to painful joint; minimize weight gain associated with reduced exercise.
• Supplementation with omega-3 fatty acids (in commercial diets or as food additive) beneficial to decrease pain and inflammation and improve function. While optimum dosage/feeding of omega-3 fatty acids yet to be determined, clinical efficacy of commercial diets containing 1.7–3.4% of omega-3 fatty acids and precursors has been established.

CLIENT EDUCATION

• Discuss heritability of the disease, recommend neutering of affected animals and elimination as breeding sources.
• Explain that medical therapy is palliative.
• Warn client that joint degeneration often progresses unless corrective osteotomy procedure is performed early in disease.
• Explain that surgical procedures can salvage joint function once severe joint degeneration occurs.

SURGICAL CONSIDERATIONS

Triple, Double, or 2.5 Pelvic Osteotomy

• Corrective procedure; designed to reestablish congruity between femoral head and acetabulum.
• Immature patient (6–10 months of age) without signs of OA.
• Rotate acetabulum—improve dorsal coverage of femoral head; correct forces acting on joint; minimizes progression of OA, but OA frequently progresses on radiographs even though progression not clinically apparent.
• Surgical procedure necessitates implantation of surgical implants, commonly bone plate and screws specially designed for procedure; large dogs may necessitate use of two bone plates; outcomes improved and complication rates decreased with use of locking implants.

Juvenile Pubic Symphysiodesis

• Pubic symphysis is fused at early age (8–16 weeks) using electrocautery.
• Requires extremely early diagnosis of condition, or use as preventative in nonbreeding animals to decrease need for more aggressive surgical procedure in dogs likely to develop secondary OA or more several clinical signs.
• Causes ventroversion of acetabulum during growth to better cover femoral head.
• Improves joint congruence and stability—similar effects to triple pelvic osteotomy without osteotomy and surgical implants.
• Minimal morbidity; easy to perform—must be performed very early (ideally 3–4 months of age) to achieve effect; minimal effect achieved if performed after 5 months of age.

Total Hip Replacement

• Indicated to salvage function in mature dogs with severe degenerative disease unresponsive to medical therapy.
• Multiple systems exist to replace both acetabular and femoral head surfaces and comprising both cemented and noncemented (ingrowth) implants; noncemented implants have best prognosis for long-term use and implant stability.
• Pain-free joint function—reported in >90% of cases.
• Unilateral joint replacement—provides acceptable function in ~80% of cases.
• Staged bilateral joint replacement now chosen by 50% of owners.
• Complications—luxation; femoral fracture, sciatic neuropraxia; infection; incidence of infection decreased with use of noncemented implant systems compared to cemented systems.

Excision Arthroplasty

• Removal of femoral head and neck to eliminate joint pain.
• Extremely important to achieve smooth osteotomy close to femoral shaft.
• Primarily a salvage procedure—for significant OA; when pain cannot be controlled medically; when total hip replacement is cost-prohibitive.
• Best results—small, light dogs (<20 kg); patients with good hip musculature.
• Can provide good results in larger dogs.
• Slightly abnormal gait often persists and consistently seen on objective gait analysis of patients, despite lack of lameness detection by owners or veterinarians on casual observation.
• Postoperative muscle atrophy—common, particularly in large dogs.

Denervation Procedure

• Surgical procedure described in anecdotal and research literature to reduce pain associated with HD.
• Does not improve joint conformation or OA.
• Little objective scientific evidence exists for this procedure's effectiveness despite numerous clinical reports.
• Recent blinded studies suggest the treatment does not improve the treated hip, but may slow development of further clinical signs.

MEDICATIONS

DRUG(S) OF CHOICE

• Analgesics and anti-inflammatory drugs—minimize joint pain (and thus stiffness and muscle atrophy caused by limited usage); decrease synovitis.
• Medical therapy—does not correct biomechanical abnormality; degenerative process likely to progress; often provides only temporary relief of signs.
• Agents—carprofen (2.2 mg/kg POq12h or 4.4 mg/kg PO q24h); etodolac (10–15 mg/kg PO q24h); deracoxib (3–4 mg/kg PO q12h for 1 week, then 2 mg/kg PO q12h); firocoxib (4 mg/kg PO q24h).
• Diet supplementation with omega-3 fatty acids (fish oils) decreases joint inflammation and provides pain relief; commercial diets containing 1.7–3.4% omega-3 fatty acids and precursors are most consistent and easiest method of administration.

CONTRAINDICATIONS

Avoid corticosteroids—potential side effects; articular cartilage damage associated with long-term use.

PRECAUTIONS

• Nonsteroidal anti-inflammatory drugs—gastrointestinal upset may preclude use in some patients.
• Carprofen—reported to cause acute hepatotoxicity in some dogs.

ALTERNATIVE DRUG(S)

• Polysulfated glycosaminoglycan injections, or oral glucosamine, and chondroitin sulfate—may have chondroprotective effect in OA, but recent evidence suggests are not or are only minimally efficacious.
• There are single reports of agents such as elk antler velvet suggesting their efficacy for OA, but no confirmation or widespread acceptance for efficacy.
• Prophylactic laser therapy, extracorporeal pulse therapy, and acupuncture have been suggested for treatment, but no documented evidence demonstrating efficacy of these modalities for OA despite numerous research studies.
• Stem cell therapy, primarily mesenchymal stromal cell extractions, have been investigated in research studies and individual clinical patients, but show no clinical benefit at present.

FOLLOW-UP

PATIENT MONITORING

• Clinical and radiographic monitoring—assess progression.
• Medical treatment—clinical deterioration suggests alternative dosage or medication or

surgical intervention; weight management is important continuing consideration in management of HD.
• Triple pelvic osteotomy—monitored radiographically; assess healing, implant stability, joint congruence, and progression of OA; over 50% of dogs may develop radiographic signs of OA after pelvic osteotomy, but clinical signs or their lack remain stable in spite of OA.
• Hip replacement—monitored radiographically on annual basis; assess implant stability.

PREVENTION/AVOIDANCE

• Best prevented by not breeding affected dogs.
• Pelvic radiographs—may help identify phenotypically abnormal dogs; may not identify all dogs carrying the disease.
• Do not repeat dam–sire breedings that result in affected offspring.
• Special diets designed for rapidly growing large-breed dogs—may decrease severity.

EXPECTED COURSE AND PROGNOSIS

Joint degeneration usually progresses—most patients lead normal lives with proper medical or surgical management.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Do not breed affected dogs; added weight owing to pregnancy may exacerbate clinical signs.

ABBREVIATIONS

• HD = hip dysplasia.
• OA = osteoarthritis.

HISTIOCYTIC DISEASES—DOGS AND CATS

BASICS

DEFINITION

Histiocytic diseases encompass a wide spectrum of heterogenous dendritic or macrophage-derived proliferative disorders. Most of these histiocytic diseases are of dendritic cell lineage and in dogs include cutaneous histiocytoma, Langerhans cell histiocytosis (LCH), reactive histiocytoses (cutaneous histiocytosis [CH] and systemic histiocytosis [SH]), and histiocytic sarcoma (HS) complex, with hemophagocytic HS representing the only macrophage-derived disease entity. In cats, histiocytic diseases are limited to feline progressive histiocytosis (FPH), HS, and feline pulmonary Langerhans cell histiocytosis (FPLCH). All of these disorders represent neoplastic processes, except for the canine reactive histiocytoses, which are inflammatory diseases associated with underlying immune dysregulation.

SIGNALMENT

Canine

Cutaneous Histiocytoma
- Most common in young dogs; 50% of affected patients <2–3 years of age.
- Occurs in all breeds; predisposition in purebred dogs, particularly boxers and dachshunds, cocker spaniels, Great Danes, and bobtails.

Cutaneous LCH
- Rare entity in dogs, with similar signalment as for cutaneous histiocytoma.
- Occurs in many breeds.

CH
- Only described in the dog; age range: 2–13 years.
- Most common in collies, border collies, Shetland sheepdogs, briards, Bernese mountain dogs (BMDs), and golden retrievers, with no clear age or sex predilection.

SH
- Disease predominantly affecting young to middle-aged dogs (2–8 years).
- Familial association in BMDs (male predilection), but other large-breed dogs are affected (e.g., Rottweiler, Labrador retriever, basset hound, Irish wolfhound).

HS
- Middle-aged or older dogs, uncommon in cats.
- Strong breed predilections in BMD and flat-coated retrievers (FCRs), with other predisposed breeds including Rottweiler, golden retriever, Labrador retriever, and miniature schnauzer.

Hemophagocytic Histiocytic Sarcoma (HHS)
- Dogs, very rarely cats.
- Similar signalment to HS.

Feline

FPH
- Most common histiocytic disease in middle-aged to older cats (7–17 years).
- No sex or breed predilection.

FPLCH
Aged cats (10–15 years).

SIGNS

Canine

Cutaneous Histiocytoma
- Benign, solitary "button-like," raised, well-circumscribed, hairless dermal neoplasm that typically spontaneously regresses within 2–3 months.
- Common sites—head and limbs.
- Extremely low recurrence rates; de novo development or local metastasis rare.

Cutaneous LCH
- Multiple cutaneous histiocytomas with possible metastasis to lymph nodes and internal organs is a distinguishing feature from cutaneous histiocytoma.
- Delayed lesion regression common.

CH
- Multiple cutaneous/subcutaneous nodules that may wax and wane and spontaneously disappear, with new lesions appearing at different sites.
- Limited to the skin, subcutis, and local draining lymph node(s); lack of systemic extension beyond peripheral lymph nodes is a distinguishing factor from SH.

SH
- Cutaneous/subcutaneous lesions are similar to CH, with spontaneous remissions and relapses.
- Involvement of lymph nodes, bone marrow, spleen, liver, lung, kidneys, testes, and mucous membranes.
- Clinical signs include depression, anorexia, weight loss, conjunctivitis and respiratory difficulty.

HS
- Primary tumor sites include skin and subcutis, lung, lymph node, liver, spleen, and other sites; secondary sites of involvement commonly include liver, lung, and lymph node.
- Periarticular mass with synovial tissue involvement also reported.
- Clinical signs vary depending on organ involvement.

HHS
- Similar but more severe clinical signs to HS (e.g., marked anemia and thrombocytopenia).
- Subtype tends to present in a more infiltrative manner, causing hepatosplenomegaly and myelophthisis.

Feline

FPH
- Begins as nonpainful, nonpruritic, low-grade HS with indolent behavior initially.
- Some cats develop invasive masses in lymph nodes and internal organs in the terminal stage.

FPLCH
Acute or chronic presentation of respiratory failure due to extensive obliteration of all lung lobes by ill-defined coalescing nodular masses extending from peribronchiolar locations with enlargement of tracheobronchial lymph nodes and other draining lymph nodes.

CAUSES & RISK FACTORS

- Cutaneous histiocytoma is believed to represent a benign neoplasm with unique biologic behavior.
- SH/CH are believed to have an element of immune dysregulation.
- SH has probable familial causation in BMD.
- HS and HHS likely have a genetic origin due to breed predilections (specifically in BMD); abnormalities in tumor suppressor gene loci are potentially correlated to the development of HS in BMD and FCR.
- FPH—chronic antigenic stimulation is a possible triggering factor.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differentiate from focal granulomatous diseases, other sarcomas, other round cell tumors, and each distinctive subtype of the histiocytic disease.
- Differentiate HHS from immune-mediated anemia/thrombocytopenia, myelodysplastic syndromes, leukemias, and tick-borne diseases.

CBC/BIOCHEMISTRY/URINALYSIS

HHS—moderate to severe anemia (often regenerative), thrombocytopenia, neutrophilic/monocytic leukocytosis, increased liver enzymes, hypoalbuminemia, hypocholesterolemia.

OTHER LABORATORY TESTS

- Immunohistochemistry—used to differentiate cutaneous reactive histiocytosis from inflamed nonepitheliotropic T-cell lymphoma and HS from other sarcomas and round cell tumors.
- Serum ferritin—hyperferritinemia has been documented in dogs with HS and has potential as a biomarker for early screening.

IMAGING

- Thoracic radiography—pulmonary parenchymal involvement commonly observed:
  - LCH—peribronchial.
  - SH—perihilar/sternal lymphadenopathy, pulmonary infiltrates.
  - HS/HHS—diffuse interstitial infiltrate, patchy consolidated areas, focal or multifocal nodules or mass lesions.
  - Feline LCH—diffuse bronchointerstitial pattern of miliary to nodular opacities throughout all lung lobes.

• Extremity radiography—soft tissue mass ± lytic lesions may be noted for periarticular HS.
• Abdominal ultrasonography—hepatosplenic masses and lymphadenopathy characteristic of HS; diffuse hepatosplenomegaly with mottling and mild lymphadenopathy more common with HHS.

DIAGNOSTIC PROCEDURES
Cytology and histopathology of lesions—provides definitive diagnosis based upon specific cellular morphologic criteria.

TREATMENT

Canine

Cutaneous Histiocytoma
• Surgical excision or cryosurgery is generally curative.
• Cutaneous histiocytomas usually spontaneously regress within 2–3 months.

Cutaneous LCH
• If localized, surgical removal may be curative.
• If multifocal or lymph node involvement, consider treatment with immunosuppressive drugs.

CH/SH
Cutaneous lesions may wax and wane or spontaneously regress, but both diseases are usually progressive and require treatment with immunosuppressive drugs.

HS/HHS
• Localized HS can be treated with wide-margin surgical excision or palliative radiation therapy.
• Due to high metastatic risk, adjuvant chemotherapy (CCNU) is indicated following surgery or radiation for localized HS.
• Disseminated HS and HHS treated with chemotherapy (CCNU), corticosteroids, and other immunosuppressive drugs.

FPH/Feline HS
• If localized, surgical removal or radiation therapy can provide long-term control.
• Due to high metastatic risk, adjuvant chemotherapy is indicated following surgery or radiation for localized feline HS.
• Disseminated FPH/HS typically treated with chemotherapy and corticosteroids.

FPLCH
Treated with corticosteroids and other immunosuppressive drugs.

MEDICATIONS

DRUG(S) OF CHOICE

HS/HHS
Lomustine (CCNU)—dogs: 60–90 mg/m^2 q3 weeks; cats: 40–60 mg/ m^2 q3–4 weeks.

CH/SH
• Prednisone/prednisolone—1–2 mg/kg/day continuously.
• Leflunomide—dogs: 3–4 mg/kg/day.
• Cyclosporine—dogs: 5 mg/kg q12–24h.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Lomustine can lead to severe myelosuppression and hepatotoxicity.

ALTERNATIVE DRUG(S)
Doxorubicin, vincristine, Doxil®, paclitaxel, cyclophosphamide, mitoxantrone, dacarbazine, epirubicin, vinorelbine, and vinblastine have all been used for HS/HHS with marginal success.

FOLLOW-UP

POSSIBLE COMPLICATIONS
Bleeding due to thrombocytopenia.

EXPECTED COURSE AND PROGNOSIS

Canine Cutaneous Histiocytoma
• Spontaneous regression is likely within 2–3 months.
• If required, surgical removal is typically curative.

LCH/CH/SH
• Rarely imminently fatal.
• Cutaneous lesions may wax and wane or spontaneously regress, but are usually progressive and require treatment with immunomodulatory drugs or surgical excision (if localized).
• SH is associated with a poorer prognosis; dogs are often ill from the disease and relapses are common.

HS/HHS
• Localized HS—long-term (>12 months) survival has been documented for dogs that undergo surgery/radiation therapy and chemotherapy.
• Disseminated HS—reported response rates to CCNU are 40–50% for median remission duration of 3–6 months.
• HHS is associated with rapid progression and a grave prognosis (median 7 weeks) even with treatment.

FPH
An indolent cutaneous disease initially, but may spread internally and become life-threatening.

FPLCH
Aggressive disease course; most cats succumb to respiratory failure and illness due to other organ involvement.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING
Chemotherapy drugs may be carcinogenic and mutagenic.

SYNONYMS
N/A

ABBREVIATIONS
• BMD = Bernese mountain dog.
• CH = cutaneous histiocytosis.
• FCR = flat-coated retriever.
• FPH = feline progressive histiocytosis.
• FPLCH = feline pulmonary Langerhans cell histiocytosis.
• HHS = hemophagocytic histiocytic sarcoma.
• HS = histiocytic sarcoma.
• LCH= Langerhans cell histiocytosis.
• SH = systemic histiocytosis.

HISTIOCYTOSIS, CUTANEOUS

BASICS

OVERVIEW
Skin diseases characterized by infiltration of histiocytic cells.

SIGNALMENT

Histiocytoma
• Most common in dogs <3 years of age. • Boxers, dachshunds, cocker spaniels, Great Danes, Shetland sheepdogs, bull terriers. • Shar peis—Langerhans cell histiocytosis (LCH): multiple cutaneous histiocytoma syndrome.

Reactive Histiocytosis (RH)
• Cutaneous (cRH)—middle-aged to older dogs. • Systemic (sRH)—middle-aged dogs; male Bernese mountain dogs, Rottweilers, golden retrievers, Labrador retrievers.

Histiocytic Sarcoma (HS)
Middle-aged to older dogs—Bernese mountain dogs, flat-coated retrievers, Rottweilers, golden retrievers.

Feline Progressive Histiocytosis (fPH)
Middle-aged to older cats; female predisposition.

SIGNS

Histiocytoma
Solitary erythematous and/or ulcerated cutaneous nodule usually on head, extremities, and ears.

Cutaneous LCH
• Multiple histiocytomas; may persist for prolonged period or may never regress. • Lymphadenopathy with metastasis—affects lungs and other organs.

cRH
• Erythematous or ulcerated nodules or plaques affecting the face, nose, neck, trunk, extremities, footpads, perineum; no systemic involvement. • Depigmentation of mucous membranes and nasal planum (with ulceration).

sRH
• Similar to cRH but with systemic organ involvement. • Peripheral lymphadenopathy. • Stertor due to nasal mucosal infiltration. • Ocular manifestations.

HS
• Cutaneous lesions uncommon; subcutaneous nodules develop. • Systemic signs depend on organ system involved.

fPH
• Initial solitary skin nodule with slow progression to multifocal alopecic or ulcerated nodules and plaques; nonpruritic and nonpainful. • Lesions wax and wane, do not regress on their own.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Histiocytoma and RH—other causes of nodular lesions; solitary round cell tumors: plasmacytoma, mast cell tumor, epitheliotropic cutaneous T-cell lymphoma (CTCL) • With depigmentation or ulceration—immune-mediated or neoplastic diseases.

CBC/BIOCHEMISTRY/URINALYSIS
Normal with cutaneous histiocytic diseases.

IMAGING
Chest radiographs/abdominal ultrasound—differentiate cRH from sRH; may provide evidence of metastasis: HS, disseminated HS, or fPH.

DIAGNOSTIC PROCEDURES
• Histopathology required for diagnosis of LCH, RH, HS, fPH, and nonregressing histiocytoma. • Fine-needle aspirates may be diagnostic for histiocytoma—cytology from lymph nodes or internal organs may provide evidence of sRH or HS.

PATHOLOGIC FINDINGS

Histiocytoma
• Top-heavy appearance; histiocytic cells invade dermis with occasional nests of cells in epidermis. • Cellular atypia uncommon; mitotic index often high. • Lymphocytic infiltrate associated with tumor regression. • Immunophenotype—CD1a, CD11c/CD18, E-cadherin positive.

Cutaneous LCH
• Similar to histiocytomas, with more anisokaryosis and multinucleated giant cells. • Immunophenotype same as histiocytoma.

RH
• Bottom-heavy appearance; cells invade mid to deep dermis, or extend into subcutis; composed primarily of lymphocytes and histiocytes; frequent vessel wall invasion. • Similar to inflamed nonepitheliotropic CTCL; definitive diagnosis requires T-cell receptor γ gene rearrangement analysis to detect clonal T-cell population. • Immunophenotype—CD1a, CD4, CD11c/CD18, CD90 positive. • Histopathology identical for cRH and sRH.

HS
• Sheets of large, pleomorphic, mononuclear cells; cellular and nuclear atypia with mitotic figures and giant cells. • Immunophenotype—CD1a, CD11c/CD18 positive.

fPH
• Infiltration of dermis with well-differentiated histiocytic cells; occasionally extends to subcutis. • Epitheliotropism common; single cells or aggregates of histiocytic cells within epidermis. • Cellular and nuclear atypia increase with progression. • Immunophenotype—CD1a, CD11b/CD18 positive, CD5 positive in 50% of cases.

TREATMENT

Histiocytoma
• No treatment necessary; lesions usually regress within 3 months. • Surgical excision curative for persistent lesions.

HS
• Surgical excision of localized lesions recommended. • Variable response to medical therapy. • Poor prognosis—majority of patients survive a few months after diagnosis.

fPH
• Poor response to medical therapy. • Guarded prognosis—cats usually succumb to metastasis beyond the skin.

Cutaneous LCH
• Poor response to medical therapy; short-term improvement reported with lomustine. • Guarded prognosis—cutaneous lesions as well as metastatic lesions progress, with 50% of patients euthanized.

RH
• Clinical signs wax and wane and may not necessitate therapy. • cRH or sRH—variable prognosis: some dogs respond to long-term therapy. • 50–100% response rate to steroids. • Other drugs—azathioprine, modified cyclosporine, mycophenolate, leflunomide, and doxycycline/niacinamide. • Localized cutaneous lesions—topical tacrolimus or steroids.

MEDICATIONS
See Treatment.

FOLLOW-UP
Depends on disease.

MISCELLANEOUS

ABBREVIATIONS
• cRH = cutaneous RH. • CTCL = cutaneous T-cell lymphoma. • fPH = feline progressive histiocytosis. • HS = histiocytic sarcoma. • LCH = Langerhans cell histiocytosis. • RH = reactive histiocytosis. • sRH = systemic RH.

Moore PF. A review of histiocytic diseases of dogs and cats. Vet Pathol 2014, 51:167–184.

Author Kathryn A. Rook
Contributing Editor Alexander H. Werner Resnick

HISTOPLASMOSIS

BASICS

DEFINITION
Systemic fungal infection caused by *Histoplasma capsulatum*.

PATHOPHYSIOLOGY
• Soil-borne dimorphic fungus; mycelial form grows best in bird manure or organically enriched soil. • Mycelium in the soil—produces infectious spores (microconidia); inhaled into terminal airways. • Spores—germinate in the lungs, develop into yeast form at mammalian body temperature, reproduce by budding. • Yeast are phagocytized by mononuclear phagocytes that distribute the organisms throughout the body. • Ingested organisms may directly infect intestinal tract. • Immune response—determines whether disease develops; affected animals often develop transient, asymptomatic infection.

SYSTEMS AFFECTED
• Cats—respiratory tract, musculoskeletal, hepatobiliary, spleen, skin, and lymphatics; gastrointestinal, ophthalmic, renal, and nervous systems less frequent. • Dogs—gastrointestinal system, hepatobiliary, respiratory, spleen, and lymphatics; musculoskeletal, renal, ophthalmic, and reproductive systems less frequent.

GENETICS
N/A

INCIDENCE/PREVALENCE
Prevalence of clinically relevant histoplasmosis low in cats and dogs.

GEOGRAPHIC DISTRIBUTION
• Endemic areas—Ohio, Missouri, Mississippi, Tennessee, and St. Lawrence river basins. • Also Texas, southeastern United States, Great Lakes region, and California. • Has been isolated from the soil of 31 US states.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
N/A

Mean Age and Range
• Cats—young (many <1 year of age); all ages can be infected. • Dogs—young to middle-aged; all ages can be infected.

Predominant Sex
• Cats—females may be overrepresented.
• Dogs—N/A.

SIGNS

Historical Findings
Cat
• Insidious onset (days–weeks). • Anorexia, weight loss, and dyspnea. • Occasional cough. • Lameness. • Ocular discharge. • Diarrhea.

Dogs
• Weight loss, depression, diarrhea with straining. • Coughing. • Dyspnea. • Exercise intolerance. • Lymphadenopathy. • Lameness and eye and skin changes less common.

Physical Examination Findings
Cats
• Fever to 104 °F (40 °C). • Increased respiratory effort, harsh lung sounds. • Mucous membranes pale. • Enlarged lymph nodes. • Lameness, ocular changes, and skin lesions possible.

Dogs
• Thin to emaciated. • Fever to 104 °F (40 °C). • Hepatosplenomegaly. • Mucous membranes pale. • Icterus and ascites possible. • Coughing and dyspnea, harsh lung sounds. • Ocular and skin lesions less common.

CAUSES
Histoplasma capsulatum.

RISK FACTORS
• Bird roosts where the soil is enriched with bird or bat droppings are high-risk environments; old chicken coops and caves have been implicated. • Exposure to airborne dust contaminated with fungal spores (especially indoor cats). • Tissue samples from nearly half of stray dogs and cats from an endemic area were positive for *Histoplasma*; many animals are infected but few develop clinical disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Cats
• Dyspnea—differentiate from heart failure, feline asthma, lymphoma, other infectious pneumonia, pleural effusion. • Lameness—trauma, neoplasia. • Ocular changes—differentiate from lymphoma, toxoplasmosis, and feline infectious peritonitis.

Dogs
• Severe chronic diarrhea, weight loss, and anemia—consider lymphocytic plasmacytic or eosinophilic enteritis, protein intolerance, lymphoma or other intestinal neoplasia, chronic parasitism, and hypoadrenocorticism. • Hepatosplenomegaly and peripheral lymphadenopathy—consider lymphoma or other neoplasia. • Respiratory signs—differentiate from infectious causes (distemper, bacterial, or other fungal pneumonia), chronic bronchitis, pleural effusion, heart failure, and pulmonary hypertension.

CBC/BIOCHEMISTRY/URINALYSIS
• Moderate to severe nonregenerative anemia. • Leukogram—usually normal; some have leukocytosis; leukopenia with bone marrow involvement. • *Histoplasma* organisms—may be found in circulating neutrophils and monocytes; 2–4 µm round body with basophilic center and lighter halo. • Liver involvement—may see hyperbilirubinemia and high alanine aminotransferase (ALT) enzyme activity. • Panhypoproteinemia in dogs with severe intestinal histoplasmosis.

OTHER LABORATORY TESTS
• Agar gel immunodiffusion (AGID) test—for antibodies; supports diagnosis; positive results indicate active disease; previous infections may produce false-positive results; many animals with active disease are negative on serology. • Urine antigen test—highly sensitive and specific test for diagnosis in dogs and cats. • Coombs' test—may be positive because antibodies to *Histoplasma* can cross-react with red blood cells; caution before diagnosing immune-mediated disease.

IMAGING

Thoracic Radiography
• Dogs—diffuse interstitial to nodular pneumonia, enlarged tracheobronchial lymph nodes; chronic lesions may be calcified, coin-like opacities that appear like metastatic tumors. • Cats—diffuse interstitial pulmonary pattern; calcification and tracheobronchial lymphadenopathy uncommon.

Abdominal Radiography and Ultrasonography
Dogs—hepatosplenomegaly, mesenteric lymphadenopathy, potentially ascites.

Bone Radiography
Cats and less often dogs—bone lesions predominantly osteolytic and usually distal to elbows and stifles.

DIAGNOSTIC PROCEDURES
• Identification of organisms on cytology, histopathology, or culture—definitive. • Tissue samples: ○ Needle aspiration of enlarged lymph nodes, liver, and spleen. ○ Rectal scrapings may be rich in organisms (yeast form packed in macrophages). ○ Bone marrow or lung aspirates (when less invasive procedures are not diagnostic); tracheal washes inconsistent.

PATHOLOGIC FINDINGS
• Multifocal, granulomatous lesions in reticuloendothelial organs (e.g., spleen, liver, lymph nodes, lungs, and bone marrow).
• Dogs—gastrointestinal tract is primary site; enlarged tracheobronchial lymph nodes.
• Cats—predominantly respiratory lesions.

TREATMENT

APPROPRIATE HEALTH CARE
• Usually outpatient with oral itraconazole.
• Inpatient with IV amphotericin B—dogs with severe intestinal disease and

HISTOPLASMOSIS (CONTINUED)

malabsorption, dogs or cats with severe respiratory disease.

NURSING CARE

• Amphotericin B therapy—keep well hydrated to decrease potential for nephrotoxicity. • Emaciated animals with malabsorption—consider parenteral nutrition until intestinal disease sufficiently resolves. • Animals with severe dyspnea—oxygen supplementation.

ACTIVITY

Animals with dyspnea—reduce.

DIET

N/A

CLIENT EDUCATION

• Discuss possible areas of exposure in the home environment.
• Both pets and family members may have been exposed to the same source, but pet is not a hazard to the family.

MEDICATIONS

DRUG(S) OF CHOICE

Azole Antifungal Drugs

• No differences reported between itraconazole and fluconazole in survival, clinical remission, or disease relapse rates. • Duration of therapy depends on clinical response; minimum treatment 90 days.

Itraconazole

• Dogs and cats—5 mg/kg PO q12h; with high-fat meal. • Absorption of compounded itraconazole is inconsistent and these formulations are not recommended.

Fluconazole

• May be preferred for animals with eye or nervous system involvement (penetrates the blood–brain barrier). • Injectable (5 mg/kg IV q12h) for animals unable to take oral form and high risk for amphotericin B.

Intravenous Amphotericin B

Dogs

• With severe intestinal disease and malabsorption—use until intestinal absorption improves, then start on itraconazole. • Patient must be well hydrated before starting treatment. • Usual dose—0.5–1.0 mg/kg IV q48h. ○ Reconstitute in 5% dextrose and dilute for administration. ○ Dilution in electrolyte solution may precipitate drug. ○ Patients with normal renal function—dilute in 60–120 mL 5% dextrose and give over 2 hours. ○ Patients with renal compromise—dilute in 0.5–1 L 5% dextrose and give over 3–4 hours. • Liposomal amphotericin (Abelcet®) can reduce risk of renal toxicity.

Cats

• Use cautiously. • Usual dose—0.25 mg/kg IV in 5% dextrose over 3–4 hours q48h. • More sensitive to drug than dogs.

CONTRAINDICATIONS

Amphotericin B—caution with azotemic patients (in life-threatening situation, may still consider); monitor creatinine: elevation above normal or 20% greater than baseline considered significant.

PRECAUTIONS

• Corticosteroids—use with caution; may be useful in patients with severe pulmonary disease; dexamethasone 0.1 mg/kg IV q24h for 2–3 days. • Itraconazole and fluconazole—hepatic toxicity; temporarily discontinue if patient becomes anorexic or if serum ALT activity >300 U/L; restart at half dose after appetite improves.

POSSIBLE INTERACTIONS

Itraconazole—can increase concentrations of cyclosporine, digoxin, and midazolam (P450 inhibition).

ALTERNATIVE DRUG(S)

N/A

FOLLOW-UP

PATIENT MONITORING

• Serum ALT—with itraconazole treatment; check monthly or as needed. • Thoracic radiographs—with pulmonary involvement; check after 60 days of treatment and repeat monthly until infiltrates are clear or remaining lesions are static (likely scarring); continue treatment for 1 month after all signs of active disease resolved. • Urinary antigen levels sensitive for monitoring remission in cats.

PREVENTION/AVOIDANCE

• Avoid suspected areas of exposure (e.g., bird roosts). • Recovered dogs may be immune.

POSSIBLE COMPLICATIONS

Recurrence possible.

EXPECTED COURSE AND PROGNOSIS

• Treatment—duration usually 4–6 months; drugs are expensive; some dogs require longer therapy. • Prognosis—good for stable patients without severe dyspnea; influenced by severity of lung involvement and debility of patient.

• Negative prognostic factors include Great Pyrenees breed, dyspnea, oxygen dependency, icterus/hyperbilirubinemia, palpable abdominal organomegaly, anemia, thrombocytopenia, hypercalcemia, high serum alkaline phosphatase activity.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

• Yeast form is not spread from animals to humans. • Avoid needlestick injury when collecting aspirates. • Infection can occur from cuts during necropsies on infected animals.

PREGNANCY/FERTILITY/BREEDING

Azole drugs can be teratogenic, use with caution in pregnant animals.

ABBREVIATIONS

• AGID = agar gel immunodiffusion.
• ALT = alanine aminotransferase.

HOOKWORMS (ANCYLOSTOMIASIS)

BASICS

OVERVIEW

• Nematode parasites of small intestine—dogs: *Ancylostoma caninum*, *A. braziliense*, *Uncinaria stenocephala*; cats: *A. tubaeforme*, *A. braziliense*, *U. stenocephala*. • Eggs larvate, hatch, develop into third-stage larvae (L3) in environment; transmitted by ingestion of infective larvae in food, water, or transport hosts and by larval skin penetration; *A. caninum* is transmitted via colostrum/milk to pups. • Some L3 migrate through lungs, enter somatic tissue, and become dormant; pregnancy and removal of adults from intestine can reactivate these larvae; many ingested larvae remain in gastrointestinal (GI) tract and mature. • Blood-sucking adults and fourth-stage larvae of *A. caninum* and *A. tubaeforme* cause blood-loss anemia and enteritis; leave bite sites with ongoing hemorrhage.
• Disease severity: ○ Peracute—neonates; results from transmammary infection. ○ Acute disease—older pups. ○ Acute, chronic compensatory—adults. ○ Chronic noncompensatory—immunosuppressed or debilitated dog. • *Uncinaria*—of little clinical concern.
• *A. braziliense*—major cause of cutaneous larval migrans (CLM) in humans.
• Respiratory disease may result from larval migration in lungs.

SIGNALMENT

• Peracute to acute disease (young animals); asymptomatic or chronic (mature animals). • More severe clinical disease in dogs than cats.

SIGNS

Historical Findings

• Pallor, melena, diarrhea, constipation, loss of condition, poor appetite, and/or dry cough. • Sudden death.

Physical Examination Findings

• Poor body condition, ill-thrift, poor hair coat. • Pallor. • Erythematous, pruritic lesions, papules on feet (especially between toes). • Shock—tachycardia, weak pulse, prolonged/absent capillary refill time.

CAUSES & RISK FACTORS

• Neonatal animals at highest risk. • Infected bitch or queen. • Environmental contamination.
• Concurrent enteric infections.
• Immunocompromise.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Causes of anemia and hypovolemic/hemorrhagic shock; trichuriasis. • Ascariasis, coccidiosis, strongyloidosis—similar signs *without* significant anemia. • Physalopterosis—melena, mild anemia.

CBC/BIOCHEMISTRY/URINALYSIS

• Eosinophilia. • Anemia—normochromic, normocytic, regenerative; chronically microcytic, hypochromic (iron deficiency).

DIAGNOSTIC PROCEDURES

• Disease/death may occur prior to egg shedding. • Fecal flotation with centrifugation—morulated strongylid eggs; minor size differences among species. • Fecal ELISA—detects antigen from adult and immature worms, can detect prepatent infection. • Necropsy of littermates with similar clinical signs.

PATHOLOGIC FINDINGS

• Gross—hookworms attached to small intestinal mucosa, multifocal hemorrhagic ulcerations (bite sites) on mucosa, blood in intestinal lumen. • Microscopic—eosinophilic enteritis.

TREATMENT

• Peracute and severe acute cases treated as inpatients—anthelmintic, fluid therapy, blood transfusion, supplemental oxygen, symptomatic/supportive care as indicated.
• Chronic compensatory cases—anthelmintic, iron supplement.

MEDICATIONS

DRUG(S) OF CHOICE

Adulticide/Larvicide Anthelmintics

• Fenbendazole 50 mg/kg PO q24h for 3 consecutive days (dogs). • Milbemycin oxime 0.5 mg/kg (dogs) or 2 mg/kg (cats) PO q30 days. • Emodepside 3 mg/kg/praziquantel 12 mg/kg topically once (cats). • Moxidectin 0.17 mg/kg SC q6 months (dogs). • Moxidectin 2.5 mg/kg (dogs) or 1.0 mg/kg (cats)/imidoclopramide 10 mg/kg, topically q30 days. • Ivermectin 24 µg/kg PO q30 days (cats).

Adulticide Activity (Label Dose unless Stated)

• Pyrantel pamoate (dogs) 10–20 mg/kg PO (cats: extra-label). • Praziquantel/pyrantel pamoate/febantel (dogs).
• Praziquantel/pyrantel pamoate (cats).
• Ivermectin/pyrantel pamoate or ivermectin/pyrantel pamoate/praziquantel (dogs). • Selamectin 6 mg/kg topically q30 days (cats).

FOLLOW-UP

Monitor fecal egg counts and hematocrit after treatment.

PREVENTION/AVOIDANCE

• Routine deworming does not eliminate dormant L3; eliminate intestinal stages and reactivated larvae in breeding bitch using fenbendazole (50 mg/kg/day PO from day 40 of gestation to day 14 of lactation) or ivermectin (0.5 mg/kg PO 4–9 days prior to whelping, again 10 days later). • Begin biweekly anthelmintic treatment of pups at 2 weeks; continue until weaned, especially high-risk pups; treat monthly after weaning. • Treat queen with adulticide/larvicide anthelmintic prior to breeding, after queening. • Begin anthelmintic treatment of kittens at 3–4 weeks of age; treat monthly thereafter. • Promptly remove, dispose of feces to prevent environmental contamination. • Prevent hunting and ingestion of potential transport hosts.

EXPECTED COURSE AND PROGNOSIS

• Puppies (and rarely adults) with peracute/acute *A. caninum* infection may die despite treatment.
• Early recognition, anthelmintic treatment, prompt treatment of anemia, nutritional support necessary for successful outcome. • Anthelmintic treatment of adults can result in larval reactivation, repopulation of small intestine.

MISCELLANEOUS

AGE-RELATED FACTORS

• Disease more acute in young, usually chronic in adults. • Transmission of *A. caninum* from bitch to offspring results in high rate of infection in pups.

ZOONOTIC POTENTIAL

• All hookworms, especially *A. braziliense*, cause human CLM. • *A. caninum* larvae can cause visceral larva migrans or migrate to GI tract, causing abdominal pain and eosinophilia without becoming patent.

ABBREVIATIONS

• CLM = cutaneous larva migrans.
• GI = gastrointestinal.
• L3 = third-stage larvae.

Author Matt Brewer and Katy A. Martin
Consulting Editor Amie Koenig

HORNER'S SYNDROME

BASICS

OVERVIEW
- Sympathetic denervation to the eye.
- Anatomic pathway very important.
- Affects the ophthalmic and nervous systems (see Figure 1).

SIGNALMENT
- Idiopathic—one study suggests male golden retrievers 4–13 years of age at increased risk. Most of these localize to a postganglionic lesion. • Idiopathic—50–93% of Horner's syndrome in dogs; 45% in cats.

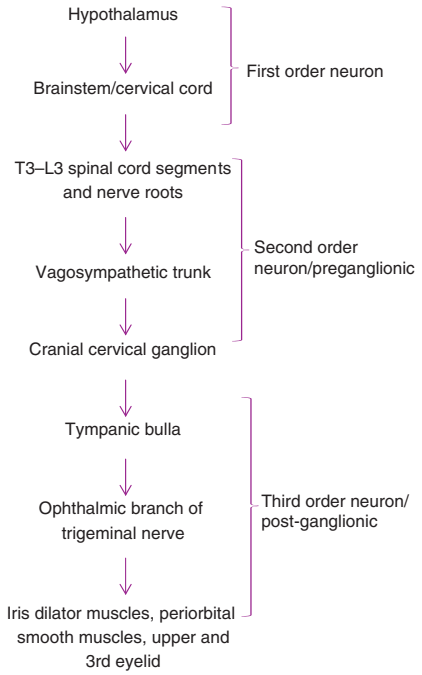

Figure 1.

SIGNS
- Miosis. • Protruding third eyelid. • Ptosis (drooping) of upper eyelid. • Enophthalmos. • Other neurologic and non-neurologic signs dependent on the underlying cause.

CAUSES & RISK FACTORS
See Table 1.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Anterior uveitis—intraocular pressure (IOP) usually low; aqueous flare present.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
- See Table 1. • Thoracic radiographs—may reveal cause of injury to the sympathetic trunk (e.g., trauma or mediastinal tumor).
- CT to image skull and middle ear.
- MRI—may help identify brainstem lesion, retrobulbar mass, cervical spinal cord problem, or jugular groove lesions.
- Ultrasonography—orbit; may reveal retrobulbar mass; jugular groove; may reveal jugular groove mass.

DIAGNOSTIC PROCEDURES
- See Table 1. • Cerebral spinal fluid (CSF) tap—identify brain and spinal cord inflammation. • Electromyography— look for brachial plexus denervation consistent with avulsion. • Pharmacologic testing—see Anisocoria.

TREATMENT
Treat underlying disease.

MEDICATIONS

DRUG(S) OF CHOICE
- Depends on underlying disease.
- Idiopathic—none.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
Do not use drugs that alter the autonomic nervous system prior to referral for lesion localization.

FOLLOW-UP
- Depends on severity of underlying disease.
- Idiopathic—may take up to 4 months for a partial or complete recovery.

MISCELLANEOUS

ABBREVIATIONS
- CN = cranial nerve. • CSF = cerebrospinal fluid. • FCE = fibrocartilaginous embolism. • IOP = intraocular pressure. • IVDH = intervertebral disc herniation.

Suggested Reading
Cottrill NB. Differential diagnosis of anisocoria. In: Kirk's Current Veterinary Therapy, 14th ed. St. Louis, MO: Saunders, 2009, pp. 1168–1174.

Author Heidi L. Barnes Heller
Consulting Editor Kathern E. Myrna

Table 1

Summary of lesions resulting in Horner's syndrome.

Lesion Location	*Causes*	*Common Concurrent Neurologic Abnormalities*	*Diagnostic Plan*
Brainstem	Neoplasia, encephalitis, vascular, trauma	Altered mental status, ipsilateral hemiparesis, ipsilateral postural reaction deficits	MRI; CSF analysis
C1–T3 spinal cord	IVDH, trauma, neoplasia, FCE	Ipsilateral or bilateral paresis/plegia, ± reduced reflexes to thoracic limbs, normal mentation	MRI preferred, myelogram also may show lesion. CSF analysis
T1–T3 nerve roots	Brachial plexus avulsion, peripheral nerve tumor (lymphoma, nerve sheath tumor most common)	Ipsilateral loss of thoracic limb reflexes, ipsilateral loss of cutaneous trunci, ipsilateral monoparesis/plegai, absent postural reactions in affected thoracic limb only	MRI, electrodiagnostic testing
Sympathetic trunk, cranial cervical ganglion	Trauma, iatrogenic following jugular venipuncture, mediastinal or thyroid neoplasia	Possibly laryngeal dysfunction	Neck ultrasound, MRI, thoracic radiographs
Tympanic bulla	Otitis media, polyp (cat), neoplasia, trauma	Ipsilateral vestibular disease, ipsilateral facial nerve paralysis	MRI, CT, bulla radiographs, myringotomy
Retrobulbar	Neoplasia, abscess, trauma	None, or dysfunction of CN II, III, IV, and VI.	MRI, orbital ultrasound

HOUSESOILING—CATS

BASICS

DEFINITION
- Deposition of urine or feces outside the litter box.
- Urine housesoiling (also called periuria) includes toileting, a behavior in which urine is found on horizontal surfaces outside the litter box, and urine marking, in which urine is sprayed on vertical (occasionally horizontal) surfaces as part of a ritualistic tail-up display.
- Fecal housesoiling includes both toileting, a behavior characterized by feces deposited outside the litter box, and fecal marking, called middening, characterized by feces deposited in prominent locations.
- Marking behavior serves a normal communicative function in cats, particularly in response to other cats inside or outside the home.
- Housesoiling will negatively impact the human–animal bond and can lead to relegation outside, rehoming, relinquishment, or euthanasia.

PATHOPHYSIOLOGY
- Toileting—may be dissatisfaction with the litter box environment or preference for an alternative location or substrate, or may reflect an underlying pathophysiologic state such as a negative (pain) association with the litter box secondary to feline idiopathic cystitis (FIC) or feline lower urinary tract disease (FLUTD), uroliths, constipation, or orthopedic pain.
- Urine marking—a normal behavior observed in free-ranging and confined cats; significant individual differences exist in the propensity to urine mark in a given environment. Cat density is correlated to probability of urine marking. Cats who urine mark also commonly use a litter box for toileting (both urine and feces).
- Fecal marking (middening) is rarely observed; it should be a diagnosis of exclusion.
- Social or environmental stressors may contribute to housesoiling, primarily marking.

SYSTEMS AFFECTED
- Behavioral.
- Endocrine.
- Gastrointestinal (GI).
- Neurologic/musculoskeletal.
- Renal/urologic.

GENETICS
- Not specifically identified.
- Persians and Himalayans who exhibit toileting should be DNA tested for the genetic disorder polycystic kidney disease.

INCIDENCE/PREVALENCE
- Housesoiling is the most common behavioral problem for which cat owners seek veterinary advice and the second most common reason for relinquishment of cats to animal shelters.
- Toileting—in one survey, 11% of indoor cat owners reported toileting outside the litter box as a problem.
- Urine marking—exhibited by approximately 10% of castrated male and 5% of ovariectomized female house cats.

GEOGRAPHIC DISTRIBUTION
Housesoiling may be more problematic where cats are restricted indoors.

SIGNALMENT

Species
Cat

Breed Predilections
Housesoiling may occur in any breed, although Persians, Himalayans, and relatives are overrepresented in some studies.

Mean Age and Range
Toileting can occur at any age. Marking behaviors are typically seen in cats >6 months.

Predominant Sex
- Housesoiling can occur in either sex, intact or altered.
- Urine marking is more common in males (intact and neutered) than females (intact and neutered).

SIGNS

General Comments
Identify the Affected Cat in a Multicat Household
- Direct observation—although if punished, cats may become secretive.
- Videotaping or video monitoring.
- Separate the cats to identify the culprit. Note that this protocol may alter the social milieu sufficiently to inhibit toileting behavior.
- Add a urine indicator. Administer the dye fluorescein (6 fluorescein test strips in a gel capsule PO or 10 mg/cat). Urine outside the litter box will fluoresce under a Wood's light for approximately 24 hours. If negative, the test can be repeated on another cat. Negative results are common in households in which the frequency of urine housesoiling is low. Fluorescein may stain fabrics. If urine PH is alkaline, urine is more likely to fluoresce.
- Add a feces indicator. Small shavings of nontoxic crayons may be mixed into food, with different colors fed to each cat.

Identify the Locations of Housesoiling within the House
The owner should draw a diagram of the home layout, indicating the locations of urine and fecal housesoiling and locations of litter boxes. Location of housesoiling can provide insight into the type of housesoiling and etiology.

Historical Findings
Toileting Behavior
- Abnormal pattern of urination (incontinence, polyuria, hematuria, stranguria, dysuria) suggests an underlying congenital or medical problem.
- History of straining to defecate; vocalizing or running away when defecating; hard, dry, or bulky feces suggest painful defecations.
- Painful elimination or increases in volume or frequency of elimination could lead to soiling, conditioned avoidance, and new location or surface preferences.
- History of polydipsia, anorexia, vomiting, or diarrhea suggests an underlying medical etiology.

Urine Marking
- History of conflict, aggression, or avoidance behavior between cats in a multicat household.
- Observation of the posture of spraying urine—the cat orients caudally to a vertical surface, stiffens its posture, raises and quivers its tail, and directs a small burst of urine caudally.
- Observation of urine marks on vertical surfaces or puddled at the bottom of a wall.
- Urine marks can be found on prominent furniture or other objects, or on new objects brought into the house.
- Horizontal urine marks may be found on clothing or bedding associated with a particular person, cat, or dog, or in response to visitors or novel objects.

Fecal Marking
Feces deposited on prominent, conspicuous locations.

Physical Examination Findings
- If strictly behavioral, physical examination will be normal.
- Apparently neutered males that urine mark should be examined for the presence of penile spines, indicating the presence of endogenous testosterone, or quantify serum testosterone.

CAUSES

Medical Causes
- Any metabolic or GI condition that causes polyuria (e.g. diabetes mellitus), diarrhea, or constipation.
- Lower urinary tract disease including interstitial cystitis (may be associated with environmental stressors).
- Urolithiasis.
- Hyperthyroidism.
- Feline leukemia virus (FeLV).
- Feline immunodeficiency virus (FIV).
- Liver disease.
- CNS disease/cognitive dysfunction (senility).
- Iatrogenic—administration of fluids, corticosteroids, diuretics, laxatives.
- Musculoskeletal pain that makes entry to/exit from the litter box or elimination

HOUSESOILING—CATS (CONTINUED)

postures difficult can contribute to litter box aversion.
• Hormonal influences may contribute to urine marking.

Behavioral Causes

Toileting Behavior
• Inadequate cleaning of litter box.
• Inadequate number of boxes or locations (one box per cat plus one is recommended).
• Box located in remote or unpleasant surroundings or subject to interference by dogs or children.
• Inappropriate type of box—covered or uncovered, too small; or allows other cats, pet dogs, and young children to target the cat as it exits.
• Time factors—daily or weekly temporal patterns of toileting suggest an environmental cause; acute onset in a cat who has previously used the litter box suggests a medical or social problem.
• Substrate—unacceptable litter type; preference tests indicate that most cats prefer unscented, fine-grained (clumping) litter, but individual variability; coincident change in litter box habits with new litter type suggests an association; sudden shift from one substrate (e.g., litter) to an unusual substrate (e.g., porcelain sink) suggests a lower urinary tract disorder.
• Location—urination outside the litter box may suggest a location preference or social factors; urination in the vicinity of the litter box may suggest dissatisfaction with qualities of the litter box, including litter box hygiene.
• Social dynamics—consider social conflicts between cats at the time the problem started (e.g., addition of a new cat).

Marking
• Marking is associated with arousal, anxiety, or territorial behavior.
• The probability of urine marking is directly proportional to the number of cats in the household.
• Marking can be a response to household disruption or another cat(s) in or outside the home; urine marks around windows and doors to the outside suggest a response to the presence of an outdoor cat.
• Urine marking grocery bags or new furniture suggests arousal in response to new stimuli.

RISK FACTORS

Toileting
• Inadequate litter box hygiene.
• Litter box features (litter type or scent, box size or style).

Urine Marking
• Male.
• Sexually intact.
• Multicat household.
• History of urine marking by a parent.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Must identify if a medical problem underlies the behavioral problem.
• If behavioral, must differentiate toileting from urine/fecal marking.

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal when urine marking and toileting are strictly behavioral; urinalysis via cystocentesis is the minimum database in any cat with toileting behavior; collect serial samples from cats whose behavioral signs wax and wane; CBC and biochemistry are recommended prior to administration of medication and to evaluate medical status.

OTHER LABORATORY TESTS
Cats with refractory toileting behavior or progressive signs should be tested for hyperthyroidism, FeLV, and FIV.

IMAGING
Abdominal ultrasonography, abdominal radiographs, and contrast studies if indicated to rule out urolithiasis and medical causes for toileting behavior.

DIAGNOSTIC PROCEDURES
Helpful historical information—map of the house with litter boxes and urine/fecal housesoiling identified; behavioral diary with daily frequency of urinations/defecations inside each litter box and outside the litter boxes. Requires daily household monitoring.

PATHOLOGIC FINDINGS
None, unless an underlying medical etiology.

TREATMENT

APPROPRIATE HEALTH CARE
• Use environmental and behavioral therapies before or concomitant with pharmacologic treatment.
• The environment for indoor cats should include safe resting places, separated and plentiful resources, and positive and predictable human–cat interactions.
• Restrict the cat from rooms or areas in which housesoiling occurs.
• For immediate management and in cases of agonistic relationships between cats in a multicat household, it may be necessary to confine the cat to one room in the owner's absence. Provide a litter box (see specifications below), water, food, and resting sites. The cat can be let out of the room when the owner returns and is available for strict supervision. Initiate other, more permanent treatments.
• Clean urine "accidents" with an enzymatic cleaner specific for this purpose.

Toileting Behavior
• Scoop out litter boxes daily. Clean out and wash litter box and refill regularly.
• Avoid deodorizers, scented litters, or other strong odors in the vicinity of the litter box.
• Move food bowls away from litter boxes.
• Provide one litter box per cat, plus one, distributed in more than one location; positioned away from high traffic or noisy areas and with adequate opportunity for entry and exit to avoid conflict with other pets.
• If the litter box is covered, provide an additional large, plain, uncovered litter box filled with unscented, fine-grained, clumping litter, with no liner, and quantify cat use in a behavioral diary.
• Additional boxes may be provided ("litter box buffet") to determine preference for litter box type and substrate. Insure box is large enough for cat's needs for elimination and scratching.
• If one site in the home is preferred for toileting urination, place another litter box over this site. After it is in regular use, move very gradually each day to a site more acceptable to the owner.

Urine Marking
• If there are signs that the cat is marking in response to cats outside the home, use mechanical or olfactory products to deter outside animals, or trap and remove.
• Reduce cat numbers to lessen conflicts if possible.
• Synthetic feline F3 facial pheromone (Feliway® Classic) is commercially available as a treatment for urine marking. The product is sprayed on marked locations or diffused in the environment. For intraspecific social conflict, consider use of feline maternal-appeasing pheromone diffuser (Feliway Multi-cat or Feliway Friends).
• Litter box management, as described above, has been shown to decrease urine marking.
• Pharmacotherapy plays an important role in the control of urine marking.

ACTIVITY
Opportunities for active play that incorporate behavioral patterns of predatory stalking and pouncing should be provided daily.

DIET
No specific diet unless underlying medical etiology, such as urolithiasis or constipation. Consider use of urinary stress diets for stress-related cystitis.

CLIENT EDUCATION
• Cats do not housesoil to be spiteful.
• Scolding and punishment are contraindicated—they may increase cat anxiety and avoidance or fear of the owner.

• Understanding the underlying motivation for housesoiling is critical for treatment success.
• Creating a predictable environment will decrease anxiety and arousal that may contribute to housesoiling.
• Work to resolve cat conflicts within the home (see Aggression, Intercat Aggression).
• Meet the cat's behavioral needs for play, sufficient resources, and safe elevated resting sites.

SURGICAL CONSIDERATIONS
Castration reduces urine marking in up to 90% of males and 95% of females.

MEDICATIONS

DRUG(S) OF CHOICE

Toileting
Psychotropic medication not usually indicated, except in treatment-resistant cases or when associated with generalized anxiety or heightened arousal.

Urine Marking
• Medication to decrease arousal is often needed for treatment success.
• Drugs from a number of drug classes may be used. All have the general effect of decreasing arousal and anxiety. Side effects can be sedation and/or altered social behavior (see Table 1). Drugs commonly used include fluoxetine, paroxetine, clomipramine, amitriptyline, buspirone.

Fecal Marking
Medication may be needed to decrease the arousal that drives this behavior.

CONTRAINDICATIONS
• Benzodiazepines—use cautiously or avoid because of rare cases of fatal idiopathic hepatic necrosis in cats receiving oral diazepam.
• Tricyclic antidepressants—cats with a history of cardiac conduction disturbances, urinary or fecal retention, megacolon, lower urinary tract blockages, seizures, and glaucoma.
• Transdermal route does not appear to consistently produce satisfactory drug levels.

PRECAUTIONS
All drugs listed are extra-label. Inform the client of extra-label use and potential side effects; document the discussion in the medical record or use a release form. Start psychotropic drugs when the owner is present to monitor the patient.

POSSIBLE INTERACTIONS
Do not use monoamine oxidase inhibitors (e.g., selegiline) concurrently with tricyclic antidepressants (TCAs) or selective serotonin reuptake inhibitors (SSRIs).

ALTERNATIVE DRUG(S)
• Synthetic progestins—the risk of serious side effects, including blood dyscrasias, pyometra, mammary hyperplasia, mammary carcinoma, diabetes mellitus, and obesity, has diminished their once-common use.
• Pheromone therapy (Feliway Classic) may reduce urine spraying.
• L-theanine (Anxitane®) or alpha-casozepine (Zylkene®) may reduce cat anxiety.
• L-tryptophan and alpha-casozepine supplemented diets (Multifunction Urinary + Calm Diet, Royal Canin, Hill's® Prescription Diet® c/d® Multicare Stress) may reduce cat anxiety and urine housesoiling.

FOLLOW-UP

PATIENT MONITORING
• Regular follow-up is essential.
• The owner should keep a daily log of elimination patterns so that treatment success can be evaluated and appropriate adjustments can be made. Number the litter boxes and request that client count and record the number of urinations/defecations in each box and outside the litter boxes each day.
• For marking behavior, after 2 months of successful medication management, medication might be withdrawn gradually over 2 weeks. However, if the social features that underlie the behavior are still present, medication may need to be continued for treatment success.
• For medication monitoring, an annual CBC, chemistry profile, urinalysis, and physical examination are recommended as a minimum.

PREVENTION/AVOIDANCE
• Neuter cats.
• Restrict cat numbers to decrease the probability of urine marking.
• Counsel clients on appropriate litter box selection, location, and hygiene.
• Veterinary practitioners should inquire about housesoiling at each veterinary visit. Early identification and treatment optimize treatment success.

POSSIBLE COMPLICATIONS
Client expectations must be realistic. Immediate control of a longstanding problem of housesoiling is unlikely; the goal is gradual improvement over time.

EXPECTED COURSE AND PROGNOSIS
• Prognosis for improvement is good if underlying etiology is identified and managed.
• Housesoiling is destructive to household belongings and erosive to the human–animal bond, which can lead to abandonment, relegation outside, relinquishment, and euthanasia.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Aggression between cats may be associated with urine marking.

AGE-RELATED FACTORS
• Older cats might find litter box access difficult and seek alternative locations. Low-rise litter boxes in accessible areas can provide better access for these cats.
• Failure to use the litter box could be associated with age-related cognitive decline.

ZOONOTIC POTENTIAL
Pregnant women should avoid or take appropriate precautions when cleaning cat feces because of the risk of toxoplasmosis.

PREGNANCY/FERTILITY/BREEDING
TCAs are contraindicated in animals used for breeding.

SYNONYMS
• General—feline housesoiling.
• Urine—feline inappropriate elimination, urine marking, urine spraying, periuria.

Table 1

Drugs and dosages used to manage feline urine marking.

Drug	*Drug Class*	*Oral Dosage in Cats*	*Frequency*	*Side Effects (Usually Transient)*
Fluoxetine	SSRI	0.5–1.0 mg/kg	q24h	Decreased appetite, sleepiness
Paroxetine	SSRI	0.25–0.50 mg/kg	q24h	Constipation
Clomipramine	TCA	0.25–1.0 mg/kg	q24h	Sleepiness
Amitriptyline	TCA	0.25–1.0 mg/kg	q24h	Sleepiness
Buspirone	Azapirone	0.5–1.0 mg/kg	q12h	GI tract side effects (rare)

HOUSESOILING—CATS (CONTINUED)

• Feces—feline inappropriate defecation, fecal marking, middening.

SEE ALSO

• Aggression, Intercat Aggression.
• Fears, Phobias, and Anxieties—Cats.
• Kitten Behavior Problems.
• Marking, Roaming, and Mounting Behavior—Cats.

ABBREVIATIONS

• FeLV = feline leukemia virus.
• FIC = feline idiopathic cystitis.
• FIV = feline immunodeficiency virus.
• FLUTD = feline lower urinary tract disease.
• GI = gastrointestinal.
• SSRI = selective serotonin reuptake inhibitor.
• TCA = tricyclic antidepressant.

HOUSESOILING—DOGS

BASICS

DEFINITION
Urination and/or defecation, for elimination or marking of territory, in locations that owners consider inappropriate.

PATHOPHYSIOLOGY
• Improper or incomplete housetraining. • Submissive or excitement urination. • Marking behavior, due to territoriality, anxiety, testosterone influence. • Anxiety. • Cognitive dysfunction.

SYSTEMS AFFECTED
Behavioral—shelter relinquishment, euthanasia, or rehoming.

GENETICS
Some breeds appear to be more easily housetrained than others.

INCIDENCE/PREVALENCE
• Approximately 15%. • Almost 20% of owners relinquishing a dog to a shelter did so because it soiled in the house. • 37% of owners who reported talking to their veterinarian about a behavior problem reported housesoiling. • Housesoiling is a common reason to see a veterinary behaviorist.

GEOGRAPHIC DISTRIBUTION
None described.

SIGNALMENT

Species
Dog

Breed Predilections
Potential genetic breed predisposition for ease of housetraining and submissive or excitement urination. Dogs obtained from a commercial breeding establishment are more likely to urinate vertically or submissively urinate than those obtained from a noncommercial breeder.

Mean Age and Range
• Inappropriate elimination due to improper or incomplete housetraining, primarily in younger dogs. • Submissive and excitement urination, primarily in younger dogs. • Urine marking begins as the dog reaches sexual maturity. • Housesoiling is a common complaint from owners of elderly dogs.

Predominant Sex
The incidence of inappropriate elimination, including marking, in intact male dogs is almost 60% higher than in castrated male dogs and intact or spayed female dogs.

SIGNS

General Comments
• Inappropriate elimination is the most common individual reason for shelter relinquishment. • Proper housetraining must be discussed with clients. • Housesoiling can be associated with medical problems.

Historical Findings
• History of urination and/or defecation in inappropriate areas. • May be associated with signs of other behavioral disorders (such as separation anxiety). • May be associated with lack of time or knowledge to properly housetrain. • May be associated with punishment. • A complete history will help determine potential triggers, including when, where, and how frequently the elimination occurs, and reliability of outdoor elimination training.

Physical Examination Findings
• If examination findings and laboratory results are normal, housesoiling is more likely due to a behavioral cause. • There may have been an inciting medical cause that has been resolved but the animal continues to eliminate inappropriately.

CAUSES
Canine inappropriate elimination can be due to a primary behavioral problem or secondary to/concurrent with a medical disorder. Medical causes should be ruled out if a previously housetrained dog begins to soil, in dogs that are refractory to training, and when volume or frequency of elimination is increased.

Behavioral
• Lack of, improper, or incomplete housetraining. • Marking behavior. • Submissive urination. • Excitement urination. • Separation anxiety. • Cognitive dysfunction syndrome. • Noise phobia. • Fear induced. • Psychogenic polydipsia/polyuria.

Medical Causes

Degenerative
• Osteoarthritis. • Renal failure. • Neuromuscular.

Anatomic
Ectopic ureters

Metabolic/Endocrine
• Incontinence. • Diabetes mellitus. • Diabetes insipidus. • Hepatic insufficiency. • Hyperadrenocorticism. • Hypoadrenocorticism. • Neurologic.

Neoplastic
• Genitourinary neoplasia. • Neurologic. • Other neoplastic diseases causing weakness.

Infectious/Inflammatory
• Urinary tract infection or inflammation. • Crystalluria with cystitis. • Inflammatory bowel disorder. • Pancreatic disease. • Intestinal parasites.

RISK FACTORS
• Intact male. • Greater number of hours worked. • Concurrent behavioral problem, such as separation anxiety. • Owners unable to properly housetrain. • Owner using punishment or aversive training methods.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Differentiate behavioral causes of inappropriate elimination from medical causes (see Causes) with a proper workup.

CBC/BIOCHEMISTRY/URINALYSIS
Indicated to rule out medical causes.

IMAGING
Not indicated except to diagnose or rule out medical causes.

DIAGNOSTIC PROCEDURES
• Complete behavioral and medical history, including household layout and locations soiled. • Videorecording when the owner is present to view household interactions with the dog. • Journal to monitor potential causal factors, as well as to monitor improvement of the problem. • Videorecording when the owner is gone from the home to rule in/out separation anxiety or other anxiety disorders.

PATHOLOGIC FINDINGS
None for behavioral causes.

TREATMENT

APPROPRIATE HEALTH CARE
Appropriate measures to assure continued good health of the dog.

ACTIVITY
• Take dog outside often on a schedule to ensure enough access to eliminate outside, or provide acceptable access to the outside, e.g., via a dog door if the dog is trained properly. • Increase activity level to potentially help in the treatment of other problem behaviors, as well as to improve the dog's mental and physical health.

DIET
• If the dog is inappropriately eliminating stool, feeding scheduled meals may help to maintain the dog on a schedule of elimination. • Feeding a diet of higher caloric density may help decrease the urge to defecate as frequently. • Water should not be withheld.

CLIENT EDUCATION

General Comments
• Counsel the owner as to the cause(s) of the inappropriate elimination, as well as potential long-term management of the problem. • Treat underlying/contributing medical problems. • Treat other underlying/contributing behavioral problems. • Counsel owners on proper housetraining techniques that focus on reinforcing desirable and preventing undesirable behavior through supervision and confinement/safe haven training. • Counsel owners not to use punishment-based or aversive training methods—punishment creates fear, anxiety, and stress, which can increase housesoiling. • Do not use punishment to housetrain a dog, such as rubbing its nose in the soiled area, or verbally or physically reprimanding. • Clean the soiled areas with an enzymatic cleaner to help eliminate any odor that may attract the dog to eliminate there again; if the soiled object is a piece of clothing or other smaller cloth object, such as a throw rug, wash it. • Change the

HOUSESOILING—DOGS (CONTINUED)

significance of the soiled area, such as by feeding the dog in the area.

Incomplete Housetraining

• Supervise the dog at all times. Monitor for pre-elimination signs to immediately take to the appropriate site. • If not supervised, keep confined to an area where the dog will not eliminate or where an elimination site is offered (indoor elimination area); confinement areas should be in a room, behind a barricade (safety gate), or a crate or pen where the dog is comfortably housed (safe haven; see Puppy Behavior Problems); do not confine to an area that causes panic, destruction, and/or injury to the dog. • In some cases, tethering the dog to owners or nearby allows better supervision; never tether without supervision. • Take the dog outside frequently to eliminate; schedule outdoor times to meet the frequency and timing of elimination. • Accompany the pet to the appropriate elimination site and immediately reward elimination. • Use a consistent "key phrase" to help associate the act with the location and timing of elimination. • Feed on a set schedule, with water always available.

Submissive or Excitement Urination

• Do not punish the behavior, as this will contribute to further fear and conflict. • People should ignore the dog when they enter the house (no verbal or physical interactions or eye contact). • The dog should go outside to urinate before greeting. • The dog should be greeted in a nonconfrontational and quiet manner; do not lean over the dog or institute interactive play at the time of greeting. • Tossing treats or a toy or teaching an alternate behavior at homecoming such as "sit" may change the dog's greeting response.

Urine Marking Behavior

• Educate owners on effectiveness of neutering to decrease urine marking. • Determine all triggers to the behavior, including anxiety-provoking stimuli. • Address those triggers with desensitization and counter-conditioning and/or avoidance of the trigger where appropriate. • Prevent access to the preferred marking locations. • Medications may be indicated to treat underlying anxiety disorder.

SURGICAL CONSIDERATIONS

Neutering intact male dogs decreases urine marking rapidly in 30% of dogs, with a gradual decline in 20% of dogs, and no change in 50%. The results are the same regardless of age of neutering.

MEDICATIONS

DRUG(S) OF CHOICE

• Negligible effect in animals if displaying submissive or excitement urination; not indicated unless anxiety is part of the problem behavior. • If urine marking or inappropriate elimination is anxiety induced, medications may be helpful, in conjunction with behavior modification. • Selective serotonin reuptake inhibitors (SSRIs), tricyclic antidepressants (TCAs)/anti-anxiety medications, or other anti-anxiety medications may be helpful, especially with underlying anxiety—SSRI: fluoxetine at 1–2 mg/kg PO q24h; TCA: clomipramine at 1–3 mg/kg PO q12h. • For SSRIs and TCAs, the full onset of action can be 4–6 weeks after initiation of treatment; inform owners of time required for response to be noted. • Side effects of SSRIs and TCAs can include nausea, vomiting, diarrhea, and lethargy. • Additional side effects of TCAs can include potentiation of seizure activity.

CONTRAINDICATIONS

• Medication without concurrent behavior modification. • Tricyclic antianxiety medications are contraindicated in seizures and cardiac disease, and may interfere with thyroid medications.

PRECAUTIONS

Based on drug chosen.

POSSIBLE INTERACTIONS

Do not use an SSRI and TCA together or in conjunction with a monoamine oxidase (MAO) inhibitor or opioid.

ALTERNATIVE DRUG(S)

Pheromones, or supplements containing alpha-casozepine, L-theanine, or a calming probiotic may help to decrease anxiety.

FOLLOW-UP

PATIENT MONITORING

Monitor with owner by follow-up visits or telephone calls. The owner should keep a journal of incidents, inciting factors, and treatments instituted to have an objective view of improvement.

PREVENTION/AVOIDANCE

• Properly housetrain. • Neuter male dogs. • Monitor for signs and treat any underlying medical condition. • Treat any underlying behavioral condition.

POSSIBLE COMPLICATIONS

Recurrence if owner relapses in treatment, perhaps pet relinquishment.

EXPECTED COURSE AND PROGNOSIS

• Prognosis for any behavioral problem is highly dependent on an owner's ability and willingness to follow guidance—the following estimations of prognosis are based on the owner's ability and commitment to follow instructions. • Prognosis for decreasing submissive and excitement urination is good. • Prognosis for managing incomplete housetraining is good. • Prognosis for marking in previously intact male: 50% improve (30% quickly, 20% more slowly) with neutering, even without complementary behavior modification. • Prognosis for managing urine marking in spayed or neutered dogs is good if the triggers are identified and managed with avoidance or other forms of behavior modification. • Some animals with a medical cause of inappropriate elimination will still eliminate inappropriately after the medical cause has been treated due to learning (e.g., self-reinforcing, new location preferences).

MISCELLANEOUS

AGE-RELATED FACTORS

• Puppies are more likely to present for lack of or incomplete housetraining, as well as for submissive and excitement urination. • Cognitive dysfunction becomes more likely as the dog ages.

ZOONOTIC POTENTIAL

Low unless potentially zoonotic organisms in urine or feces.

SYNONYMS

• Inappropriate defecation. • Inappropriate elimination. • Inappropriate urination. • Urine marking.

SEE ALSO

• Cognitive Dysfunction Syndrome. • Separation Anxiety Syndrome. • Submissive and Excitement Urination—Dogs.

ABBREVIATIONS

• MAO = monoamine oxidase. • SSRI = selected serotonin reuptake inhibitor. • TCA = tricyclic antidepressant.

HYDROCEPHALUS

BASICS

DEFINITION
- Abnormal dilation of the ventricular system within the cranium.
- May be symmetric or asymmetric.
- May involve the entire ventricular system or partial elements secondary to underlying cause.

PATHOPHYSIOLOGY
- Obstructive—cerebrospinal fluid (CSF) accumulates in front of an obstruction along the normal CSF circulatory pattern (noncommunicating) or at its resorption site by the meningeal arachnoid villi (communicating); depending on the balance between production of CSF (which is constant and independent of intracranial pressure [ICP]) and the capacity for absorption of CSF, ICP may be high or normal; clinical signs may be noted in either case.
- Congenital obstruction—primary obstructive hydrocephalus; most common site is at the level of the mesencephalic aqueduct due to fusion of the rostral colliculi; prenatal infections (especially parainfluenza virus) may cause aqueductal stenosis with subsequent hydrocephalus; may result in considerable disruption of the architecture of the brain; diffuse ventricular enlargement may also suggest congenital ventricular dilation or obstruction at the level of the lateral apertures or foramen magnum; it is not uncommon to have asymmetric ventricular enlargement.
- Acquired obstruction—secondary obstructive hydrocephalus; sites include the interventricular foramina, mesencephalic aqueduct, or lateral apertures of the fourth ventricle.
- Overproduction of CSF (communicating)—rare; caused, e.g., by a choroid plexus tumor.
- "Compensatory hydrocephalus"—condition wherein CSF fills the space where the neural parenchyma was destroyed; not true hydrocephalus; terminology obsolete (hydrocephalus ex vacuo).
- External hydrocephalus—condition where CSF accumulates on the surface of the brain.
- Clinical signs of neurologic dysfunction result from damage to neural parenchyma, loss of neurons, and abnormal neuronal function.
- May also be associated with abnormalities in the spinal cord such as syringohydromyelia.

SYSTEMS AFFECTED
Nervous system.

GENETICS
Siamese cats—autosomal recessive.

INCIDENCE/PREVALENCE
Unknown

SIGNALMENT
Species
Dog and cat.

Breed Predilections
- Congenital—small and brachycephalic dogs: bulldogs, Chihuahuas, Maltese, Pomeranians, toy poodles, Yorkshire terriers, Lhasa apsos, Cairn terriers, Boston terriers, pug dogs, and Pekingese.
- Inherited—Siamese cats and Yorkshire terriers; high incidence of clinically asymptomatic ventriculomegaly in normal adult beagles.
- Acquired—any breed of cat or dog.

Mean Age and Range
- Congenital—usually becomes apparent at a few weeks up to 1 year of age; acute onset of signs can occur in dogs with previously undiagnosed congenital hydrocephalus; exact cause of this decompensation is uncertain.
- Acquired—any age.

Predominant Sex
None

SIGNS
General Comments
- Congenital—may occur without clinical signs, especially in dogs of toy breeds; other malformations or anomalies of the CNS may be noted (e.g., malformations of the cerebellum or syringomyelia), which may further contribute to the constellation of signs.
- Acquired—signs attributable to the underlying disease may be as or more prominent than the signs attributable to the hydrocephalus.
- Severity of the clinical signs may not correspond to the degree of ventricular enlargement.

Historical Findings
- Behavioral—decreased awareness; lack of or loss of training ability (including housetraining); excessive sleepiness; vocalization; sometimes hyperexcitability.
- Visual deficits including blindness.
- Seizures—may be noted.

Physical Examination Findings
- Head—may appear large and dome-shaped with an exaggerated "stop"; open sutures and/or persistent fontanelles often present, but these may be present without hydrocephalus and vice versa; bilaterally divergent strabismus in some dogs with severe congenital hydrocephalus: due to malformation of the orbit or to brainstem dysfunction.

Neurologic Examination Findings
- Signs may be acute or gradual in onset, and may be static or progressive.
- A wide variety of signs of brain dysfunction can occur.
- Cerebral disease—abnormal behavior (obtundation and drowsiness), cortical blindness (loss of vision with normal eyes and pupillary light reflexes), inappropriate vocalization, sometimes hyperexcitable, circling.
- Gait abnormalities—incoordination, ataxia, and decreased postural reactions.
- Seizures—may occur.
- Congenital form—malformation of the orbit during growth may result in a ventrolateral strabismus with normal oculocephalic movements; oculocephalic movements may be abnormal if brainstem dysfunction is the cause of strabismus.
- Severely increased ICP—stupor or coma, pinpoint or dilated fixed pupils, loss of normal oculocephalic movements (physiologic nystagmus), abnormal respiratory patterns, decerebrate posture; may lead to fatal tentorial herniation.
- Severity of clinical signs may not correlate with ventricular size, although there is a tendency for worse clinical signs with greater enlargement of the ventricles.

CAUSES
- Congenital—numerous congenital malformations cause obstruction of the ventricular system and result in hydrocephalus; heritable malformation, prenatal infection (e.g., dogs: parainfluenza virus; cats: coronavirus), exposure to teratogens, brain hemorrhage secondary to dystocia, nutritional deficiency (vitamin A), other.
- Acquired—tumors, abscesses, and inflammatory diseases (including inflammation resulting from hemorrhage caused by traumatic injuries or other causes of bleeding).

RISK FACTORS
Animals with compensated hydrocephalus may decompensate in the face of an insult such as infection or trauma, resulting in development of clinical signs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other congenital brain anomalies.
- Metabolic or toxic diseases resulting in cerebral dysfunction.
- Brain mass lesions or infectious diseases resulting in high ICP (hydrocephalus may coexist).
- Traumatic injury to the brain (hydrocephalus may coexist).

CBC/BIOCHEMISTRY/URINALYSIS
Usually normal.

IMAGING
- Skull radiography (congenital)—enlarged domed cranium with open sutures and persistent fontanelles; cranial vault may have a ground-glass appearance; also may reveal calvarial thinning.
- CT and MRI—provide definite diagnosis.
- Ultrasonography through fontanelles may reveal enlarged ventricles.

HYDROCEPHALUS (CONTINUED)

DIAGNOSTIC PROCEDURES

• CSF—use caution when collecting sample if patient has high ICP (may lead to fatal brain herniation through the foramen magnum and/or beneath the tentorium cerebelli); composition normal if no other intracranial disease (e.g., neoplasia, inflammation), but frequently abnormal when acquired underlying disease is present.
• Electroencephalography (EEG)—congenital: usually characteristic, including hypersynchrony, high amplitude (25–300 μV), and low frequency (1–7 Hz); acquired: varies.

PATHOLOGIC FINDINGS

• Brain—may be large with loss of the normal pattern of sulci and gyri; may see distortion of the parenchyma, including thinning of the cerebral cortex, rupture of the septum pellucidum, and atrophy of other adjacent structures; with severe disease, brain herniation may occur, either of the cerebrum and midbrain under the tentorium cerebelli or of the cerebellum and caudal medulla oblongata through the foramen magnum.
• Ventricular system—mildly to severely distended (either entirely or only the part rostral to the obstructive lesion); with noncommunicating form, narrowing or blockage of the ventricular system due to inflammation or mass lesions.

TREATMENT

APPROPRIATE HEALTH CARE

• Inpatient—intensive care for patients with severe signs or when undergoing surgical therapy.
• Outpatient—patients with mild to moderate signs that can be treated medically.

NURSING CARE

Prevent secondary complications of recumbency for stuporous or comatose patients—avoid pressure sores; drying eyes; hypostatic lung congestion.

CLIENT EDUCATION

Advise client to observe for deterioration in mental alertness, vision, and behavior, which may signal worsening of the problem.

SURGICAL CONSIDERATIONS

• Surgical shunting of the CSF from the ventricles to the peritoneal cavity or right atrium—definitive treatment.
• Surgery should be considered only when medical management is ineffective or results in adverse side effects.
• Complications—shunt blockage occurs in up to 50% of patients; infection is less common; shunt revision commonly needed; overshunting may result in severe and potentially fatal complications (collapse of the cerebral mantle).
• Clinical signs may not resolve completely; residual signs usually indicate irreversible brain damage.
• Surgery for a brain tumor or other mass lesion—consider if it is the underlying cause.

MEDICATIONS

DRUG(S) OF CHOICE

• Reduce CSF production—data on the efficacy of corticosteroids in reducing CSF production are conflicting, but beneficial clinical effects usually are seen (prednisone 0.25–0.5 mg/kg PO q12h or dexamethasone 0.1 mg/kg PO q12h); should be tapered to an alternate-day regimen and the dose lowered as far as possible.
  ◦ Carbonic anhydrase inhibitors: acetazolamide (10 mg/kg PO q8h) with or without furosemide (1 mg/kg q24h); electrolytes must be monitored frequently; long-term use is unlikely to be beneficial and may lead to adverse consequences.
  ◦ Omeprazole has been reported to reduce CSF production in normal dogs in an experimental model, but no data are available on the usefulness of this drug in the clinical setting; anecdotal reports have been disappointing.
• Reduce ICP—osmotic diuretics: mannitol (1 g/kg slow IV infusion over 20 min, may repeat twice at 6-hour intervals) and/or loop diuretics: furosemide (dogs: 2–8 mg/kg IV/IM/SC q12h; cats: 1–2 mg/kg IV/IM/SC q12h); these are short-term treatments only, helpful for acute treatment of severe cases.
• Treat underlying cause—administer specific drugs when possible (e.g., antibiotics for bacterial infection, irradiation, or surgery for neoplasia).

PRECAUTIONS

• Corticosteroids—long-term treatment may cause iatrogenic hyperadrenocorticism or hypoadrenocorticism if drug is suddenly withdrawn.
• Diuretics—may cause shock or electrolyte imbalances, especially hypokalemia with furosemide administration.

FOLLOW-UP

PATIENT MONITORING

Monitor for exacerbation of the hydrocephalus and for signs attributable to an underlying cause (e.g., intracranial neoplasia).

POSSIBLE COMPLICATIONS

• Brain herniation and death.
• Infection and blockage when ventriculoperitoneal shunting is carried out; shunt revision and specific treatment for bacterial infection are then indicated.

EXPECTED COURSE AND PROGNOSIS

• Good to poor—depend on cause and severity.
• Mild congenital form—good prognosis; may require only occasional medical treatment.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Cerebellar hypoplasia in kittens congenitally infected with feline panleukopenia virus.

AGE-RELATED FACTORS

Congenital—usually seen in animals <1 year old.

SEE ALSO

Stupor and Coma.

ABBREVIATIONS

• CSF = cerebrospinal fluid.
• EEG = electroencephalography.
• ICP = intracranial pressure.

HYDRONEPHROSIS

BASICS

OVERVIEW

• Hydronephrosis is progressive distention of the renal pelvis resulting in compression and atrophy of the renal parenchyma secondary to ureteral outflow tract obstruction and associated increased hydrostatic pressure.
• Most often hydronephrosis is unilateral (~80–85%) and occurs secondary to complete or partial obstruction of the ureter by uroliths, ureteral strictures, ureteral or trigonal neoplasia, retroperitoneal disease causing extraluminal compression, spay stump granuloma, trauma, radiotherapy, and accidental ligation of the ureter during ovariohysterectomy, cryptorchectomy, or after ectopic ureter surgery.
• Bilateral hydronephrosis is less common, resulting from ureteral stone disease, congenital ureteral strictures, trigonal neoplasia, or a urethral outflow obstruction. Severe hydronephrosis can also be seen in dogs with ectopic ureters (commonly males) associated with a ureterovesical junction (UVJ) stenosis.

SIGNALMENT

Dog and cat.

SIGNS

Historical Findings

• Subclinical in some dogs/cats.
• Inappetence.
• Weight loss.
• Polyuria and/or polydipsia (PU/PD).
• Hematuria.
• Depression, diarrhea, vomiting associated with uremia in patients with bilateral hydronephrosis or with compromised function in the contralateral kidney.
• May be referable to the cause of the obstruction (e.g., abdominal pain).
• Most dogs and cats with a ureteral obstruction will continue to produce urine due to the unilateral nature of the condition or the presence of a partial, rather than complete, ureteral obstruction.

Physical Examination Findings

• Normal in some patients.
• Renomegaly.
• Big kidney–little kidney syndrome associated with a previous ureteral obstruction.
• Renal, abdominal, or lumbar pain.
• Abdominal mass—bladder or prostate.
• Trigonal, prostatic, vaginal or urethral mass palpable on rectal exam.

CAUSES & RISK FACTORS

Ureteral Diseases

• Ureteroliths.
• Congenital ureteral stricture or circumcaval ureter.
• Acquired ureteral stricture/fibrosis.
• Pyonephrosis/pyoureter.
• Neoplasia.
• Ureteral ligation during ovariohysterectomy.
• Secondary to congenital ectopic ureter.
• Complication from previous ectopic ureter surgery.

Lower Urogenital Tract Diseases

• Urinary bladder neoplasia (e.g., transitional cell carcinoma).
• Prostatic disease (e.g., neoplasia).
• Vaginal mass.
• Cryptorchectomy resulting in inadvertent prostatectomy.

Retroperitoneal Disease

• Masses—granuloma, neoplasm, cyst, abscess, hematoma.
• Perineal hernia.
• Post-radiotherapy-induced fibrosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Other causes for renal pelvic dilation—e.g., ureteral obstruction (stone, stricture, tumor), pyelonephritis, pyelonephrosis, IV fluid therapy, chronic kidney disease, PU/PD.
• Other causes of renomegaly—e.g., neoplasia, cysts, and perinephric pseudocysts (cats).
• Other causes of abdominal pain—e.g., pancreatitis and peritonitis.
• Intervertebral disc disease leading to lumbar pain.
• Other causes for azotemia—e.g., acute kidney injury, chronic kidney disease, dehydration, urethral obstruction.

CBC/BIOCHEMISTRY/URINALYSIS

• Normal in some patients.
• Loss of urine-concentrating ability (first abnormality detected), hematuria, pyuria.
• Azotemia, hyperphosphatemia, hyperkalemia, thrombocytopenia, and acidemia with either bilateral ureteral obstructions, concurrent renal parenchymal disease, or obstructive pyonephrosis.

IMAGING

• Abdominal radiographs may be normal or show nephroliths, ureteroliths, cystoliths, urethroliths, renomegaly, prostatomegaly, reduced retroperitoneal contrast, ureteral distension, or urinary bladder distension.
• Ultrasonography reveals dilation of the renal pelvis and diverticula, with thinning of the renal parenchyma; proximal dilation of affected ureter is detected in some dogs/cats if the hydronephrosis is associated with a ureteral obstruction (most common cause). If ureteral dilation is present, evaluation for cause (UVJ tumor, stenosis; ureteral stones; ureteral stricture).
• Injection of radiographic contrast material via either excretory urography (not recommended) or by nephropyelocentesis and ureteropyelography/retrograde ureterogram may be required to determine the location and cause of obstruction.
• CT can be helpful in cases where ultrasound and radiographs cannot determine cause.

DIAGNOSTIC PROCEDURES

Cystoscopy or vaginoscopy may help determine the location and cause of lower urinary tract obstruction or presence of ureteral ectopia, UVJ stenosis.

TREATMENT

• Emergency intervention is required for ureteral obstruction; metabolic and electrolyte abnormalities should be corrected prior to intervention. If severe enough then hemodialysis may be indicated.
• Treat as an inpatient.
• Start supportive care (e.g., fluids ± antibiotics) while performing diagnostic tests.
• Correct fluid and electrolyte deficits conservatively with IV fluid therapy over 12–24 hours, followed by maintenance fluids as needed. Patients with extreme PU may need higher maintenance fluid rates to maintain hydration. Do not fluid overload patients.
• Pending reestablishment of urinary patency, relieve lower urinary tract obstruction by catheterization, serial cystocentesis, or tube cystostomy as soon as possible.
• Specific treatment (e.g., interventional or surgical) depends on the cause and whether there is concurrent kidney disease or other disease processes (e.g., bilateral uroliths affecting contralateral kidney and/or ureter, metastatic neoplasia, etc.).
• Nephrectomy is rarely ever indicated (e.g., neoplasia).

MEDICATIONS

DRUG(S) OF CHOICE

• Success rate for medical management of obstruction is 8–13%.
• For a ureteral obstruction caused by uroliths—alpha-adrenergic blockade should be considered (cat: prazosin 0.25 mg/cat q12h; dog: 1 mg/15 kg q8–12h).
• IV fluid diuresis—being careful to avoid overhydration.
• Diuretics, e.g., mannitol 0.25 g/kg bolus over 30 min; consider CRI (1 mg/kg/min) if effective.

HYDRONEPHROSIS (CONTINUED)

• Hyperkalemia is often absent. Mild to moderate hyperkalemia often resolves with fluid replacement and/or bicarbonate administration unless bilateral obstruction and/or oliguria is present. Severe, symptomatic hyperkalemia requires prompt and aggressive medical or surgical management for emergent decompression.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Do not add or mix sodium bicarbonate with calcium-containing fluids.
• Do not give radiographic contrast material intravenously until the patient is rehydrated. Use radiographic contrast material with caution in azotemic patients.

Special Considerations

A patient with ureteral obstruction(s) should be considered an emergency and referred to colleagues who are highly experienced in managing this condition.

FOLLOW-UP

PATIENT MONITORING

• Ultrasonography—can repeat at 2–4-week intervals after relief of obstruction to assess improvement. Often some signs of resolution appear within days after relief of obstruction, but can take up to 3–4 months.
• Monitor serum chemistries and electrolytes as needed. Symmetric dimethylarginine (SDMA) likely has a place in the months following obstruction to track chronic kidney disease development.
• After relief of obstruction— PU and postobstructive diuresis may lead to hypokalemia, weight loss, dehydration, and possibly permanent renal injury, so care should be taken to monitor these patients carefully.

POSSIBLE COMPLICATIONS

Rupture of the excretory system and irreversible renal damage. Decompression should be considered when medical management fails to relieve obstruction.

EXPECTED COURSE AND PROGNOSIS

• Variable depending on the cause, duration of obstruction, and presence or absence of concurrent infection.
• Irreversible damage to the kidney usually begins 15–45 days after obstruction.
• If the obstruction is relieved within 2–4 weeks, some renal damage is reversible. If the obstruction is partial (over 80% of cases), the time before irreversible damage is prolonged.
• Concurrent infection accelerates the severity of renal damage. Antimicrobial therapy is often initiated empirically, however recent research recommends performing ultrasound guided pyelocentesis followed by anterograde pyelographic contrast study to confirm or rule-out ureteral obstruction.

MISCELLANEOUS

SEE ALSO

• Acidosis, Metabolic.
• Acute Kidney Injury.
• Chronic Kidney Disease.
• Hyperkalemia.

ABBREVIATIONS

• PU/PD = polyuria/polydipsia.
• SDMA = symmetric dimethylarginine.
• UVJ = ureterovesicular junction.

HYPERADRENOCORTICISM (CUSHING'S SYNDROME)—CATS

BASICS

OVERVIEW

Feline Cushing's syndrome (FCS) or hyperadrenocorticism is a consequence of abnormally increased functional activity of the adrenal cortex.

Pathophysiology

- Caused by increased glucocorticoid secretion by the adrenal gland(s).
- Approximately 85% of cases due to bilateral adrenocortical hyperplasia from pituitary hyperplasia or tumor— pituitary-dependent hyperadrenocorticism (PDH).
- Remaining 15% caused by adrenal tumor (AT), half of which are benign.
- Regardless of etiology, concurrent unregulated diabetes mellitus (DM) is frequent (90%) and other concurrent diseases (e.g., pancreatitis, chronic kidney, or cardiac disease) are reported.

SIGNALMENT

- Middle-aged to old cat.
- No known breed or sex predisposition.

SIGNS

- Dermatologic abnormalities (alopecia; unkempt hair coat; thin, fragile skin that is easily bruised or torn), polyuria, polydipsia, polyphagia, weight loss, muscle wasting, and pot-bellied appearance.
- Weight gain (unless concurrent DM causes weight loss), hepatomegaly, and curled pinnae also seen.
- Lethargy (dullness) secondary to muscle weakness or effects of pituitary mass.
- Excess sex hormones can cause signs such as penile barbs and behavioral changes (sexual).

CAUSES & RISK FACTORS

- Pituitary adenoma with subsequent corticotropic hyperplasia and excess glucocorticoid secretion.
- Autonomously functioning benign adrenal adenoma (50%) or malignant adenocarcinoma (50%).
- Iatrogenic from glucocorticoid administration (rare).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Insulin-resistant DM.
- Acromegaly.
- Hepatopathy.
- Renal disease.
- Sex hormone–secreting adrenal tumor.
- Hyperprogesteronism.
- Dermatologic disease.

CBC/BIOCHEMISTRY/URINALYSIS

- Lymphopenia, anemia.
- Hyperglycemia, hypercholesterolemia, hypertriglyceridemia, hypochloremia.
- Elevated urine cortisol : creatinine (UC : Cr) ratio, proteinuria.
- Azotemia, hyperglobulinemia (less common).
- Elevated serum alkaline phosphatase uncommon.

OTHER LABORATORY TESTS

Screening Tests

- UC : Cr—sensitive (good negative predictive value).
- Low-dose dexamethasone-suppression test—good sensitivity. Dose: 0.1 mg/kg IV. Failure to suppress consistent with FCS.
- Adrenocorticotropic hormone (ACTH) stimulation test—specific but poorly sensitive, not recommended as initial diagnostic test.
- Assays for plasma sex hormone and progesterone concentrations may rule out differentials.

Differentiating Tests

- Plasma endogenous ACTH concentration high normal or greater with PDH compared to low plasma ACTH levels with AT (<10 pg/mL). Reference ranges vary with laboratories.
- Imaging.

IMAGING

- Abdominal ultrasound—accurate to differentiate PDH from AT in most cases; operator dependent. Symmetric adrenal glands of normal or enlarged size are suggestive of PDH; unilateral enlargement or asymmetric adrenal glands support AT.
- CT and MRI—visualization and measurement of pituitary tumors or characterization of adrenal tumors.

TREATMENT

- FCS is a debilitating disease. Prognosis is guarded due to severity of complications and concurrent diseases.
- Presurgical medical treatment is beneficial to prevent complications from fragile skin and infections.
- Radiation therapy of macroadenomas allows better control of the disease and insulin resistance.
- Unilateral adrenalectomy for AT and medical therapy for PDH are the most readily available effective treatment options.
- Hypophysectomy (microsurgical transsphenoidal) is effective and available at some institutions.

MEDICATIONS

DRUG(S) OF CHOICE

- Trilostane reversibly blocks steroid synthesis. In most patients with FCS from PDH, trilostane reduces clinical signs and improves endocrine test results. A starting dose of 5–10 mg/cat PO q12h is recommended.
- Mitotane (Lysodren®; o,p′-DDD) is not recommended for treatment of FCS.
- Other medications have limited efficacy (ketoconazole, metyrapone, and aminoglutethimide).

FOLLOW-UP

- Clinical improvement and improved diabetic control are indicative of successful drug therapy.
- ACTH stimulation tests are recommended for dose adjustments of trilostane.

MISCELLANEOUS

ABBREVIATIONS

- ACTH = adrenocorticotropic hormone.
- AT = adrenal tumor.
- DM = diabetes mellitus.
- FCS = feline Cushing's syndrome.
- PDH = pituitary-dependent hyperadrenocorticism.
- UC : Cr = urine cortisol : creatinine.

HYPERADRENOCORTICISM (CUSHING'S SYNDROME)—DOGS

BASICS

DEFINITION
• Spontaneous hyperadrenocorticism (HAC)—disorder due to excessive production of cortisol by adrenal cortex.
• Iatrogenic HAC—from excessive exogenous administration of glucocorticoids by any route.
• Clinical signs due to effects of elevated circulating glucocorticoid concentrations.

PATHOPHYSIOLOGY
• ~80–85% of cases of naturally occurring HAC due to bilateral adrenocortical hyperplasia resulting from pituitary corticotroph adenoma or hyperplasia with oversecretion of adrenocorticotropic hormone (ACTH).
• In remaining 15–20%, cortisol-secreting adrenocortical neoplasia (AN) present; ~50% malignant.
• Rarely caused by ectopic ACTH secretion from nonpituitary tumor.
• One case of food-dependent hypercortisolemia reported, with increased cortisol concentration after meal; likely due to aberrant gastric inhibitory peptide receptors stimulating adrenal steroidogenesis.
• Iatrogenic HAC from excessive administration of exogenous glucocorticoids.

SYSTEMS AFFECTED
• Variable.
• Signs referable to urinary tract or skin common.
• Skin—bilaterally symmetric alopecia, comedones, hyperpigmentation, recurrent pyoderma.
• Renal/urologic—polyuria/polydipsia (PU/PD; 85–90% of cases), proteinuria, urinary tract infections (UTIs).
• Endocrine/metabolic—hyperglycemia; diabetes mellitus (DM) in 10%.
• Cardiovascular—hypertension (usually mild).
• Gastrointestinal—polyphagia.
• Hemic/lymphatic/immune—stress leukogram, immunosuppression, mild erythrocytosis and thrombocytosis, occasional nucleated red blood cells.
• Hepatobiliary—hepatopathy due to glycogen deposition, increased serum alkaline phosphatase (ALP) activity due to corticosteroid-induced isoenzyme; alanine aminotransferase (ALT) activity also increased, but by less.
• Neuromuscular—muscle weakness; CNS signs from macroadenoma may include anorexia, abnormal mentation, blindness, rarely seizures.
• Reproductive—testicular atrophy, anestrus.
• Respiratory—panting, pulmonary thromboembolism possible.

INCIDENCE/PREVALENCE
One of most common endocrine disorders in dogs.

SIGNALMENT

Species
Dog

Breed Predilections
Poodle, dachshund, Boston terrier, German shepherd dog, beagle.

Mean Age and Range
Generally, middle-aged to older animals; pituitary-dependent HAC (PDH) rarely seen in dogs as young as 1 year.

SIGNS

General Comments
• Severity varies greatly, depending on duration and extent of cortisol excess.
• In some cases physical presence of neoplastic process (pituitary or adrenal) contributes to illness.

Historical and Physical Examination Findings
PU/PD, polyphagia, pendulous abdomen, increased panting, hepatomegaly, hair loss, cutaneous hyperpigmentation, thin skin, muscle weakness, obesity, lethargy, muscle atrophy, comedones, bruising, testicular atrophy, anestrus, calcinosis cutis, facial nerve palsy.

CAUSES
• PDH—adenoma most common; adenocarcinomas rare; anterior pituitary involved in ~80% of cases, intermediate lobe in remainder; exact incidence of pituitary macroadenomas (tumors >1 cm diameter) unknown, may be 10–25%.
• AN—adenoma or carcinoma (50%).
• Ectopic ACTH secretion and food-dependent hypercortisolism—rare.
• Iatrogenic—due to glucocorticoid administration.

RISK FACTORS
• None known for spontaneous disease.
• Administration of exogenous glucocorticoids (risk for iatrogenic HAC).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Depends on clinical and laboratory abnormalities.
• Hypothyroidism, sex hormone dermatoses, alopecia X, sex hormone–secreting tumors, acromegaly, DM, hepatopathies, renal disease, other causes of PU/PD.
• Cortisol can decrease concentration of total T_4; important to check for HAC in dogs with weight gain or dermatologic disease that could be misdiagnosed as hypothyroidism.

CBC/BIOCHEMISTRY/URINALYSIS
• Hemogram may show eosinopenia, lymphopenia, leukocytosis, neutrophilia, erythrocytosis, thrombocytosis.
• Serum chemistry may show elevated cholesterol concentration; ALP activity high in ~85–90% and elevations proportionately greater than for ALT.
• Mild hyperglycemia common but only ~10% of dogs with HAC have concurrent DM.
• Urinalysis may reveal low specific gravity, proteinuria, hematuria, pyuria, and/or bacteriuria.

OTHER LABORATORY TESTS
• Endocrine testing required in dogs with history, clinical signs, and laboratory abnormalities suggestive of HAC; see Appendix II.
• Do not perform HAC testing in sick dogs unless clinical signs consistent with HAC.
• *Screening tests* determine if HAC present or not.
• Once diagnosis of HAC made, perform *differentiation test* to determine if PDH or AN present; differentiation crucial for therapeutic decisions and prognosis.
• To convert cortisol concentration in nmol/L to µg/dL, divide by 27.6.
• All cortisol concentrations below for illustration; normal ranges and cut-off values vary with lab.

Screening Tests

Urine Cortisol : Creatinine Ratio (UC : Cr)
• Urine cortisol excretion increases with augmented adrenal secretion of cortisol, whether due to PDH or AN.
• Should be measured in urine sample collected at home when pet not stressed.
• Elevated UC : Cr is sensitive marker of HAC, present in 90–100% of affected dogs; normal ratio makes diagnosis of HAC very unlikely.
• False-positive results common; only ~20% of dogs with elevated UC : Cr have HAC.
• Due to chance of false-positive, always do ACTH stimulation test or low-dose dexamethasone suppression test to confirm presence of HAC.

Low-Dose Dexamethasone Suppression Test (LDDST)
• Lack of suppression 8h after injection of low dose of dexamethasone consistent with diagnosis of HAC.
• Sensitivity ~95% in dogs.
• In dogs with nonadrenal illness, relatively high chance of false-positive.
• Lack of suppression at 4h but full suppression at 8h technically not consistent with HAC, but suspicious for its presence; further testing warranted.
• LDDST may also serve as differentiation test; if 8h sample >1.4 µg/dL, result consistent with HAC; if also suppression to <1.4 µg/dL at 4h post dexamethasone (i.e., "escape" at 8h post dexamethasone) or 4h and/or 8h post-dexamethasone samples <50% of baseline, results consistent with

(CONTINUED) HYPERADRENOCORTICISM (CUSHING'S SYNDROME)—DOGS

PDH; if criteria for PDH not met, chances still ~⅔ for PDH vs. AN.
• If baseline values close to 1.4 µg/dL or suppression just at 50%, confirm presence of PDH by other means.
• Protocol exists in Utrecht, Netherlands, where min 2 morning urine samples collected and then dexamethasone administered (3 doses over 24h) for differentiating purposes and another urine sample collected; protocol reportedly has high sensitivity and specificity, but urinary cortisol assay proprietary and not commercially available; accuracy of protocol using cortisol assays commercially available in United States not established, so method not recommended in North America.

ACTH Stimulation Test
• Response > normal consistent with diagnosis of spontaneous HAC, but cannot differentiate between PDH and AN.
• Overall sensitivity of test ~80%; for PDH, sensitivity ~87%; for HAC due to AN sensitivity ~61%.
• More specific in dogs than LDDST (only 15% chance of false-positive with nonadrenal illness).
• Only test that can diagnose iatrogenic HAC; diagnosis made with history of glucocorticoid exposure by any route, consistent clinical signs, and post-ACTH cortisol concentration < reference range.
• Cosyntropin (or tetracosactrin) recommended form; if using compounded ACTH, collect samples before and at 1h and 2h post ACTH administration so peak response not missed.

Differentiating Tests

High-Dose Dexamethasone Suppression Test (HDDST)
• Two responses consistent with PDH—suppression to <1.4 µg/dL at 4h and/or 8h post dexamethasone; or 4h and/or 8h post-dexamethasone samples <50% of baseline.
• If baseline values close to 1.4 µg/dL or suppression just at 50%, confirm presence of PDH by other means.
• Can *never* confirm presence of AN; if criteria for diagnosis of PDH not met, 50/50 chance patient has PDH or AN; since HDDST does not significantly increase ability to differentiate PDH from AN, endogenous ACTH (eACTH) and/or abdominal US used instead.

eACTH Concentration
• Requires only single blood sample, but inappropriate handling can lead to decreased eACTH concentrations due to degradation.
• In patients with PDH, eACTH concentration usually normal to increased; with AN, eACTH concentration < normal.
• If concentration increased, consistent with PDH, but due to episodic secretion of ACTH even in patients with PDH, low value does not always confirm AN.
• If eACTH concentration falls in gray zone, results not diagnostic.

IMAGING
• Abdominal radiographs—~40–50% of canine ANs seen; adrenal mineralization suspicious for AN.
• Thoracic radiographs indicated in patients with AN to check for metastases.
• US—useful for staging AN, but poor screening test (adrenal enlargement occurs with chronic nonadrenal illness, AN may be difficult to see with US); adrenal atrophy can be difficult to determine with US, but bilaterally enlarged adrenal glands consistent with PDH; vena caval invasion and metastasis may be present with AN.
• CT and MRI—can show pituitary macroadenomas and assess AN invasion into adjacent structures; follow-up and treatment recommendations (e.g., radiation therapy) may vary with tumor size.

DIAGNOSTIC PROCEDURES
Adrenal histopathology following adrenalectomy for AN often needed to differentiate benign vs. malignant tumor; biopsy prior to removal may result in complications.

PATHOLOGIC FINDINGS
• PDH—normal to enlarged pituitary and bilateral adrenocortical enlargement.
• Microscopically, pituitary adenoma, adenocarcinoma, or corticotroph hyperplasia of pars distalis or pars intermedia and adrenocortical hyperplasia.
• AN—variable-sized adrenal mass, atrophy of contralateral gland (rarely bilateral tumors), metastasis and invasion into vena cava with thrombosis possible.
• Microscopically, adrenocortical adenoma or carcinoma.

TREATMENT

APPROPRIATE HEALTH CARE
Dictated by severity of clinical signs, patient's overall condition, any complicating factors (e.g., DM, pulmonary thromboembolism).

CLIENT EDUCATION
• For medical therapy, lifelong therapy required.
• If adverse reaction to mitotane or trilostane occurs—discontinue drug, give dexamethisone, have veterinarian reevaluate next day; if no response noted in few hours, veterinarian should evaluate immediately.

SURGICAL CONSIDERATIONS
• Hypophysectomy—described, but limited availability.
• Bilateral adrenalectomy not used for treatment of PDH.
• Surgery treatment of choice in dogs with adrenocortical adenomas and carcinomas unless patient poor surgical candidate.
• Appropriate personnel and facilities required as adrenalectomy (especially with vena caval thrombi) is technically demanding and intensive postoperative management required.
• Surgery not curative, but long-term survival possible
• Medical control of HAC may be desirable prior to surgery.

MEDICATIONS

DRUG(S) OF CHOICE

Trilostane
• Trilostane (Vetoryl®) inhibits adrenocortical enzyme 3-β-hydroxysteroid dehydrogenase and maybe others, thereby suppressing production of progesterone and its end-products, including cortisol and aldosterone (less than cortisol); efficacy and survival time for treatment of PDH excellent.
• Initial dose 2–3 mg/kg PO q24h (in morning) or divided q12h with food; twice-daily dosing more expensive, but quicker resolution of clinical signs, fewer dose changes and monitoring tests; if q24h dosing elected and patient controlled during day but has more clinical signs at night, splitting daily dose ½ morning and ½ evening may improve clinical signs.
• Side effects include lethargy, decreased appetite, vomiting, diarrhea; sometimes occur within first few days of therapy and associated with gastrointestinal upset due to administration of oral medication; hypocortisolemia can also occur due to oversuppression of cortisol production and cause same clinical signs; rarely, idiosyncratic adrenal necrosis with hypocortisolemia and hypoaldosteronism, but less common with lower doses (as recommended above).
• Monitoring—primary goals to control clinical signs and avoid complications (especially hypocortisolemia); should include assessment of clinical signs (PU/PD, polyphagia, panting) and cortisol testing (see below) to ensure cortisol not suppressed excessively; obtaining detailed history and evidence of potential oversuppression of cortisol imperative.
• Historically, ACTH stimulation test used to monitor trilostane therapy, 4–6h post trilostane administration; 1 µg/kg cosyntropin IV effective for monitoring, but *not* for diagnosis (must use 5 µg/kg); ideal post-ACTH cortisol concentration 2–6 µg/dL, but must consider clinical signs; e.g., if patient clinically controlled with post-ACTH cortisol of 7.2 µg/dL, no need to increase dose; if clinical signs persist, dose increase recommended.

HYPERADRENOCORTICISM (CUSHING'S SYNDROME)—DOGS (CONTINUED)

• Studies show post-ACTH stimulation cortisol values do not always correlate well with clinical signs, measuring cortisol concentration before morning dose of trilostane may correlate better; assessing clinical signs imperative when using pre-pill cortisol concentration for monitoring; if patient showing signs of hypocortisolemia (vomiting, diarrhea, decreased appetite), must use ACTH stimulation test; data lacking on decision-making using pre-pill cortisol, but some guidelines: cortisol concentration used to confirm patient not cortisol deficient (<1.4-2 µg/dL), clinical signs used to determine whether dose adequate; if patient clinically controlled and cortisol 2–6 µg/dL, appropriate to continue current dose; if <2 µg/dL, perform ACTH stimulation test or decrease dose; if patient still clinical (PU/PD, polyphagic, panting) and pre-pill cortisol >6 µg/dL, safe to increase dose; in clinically uncontrolled patient, cortisol concentration 2–6 µg/dL is gray zone: probably safe to increase dose if pre-pill cortisol 5 µg/dL, but probably not at 2.5 µg/dL; perform ACTH stimulation test in this situation.
• Perform either ACTH stimulation test or pre-pill cortisol at 10–14 days, 30 days, and 90 days after each dose change; if at 10–14-day recheck any improvement seen, do not increase dose even if cortisol concentration above ideal; wait until 30-day recheck and change dose then if necessary, as effect of trilostane often increases between 2 and 4 weeks; assess renal profile, including electrolytes, at 14- or 30-day exam; once clinical condition and dose stabilized, perform pre-pill cortisol or ACTH stimulation test, and electrolyte panel, q3–6 months.
• If lethargy, decreased appetite, vomiting, or diarrhea occurs, ACTH stimulation test to confirm dog not hypocortisolemic (post-ACTH stimulation cortisol <2 µg/dL); if hypocortisolemia confirmed, assess electrolyte panel to ensure hyponatremia and hyperkalemia not present; discontinue trilostane until clinical signs of HAC recur and baseline and/or post-ACTH cortisol concentrations >5-6 µg/dL.
• If signs of hypocortisolemia more severe than mild lethargy, vomiting, decreased appetite, give dexamethasone 0.1 mg/kg/day PO/IV, then taper to lowest effective dose to control signs; if signs of HAC recur, taper dexamethasone and discontinue, then perform baseline cortisol and/or ACTH stimulation test interpreted as above; if dexamethasone unavailable and prednisone used instead, delay cortisol testing until at least 24h after last prednisone dose, as prednisone can cross-react with cortisol assay.
• If more severe signs occur, hospitalization with IV fluids, dexamethasone, and other supportive therapy necessary.
• Hypocortisolemia secondary to trilostane administration usually resolves within 48–72h of drug discontinuation, but temporary cortisol suppression of weeks to months and even permanent suppression can occur.
• Trilostane can be used to treat hypercortisolemia from AN and usually controls clinical signs; although mitotane theoretically preferred due to chemotherapeutic properties, no difference shown between survival of patients with AN treated with mitotane or trilostane.

Mitotane

• Mitotane (o,p′-DDD, Lysodren®) selectively destroys glucocorticoid-secreting cells of adrenal cortex; in patients with AN may destroy tumor cells as well as controlling cortisol secretion, but no difference in survival between dogs with AN receiving mitotane vs. trilostane.
• PDH—initial loading dose 40–50 mg/kg PO divided twice daily; evaluate efficacy with ACTH stimulation test after 8 days, or sooner if decreased appetite, vomiting, diarrhea, listlessness, decreased water intake (<60 mL/kg/day); target for both basal and post-ACTH cortisol concentration 1–5 µg/dL; continue induction with repeat testing as necessary until adequate response, then initiate maintenance therapy at 50 mg/kg/week PO divided in 2–3 doses; adjust dosage based on ACTH stimulation testing (to maintain basal and post-ACTH cortisol levels in ideal range); if serum cortisol concentration pre- or post-ACTH <1 µg/dL, measure electrolyte concentrations, stop administering mitotane, and give physiologic doses of prednisone (0.1 mg/kg PO q12h; do not give within 24h before ACTH stimulation test); cortisol secretion usually recovers in weeks to months but can take longer; once cortisol concentration in ideal range, discontinue prednisone and begin maintenance therapy; if dog was on maintenance therapy when became cortisol deficient, restart maintenance at 25% lower dose; if relapse occurs at any time on maintenance therapy (as indicated by cortisol levels above ideal range), dose adjustment required; if post-ACTH serum cortisol concentration 5–10 µg/dL, increase maintenance mitotane dose by 25% and reevaluate in 4 weeks; if post-ACTH serum cortisol concentration >10 µg/dL, repeat loading sequence for 5–7 days and repeat ACTH stimulation test; continue loading until cortisol concentration in ideal range, then reinitiate weekly maintenance dose at ~50% higher dose.
• AN—goal of mitotane to achieve low to nondetectable (<1 µg/dL) basal and post-ACTH cortisol concentrations; starting dose 50–75 mg/kg PO divided daily; perform ACTH stimulation test after 10–14 days of therapy to evaluate efficacy, sooner if decreased appetite, vomiting, diarrhea, lethargy, decreased water intake (<60 mL/kg/day); induction typically requires higher doses and longer duration than for treatment of PDH and dose should be increased by 50 mg/kg/day q10–14 days if control not achieved (based on ACTH stimulation test); if adverse effects develop, continue administration at highest tolerable dose; once control achieved, begin maintenance therapy at 75–100 mg/kg/week PO divided into 2–3 doses; if cortisol levels pre- and post-ACTH rise into normal resting range (1–5 µg/dL), increase maintenance dose by 50%; if cortisol levels rise above normal resting range pre- and post-ACTH, reload until control achieved and increase weekly maintenance dose ~50%; because goal of induction and maintenance is to create glucocorticoid insufficiency, prednisone should be administered at 0.2 mg/kg/day PO.
• Aldosterone deficiency possible from mitotane therapy; if it occurs, patient will likely have permanent complete adrenocortical insufficiency and treatment for hypoadrenocorticism should be initiated.

l-Deprenyl

• l-Deprenyl (selegiline hydrochloride); FDA approved for treatment of PDH; decreases pituitary ACTH secretion, thus decreasing serum cortisol concentration.
• Questionable efficacy; not currently recommended.

Ketoconazole

Ketoconazole (10 mg/kg PO q12h initially; up to 20 mg/kg PO q12h in some dogs) inhibits cortisol synthesis; no longer recommended (trilostane causes fewer side effects).

CONTRAINDICATIONS

• Do not use ketoconazole with trilostane therapy (increased potential for hypocortisolism)
• Monitor for hyperkalemia if concurrent angiotensin-converting enzyme inhibitor therapy.

PRECAUTIONS

• Side effects of trilostane include anorexia, lethargy, vomiting, diarrhea; usually mild and resolve with discontinuation and dose adjustment; Addisonian crisis and adrenocortical necrosis reported.
• Use trilostane and mitotane with caution in patients with renal insufficiency and hepatic disease; trilostane contraindicated in pregnancy.
• Side effects of mitotane mild in most dogs; include lethargy, anorexia, vomiting, diarrhea, ataxia, iatrogenic hypoadrenocorticism.
• Side effects more common in dogs with AN given high dose mitotane.
• In diabetic patients, insulin requirement can decrease with control of HAC.

(CONTINUED) HYPERADRENOCORTICISM (CUSHING'S SYNDROME)—DOGS

ALTERNATIVE DRUG(S)

Radiation therapy possible to treat pituitary macroadenomas. Treatment with trilostane or mitotane still usually required afterwards. ACTH levels may take several months to decrease and HAC controlled with drugs in interim.

FOLLOW-UP

PATIENT MONITORING

- Response to therapy—use periodic ACTH stimulation and/or cortisol testing to assess trilostane and mitotane efficacy (see above); once on maintenance mitotane therapy, test at 1, 3, and 6 months and q3–6 months thereafter or if clinical signs of HAC recur.
- Adequacy of any mitotane reloading period checked with ACTH stimulation test before higher maintenance dose initiated.
- Adequacy of trilostane dose alterations checked with ACTH stimulation test performed 4–6h after dosing.

PREVENTION/AVOIDANCE

For prevention of recurrence and hypocortisolemia, regular administration of medications with appropriate follow-up required.

POSSIBLE COMPLICATIONS

- Hypertension.
- Proteinuria.
- Recurrent infections.
- Urinary calculi (calcium oxalate).
- DM.
- Pulmonary thromboembolism.
- Neurologic signs secondary to pituitary macroadenoma.
- Hypoadrenocorticism secondary to treatment.

EXPECTED COURSE AND PROGNOSIS

- Untreated HAC—progressive disorder with survival of 6–18 months.
- Treated PDH—usually good prognosis; median survival time with mitotane or trilostane treatment ~2 years; at least 10% survive 4 years; dogs living >6 months tend to die of causes unrelated to HAC.
- Macroadenomas in animals with no or mild neurologic abnormalities have fair to good prognosis with radiation and medical therapy; in patients with significant neurologic abnormalities, prognosis poor to grave.
- Adrenal adenomas—usually good to excellent prognosis; small carcinomas (not metastasized) fair to good prognosis overall, good to excellent with surgical resection.
- Large carcinomas and AN with widespread metastasis—generally poor to fair prognosis, but impressive responses to high doses of mitotane occasionally seen.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Neurologic signs in dogs with pituitary tumors; glucose intolerance or concurrent DM; pulmonary thromboembolism; increased incidence of infections, especially UTI and skin; hypertension; proteinuria/glomerulopathy.

ABBREVIATIONS

- ACTH = adrenocorticotropic hormone.
- ALP = alkaline phosphatase.
- ALT = alanine aminotransferase.
- AN = adrenal neoplasia.
- DM = diabetes mellitus.
- eACTH = endogenous ACTH.
- HAC = hyperadrenocorticism.
- HDDST = high-dose dexamethasone-suppression test.
- LDDST = low-dose dexamethasone-suppression test.
- PDH = pituitary-dependent HAC.
- PU/PD = polyuria/polydipsia.
- UC : Cr = urine cortisol : creatinine.
- UTI = urinary tract infection.

HYPERCALCEMIA

BASICS

DEFINITION
- Serum total calcium >11.5 mg/dL (dogs).
- Serum total calcium >10.5 mg/dL (cats).
- Serum ionized calcium >1.45 mmol/L (dogs).
- Serum ionized calcium >1.4 mmol/L (cats).
- Hypercalcemia must be confirmed by demonstration of increased concentrations of *ionized* calcium.
- Total calcium concentrations and correction formulas do not accurately predict ionized calcium and their use is discouraged.

PATHOPHYSIOLOGY
- Control of calcium is complex, tightly regulated, and influenced by the actions of parathyroid hormone (PTH), vitamin D, and the interaction of these hormones with the gastrointestinal tract, bone, kidneys, and parathyroid glands.
- Derangement in the function of these can lead to hypercalcemia.
- Secretory products of some neoplastic cells can also disturb calcium homeostasis.

SYSTEMS AFFECTED
- Cardiovascular—hypertension and altered cardiac contractility.
- Gastrointestinal—reduced smooth muscle excitability and potentially altered gastrointestinal function.
- Neuromuscular—depressed skeletal muscle contractility causes weakness.
- Renal/urologic—high calcium concentrations are toxic to the renal tubules and can cause polyuria and polydipsia (PU/PD) and renal failure; can also lead to urolithiasis and associated lower urinary tract disease.

SIGNALMENT
- Dog and cat.
- Primary hyperparathyroidism in the keeshond and Siamese cats.
- Primary hyperparathyroidism and neoplasia are more likely in geriatric dogs.

SIGNS
General Comments
- Depend on the cause of hypercalcemia.
- Patients with underlying neoplasia, renal failure, or hypoadrenocorticism generally appear ill.
- Patients with primary hyperparathyroidism show mild clinical signs, if any.
- Signs become apparent when hypercalcemia is severe and chronic.

Historical Findings
- Many asymptomatic.
- PU/PD—most common in dogs.
- Lethargy—most common in cats.
- Anorexia.
- Vomiting.
- Constipation.
- Weakness.
- Stupor and coma—severe cases.
- Lower urinary tract signs (e.g., stranguria) in animals with secondary calcium-containing uroliths.

Physical Examination Findings
- Lymphadenomegaly or abdominal organomegaly (patients with lymphoma).
- Rectal or mammary masses.
- Fundic examination may reveal evidence for granulomatous disease.
- Unremarkable in dogs with primary hyperparathyroidism.
- Parathyroid gland adenoma may be palpable in cats with primary hyperparathyroidism, but can be confused with the thyroid gland.

CAUSES
- Neoplasia—lymphoma (most common in dogs, less common in cats), anal sac apocrine gland adenocarcinoma (dogs), multiple myeloma, lymphocytic leukemia, metastatic bone tumor, fibrosarcoma (cats), other carcinomas.
- Primary hyperparathyroidism.
- Renal failure (acute or chronic).
- Granulomatous diseases (blastomycosis, histoplasmosis, schistosomiasis).
- Hypoadrenocorticism.
- Vitamin D intoxication from ingestion of human psoriasis medication or cholecalciferol rodenticide, or from plant or food sources.
- Osteolytic diseases.
- Idiopathic (most common cause in cats).
- Laboratory error.
- Occasionally observed in cats with hyperthyroidism.

RISK FACTORS
- Keeshond breed (hyperparathyroidism).
- Renal failure.
- Neoplasia.
- Use of calcium supplements or calcium-containing intestinal phosphate binders.
- Use of calcitriol or other vitamin D preparations.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- History should include questions regarding exposure to exogenous vitamin D sources and any previous response to corticosteroids.
- History of waxing/waning illness suggests hypoadrenocorticism, renal failure, or emerging neoplasia.
- Complete lymph node, rectal, and abdominal palpation may raise index of suspicion for lymphoma or other neoplasia.
- Assessment of hydration status, renal palpation, and urinary history may point toward renal or lower urinary tract disease.

LABORATORY FINDINGS
Drugs That May Alter Laboratory Results
- Oxalate, citrate, and EDTA anticoagulants bind calcium and falsely lower calcium measurement.
- Thiazide diuretics can raise serum calcium concentrations.

Disorders That May Alter Laboratory Results
- Hemolysis and lipemia can falsely raise calcium concentrations.
- Hypoalbuminemia can lower total calcium concentration.

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Serum calcium—total calcium concentrations reflect the combination of protein-bound calcium, complexed calcium, and biologically active ionized calcium; elevations in total calcium should prompt clinicians to evaluate ionized calcium concentrations.
- Azotemia and urine specific gravity help to define degree of renal impairment.
- Serum phosphorus is usually low or low-normal in patients with primary hyperparathyroidism or hypercalcemia associated with malignancy.
- Hyperphosphatemia in the absence of azotemia suggests a nonparathyroid cause of hypercalcemia.
- Combination of hyperphosphatemia and azotemia is difficult to interpret because renal failure can be the cause or effect of hypercalcemia.
- Hyperkalemia and hyponatremia suggest hypoadrenocorticism.
- Hyperglobulinemia is associated with multiple myeloma.
- Cytopenias are seen in patients with myelophthisic disease.

OTHER LABORATORY TESTS
- Serum ionized calcium is high in patients with primary hyperparathyroidism or hypercalcemia associated with malignancy; usually normal or low in patients with hypercalcemia associated with renal failure.
- Serum PTH measurement—intact molecule and two-site assay methods have the greatest specificity; high-normal or high concentration suggests primary hyperparathyroidism; can be high in patients with chronic renal failure; low concentration makes neoplasia more likely; normal PTH concentrations do *not* exclude a diagnosis of primary hyperparathyroidism.
- Serum PTH-related peptide (PTH-rp) measurement is often high in patients with hypercalcemia associated with malignancy; lack of elevation in PTH-rp concentration does *not* exclude neoplasia as a possible cause of hypercalcemia.

• Serum Vitamin D assays are available at specific laboratories.
• Fecal PCR testing for schistosomiasis.

IMAGING
• Radiography is useful for assessing renal size and shape, urolithiasis, bone lysis, pulmonary infiltration, lymphadenomegaly, and occult neoplasia.
• Ultrasonography is valuable for assessing renal architecture, abdominal lymphadenomegaly, parathyroid tumors, and urolithiasis.

DIAGNOSTIC PROCEDURES
• Cytologic examination of fine-needle aspirate of lymph nodes, liver, spleen, anal glands, or other tumors or masses to diagnose neoplasia.
• Bone marrow aspirate or biopsy—to identify occult hematopoietic neoplasia.
• Adrenocorticotropic hormone (ACTH) stimulation testing to confirm hypoadrenocorticism.

TREATMENT
• Definitive treatment of hypercalcemia is achieved by identification and correction of the primary cause.
• Inpatient care may be necessary because of the deleterious effects of hypercalcemia and the need for fluid therapy (diuresis).
• Consider severe hypercalcemia (ionized calcium >2.2 mmol/L) a medical emergency.

MEDICATIONS
DRUG(S) OF CHOICE
• Normal saline—fluid of choice (sodium promotes calcium excretion).
• Diuretics (furosemide) and corticosteroids promote calciuresis.
• Pamidronate or other bisphosphonate drugs (e.g., alendronate) have been used successfully for treatment of hypercalcemia of various causes in dogs and cats.

CONTRAINDICATIONS
• Do not use glucocorticoids until the diagnosis of lymphoma or other round cell neoplasia is excluded; they can obfuscate the diagnosis; if hypoadrenocorticism is suspected, do not give glucocorticoids until after ACTH stimulation testing, or use dexamethasone, which will not interfere with the serum cortisol assay.
• Thiazide diuretics can cause calcium retention.
• Oral bisphosphonates can cause esophageal erosions and should be used with caution.

PRECAUTIONS
Do not give diuretics to a dehydrated patient.

POSSIBLE INTERACTIONS
Avoid the use of calcium or phosphorus-containing compounds; they can cause soft tissue mineralization in severely hypercalcemic and hyperphosphatemic patients.

ALTERNATIVE DRUG(S)
• Sodium bicarbonate (1–4 mEq/kg) may be useful in combination with other treatments when metabolic acidosis is present.
• Calcitonin may be useful in the treatment of hypervitaminosis D.
• Hemodialysis and peritoneal dialysis are alternative treatments for some causes of hypercalcemia, but cost and availability limit their use.
• Novel therapies like calcimimetic drugs may hold potential for certain causes of hypercalcemia such as idiopathic hypercalcemia or primary hyperparathyroidism; cost is currently a deterrent, as is lack of routine efficacy.
• Mithramycin has been used in severe hypercalcemic crises; avoid its use because of associated nephrotoxicity and hepatotoxicity.

FOLLOW-UP
PATIENT MONITORING
• Serum calcium every 12 hours (ionized calcium if possible).
• Renal function assessment—the first sign of tubular damage may be casts in the urine sediment.
• Must closely monitor urine output, particularly if oligo-anuric renal failure is present.
• Hydration status must be monitored; indicators of overhydration include increased bodyweight, chemosis, and edema (pulmonary or subcutaneous).

POSSIBLE COMPLICATIONS
• Irreversible renal failure.
• Soft tissue mineralization.

MISCELLANEOUS
ASSOCIATED CONDITIONS
Calcium-containing urolithiasis.

AGE-RELATED FACTORS
• Mild elevations in calcium and phosphorus may be normal in growing animals.
• Middle-aged and older dogs and cats are at increased risk for cancer.

PREGNANCY/FERTILITY/BREEDING
A fetus is at the same risk as the dam; do not alter treatment because of pregnancy.

SEE ALSO
• Acute Kidney Injury.
• Chronic Kidney Disease.
• Hyperparathyroidism.
• Lymphoma—Dogs.
• Paraneoplastic Syndromes.

ABBREVIATIONS
• ACTH = adrenocorticotropic hormone.
• PTH = parathyroid hormone.
• PTH-rp = parathyroid hormone–related peptide.
• PU/PD = polyuria/polydipsia.

HYPERCAPNIA

BASICS

DEFINITION
• An increase in the partial pressure of carbon dioxide in arterial blood ($PaCO_2$).
• Normal $PaCO_2$ values—35–45 mmHg.
• Hypercapnia is synonymous with hypercarbia.

PATHOPHYSIOLOGY
• CO_2—end product of aerobic cellular metabolism; considered the primary drive for ventilation by stimulation of central chemoreceptors in the medulla oblongata; carried in the blood in three forms: bicarbonate (65%), bound to hemoglobin (30%), and dissolved in plasma (5%; the source of $PaCO_2$ values); constantly being added to alveolar gas from the pulmonary circulation and removed by alveolar ventilation.
• Uncommonly encountered in nonanesthetized, clinically normal patient; result of alveolar hypoventilation.

SYSTEMS AFFECTED
• Cardiovascular—may result in endogenous catecholamine release, which may induce cardiac arrhythmias; may cause vasodilation leading to hypotension.
• Hemic/lymphatic/immune—may alter acid-base balance; acute increase results in production of excess hydrogen ions and decrease in pH (respiratory acidosis).
• Nervous—brain is primary affected organ; cerebral blood flow related to $PaCO_2$ in a linear fashion; hypercapnia results in increased cerebral blood flow and intracranial pressure; $PaCO_2$ >90 mmHg may lead to CO_2 narcosis and unconsciousness.

SIGNALMENT
Any breed, age, and sex of dog and cat.

SIGNS

Historical Findings
• Abnormal breathing pattern.
• Weakness—secondary to concurrent hypoxemia or primary neuromuscular disease.

Physical Examination Findings
• Anesthetized patients—usually no obvious signs; severe condition may lead to tachypnea, hypotension, and tachycardia.
• Hypoventilation owing to muscle weakness or neuropathy—weak respiratory efforts; decreased thoracic excursion; excessive abdominal effort; exaggerated movement of facial muscles during inspiration; possibly generalized weakness as a result of primary neuromuscular disorder (myasthenia gravis, polyradiculoneuropathy).
• Upper airway obstruction—marked, prolonged inspiratory efforts with variable expirations, depending on whether the obstruction is fixed (e.g., mass) or nonfixed (e.g., laryngeal paralysis); stertor or stridor common.
• Pleural effusion—may have shallow rapid respirations; may note a marked abdominal component; lung sounds decreased in ventral thorax.
• Pulmonary parenchymal disease—increased bronchovesicular sounds; crackles (edema, infection, contusions).

CAUSES
• Hypoventilation can result from anesthesia, muscular paralysis, upper airway obstruction, air or fluid in the pleural space, restriction in movement of the thoracic cage, diaphragmatic hernia, pulmonary parenchymal disease, drug therapy to control seizures, opioid and alpha-2 agonist use for analgesia, and CNS disease. Can occur in spontaneously breathing patients during inhalation anesthesia (isoflurane or sevoflurane).
• Increased inspired CO_2—rebreathing of expired gases because of accumulation of exhausted CO_2 absorbent in an anesthesia machine most common cause; also inadequate fresh gas flow in a non-rebreathing anesthesia circuit (e.g., Bain and Ayres T-Piece).
• Exogenous administration of sodium bicarbonate, which dissociates into CO_2, with inadequate ventilation.

RISK FACTORS
• Use of inhalation agent (isoflurane or sevoflurane) as sole anesthetic, since inhalation anesthetics are potent respiratory depressants.
• Use of opioid or alpha-2 agonist analgesia.
• Deep planes of inhalation anesthesia.
• Inadequate fresh flow of oxygen with non-rebreathing anesthesia circuits.
• Bronchial or alveolar disease.
• Upper airway obstruction.
• Pleural disease.
• Inadequate ventilation during administration of sodium bicarbonate.
• Severe cervical spinal cord compression.
• Severe lower motor neuron disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Conscious patient—hyperthermia; hypoxemia; head trauma.
• Anesthetized patient—hypoxemia.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results
N/A

Disorders That May Alter Laboratory Results
Air bubbles in the arterial blood sample and/or improper packaging of the arterial blood sample—falsely low $PaCO_2$ values after approximately 30 min.

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Arterial blood gas analysis—diagnosis determined from a blood sample collected in an anaerobic manner, as follows: use enough heparin to coat the needle and the inside of the syringe; obtain sample from femoral or dorsal pedal artery; place a rubber stopper on the needle or cover the hub of the syringe to prevent room air from entering the sample.
• Analyze sample within 15 minutes if left at room temperature; place sample on ice to extend time for safe and accurate analysis to 2–4 hours.
• Bedside or portable blood gas analyzers—several models available; make analysis more convenient.

IMAGING
Thoracic radiography—may reveal bronchial, alveolar, or pleural space disease. Cervical radiography can suggest a large airway obstruction.

DIAGNOSTIC PROCEDURES
• Upper airway endoscopy used to rule out laryngeal mass or paralysis.
• Alternative method of analysis—capnometer (see Figures 1 and 2).
• End-tidal gas ($PetCO_2$) is almost entirely alveolar gas and provides nearly the same value

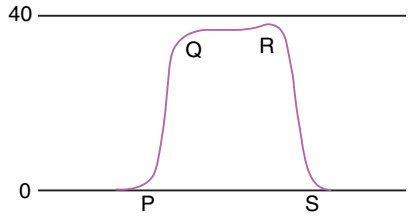

Figure 1.

Normal capnogram. The wave segment from P to Q is exhalation; Q to R is the plateau after exhalation; point R is the end tidal CO_2; R to S is inhalation.

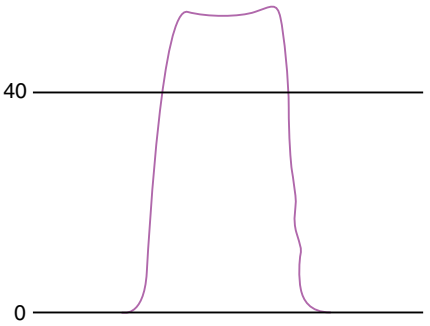

Figure 2.

Capnogram with hypercapnia. The plateau and end tidal CO_2 are above normal.

for CO_2 as $PaCO_2$, which closely approximates the mean value of perfused alveoli.
• Advantage of capnometry—can monitor $PaCO_2$ on a breath-by-breath basis, whereas a blood gas sample is a finite value at a finite time.
• Disadvantages—tachypnea and insufficient tidal volume will result in falsely low $PetCO_2$; $PaCO_2$ much higher than $PetCO_2$ with pulmonary thromboembolism; open thoracic cavity (surgery) reports falsely low $PetCO_2$ due to excessive dead space.

TREATMENT

• Provide adequate alveolar ventilation.
• Anesthesia—ventilation accomplished manually or mechanically with anesthesia ventilator.
• Nonanesthetized patient with severe pulmonary or CNS disease—mechanical ventilation with critical care ventilator; generally requires heavy sedation.
• Supplemental oxygen—need determined by primary disease; providing supplemental oxygen without providing ventilation will likely not correct hypercapnia.
• Definitive treatment—treat primary cause; discontinue inhalation anesthesia or provide ventilation during anesthesia; diagnostics for neuromuscular disease.

MEDICATIONS

DRUG(S) OF CHOICE

Respiratory stimulants not indicated and rarely reverse hypoventilation.

CONTRAINDICATIONS

Anesthetic drugs or other respiratory depressants—contraindicated with CNS disease if adequate ventilatory support cannot be provided; increased $PaCO_2$ may result in dangerous elevations of intracranial pressure and predispose patient to herniation of the brainstem.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

• Assess effectiveness of supportive therapy (ventilation) and definitive treatment—should result in decreased respiratory effort.
• Reevaluate arterial blood gas or capnometry—determine improvement; assess adequacy of ventilation.

POSSIBLE COMPLICATIONS

Concurrent CNS disease may cause high intracranial pressure and predispose the patient to herniation of the brainstem and death.

HYPERCHLOREMIA

BASICS

DEFINITION
Serum chloride concentration above reference interval (generally >122 mEq/L in dogs and >129 mEq/L in cats).

PATHOPHYSIOLOGY
- Chloride is the most abundant anion in extracellular fluid.
- Hyperchloremia is associated with free water loss or excessive NaCl intake (oral or parenteral).
- Serum chloride concentration varies inversely to bicarbonate concentration; high bicarbonate loss (i.e., vomiting or renal wasting) is followed by renal chloride resorption and hyperchloremia.

SYSTEMS AFFECTED
Relate to underlying cause.

SIGNALMENT
Species
Dog and cat.

SIGNS
General Comments
- Related to concurrent hypernatremia (i.e., free water loss) or underlying disorder, or both.
- Severity of neurologic signs related to degree of hypernatremia and rate of development.

Historical and Physical Examination Findings
- Polydipsia.
- Disorientation.
- Seizures.
- Coma.

CAUSES
High Total Body Chloride
- Oral ingestion (salt or salt water)—rare.
- NaCl (0.9% or hypertonic) or other chloride salts administered IV.

Normal Total Body Chloride with Water Deficit
- High urinary water loss (e.g., diabetes insipidus).
- Low intake (e.g., no access to water).
- Insensible water loss (e.g., panting).

Low Total Body Chloride with Hypotonic Fluid Loss
- Urinary loss—diabetes mellitus, hypoadrenocorticism, osmotic diuresis, postobstructive diuresis.
- Drugs that interfere with ability to concentrate urine—lithium, demeclocycline, and amphotericin.
- Drugs that cause renal chloride retention—acetazolamide, ammonium chloride, androgens, cholestyramine, and spironolactone.

Hyperchloremic Metabolic Acidosis
- Normal anion gap.
- Renal tubular acidosis—renal tubular disorders causing wasting of bicarbonate or low hydrogen ion secretion.
- Diarrhea causing gastrointestinal loss of bicarbonate and renal resorption of chloride.
- Chronic respiratory alkalosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Diabetes insipidus.
- Dehydration.
- Renal tubular acidosis.
- Diabetic ketoacidosis.
- Salt or salt water ingestion—rare.

LABORATORY FINDINGS
Drugs That May Alter Laboratory Results
A falsely high chloride concentration can occur with high serum concentrations of iodide or bromide (e.g., patients treated with potassium bromide) if ion-selective electrodes are used for measurement.

Disorders That May Alter Laboratory Results
Hemoglobin and bilirubin cause falsely high chloride readings if colorimetric tests are used. Lipemia may result in an artifactual hyperchloremia.

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Often coupled with hypernatremia.
- Diabetes insipidus—hyposthenuria, azotemia.
- Diabetic ketoacidosis—hyperglycemia, ketonemia, and ketonuria.
- Dehydration—urine specific gravity >1.030, prerenal azotemia.
- Renal tubular acidosis—metabolic acidosis in the presence of alkaline urine, hypokalemia, other causes of metabolic acidosis (e.g., azotemia, hyperlactatemia, ketonemia) not present.

OTHER LABORATORY TESTS
- Blood-gas analysis—metabolic acidosis, may have respiratory compensation.
- Anion gap—normal if primary hyperchloremia or bicarbonate loss.

IMAGING
CT or MRI in patients with diabetes insipidus to rule out pituitary tumor.

TREATMENT

APPROPRIATE HEALTH CARE
- If hyperchloremia and hypernatremia due to free water loss, administer free water either orally or IV (see below); target a sodium concentration decrease of 12 mEq/day; serum sodium concentration should be rechecked every 4–6 hours and fluids adjusted as necessary to maintain appropriate rate.
- If renal tubular acidosis, treat underlying cause (usually pyelonephritis).
- If renal or gastrointestinal bicarbonate loss, administration of $NaHCO_3$ can be considered.

MEDICATIONS

DRUG(S) OF CHOICE
- Sodium bicarbonate—calculate bicarbonate deficit (0.3 * bodyweight (kg) * [24 mEq – current [$HCO3^-$]]) and give ⅓–½ of this dose slowly IV.
- 5% dextrose in water—calculate free water deficit (see hypernatremia) and administer so that serum sodium does not decrease by more than 0.5 mEq/h (or 12 mEq/day).

PRECAUTIONS
- Rapid correction of hypernatremia can cause cerebral edema.
- Hypocalcemia may develop during correction of serum pH, in patients with borderline low serum ionized calcium concentrations.

FOLLOW-UP

PATIENT MONITORING
Electrolytes, bodyweight, and hydration status.

PREVENTION/AVOIDANCE
Animals should always have access to water.

POSSIBLE COMPLICATIONS
Rapid correction of hypernatremia can lead to cerebral edema.

EXPECTED COURSE AND PROGNOSIS
Vary with underlying cause.

HYPERCOAGULABILITY

BASICS

OVERVIEW

- Hypercoagulability (aka thrombophilia) is an imbalance between procoagulant and anticoagulant factors that favors thrombosis.
- Thrombus formation occurs in the presence of endothelial injury, altered blood flow, and/or hypercoagulability (Virchow's triad).
- Hypercoagulability may result from platelet hyperaggregability, increased amounts or activation of clotting factors, reduced or inhibited anticoagulant proteins, or defective fibrinolysis.
- Common sites of thrombosis—pulmonary arteries, distal aorta, cranial vena cava, intestinal/mesenteric vessels, portal vein.

SIGNALMENT

Depends on underlying condition.

SIGNS

- Hypercoagulability is symptomless; thrombosis causes site-dependent signs.
- Pulmonary thromboembolism (PTE)—acute severe dyspnea and tachypnea.
- Arterial thromboembolism (ATE)—acute paresis/paralysis, limb pain (ischemic myopathy), decreased pulse and cold limbs; onset in dogs may be gradual vs. peracute in cats.
- Portal vein or caudal vena cava thrombosis—ascites.

CAUSES & RISK FACTORS

- Immune-mediated hemolytic anemia (IMHA).
- Protein-losing nephropathy.
- Hypoproteinemia.
- Systemic inflammation.
- Neoplasia.
- Cardiac disease.
- Hyperadrenocorticism or corticosteroid therapy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- PTE may mimic pneumonia, pulmonary edema, dirofilariasis.
- Distal ATE—other causes of paraparesis and paraplegia (e.g., neurologic).

CBC/BIOCHEMISTRY/URINALYSIS

Reflect underlying disease or effects of thrombosis in specific organs. Animals with protein-losing nephropathy have proteinuria and elevated urine protein : creatinine ratio, possibly signs of nephrotic syndrome.

OTHER LABORATORY TESTS

- D-dimer—sensitive for fibrinolysis; thrombosis unlikely if normal; nonspecific for cause.
- Antithrombin (AT)—decreased activity increases risk of thrombosis.
- Prothrombin time (PT), activated partial thromboplastin time (APTT)—shortened clotting times are unreliable markers for thrombophilia.
- Thromboelastography, thromboelastometry, rotational thromboelastometry—can potentially identify hypercoagulability.
- Arterial blood gas, pulse oximetry—hypoxemia.

IMAGING

- Ultrasonography—confirm presence of arterial or venous thrombi.
- Echocardiography—identify cardiac disease, intracardiac thrombi, or spontaneous echocontrast ("smoke"); pulmonary hypertension associated with PTE.

DIAGNOSTIC PROCEDURES

- Angiography (standard or CT angiography).
- Nuclear perfusion scintigraphy—can support diagnosis of PTE.

TREATMENT

- Inpatient—supportive care, analgesia, anticoagulation.
- Supportive care—ensure hydration, maintain perfusion, minimize vascular stasis, correct and monitor acid-base and electrolyte abnormalities, use venous catheters appropriately.
- Oxygen therapy for hypoxemia.

MEDICATIONS

DRUG(S) OF CHOICE

Anticoagulants

- Unfractionated heparin for initial therapy, starting dose: 150–200 IU/kg SC q6-8h; titrate to achieve 1.5-fold increase in APTT; check APTT daily (4h post heparin dose).
- Low molecular weight heparin—enoxaparin: 1 mg/kg (1,000 U/kg) SC q6–12h; dalteparin: 150 mg/kg SC q 6–8h. Monitor anti-Xa activity.
- Rivaroxaban—0.5 mg/kg PO q24h for chronic therapy; no reversal agents available.
- Warfarin for chronic therapy, starting dose: 0.1–0.2 mg/kg PO q24h; adjust dose based on international normalized ratio.

Platelet Inhibition

- Clopidogrel—prophylaxis, prevents repeat thrombosis; dogs: 0.5–1 mg/kg PO q24h; cats: 18.75 mg PO q24h; more effective than aspirin in preventing recurrence of ATE in cats.
- Aspirin—prophylaxis, after thrombosis; dogs: 0.5–5.0 mg/kg PO q12–24h.

Thrombolysis

- Severe side effects possible. Reperfusion injury is common.
- Tissue plasminogen activator (tPA)—1 mg/kg incrementally IV once; most effective in first 3–6 hours after thromboembolism.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Do not treat with warfarin initially; overlap with heparin therapy for 2 days.
- Reassess coagulation with any medication changes.
- If bleeding occurs, discontinue and administer protamine or vitamin K and plasma as indicated to correct hemorrhage.

FOLLOW-UP

- Monitor patients for clinical signs or imaging evidence of resolution of thrombosis.
- Risk of future thromboembolic events.

MISCELLANEOUS

SEE ALSO

- Amyloidosis.
- Anemia, Immune-Mediated.
- Aortic Thromboembolism.
- Disseminated Intravascular Coagulation.
- Pulmonary Thromboembolism.

ABBREVIATIONS

- APTT = activated partial thromboplastin time.
- AT = antithrombin.
- ATE = arterial thromboembolism.
- IMHA = immune-mediated hemolytic anemia.
- PT = prothrombin time.
- PTE = pulmonary thromboembolism.
- tPA = tissue plasminogen activator.

Author John A. Christian
Consulting Editor Melinda S. Camus

HYPEREOSINOPHILIC SYNDROME (HES)

BASICS

OVERVIEW
- Idiopathic, persistent eosinophilia with infiltration of organs causing dysfunction, often leading to death.
- May be caused by a severe reaction to an unidentified antigen and/or dysregulation of immunologic control of eosinophilopoiesis.
- Organ damage caused by effects of eosinophil granule products and eosinophil-derived cytokines that are released in tissues from activated and/or necrotic cells.
- Common sites of infiltration: gastrointestinal (GI) tract (especially intestine and liver), spleen, bone marrow, lung (dogs), and lymph nodes (especially mesenteric).
- More common in cats than dogs.
- Unclear whether HES is a distinct entity from eosinophilic leukemia.
- Generally poor prognosis, especially cats.

SIGNALMENT
- Cats—occurs more frequently in female, middle-aged domestic shorthairs.
- Dogs—Rottweilers may be overrepresented.

SIGNS
- Lethargy.
- Anorexia.
- Intermittent vomiting and diarrhea.
- Hepatosplenomegaly.
- Weight loss.
- Thickened (diffuse or segmental) intestine that is often nonpainful.
- Lymphadenopathy (especially mesenteric).
- Dyspnea.
- Mass lesions caused by eosinophilic granulomatous inflammation and infiltration.
- Less frequently—fever, pruritus, seizures, thromboembolic events.

CAUSES & RISK FACTORS
- Unknown; probably severe reaction to unidentified antigen.
- Cats—eosinophilic enteritis may be early form.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Reactive eosinophilia—parasitism, allergic/hypersensitivity reactions, infectious disease, immune-mediated disease, fungal infections, neoplasia; with these conditions, eosinophilia usually limited in magnitude and remains confined to specific organ.
- Eosinophilic leukemia—differentiating criteria: eosinophilic leukemia tends to have immature eosinophils seen in higher numbers in circulation, constituting higher percentage of leukocyte differential; anemia more common and often more severe; myeloid : erythroid (M : E) ratio in bone marrow higher (>10 : 1) with more immature/blast forms and disorderly maturation; tissue infiltrates consist of immature eosinophils and may show sinusoidal pattern in liver without fibrosis; in cats, chloroma-like masses in kidneys are reported.

CBC/BIOCHEMISTRY/URINALYSIS
- Leukocytosis with marked eosinophilia, possibly with left shift in eosinophil series; mature eosinophil count from 5,000 to >130,000/μL.
- Basophilia.
- Mild anemia.
- With organ damage or dysfunction, associated abnormalities seen.

OTHER LABORATORY TESTS
Rule out identifiable etiologies—fecal flotation, heartworm test, biopsy.

IMAGING
- Organ enlargement/infiltration may be visualized with survey radiographs and/or ultrasound.
- Intestinal mucosal irregularities and thickening seen on ultrasound or contrast radiography.

DIAGNOSTIC PROCEDURES
- Bone marrow aspiration and/or core biopsy.
- Fine-needle aspirate or biopsy of affected tissues.

PATHOLOGIC FINDINGS
- Spleen—eosinophilic infiltrates in red pulp, sometimes white.
- GI tract—mucosal and submucosal eosinophilic infiltrates in small intestine, sometimes in colon and stomach.
- Bone marrow—hypercellularity, eosinophilic hyperplasia (up to 40% of all nucleated cells), unremarkable maturation and morphology with high M : E ratio (mean 7.27 : 1).
- Lymph nodes—reactive with eosinophilic infiltration.
- Other (less frequent)—eosinophilic infiltrates in skin, myocardium, body cavity effusions.

TREATMENT
- Eliminate identifiable primary disease.
- Address any specific organ dysfunction/failure.

MEDICATIONS

DRUG(S) OF CHOICE
- Corticosteroids—prednisone 1–2 mg/kg/day PO initially, then taper therapy if eosinophilia suppressed; if eosinophilia returns, resume higher daily dose.
- Imatinib mesylate approved in humans to treat chronic myelogenous leukemia as well as HES, used with possible efficacy in cats at 9.6 mg/kg PO q24h.
- Hydroxyurea—to reduce eosinophil count if not normal or near normal after 7–14 days of steroid treatment; used long term if effective in conjunction with steroids.
- Cyclosporine A—suppresses production of eosinophilopoietic factors by T cells.
- Vincristine and alkylating agents such as chlorambucil effective in humans.
- Reduce dosage or discontinue drugs if bone marrow suppression or thrombocytopenia develops.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Specific drug toxicities for each agent, most notably myelosuppression.
- Imatinib mesylate may lead to protein-losing nephropathy, although association uncertain.

FOLLOW-UP
- Serial CBC monitoring of eosinophil count (not always indicative of tissue infiltrates) and to detect myelosuppression if myelotoxic drugs used.
- Monitor clinical signs and any physical abnormalities.
- Other testing for specific organ function.

MISCELLANEOUS

HYPERESTROGENISM (ESTROGEN TOXICITY)

BASICS

OVERVIEW

• A syndrome characterized by high serum concentration of estrogen (estradiol, estriol, or estrone).
• Can occur secondary to endogenous estrogen secretion or exogenous administration of estrogens, such as diethylstilbestrol or estriol.
• Sites of endogenous estrogen production include ovarian follicles, follicular ovarian cysts, Leydig cells, and the adrenal cortex (zona fasciculata and reticularis); can also occur as a result of peripheral conversion of excessive androgens.
• Endogenous estrogens in females are responsible for normal sexual behavior and development and function of the reproductive tract; in the male, estrogens are responsible for Leydig cell function.
• In females, estrogens potentiate the stimulatory effect of progesterone in the endometrium and permit cervical relaxation; these two effects increase the risk of cystic endometrial hyperplasia and pyometra. In the male, estrogens potentiate the action of androgens in the prostate. Estrogens also increase osteoblastic activity, retention of calcium and phosphorus, total body protein, and metabolic rate.
• High serum concentration of estrogen provides a source of negative feedback in the hypothalamic-pituitary axis, suppressing gonadotropin secretion, and interferes with stem cell differentiation in the bone marrow and erythrocyte iron metabolism.

SIGNALMENT

Endogenous Hyperestrogenism

• Older male dog (secondary to functional testicular tumors).
• Older female dog (secondary to granulosa cell or other functional ovarian tumors, follicular ovarian cysts).
• Young female dog (follicular ovarian cysts).

Exogenous Hyperestrogenism

• All breeds, genders, and ages, associated with estrogen administration or exposure.
• Toy breed dogs are at increased risk for exposure to human transdermal hormone medications.

SIGNS

Historical Findings

• Attractive to intact male dogs.
• Infertility.
• Prolonged proestrus and estrus (female).
• Decreased libido (male).
• Nymphomania (female).
• Variable vulvar bleeding and enlargement, excessive vulvar licking.
• Epistaxis, hematuria (thrombocytopenia); lethargic, febrile (neutropenia); lethargic (anemia).

Physical Examination Findings

• Skin/endocrine—nonpruritic, symmetric alopecia (endocrine alopecia), hyperpigmentation.
• Reproductive (male)—palpable testicular mass, testicular asymmetry (tumor and/or atrophy), cryptorchidism (unilateral or bilateral), prostatomegaly (squamous metaplasia), gynecomastia.
• Reproductive (female)—vulvar edema and enlargement, vulvar discharge, gynecomastia mammary gland enlargement.
• Hemic/lymphatic/immune—pale mucous membranes, petechia, fever, lethargy (blood loss).

CAUSES & RISK FACTORS

• Follicular ovarian cysts.
• Functional ovarian tumor (granulosa cell tumor and other ovarian tumors).
• Testicular tumor (specifically Sertoli cell tumor, but also Leydig and interstitial cell tumors).
• Exogenous estrogen exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Nonpruritic, Symmetric Alopecia

• Hypothyroidism—diagnose on clinical signs, biochemistry, CBC, and thyroid function testing.
• Hyperadrenocorticism—diagnose on clinical signs (polyuria, polydipsia, exercise intolerance), CBC, serum biochemistry, specific testing (urine cortisol : creatinine ratio, adrenal function testing).
• Growth hormone–responsive dermatosis (breed risk: Pomeranian).

Attractive to Male Dogs

• Vaginitis, perivulvar dermatitis (differentiate from hyperestrogenism by lack of vaginal superficial epithelial cell predominance on vaginal cytology), lack of evidence of ovarian abnormalities, or confirmation of complete ovariohysterectomy or ovariectomy.
• Genitourinary tract infection, inflammation, foreign body, or neoplasia.

Infertility

• Testicular degeneration/atrophy/immune-mediated orchitis—diagnosis based on physical examination, lack of testicular or intra-abdominal masses, semen evaluation, and testicular biopsy or fine-needle aspirate.
• Intersex abnormalities—uncommon; diagnosis supported by abnormal external genitalia, abnormal karyotype, and histologic examination of the reproductive tract, when available.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC—variable; initially characterized by thrombocytopenia or thrombocytosis, progressive anemia, and leukocytosis (may exceed 100,000 white blood cells [WBCs]/µL); after 3 weeks, pancytopenia and aplastic anemia seen.
• Chemistry panel and urinalysis are usually unremarkable, but hematuria can be present with thrombocytopenia.

OTHER LABORATORY TESTS

• Serum estrogen (estradiol) concentrations—prolonged (>30 days) elevation at levels above baseline is responsible for clinical signs rather than the actual concentration; serum concentrations may be within normal limits, and accuracy of radioimmunoassay is variable.
• Vaginal and preputial cytology—extremely reliable as a bioassay for estrogen; under the influence of estrogen, cytology reveals a predominance of superficial epithelial cells that are anuclear or have pyknotic nuclei; preputial cytology with greater than 20% superficial cells is consistent with elevated serum estrogen.
• Evaluation for ovarian remnant syndrome (ORS)—anti-Müllerian hormone (AMH) testing: a positive test in a bitch >6 months of age or >30 days from ovariohysterectomy supports the presence of ovarian tissue; in cases with negative AMH but convincing clinical evidence supporting ORS, some investigators advise measurement of serum progesterone to identify persistent luteal structures lacking AMH; the AMH test will differentiate between ORS and exogenous estrogen exposure.
• The semi-quantitative luteinizing hormone (LH) assay (Zoetis), if elevated, suggests a lack of ovaries, but cannot differentiate exogenous vs. endogenous estrogen exposure if low.

IMAGING

• Thoracic radiography—to evaluate for metastatic neoplasia.
• Ultrasonography of the abdomen, inguinal canal, and testes—to assess for testicular masses, cystic or enlarged ovarian structures, intra-abdominal masses, lymphadenopathy, and prostatomegaly.
• Vaginoscopy to evaluate the vaginal mucosa; under the influence of estrogen, the vaginal mucosa should appear edematous and pink.

DIAGNOSTIC PROCEDURES

• Fine-needle aspiration of testicular masses—cytologic diagnosis prior to surgery.
• Percutaneous ultrasound-guided aspiration of large ovarian follicular cysts—rarely results in clinical resolution (cystic structure persists); hormone concentration can be measured in the cystic fluid.

HYPERESTROGENISM (ESTROGEN TOXICITY) (CONTINUED)

• Examination and aspiration/biopsy of local lymph nodes—for evaluation of metastatic disease (via ultrasound or surgical biopsy).
• Bone marrow aspirate or core biopsy—assess myelosuppression.
• Skin biopsy—may reveal nonspecific changes associated with endocrine alopecia such as orthokeratotic hyperkeratosis, epidermal atrophy and melanosis, follicular keratosis, predominance of telogen hair follicles, and sebaceous gland atrophy.

TREATMENT

• Treatment of choice in the intact or partially neutered female and male is surgical neutering; the prognosis is good if residual or malignant gonadal tissue can be completely removed.
• Unilateral orchiectomy or ovariectomy of the affected neoplastic testicle or cystic or neoplastic ovary may be considered in valuable breeding animals; use of testicular prosthetic devices is neither advised nor ethical; contralateral testicular changes (male) or endometrial changes (female) secondary to prolonged estrogen exposure can contribute to subfertility even if the abnormal gonad has been removed, with a guarded prognosis for fertility; histopathology should always be performed to evaluate for neoplasia and local lymphatic metastasis.
• Discontinue estrogen exposure in cases of exogenous hyperestrogenism; discontinue or reduce the dose of exogenous estrogen if used therapeutically; prognosis is good.

MEDICATIONS

DRUG(S) OF CHOICE

• Supportive care—including administration of appropriate antimicrobial therapy, IV fluids, and blood products to treat febrile neutropenia or anemia.
• Synthetic erythropoietin, darbopoietin, granulocyte colony-stimulating factor (G-CSF), granulocyte-macrophage colony-stimulating factor (GM-CSF)—may be considered to stimulate erythroid and granulocytic production at the level of the bone marrow; lithium has reportedly been of benefit in cases of estrogen-induced bone marrow aplasia.
• Gonadotropin-releasing hormone (GnRH)—unlikely to induce ovulation in cases of follicular cysts.
• Iron dextran to support erythrocyte regeneration—dog: 10–20 mg/kg (max 300 mg/dog) IM monthly PRN; cat: 10 mg/kg IM monthly PRN.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Chemotherapeutic agents for treatment of metastatic testicular or ovarian neoplasia should be used cautiously due to increased risk of bone marrow suppression. Consult with a veterinary oncologist.

FOLLOW-UP

• Serial CBC analysis to evaluate response to therapy and progression of disease.
• Serial bone marrow cytology—to evaluate bone marrow response and erythroid, myeloid, and megakaryocytic regeneration when myelosuppression is chronic; peripheral signs of regeneration may not occur for weeks to months after initial insult.
• Clinical signs of male feminization syndrome should resolve 2–6 weeks after testicular tumor removal.
• Lack of resolving pancytopenia and continued bone marrow hypoplasia 3 weeks after surgical removal of ovarian or testicular neoplasia or removal of follicular cysts is associated with a grave prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• ORS.
• Prostatomegaly.
• Cystic endometrial hyperplasia and subfertility/infertility.
• Hepatic insufficiency.
• Bone marrow aplasia, pancytopenia.
• Sepsis.

ABBREVIATIONS

• AMH = anti-Müllerian hormone.
• G-CSF = granulocyte colony-stimulating factor.
• GM-CSF = granulocyte-macrophage colony-stimulating factor.
• GnRH = gonadotropin-releasing hormone.
• LH = luteinizing hormone.
• ORS = ovarian remnant syndrome.
• WBC = white blood cell.

HYPERGLYCEMIA

BASICS

DEFINITION
- Blood glucose (BG) concentration above the reference interval: >130 mg/dL (>7 mmol/L).
- For cats >8 years of age, BG concentration >189 mg/dL (10.5 mmol/L).

PATHOPHYSIOLOGY
- Physiologic (stress hyperglycemia)—normal, transient response to stress, especially in cats.
- Laboratory or portable glucometer error—anemia results in artificially high BG concentration with some portable glucometers.
- IV infusion of dextrose-containing fluids.
- Drugs that inhibit insulin secretion (e.g., dexmedetomidine).
- Diabetes mellitus (DM)—absolute or relative insulin deficiency.

SYSTEMS AFFECTED
- Endocrine/metabolic—insulin deficiency causes disorders of carbohydrate, protein, and fat metabolism; insulin resistance occurs via various mechanisms.
- Renal/urologic—osmotic diuresis from BG exceeding renal threshold causes polyuria (PU) with secondary polydipsia.
- Pancreas/hepatobiliary—beta cell loss; endocrine hepatopathy, hepatomegaly.
- Ophthalmic—persistent hyperglycemia can cause cataracts in dogs.
- Nervous—severe hyperglycemia may cause CNS dehydration from high serum osmolality; diabetic neuropathy in cats causes hind limb weakness and plantigrade, ± palmigrade, gait; other neuropathies are also possible (e.g., Horner's syndrome).

GENETICS
Breed predispositions indicate likely genetic influences for DM in dogs and cats.

INCIDENCE/PREVALENCE
Prevalence of DM in hospital populations is 6 in 1,000 cats and 3 in 1,000 dogs.

SIGNALMENT

Species
Dog and cat.

Mean Age and Range
Onset of DM typically occurs after 5 years of age; highest prevalence from 8–12 years of age.

Predominant Sex
Neutered males (cats and dogs) and intact females (dogs) are predisposed to DM.

SIGNS

General Comments
- DM—signs have insidious onset over weeks to months.
- Animals with concurrent disease, such as pancreatitis, might not show "classic" signs of hyperglycemia.

Historical Findings
- Polydipsia and PU—PU might manifest as inappropriate urination or urinary incontinence.
- Weight loss with normal or increased appetite.
- Lethargy.
- Vision loss due to diabetic cataracts (dogs).
- Weak plantigrade gait due to diabetic neuropathy (cats).
- Previous overweight/obesity (especially cats and intact female dogs).
- Severe hyperglycemia can cause decreased mentation, coma.

Physical Examination Findings
- May be normal.
- Obese, normal, or underweight.
- Sarcopenia.
- Lethargy.
- Dehydration.
- Plantigrade ± palmigrade gait (cats).
- Cataracts (dogs).
- Hepatomegaly.
- Chronic infections—respiratory, skin, urinary tract.
- Poor hair coat.
- Ketotic or sweet odor to breath.
- Separation of incisors, broadening of the face, and organomegaly in cats with hypersomatotropism.

CAUSES
- DM—a heterogeneous group of diseases characterized by hyperglycemia resulting from inadequate insulin secretion, inadequate insulin action, or both.
- Inadequate insulin action (insulin resistance) is associated with hyperadrenocorticism, pheochromocytoma, glucagonoma, hypersomatotropism, hyper- and hypothyroidism, high progesterone during diestrus (dogs), and drugs (e.g., thiazide diuretics, progestogens [e.g., megestrol acetate], growth hormone, topical and systemic corticosteroids, and dexmedetomidine.
- Chronic hyperglycemia (glucose toxicity) can cause insulin resistance.

RISK FACTORS
- Breed predispositions for DM vary with geographic region.
- Older age.
- Obesity.
- Sedentary/indoor lifestyle.
- Stress.
- Concurrent disease, particularly hyperadrenocorticism, hypersomatotropism, pancreatitis.
- Diestrus in dogs.
- Diabetogenic drugs—corticosteroids, progestogens.
- Dextrose-containing fluids.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Stress hyperglycemia—differentiated from DM by documentation of persistent fasting hyperglycemia for more than 24 hours, or increased serum glycated protein concentrations.
- DM.
- Diagnosis of DM in cats:
  - Random (fasted or unfasted) BG ≥270 mg/dL (15 mmol/L) with clinical signs of hyperglycemia (with no other plausible cause) or hyperglycemic crisis *and* at least one of the following: increased serum glycated protein concentrations; glycosuria on more than one occasion on a voided sample acquired in a home environment at least 2 days after any stressful events.
  - Random (fasted or unfasted) BG between 130 and 270 mg/dL (7–15 mmol/L) *and* at least two of the following: clinical signs of hyperglycemia or hyperglycemic crisis; increased serum glycated protein concentrations; glycosuria on more than one occasion on a voided sample acquired in a home environment at least 2 days after any stressful events.
- Diagnosis of DM in dogs:
  - Fasted or unfasted BG ≥200 mg/dL (11 mmol/L) with clinical signs of hyperglycemia or hyperglycemic crisis.
  - Fasting BG 130–200 mg/dL (7–11 mmol/L) with or without clinical signs of hyperglycemia or hyperglycemic crisis.
- DM is likely when hyperglycemia occurs in combination with ketosis and/or ketonuria.

LABORATORY FINDINGS

Factors That May Alter Laboratory Results
- Delayed serum or plasma separation lowers glucose concentration; glucose concentration should be measured within 30 minutes of collection; whole blood samples collected in fluoride oxalate anticoagulant may be stored.
- Lipemia, hemolysis, and icterus may interfere with spectrophotometric assays.
- Glucometers intended for human use tend to underestimate the true BG in cats and dogs; wide variability in the accuracy of different meters necessitates correlation of results from each meter with results from a veterinary diagnostic laboratory prior to use.
- Veterinary-specific glucometers provide more accurate results than human glucometers.
- BG reagent strips require whole blood, must be stored correctly, and be in date.

CBC/BIOCHEMISTRY/URINALYSIS
- Hyperglycemia might be the only abnormal finding.
- For findings associated with DM, see specific chapters.

HYPERGLYCEMIA (CONTINUED)

OTHER LABORATORY TESTS
• Fructosamine concentration identifies degree of glycemia over the previous 2–3 weeks; results are assay dependent and may be affected by hemolysis or lipemia; provides no information on variability of BG concentrations.
• Glycosylated hemoglobin concentration identifies degree of glycemia over the previous 10 weeks (cats) or 16 weeks (dogs); provides no information on variability of BG concentrations.
• Adrenocorticotropic hormone (ACTH) stimulation test or low-dose dexamethasone-suppression test to diagnose hyperadrenocorticism in dogs; false-positive results might be obtained if there is poor diabetic control.
• Serum insulin-like growth factor 1 (IGF-1) assay to diagnose hypersomatotropism in cats; false-negative results are more likely when there is severe insulin deficiency; cats should be treated with insulin for 4–6 weeks prior to testing.

TREATMENT

APPROPRIATE HEALTH CARE
• Stress hyperglycemia is self-limiting.
• Diabetic cats and dogs that are eating well—outpatient management.
• Those that are unwell, inappetent, or have other signs such as vomiting require inpatient management with insulin and IV fluids.
• Concurrent disease can compromise DM management and should be promptly diagnosed and treated.

NURSING CARE
Glucose monitoring is recommended for all hospitalized hyperglycemic patients. Venous or capillary blood testing using a veterinary glucometer is appropriate. Real-time continuous glucose monitoring systems (CGMS) or flash glucose monitoring systems (FGMS) can simplify glucose monitoring of hospitalized patients.

ACTIVITY
Activity does not need to be limited in dogs and cats with DM and may decrease insulin requirement in working diabetic dogs.

DIET
• See relevant chapters on DM.
• Nutritional requirements for concurrent diseases take precedence over nutritional requirements for DM; good diabetic control can be achieved with insulin treatment regardless of diet.

CLIENT EDUCATION
• Client education is critical, because most treatment and monitoring of a diabetic patient will be done by the owner at home, and clinical signs will guide treatment decisions.
• Owner concerns relating to the impact that treating their pet will have on their lifestyle should be addressed.

SURGICAL CONSIDERATIONS
• Approximately 8% chance of diabetic remission following neutering and insulin therapy in female dogs; those that do not achieve remission generally have improved diabetic control.
• Improved diabetic control and possibly remission will occur following hypophysectomy in cats with hypersomatotropism; however, this treatment is expensive with limited availability.

MEDICATIONS

DRUG(S) OF CHOICE
• Exogenous insulin is the mainstay of treatment of DM.
• See chapters on DM.

PRECAUTIONS
• See chapters on DM.
• Drugs that cause insulin resistance (e.g., systemic or topical corticosteroids) should be used with caution in hyperglycemic animals; an increased insulin dose may be necessary.

POSSIBLE INTERACTIONS
Concurrent use of insulin and oral hypoglycemic agents might lead to hypoglycemia.

ALTERNATIVE DRUG(S)
• Glipizide and acarbose.
• See chapters on DM.

FOLLOW-UP

PATIENT MONITORING
• See chapters on DM.
• Animals in diabetic remission require ongoing monitoring for recurrence of hyperglycemia.

PREVENTION/AVOIDANCE
• Minimize use of diabetogenic drugs, particularly in susceptible individuals.
• Prevent obesity in cats and intact female dogs.
• Neuter female dogs at risk of developing DM.

POSSIBLE COMPLICATIONS
• Severe hyperglycemia may be associated with CNS depression and coma because of hyperosmolality.
• Diabetic cataracts (dogs).
• Diabetic neuropathy in cats with poor diabetic control.
• Insulin-induced hypoglycemia.

EXPECTED COURSE AND PROGNOSIS
• Transient stress hyperglycemia is self-limiting.
• Treatment of DM often is associated with an excellent prognosis, and typically results in a very good quality of life and similar life expectancy to animals without diabetes.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Hyperosmolality.
• Diabetic ketoacidosis.
• Hyperadrenocorticism.
• Hypersomatropism.
• Pancreatitis.

PREGNANCY/FERTILITY/BREEDING
• In intact bitches, a form of diabetes analogous to human gestational diabetes can occur during diestrus or pregnancy; if insulin therapy is initiated promptly, diabetic remission can sometimes be achieved following spay or whelping.
• Increased incidence of dystocia (large fetal size) and hypoglycemia in neonates when hyperglycemia has been present during pregnancy.

SYNONYMS
High blood sugar.

SEE ALSO
• Diabetes Mellitus with Ketoacidosis.
• Diabetes Mellitus Without Complication—Cats.
• Diabetes Mellitus Without Complication—Dogs.
• Hyperosmolality.

ABBREVIATIONS
• ACTH = adrenocorticotropic hormone.
• BG = blood glucose.
• CGMS = continuous glucose monitoring system.
• DM = diabetes mellitus.
• FGMS = flash glucose monitoring system.
• IGF-1 = insulin-like growth factor 1.
• PU = polyuria.

HYPERKALEMIA

BASICS

DEFINITION
Serum potassium concentration higher than the testing laboratory's upper limit of normal, generally >5.7 mEq/L (mmol/L).

PATHOPHYSIOLOGY
• Potassium is primarily intracellular; serum concentrations do not accurately reflect tissue concentrations. • Hyperkalemia is often associated with cellular injury (e.g., trauma and ischemia) and other causes of translocation of potassium out of the intracellular space (e.g., acidosis). • Potassium is eliminated in the kidneys and elimination is enhanced by aldosterone; conditions that inhibit renal elimination of potassium will cause hyperkalemia.

SYSTEMS AFFECTED
• Cardiovascular—potassium affects cardiac conduction, and changes are reflected on the ECG; as potassium rises, the T waves become tall and spiked with a narrow base, the QRS complexes widen, and the P–R intervals lengthen; the P waves become smaller and wider and, in animals with severe hyperkalemia, disappear (atrial standstill); higher concentrations of potassium cause fusion of the QRS–T, which causes a wide complex idioventricular bradyarrhythmia followed by ventricular fibrillation or asystole; ECG changes in animals with hyperkalemia vary and are diminished by hypernatremia, hypercalcemia, and alkalosis. • Nervous—neuromuscular weakness.

SIGNALMENT
• Dog and cat. • Pseudohyperkalemia in certain East Asian dog breeds (e.g., Akita, Shiba, Jindo, and Chinese Shar-Pei).

SIGNS
Historical Findings
• Weakness. • Collapse. • Stranguria, pollakiuria, pigmenturia (animals with urethral obstruction). • Flaccid paralysis. • Death.

Physical Examination Findings
• In addition to historical findings, arrhythmias, especially bradyarrhythmias. • Firm, nonexpressible urinary bladder, abdominal pain in animals with urethral obstruction. • Abdominal fluid wave, distended abdomen in patients with urinary bladder rupture.

CAUSES
• Pseudohyperkalemia—some blood cells (generally reported in red blood cells [RBCs] of East Asian dog breeds including Akita, Shiba, Jindo, and Chinese Shar-Pei; also platelets and white blood cells [WBCs] in any breed) contain high concentrations of potassium; if the blood sample is not analyzed or separated promptly, this intracellular potassium is released into the serum, causing the potassium concentration to be artificially high (pseudohyperkalemia); seen in patients with thrombocytosis or severe leukocytosis. • Low potassium elimination—anuric or oliguric renal failure; hypoadrenocorticism; renal hypoperfusion; urinary tract rupture or urethral obstruction; administration of potassium-sparing diuretics, angiotensin-converting enzyme (ACE) inhibitors, trimethoprim, nonsteroidal anti-inflammatory drugs, or heparin (causing hypoaldosteronism); some gastrointestinal diseases (e.g., salmonellosis, trichuriasis). • Translocation of potassium—metabolic acidosis, reperfusion syndrome, thrombolysis in feline aortic thromboembolism, tumor lysis syndrome, muscle injury (trauma, phosphofructokinase deficiency), digitalis overdose, infusion of mannitol and hyperglycemia (causing hyperosmolality). • High potassium intake—oral or parenteral potassium supplements or potassium bromide toxicosis. • Miscellaneous—third space fluid accumulation (e.g., pleural effusion, ascites).

RISK FACTORS
• IV fluid therapy with excessive potassium supplementation. • Administration of potassium-sparing diuretics (e.g., spironolactone) and ACE inhibitors (e.g., enalapril, benazepril), primarily in patients with renal disease. • Hypoadrenocorticism. • Trauma. • Renal disease. • Lower urinary tract disease including cystic calculi. • Thrombocytosis and leukemia. • Akita, Shiba, Jindo, and Chinese Shar-Pei—pseudohyperkalemia; not all animals within a breed are at risk for pseudohyperkalemia; approximately 20% of Akitas have the high potassium phenotype. • Phosphofructokinase deficiency.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Waxing and waning history of gastrointestinal complaints, weakness, collapse—consider hypoadrenocorticism. • Straining to urinate or low urine output—consider urinary obstruction or oliguric/anuric renal failure.

LABORATORY FINDINGS
Disorders That May Alter Laboratory Results
Thrombocytosis (>1,000,000 cells/mm^3), leukocytosis (>200,000 cells/mm^3), and abnormal (leukemic) leukocytes can cause release of large amounts of potassium into the serum.

CBC/BIOCHEMISTRY/URINALYSIS
• In patients with Na : K ratio <27, consider hypoadrenocorticism; some patients with metabolic acidosis due to diarrhea or renal tubular acidosis, ascites, chylothorax, or pregnancy may also have a low Na : K ratio. • In patients with azotemia, consider hypoadrenocorticism, anuric or oliguric renal failure, and ruptured or obstructed urinary tract. • In patients with high creatine kinase, aspartate aminotransferase, and lactic dehydrogenase, consider muscle injury. • In patients with severe thrombocytosis or leukocytosis or if the patient is an East Asian dog breed, consider pseudohyperkalemia.

OTHER LABORATORY TESTS
Adrenocorticotropic hormone (ACTH) stimulation test—patients with hypoadrenocorticism generally have undetectable (<0.2 µg/dL) baseline and poststimulation serum cortisol concentration.

IMAGING
• Radiographic contrast studies or ultrasound to rule out urinary tract rupture or obstruction. • Ultrasonography to evaluate urinary tract, adrenal gland size, presence of third-space fluid accumulation.

TREATMENT
• Varies, depending on the underlying cause of hyperkalemia. • Aggressiveness is dictated by patient's appearance and severity of ECG abnormalities. • Initiate supportive measures to lower potassium while pursuing definitive diagnosis. • Isotonic crystalloid fluids can be used to treat hypovolemia and will help decrease serum potassium; however, other treatments (see below) more rapidly decrease potassium concentration or blunt the effects on the heart; fluids can be administered in bolus doses of 20–30 mL/kg to effect; patients with primary cardiac disease or anuric renal failure may not tolerate large volumes of IV fluids (susceptible to volume overload). • Reduced potassium diet in animals with hyperkalemia secondary to chronic renal disease. • In patients with renal or postrenal oligo-anuria, urine flow must be restored emergently, either through relief of obstruction or restoration of urine production (see Urinary Tract Obstruction). • Hemodialysis may be necessary in patients with oligo-anuric renal failure.

MEDICATIONS

DRUG(S) OF CHOICE
• For patients with life-threatening hyperkalemia, administer calcium gluconate 10% (0.5–1 mL/kg slow IV over 10 min) while monitoring the ECG; calcium antagonizes the effect of potassium on cardiac conduction without lowering the serum potassium concentration. • To decrease serum potassium: ◦ Regular insulin (0.25–0.5 U/kg IV) with dextrose (0.5 g/kg IV) activates Na^+/K^+ ATPase to move potassium into cells; may require additional supplementation of dextrose (e.g., 2.5% dextrose added to IV fluids). ◦ Dextrose (0.5 g/kg IV) can be used without insulin for mild hyperkalemia. ◦ Sodium bicarbonate (1 mEq/kg slow IV) induces exchange of potassium for hydrogen ions, moving potassium into cells. ◦ Albuterol (1–2 puffs from inhaler) activates beta receptors and Na^+/K^+ ATPase to move potassium into cells.

HYPERKALEMIA (CONTINUED)

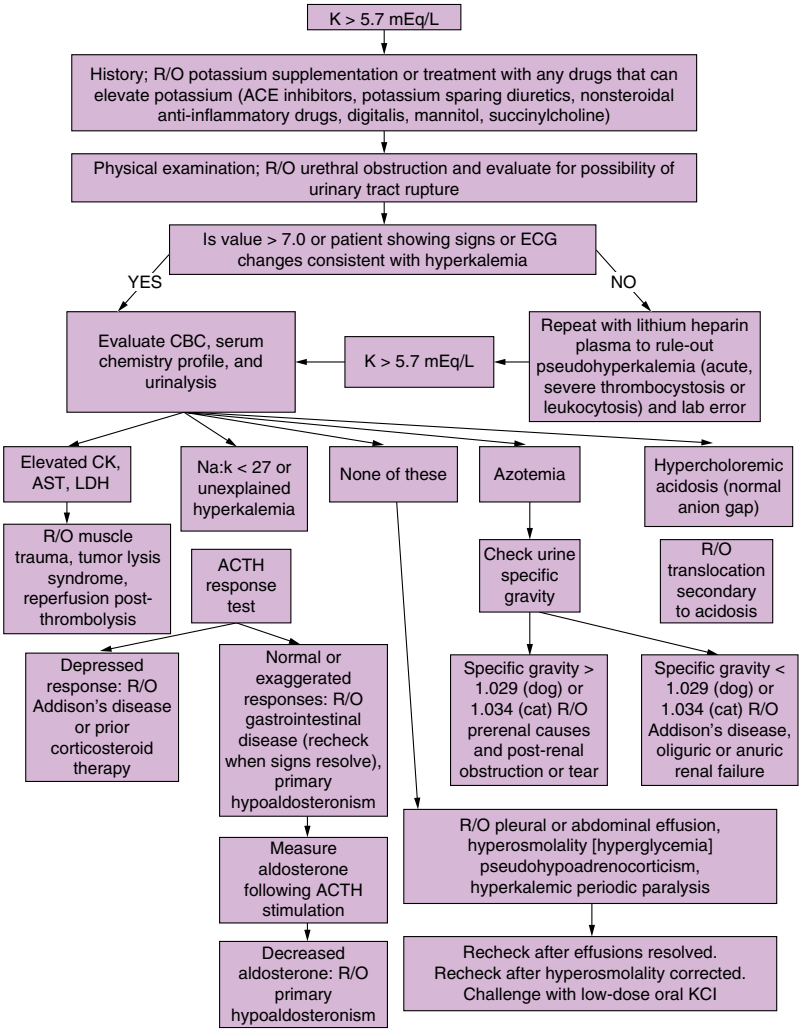

Figure 1.

Algorithm for diagnosing hyperkalemia.

CONTRAINDICATIONS

• Avoid IV fluids with high concentrations (>10 mEq/L) of potassium and fluids that cause hyponatremia, acidosis, or hypocalcemia. • Avoid drugs that contain potassium or interfere with potassium elimination (e.g., ACE inhibitors, trimethoprim antibiotics, potassium-sparing diuretics) or interfere with renal function (e.g., nonsteroidal anti-inflammatory drugs).

PRECAUTIONS

• Kayexalate and sodium bicarbonate cause a sodium load that may lead to fluid retention in patients with cardiac or renal failure. • Sodium bicarbonate lowers ionized calcium levels—use cautiously in hypocalcemic patients. • Sodium bicarbonate elevates blood carbon dioxide concentration—use cautiously in patients with hypoventilation.

ALTERNATIVE DRUG(S)

Patiromer and sodium zirconium cyclosilicate are recently approved agents that bind potassium within the intestinal tract, limiting absorption and reabsorption; rarely used in veterinary practice; may have application in chronic hyperkalemia.

FOLLOW-UP

PATIENT MONITORING

• Recheck potassium at frequency dictated by the underlying disease. • Continuous ECG monitoring until rhythm disturbances resolve.

PREVENTION/AVOIDANCE

• Monitor potassium in patients receiving drugs that alter potassium elimination. • The maximum rate of IV potassium administration is 0.5 mEq/kg/h, and should be used only in the face of severe hypokalemia (average supplementation rate is between 0.05 and 0.2 mEq/kg/h in patients without acute renal disease).

POSSIBLE COMPLICATIONS

• Prolonged hypoglycemia following insulin administration. • Death of animals with severe hyperkalemia.

MISCELLANEOUS

PREGNANCY/FERTILITY/BREEDING

Combined hyperkalemia and hyponatremia may be seen in pregnant dogs due to third-space fluid accumulation in the uterus.

SEE ALSO

• Acidosis, Metabolic. • Acute Kidney Injury. • Atrial Standstill. • Hypoadrenocorticism (Addison's Disease). • Phosphofructokinase Deficiency. • Urinary Tract Obstruction.

ABBREVIATIONS

• ACE = angiotensin-converting enzyme.
• ACTH = adrenocorticotropic hormone.
• RBC = red blood cell.
• WBC = white blood cell.

Consulting Editor Patty A. Lathan

HYPERLIPIDEMIA

BASICS

DEFINITION

- Increased concentration of lipid in the blood of a fasted (>12 hours) patient; includes hypercholesterolemia, hypertriglyceridemia, or both.
- Lipemia—serum or plasma separated from blood that contains an excess concentration of triglycerides (>200 mg/dL).
- Lactescence—opaque, milk-like appearance of serum or plasma that contains an even higher concentration of triglycerides (>1,000 mg/dL) than lipemic serum.

PATHOPHYSIOLOGY

Primary Hyperlipidemia

- Primary (idiopathic) hyperlipidemia—defect in lipid metabolism causing hypertriglyceridemia with or without hyperchylomicronemia; likely hereditary in miniature schnauzer, but the genetic defect has yet to be determined.
- Idiopathic hyperchylomicronemia in cats—familial, autosomal recessive defect in lipoprotein lipase activity.
- Primary hypercholesterolemia—occurs in some families of briard, rough collie, Shetland sheepdog, Doberman pinscher, and Rottweiler; low-density lipoprotein (LDL) cholesterol is high.

Secondary Hyperlipidemia

- Postprandial—absorption of chylomicrons from the gastrointestinal tract occurs 30–60 minutes after ingestion of a meal containing fat; may increase serum triglycerides for up to 12 hours.
- Diabetes mellitus—low lipoprotein lipase (LPL) activity; high synthesis of very-low-density lipoprotein (VLDL) by the liver.
- Hypothyroidism—low LPL activity and lipolytic activity by other hormones (e.g., catecholamines); reduced hepatic degradation of cholesterol to bile acids.
- Hyperadrenocorticism—increased synthesis of VLDL by the liver and low LPL activity causes both hypercholesterolemia and hypertriglyceridemia.
- Cholestatic liver disease—hypercholesterolemia caused by reduced excretion of cholesterol in the bile.
- Nephrotic syndrome—upregulation of common synthetic pathway for albumin and cholesterol and possibly low oncotic pressure lead to increased cholesterol synthesis.
- Pancreatitis—associated with hypertriglyceridemia in dogs, especially miniature schnauzers.
- Obesity—excessive hepatic synthesis of VLDL.

Drug-Induced Hyperlipidemia

- Glucocorticoids.
- Megestrol acetate (cat).

SYSTEMS AFFECTED

- Endocrine/metabolic.
- Gastrointestinal.
- Hepatobiliary.
- Nervous.
- Ophthalmic.

SIGNALMENT

- Dog and cat.
- Variable, depending on the cause.
- Hereditary hyperlipidemias—age of onset is >8 months in cats and >4 years in predisposed breeds of dog such as the miniature schnauzer.

SIGNS

Historical Findings

- Asymptomatic.
- Recent ingestion of a meal.
- Seizures, neurologic signs.
- Abdominal pain and distress.
- Neuropathies.

Physical Examination Findings

- Lipemia retinalis.
- Lipemic aqueous.
- Neuropathy.
- Cutaneous xanthomata.
- Lipid granulomas in abdominal organs.

CAUSES

Increased Absorption of Triglycerides or Cholesterol

Postprandial

Increased Production of Triglycerides or Cholesterol

- Idiopathic.
- Nephrotic syndrome.
- Pregnancy.
- Defects in lipid clearance enzymes or lipid carrier proteins.
- Idiopathic hyperchylomicronemia.
- Hyperchylomicronemia in cats.

Decreased Clearance of Triglycerides or Cholesterol

- Hypothyroidism.
- Hyperadrenocorticism.
- Diabetes mellitus.
- Pancreatitis.
- Cholestasis.

RISK FACTORS

- Obesity.
- High dietary intake of fats.
- Genetic predisposition in miniature schnauzer and Himalayan cat.
- Idiopathic hypercholesterolemia observed in families of briard, rough collie, Shetland sheepdog, Doberman pinscher, and Rottweiler.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Fasting Hyperlipidemia

Rule out postprandial lipemia with a 12-hour fast.

Primary Hyperlipoproteinemia

- Idiopathic hyperlipidemia is observed most commonly in the miniature schnauzer breed.
- Hyperchylomicronemia in cats often manifests as polyneuropathies and lipogranulomas.
- Idiopathic hypercholesterolemia is observed in a variety of breeds; animals are often asymptomatic.

Secondary Hyperlipidemia

- Diabetes mellitus.
- Hypothyroidism.
- Pancreatitis.
- Hyperadrenocorticism.
- Hepatic disease and cholestatic disorders.
- Nephrotic syndrome.

LABORATORY FINDINGS

Sample Handling

- Submit serum.
- Lipemia causes hemolysis if serum remains with red blood cells for a long time; inquire about the laboratory method of clearing lipemic samples before submission.
- Two samples may be submitted—one for biochemical analysis, which may be cleared, and one for triglycerides and cholesterol concentrations.

Drugs That May Alter Laboratory Results

- Corticosteroids.
- Phenytoin.
- Prochlorperazine.
- Thiazides.
- Phenothiazines.

Disorders That May Alter Laboratory Results

- Falsely high cholesterol.
- Nonfasted samples (<12 hours).
- Icterus—spectrophotometric techniques.
- Fluoride and oxalate anticoagulants—enzymatic techniques.
- Lipemia.

Valid If Run in Human Laboratory?

Yes

CBC/BIOCHEMISTRY/URINALYSIS

- Results of hemogram usually normal.
- High serum triglyceride concentration—dogs: >150 mg/dL; cats: >100 mg/dL.
- High serum cholesterol concentration—dogs: >300 mg/dL; cats: >200 mg/dL.
- Serum biochemistry may reveal abnormalities consistent with causes of secondary hyperlipidemia.

HYPERLIPIDEMIA (CONTINUED)

• Results of urinalysis often normal; proteinuria if nephrotic syndrome present.

OTHER LABORATORY TESTS

• High-density lipoprotein (HDL) and LDL determinations—used in human medicine; values reported for HDL and LDL in dogs and cats cannot be assumed to be reliable.
• Chylomicron test—obtain serum sample after a 12-hour fast and refrigerate for 12–14 hours; do not freeze; chylomicrons rise to the surface and form a creamy layer.
• Lipoprotein electrophoresis—separates LDL, VLDL, and HDL1 and HDL2 subfractions.
• LPL activity—collect serum for triglycerides and cholesterol concentrations and lipoprotein electrophoresis before and 15 minutes after administration of heparin (90 IU/kg, IV); if there is no change in values before and after heparin administration, a defective LPL enzyme system should be suspected.
• Definitive diagnostics for hypothyroidism or hyperadrenocorticism, if suspected.

TREATMENT

Diet should contain <10% fat (e.g., Royal Canin® Low Fat; Hill's Prescription Diet r/d®, w/d®, and i/d® Low Fat; Purina® OM).

MEDICATIONS

DRUG(S) OF CHOICE

Initial management is dietary; omega-3 fatty acids, fibrates, and then niacin are added to refractory cases.

ALTERNATIVE DRUG(S)

• Gemfibrozil 10 mg/kg PO q12h; cats and dogs.
• Bezafibrate 4–10 mg/kg PO q12h; dogs only.
• Fish oils—omega-3 polyunsaturated fat 50–300 mg/kg PO q24h; dogs only.
• Niacin 50–200 mg/dog/day PO (slow release); dogs only.

FOLLOW-UP

PATIENT MONITORING

• Keep serum triglyceride concentrations <500 mg/dL to avoid possibly fatal episodes of acute pancreatitis.
• Monitoring serum cholesterol concentrations often is not necessary because hypercholesterolemia is not associated with clinical signs.
• Monitor alanine aminotransferase (ALT) and alkaline phosphatase (ALP) enzyme activities when using a fibrate and/or niacin, as toxicity may occur.

POSSIBLE COMPLICATIONS

• Pancreatitis and seizures are common complications of hyperlipidemia in the miniature schnauzer.
• In cats with hereditary chylomicronemia, xanthoma formation, lipemia retinalis, and neuropathies have been reported; peripheral neuropathies usually resolve 2–3 months after institution of a low-fat diet.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Pancreatitis.
• Seizures.
• Neuropathies.

AGE-RELATED FACTORS

None

PREGNANCY/FERTILITY/BREEDING

Potential cause of high cholesterol.

SYNONYMS

• Lipemia—turbid serum or plasma secondary to significant hypertriglyceridemia.
• Hyperlipoproteinemia—increased blood concentration of lipoproteins.

SEE ALSO

ABBREVIATIONS

• ALP = alkaline phosphatase.
• ALT = alanine aminotransferase.
• HDL = high-density lipoprotein.
• LDL = low-density lipoprotein.
• LPL = lipoprotein lipase.
• VLDL = very-low-density lipoprotein.

HYPERMAGNESEMIA

BASICS

DEFINITION
• Dogs—serum magnesium >2.51 mg/dL; ionized magnesium >0.58 mmol/L.
• Cats—serum magnesium >2.99 mg/dL; ionized magnesium >0.65 mmol/L.

PATHOPHYSIOLOGY
• Hypermagnesemia is less clinically significant than low total body magnesium in veterinary patients.
• Magnesium is second only to potassium as the most abundant intracellular cation. Found primarily in bone and muscle, it is required for many metabolic functions.
• Serum magnesium is present in three forms—protein-bound form (approximately 25–30%) and chelated and ionized forms (together account for 70–75%).
• Magnesium absorption occurs primarily in the ileum, but also in the jejunum and colon.
• Magnesium is an important cofactor in the sodium-potassium ATPase pump that maintains electrical gradients across membranes.
• Interference with the electrical gradient can change resting membrane potentials; repolarization disturbances result in neuromuscular and cardiac abnormalities.
• The kidneys maintain magnesium balance with 10–15% reabsorbed in the proximal tubule, 60–70% in the thick ascending limb of the loop of Henle, and 10–15% reabsorbed in the distal convoluted tubule. Reabsorption within the distal convoluted tubule is under hormonal and neurohormonal control and determines the final urine concentration of magnesium.
• Any condition that severely lowers the glomerular filtration rate can elicit hypermagnesemia because magnesium homeostasis is largely controlled by renal elimination.
• Clinically significant hypermagnesemia is more commonly associated with acute kidney injury, and the degree of hypermagnesemia is proportional to the severity of renal failure.
• Exuberant supplementation of magnesium can lead to iatrogenic hypermagnesemia, especially in patients with decreased renal function.
• High magnesium concentration impairs transmission of nerve impulses and decreases postsynaptic responses at the neuromuscular junction. When magnesium was given to anesthetized dogs at 0.12 mEq/kg/min, cardiovascular effects were not noted until plasma levels exceeded 12.2 mEq/L. The total dose of magnesium required to reach that level was 1–2 mEq/kg. It took cumulative doses of 5.9–10.9 mEq/kg to cause fatal cardiac arrhythmias (ventricular fibrillation).
• Magnesium has been called nature's calcium blocker; the most serious complications of hypermagnesemia result from calcium antagonism in the cardiac conduction system.

SYSTEMS AFFECTED
• Cardiovascular.
• Musculoskeletal.
• Nervous.

INCIDENCE/PREVALENCE
Increased plasma ionized magnesium concentration was found in 2% of 9,950 canine submissions to a clinical laboratory. In that study, 40% of the cases were caused by azotemia, 19% were iatrogenic, 11% had tissue damage, and 6% had endocrine disease. In another study, hypermagnesemia was found in 18% of hospitalized cats and 13% of hospitalized dogs. Most of these patients also had renal insufficiency or postrenal azotemia.

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
Species
Dog and cat.

Breed Predilections
N/A

SIGNS
General Comments
• Usually caused by renal failure; clinical signs might be referable to azotemia and renal insufficiency. Clinical hypermagnesemia is reported most often in patients with preexisting renal disease that are oversupplemented with parenteral magnesium salts.
• Characterized by progressive loss of neuromuscular, respiratory, and cardiovascular function.

Historical and Physical Examination Findings
• Nausea, vomiting, weakness, bradycardia, flaccid paralysis, mental depression, and hyporeflexia (including menace and palpebral reflex).
• Hypotension and ECG changes, including delayed intraventricular conduction and prolonged QT interval.
• Atrioventricular block, respiratory depression, coma, and cardiac arrest have been observed in humans with serum magnesium concentrations >16 mg/dL.

CAUSES
• Renal failure.
• Intestinal hypomotility disorders and constipation.
• Endocrine disorders including hypoadrenocorticism, hypothyroidism, and hyperparathyroidism.
• Combined angiotensin-converting enzyme inhibitors and spironolactone administration.
• Excessive magnesium administration from magnesium-containing cathartic solutions given in conjunction with activated charcoal, magnesium-containing laxatives, and excess magnesium in peritoneal dialysis solutions.
• Iatrogenic oversupplementation, especially in patients with concurrent renal disease.

RISK FACTORS
• Dehydration.
• Renal disease.
• Intestinal hypomotility.
• Massive hemolysis.
• Hypoadrenocorticism.
• Hyperparathyroidism.
• Hypothyroidism.
• Patients receiving angiotensin-converting enzyme inhibitors and spironolactone concurrently.
• Excessive use of magnesium-containing cathartic solutions, especially in patients with renal insufficiency.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Signs are most similar to those of hypocalcemia, which often occurs simultaneously.
• Bradycardia can be caused by neurologic disease, hyperkalemia, hypertension, hypothyroidism, sick sinus syndrome, and various drugs.

LABORATORY FINDINGS
Note: 12 mg of magnesium = 1 mEq of magnesium; to convert from mg/dL to mEq/L, divide by 1.2.

Drugs That May Alter Laboratory Results
• Serum is favored over plasma because the anticoagulant used for plasma samples can contain citrate or other ions that bind magnesium.
• EDTA, sodium fluoride-oxalate, sodium citrate, and intravenous calcium gluconate can cause falsely low serum magnesium values.

Disorders That May Alter Laboratory Results
• Hemolysis can result in falsely increased serum magnesium; the magnesium concentration in erythrocytes is approximately three times that in serum.
• Storage of serum or urine in metal containers can falsely elevate magnesium values.
• Hyperbilirubinemia can cause falsely decreased serum magnesium.

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
• Serum magnesium—dogs: >2.5 mg/dL; cats: >2.99 mg/dL.
• Hypocalcemia is common.
• Azotemia in some patients.

HYPERMAGNESEMIA (CONTINUED)

OTHER LABORATORY TESTS
- Ionized magnesium can be measured with an ion-selective electrode or by ultrafiltration of plasma; alternative methods of evaluating magnesium status include mononuclear blood cell magnesium levels or quantifying retention from a loading dose.
- Ionized hypermagnesemia is characterized as >0.58 mmol/L in dogs and >0.65 mmol/L in cats, but may vary slightly with the analyzer.

DIAGNOSTIC PROCEDURES
- Electrodiagnostics (e.g., electromyelography and electrocardiography) reveal effects of hypermagnesemia but do not differentiate the cause.
- Though not described in critically ill veterinary patients, hypermagnesemia can cause prolonged PR intervals and QRS duration in humans.

TREATMENT

APPROPRIATE HEALTH CARE
- Management involves enhancing elimination from the body and symptomatic therapy.
- Discontinue all magnesium-containing medications and nutritional supplements.
- Saline diuresis and loop diuretics enhance renal clearance of magnesium.
- Fluid therapy with 0.9% NaCl provides fluid volume to address hypovolemia, hypotension, and azotemia.
- Patients with oliguria might require peritoneal dialysis to treat severe hypermagnesemia.
- Parenteral calcium supplementation directly antagonizes the effects of magnesium, reversing respiratory depression, cardiac arrhythmias, and hypotension; calcium also enhances magnesium excretion.
- Hypermagnesemia associated with combined angiotensin-converting enzyme inhibitors and spironolactone is rare, mild, and unlikely to be clinically significant.
- Physostigmine, an anticholinesterase, can be used to treat severe neurotoxic effects.

NURSING CARE
Patients with neurologic manifestations of hypermagnesemia might require intensive nursing care to prevent aspiration pneumonitis, pulmonary atelectasis, pressure necrosis (bed sores), and urine and fecal scalding.

ACTIVITY
Patient activity is dependent on underlying conditions and response to therapy.

DIET
Any magnesium supplementation should be discontinued.

CLIENT EDUCATION
Clients should be advised if preexisting conditions contributed to hypermagnesemia.

MEDICATIONS

DRUG(S) OF CHOICE
- Furosemide promotes renal excretion of magnesium by decreasing absorption of magnesium in the loop of Henle.
- Enteral and parenteral calcium administration helps reverse clinical manifestations of hypermagnesemia and correct concurrent hypocalcemia; oral supplementation with any preparation can be given at a dosage of 25–50 mg/kg/day; severe hypermagnesemia can be treated with 10% calcium gluconate: 1–2 mL/kg (diluted 1 : 1 with saline) IV or SC q8h, administered slowly (may cause bradycardia).

CONTRAINDICATIONS
Magnesium-containing compounds and fluids.

PRECAUTIONS
Monitor ECG during calcium infusion.

FOLLOW-UP

PATIENT MONITORING
- Serum magnesium and calcium concentrations.
- Renal function—azotemia and urine output.
- Continuous ECG if possible.

PREVENTION/AVOIDANCE
Magnesium supplementation should be approached cautiously in patients with renal insufficiency.

POSSIBLE COMPLICATIONS
- Severe hypermagnesemia and hypocalcemia can be fatal.
- Hypermagnesemic dogs were 2.6 times less likely to survive their illness than patients with normal serum magnesium levels.

EXPECTED COURSE AND PROGNOSIS
- Veterinary patients with iatrogenic overdose can have a good outcome with prompt recognition and supportive care.
- Increased ionized magnesium is rare and indicative of severe disease in noniatrogenic cases, particularly patients with acute renal disease, and can be associated with increased mortality.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Hypocalcemia.
- Hyperphosphatemia.
- Azotemia.

PREGNANCY/FERTILITY/BREEDING
Effects on the fetus are identical to effects on the dam.

HYPERMETRIA AND DYSMETRIA

BASICS

DEFINITION
- Dysmetria—incoordination of the limbs during voluntary movement because of an inability to judge the rate, range, and force of movements.
- Hypermetria—overreaching limb movements giving a characteristic goose-stepping gait; the term dysmetria includes both hypo- and hypermetria.

PATHOPHYSIOLOGY
- The cerebellum plays a central role in generating skilled movements and maintaining muscle tone and body posture; it does not initiate but coordinates and smoothes movements.
- Damage to the cerebellum results in inaccurate gauging of voluntary movements; motor strength is preserved; conscious proprioception is unaffected.
- Rarely, compression of the spinocerebellar tracts in spinal cord disorders can produce dysmetria; this is more likely to occur with dorsally located lesions.

SYSTEMS AFFECTED
Nervous system.

GENETICS
- The hereditary ataxias are an important group of diseases in which cerebellar degenerations causes dysmetria and hypermetria in dogs.
- The majority of breed-related hereditary ataxias are autosomal recessive, highly penetrant traits.
- An X–linked hereditary ataxia has been described in pointers.
- Lysosomal storage diseases are genetic disorders, typically autosomal recessive in both dogs and cats.
- Immune-mediated encephalitis likely has a hereditary component—the mode of inheritance has not been described but is complex.

INCIDENCE/PREVALENCE
The incidence and prevalence of this presenting problem have not been reported.

GEOGRAPHIC DISTRIBUTION
There are no data on geographic distribution.

SIGNALMENT
Dog and cat of any age, breed, or sex.

SIGNS
Other signs of cerebellar disease that may be present include truncal sway, intention tremor, wide-based stance, head tilt, opsoclonus, spontaneous nystagmus, loss of menace response with normal vision, and anisocoria.

CAUSES

Cerebellar
- Dogs—hypoplasia (inherited or secondary to infection with canine herpesvirus in the perinatal period); hereditary ataxia (cerebellar abiotrophy or cerebellar cortical degeneration); lysosomal storage diseases; canine distemper virus (CDV); protozoal infections (*Neospora caninum* is most common, *Toxoplasma gondii* is possible but rare); rickettsial infections (*Ehrlichia canis* and Rocky Mountain spotted fever); *Cryptococcus* and other fungal infections; granulomatous meningoencephalitis; meningoencephalitis of unknown etiology; steroid-responsive tremor syndrome; neoplasia; trauma; infarct; hemorrhage; metronidazole toxicity.
- Cats—hypoplasia secondary to in utero infection with feline panleukopenia virus; lysosomal storage diseases; feline infectious peritonitis (FIP), feline leukemia virus (FeLV), feline immunodeficiency virus (FIV; associated immunosuppression predisposes to other encephalitides and to neoplasia); protozoal infections (*Toxoplasma gondii*); *Cryptococcus* and other fungal infections; neoplasia; hemorrhage; trauma.

Spinal
- While there are many causes of spinal cord disease, centro-dorsally located cervical lesions are more likely to produce hypermetria.
- Dogs—subarachnoid diverticula; neoplasia; vertebral malformation (atlantoaxial subluxation); and calcinosis circumscripta.

RISK FACTORS

Cerebellar
- Hereditary ataxia reported in Gordon and Irish setters, Kerry blue terriers, Airedale terriers, Finnish harriers and hounds, Samoyeds, Bern running dogs, cocker spaniels, Cairn terriers, Australian kelpies, bull mastiffs, Italian spinones, the terrier group, Lagotto-Romangolos, Old English sheepdogs, Rhodesian ridgebacks, border and rough-coated collies, Brittany spaniels, beagles, and Scottish terriers.
- Cerebellar hypoplasia has been reported in chow chows, Irish setters, and wire fox terriers.
- Lysosomal storage diseases causing dysmetria have been reported in Siamese, Balinese, Persian, and domestic shorthair cats, and in English springer spaniels, American Staffordshire terriers, Portuguese water dogs, German shorthaired pointers, Australian silky terriers, schipperkes, English setters, border collies, salukis, Chihuahuas, Queensland blue heelers, dachshunds, Yugoslavian shepherds, and Tibetan terriers.
- Small-breed dogs, such as Maltese, Yorkshire and West Highland white terriers, miniature pinschers, and Chihuahuas, are predisposed to immune-mediated encephalitis, including meningoencephalitis of unknown etiology and steroid-responsive tremor syndrome.
- Metronidazole at dosages >60 mg/kg/day can induce cerebello-vestibular signs in dogs; signs are induced in some dogs at lower doses.
- Vascular events, both thromboembolic and hemorrhagic, can cause cerebellar signs, typically due to thrombosis of the rostral cerebellar artery; disorders that cause a hypercoagulable state (such as hyperadrenocorticism) or hypertension (such as hyperthyroidism in cats, or chronic renal disease) can predispose to stroke; hypothyroidism has also been associated with cerebellar stroke; thrombosis of the rostral cerebellar artery occurs in older dogs—an underlying cause is not always identified.

Spinal
- Giant-breed dogs are predisposed to vertebral malformation.
- Toy-breed dogs are predisposed to atlanto-axial instability.
- Young large-breed dogs are predisposed to subarachnoid diverticula and calcinosis circumscripta.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Some dogs, especially small breeds, have a high-stepping gait in their thoracic limbs as a normal finding. If there are no other signs of cerebellar disease, establish with the owners whether a high-stepping thoracic limb gait is normal for the dog.

CBC/BIOCHEMISTRY/URINALYSIS
- CBC may reflect infectious/inflammatory disease.
- Storage products may be present in leukocytes in some lysosomal storage diseases.

OTHER LABORATORY TESTS
- Acute and convalescent serologic titers—to diagnose rickettsial, protozoal, fungal, and viral diseases.
- Cerebrospinal fluid (CSF) antibody or antigen (*Cryptococcus*) titers—for some infections (e.g., *Toxoplasma, Cryptococcus*), measure in addition to serologic titers.
- PCR on CSF and serum—to diagnose rickettsial, bacterial, protozoal, fungal, and viral diseases; sensitive and specific if the infectious agent is present in the CSF or serum.
- Genetic tests available for hereditary ataxia in beagles, Finnish hounds, Italian spinones, Gordon setters, Old English sheepdogs, Lagotto-Romangolos, and the terrier group (Jack and Parson Russell terriers).

IMAGING
- Thoracic radiography—to identify metastatic disease in older patients.
- Abdominal ultrasonography—if intra-abdominal neoplasia is suspected.
- Brain CT or MRI—to diagnose neoplasia, vascular disease, encephalitis, cerebellar atrophy due to hypoplasia or abiotrophy; MRI is the preferred modality for evaluating the caudal fossa.

HYPERMETRIA AND DYSMETRIA (CONTINUED)

• Survey spinal radiography—if spinal cord disease is suspected; may be helpful in identifying vertebral malformations and calcinosis circumscripta.
• Spinal MRI—noninvasive and informative about spinal cord parenchyma.

DIAGNOSTIC PROCEDURES

• Fundic examination—to identify chorioretinitis (evidence of infectious/inflammatory disease) and vascular lesions associated with vasculitis or hypertension.
• CSF—to diagnose encephalitis; storage products may be present in CSF leukocytes in some lysosomal storage diseases.
• Liver biopsy—may be helpful in diagnosing certain lysosomal storage diseases in animals with hepatomegaly.

PATHOLOGIC FINDINGS

• These will depend on the underlying condition.
• Hereditary ataxias are associated with loss of neurons of the cerebellar cortex, as well as axonal pathology and gliosis.
• Lysosomal storage diseases are associated with accumulation of storage product within neurons and glial cells; frequently the Purkinje neuron is most severely affected.
• Infectious encephalitis is associated with infiltration of the cerebellum with inflammatory cells, and infectious organisms may be present (e.g., *Neospora caninum*; *Cryptococcal* infections); meningitis and perivascular cuffing may be present and there is frequently multifocal involvement of the CNS; there is profound cerebellar atrophy associated with *Neospora caninum* infections.
• Immune-mediated encephalitis is associated with infiltration of the CNS by inflammatory cells.

TREATMENT

APPROPRIATE HEALTH CARE

• Severe and/or rapidly progressive clinical signs—hospitalization for diagnostic workup and treatment.
• Mild and slowly progressive clinical signs—outpatient, but diagnostic tests requiring anesthesia necessitate hospitalization.
• Appropriate treatment of the underlying cause should be undertaken once a diagnosis has been established.

NURSING CARE

Severe intention tremors may make hand-feeding and IV fluids necessary.

ACTIVITY

Patients should be restricted to areas and activities where they are unlikely to fall and injure themselves.

DIET

No change. Dogs may benefit from a raised feeding bowl or hand-feeding.

SURGICAL CONSIDERATIONS

Surgical decompression of the spinal cord indicated for compressive myelopathies.

MEDICATIONS

DRUG(S) OF CHOICE

Discontinue metronidazole, regardless of the dose rate, to see if signs improve.

FOLLOW-UP

PATIENT MONITORING

• Periodic repeat neurologic examinations.
• Additional monitoring will depend on the underlying cause (e.g., serial monitoring of blood pressure in hypertensive patients).

MISCELLANEOUS

ZOONOTIC POTENTIAL

Fungal infections can be zoonotic.

ABBREVIATIONS

• CDV = canine distemper virus.
• CSF = cerebrospinal fluid.
• FeLV = feline leukemia virus.
• FIP = feline infectious peritonitis.
• FIV = feline immunodeficiency virus.

Author Natasha J. Olby

HYPERNATREMIA

BASICS

DEFINITION
Serum sodium (Na^+) concentration >158 mEq/L in dogs or >165 mEq/L in cats.

PATHOPHYSIOLOGY
- Na^+ is the most abundant cation in the extracellular fluid, so hypernatremia usually results in hyperosmolality.
- Hypernatremia can be caused by excessive free water loss, increased intake of Na^+, or a combination of both.
- Common causes of hypernatremia include renal or gastrointestinal loss of water in excess of sodium loss and low water intake. Excessive Na^+ ingestion is a rare cause.

SYSTEMS AFFECTED
- Endocrine/metabolic.
- Nervous.

SIGNALMENT
Dog and cat.

SIGNS
- Polydipsia.
- Disorientation.
- Coma.
- Seizures.
- Other findings depend on underlying cause.
- Severity of signs usually correlates to the degree of hypernatremia.

CAUSES
- Free water deficit (most common cause)—low water intake (e.g., no access to water, adipsia, or hypodipsia); high urinary water loss; high insensible water loss (e.g., panting, hyperthermia).
  - Urinary loss (e.g., diabetes insipidus, diabetes mellitus, osmotic diuresis, diuresis after acute urinary obstruction).
  - Gastrointestinal sodium loss (e.g., administration of osmotic cathartic, vomiting, diarrhea).
  - A wide variety of drugs interfere with renal capacity to concentrate urine, leading to water loss in excess of Na^+; these drugs include lithium, demeclocycline, and amphotericin.
- Oral sodium ingestion (rare); IV administration of 0.9% or 7% NaCl; hyperaldosteronism (rarely hypernatremic); hyperadrenocorticism (mild).
- Alterations in thirst reaction pathway—rare.
- Salt ingestion—rare.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Central diabetes insipidus (due to neoplasia or head trauma).

LABORATORY FINDINGS

Disorders That May Alter Laboratory Results
Lipemia or hyperproteinemia (>11 g/dL) can artifactually raise Na^+ concentration when the flame photometry method is used.

Valid if Run in a Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Consistent with underlying disease, if applicable.
- Diabetes insipidus—polyuria, hyposthenuria, and low urinary Na^+ concentration.
- Diabetes mellitus—hyperglycemia, isosthenuria.

IMAGING
CT scan or MRI in patients with diabetes insipidus to rule out pituitary tumor.

TREATMENT
- Fluid therapy and treatment of underlying disease.
- Water must be available at all times for patients with diabetes insipidus.

MEDICATIONS

DRUG(S) OF CHOICE
- If hypovolemia is present, replace volume with an isotonic crystalloid with a Na^+ concentration within 10 mEq/L of the patient's Na^+ concentration (0.9% saline has a Na^+ of 154 mEq/L, while lactated Ringer's has 130 mEq/L and Normosol®-R has 140 mEq/L). Volume replacement with this fluid may be continued as the free water deficit is replaced (below).
- Following volume resuscitation, administer hypotonic fluids (e.g., 5% dextrose in water or 5% dextrose with 0.45% saline) to reduce serum sodium by 0.5 mEq/h (12 mEq/L/day); supplement with potassium and phosphate if needed.
- Free water deficit—Wt (kg) × $\{[Na_{(presentation)}]/[Na_{(previous\ or\ normal)}] - 1\}$: administer this amount to achieve an ideal decrease of 0.5 mEq/h (i.e., if the sodium is 20 mEq above reference range, this should be administered over 40 hours).
- Formula to estimate how much each L of fluids will decrease the patient's serum Na^+—Δ in patient $[Na^+]$ = ($[Na^+]$ + $[K^+]$ in 1 L of solution – patient $[Na^+]$) / (0.6 × Wt (kg) +1).
- If the patient has oral water intake, this should be calculated as part of the free water restoration.

PRECAUTIONS
- Rapid correction of hypernatremia can cause cerebral edema. More rapid correction is only recommended if the hypernatremia is acute (<12 hours) or if the patient has neurologic abnormalities; correction should be slowed once signs abate.
- Cerebral edema is generally manifest as decreased mentation, and can be treated using hyperosmolar fluids (e.g., 7% NaCl, mannitol).

FOLLOW-UP

PATIENT MONITORING
- Acute setting—electrolytes, urine output, and bodyweight.
- Check sodium q4–6h initially and adjust fluid therapy as required to limit rapid changes.

POSSIBLE COMPLICATIONS
- CNS thrombosis or hemorrhage.
- Hyperactivity.
- Seizures.
- Serum sodium >180 mEq/L often associated with residual CNS damage.

MISCELLANEOUS

AGE-RELATED FACTORS
None

SYNONYMS
None

SEE ALSO
- Diabetes Insipidus.
- Hyposthenuria.

HYPEROSMOLARITY

BASICS

DEFINITION
• Osmolarity—mOsm/L: the number of solute particles per liter of solution.
• Osmolality—mOsm/kg: the number of solute particles per kilogram of solution.
• Hyperosmolarity—a high concentration of solute particles per liter of solution.
• Serum concentrations >310 mOsm/L in dogs and >330 mOsm/L in cats are considered hyperosmolar.
• Morbidity from hyperosmolarity is related more to rapid changes in osmolarity than to the actual amount of change.

PATHOPHYSIOLOGY
• Serum sodium is responsible for most of the osmotically active particles that contribute to serum osmolarity; serum glucose and urea also contribute.
• Anything that causes free water loss increases concentrations of solutes in plasma or serum, thereby increasing serum osmolarity.
• Blood volume, hydration status, and antidiuretic hormone (ADH) are intimately involved in controlling extracellular fluid volume.
• Low circulating blood volume and low blood pressure stimulates carotid and aortic baroreceptors to cause ADH secretion.
• Hyperosmolarity affects the osmoreceptors in the hypothalamus and stimulates ADH secretion from the posterior pituitary; the hypothalamic thirst center is also stimulated and causes an increase in water consumption.
• Rapid increases in serum osmolarity cause water movement along its concentration gradient from intracellular to extracellular spaces, resulting in neuronal dehydration, cell shrinkage, and cell death; cerebral vessels may weaken and hemorrhage.

SYSTEMS AFFECTED
• Cardiovascular—hypovolemia, hypotension, decreased ventricular contractility.
• Nervous—excessive thirst may be the first sign of hyperosmolarity. CNS depression may lead to coma.
• Renal/urologic—low urine output unless kidneys are source of free water loss.

SIGNALMENT
• Dog and cat.
• Hypodipsia and hyperosmolarity have been reported in young female miniature schnauzers.

SIGNS

General Comments
• Primarily neurologic or behavioral.
• Severity is related more to how quickly hyperosmolarity occurs than to the absolute magnitude of change.
• Clinical signs most likely if serum osmolarity is >350 mOsm/L and severe if >375 mOsm/L.

Historical Findings
Anorexia, lethargy, vomiting, weakness, disorientation, ataxia, seizures, and coma; polydipsia followed by hypodipsia.

Physical Examination Findings
• Normal, or abnormalities may reflect underlying disease.
• In addition to historical findings, dehydration, tachycardia, hypotension, weak pulses, and fever may be detected.

CAUSES

Increased Solute Concentrations
Hypernatremia, hyperglycemia, severe azotemia, ethylene glycol toxicosis, salt poisoning, sodium phosphate enemas in cats and small dogs, mannitol, radiographic contrast solution, administration of ethanol, aspirin toxicosis, shock, and parenteral nutrition solutions.

Decreased Extracellular Fluid Volume
Dehydration—gastrointestinal loss, cutaneous loss, third-space loss, low water consumption, polyuria without adequate compensatory polydipsia, excessive losses from panting.

RISK FACTORS
• Medical conditions that predispose—renal failure, diabetes insipidus (DI), diabetes mellitus (DM), hyperadrenocorticism, hyperaldosteronism, and heat stroke.
• Therapeutic hyperosmolar solutions—hypertonic saline, sodium bicarbonate, sodium phosphate enemas in cats and small dogs, mannitol, and parenteral nutrition solutions.
• High environmental temperatures, pain.
• Fever.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Primary CNS disease and neoplasia may be characterized by altered mentation, but serum osmolarity is usually normal.
• Physical evidence or history of injury usually helps to rule out CNS depression caused by cranial trauma.
• Perform a thorough physical examination to assess hydration status and obtain information regarding previous therapy that may have included sodium-containing fluids or hyperosmolar solutions.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results
N/A

Disorders That May Alter Laboratory Results
N/A

Valid if Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
High hematocrit, hemoglobin, and plasma proteins in dehydrated patients; serum electrolytes may also be increased.

OTHER LABORATORY TESTS
• Osmolarity is generally measured in the laboratory using freezing point depression but can be estimated from serum chemistry results (assuming the absence of unmeasured osmoles) using the formula: $2(Na^+ + K^+)$ + glucose/18 + BUN/2.8 = mOsm/L. Na^+ and K^+ concentrations are in mEq/L, glucose and blood urea nitrogen (BUN) concentrations are in mg/dL.
• Hyperosmolarity is an indication to evaluate serum sodium and glucose concentrations.
• Calculated osmolarity should not exceed measured osmolarity; if it does, consider laboratory error.
  ◦ If measured osmolarity exceeds calculated osmolarity, determine the osmolar gap.
  ◦ Osmolar gap = measured osmolarity – calculated osmolarity.
  ◦ High measured osmolarity and normal calculated osmolarity with a high osmolar gap indicate the presence of unmeasured solutes (not Na^+, K^+, glucose, BUN).
  ◦ High measured osmolarity and high calculated osmolarity with a normal osmolar gap usually indicate that the hyperosmolarity is caused by hyperglycemia or hypernatremia.
• Serum sodium concentration may be low in patients with severe hyperglycemia.
• Fasting hyperglycemia and glucosuria support a diagnosis of DM.
• Calcium oxalate monohydrate crystalluria suggests ethylene glycol toxicosis.
• High urine specific gravity (USG) rules out DI.
• Low USG, especially hyposthenuria, suggests DI.
• Urinary osmolarity lower than serum osmolarity suggests DI; concentrated urine rules out DI.

IMAGING
Renal ultrasonography may reveal bright hyperechoic kidneys in patients with ethylene glycol toxicosis.

TREATMENT
• Mild hyperosmolarity without clinical signs may not warrant specific treatment, but underlying disease(s) should be diagnosed and treated.
• Hospitalize patients with moderate to high osmolarity (>350 mOsm/L) and patients exhibiting clinical signs, and gradually lower serum osmolarity with IV fluids while a definitive diagnosis is pursued.
• Free water deficit can be calculated by the following formula: Free water deficit = 0.4 × lean bodyweight (kg) × [(Plasma Na/140) – 1].

• Administer 5% dextrose in water (D_5W) or 0.45% saline to slowly replace free water deficit.
• The goal is to not drop sodium more than 12 mEq/L in an 24-hour period. For example, if the free water deficit is 1 L and serum sodium concentration is 180 mEq/L, to normalize serum sodium concentration (to 145 mEq/L), the sodium concentration should drop over 35 hours (0.5 mEq/h). Thus, the 1 L of free water deficit should be given over 35 hours, or a rate of 28.5 mL/h (1000 mL/35h) if using D_5W. Maintenance isotonic IV fluids should be administered concurrently.
• Initially, 0.9% saline may be used to restore vascular volume; once hemodynamically stable, D_5W or 0.45% saline therapy may be initiated.
• If hyperosmolarity is acute (e.g. in patients with salt intoxication) and the duration is less than 6-8 hours, the free water deficit can be replaced more rapidly, through a combination of oral and IV water.
• If the patient is able to drink, free water deficit may be replaced orally; however, care must be taken to prevent excessive water ingestion.

MEDICATIONS

DRUG(S) OF CHOICE
• Intravenous free water replacement is best performed using D_5W or 0.45% NaCl.
• Seizures can be controlled with benzodiazepines or phenobarbital.

CONTRAINDICATIONS
Hypertonic saline and hyperosmolar solutions.

PRECAUTIONS
• Initial volume replacement should use a fluid with a Na^+ concentration closest to that of the patient.
• Rapid administration of hypotonic fluids (e.g., D_5W and 0.45% saline) may cause cerebral edema and worsen neurologic signs due to acute fluid shifts in the brain.

ALTERNATIVE DRUG(S)
Regular insulin 0.1 unit/kg IM/IV can be administered if a hyperglycemic crisis occurs secondary to parenteral nutrition administration.

FOLLOW-UP

PATIENT MONITORING
• Hydration status; avoid overhydration.
• Bladder size, urine output, serial bodyweight, and breathing patterns during IV fluid administration.
• Anuria, irregular breathing patterns, worsening depression, coma, or seizures are signs of deterioration.

POSSIBLE COMPLICATIONS
Altered consciousness and abnormal behavior.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Hypernatremia and hyperglycemia.

AGE-RELATED FACTORS
None

HYPERPARATHYROIDISM

BASICS

DEFINITION
A pathologic, sustained, high, circulating concentration of parathyroid hormone (PTH).

PATHOPHYSIOLOGY
- PTH is secreted by the parathyroid glands in response to changes in the concentration of ionized calcium in the serum, and causes an increase in serum calcium concentration through direct effects on bone and renal tubular calcium resorption and indirectly by vitamin D–dependent intestinal calcium absorption.
- Hyperparathyroidism can develop as a primary condition or be secondary to a disorder of calcium homeostasis; primary hyperparathyroidism is usually associated with benign adenoma of the parathyroid gland(s), although adenocarcinoma and hyperplasia are possible; secondary hyperparathyroidism can be caused by a deficiency of calcium and vitamin D associated with malnutrition or chronic renal disease.

SYSTEMS AFFECTED
- Cardiovascular.
- Gastrointestinal.
- Neuromuscular.
- Renal/urologic.

GENETICS
- Autosomal dominant with possible age-dependent penetrance in the keeshond; genetic test available from Cornell.
- Secondary hyperparathyroidism can develop in association with hereditary nephropathy.

INCIDENCE/PREVALENCE
- Prevalence of primary form is unknown.
- More common in dogs than in cats.
- Common among causes of hypercalcemia, but less common than hypercalcemia of malignancy in dogs; more common in middle-aged to geriatric dogs.
- Chronic renal failure with secondary hyperparathyroidism is extremely common, more so in cats than in dogs.
- Nutritional secondary hyperparathyroidism is decreasing in prevalence as the public becomes more educated in pet nutrition.

SIGNALMENT

Species
Cat and dog.

Breed Predilections
- Keeshond, but seen in almost any breed.
- Siamese and domestic shorthair cats.

Mean Age and Range
- Cats—mean age 13 years; range: 8–20 years.
- Dogs—mean age 10 years; range: 4–17 years.

Predominant Sex
None

SIGNS

General Comments
- Most dogs and cats with primary hyperparathyroidism do not appear ill.
- Signs are usually mild and due to the effects of hypercalcemia, or lower urinary tract signs if urolithiasis is present.
- Signs become apparent when hypercalcemia is severe and chronic.

Historical Findings
- Polyuria.
- Polydipsia.
- Anorexia.
- Lethargy.
- Vomiting.
- Weakness.
- Urolithiasis.
- Stupor and coma.

Physical Examination Findings
- Often unremarkable.
- Parathyroid adenoma is not palpable in dogs but often is in cats.
- Nutritional secondary disease is sometimes associated with pathologic bone fractures and general poor body condition.

CAUSES
- Primary hyperparathyroidism—PTH-secreting adenoma of the parathyroid gland; in most cases only one gland is adenomatous; malignant tumors of the parathyroid glands are uncommon and usually noninvasive.
- Renal secondary hyperparathyroidism—renal calcium loss and reduced gut absorption of calcium due to deficiency in calcitriol production by the renal tubular cells.
- Nutritional secondary hyperparathyroidism—a nutritional deficiency of calcium and vitamin D.

RISK FACTORS
- Primary hyperparathyroidism—unknown.
- Secondary hyperparathyroidism—renal tubular disease or calcium/vitamin D malnutrition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- The differential list includes causes of hypercalcemia.
- Lymphoma—common to cause hypercalcemia in dogs, rare to do so in cats.
- Anal sac apocrine gland adenocarcinoma—dogs.
- Other miscellaneous carcinomas—dogs and cats.
- Myeloproliferative disease—cats.
- Fibrosarcoma—cats.
- Chronic kidney disease.
- Hypoadrenocorticism.
- Vitamin D intoxication—cholecalciferol-containing rodenticides, plant sources, human anti-psoriasis topical creams, and vitamin supplements.
- Granulomatous diseases.
- Idiopathic hypercalcemia in cats.

CBC/BIOCHEMISTRY/URINALYSIS
- High serum total and ionized calcium concentrations.
- Low or low-normal serum phosphorus concentration in primary hyperparathyroidism.
- Hyperphosphatemia in renal secondary hyperparathyroidism or hypervitaminosis D.
- Serum blood urea nitrogen (BUN) and creatinine concentrations are usually normal in patients with primary hyperparathyroidism, except those with hypercalcemia-induced renal failure.

OTHER LABORATORY TESTS
- Serum ionized calcium determination is often normal (or low) in patients with chronic renal failure and high in patients with primary hyperparathyroidism or hypercalcemia associated with malignancy.
- High serum intact PTH concentration is diagnostic for primary hyperparathyroidism in the absence of azotemia; a serum PTH concentration within the normal reference range in an animal with ionized hypercalcemia should be considered *abnormal* and can signal parathyroid-dependent hypercalcemia.
- Measurement of PTH-related peptide (PTH-rp) may detect hyperparathyroidism related to neoplasia.

IMAGING
- Radiography can be useful to identify urolithiasis and occult neoplasia, as well as to assess renal morphology and bone density.
- Ultrasonography of the ventral cervical area sometimes reveals a parathyroid gland adenoma.
- Ultrasound of the abdomen can reveal lymphadenomegaly, urolithiasis, or renal morphologic abnormalities.

DIAGNOSTIC PROCEDURES
Surgical exploration of the ventral cervical area.

PATHOLOGIC FINDINGS
- Parathyroid adenoma is usually a solitary, small (=1 cm), round, light brown or reddish mass located in the proximity of the thyroid gland.
- Occasionally multiple adenomas are found.
- The histologic distinctions between adenomas, hyperplasia, and carcinomas of the parathyroid gland are often unclear.

TREATMENT

APPROPRIATE HEALTH CARE
- Primary hyperparathyroidism generally requires inpatient care and surgery.
- Nutritional or renal secondary hyperparathyroidism in noncritical patients can be managed on an outpatient basis.

(CONTINUED) # HYPERPARATHYROIDISM

ACTIVITY
No alterations recommended.

DIET
Calcium supplementation for secondary forms.

CLIENT EDUCATION
Explain signs referable to changes in calcium status, because hypocalcemia is a potential complication of parathyroidectomy.

SURGICAL CONSIDERATIONS
- Surgery is the treatment of choice for primary hyperparathyroidism and is often important in establishing the diagnosis.
- Percutaneous ultrasound-guided heat ablation has been used successfully for treatment of parathyroid adenomas, and may be recommended if available.
- Percutaneous ultrasound-guided ethanol ablation has been reported to be less successful than surgery or heat ablation.

MEDICATIONS

DRUG(S) OF CHOICE
- Normal saline is the fluid of choice for treatment of hypercalcemia.
- Diuretics (furosemide) and corticosteroids can be useful in treating hypercalcemia.
- No medical treatment exists for primary hyperparathyroidism per se.
- Renal secondary hyperparathyroidism is sometimes treated with calcitriol, but its use has not gained uniform acceptance.
- A new class of calcimimetic drugs is being used to treat renal secondary hyperparathyroidism in human patients, but studies of these drugs in dogs and cats have not been reported and expense limits their use.

CONTRAINDICATIONS
Do not use glucocorticoids until the diagnosis of lymphoma has been excluded; they can obfuscate the diagnosis.

PRECAUTIONS
Use furosemide only in patients with adequate hydration.

ALTERNATIVE DRUG(S)
Pamidronate and other bisphosphonate drugs have been used to treat hypercalcemia of various causes in dogs and cats.

FOLLOW-UP

PATIENT MONITORING
- Postoperative hypocalcemia is relatively common after treatment of primary hyperparathyroidism; recent studies have shown that preoperative ionized calcium and PTH concentrations are poor predictors of postsurgical hypocalcemia, so monitoring is essential in all cases.
- Postoperative hypocalcemia requires treatment with vitamin D (calcitriol is recommended) and calcium supplements (see treatment of hypoparathyroidism), and ionized calcium should be monitored to guide dosage adjustments; contradictory evidence exists with respect to preoperative administration of calcitriol.
- In patients with renal impairment, check serum concentrations of BUN and creatinine.

PREVENTION/AVOIDANCE
- Avoid breeding affected keeshonden.
- Nutritional secondary hyperparathyroidism is prevented by proper nutrition.

POSSIBLE COMPLICATIONS
- Irreversible renal failure secondary to hypercalcemia.
- Fractures due to decreased bone density with chronic hyperparathyroidism.

EXPECTED COURSE AND PROGNOSIS
- Untreated primary hyperparathyroidism may progresses to end-stage kidney or neuromuscular disease depending on severity; many dogs clinically seem to do well even with no treatment, provided urolithiasis does not develop.
- Prognosis for surgical treatment of parathyroid adenoma is excellent.
- Recurrence is seen in a small percentage of cases.
- In animals that develop postoperative hypoparathyroidism, the return of normal parathyroid function is unpredictable and can take weeks to months.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Calcium-containing urolithiasis.

AGE-RELATED FACTORS

Client Education Handout available online

HYPERPARATHYROIDISM, RENAL SECONDARY

BASICS

OVERVIEW

• Syndrome characterized by a high parathyroid hormone (PTH) concentration secondary to chronic kidney disease (CKD); results from impaired renal excretion of phosphorus leading to hyperphosphatemia and ionized hypocalcemia, elevation of FGF-23, and suppression of renal calcitriol synthesis.
• In advanced CKD the diminished renal tubular mass produces less calcitriol. Calcitriol exerts negative feedback on PTH synthesis within the parathyroid gland. Low calcitriol, ionized hypocalcemia, and hyperphosphatemia result in increased PTH production and parathyroid gland hyperplasia.
• PTH may act as a uremic toxin, promoting nephrocalcinosis and progression of CKD.

SIGNALMENT

Dog and cat; see Chronic Kidney Disease for age and breed predilections.

SIGNS

• Uremia due to underlying CKD.
• Renal osteodystrophy or "rubber jaw" most commonly occurs in young dogs with severe renal secondary hyperparathyroidism (RSHPT).
• Pain around the head or long bones.

CAUSES & RISK FACTORS

• Any disease that causes CKD.
• Excess consumption of phosphorus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Hypercalcemic nephropathy—kidney disease caused by ionized hypercalcemia; can be difficult to differentiate from longstanding RSHPT, in which hyperplasia of the parathyroid glands disrupts the normal feedback arc between PTH release and ionized calcium (tertiary hyperparathyroidism).
• Ionized serum calcium concentration is usually low or normal with RSHPT, but high with hypercalcemic nephropathy.
• Low serum PTH and PTH-related protein (PTHrP) high in animals with hypercalcemia of malignancy.
• Primary hyperparathyroidism—characterized by hypercalcemia, normal or low serum phosphorus, and inappropriate PTH concentration; kidney function is initially normal but may become compromised later.

CBC/BIOCHEMISTRY/URINALYSIS

• Azotemia.
• Hyperphosphatemia.
• Dilute urine.
• Total serum calcium does not reliably predict ionized calcium.

OTHER LABORATORY TESTS

Definitive diagnosis and therapeutic monitoring of RSHPT require measurement of serum PTH concentration using validated assay.

IMAGING

Radiographs may reveal low bone density, loss of the lamina dura around the teeth, and soft tissue mineralization of the gastric mucosa or other tissues.

TREATMENT

• See Chronic Kidney Disease for general treatment principles.
• Minimize hyperphosphatemia by feeding a low phosphorus diet formulated for kidney disease and intestinal phosphate binders in order to achieve IRIS phosphorus goals.

MEDICATIONS

DRUG(S) OF CHOICE

Intestinal Phosphate Binders

• If dietary management alone does not achieve the IRIS target serum phosphorus concentration, phosphorus binders can be used to further reduce serum phosphorus. Serum phosphorus targets based on the IRIS stages are stages 1 and 2: >2.7 to <4.6 mg/dL; Stage 3: >2.7 to <5.1 mg/dL; and Stage 4: >2.7 to <6.0 mg/dL.
• Aluminum hydroxide (60–90 mg/kg/day), calcium carbonate (90–150 mg/kg/day), calcium acetate (60–90 mg/kg/day), or lanthanum carbonate (60–90 mg/kg/day)—dose to achieve target serum phosphorus concentration, but do not exceed max dosage. All must be given with meals.
• Calcium-containing phosphate binders should be avoided with calcitriol therapy as hypercalcemia may occur. Combine different phosphate binders to reduce the dosage of each and minimize the risk of hypercalcemia or aluminum toxicity.

Calcitriol

• Low-dose calcitriol (2.0–3.5 ng/kg PO q24h)—may use after serum phosphorus is controlled, should be administered on an empty stomach and before bedtime (no food for 6–8 hours after administration).
• Maintain serum phosphorus concentration within the recommended IRIS target ranges before and during calcitriol therapy.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

• Calcitriol therapy may result in hypercalcemia, especially if combined with a calcium-containing phosphate binder. Increased total calcium concentration may develop in patients with long-standing CKD, but is unrelated to calcitriol treatment. Ionized calcium concentration is normal or low in these patients.
• Do not use calcium-containing intestinal phosphate binders in patients with a calcium × phosphorus product >70. Use aluminum- or lanthanum-containing intestinal phosphate binders initially to correct hyperphosphatemia. Calcium-containing phosphate binders can be used once the serum phosphorus concentration is within the target range.

FOLLOW-UP

PATIENT MONITORING

• Initially and in unstable patients, serum concentrations of calcium, phosphorus, creatinine, and urea nitrogen—monitor weekly to monthly depending on therapy and the severity of CKD.
• Patients receiving calcitriol should be monitored for hypercalcemia and hyperphosphatemia weekly for 4 weeks, then every 3–4 months.
• Serial evaluations of PTH concentration—most treated with low-dose calcitriol achieve near-normal levels of PTH within 3 months; it may be necessary to increase the dose in those with severe parathyroid gland hyperplasia.
• If hypercalcemia develops discontinue calcitriol; calcium should normalize within 5 days of discontinuation. Measurement of ionized calcium is recommended—animals with CKD may develop nonionized hypercalcemia that is unrelated to calcitriol treatment.

PREVENTION/AVOIDANCE

Dietary phosphorus restriction may delay the onset of RSHPT.

POSSIBLE COMPLICATIONS

Renal osteodystrophy and pathologic fractures (rare).

EXPECTED COURSE AND PROGNOSIS

• Progression of the underlying CKD may be slowed by minimizing phosphorus retention and RSHPT.
• Long-term prognosis is guarded to poor for patients with CKD and RSHPT.

(CONTINUED) # HYPERPARATHYROIDISM, RENAL SECONDARY

MISCELLANEOUS

AGE-RELATED FACTORS

Young animals can develop severe renal osteodystrophy; calcitriol may be beneficial.

ABBREVIATIONS

- CKD = chronic kidney disease.
- PTH = parathyroid hormone.
- PTHrP = PTH-related protein.
- RSHPT = renal secondary hyperparathyroidism.

HYPERPHOSPHATEMIA

BASICS

DEFINITION
- Serum total phosphorus >5.5 mg/dL (dogs).
- Serum total phosphorus >6 mg/dL (cats).

PATHOPHYSIOLOGY
- Control of phosphorus is complex and is influenced by the actions of parathyroid hormone (PTH) and vitamin D and the interaction of these hormones with the gastrointestinal tract, bone, kidneys, and parathyroid glands. The phosphatonin fibroblast growth factor-23 (FGF-23) also regulates phosphorus levels.
- High serum phosphorus results from excessive gastrointestinal absorption of phosphorus, excessive bone resorption of phosphorus, and/or reduced renal excretion of phosphorus.

SYSTEMS AFFECTED
- Endocrine.
- Metabolic.
- Renal.

GENETICS
N/A

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT
- Dogs and cats.
- Any age, but commonly young, growing animals or older animals with renal insufficiency.

SIGNS

Historical Findings
- Depends on the underlying cause of hyperphosphatemia.
- No specific signs directly attributable to hyperphosphatemia.
- Acute hyperphosphatemia causes hypocalcemic tetany, seizures, or vascular collapse.

Physical Examination Findings
Chronic hyperphosphatemia causes calcification of soft tissues, resulting in chronic renal failure and tumoral calcinosis.

CAUSES
- Reduced glomerular filtration rate.
- Renal hypoperfusion (e.g., hypovolemia, systolic cardiac disease).
- Renal disease.
- Postrenal urinary tract disease (e.g., obstruction, ruptured urinary bladder).
- Metabolic acidosis.
- Excessive bone resorption.
- Rhabdomyolysis or massive tissue trauma.
- Young growing dogs.
- Hypoparathyroidism.
- Hypersomatotropism.
- Excessive gastrointestinal absorption of phosphorus.
- Osteolysis.
- Disuse osteoporosis.
- Osseous neoplasia.
- Hyperthyroidism.
- Phosphorus-containing enemas.
- Vitamin D toxicosis.
- Dietary supplementation.
- Nutritional secondary hyperparathyroidism.

RISK FACTORS
- Renal disease.
- Use of phosphorus-containing enemas, especially in smaller animals.
- Massive tissue injury.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Hypoparathyroidism—also characterized by clinical signs of hypocalcemia such as seizures and tetany.
- Prerenal azotemia as a cause of hyperphosphatemia—associated with disease states that result in low cardiac output such as congestive heart failure, hypovolemia, hypoadrenocorticism, and shock.
- Renal insufficiency, either acute or chronic renal failure—attended by azotemia and abnormal findings on urinalysis (low urinary specific gravity).
- Postrenal azotemia—associated with urinary obstruction or uroabdomen.
- Young, growing animals—can have serum phosphorus concentrations twice those of adults.
- Vitamin D intoxication—history of vitamin D supplementation or ingestion of rodenticides (e.g., Rampage® and D-CON®) or calcipotriene.
- Nutritional secondary hyperparathyroidism—history of dietary calcium–phosphorus imbalance.
- Hyperthyroidism in cats—clinical signs of weight loss, polyphagia, and polydipsia and polyuria.
- Hypersomatotropism—attended by a history of progesterone administration in dogs and insulin-resistant diabetes mellitus in cats.
- Nonazotemia tumoral calcinosis—observed in human beings as an autosomal dominant disorder; rare cause of hyperphosphatemia associated with large bone lesions.
- Jasmine toxicity—history of plant ingestion.
- Massive tissue injury.
- Rhabdomyolysis.
- Tumor lysis syndrome.
- Spurious.

LABORATORY FINDINGS

Drugs That May Alter Laboratory Results
Intravenous potassium phosphate.

Disorders That May Alter Laboratory Results
- Hemolysis, hyperbilirubinemia, and lipemia can falsely raise phosphorus concentrations.
- Collection in citrate, oxalate, or EDTA.

Valid If Run in Human Laboratory?
Yes

CBC/BIOCHEMISTRY/URINALYSIS
- Serum phosphorus >6 mg/dL.
- Low serum calcium in patients with primary hypoparathyroidism.
- High serum calcium in patients with vitamin D intoxication.
- Degree of azotemia and urine specific gravity help define level renal impairment.
- Hyperkalemia and hyponatremia suggest hypoadrenocorticism.

OTHER LABORATORY TESTS
- Serum PTH measurement—intact molecule and two-site assay methods have the greatest specificity; high-normal or high concentrations with concurrent hyperphosphatemia suggest primary hyperparathyroidism; low concentrations with concurrent hypocalcemia and hyperphosphatemia suggest neoplasia.
- Thyroxine concentrations—indicated in cats with hyperphosphatemia and clinical signs consistent with hyperthyroidism.
- Insulin-like growth factor 1 (IGF-1) concentrations—indicated in dogs or cats with unexplained hyperphosphatemia and clinical signs consistent with acromegaly; IGF-1 concentrations are elevated in animals with hypersomatotropism.
- Vitamin D assays are not readily available.
- Adrenocorticotropic hormone (ACTH) stimulation testing to confirm hypoadrenocorticism.

IMAGING
- Abdominal radiography to assess renal size and symmetry.
- Renal ultrasonography to detect soft tissue mineralization.
- Nuclear scintigraphy to rule out hyperthyroidism.
- Radiography of long bones to detect osteoporosis or neoplasia.

DIAGNOSTIC PROCEDURES
Renal biopsy.

PATHOLOGIC FINDINGS
Mineralization of soft tissues may be noted radiographically or histopathologically.

TREATMENT

APPROPRIATE HEALTH CARE
Inpatient, because of the deleterious effects of hyperphosphatemia and the need for fluid therapy; consider severe hyperphosphatemia a

medical emergency. Long-term monitoring and management may be necessary.

NURSING CARE
Isotonic crystalloid fluids to increase glomerular filtration rate and promote phosphorus excretion.

ACTIVITY
N/A

DIET
Restrict dietary phosphorus.

CLIENT EDUCATION
Long-term monitoring and management may be necessary with phosphorus-restricted diets and/or oral phosphate binders.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUG(S) OF CHOICE

Acute Hyperphosphatemia
- Dextrose (0.5–1 g/kg IV) and regular insulin (0.25–0.5 U/kg IV), to shift phosphorus intracellularly.
- Avoid phosphorus-containing fluids.

Chronic Hyperphosphatemia
Oral administration of phosphorus binders (e.g., aluminum hydroxide or aluminum carbonate, 30–100 mg/kg/day PO, or calcium carbonate at 90–150 mg/kg/day PO, both with meals).

CONTRAINDICATIONS
N/A

PRECAUTIONS
Calcium carbonate should be avoided with hypercalcemia.

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
The oral phosphate binders sevelamer hydrochloride and lanthanum carbonate may be used as oral phosphate binders, but relatively little information is available in the veterinary literature.

FOLLOW-UP

PATIENT MONITORING
- Serum calcium every 12 hours.
- Renal function tests—urine output must be monitored, particularly if oliguric renal failure is suspected, in which case urine output should be measured carefully; oliguria cannot be determined unless the patient is fully hydrated.
- Hydration status—indicators of over-hydration include increased bodyweight, chemosis, increased central venous pressure, and edema (pulmonary or subcutaneous).
- Long-term serial monitoring of phosphorus is used to make dose adjustments in oral phosphate binders.

PREVENTION/AVOIDANCE
- Avoid ingestion of cholecalciferol rodenticides, calcipotriene, or Vitamin D supplementation.
- Avoid phosphate-containing enemas.
- Well-balanced veterinary diets prevent nutritional secondary hyperparathyroidism.

POSSIBLE COMPLICATIONS
- Hypophosphatemia resulting in hemolysis.
- Soft tissue mineralization.

EXPECTED COURSE AND PROGNOSIS
Depends on the underlying cause. Chronic kidney disease often causes chronic hyperphosphatemia and has a poor to guarded prognosis in dogs.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Hypocalcemia

AGE-RELATED FACTORS
Mild elevations in phosphorus may be normal in growing animals.

ZOONOTIC POTENTIAL

HYPERSOMATOTROPISM/ACROMEGALY IN CATS

BASICS

OVERVIEW

• Caused by excessive growth hormone (GH) secretion from the anterior pituitary by an adenoma or somatotroph hyperplasia.
• GH induces hepatic insulin-like growth factor-1 (IGF-1) secretion. The combination of increased GH and IGF-1 causes lipolysis, protein synthesis, impaired carbohydrate metabolism, and insulin resistance (IR).
• Prevalence in Europe ranges from 1 : 3 to 1 : 5.5 diabetic cats.

SIGNALMENT

• Median age—11 years (range: 9.5–13 years).
• Male : female ratio is 2 : 1.
• No breed predisposition.

SIGNS

• Clinical signs of diabetes mellitus (DM; e.g., polyuria, polydipsia, and polyphagia) occur from GH-induced IR. IR can be variable or persistent, which makes the DM difficult to control.
• Many (~40%) diabetics with hypersomatotropism (HST) lose weight due to poorly controlled DM; a small proportion (~17%) gain weight.
• Anabolic state—patients may present with polyphagia (without DM), or soft tissue growth resulting in upper airway obstruction, broad facial features, or clubbed feet.
• A small proportion (~2%) develop neurologic signs due to pituitary adenoma.

CAUSES & RISK FACTORS

• GH-secreting pituitary adenoma or somatotroph hyperplasia.
• In dogs, but not cats, progestins can result in increased GH concentration.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

• Uncomplicated DM.
• Pituitary-dependent hyperadrenocorticism.
• Causes of polyphagia such as exocrine pancreatic insufficiency, gastrointestinal inflammatory diseases, hyperthyroidism, and inflammatory liver diseases. Cats with HST and polyphagia but without DM typically gain weight, unlike other differentials.

CBC/BIOCHEMISTRY/URINALYSIS

• Consistent with DM.
• Diabetic ketoacidosis uncommon.

OTHER LABORATORY TESTS

• Serum IGF-1 concentration using validated assays is test of choice.
  ◦ Positive predictive value of IGF-1 >1000 ng/mL (131 nmol/L) of 95%.
  ◦ Roughly one-third of cats with HST have a low IGF-1 at diagnosis, which increases to >1000 ng/mL after insulin therapy.
  ◦ IGF-1 concentrations between 700 and 1000 ng/mL (92–131 nmol/L) is a "gray" zone—many non-HST diabetic cats are in this range.
• There is no commercially available GH assay.

IMAGING

• Abdominal ultrasound might identify organomegaly.
• Contrast-enhanced CT can assess pituitary size.
• Echocardiographic findings—increased left ventricular wall thickness, left atrial enlargement, aortic insufficiency.

TREATMENT

Surgery

Hypophysectomy most consistently normalizes IGF-1 concentration (80% of cases) and results in highest diabetic remission rates (50% achieve long-term remission).

Medical Management

• Somatostatins (SSTs) are primary negative regulatory hormones of GH secretion.
• Pasireotide is an SST analogue. Short-acting pasireotide (0.03 mg/kg SC q12h) decreased IGF-1 in 12 cats after 3 days of treatment, while long-acting pasireotide (8 mg/kg SC monthly) resulted in normalization of IGF-1 in 2/8 cats; all cats experienced increased insulin sensitivity and 3/8 cats achieved diabetic remission.
• Octreotide is an SST analogue with a different binding profile that temporarily decreases GH without improvement in clinical control of HST or DM.
• Dopamine receptor 2 inhibits GH secretion. Cabergoline, a dopamine receptor 2 agonist, decreases IGF-1 and increases insulin sensitivity in some cats with HST.

Radiotherapy

Fractionated radiotherapy improves neurologic signs and may improve diabetic control. Stereotactic radiotherapy might be more favorable as improved diabetic control and diabetic remission is more likely.

Palliative Treatment

• Maximizing diabetic control (e.g. with insulin and diet) is recommended but may be challenging.
• Comorbidities (e.g., osteoarthritis, cardiac disease) should be managed.
• Controlling polyphagia in some cats with HST is challenging. Despite lack of endocrine improvement after cabergoline, many owners reported normalization of appetite.

MEDICATIONS

See Medical Management.

FOLLOW-UP

• Depends on treatment modality.
• Survival varies from months to years; most euthanized due to poor quality of life or causes unrelated to HST.
• Diabetic control should be monitored as for an uncomplicated diabetic. A small proportion of cats gain weight despite poor diabetic control and have persistent polyphagia despite good diabetic control.

MISCELLANEOUS

ABBREVIATIONS

• DM = diabetes mellitus.
• GH = growth hormone.
• HST = hypersomatotropism.
• IGF-1 = insulin like growth factor-1.
• IR = insulin resistance.
• SST = somatostatin.

HYPERTENSION, PORTAL

BASICS

DEFINITION
Portal pressure >13 cm H_2O (10 mmHg).

PATHOPHYSIOLOGY
- Causes—increased portal blood flow (arterialized system), increased resistance to portal blood flow, or combination.
- Increased portal flow—arterialization of portal circulation occurs in arteriovenous (AV) malformation or subsequent to increased hepatic resistance causing retrograde blood flow into valveless splanchnic portal circulation.
- Hepatofugal—portal splanchnic circulation away from liver.

Increased Resistance Relative to Liver
- Prehepatic—abdominal portion of portal vein.
- Hepatic—within liver.
- Posthepatic—cranial to liver: terminal hepatic veins, vena cava, heart, pericardium.

Intrahepatic Increase in Resistance
- Presinusoidal—within portal tract.
- Sinusoidal—within sinusoid or space of Disse.
- Postsinusoidal—hepatic venular outflow tract causing sinusoidal occlusion or Budd Chiari syndrome.
- Consequences—development of multiple acquired portosystemic shunts (APSS), abdominal effusion due to increased lymph formation, predisposition to hepatic encephalopathy (HE).
- Acquired portosystemic shunts (APSS)—develop within 1–2 months of acquired portal hypertension (PH).

Effusion Protein Content
- Hepatic causes—pure transudate reflects concurrent PH and hypoalbuminemia (protein <1.5 g/dL).
- Posthepatic causes—modified transudate (protein >2.5 g/dL).
- Prehepatic causes—pure or modified transudate, low cellularity.

SYSTEMS AFFECTED
- Hepatobiliary disorders—obstructed blood flow in any zone or diffusely across sinusoids causes intrahepatic PH, splanchnic PH, ± passive splenic congestion (splenomegaly).
- Posthepatic disorders—hepatic passive congestion, hepatomegaly, variable PH; *APSS usually absent*.
- Prehepatic disorders—cause splanchnic PH, splenic congestion, APSS; portal venous thrombi, stenosis, stricture, entrapment in porta hepatis (e.g., pancreatitis, neoplasia), mass compression (pancreatic inflammation; neoplasia).
- Nervous—HE due to APSS.
- Cardiovascular—APSS and ascites may develop with vena caval/hepatic vein obstruction (at level of diaphragm), *but not* with congestive heart failure or pericardial tamponade.
- Portal thrombi—caused by gastrointestinal (GI) inflammation/necrosis and splanchnic vasculitis, neoplasia, disseminated intravascular coagulation, loss of anticoagulants, accelerated thrombosis.
- GI—splanchnic hypertension can provoke enteric edema, increased gut wall permeability provoking transmural bacterial translocation (endotoxemia, bacteremia), hypertensive enteric vasculopathy (enteric bleeding, ulceration), diapedesis blood loss, protein malassimilation.

GENETICS
- Vascular malformations causing portal atresia (intrahepatic, prehepatic) are congenital and represent severe phenotype of polygenic portal venous malformations in small-breed dogs.
- Ductal plate malformation (DPM)—congenital hepatic fibrosis (CHF) phenotype causes APSS; occurs in numerous dog breeds and Persian-related cats; increased frequency in boxers.
- Noncirrhotic PH—adult-onset diminution of tertiary portal branches, affects individual dogs of many breeds, described in Doberman pinschers (rare).
- Acquired sinusoidal PH due to necroinflammatory liver injury—immune-mediated chronic hepatitis (anecdotal in some breeds).
- Copper associated hepatopathy—Bedlington terrier *COMMD1* mutation, predisposition for copper associated hepatopathy in Labrador retrievers, Dalmatian, Doberman pinscher, and numerous other dogs may reflect pharmacogenetic breed differences in copper transporters.

SIGNALMENT

Species
Dog > cat.

Breed Predilections
Familial hepatic vascular disorders—Doberman pinschers (noncirrhotic PH); Saint Bernard (AV malformation); cocker spaniel hepatopathy; copper associated hepatopathy: Bedlington terriers, Doberman pinschers, Labrador retriever, others; DPM with CHF phenotype: boxers predisposed, any large or small dog breed, cats.

Mean Age and Range
- Juveniles—inherited or congenital disorders; vena caval and cardiac malformations.
- Young dogs and cats <1.5 years of age—congenital hepatic vascular malformations with portal venous atresia: may be more common in Yorkshire terriers, Maltese, pugs, cats.
- Juvenile and young adult dogs and cats—DPM with CHF phenotype.
- Young dogs and cats—hepatic AV malformations, onset of signs <1.5 years of age.
- Middle-aged and older animals—acquired hepatobiliary disorders and portal thrombi.

SIGNS

General Comments
- Depend on site, degree, rate of onset of PH, and causal factors.
- Acquired disorders—slowly progressive, chronic in onset.

Historical Findings
- Portal thromboembolism may acutely appear but remain unnoticed until APSS form; vague GI signs at occurrence including bloody diarrhea, ileus, abdominal pain, lethargy, inappetence.
- Abdominal distention—ascites.
- HE—secondary to APSS.
- Cardiac disorders or pericardial restriction—cough; exercise intolerance; dyspnea, jugular pulse, weak femoral pulses or pulsus alternans, reduced heart sounds on auscultation.

Physical Examination Findings
- Abdominal effusion.
- Hepatomegaly—posthepatic causes only.
- Splenomegaly—reflects splanchnic congestion or venous thrombi, inconsistent.
- Jugular vein distention—posthepatic cardiac or pericardial causes.
- Muffled heart sounds—pericardial or pleural effusion.
- Cardiac arrhythmias or murmur—cardiac disease.
- Pulmonary "crackles" (edema)—cardiac or pericardial causes.
- Confusion, stupor, coma, blindness, other neurobehavioral abnormalities—HE.
- Jaundice—hepatic causes.
- Hepatic bruit (hepatic AV malformation).
- Signs consequent to surgical ligation of portosystemic venous anomaly (PSVA).

CAUSES

Prehepatic
- Portal vein thrombosis, stenosis, or neoplasia.
- Portal vein compression—large lymph nodes; neoplasia, granuloma; abscess; pancreatitis, entrapment in diaphragmatic hernia.
- Postoperative complication of PSVA ligation.
- Congenital portal vein atresia.

Intrahepatic
- Hepatic fibrosis/cirrhosis.
- Chronic inflammatory liver disease.
- Chronic extrahepatic bile duct obstruction (EHBDO) >6 weeks.
- DPM with CHF phenotype.
- Hepatic neoplasia—porta hepatis location.
- Liver entrapment—in diaphragmatic hernia.
- Sinusoidal occlusion syndrome.
- Veno-occlusive disease (zone 3 lesion).
- Noncirrhotic portal hypertension.
- Portal vein atresia (intra- or extrahepatic).
- Hepatic AV malformation.

HYPERTENSION, PORTAL (CONTINUED)

Posthepatic

- Right-sided congestive heart failure.
- Heartworm disease.
- Pericardial tamponade.
- Pericarditis—restrictive or constrictive.
- Cardiac neoplasia.
- Cor triatriatum dexter.
- Pulmonary thromboemboli (TE).
- Disorders affecting supradiaphragmatic caudal vena cava— thrombosis; congenital kink or web; heartworm vena cava syndrome; occlusion by neoplasia; entrapment in diaphragmatic hernia; trauma.
- Budd Chiari syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Physicochemical analysis of abdominal effusion—helps narrow diagnoses.
- Pure transudate—hypoalbuminemia secondary to protein-losing enteropathy (PLE), protein-losing nephropathy (PLN), liver failure.
- Modified transudate with normal or low albumin—PLE, PLN, liver failure (chronic effusion), neoplasia, splanchnic TE, liver (visceral) entrapment in diaphragmatic hernia.
- Modified transudate with large liver and jugular distention—cardiac or pericardial abnormalities; heartworm; right atrial tumor.
- Modified transudate with large liver without jugular distention, muffled heart, or pulmonary edema—kinked vena cava; Budd Chiari–like or sinusoidal occlusion syndrome.
- HE— liver fibrosis; cirrhosis; CHF; hepatic AV malformation; any cause of APSS.
- Jaundice—chronic hepatitis, cholangitis; EHBDO; infiltrative hepatic neoplasm.
- Bloody diarrhea, abdominal pain, ileus, signs of endotoxemia—acute splanchnic portal TE.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC—schistocytes with TE; red blood cell microcytosis with PSVA or APSS; icteric plasma with liver disease or microangiopathic shearing anemia.
- Biochemistry—liver disease associated with variable liver enzymes, low blood urea nitrogen, creatinine, cholesterol, and/or glucose concentrations, hyperbilirubinemia, coagulation abnormalities; posthepatic disorders associated with high liver enzymes, ± azotemia, normal plasma color.
- Urinalysis—ammonium biurate crystalluria with APSS; may note granular casts with TE affecting renal perfusion; may note proteinuria with heartworm disease.

OTHER LABORATORY TESTS

- Total serum bile acids (TSBA)—variable fasting and high 2h postprandial concentrations with APSS or hepatobiliary disease; shunting pattern (normal fasting and markedly high postprandial values) common.
- Blood ammonia—hyperammonemia with APSS or inferred by finding ammonium biurate crystalluria; less reliable compared to TSBA.
- Physicochemical characterization of abdominal effusion—high serum : effusion albumin ratio (>1.1) consistent with PH.

IMAGING

Radiography

- Thoracic radiography—may reveal cause of posthepatic PH.
- Abdominal radiography—may reveal effusion, splenomegaly, hepatomegaly; microhepatica in most hepatic disorders and portal atresia causing APSS.

ABDOMINAL US

- Identify abnormalities involving abdominal or extrahepatic portal vein—atresia, stricture, thrombi, occlusive lesions in porta hepatis.
- Identify lobe(s) containing AV malformations.
- Inspect splanchnic circulation using Doppler color flow; document hepatofugal circulation, identify portal thrombi, APSS, PSVA.
- Evaluate echogenicity of nonhepatic viscera, identify lymphadenomegaly, mass lesions, adhesions.
- Estimate hepatic venous distention—intrahepatic and supradiaphragmatic segments.

Echocardiography

Detects congenital and acquired cardiac and pericardial disorders, neoplasia, thrombi, heartworms, pleural effusion, malformed or thrombosed vena cava, diaphragmatic hernia.

Angiography and Nuclear Imaging

- Colorectal or splenoportal scintigraphy—confirms portosystemic shunting but not anatomic details.
- Radiographic angiography—celiac trunk and hepatic artery contrast studies confirm hepatic AV malformation; nonselective or selective studies: congenital cardiac disease, TE, hepatic vein disorders, AV malformation.
- Portovenography—confirms APSS.
- Multisector CT—displays arterial and venous phases.

DIAGNOSTIC PROCEDURES

- ECG and central venous pressure—with cardiac disease, cranial mediastinal obstructions.
- Liver biopsy—required for diagnosis of hepatobiliary disorders.
- Portal pressure—may be measured during laparotomy but not recommended; PH adequately confirmed with imaging studies and on gross inspection.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient—for severe HE, amelioration of tense ascites by therapeutic abdominocentesis, supportive care for acute TE.

NURSING CARE

- Fluid therapy—restrict sodium concentration (avoid 0.9% NaCl); avoid iatrogenic pulmonary edema during fluid therapy (*caution*: if hypoalbuminemia, monitor respiration rate/effort).
- Monitor bodyweight and condition, girth circumference, plasma proteins, packed cell volume—assess hydration status, volume of abdominal effusion, IV fluid tolerance.
- Low oncotic pressure—may require plasma or colloid administration (plasma preferred for liver patient); Voluven® or VetStarch® (6%; 130 MW/0.4 molar substitution) 10–20 mL/kg/day IV CRI) may be necessary for acute adjustments; avoid hetastarch as can reduce platelet function.
- Glucose supplementation—with hepatic dysfunction and hypoglycemia; 2.5–5.0% dextrose with half-strength polyionic fluids initially; avoid hyperglycemia.

Mobilization of Ascites

- *Abdominal effusion*—sequentially assess: bodyweight, girth, body condition score; initially exercise restrict; enforce dietary sodium restriction.
- *Conventional diuretics*—combine furosemide and spironolactone; furosemide (0.5–2 mg/kg PO q12–24h) and spironolactone (0.5–2 mg/kg PO q12h, use single doubled dose for loading one time): dose titrations based on response q4 days; adjust using incremental 25–50% dose increase; serum : effusion albumin ratio (>1.1) may predict response to diuretics.
- *Vasopressin V_2 antagonists* (aquaretics) *may* assist with management of diuretic-resistant ascites; tolvaptan successful in dogs with experimentally induced (rapid pacing) congestive heart failure; human dose in cirrhosis 7.5 mg/day; metabolized exclusively in liver primarily by cytochrome P450; dose undetermined in dogs with liver disease.
- *Telmisartan*—angiotensin receptor blocker is alternative diuretic worthy of consideration; administration PO at 1.0 mg/kg/day significantly increased urine volume and sodium excretion in healthy dogs in one study.
- Taper diuretic dose after initial positive response; individualize chronic treatment to response; may be used intermittently for recurring ascites.
- Avoid dehydration, can lead to HE.
- Avoid hypokalemia, can provoke HE.
- If ascites due to right-sided congestive heart failure, treat accordingly.

• *Diuretic-resistant ascites*—large-volume (therapeutic) abdominocentesis if ascites resistant to medical intervention or compromises food intake, ventilation, or sleep: requires aseptic technique, fluid removal over 45–90 min, concurrently provide polyionic fluids in moderation with colloids to reduce risk for postcentesis hypotension and acute renal failure (ARF); repeated large-volume fluid removal may result in hypovolemia, hypoproteinemia, electrolyte depletion; iatrogenic infection; postcentesis hypovolemia/hypoperfusion syndrome, ARF; general rule in humans: provide 4–8 g albumin per L of ascites removed (consider colloids, discussed above).
• If ascites fails to mobilize, consider measuring urine sodium output vs. sodium intake (dietary) to determine whether intake requires restriction or diuretics upward titration; urine output should be measured over min 12h.

ACTIVITY
Depends on cause—restrict activity if ascites.

DIET
• Ascites—restrict dietary sodium <100 mg/100 kcal.
• If HE—restrict dietary protein; *caution*: only do so if nitrogen intolerance suspected.

CLIENT EDUCATION
Inform client definitive diagnosis requires logical diagnostic strategies and no prediction for cure or chronic amelioration until diagnosis definitive.

SURGICAL CONSIDERATIONS
• Ligation of APSS or vena caval banding strongly contraindicated.
• If acute symptomatic PH after surgical ligation of PSVA—ligature removal imperative.
• Embolectomy of thrombi not recommended; emboli may recanalize with supportive care; clot dissolution (streptokinase, tissue plasminogen activator) complicated, expensive, requires ICU hospitalization and monitoring, warrants grave prognosis.
• Low molecular weight heparin—see Coagulopathy of Liver Disease.
• Correction of chronic diaphragmatic hernia—release of entrapped viscera may provoke perioperative/postoperative endotoxemia, hypotension, shock, ARF.
• Surgical correction and cure of cor triatriatum and kinked vena cava possible.
• Pericardectomy—pericardial restriction or tamponade; thoracoscopic procedure least invasive, with lowest mortality and best outcome.
• Removal of tumor or fibrous adhesions causing hepatic vein occlusion may be difficult.
• Removal (lobectomy) or embolization (acrylamide) of hepatic AV malformation may not be curative as microscopic intrahepatic AV shunting usually continues PH and APSS.

MEDICATIONS

DRUG(S) OF CHOICE
Treatment of abdominal effusion—sodium restriction (see Diet); combined diuretic therapy (spironolactone and furosemide), consider tolvaptan or telmisartan (see above), use large-volume paracentesis sparingly.

POSSIBLE INTERACTIONS
• Avoid drugs relying on first-pass hepatic extraction, biotransformation, or hepatic elimination; if not possible, adjust dosage based on available information.
• Reduce dose of highly protein-bound drugs if patient hypoalbuminemic.
• Avoid nonsteroidal anti-inflammatory drugs—may provoke ARF, sodium retention, and enteric bleeding that may augment HE.

FOLLOW-UP

PATIENT MONITORING
• Sequentially monitor bodyweight, condition, abdominal girth.
• Sequentially assess hydration, electrolytes, acid-base, BP as necessary.
• Monitor albumin and glucose—with liver disease or APSS.
• Monitor lung sounds, pulse oximetry, ventilatory effort—in cardiovascular disorders.

POSSIBLE COMPLICATIONS
• Thrombosis.
• Endotoxemia.
• Hypotension.
• Hepatic encephalopathy.
• Acute renal failure.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Chronic liver disease.
• Numerous disorders may cause prehepatic or posthepatic portal hypertension.

PREGNANCY/FERTILITY/BREEDING
Affects uterine perfusion and likely leads to abortion or stillbirths.

SEE ALSO
• Ascites.
• Cirrhosis and Fibrosis of the Liver.
• Congestive Heart Failure, Right-Sided.
• Hepatic Encephalopathy.
• Pericardial Disease.
• Portosystemic Shunt, Acquired.
• Portosystemic Vascular Anomaly, Congenital.

ABBREVIATIONS
• ARF = acute renal failure.
• APSS = acquired portosystemic shunt(s).
• AV = arteriovenous.
• CHF = congenital hepatic fibrosis.
• DPM = ductal plate malformation.
• EHBDO = extrahepatic bile duct obstruction.
• GI = gastrointestinal.
• HE = hepatic encephalopathy.
• PH = portal hypertension.
• PLE = protein-losing enteropathy.
• PLN = protein-losing nephropathy.
• PSVA = portosystemic venous anomaly.
• TE = thromboembolism.
• TSBA = total serum bile acids.

HYPERTENSION, PULMONARY

BASICS

DEFINITION
Peak systolic pulmonary artery (PA) pressure >35 mmHg and/or peak diastolic PA pressure >15 mmHg.

PATHOPHYSIOLOGY
• Causes of elevated PA pressure: ○ PA vasoconstriction. ○ PA obstruction. ○ High left atrial (LA) pressure. ○ Excessive pulmonary blood flow. • As a result of pulmonary hypertension (PH) right heart pressures increase to maintain pulmonary blood flow. ○ May result in dysfunction of right ventricle RV and decreased pulmonary blood flow, which interferes with left heart filling and can lead to reduced cardiac output. ○ High right heart pressures can cause venous congestion, tricuspid regurgitation (TR), and right-sided CHF.

SYSTEMS AFFECTED
• Cardiovascular. • Respiratory.
• Hepatobiliary (if right-sided CHF).

GENETICS
• No specific genetic basis found. • Causes of primary disease (congenital heart disease [CHD], left heart disease, pulmonary disease) may have a genetic basis.

GEOGRAPHIC DISTRIBUTION
Unknown; higher prevalence in heartworm-endemic areas and high altitudes.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
• Possibly based on underlying cause of PH.
• Increased incidence suggested in terrier breeds.

Predominant Sex
Increased incidence reported in females.

SIGNS

General Comments
Signs due to hypoxia and cardiac dysfunction.

Historical Findings
• Exercise intolerance. • Dyspnea/tachypnea.
• Coughing/hemoptysis. • Syncope.
• Abdominal distention. • Weight loss.
• Lethargy. • Sudden death.

Physical Examination Findings
• Dyspnea/tachypnea. • Coughing/hemoptysis. • Loud and/or split second heart sound. • Pulmonary crackles and/or increased bronchovesicular sounds.
• Cyanosis. • Heart murmur. • Abdominal distention. • Jugular distention.
• Subcutaneous edema. • Weight loss.

CAUSES

Primary/Idiopathic/Familial PH
• Congenital disorders of the pulmonary vasculature identified in humans.
• Abnormalities in endothelial derived vasodilator/vasoconstrictor substances result in vascular obstruction and vasoconstriction. • Not reported in companion animals.

Pulmonary Parenchymal Disease
• *Vascular obstruction*—resulting from pulmonary lesions (e.g., fibrosis, neoplasia), vascular hypertrophy/inflammation.
• *Vasoconstriction*—secondary to hypoxia and acidemia. • *Causes*—pneumonia (bacterial, viral, fungal, parasitic); chronic bronchitis; pulmonary fibrosis; eosinophilic bronchitis; pulmonary neoplasia; acute respiratory distress syndrome.

Pulmonary Thromboembolism (PTE)
• *Vascular obstruction*—secondary to thrombus. • *Vasoconstriction*—secondary to hypoxia and vasoconstrictive substances released from the thrombus. • *Causes*—hyperadrenocorticism; protein-losing nephropathy/enteropathy; sepsis; immune-mediated hemolytic anemia; neoplasia; pancreatitis; endocarditis; disseminated intravascular coagulation; primary cardiac disease (typically right-sided).

Heartworm Disease (HWD)
• *Vascular obstruction*—vascular hypertrophy, inflammation, thromboembolism, and presence of heartworms. • *Vasoconstriction*—secondary to hypoxia/thrombi.

Left-to-Right-Shunting CHD
• *Excessive pulmonary blood flow*—results in damage to pulmonary vasculature.
• *Vasoconstriction/vascular obstruction*—due to vascular damage and hypertrophy. • *Causes*—patent ductus arteriosus; ventricular septal defect; atrial septal defect; atrioventricular septal defect.

Left Heart Disease
• *High LA pressure*—results in pulmonary venous hypertension. • *Vasoconstriction/vascular obstruction*—result of elevated pressure and vascular hypertrophy. • *Causes*—mitral regurgitation; cardiomyopathy (dilated, hypertrophic, restrictive, unclassified); mitral stenosis; congenital pulmonary venous obstruction; LA tumors.

Extrapulmonary Causes of Chronic Hypoxia
• *Vasoconstriction and secondary vascular hypertrophy*—due to environmental/extrapulmonary factors that result in hypoxia and acidemia. • *Causes*—hypoventilation (Pickwickian syndrome, neuromuscular disorders); high altitude disease.

RISK FACTORS
• Cardiac and pulmonary disease. • HWD.
• Diseases causing hypercoagulability.
• Obesity. • High altitude.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Left-sided CHF*. • Tracheal collapse.
• Right-sided CHF*. • Primary pulmonary disease*. • HWD*. • Pneumothorax.
• Pleural effusion (pyothorax, chylothorax, hemothorax, hydrothorax). • Laryngeal disease. * = without concurrent PH.

CBC/BIOCHEMISTRY/URINALYSIS
• Polycythemia if hypoxemic. • Leukocytosis with infectious lung disease. • Possible evidence of hypercoagulability.

OTHER LABORATORY TESTS
• Arterial blood gases (hypoxemia). • Occult heartworm test. • Workup for PTE (urine protein : creatinine ratio, antithrombin III level, D-dimer, coagulation profile, urine cortisol : creatinine ratio, adrenocorticotropic hormone stimulation test, dexamethasone suppression test). • Cytology of effusions.

IMAGING

Radiography
• Dilated PA and/or torturous pulmonary vessels. • Enlarged RV and right atrium (RA).
• Dilated caudal vena cava. • Pleural effusion.
• Hepatomegaly. • Ascites. • Evidence of primary pulmonary disease, PTE, or HWD.

Echocardiography
• RV concentric/eccentric hypertrophy.
• Flattening of interventricular septum and/or paradoxical septal motion. • RA dilation. • PA dilation with decreased distensibility. • Pleural/pericardial effusion. • Evidence of left heart disease, HWD, CHD, or PTE. • Asymmetric, notched pulmonary outflow tracing. • TR gradient, if present without pulmonic stenosis or PA stenosis, estimates systolic PH severity. ○ *Systolic pressure gradient* between PA and RA estimated with spectral Doppler using modified Bernoulli equation: 4 × (peak TR velocity)^2. ○ Pressure gradient >35 mmHg (TR velocity ≥3.0 m/s) suggestive of PH. ○ Gradient determines severity—mild: 35–50 mmHg; moderate 51–80 mmHg; severe: >80–mmHg.
• Pulmonary valve insufficiency (PI), if present without PA stenosis, estimates diastolic PH severity. ○ Diastolic pressure gradient between PA and RV estimated with spectral Doppler using modified Bernoulli equation: 4 × (end PI velocity)^2. ○ Pressure gradient >15 mmHg (end PI velocity >2.0 m/s) suggestive of PH.

CT/MRI
May be of value if pulmonary neoplasia or other infiltrative/obstructive disease.

DIAGNOSTIC PROCEDURES
Transtracheal wash, bronchoscopy/bronchoalveolar lavage, or lung aspirate/biopsy may be of value if evidence of primary pulmonary disease.

(CONTINUED) HYPERTENSION, PULMONARY

ECG

• Right mean electrical axis deviation. • Deep S waves (leads I, II, III, and aVF), • Widened QRS complex. • P-pulmonale. • ST segment depression/elevation. • Hypoxia-induced arrhythmias (ventricular premature complexes [VPCs]).

Cardiac Catheterization and Pulmonary Angiography

• Gold standard for diagnosis. • Uncommonly performed due to risk and usefulness of echocardiography. • Indicated if necessary to confirm diagnosis or cause.

PATHOLOGIC FINDINGS

Depend on underlying disease and severity—primary pulmonary lesions; PTE; dilated PA/RV/RA/vena cava; heartworms; pleural/pericardial/abdominal effusions; medial hypertrophy, intimal proliferation, and sclerosis of pulmonary vessels; necrotizing arteritis.

TREATMENT

APPROPRIATE HEALTH CARE

• Hospitalize patients in severe respiratory distress. • Perform diagnostics based on patient stability.

NURSING CARE

• Judicious fluid therapy may help improve pulmonary blood flow. • Risk of CHF must be considered. • Maintain low-stress environment.

CLIENT EDUCATION

• Prognosis varies with the underlying disease but generally very guarded. • Avoid respiratory triggers—heat/humidity extremes, secondhand smoke, high altitudes.

SURGICAL CONSIDERATIONS

Surgical heartworm extraction is a consideration in patients with severe infestation.

MEDICATIONS

DRUG(S) OF CHOICE

• Treat the primary underlying disease whenever possible. • The ideal therapeutic agent for PH causes pulmonary vasodilation without causing significant systemic hypotension.

Oxygen

• Treatment of choice but long-term administration unfeasible. • Useful in acute setting to correct hypoxia and cause pulmonary vasodilation.

Phosphodiesterase Type V (PDE5) Inhibitors

• Inhibit the breakdown of cyclic guanosine monophosphate (cGMP) causing increased nitric oxide and pulmonary vasodilation. • Avoid other drugs with similar effects (nitrates). • Sildenafil (1–2 mg/kg q8–12h)—drug of choice for most causes of PH in dogs. • Tadalafil—limited studies suggest benefit in dogs.

Phosphodiesterase Type III (PDE3) Inhibitor

• Pimobendan. • Causes pulmonary and systemic vasodilation. • Positive inotropic effect supports right heart dysfunction. • Indicated if PH secondary to left heart disease. • Unclear if useful with other causes of PH.

Other Vasodilators

• Limited benefit due to concurrent systemic vasodilation and hypotension. • Important in PH due to left heart disease. • Amlodipine, hydralazine, and angiotensin-converting enzyme (ACE) inhibitors.

Bronchodilators

• May help patients with pulmonary disease. • Sympathomimetics (e.g., terbutaline). • Methylxanthines (e.g., theophylline)—may also cause mild PA vasodilation.

Anticoagulants

• Common therapy for all causes of PH due to primary and/or secondary thromboembolism in humans. • Use in companion animals unclear except in patients with PTE.

Thrombolytics

• Streptokinase and tissue plasminogen activator indications and effectiveness debated in companion animals. • Likely only indicated if acute PTE with significant cardiac compromise.

Anti-inflammatories and Antibiotics

• Steroids may help if cause of PH has inflammatory component (e.g., HWD or primary pulmonary disease). • Antibiotics if bacterial component.

Other Therapies

• No large veterinary clinical trials to support use. • Endothelin receptor antagonists (Bosentan®)—pulmonary vasodilator that improves outcome in humans; cost prohibitive in veterinary patients. • Platelet-derived growth factor antagonists (toceranib, sorafenib, imatinib)—shown to decrease right heart pressure in rat PH model; preliminary studies of imatanib in dogs is promising. • L-arginine—possible benefit due to conversion to nitric oxide.

CONTRAINDICATIONS

• Respiratory depressants. • Cardiac myocardial depressants (e.g., beta blockers). • Bronchoconstrictors (e.g., nonspecific beta blockers). • Vasoconstrictors.

PRECAUTIONS

• Vasodilators can cause systemic hypotension. • Pulmonary vasodilation in patients with left heart disease may induce pulmonary edema. • Bronchodilators can cause tachycardia and hyperexcitability. • Hypovolemia may reduce pulmonary blood flow.

FOLLOW-UP

PATIENT MONITORING

• Serial echocardiography to assess improvement/progression. • Repeat thoracic radiographs, ECG, labwork, blood pressure as needed.

POSSIBLE COMPLICATIONS

• Right-sided CHF. • Syncope. • Arrhythmias. • Sudden death.

EXPECTED COURSE AND PROGNOSIS

• Based on ability to reverse underlying disease. • Often very guarded prognosis.

MISCELLANEOUS

ABBREVIATIONS

• ACE = angiotensin-converting enzyme.
• cGMP = cyclic guanosine monophosphate.
• CHD = congenital heart disease.
• CHF = congestive heart failure.
• HWD = heartworm disease.
• LA = left atrium.
• PA = pulmonary artery.
• PH = pulmonary hypertension.
• PI = pulmonary valve insufficiency.
• PTE = pulmonary thromboembolism.
• RA = right atrium.
• RV = right ventricle.
• TR = tricuspid valve regurgitation.
• VPCs = ventricular premature complexes.

HYPERTENSION, SYSTEMIC ARTERIAL

BASICS

DEFINITION
Sustained increase in arterial blood pressure, corresponding to systolic BP (SBP) ≥160 mmHg confirmed during multiple measurement sessions. BP increases may be transient and related to the measurement process (situational or "white-coat" hypertension), or sustained and pathologic. In veterinary patients, systemic arterial hypertension (HT) usually occurs in association with a clinical disease or treatment known to cause HT and is categorized as secondary. If an underlying disease is not present or able to be determined, HT is considered idiopathic.

PATHOPHYSIOLOGY
- BP is the force exerted by a blood column against the vessel wall, and is determined by cardiac output, aortic impedance and systemic vascular resistance.
- Normally, BP is under close regulation, such that rapid or wide swings are avoided.
- Factors that favor BP increases by augmenting cardiac output (e.g., increases in intravascular volume, heart rate, or myocardial contractility) or systemic vascular resistance (e.g., arteriolar vasoconstriction, increased blood viscosity) are usually balanced by autonomic, renal, and local vascular responses that restore normal BP.
- Systemic HT may develop in association with diseases or pharmacologic agents that overwhelm or interfere with normal homeostatic mechanisms or with vascular responsiveness to these mechanisms.
- Chronic, sustained BP increases may cause injury to several organs, referred to as target organ damage (TOD).

SYSTEMS AFFECTED
- Renal/urologic.
- Cardiovascular.
- Ophthalmic.
- Nervous.

GENETICS
Rare instances of familial idiopathic HT are reported.

INCIDENCE/PREVALENCE
- Prevalence estimates are difficult to interpret due to differences in HT definitions, inclusion criteria, and measurement techniques among studies.
- Pathologic HT are rare in young, healthy dogs and cats.
- Reported prevalence in HT-associated diseases—chronic kidney disease (CKD), 9–93% (dogs) and 19–65% (cats); diabetes mellitus, 24–67% (dogs) and 0–15% (cats); hyperadrenocorticism, 20–80% (dogs); hyperthyroidism, 5–25% (cats); pheochromocytoma, 43–86% (dogs).

SIGNALMENT

Species
Dog and cat.

Breed Predilections
None

Mean Age and Range
- Usually older animals; median age 13–15 years (cats).
- May be noted in younger animals, especially those affected by infectious (e.g., leptospirosis) or heritable (e.g., polycystic kidney disease, renal dysplasia) disease.

SIGNS

General Comments
Clinical signs vary with affected target organ and underlying disease; may be apparently asymptomatic or display signs that are acute, severe, or rapidly progressive.

Historical Findings
- Signs attributable to underlying disease (e.g., polyuria/polydipsia, anorexia, vomiting, weight loss with CKD; hindlimb weakness, cervical ventroflexion with hyperaldosteronism).
- Acute-onset or progressive blindness.
- Altered mental state, lethargy, seizures (generalized or focal), or ataxia.
- Rarely, respiratory signs due to congestive heart failure (CHF), e.g., dyspnea/orthopnea (cats/dogs), cough (dogs).
- Epistaxis (rare).
- Headaches, blurred vision, and anxiety, reported by people with HT, may manifest as nonspecific signs in dogs and cats.

Physical Examination Findings
- Ocular—blindness, mydriasis, exudative retinal detachment, retinal hemorrhage/edema, retinal vascular tortuosity or perivascular edema, vitreal hemorrhage, bullous retinal detachment, hyphema, glaucoma, retinal degeneration.
- Neurologic—abnormal mentation, central blindness, nystagmus, ataxia.
- Renal—palpable renal abnormalities.
- Cardiovascular—heart murmur, arrhythmia, gallop sound, pulmonary crackles.

CAUSES

Idiopathic
Subclinical CKD thought to contribute in some cases.

Secondary Hypertension
- CKD.
- Acute kidney injury (AKI).
- Hyperadrenocorticism.
- Hyperthyroidism.
- Diabetes mellitus.
- Pheochromocytoma.
- Primary hyperaldosteronism.
- Hypothyroidism.
- Polycythemia.
- Drug-related—glucocorticoids (uncommon), mineralocorticoids (high dosages), erythropoietin/darbepoetin, phenylpropanolamine, phenylephrine, ephedrine, toceranib phosphate.
- Intoxicants—cocaine, methamphetamine/amphetamine, 5-hydroxytryptophan.

RISK FACTORS
Renal disease or endocrinopathy.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Differential signs—differentiate from other causes of acute-onset blindness, central neurologic signs, CHF, or epistaxis, depending on presenting signs and clinical findings.

CBC/BIOCHEMISTRY/URINALYSIS
- Abnormalities vary depending on underlying disease.
- Packed cell volume may be decreased (CKD) or mildly increased (hyperthyroidism).
- CBC may reveal stress leukogram and/or thrombocytosis (hyperadrenocorticism).
- May note azotemia, hyperphosphatemia, hyperkalemia (AKI, CKD); hyperglycemia (diabetes mellitus); increased serum alkaline phosphatase (hyperadrenocorticism); increased serum alanine aminotransferase (hyperthyroidism); hypokalemia (hyperaldosteronism).
- Urinalysis may reveal low urine specific gravity, proteinuria, hematuria, pyuria, bactiuria (AKI, CKD, hyperadrenocorticism); glucosuria (diabetes mellitus).

OTHER LABORATORY TESTS
- Assessment of glomerular filtration rate may detect early renal dysfunction.
- Urinary protein : creatinine ratio may disclose proteinuria.
- Serum total T_4 concentration, T_3 suppression test to evaluate for hyperthyroidism (cats).
- Serum T_3, T_4, free T_3, free T_4, and thyroid-stimulating hormone concentrations; T_3 and T_4 autoantibodies to evaluate for hypothyroidism (dogs).
- Screening tests for hyperadrenocorticism in dogs with other suggestive findings.
- Plasma aldosterone concentration if primary hyperaldosteronism suspected (cats).
- Plasma and urinary catecholamine concentrations if pheochromocytoma suspected.

IMAGING
- Abdominal ultrasonography to evaluate kidneys, liver, and adrenal glands.
- Echocardiography to evaluate for cardiac TOD—may be normal, or disclose left ventricular concentric and/or eccentric hypertrophy, diastolic dysfunction, left atrial enlargement.
- CT or MRI if cerebral hemorrhage, hyperadrenocorticism suspected.
- Thyroid scintigraphy to evaluate hyperthyroidism.

(CONTINUED) # HYPERTENSION, SYSTEMIC ARTERIAL

DIAGNOSTIC PROCEDURES

- Diagnosis requires documentation of persistently (i.e., during ≥2 sessions, performed on different days) high SBP, using reliable direct or indirect measurement methods.
- Methods should be standardized to avoid inaccuracies caused by common technical errors.
- Substantial effort should be made to minimize patient stress to reduce risk of falsely diagnosing "true" HT in patient with situational HT.
- See Suggested Reading to consult detailed published guidelines for BP measurement.

Direct (Invasive) BP Measurement Methods

- Gold standard—involve catheterization or needle puncture of peripheral artery.
- Reserved for monitoring under anesthesia or during emergency management of severe HT.

Indirect (Noninvasive) BP Measurement Methods

- More clinically useful than direct methods for outpatient setting.
- Utilize devices that rely on Doppler ultrasonography or oscillometry.
- Require placement of inflatable cuff to temporarily occlude arterial blood flow in extremity by applying external, compressive force.

Ancillary Diagnostics

Fundoscopic examination to evaluate for retinal lesions.

PATHOLOGIC FINDINGS

- Widespread, multisystemic arteriolosclerosis.
- Increased cardiac mass due to left ventricular hypertrophy.
- Aortic aneurysm/dissection (rare).
- Lesions associated with underlying disease.

TREATMENT

Treatment Guidelines for Dogs and Cats

- General goal to reverse/limit ongoing TOD and prevent future TOD.
- If identified, treatment of underlying disease may resolve HT.
- Antihypertensive therapy indicated in dogs and cats with:
  - SBP ≥160 mmHg on two or more occasions for which situational hypertension considered unlikely.
  - SBP ≥160 mmHg on single occasion if clear evidence of ongoing neurologic or ocular TOD.
- Animals without evidence of TOD and mildly increased SBP (140–159 mmHg, "prehypertensive"), or suspected situational HT, should not be treated.
- Therapeutic targets—ideally, normotension (SBP 120–140 mmHg); SBP <160 mmHg at minimum.
- Gradual (i.e., over several weeks) reduction in BP should be targeted.
- HT considered an emergency if severe neurologic or ocular TOD is present; in these cases, goal is to cautiously reduce SBP to approximately 160 mmHg over 3–6 hours and to <140 mmHg over 1–2 days, with continuous/frequent BP monitoring.

APPROPRIATE HEALTH CARE

Usually managed on outpatient basis. Inpatient care may be necessary depending on underlying condition and severity of target organ damage.

ACTIVITY

No restrictions.

DIET

- Dietary sodium restriction is controversial.
- Avoid high sodium intake.

CLIENT EDUCATION

- Unless underlying cause is curable or controllable, patient is likely to require lifelong antihypertensive therapy.
- HT may persist or develop even with control of underlying disease (e.g., hyperthyroidism).
- Multiple agents and periodic dosage adjustments may be required for adequate control of HT.
- Frequent monitoring necessary until adequate BP control is achieved.

SURGICAL CONSIDERATIONS

May be indicated for pheochromocytoma, primary hyperaldosteronism, hyperthyroidism, and some forms of hyperadrenocorticism.

MEDICATIONS

DRUG(S) OF CHOICE

- Depend on underlying disease (e.g., adrenergic antagonists preferred in patients with pheochromocytoma, aldosterone antagonists in those with primary aldosteronism).
- Cats—amlodipine or telmisartan first line for SBP 160–200 mmHg; amlodipine first line if SBP >200 mmHg or ocular/neurologic TOD; angiotensin-converting enzyme (ACE) inhibitor or telmisartan may be added if proteinuria or poor control with amlodipine alone.
- Dogs—ACE inhibitor or angiotensin receptor blocker (ARB) first line; amlodipine coadministered as first line if SBP >200 mmHg, or added if SBP 160–200 mmHg and poor control with ACE inhibitor or ARB.
- In hypertensive emergency (HT with severe ocular or neurologic TOD), parenteral hydralazine, sodium nitroprusside, or fenoldopam can be used; continuous direct BP monitoring is necessary in these cases.

Dihydropyridine Calcium Channel Blocker

Amlodipine—dogs: 0.1–0.5 mg/kg PO q24h; cats: 0.625–1.25 mg/cat PO q24h (consider 1.25 mg/cat if SBP >200 mmHg; may be increased to 2.5 mg/cat if necessary).

ACE Inhibitor

Enalapril or benazepril—dogs: 0.5–1.0 mg/kg PO q12h; cats: 0.5 mg/kg PO q12–24h.

ARB

Telmisartan—dogs: 1.0 mg/kg PO q24h; cats: 2.0 mg/kg PO q 24h; in United States labeled to start with 1.5 mg/kg PO BID protocol for 2 weeks and then adjust to 2.0 mg/kg q24h.

Direct-Acting Vasodilator

Hydralazine—dogs: 0.5 mg/kg PO q12h, stepwise increase to 3 mg/kg PO q12h if needed; cats: 2.5 mg/cat q12–24h.

Alpha-Adrenergic Receptor Antagonist

Phenoxybenzamine—dogs: 0.25 mg/kg PO q8–12h; cats: 2.5 mg/cat PO q8–12h.

Aldosterone Antagonist

Spironolactone—dogs and cats: 1.0–2.0 mg/kg PO q12h.

CONTRAINDICATIONS

Decrease or discontinue vasoconstricting drugs (e.g., phenylpropanolamine).

PRECAUTIONS

- Abrupt BP reduction and hypotension (SBP <120 mmHg) should be avoided; use of rapidly acting drugs or combinations of vasodilators increases this risk.
- Direct arteriolar vasodilators and IV antihypertensives may cause reflex tachycardia.

POSSIBLE INTERACTIONS

- Use of antihypertensives in combination increases risk of hypotension.
- Hyperkalemia may result from coadministration of any combination of ACE inhibitor, ARB, and spironolactone.

ALTERNATIVE DRUG(S)

For Hypertensive Emergency

- Sodium nitroprusside (inorganic nitrate)—dogs and cats: 0.5–5 µg/kg/min IV, start low and increase by increments of 0.1–0.5 µg/kg/min to effect.
- Hydralazine (direct arteriolar vasodilator)—dogs: 0.5–2 mg/kg SC/IM q8–12h *or* 0.1–0.5 mg/kg IV q2–8h, CRI 1.5–5.0 µg/kg/min; cats: 1.0–2.5 mg/cat SC.
- Fenoldopam (dopamine-1 antagonist)—dogs and cats: 0.1–1.6 µg/kg/min; start low, increase by increments of 0.1 µg/kg/min to effect.

HYPERTENSION, SYSTEMIC ARTERIAL (CONTINUED)

FOLLOW-UP

PATIENT MONITORING

• BP and manifestations of ocular or neurologic TOD should be checked weekly (or every 1–3 days if severe TOD) until normotension (SBP 120–140 mmHg) achieved (ideally), or SBP <160 mmHg (at minimum).
• Periodic monitoring of laboratory tests to evaluate for side effects of medications and clinical response (e.g., proteinuria, hematuria, anemia, thrombocytopenia, potassium balance, sodium balance, azotemia).

POSSIBLE COMPLICATIONS

• Progression of underlying renal disease.
• Retinopathy, choroidopathy.
• Encephalopathy, cerebral vascular accident.
• CHF (uncommon), aortic aneurysm/dissection/rupture (rare).
• Gingival hyperplasia may develop with amlodipine treatment in dogs.
• Facial dermatitis/excoriation may develop with spironolactone treatment in cats (uncommon).

EXPECTED COURSE AND PROGNOSIS

• Treatment of systemic hypertension may reverse or slow progression of TOD.
• Rapid and complete improvement of neurologic signs (usually within 24–48 hours) is expected with adequate BP control.
• Improvement/resolution of visual deficits may take weeks with BP control; most blind eyes do not regain normal vision.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• CKD.
• Endocrinopathies.

AGE-RELATED FACTORS

• CKD.
• Hyperthyroidism.
• Hyperadrenocorticism.

ZOONOTIC POTENTIAL

None, unless underlying leptospirosis.

PREGNANCY/FERTILITY/BREEDING

Pregnancy may exacerbate HT.

SYNONYMS

• High blood pressure.
• Systemic hypertension.

SEE ALSO

• Diabetes Mellitus Without Complication—Cats.
• Diabetes Mellitus Without Complication—Dogs.
• Glomerulonephritis.
• Hyperadrenocorticism (Cushing's Syndrome)—Cats.
• Hyperadrenocorticism (Cushing's Syndrome)—Dogs.
• Hyperthyroidism.
• Pheochromocytoma.

ABBREVIATIONS

• ACE = angiotensin-converting enzyme.
• AKI = acute kidney injury.
• ARB = angiotensin receptor blocker.
• CHF = congestive heart failure.
• CKD = chronic kidney disease.
• HT = systemic arterial hypertension.
• SBP = systolic arterial blood pressure.
• TOD = target organ damage.

HYPERTHYROIDISM

BASICS

DEFINITION
A state of increased metabolism caused by increased circulating concentrations of thyroid hormone.

PATHOPHYSIOLOGY
• Feline hyperthyroidism most often caused by benign adenomatous hyperplasia or follicular cell adenoma, causing increased secretion of thyroxine (T_4) and triiodothyronine (T_3).
• Naturally occurring hyperthyroidism rare in dogs; most often malignant carcinoma (<2% of cats have malignant thyroid carcinoma).
• Oversupplementation with exogenous thyroid hormone may cause hyperthyroidism in dogs.

SYSTEMS AFFECTED
• Cardiovascular—systemic hypertension, thyrotoxic cardiomyopathy. • Gastrointestinal (GI)—malabsorption, hypermotility.
• Nervous/behavioral—restlessness, irritability, aggression, vocalization, pacing. • Urologic—increased glomerular filtration rate (GFR).
• Musculoskeletal—catabolism, cachexia.

GENETICS
None known.

INCIDENCE/PREVALENCE
• Most common feline endocrinopathy; affects 3–8% of cats >10 years old. • Rare in dogs.

SIGNALMENT
• Cats 4–22 years old; mean age of onset is 13 years. • <5% of affected cats <8 years old.
• Most common in dogs >10 years old.

SIGNS

General Comments
• Signs related to increased metabolism.
• Small number of cats show atypical signs; the human term "apathetic hyperthyroidism" is characterized by lethargy, decreased appetite, and muscle weakness; signs may be more common with advanced hyperthyroidism.

Historical Findings
• Weight loss. • Polyphagia. • Hyperactivity/irritability/restlessness. • Polyuria/polydipsia.
• Vomiting. • Diarrhea. • Increased vocalization. • Tachypnea. • Muscle weakness.

Physical Examination Findings
• Cachexia/muscle loss. • Palpable thyroid gland (unilateral or bilateral). • Tachycardia/heart murmur/gallop rhythm. • Systemic hypertension/retinopathy. • Unkempt hair/hair loss. • Thickened nails. • Ventroflexion of neck (advanced disease).

CAUSES
• In cats, benign adenomatous hyperplasia and follicular cell adenoma lead to oversecretion of T_4 and T_3; thyroid carcinoma is rare.
• In dogs, thyroid carcinoma is more likely; hyperthyroidism in dogs may be secondary to oversupplementation of T_4.

RISK FACTORS
• Increased risk with aging. • Decreased risk in Burmese, Tonkinese, Persian, Siamese, Abyssinian, and British shorthair cats; possible increased risk in domestic longhair cats. • Multifactorial environmental contributors are possible, including bisphenol A (BPA) associated with canned food diets, and polybrominated diphenyl ether (PBDE) flame retardants, but further study is needed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Any of the differentials for hyperthyroidism can reflect concurrent disease. • Neoplasia.
• Inflammatory bowel conditions. • Diabetes mellitus. • Chronic kidney disease.
• Cardiomyopathy.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC—mild packed cell volume (PCV) elevation or stress leukogram. • Elevated alanine aminotransferase (ALT) activity is common. • Elevated alkaline phosphatase (ALP), aspartate aminotransferase (AST) activities, and blood urea nitrogen, creatinine, phosphorus, bilirubin, and glucose concentrations may be seen. • Urinalysis (UA) shows variable urine specific gravity; pre-treatment specific gravity does not predict post-treatment renal function.
• Glucosuria and evidence of urinary tract infection possible.

OTHER LABORATORY TESTS
• Elevated serum total T_4 (TT_4) concentration is diagnostic for hyperthyroidism in cats with clinical signs. ○ T_4 concentrations naturally decrease with age; early hyperthyroid cats may have T_4 levels in high-normal range. ○ T_4 concentration may be decreased by concurrent disease. • Free T_4 concentration measured by equilibrium dialysis may be helpful in cats with concurrent disease or early hyperthyroidism, but is not a screening test. • T_3 concentration is not useful for diagnosis in cats. • Thyroid-stimulating hormone (TSH) concentration should not be used for diagnosis in cats. • T_3 suppression test or thyrotropin-releasing hormone (TRH) stimulation test can help to confirm diagnosis in mild cases. • Fructosamine concentration may be decreased by concurrent hyperthyroidism. • Cardiac biomarker concentrations (*N*-terminal pro brain natriuretic peptide, cardiac troponin I) may be elevated; myocardial disease and biomarkers may return to normal after control of hyperthyroidism.

IMAGING
• Thoracic and abdominal radiography helpful to evaluate for neoplasia and cardiac disease. • Abdominal ultrasound helpful in determining concurrent disease.
• Echocardiography to evaluate cardiac function. • Thyroid scintigraphy can determine location of abnormal and ectopic thyroid tissues.

DIAGNOSTIC PROCEDURES
• BP measurement is part of baseline database. • GFR measurement is possible but not always practical.

PATHOLOGIC FINDINGS
• Multinodular adenomatous hyperplasia can be unilateral or bilateral (98% of cats).
• Thyroid carcinoma in dogs and <2% of hyperthyroid cats.

TREATMENT

APPROPRIATE HEALTH CARE
• Advanced hyperthyroidism with concurrent congestive heart failure requires hospitalization for stabilization. • Most cases managed on an outpatient basis. • Radioactive iodine and surgical treatments require hospitalization.

ACTIVITY
No activity restrictions.

DIET
• Because of increased metabolism and hypermotility of intestinal tract, highly digestible diets preferred. • Malabsorption improves with resolution of hyperthyroid state.
• Vitamin B_{12} supplementation may be helpful. • An iodine-deficient therapeutic diet is available and effective in appropriate situations.

CLIENT EDUCATION
• Hyperthyroidism in cats is common and treatable. • Treatment with medication or diet restriction is lifelong. • Medication dosing needs to be monitored regularly and adjusted accordingly. • Comorbidities are possible. • Hyperthyroidism in dogs is usually a malignancy and carries a poor long-term prognosis. • Possible side effects of medication. • Surgical thyroidectomy—anesthetic risks, risk of damage to parathyroid glands. • In some cases, radioactive iodine (I-131) treatment may need to be repeated.
• Resolution of thyrotoxicosis may reveal other, previously masked conditions (e.g., renal disease).

SURGICAL CONSIDERATIONS
• Surgical thyroidectomy is an accepted treatment option. • Thyroidectomy for carcinoma is not curative, but may be helpful with or without subsequent radioactive iodine treatment.

HYPERTHYROIDISM (CONTINUED)

MEDICATIONS

DRUG(S) OF CHOICE

• I-131 is treatment of choice for hyperthyroidism. • Methimazole (2.5–5 mg/cat PO q12–24h) is most common medication. ○ Methimazole should be dosed below expected therapeutic dose and titrated upward to minimize side effects. ○ Transdermal methimazole is available and effective; ideally, initial management with oral methimazole will stabilize patient, then transition to transdermal; resolution may be prolonged if treatment initiated with transdermal medication. ○ Methimazole may cause anorexia, vomiting, skin excoriations, thrombocytopenia, hepatopathy, and hypothyroidism; side effects occur within first weeks to months of treatment. ○ Anorexia, vomiting, and skin excoriations can be mitigated by starting at very low doses of methimazole and increasing to therapeutic levels; cessation of drug can resolve these issues, and restarting with transdermal methimazole may avoid recurrence of GI side effects. ○ Bleeding disorders, bone marrow dyscrasias, and hepatic issues require discontinuation of methimazole and choosing an alternative therapy. ○ Severe blood dyscrasias may require hospitalization and supportive care, but should resolve with appropriate treatment. • Atenolol may be used for severe tachycardia.

POSSIBLE INTERACTIONS

Concurrent use of phenobarbital may reduce effectiveness of methimazole.

ALTERNATIVE DRUG(S)

• Carbimazole—converted to methimazole after absorption; effective, may have fewer side effects than methimazole; not available in United States. • Propylthiouracil—not recommended. • Ipodate—for short-term treatment only, not effective for most hyperthyroid cats; not recommended in most cases.

FOLLOW-UP

PATIENT MONITORING

• Regardless of treatment option, GFR and renal function may decline after treatment, but will stabilize within 1 month of thyroid control. • I-131—physical exam (PE), BP, T_4, serum chemistry, and UA at 1, 3, 6, and 12 months post treatment.
• Methimazole—PE, CBC, serum chemistry, T_4, and UA every 2–4 weeks after starting treatment and after every dose change until T_4 is stabilized between 1 and 2.5 µg/L.
• In cats with renal insufficiency, serum T_4 should be maintained in upper half of reference interval. • Thyroidectomy—hypocalcemia can occur within several days post surgery; monitor for postoperative laryngeal paralysis; PE, T_4, serum chemistry, and UA 2–4 weeks post surgery, then every 3–6 months; supplementation should not be started postsurgically unless T_4 levels remain low after 3 months; hypothyroidism may be transient with subtotal thyroidectomy. • Therapeutic diet—PE, BP, serum chemistry, CBC, T_4, and UA every 4–6 months; may take as long as 6 months for cats with severe T_4 elevations to become euthyroid, if at all.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

• Fatal, if untreated. • Complications of thyroidectomy include hypothyroidism, hypoparathyroidism, laryngeal paralysis.
• I-131, antithyroid drugs, and thyroidectomy can all lead to hypothyroidism; proper dosing of I-131 and methimazole is imperative. • Iatrogenic hypothyroidism associated with worsening renal function and decreased survival.

EXPECTED COURSE AND PROGNOSIS

• Prognosis is excellent in cats without concurrent disease. • Cats on methimazole are likely to relapse if medication is not administered correctly. • Cats eating a therapeutic diet who do not strictly follow diet will not be successful. • Post I-131 treatment—mean survival time is 4 years.
• Treatment with methimazole—mean survival time is 2 years. • Overall mean survival time can be up to 5.3 years. • Cats with preexisting renal disease have a poorer prognosis. • Cats and dogs with carcinoma have a poor prognosis—best option for treatment may be surgical debulking of tumor followed by high dose I-131; recurrence is common.

MISCELLANEOUS

ASSOCIATED CONTITIONS

• Because hyperthyroidism is life-threatening, treatment of all hyperthyroid cats is recommended, with concurrent management of any comorbidities. • Less aggressive treatment options should be considered for cats with advanced (IRIS stage 3–4) renal disease.

AGE-RELATED FACTORS

Mature to geriatric cats and dogs.

ZOONOTIC POTENTIAL

N/A

PREGNANCY/FERTILITY/BREEDING

N/A

SYNONYMS

• Thyrotoxicosis. • Plummer's disease.

SEE ALSO

• Cardiomyopathy, Hypertrophic—Cats.
• Chronic Kidney Disease.
• Congestive Heart Failure, Right-Sided.
• Hypertension, Systemic Arterial.
• Hypoparathyroidism.

ABBREVIATIONS

• ALT = alanine aminotransferase.
• ALP = alkaline phosphatase.
• AST = aspartate aminotransferase.
• BPA = bisphenol A.
• GFR = glomerular filtration rate.
• GI = gastrointestinal.
• I-121 = radioactive iodine.
• PBDE = polybrominated diphenyl ether.
• PCV = packed cell volume.
• PE = Physical exam.
• T_3 = triiodothyronine.
• T_4 = thyroxine.
• TRH = thyrotropin-releasing hormone.
• TSH = thyroid-stimulating hormone.
• TT_4 = total thyroxine.
• UA = urinalysis.

HYPERTROPHIC OSTEODYSTROPHY

BASICS

DEFINITION
An inflammatory disease of bone that affects rapidly growing giant- and large-breed puppies.

PATHOPHYSIOLOGY
- Characterized by nonseptic, suppurative inflammation within metaphyseal trabeculae of long bones.
- Rapidly growing bones more severely affected (distal radius, ulna, and tibia).
- Metaphysis—widened owing to perimetaphyseal swelling and bone deposition.
- Trabecular microfracture and metaphyseal separation—occur adjacent and parallel to the physis.
- Bone formation defective.
- Ossifying periostitis—may be extensive and in some cases may bridge the physis, hindering growth.
- Etiology unknown.

SYSTEMS AFFECTED
- Gastrointestinal—diarrhea.
- Musculoskeletal—symmetric distribution; distal forelimbs most severely affected; may note soft tissue mineralization in other organs; widened costochondral junctions.
- Respiratory—interstitial pneumonia.

GENETICS
Suspect hyperreactivity to immune stimulation (vaccination).

INCIDENCE/PREVALENCE
Low

GEOGRAPHIC DISTRIBUTION
Northeastern United States—highest in fall; lowest in winter.

SIGNALMENT

Species
Dog

Breed Predilections
- Large and giant breeds.
- Great Danes; Weimaraners—most common.
- Reported—Irish wolfhounds; Saint Bernards; kuvaszes; Irish setters; Doberman pinschers; German shepherds; Labrador retrievers; boxers; Chesapeake Bay retriever; golden retriever; Irish setter; others.

Mean Age and Range
- Affects puppies 3–6 months old.
- Range of onset—2–8 months of age.

Predominant Sex
Males 2.3 times more than females.

SIGNS

General Comments
Lameness—may be episodic; degree varies from mild to non-weight-bearing; initial episode may resolve with or without relapse.

Historical Findings
- Depend on severity of the episode.
- Owners often describe a depressed puppy that is reluctant to move.
- Inappetence—common.
- Painful.
- Shifting leg lameness.

Physical Examination Findings
- Lameness—symmetric, more severe in forelimbs.
- Metaphyses—painful; warm; swollen distal metaphyses of radius, ulna, and tibia.
- Pyrexia—as high as 41.1 °C (106 °F).
- Inappetence.
- Depression.
- Weight loss.
- Dehydration.
- Diarrhea.
- Cachexia.
- Debilitation.
- Manifestations of systemic illness—respiratory or gastrointestinal.
- Foot pad hyperkeratosis.
- Anemia.

CAUSES
Unknown; the following hypotheses have been proposed.

Metabolic
- Hypovitaminosis C—discounted; may be seen as a result of overuse of available vitamin C in hyperactive bone formation.
- Hypocuprosis—in rats but not in dogs.

Nutritional
- Overnutrition and oversupplementation—association inconsistent.
- Incomplete occurrence in litters.
- Correcting diet does not always alter the course of the disease or eliminate relapses.

Infectious
- Bacterial or fungal organisms—may be secondary when found.
- Not transmissible.
- Temporal association with canine distemper virus vaccination.
- Secondary development may depend on the timing of the neonate's exposure.

RISK FACTORS
Vaccination against canine distemper virus may precipitate an uncontrolled inflammatory reaction in the osteogenic centers.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Panosteitis—no metaphyseal swelling; cottony intramedullary densities in long bones on radiographs.
- Septic metaphysitis/epiphysitis—radiographs of the extremities not typical of hypertrophic osteodystrophy; asymmetric; may note septic suppurative inflammation on needle aspiration of metaphyseal/epiphyseal lesions; hematologic findings implicate bacterial infection (neutrophilia plus left shift).
- Elbow dysplasia—no metaphyseal swelling; no fever; pain localized to the elbow(s); typical radiographic signs.
- Osteochondritis dissecans—no metaphyseal swelling or fever; pain localized to shoulder or elbow; subchondral defects on radiographs.
- Septic polyarthritis—septic suppurative inflammation on arthrocentesis; culture.
- Nonseptic polyarthritis—nonseptic suppurative inflammation on arthrocentesis.

CBC/BIOCHEMISTRY/URINALYSIS
- Do not positively contribute to diagnosis.
- Stress leukogram.
- Normal serum parameters.
- Hypocalcemia uncommon.

OTHER LABORATORY TESTS
N/A

IMAGING
- Distal extremity radiographs—irregular radiolucent zones within metaphyses, parallel and adjacent to physes; flared metaphyses; extraperiosteal new bone extending up the diaphyses; mineralization of perimetaphyseal soft tissues; asynchronous growth in paired bones; cranial bowing; valgus deformity; usually bilaterally symmetric.
- Vertebrae, metacarpal bones, metatarsal bones, ribs, scapula, humerus, and mandible—rarely affected.
- Thoracic radiographs—may reveal interstitial infiltrates.

PATHOLOGIC FINDINGS
- Distal metaphysis of the radius and ulna—most severe changes; similar abnormalities in all long bones.
- Gross—wide metaphysis; peripheral mineralization; soft tissue swelling.

Histologic
- Nonseptic suppurative inflammation of the metaphysis (osteochondritis), especially adjacent to growth plates.
- Necrosis and probable secondary failure of osseous tissue deposition onto the calcified cartilage lattice of the primary spongiosa.
- Trabecular microfractures and impaction.
- Mineralization of perimetaphyseal soft tissues and soft tissues in other regions of the body.
- Interstitial pneumonia.

TREATMENT

APPROPRIATE HEALTH CARE
- None specific.
- Supportive—from none to intensive care for severely affected puppies.
- Depends on the severity of the episode, pyrexia, and the patient's ability to maintain normal hydration and willingness to eat.

HYPERTROPHIC OSTEODYSTROPHY (CONTINUED)

NURSING CARE
• Some patients will not stand or move—prone to develop pressure sores; turn every 2–4 hours to prevent sores and hypostatic congestion of the dependent lung.
• Intravenous fluid therapy—for dehydration; maintenance fluid thereafter.

ACTIVITY
• Restricted—running and jumping may exacerbate metaphyseal injury and result in further inflammation.
• Confine to a small well-padded area—recommended.
• Leash-walking only.

DIET
• Normal commercial puppy ration.
• Avoid supplements.

CLIENT EDUCATION
• Warn the client of the disease's relapsing nature.
• Inform client that bony deformities will remodel to some degree with time, but that bowing and valgus deformations are permanent.
• Warn client that the more severe the disease, the more severe the bowing deformity.

SURGICAL CONSIDERATIONS
• None specific.
• May implement surgical methods of alimentation (pharyngostomy tube, esophagostomy tube, gastrostomy tube)—in debilitated puppies that will not eat or drink and have frequently relapsing episodes of acute clinical signs.
• Corrective osteotomy if growth deformity develops from physeal disruption.

MEDICATIONS

DRUG(S) OF CHOICE
• Anti-inflammatory drugs—for pain and antipyretic effects; may try:
  ◦ Aspirin 10 mg/kg PO q12h.
  ◦ Carprofen 2.2 mg/kg IM/PO q12h.
  ◦ Deracoxib 1–2 mg/kg PO q24h; 3–4 mg/kg PO q24h, 7-day limit.
  ◦ Firocoxib 5 mg/kg PO q24h,
  ◦ Grapiprant 2 mg/kg PO q24h, to animals >3.6 kg.
  ◦ Meloxicam—dogs: load 0.2 mg/kg PO, then 0.1 mg/kg PO q24h; cats: 0.1 mg/kg PO q24h—liquid.
• Analgesics—can be used in conjunction with anti-inflammatory medication:
  ◦ Tramadol 1–4 mg/kg PO q8–12h.
  ◦ Prednisone 0.5–1 mg/kg PO q24h; may cause physeal growth disturbances.
  ◦ Opiates may be needed in severe cases.

CONTRAINDICATIONS
Vitamin C—may be contraindicated; may accelerate dystrophic calcification and decrease bone remodeling.

PRECAUTIONS
• Avoid immunosuppressive drugs if secondary infection is present.
• Nonsteroidal anti-inflammatory drugs (NSAIDs)—may cause gastric ulceration; watch for hematemesis or melena; *never* use in conjunction with other NSAIDs or steroids.

POSSIBLE INTERACTIONS
None

ALTERNATIVE DRUG(S)
None

FOLLOW-UP

PATIENT MONITORING
Signs of improvement—less metaphyseal sensitivity; patient gets up; appetite improves; pyrexia resolves.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
• Cachexia.
• Permanent bowing deformities due to premature asymmetric physeal closure.
• Secondary bacterial infection.
• Pressure sores.
• Muscle fasciculations, seizure—with hypocalcemia.
• May see secondary septicemia.
• Recurrence.
• Death.

EXPECTED COURSE AND PROGNOSIS
• Course—days to weeks.
• Most patients—one or two episodes and recover.
• Some patients—seem to have intractable relapsing episodes of pain and pyrexia; rarely die or are euthanized.
• Prognosis—usually good; guarded with multiple relapses or complicating secondary problems.
• Persistent bowing deformity—eliminates many purebred puppies from the show ring.

MISCELLANEOUS

ASSOCIATED CONDITIONS
None proven.

AGE-RELATED FACTORS
Vaccination (canine distemper virus).

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
Occurs only in juveniles.

SYNONYMS
• Metaphyseal osteopathy.
• Vitamin C deficiency.
• Scurvy.
• Moller Barlow's disease.
• Osteodystrophy II.

SEE ALSO
• Elbow Dysplasia.
• Osteochondrosis.
• Panosteitis.

ABBREVIATIONS
• NSAID = nonsteroidal anti-inflammatory drug.

Client Education Handout available online

HYPERTROPHIC OSTEOPATHY

BASICS

OVERVIEW

- Disease of the distal extremities resulting from peripheral blood flow changes that stimulate an overgrowth of vascular connective tissue and subsequent periosteal proliferation.
- Pathogenesis—speculative; increased blood circulation in the limb due to neural or humoral mechanisms is likely secondary to an underlying disease process: most notably intra-thoracic or intra-abdominal neoplasia.
- Predominantly affects the diaphyseal region of phalanges, metacarpals, and metatarsals.

SIGNALMENT

- More common in dogs than cats.
- Age of highest frequency >8 years; coincides with the peak incidence of neoplasia.

SIGNS

Historical Findings

- Chronic or acute lameness with pain in one or more limbs.
- Reluctance to move or use affected limb(s).
- Large firm swelling of affected limb(s).
- Respiratory clinical signs if intra-thoracic disease present (rare).

Physical Examination Findings

- Long bone or distal extremities—enlarged, firm, taut, thickened; not edematous.
- Single or multiple limbs.
- Firm swelling may extend proximally with progression of disease.
- Lameness and pain noted in affected limb(s).

CAUSES & RISK FACTORS

- Primary and metastatic neoplasia—lung tumors; esophageal sarcoma; rhabdomyosarcoma; adenocarcinoma of the adrenal gland, liver, or prostate; nephroblastoma; renal cell carcinoma; thoracic and abdominal mesotheliomas.
- Non-neoplastic conditions—pneumonia, lung abscess/granulomas, dirofilariasis; congenital or acquired heart disease, bronchial foreign bodies; *Spirocerca lupi* infestation of the esophagus; focal lung atelectasis; obscure toxins; hypertension; hyperestrogenism; congenital idiopathic megaesophagus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Osteomyelitis—asymmetric; edematous; lytic bone lesions; history of penetrating trauma or systemic infection.
- Metastatic neoplasia—asymmetric.
- Hypervitaminosis A (feline)—asymmetric; generally involves joint surface.
- Hypertrophic osteodystrophy—metaphyseal abnormality, young dogs.
- Multiple cartilaginous exostosis—metaphyseal abnormality, young dogs.
- Degenerative joint disease—involves articular surface changes in multiple joints.

CBC/BIOCHEMISTRY/URINALYSIS

Dependent on underlying cause and concurrent conditions.

OTHER LABORATORY TESTS

Fecal examination—rule out gastrointestinal and respiratory parasitism.

IMAGING

- Radiographs of affected long bones—bilaterally symmetric extensive, aggressive, or nonaggressive periosteal new bone formation on diaphysis; palisading periosteal reaction; joints not affected.
- Thoracic and abdominal imaging (radiographs, ultrasound, and/or CT)—identify and differentiate primary lesions.

DIAGNOSTIC PROCEDURES

Bone biopsy and culture (bacterial and fungal)—in atypical cases to rule out neoplasia and osteomyelitis.

TREATMENT

- Directed at managing, treating, or removing the underlying cause.
- Options in selected cases—unilateral vagotomy on the side of a lung lesion or bilateral cervical vagotomy; incising through parietal pleura; subperiosteal rib resection.

MEDICATIONS

DRUG(S) OF CHOICE

- Dictated by underlying cause.
- Analgesics/anti-inflammatories—as needed.
- No known clinically proven benefit for steroid therapy.

FOLLOW-UP

PATIENT MONITORING

Condition indicates other disease processes—identify the primary cause.

EXPECTED COURSE AND PROGNOSIS

- Clinical signs and bone changes may resolve with treatment of underlying disease.
- Bone changes may take several months to regress.
- Prognosis—guarded to poor due to the common occurrence of neoplastic causes; non-neoplastic lesions may resolve with appropriate treatment of primary cause.
- Tumor recurrence or metastasis may result in recurrence of osteopathy.
- No relationship between size, site, or histologic type of primary lesion, the development of or recurrence of hypertrophic osteopathy postoperatively.

MISCELLANEOUS

SYNONYMS

- Hypertrophic pulmonary osteopathy/osteoarthropathy (HPO/HPOA).
- Hypertrophic osteoarthropathy (HOA).

HYPERTROPHIC PYLORIC GASTROPATHY, CHRONIC

BASICS

DEFINITION
Pyloric stenosis or chronic hypertrophic pyloric gastropathy is an obstructive narrowing of the pyloric canal resulting from varying degrees of muscular hypertrophy or mucosal hyperplasia.

PATHOPHYSIOLOGY
- Can result from a congenital lesion composed primarily of hypertrophy of the smooth muscle or be one of three types of acquired form—primarily circular muscle hypertrophy (type 1), a combination of muscular hypertrophy and mucosal hyperplasia (type 2), or primarily mucosal hyperplasia (type 3).
- The cause is unknown; proposed factors include increased gastrin concentrations (which have a trophic effect on the muscle and mucosa) or changes in the myenteric plexus that lead to chronic antral distension and its associated effects.

SYSTEMS AFFECTED
- Gastrointestinal (GI)—chronic intermittent vomiting; regurgitation has also been reported.
- Musculoskeletal—weight loss.
- Respiratory—possible aspiration pneumonia.

GENETICS
Inheritance pattern unknown.

INCIDENCE/PREVALENCE
Uncommon

GEOGRAPHIC DISTRIBUTION
N/A

SIGNALMENT

Species
- More common in the dog.
- Rare in the cat.

Breed Predilections
- Congenital—brachycephalic breeds (boxer, Boston terrier, bulldog); Siamese cats.
- Acquired—Lhasa apso, shih tzu, Pekingese, poodle.

Mean Age and Range
- Congenital—shortly after weaning (introduction of solid food) and up to 1 year of age.
- Acquired—typically middle-aged to older (average 9.8 years of age).

Predominant Sex
Twice as many males as females.

SIGNS

General Comments
- Clinical signs are related to the degree of pyloric narrowing.
- Projectile vomiting is generally not a presenting complaint.

Historical Findings
- Chronic intermittent vomiting of undigested or partially digested food (rarely containing bile), often several hours after eating.
- Congenital lesions associated with clinical signs shortly after weaning.
- Frequency of vomiting increases with time.
- Lack of response to antiemetic agents or motility modifying agents.
- Occasional anorexia with weight loss.
- Regurgitation.

Physical Examination Findings
Most dogs are generally in good physical condition.

CAUSES
- Congenital or acquired.
- May be influenced by infiltrative mural diseases.
- Chronic elevations in gastrin concentrations may play a role.
- Neuroendocrine factors may play a role.

RISK FACTORS
Chronic stress, inflammatory disorders, chronic gastritis, gastric ulcers, and genetic predispositions influence the disease process in humans and may play a role in small animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Gastric neoplasia.
- Gastric foreign body.
- Granulomatous infectious disease (e.g., pythiosis).
- Eosinophilic granuloma.
- Motility disorders.
- Cranial abdominal mass—pancreatic or duodenal.

CBC/BIOCHEMISTRY/URINALYSIS
- Findings vary, depending on degree and chronicity of obstruction.
- Hypochloremic metabolic alkalosis (characteristic of pyloric outflow obstruction), metabolic acidosis, or mixed acid-base imbalance.
- Hypokalemia.
- Anemia—if concurrent GI ulceration.
- Prerenal azotemia—if dehydration present.

OTHER LABORATORY TESTS
N/A

IMAGING

Abdominal Radiographs
Normal to markedly distended stomach.

Upper GI Barium Contrast Study
- May display a "beak" sign created by pyloric narrowing, allowing minimal barium to pass into the pyloric antrum.
- Retention of most of the barium in the stomach after 6 hours indicates delayed gastric emptying.
- Intraluminal filling defects or pyloric wall thickening.

Fluoroscopic Barium Contrast Study
- Normal gastric contractility.
- Delayed passage of barium through the pylorus.

Abdominal Ultrasound
Measurable thickening of the wall of the pylorus and antrum.

DIAGNOSTIC PROCEDURES
Endoscopy—allows evaluation of the mucosa for ulceration, hyperplasia, and mass lesions; specimens can be obtained for histopathologic evaluation.

PATHOLOGIC FINDINGS
- Include focal to multifocal mucosal polyps, diffuse mucosal thickening, and pyloric wall thickening, with variable degree of pyloric narrowing.
- Changes range from hypertrophy of the circular smooth muscle to hyperplasia of the mucosa and associated glandular structures; a wide spectrum of inflammatory cell infiltration exists.

TREATMENT

APPROPRIATE HEALTH CARE
- Depends on severity of clinical signs.
- Patients should be evaluated and surgery scheduled at the earliest convenience.

NURSING CARE
- Appropriate parenteral fluids to correct any electrolyte imbalances and metabolic alkalosis or acidosis.
- Isotonic saline (with potassium supplementation) is the fluid of choice for hypochloremic metabolic alkalosis.
- Consideration of postoperative nutritional support is important.
- In severe cases treated with gastroduodenostomy or gastrojejunostomy, surgical placement of a jejunostomy tube for enteral nutrition may be advantageous.

ACTIVITY
Restrict as needed.

DIET
Highly digestible, low fat—until surgical intervention is feasible.

CLIENT EDUCATION
- Surgical treatment is highly successful.
- If clinical signs recur postoperatively, more aggressive surgical procedures may be indicated.

SURGICAL CONSIDERATIONS
- Surgical intervention is the treatment of choice.
- Goals involve establishing a diagnosis with histopathologic samples, excising abnormal tissue, and restoring GI function with the least invasive procedure.

(CONTINUED) # HYPERTROPHIC PYLORIC GASTROPATHY, CHRONIC

• Surgical procedures depend on the extent of obstruction—pyloromyotomy (Fredet-Ramstedt), pyloroplasty (Heineke-Mikulicz or antral advancement flap), gastroduodenostomy (Billroth 1), gastrojejunostomy (Billroth 2).

MEDICATIONS

DRUG(S) OF CHOICE
• Antiemetics and motility modifiers are generally ineffective.
• H2 antagonists and proton pump inhibitors may provide symptomatic relief.

CONTRAINDICATIONS
• Evidence of complete pyloric obstruction precludes the use of promotility drugs.
• Avoid anticholinergic agents because of their inhibitory effects on GI motility.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

ALTERNATIVE DRUG(S)
N/A

FOLLOW-UP

PATIENT MONITORING
Postoperatively for recurrence of clinical signs because of poor choice of surgical procedure.

PREVENTION/AVOIDANCE
N/A

POSSIBLE COMPLICATIONS
Postoperative surgical complications include recurrence of clinical signs, gastric ulceration, pancreatitis, bile duct obstruction, and incisional dehiscence with peritonitis.

EXPECTED COURSE AND PROGNOSIS
• 85% of dogs show good to excellent results with resolution of clinical signs on proper surgical intervention.
• Poor prognosis if gastric neoplasia (especially adenocarcinoma) is an underlying cause.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Gastric ulceration.

AGE-RELATED FACTORS
Intermittent vomiting in young brachycephalic breeds on weaning is suggestive of congenital stenosis.

ZOONOTIC POTENTIAL
None

PREGNANCY/FERTILITY/BREEDING
High gastrin concentrations in pregnant females may predispose to development of the syndrome.

SYNONYMS
• Chronic hypertrophic antral gastropathy.
• Hypertrophic gastritis.
• Antral pyloric hypertrophy.
• Congenital pyloric stenosis.

ABBREVIATIONS
• GI = gastrointestinal.

HYPERVISCOSITY SYNDROME

BASICS

OVERVIEW
- An assortment of clinical signs caused by high blood viscosity.
- Typically results from markedly high concentration of plasma proteins, although can result (rarely) from extremely high erythrocyte or leukocyte counts.
- Most frequently seen as paraneoplastic syndrome, often associated with multiple myeloma or other lymphoid neoplasms.
- Total plasma protein may exceed 10 g/dL (100 g/L), with serum protein electrophoresis showing monoclonal gammopathy or rarely biclonal gammopathy.
- Clinical signs caused by reduced blood flow through smaller vessels, high plasma volume, and associated coagulopathy.
- Systems affected include hemic/lymphatic/immune, ophthalmic, and nervous; in rare cases, pulmonary thromboembolism may occur.

SIGNALMENT
- Dogs more frequently affected than cats.
- No sex or breed predilections.
- More common in older animals due to increased incidence of malignancy.

SIGNS

Historical Findings
- No consistent signs.
- Anorexia.
- Lethargy.
- Depression.
- Polyuria and polydipsia.
- Blindness, ataxia, seizures, syncope.
- Bleeding tendencies.
- Respiratory distress.
- Congestive heart failure.

Physical Examination Findings
- Neurologic deficits, including seizures and disorientation.
- Tachycardia and tachypnea due to volume overload (e.g., congestive heart failure) or pulmonary thromboembolism.
- Epistaxis or other mucosal bleeding.
- Hepatomegaly, splenomegaly, lymphadenopathy.
- Visual deficits associated with engorged retinal vessels, retinal hemorrhage or detachment, and papilledema.

CAUSES & RISK FACTORS
- Multiple myeloma and plasma cell tumors—immunoglobulin (Ig) M > IgA > IgG.
- Lymphocytic leukemia or lymphoma.
- Marked polycythemia—hematocrit (HCT) >65%, usually >75%.
- Chronic atypical inflammation with monoclonal gammopathy (e.g., ehrlichiosis or leishmaniasis in dogs).
- Chronic autoimmune disease (e.g., systemic lupus erythematosus and rheumatoid arthritis)—very rare.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Other unexplained neurologic disease or bleeding disorders.
- Hyperviscosity is a syndrome, not a final diagnosis.

CBC/BIOCHEMISTRY/URINALYSIS
- Nonregenerative anemia (in patients without erythrocytosis as a cause of hyperviscosity), thrombocytopenia, or leukopenia.
- Hyperproteinemia (total plasma protein >9 g/dL; 90 g/L) and hyperglobulinemia (>5 g/dL; 50 gm/L).
- Azotemia and hypercalcemia, if hyperviscosity caused by paraneoplastic syndrome.
- Isosthenuria and marked proteinuria.

OTHER LABORATORY TESTS
- High concentration of IgG, IgA, or IgM, as detected by radial immunodiffusion.
- High plasma or serum viscosity (>3× greater than water).
- Prolonged prothrombin time or activated partial thromboplastin time, abnormal platelet function testing.
- Other testing as indicated by primary disease.
- Bence-Jones proteinuria in patients with multiple myeloma.

IMAGING
Hepatosplenomegaly, cardiomegaly, and osteolytic lesions (in association with multiple myeloma) are possible.

DIAGNOSTIC PROCEDURES
Bone marrow aspirate or core biopsy—plasma cell or lymphoid infiltrate.

TREATMENT

Appropriate Health Care
- Generally treat as inpatient.
- Treat underlying disease.
- Phlebotomy (15–20 mL/kg) with isotonic crystalloid fluid volume replacement.
- Plasmapheresis, either manual or automated.

Nursing Care
As dictated by underlying disease.

MEDICATIONS

DRUG(S) OF CHOICE
Provide treatment for underlying neoplastic or inflammatory condition.

CONTRAINDICATIONS/POSSIBLE INTERACTIONS
- Avoid use of medications that might increase vascular volume, including synthetic colloids (e.g., hetastarch); do not try to correct compensatory low albumin.
- Avoid medications that alter platelet function.

FOLLOW-UP
- Monitor serum or plasma proteins frequently as marker of treatment efficacy.
- CBC, biochemistry panel, and urinalysis to monitor other laboratory abnormalities.

MISCELLANEOUS

SEE ALSO
- Ehrlichiosis and Anaplasmosis.
- Erythrocytosis.
- Leukemia, Chronic Lymphocytic.
- Lymphoma—Cats.
- Lymphoma—Dogs.
- Multiple Myeloma.
- Plasmacytoma, Mucocutaneous.

ABBREVIATIONS
- HCT = hematocrit.
- Ig = immunoglobulin.

HYPHEMA

BASICS

DEFINITION
Blood inside the anterior chamber in the form of a blood clot, settled blood in the ventral anterior chamber, or red blood cells suspended throughout the aqueous.

PATHOPHYSIOLOGY
- Breakdown of the blood–aqueous barrier and/or direct injury to the iris and ciliary body blood vessels; causes include direct trauma to the cornea or anterior uvea (iris and ciliary body), inflammation, and damage to blood vessel walls (e.g., caused by systemic hypertension, antigen-antibody complexes, or circulating infectious organisms or neoplastic cells).
- Abnormal hemostasis due to a coagulopathy or thrombocytopenia.
- Bleeding from abnormal vessels within the eye; this is most commonly due to pre-iridal fibrovascular membranes (PIFMs), which form in response to chronic intraocular disease (uveitis, retinal detachment, glaucoma, neoplasia); rarely, abnormal congenital blood vessels in the eye such as persistent pupillary membranes, tunica vasculosa lentis, or hyaloid artery may bleed, causing hyphema.

SYSTEMS AFFECTED
Ophthalmic

INCIDENCE/PREVALENCE
Not uncommon ophthalmic finding and one that is important to recognize, as it may be the presenting clinical sign for serious underlying systemic disease.

SIGNALMENT

Species
Dog and cat.

Breed Predilections
Collies with collie eye anomaly.

SIGNS

Historical Findings—Primary Ophthalmic Causes
- Usually a unilateral presentation in an otherwise systemically normal patient.
- Blunt globe trauma will often have a compatible history.
- Corneal perforation may have a history of a corneal ulcer, or preceding encounter with a cat resulting in a cat claw laceration, especially in puppies.

Historical Findings—Systemic Causes
- Unilateral or bilateral presentation; bilateral presentation is strongly supportive of systemic etiology.
- Weight loss, anorexia, lethargy, decreased vision, or loss of vision may accompany some systemic causes.
- Ocular pain usually accompanies infectious and neoplastic causes due to accompanying uveitis.

Physical Examination Findings—Primary Ophthalmic Causes
- Except in cases of generalized trauma, the physical exam will be unremarkable with abnormalities restricted to the globe and periorbital soft tissues.
- Blunt trauma patients will have painful periorbital soft tissue swelling and uncommonly orbital rim fractures; there is often total hyphema obscuring other intraocular structures.
