The management of a company bears the ultimate responsibility for incidents. They are responsible for creating an organizational culture that allows employees to openly report issues and provides them with the opportunity to see that their concerns are adequately addressed. An open and fair organizational culture is fundamental for the motivation of staff and is at the core of food safety management. In the case of an incident, they have to not only follow best practice in managing the ongoing incident but also be candid with analyzing the root cause of the incident, such that they can redress the situation in a fundamental way to prevent recurrence of incidents in a long-lasting manner.

As for crisis management, the lessons learned from incidents need to be reported in a final report and disseminated both internally in the organization and externally with the food safety community at large in order to prevent the recurrence of incidents in the society.

Glossary

Ethics Ethics is the philosophical study of the moral value of human conduct and of the rules and principles that ought to govern it.

Precautionary principle The precautionary principle states that if a product, an action, or a policy has a suspected risk of causing harm to the public or to the environment, protective action should be supported before there is complete scientific proof of a risk.

The common good approach The common good approach links ethics to social responsibility and calls attention to the common conditions that are important to the welfare of everybody.

The fairness approach The fairness approach treats all human beings equally based on some standards that are defensible.

The right approach The right approach states that humans have a right to be treated as ends and not merely as means to other ends.

The utilitarian approach The utilitarian approach deals with consequences, and tries to increase the good done and reduce the harm done.

The virtue approach The virtue approach emphasizes dispositions and habits that enable humans to act according to the highest potential of their character.

Food Safety and Ethics

Food production is a complex matter, affecting people' s life, organizations profits, and the well-being of the whole planet. It is not always straightforward to say what is right and what is wrong when it comes to production of food. Many ethical questions can be raised. Climate change, animal welfare, fair trade, health and safety of employees as well as consumers, fair treatment of employees and their social rights, economic sustainability, and use of natural resources are all important dimensions within the system of production, processing, and trade, and where every food item often includes value conflicts.

Ethics is defined as the philosophical study of the moral value of human conduct and of the rules and principles that ought to govern it. Simply stated, ethics refers to standards of behavior that tell us how human beings ought to act in the many situations in which they find themselves – as a friends, parents, children, citizens, businesspeople, teachers, professional food producers, consumers, etc. Some ethicists emphasize that the ethical action is the one that produces the greatest good and does the least harm for all those who are affected – customers, employees, shareholders, the community, and the environment 'the utilitarian approach.' The utilitarian approach deals with consequences; it tries both to increase the good done (e.g., ending hunger) and to reduce the harm done (e.g., environmental and social destructions). Other philosophers and ethicists suggest that the ethical action is the one that best protects and respects the moral rights of those affected 'the rights approach.' This approach starts from the belief that humans have a dignity based on their human nature per se or on their ability to choose freely what they do with their lives. On the basis of such dignity, they have a right to be treated as ends and not merely as means to other ends. According to the Rome Declaration, everybody has a right to adequate and safe food and a fundamental right to be free from hunger. The list of moral rights – including the rights to make one's own choices about what kind of life to lead, to be told the truth, not to be injured, to a degree of privacy, etc. – is widely debated; some now argue that nonhumans like animals and plants have rights, too. Also, it is often said that rights imply duties – in particular, the duty to respect others' rights. Aristotle and other Greek philosophers have contributed the idea that all equals should be treated equally 'the fairness or justice approach.' Present day, this idea is used to say that ethical actions treat all human beings equally, or if unequally, then fairly based on some standard that is defensible. The power distribution between retailers and suppliers have led many producers to state that multiple food retailers are abusing their position of power and engaging in practices that adversely affects the competitiveness of suppliers. To address these adverse effects it has been recommended that a code of practice be introduced to govern retailer–supplier relationships. The Greek philosophers have also contributed the notion that life in community is a good in itself and our actions should contribute to that life 'the common good approach.' This approach links ethics to social responsibility and calls attention to the common conditions

 doi:10.1016/B978-0-12-378612-8.00437-6

that are important to the welfare of everyone. Companies have a duty to be good citizens including their own workers and staff and 'to do the right things.' A very ancient approach to ethics is that ethical actions ought to be consistent with certain ideal virtues that provide for the full development of our humanity 'the virtue approach.' These virtues are dispositions and habits that enable us to act according to the highest potential of our character and on behalf of values like truth and beauty. Honesty, courage, compassion, generosity, tolerance, love, fidelity, integrity, fairness, selfcontrol, and prudence are all examples of virtues. Virtue ethics asks of any action, 'What kind of person will I become if I do this?' or 'Is this action consistent with my acting at my best?'

Each of these approaches mentioned above helps us determine what standards of behavior can be considered ethical. Different actors may not agree on the content of some of these specific approaches. They may not all agree to the same set of human and civil rights or on what constitutes the common good. They may not even agree on what is good and what is bad. Nonetheless, each approach gives us important information with which to determine what is ethical in a particular circumstance. And much more often than not, the different approaches do lead to similar answers.

So what are the ethical dilemmas in food safety? Is it reasonable to forbid sales of cheese made with unpasteurized milk? Here, food safety is set up against people's pleasure of eating tasty cheese, traditional food cultures, and the food industries economical interest. Is unpasteurized cheese safe enough? Similar questions can be asked about raw minced meat (steak tartar) served in some restaurants, raw milk sold in some countries, or worse, when raw milk is given to children. In theory, a fully informed consumer might decide which food-related risk to take and which to avoid. But what does it mean to be fully informed? Can we expect that all consumers are able to collect the detailed information about the wide array of food safety issues and make their own decisions? Are there any good strategies for providing relevant information in such a way that consumers understand the risk? Is it the correct thing to delegate this responsibility to responsible authorities? What does it mean in terms of responsibilities for authorities? And what if the consumers do not trust these authorities? Finally, who becomes responsible when illness occurs: Industry which has provided a contaminated product, authorities who have failed to educate consumers, or consumers themselves who have not taken the necessary precautions?

Another key question is when a food industry transfers responsibility of safety to consumers without providing proper warnings, crystal clear instructions on safety measures, or even worse, market and promote a product in a society when it knows that consumers would not be able or have means, to ensure its safety. The latter issue was raised with the question of breast milk substitute in the developing countries, until WHO established the Code of Breast milk substitute that responsible companies comply with. The issue of warnings on food package is still not well addressed in most legislation and the clarity with which drug providers or electrical equipment or aviation companies provide information has not yet been established in the food industries. This has made some companies to write an ambiguous text that do not raise concern of consumers, but in case of an incident, the company is covered and can decline any responsibility.

Food safety management relies very much on a fair and professional management of people, including ensuring that employees are competent for their job, have received the proper training and briefing about their responsibilities. They are given the means and authority to do a professional job, and also setting the right reporting structure minimizing conflict of interest in audits and investigation of incidents, and most of all a company culture which fosters reporting and openly discussing problems, protecting and rewarding whistleblowers, and a management which walk the talk and follow its own policies. Unfair practices cannot only lead to discouragement and an uncaring attitude of employees, but occasionally has also been the source of outrage and sabotage of the food (i.e., tampering), thus a risk for consumers. The company culture is an area which is not legislated and enforced by law, but is one of the most important aspects of the ethical practice of a company as it impacts on all aspects of operations, including safety and health and the social right of employees, as well as safety of products and health of consumers.

Finally, one of the most fundamental aspects of ethics in food industry is the commitment and 'real will' of the company to build a solid food safety assurance system or just to do the minimum necessary to meet the requirements of legislation and certification bodies. As safety of food products is the outcome of the food safety assurance system (including the professional management of its staff) of food companies, no matter how comprehensive and strong the regulatory system of a country may be, it cannot replace the everyday vigilance of managers, workers of a company who have to oversee the safety of products.

The Precautionary Principle

The precautionary principle states that if a product, an action, or a policy has a suspected risk of causing harm to the public or to the environment, protective action should be supported before there is complete scientific proof of a risk. In the absence of scientific consensus, the principle implies that there is a social responsibility to protect the public from potential harm. This is a 'better safe than sorry' or 'caution in advance' principle that applies both to human health and to environmental protection.

One of the primary foundations of the precautionary principles, and globally accepted definitions, results from the work of the Rio Conference, or 'Earth Summit' in 1992. Principle #15 of the Rio Declaration notes:

"In order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation."

The application of the precautionary principle has been made a statutory requirement within the European Union (EU), and according to a Food and Agriculture Organization of the United Nations Expert Consultation report on food safety

international, food safety organizations must make clear that science, although an important tool, is not sufficient in itself for food risk analysis and that it needs to operate within an ethical framework. The problematic cases are the ones where there are disagreements about the value judgments made in the risk assessment. For Novel Food, new technologies, or newly identified hazards, the answer to what is 'safe' may not be the subject of a consensus. When both the likelihood of damage and the consequences of damage are unknown, then risk assessment becomes difficult and the assessors face ethical dilemmas. Genetically modified organisms (GMO), is one example of a new technology which has created a lot of debate. The presence of different interest groups and diverse citizens' values in different political arenas triggered a range of policy responses to GMOs in the 1990s. Although GMO was strongly supported by the scientific and biotech industry in the USA, and lead to a flourish of GM crops, European citizens were strongly opposed by GM plants. Consumers were skeptical and talked about 'unnatural Frankenstein's food.' They lacked confidence due to their governments' response to a series of food scares in the 1990s. Today, the GMO regulatory framework in the EU is different from the one in US and more in line with the public's perception of risk than with the scientific definition of risk. The precautionary principle is applied in the EU and is constantly challenged. A main ethical question which raised a controversy with regard to GM foods was few years ago when EU countries would, as part of food aid, propose GM foods to the developing countries (Africa). In 2002, Zambia announced it would not accept GM food aid in any form. So the question was, why a technology and product rejected by the European population will be good for the African population? Most African countries approach GM technology applied to crops with caution. "Why shouldn't we be wary of this technology and its possible long-term health impacts, if the EU is? If it is not good for them, why should it be good for us?" said Tewolde Egziabher, Ethiopia's director of the Environmental Protection Agency. Positions were polarized to a great extent after a quote from a US state department official, "Beggars can't be choosers," hit the headlines. It prompted the then president, Levy Mwanawasa, to say hunger was no reason for feeding his people "poison."

The evolutionary aspect of the food system, influences risk assessment of food safety and triggers some ethical dilemmas. Although, consumers' food variety increases and the food industry potentials for new business grow, there are food safety issues to consider. The food market is becoming more and more global. Not only food, but also food pathogens are distributed around the world. In Norway, sugar peas from Kenya lead to an outbreak of dysentery in 2009, probably due to consumption of raw products. In Kenya, people boil or fry vegetables before consumption. This is not the case in Norway where unpeeled fruit and raw vegetables are consumed frequently. In many ways Norway is a food safety oasis in Europe, with a livestock population virtually free from Salmonella and where only one out of nine national outbreaks of infectious intestinal diseases linked to lettuce, sprouts, sugar peas, and basil in the past 20 years came from Norwegian produce. The problem is that consumers' food safety habits and routines, inherited from parents, are not always adapted to handle new food scares from imported products. When food and food pathogens change, whereas food preparation routines stay the same, then food safety becomes an issue. The solution to this food safety problem raises ethical questions related to freedom of choice, economic prosperities for developing countries, distribution of pathogens into clean areas, etc.

A related issue is the question, to what extent food safety should be regulated and harmonized across the world? On the one hand harmonization of regulation is important from a human rights perspective as all human beings, regardless of their color, race, gender, and culture should have the right to the same level of health protection and thus food safety, and products rejected in one country should not be dumped in another. However, for various reasons, presently the same level of safety is not achievable in all countries and trying to meet a high standard of food safety in some countries may be to the detriment of causing hunger and malnutrition. On the other hand, failing to harmonize food safety regulations has lead to a double standard in some countries, i.e., foods produced for export have a higher standard of quality and safety, whereas foods of inferior safety and quality standard, possibly with higher level of contamination, is directed to the domestic market and local people. However, can one deny a higher level of health protection to countries which can meet these?

Ethical Decision Making

Making good ethical decisions requires a trained sensitivity to ethical issues and a practiced method for exploring the ethical aspects of a decision and weighing the considerations that should impact our choice of a course of action. Having a method for ethical decision making is absolutely essential. The more novel and difficult the ethical choice we face, the more we need to rely on discussion and dialog with others about the dilemma. Only by careful exploration of the problem, aided by the insights and different perspectives of others, can we make good ethical choices in such situations.

In a company where ethics is a valued principle, the management ensures that food safety is managed professionally and objectively. However, the ethic of its management becomes conspicuous particularly in time of an incident or a conflict. This will be demonstrated by questions such as to what extent the company will:

1. voluntarily acknowledge a contamination or and if necessary recall its products,
2. investigate the root cause of the incident up to the management level,
3. accept loss of benefits to protect consumers,
4. act transparently and reveal information on the incident and its cause, and also,
5. take punitive actions against those who have knowingly and irresponsibly violated the policies (note: Errors are different from violations and should be not subject of punitive actions, see other articles).

In the health care or aviation sectors, reporting of noncompliance or problems, and independence in investigations of incidents is much more advanced and can be a model for the food sector if food safety is to be strengthened.

At the national level, ethics of the regulatory authorities is proven by the system of decision making that they put in place to ensure:

1. independence of health sciences and institutions generating scientific and technical data,
2. an unbiased decision making process with separation of risk assessment and risk management function,
3. priority to consumer health over economic considerations, and
4. mechanism for reporting malpractices and noncompliances, for example, protection of whistle-blowers.

Other Aspects of Ethics of Relevance to Food Industry

Over and above aspects of ethics in relation to food safety, few words should also be said on other practices in the industry that are unethical. For instance, abuse and mistreatment of animals, child labour, negligence leading to environmental damages, or fraud and deceitful practices such as the recent horse and pork meat scandal, which was revealed as this article is going into publication.

In the latter mentioned case, the deceitful practice of the food industry was perhaps not affecting safety of products *per se* but in other cases, such as the incident of melamine in USA in 2007 and repeated again in China in 2008, it did have serious health consequences for consumers.

Although the fraud of replacing beef with horse and pork meat took place at the suppliers of minced meat products, the responsibility of the processors and manufacturers who were manufacturing and marketing ready-to-eat foods is not less, as they were responsible for verifying their suppliers. The gravity of the scandal does not only lie in the fact that some people unknowingly and against their personal values ate horse or pork meat, but the fact that so many people were aware of the fraud, yet they turned a blind eye. Under such circumstances the door is open to any wrongdoings and consequently there cannot be a guarantee for food safety as what cannot be anticipated cannot be prevented. This scandal also revealed the poor conditions in which horses were maintained and transported.

To promote ethical practices in companies, the public at large should value ethic and be outspoken about it, for instance by the choice of the products they buy. The experience from the bovine spongiform encephalopathy crisis showed the power of consumer pressure in promoting health considerations in the decision making process. Subsequently, giving priority to health over economic considerations has today become a key principle in risk management. Similarly, in a national referendum in 2013 in Switzerland, referred to as the Minder Initiative, the Swiss public expressed its dismay with disproportionate high salaries of managers in companies, and forced politicians to take legislative measures to limit such practices, showing the power of public and consumers in changing practices and promoting ethics.

However, over and above that of the general public, the responsibility of poor ethical practices in any company, or any other organization, falls on the staff of the organization, who should also react and challenge the decision-makers to force them to behave ethically and respect the international standards and charters in the areas of human rights, environment, animal welfare, consumer health, etc.

Conclusion

The likelihood of becoming sick from the next meal has probably never been less than it is today, but the long-term consequences of today's food production is less known. The production process has increasingly become complex and less transparent and consumers are no longer in control of the production system. They need to trust food producers, food manufacturers, and retailers. Consumers are worried, some of these worries are directly linked to the risks involved, be it real or perceived. Other worries are more linked to ethical questions related to well-being, free choice (autonomy), and fairness (justice). Availability of safe food needs to be addressed in relation to factors, such as respect for consumer choice, right to information on safety, universally affordable food, adequate income, and working conditions for employees and workers, fair practice in trade, animal welfare, and sustainability of biotic populations. Also, consumers are worried about new technologies and if these new techniques take into consideration their health and safety, or if they merely are developed for business interest and the benefits of producers. Some consumers wonder to what degree science is being developed impartially, and if governments and public health authorities give priority to consumer's health in their opinion on risks and risk management options, and if incidents are investigated independently and transparently.

A dialog about the ethical implications of food production, processing, policy, supply, and consumption, may help involved partners making better decisions. The discussion needs to be lifted up to a level above what each company at any given point in time feels is best for them.

Aristotle says that identifying the good with pleasure is to prefer a life suitable for beasts.

"It is better to be a human being dissatisfied than a pig satisfied; better to be **Socrates** dissatisfied than a fool satisfied. And if the fool, or the pig, are of a different opinion, it is because they only know their own side of the question… "

Every company has a social responsibility. Not behaving according to accepted norms for ethical behavior may not only have consequences for food safety, but also on a company's image, reputation, and performance. Ethics is not a question of thoughtless and slavish worship of rules, and to scrupulously checking every action against a table of do's and don'ts. The fundamental question of ethics is not 'What should we do?' but 'What image would we like for our company?' Will we accept compliances, deceive full negligence or noncompliance as long as we are not caught, or will we be vigilant in any condition?

"Integrity is doing the right thing, even when no one is watching (Clive Staples Lewis,1898–1963)," and ethics is to the industry what integrity is to a person.

Glossary

Contaminant Any substance not intentionally added to food, which is present in such food as a result of the production (including operations carried out in crop husbandry, animal husbandry and veterinary medicine), manufacture, processing, preparation, treatment, packing, packaging, transport or holding of such food or as a result of environmental contamination. The term does not include insect fragments, rodent hairs and other extraneous matter.

Food Any substance, whether processed, semi-processed or raw, that is intended for human consumption, and includes drink, chewing gum and any substance that has been used in the manufacture, preparation or treatment of "food" but does not include cosmetics or tobacco or substances used only as drugs.

Food additive Any substance not normally consumed as a food by itself and not normally used as a typical ingredient of the food, whether or not it has nutritive value, the intentional addition of which to food for a technological (including organoleptic) purpose in the manufacture, processing, preparation, treatment, packing, packaging, transport or holding of such food results, or may be reasonably expected to result, (directly or indirectly) in it or its by-products becoming a component of or otherwise affecting the characteristics of such foods. The term does not include "contaminants" or substances added to food for maintaining or improving nutritional qualities.

Food hygiene Comprises conditions and measures necessary for the production, processing, storage and distribution of food designed to ensure a safe, sound, wholesome product fit for human consumption.

Hazard A biological, chemical or physical agent in, or condition of, food with the potential to cause an adverse health effect.

Pesticide Any substance intended for preventing, destroying, attracting, repelling, or controlling any pest including unwanted species of plants or animals during the production, storage, transport, distribution and processing of food, agricultural commodities, or animal feeds or which may be administered to animals for the control of ectoparasites. The term includes substances intended for use as a plant growth regulator, defoliant, desiccant, fruit thinning agent, or sprouting inhibitor and substances applied to crops either before or after harvest to protect the commodity from deterioration during storage and transport. The term normally excludes fertilizers, plant and animal nutrients, food additives, and animal drugs.

Risk A function of the probability of an adverse health effect and the severity of that effect, consequential to a hazard(s) in food.

Risk analysis A process consisting of three components: (1) Risk assessment that is a scientifically based process consisting of the following steps: (i) hazard identification, (ii) hazard characterization, (iii) exposure assessment, and

(iv) risk characterization. (2) Risk management, which is the process, distinct from risk assessment, of weighing policy alternatives, in consultation with all interested parties, considering risk assessment and other factors relevant for the health protection of consumers and for the promotion of fair trade practices, and, if needed, selecting appropriate prevention and control options. (3) Risk communication, which is the interactive exchange of information and opinions throughout the risk analysis process concerning risk, risk-related factors and risk perceptions, among risk assessors, risk managers, consumers, industry, the academic community and other interested parties, including the explanation of risk assessment findings and the basis of risk management decisions.

Traceability/product tracing The ability to follow the movement of a food through specified stage(s) of production, processing and distribution.

Veterinary drug Any substance applied or administered to any food producing animal, such as meat or milk producing animals, poultry, fish or bees, whether used for therapeutic, prophylactic or diagnostic purposes or for modification of physiological functions or behavior.

Safe, Good Food for Everyone – The Need for an International Food Code

Foodborne illness is a major cause of morbidity and mortality around the world. Outbreaks of foodborne illness can also damage trade and tourism and lead to loss of earnings, unemployment, and litigation. People have the right to expect their food to be safe, of good quality, and suitable for consumption.

In the beginnings of agriculture and food trade, traditional knowledge, based on experience and trial and error, directed what to eat and what not and how to keep food safe. People grew their own food or bought it in exchange for services, goods, or money from someone they knew, which ensured the link between them for safety, quality, and fairness. Although some may still live that way, for most people food comes from producers who they have never met and from places they have never seen. Wholesale markets that supply local sellers, source food from anywhere around the world and buyers order items that they have not seen, touched, or smelled, thus, they have to rely on the product descriptions and guarantees that the sellers provide.

The need for rules and codes for safety and quality in food production, transport, and trade grew over time as the local food chain, involving a handful of actors, transformed into a global chain involving millions of people. National food laws exist in most countries and in order to facilitate trade and ensure harmonization, the idea of a global food code (*Codex Alimentarius*) was born.

Codex Alimentarius and Codex Alimentarius Commission

The Codex Alimentarius Commission (the Commission) – jointly sponsored by the Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization (WHO) – held its first session in 1963. The Codex Alimentarius is a collection of international food standards, guidelines, and codes of practice whose main purpose is to protect the health of consumers and ensure fair practices in food trade. The Codex Alimentarius thus covers food safety matters (residues, hygiene, additives, contaminants, etc.) and quality matters (product descriptions, quality classes, labeling, and certification). Its internationally agreed texts allow harmonization of national requirements and, in this way, facilitate international trade.

The Codex Alimentarius serves as the basis for many national food standards and related regulations. All Codex standards and related texts, as well as all meeting information, are in the public domain and available at: www.codexalimentarius.org.

The Role of Codex Standards in International Trade

The Codex Alimentarius is a recommendation to its members. Application of Codex standards, guidelines, and codes of practice is voluntary until implemented in national or regional law. However, since 1995, after the establishment of the World Trade Organization (WTO) following the Uruguay Round of Trade Agreements, Codex standards and related texts have become international references for food safety under the WTO's Agreement on the Application of Sanitary and Phytosanitary Measures (SPS Agreement). Similarly, the standards of the World Organisation for Animal Health (OIE) became the reference for animal health and those of the International Plant Protection Convention (IPPC) became the reference for plant health.

For WTO members this means that, as long as they apply Codex standards for food safety measures, no other WTO member can challenge such measures as unjustified barriers to international trade. If a country wants to set stricter standards, this needs to be justified scientifically through a risk analysis process. In case of a dispute, the WTO provides the relevant dispute settlement process.

Codex texts are also recognized as international standards by the WTO Agreement on Technical Barriers to Trade (TBT) and have been used in dispute settlements. Contrary to the SPS agreement, the TBT agreement does not mention any specific standard setting organization. However, Codex texts have been used in TBT dispute settlement procedures.

How the Codex Alimentarius Commission Works

The Commission and its specialized technical subsidiary bodies (Figure 1) provide structured, neutral meetings for discussion of all topics related to food safety and trade within its mandate. Representatives from governments, consumer groups, industry, and academia meet to exchange views

Figure 1 Joint FAO/WHO Food Standards Programme (status 2012).

about food safety and trade and to adopt standards or related texts.

Statutes

The statutes are the legal basis for the Commission's work and formally reflect the concepts behind and reasons for its establishment. Article 1 of the statutes contains purposes, terms of reference, and objectives. Article 2 defines eligibility for membership of the Commission, which is open to all Member States and Associate Members of FAO and WHO.

Rules of Procedure

The Rules of Procedure of the Codex Alimentarius Commission describe: Conditions of membership; appointment and responsibilities of Commission officers (chairperson and three vice-chairpersons); appointment and responsibilities of the other members of the Executive Committee (six regional coordinators and seven members elected on a regional basis); appointment and role of the Secretary; establishment of an Executive Committee to meet between Commission sessions, to act on behalf of the Commission as its executive organ; frequency and operation of Commission sessions; nature of agendas for Commission sessions; voting procedures; observers; preparation of Commission records and reports; establishment of subsidiary bodies; procedures to be adopted in the elaboration of standards; allocation of a budget and estimates of expenditure and; languages used by the Commission.

Representation of Members and Current Meeting Schedule

In June 2012, 99% of the world's population was represented in the Commission through 184 member countries and one Member Organization (European Community). Currently, the Commission meets annually at the headquarters of FAO or WHO. Special or extraordinary sessions can be scheduled if needed. Representation at sessions is on a country basis. National delegations are led by senior officials appointed by their governments. Delegations may include representatives of industry, consumers' organizations and academic institutes. Countries that are not yet members of the Commission sometimes attend in an observer capacity. To facilitate continuous contact with member countries, members have established country Codex Contact Points, and many member countries have National Codex Committees to coordinate activities nationally.

Observers

In June 2012, over 200 International Governmental Organizations and International Nongovernmental Organizations (NGOs) had observer status with the Commission. The Codex process allows such organizations to put forward their points of view at every stage except in the final decision, which is the exclusive prerogative of members.

Codex Strategic Plan

The Commission is guided in its work by a strategic plan, which is reviewed every 5 years.

The vision statement of the present plan (2008–13) reads: "The Codex Alimentarius Commission envisages a world afforded the highest attainable levels of consumer protection including food safety and quality. To this end, the Commission will develop internationally agreed standards and related texts for use in domestic regulation and international trade in food that are based on scientific principles and fulfill the objectives of consumer health protection and fair practices in food trade."

The plan contains the following five goals which have been broken down further into a number of activities:

- Goal 1: Promoting Sound Regulatory Frameworks.
- Goal 2: Promoting Widest and Consistent Application of Scientific Principles and Risk Analysis.
- Goal 3: Strengthening Codex Work-Management Capabilities.
- Goal 4: Promoting Cooperation between Codex and Relevant International Organizations.
- Goal 5: Promoting Maximum and Effective Participation of Members.

Codex Secretariat and Administration

The Codex Secretariat is a team of less than 20 professional and technical staff located in FAO headquarters in Rome. The Secretariat deals with all aspects of the functioning of the Commission and its subsidiary bodies (e.g., preparing agendas and distributing working documents and drafting the reports of the sessions) and with the updating and publication of the Codex Alimentarius.

Work on the Codex Alimentarius

Standard Setting Process

As stated in Article 1 of the Commission's Statutes, one of the principal purposes of the Commission is the preparation of food standards and their publication in the Codex Alimentarius.

The process for preparing standards is open and transparent and ensures that all interested parties can be heard and contribute. It consists of a number of steps that starts with the submission of a project document to the Executive Committee and the Commission either by a subsidiary body or a Codex member in line with the requirements set out in the Procedural Manual justifying the need for new work and setting out the time frame. This formal proposal is often preceded by informal discussions in subsidiary bodies where members inform others of their interest and reasoning and evaluate if there is support for the project.

Step 1: Decision by the Commission that a standard be developed as proposed based on the criteria in the Procedural Manual and the priorities in the strategic plan. The Commission selects the subsidiary body to be responsible for steering

the standard through its development. If necessary, a new subsidiary body may be created.

Step 2: Preparation of a proposed draft standard is arranged by the Codex Secretariat and circulated to members and observers for comments.

Step 3: Comments are considered by the relevant subsidiary body that may present the text to the Commission as a draft standard for adoption at Step 5, or send it back for redrafting. Where relevant, the draft will be referred to the Codex Committees responsible for labeling, hygiene, additives, contaminants, and methods of analysis for endorsement of any special advice in these areas.

Steps 6 and 7: A second round of comments and discussions takes place in the subsidiary body before the standard is recommended to the Commission for adoption at Step 8.

Steps 6 and 7 may be omitted if there is a consensus on this in the subsidiary body and the Commission (adoption at steps 5/8) or it may be decided when starting a project that it should be finalized in 5 steps (accelerated procedure, adoption at step 5A).

Most standards take a number of years to develop. Once adopted by the Commission, a Codex standard is added to the Codex Alimentarius. A recent study showed that the speed of standard setting in Codex was 4.2 years overall and 3.5 years for food safety standards. The minimum time needed for adopting a standard is presently 1 year i.e., from one session of the Commission to the next. For example, the maximum limits for melamine after the food safety crisis related to adulterated milk were adopted in 1 year. Faster adoption could be possible only through an extraordinary session of the Commission.

The Commission and its subsidiary bodies keep Codex standards and related texts up to date to ensure that they are consistent with current scientific knowledge and the needs of the member countries. Countries now require less prescriptive standards, especially for commodities, than those developed in the 1970s and 1980s.

In recent years, many older, detailed individual product standards have been consolidated into more general or group standards, which allow wider coverage and innovation in the development of new food products. The procedure for revision or consolidation follows that used for the initial preparation of standards, but can be shortened in the case of editorial or consequential amendments.

Decision Making

The Commission and its subsidiary bodies strive to find a consensus on all issues under discussion. Voting is possible in accordance with the procedures, but past experience has shown that standards adopted by a vote have a lower acceptance as the original controversy does not disappear with the vote. For this reason, some issues remain on the agenda for a significantly longer time than the average because it takes longer to come to a consensus.

Subsidiary Bodies

The Commission may establish three kinds of subsidiary bodies.

- Codex Committees – which are of a standing nature (but may be adjourned or abolished) prepare draft standards for submission to the Commission or deal with Codex procedures;
- Ad hoc intergovernmental task forces – which are established for one specific purpose and are dissolved when their task is completed;
- Coordinating Committees, through which regions or groups of countries coordinate food standards activities in the region, including the development of regional standards.

There may be as many as 20 Codex Committee meetings in any 12-month period. With the exception of the Executive Committee and Coordinating Committees, Codex Committees and task forces are hosted by member countries, which are responsible for the cost of the committee's maintenance and administration and for providing the chairperson. Sessions are usually held in the host countries but recently an increasing number of industrialized country hosts have made use of the possibility to hold sessions in developing countries under cohosting agreements. The designation of host countries for the committees is a standing item on the agenda for the Commission.

The Executive Committee as well as the Commission meetings alternate between the headquarters of FAO and WHO (Rome and Geneva), and all costs are covered by the Codex budget. Coordinating Committees are usually hosted in the country of the coordinator (but may be cohosted in other countries) and the main costs (interpretation and translation) are funded by the Codex budget which is covered entirely by FAO and WHO.

General Subject Committees

General Subject Committees (horizontal committees) work on issues that can apply to any commodity or groups of commodities. They develop concepts and principles applying to foods in general, specific foods, or groups of foods, and endorse or review relevant provisions in Codex commodity standards. Based on the advice of expert scientific bodies, they develop major recommendations pertaining to consumers' health and safety.

Six of the General Subject Committees have the responsibility of ensuring that specific provisions in Codex commodity standards are in conformity with the Commission's main general standards and guidelines in their particular areas of competence. They are the committees on Food Additives; Contaminants in Foods; Food Hygiene; Food Labeling; and Methods of Analysis and Sampling.

These committees also develop standards, maximum limits for additives and contaminants, and codes of practice or other guidelines for either general application or in specific cases where the development of a complete commodity standard is not required.

For example, the Committee on Food Hygiene has developed a Code of Hygienic Practice for Spices and Dried Aromatic Plants, and the Committee on Food Additives and Contaminants (divided into two committees in 2006) has developed a Standard for Maximum Levels of Lead in Foods.

The committees on Food Labeling and on Nutrition and Foods for Special Dietary Uses have worked together to prepare the Codex Guidelines on Nutrition Claims.

The Committee on Pesticide Residues and the Committee on Residues of Veterinary Drugs in Foods prepare Maximum Residue Limits (MRLs) for these two categories of chemicals used in agricultural production. The MRLs are based on scientific advice regarding the safety of the residues that remain after the substances are used in accordance with defined good agricultural or veterinary practices.

The Committee on Food Import and Export Inspection and Certification Systems deals with the application of standards to foods moving in international trade, in particular to the regulatory measures applied by governments to assure their trading partners that foods and their production systems are correctly regulated to protect consumers against foodborne hazards and deceptive marketing practices. The guidelines developed by the Committee include advice on how governments should respond to emergencies in the food safety system, including channels of communication to the public and to other governments by means of the International Food Safety Authorities Network (INFOSAN) emergency information system operated by WHO and FAO.

The Committee on Nutrition and Food for Special Dietary Uses has a double role of serving as a general committee for questions of nutrition, and as a commodity committee for special dietary foods such as baby foods or gluten free foods.

The Committee on General Principles advises the Commission on such basic matters as definitions, the Rules of Procedure, rules and working procedures for the establishment and operation of Codex Committees and task forces, relations with other organizations, and the general principles that underlie the preparation of all Codex standards, codes of practice, and other texts.

Commodity Committees

The responsibility for developing standards for specific foods or classes of food lies with the Commodity Committees (vertical committees). Commodity Committees convene as necessary and go into recess or are abolished when the Commission decides their work has been completed.

There are currently four Commodity Committees that meet regularly: Fats and Oils, Fish and Fishery Products, Fresh Fruits and Vegetables, and Processed Fruits and Vegetables.

The following Commodity Committees work through correspondence or are adjourned: Milk and Milk Products; Cereals, Pulses and Legumes; Cocoa Products and Chocolate; Meat Hygiene; Natural Mineral Waters; Sugars and Vegetable Proteins.

Host countries convene meetings of Codex subsidiary bodies at intervals of between 1 and 2 years, according to need.

Ad hoc Intergovernmental Task Forces

In 1999, the Commission realized that its committee structure was too inflexible to cope with the demand for standards and guidelines across an ever-widening range of subjects. It decided to create a third type of subsidiary body the ad hoc Intergovernmental Task Forces, which are Codex Committees with very limited terms of reference established for a fixed period of time. To date, the Commission has established the following ad hoc Intergovernmental Task Forces:

- Task Force on Animal Feeding – 1999–2004, 2012–present;
- Task Force on Foods Derived from Biotechnology – 1999–2003 and 2005–09;
- Task Force on Fruit and Vegetable Juices – 1999–2005;
- Task Force on the Handling and Processing of Quick Frozen Foods – 2006–07.
- Task Force on Antimicrobial Resistance – 2006–11.

Coordinating Committees

Coordinating Committees ensure that the work of the Commission is responsive to regional interests and to the concerns of developing countries. They meet at 2-year intervals. The country that chairs the Coordinating Committee is also the Regional Coordinator for the region concerned. These Committees have no standing host countries but usually meet in the country that is the Coordinator as nominated by the relevant Coordinating Committee and confirmed by the Commission. There are six Coordinating Committees, one each for the following regions: Africa; Asia; Europe; Latin America and the Caribbean; Near East; and North America and the Southwest Pacific.

Contents of the Codex Alimentarius: Standards, Guidelines, and Codes of Practice

Codex Standards

By far, the largest number of specific standards in the Codex Alimentarius is the group called 'commodity standards.' The major commodities included in the Codex are:

- Cereals, pulses (legumes), and derived products including vegetable proteins.
- Fats and oils and related products.
- Fish and fishery products.
- Fresh fruits and vegetables.
- Processed and quick-frozen fruits and vegetables.
- Fruit juices.
- Meat and meat products; soups and broths.
- Milk and milk products.
- Sugars, cocoa products, and chocolate and other miscellaneous products.

Commodity standards follow a common format set out in the Procedural Manual consisting of the following categories:

- Scope – includes the name of the food to which the standard applies and, in most cases, the purpose for which the commodity will be used.
- Description – includes a definition of the product or products covered with an indication, where appropriate, of the raw materials from which they are derived.
- Essential composition – includes information on the composition and identity characteristics of the commodity, as well as any compulsory and optional ingredients.

- Food additives – contains a reference to the General Standard on Food Additives and any specific provisions needed.
- Contaminants – contains a reference to the General Standard on Contaminants and Toxins in Food and Feed.
- Where appropriate, reference is also made to the Codex MRLs for pesticide residues and for residues of veterinary drugs in foods.
- Hygiene – makes reference to relevant Codex Codes of Hygienic Practice for the commodity concerned. In almost all cases, it is required that the product shall be free from pathogenic microorganisms or any toxins or other poisonous or deleterious substances in amounts that represent a hazard to health.
- Weights and measures – contains provisions such as fill of the container and the drained weight of the commodity.
- Labeling – includes provisions on the name of the food and any special requirements to ensure that the consumer is not deceived or misled about the nature of the food. These provisions must be consistent with the Codex General Standard for the Labeling of Prepackaged Foods. Requirements for the listing of ingredients and datemarking are specified.
- Methods of analysis and sampling – contains a list of the test methods needed to ensure that the commodity conforms to the requirements of the standard. References are made to internationally recognized test methods that meet the Commission's criteria for accuracy, precision, etc.

MRLs for residues of pesticides or veterinary drugs in foods are examples of numerical standards.

Codex general standards for food additives and contaminants and toxins in foods contain both general and numerical commodity-specific provisions.

The Codex General Standard for the Labeling of Prepackaged Foods covers all foods in this category.

Codex methods of analysis and sampling, including those for contaminants and residues of pesticides and veterinary drugs in foods, are also considered Codex standards.

Codex Guidelines

Principles that set out policy in certain key areas are:

- Addition of essential nutrients to foods.
- Food import and export inspection and certification.
- Establishment and application of microbiological criteria for foods.
- Conduct of microbiological risk assessment.
- Risk analysis of foods derived from modern biotechnology.

Interpretative Codex guidelines include those for food labeling, especially the regulation of claims made on the label. This group includes guidelines for nutrition and health claims; conditions for production, marketing, and labeling of organic foods; and foods that claim to be 'halal.' There are several guidelines that interpret the provisions of the Codex Principles for Food Import and Export Inspection and Certification, and guidelines on the conduct of safety assessments of foods from DNA-modified plants and microorganisms.

Codex Codes of Hygienic Practice

Codes of practice define the production, processing, manufacturing, transport, and storage practices for individual foods or groups of foods that are considered essential to ensure the safety and suitability of food for consumption. For food hygiene, the basic text is the Codex General Principles of Food Hygiene, which introduces the use of the Hazard Analysis and Critical Control Point food safety management system. A code of practice on the control of the use of veterinary drugs provides general guidance in this area. A series of codes of practice gives indications to producers on the prevention or reduction of specific contaminants in specific foods for example, aflatoxins in tree-nuts.

Science base of Codex and Risk Analysis

Science Base

The SPS Agreement requires that health and safety requirements for food should be based on sound scientific assessment of risk. In 1995, the Commission adopted four Statements of Principle Concerning the Role of Science in the Codex Decision-Making Process and the Extent to Which Other Factors are Taken into Account. These principles were supplemented by Statements of Principle Relating to the Role of Food Safety Risk Assessment (1997) and by Criteria for the Consideration of the Other Factors Referred to in the Second Statement of Principle (2001). The Comprehensive Working Principles for Risk Analysis in the Framework of the Codex Alimentarius was adopted by the Commission in 2003 and incorporated into the Procedural Manual of the Codex Alimentarius Commission.

Other Codex Committees (Additives, Contaminants, Hygiene, Pesticide residues, Nutrition, and Residues of Veterinary Drugs in Foods) have since then adopted specific risk analysis principles for their fields of activity that have also been included in the Procedural Manual.

Codex has also adopted Working Risk Analysis Principles for Food Safety for Application by Governments, which have been included in the Codex Alimentarius.

Risk analysis in Codex

Risk analysis in Codex follows a structured approach comprising the three distinct but closely linked components of risk analysis (risk assessment, risk management, and risk communication); each component being integral to the overall risk analysis.

The three components of risk analysis are documented fully and systematically in a transparent manner and effective communication and consultation with all interested parties is ensured throughout the risk analysis process.

There is a functional separation of risk assessment and risk management, in order to: Ensure the scientific integrity of the risk assessment; avoid confusion over the functions to be performed by risk assessors and risk managers; and reduce any conflict of interest. However, it is recognized that risk analysis is an iterative process, and interaction between

risk managers and risk assessors is essential for practical application.

Risk Assessment and Scientific Advice for Codex

The scientific advice for Codex is provided by expert bodies convened by WHO and FAO. These expert bodies are independent of the Codex Alimentarius Commission (and its subsidiary bodies) in order to ensure that the provision of scientific advice remains independent of the pragmatism that is required of risk management. The main principles of developing scientific advice are as follows.

- Excellence: Use of internationally recognized expertise, supported by the creation of a platform for global scientific discussions based on best practices in elaborating guidance.
- Independence: Experts contribute in their own capacity and not on behalf of a government or institution; they are required to declare possible conflicts of interest.
- Transparency: Procedures and methods to ensure that all interested parties understand the processes for the development of scientific advice and have access to the reports, safety assessments and evaluations, and other basic information.
- Universality: A broad base of scientific data is critical for the elaboration of international standards-setting activities. Therefore, institutions and all interested parties throughout the world are invited to make data available.

FAO/WHO Expert Bodies

The expert bodies currently providing scientific advice to Codex are as follows.

- The Joint FAO/WHO Expert Committee on Food Additives (JECFA).
- The Joint FAO/WHO Meetings on Pesticide Residues (JMPR).
- The Joint FAO/WHO Expert Meetings on Microbiological Risk Assessment (JEMRA).
- An equivalent body for nutritional scientific advice (JEMNU) is under discussion.

JECFA and JMPR have been providing scientific assessments for more than 50 years. JEMRA began its work in 2000 and aims to optimize the use of microbiological risk assessment. In addition to providing scientific advice as basis for risk management decisions by Codex, the evaluations produced by these bodies are widely used by governments, industry, and research centers. These assessments contribute to the development of Codex standards, codes of practices, and other guidelines in the area of food safety. Ad hoc expert meetings to address specific topics that either require a rapid assessment or are outside the terms of reference of existing expert bodies are also organized by FAO and WHO.

Alternatives to Standards

When there is evidence that a risk to human health exists, but scientific data are insufficient or incomplete, the Codex Risk Analysis process provides that Codex should not proceed to elaborate a standard but should consider elaborating a related text, such as a code of practice, provided that such a text would be supported by the available scientific evidence.

Collaboration with Standard-Setting and Other Organizations

The Codex Alimentarius Commission works closely with the other standards-setting bodies mentioned in the SPS Agreement (OIE and IPPC) The Commission has strengthened collaboration with the standard setting activities of OIE relative to animal production food safety, in recognition that effective management of food safety risks demands a food chain approach from primary production to consumer. Codex and IPPC interact directly and inform each other through mutual participation in governing bodies.

FAO and WHO collaborate with other intergovernmental organizations to provide the best possible and most complete scientific advice. For example, the import_imagesInternational Atomic Energy Agency (IAEA) provides advice and support on levels of radionuclide contamination in foods and on food irradiation. The OIE provides advice on animal health, on animal diseases affecting humans, and on the linkages between animal health and food safety.

Ensuring Full and Effective Participation in Codex

Despite the importance of Codex in protecting health and facilitating trade, many countries have not been able to participate fully in the establishment of international food safety standards in Codex, mainly as a result of low income levels. To redress this situation, the Directors-General of FAO and WHO launched The FAO/WHO Project and Fund for Enhanced Participation in Codex (Codex Trust Fund) in 2003. The Codex Trust Fund is aimed at assisting developing countries and transition economy countries to enhance their level of effective participation in the Codex Alimentarius Commission. This is a vital step toward ensuring that the Codex system is inclusive, participatory, and equitable.

The Codex Trust Fund provides support to eligible countries to:

- Prepare for and participate in Codex Committees and related meetings;
- Participate in Codex training courses to enhance participation in Codex meetings;
- Prepare and present scientific/technical positions and data related to the work of Codex.

As of April 2011, 1418 participants from 139 countries have been supported to attend Codex meetings, task forces, and working groups, with the majority of support going to the least developed countries. A total of 336 participants from countries in all Codex regions had received Codex training to enhance their effective participation in Codex. This support was made possible with over US$ 11.7 million in contributions from 14 Codex Member States and 1 member organization.

FAO and WHO provide a range of capacity development activities aimed at ensuring that developing countries and transition economy countries participate effectively in Codex. Many of these training programs are based on an FAO/WHO training package for enhancing participation in Codex which is available on CD-ROM and the Internet.

The Codex Alimentarius Today and in the Future

Benefits of Codex for all Actors in the Food Supply Chain

Consumers

Today consumers enjoy a variety of food from all over the world. However, there is a risk that this food may be unsafe due to microbiological or chemical contaminants or additives, or may contribute to unhealthy diets due to nutrient content. The Codex Alimentarius rules for food labeling, food additives, pesticide residues, contaminants, food hygiene, and others provide a foundation for ensuring food safety and nutrient content of food. Therefore, consumers can be more confident about the safety and quality of the food they consume, regardless of its origin.

Food Exporters

The global market for trade in food continues to expand. In this growing and dynamic market, exporters need to be able to rely on a uniform and universally accepted set of standards such as those provided by the Codex Alimentarius. More and more countries participate actively in the standard-setting of the Commission and have adopted the standards on food production and processing, thereby facilitating food trade and contributing to the economic health of countries and regions around the world.

Food Producers

Food producers, including farmers and fishers, have a vital role in feeding the world. The Codex Alimentarius Commission assists them by developing standards that cover various types of food, including fats and oils, milk and milk products, fish and fishery products, and fruits and vegetables. Once producers meet these standards, they can be confident that their products are safe, of high quality, and are acceptable in export markets.

Developing Countries

FAO and WHO have capacity building programs to help developing countries comply with Codex Alimentarius standards and improve food quality and safety. Assistance includes helping countries to revise their food laws and regulations in accordance with Codex Alimentarius and strengthening their national food control systems (management, inspection, and laboratory services).

Keys to Success and Challenges

The keys to the success of Codex are that it is member driven, science based, transparent, inclusive, flexible, and based on consensus. This allows it to take on any new challenging issue brought up by a Member State.

The challenges facing Codex today include: The need to develop standards rapidly while remaining inclusive and transparent; finding consensus among members with different socioeconomic status and trade interest/needs; the need to increase the participation of developing countries and the increased use by businesses of private standards that may have different/stricter requirements than Codex standards.

INSTITUTIONS INVOLVED IN FOOD SAFETY

Food and Agriculture Organization of the United Nations (FAO)

E Boutrif, Food and Agriculture Organization of the United Nations (FAO), Rome, Italy

© 2014 Elsevier Inc. All rights reserved.

Introduction

The Food and Agriculture Organization (FAO) is the principal United Nations' specialized agency whose mandate covers all aspects of food production, storage, transportation, processing, and marketing, and the development of agricultural and food-based programs to improve nutrition and enhance rural and national economies. Since its establishment in 1945, FAO has been leading the international community's effort to improve global food safety and quality through several major programs: (1) the provision of scientific advice to member governments, food industry, and consumers on food safety and quality; (2) the development of international food standards, guidelines, and recommendations; (3) the provision of policy and operational advice; (4) direct technical assistance to member countries in establishing or strengthening their national food control systems; (5) the emergency prevention system for food safety (EMPRES Food Safety), and (6) voluntary standards and schemes.

FAO's role in food safety and quality was further enhanced during the past decade through the emergence of the 'food chain' approach to food safety as the only effective way of ensuring the safety of the food supply at the global level. As a consequence, more attention is being given in FAO programs to food safety at different stages of the food chain, that is, primary production, storage, processing, distribution, etc. In addition to the central and longitudinal food safety work of the Food Quality and Standards Service, several units (animal production and health, plant production and protection, marine fisheries and aquaculture, food processing and marketing, and water for irrigation) have stepped up their work in food safety and quality assurance including the application of good practices.

FAO's Food Quality and Standards Service in FAO's Headquarters in Rome is the main central structure that deals with food safety matters. The Service benefits from the accumulated FAO technical and operational experience resulting from the interaction of normative and operational activities undertaken in cooperation with a wide variety of national and international partners at the global level. The Service also provides the Secretariat for the Joint FAO/World Health Organization (WHO) Food Standards Program (Codex Alimentarius). These facts, coupled with the interdisciplinary nature of FAO's work covering a wide range of policy and technical matters related to agricultural (including animal production and health) and fishery production ensure that quality and safety are considered throughout the food chain.

The technical assistance provided by the Food Quality and Standards Service also benefits from the extensive government and industry experience and expertise of its staff. The staff members have many years of experience in national and international food control programs and the food industry.

Provision of Scientific Advice

Risk Assessment: Scientific Basis of Food Safety Measures

FAO (jointly with WHO) promotes the application of risk assessment in all matters involving food safety. This must be based on sound scientific advice and evidence provided by panels of competent and independent experts. Risk assessment is one of the components of risk analysis – the other two being risk management and risk communication.

The Codex Alimentarius Commission (CAC) defines risk assessment as a scientifically based process consisting of the following four steps: (1) hazard identification; (2) hazard characterization; (3) exposure assessment; and (4) risk characterization. The risk assessment process is a means of providing an estimate of the probability and severity of illness attributable to a particular pathogen–commodity combination. The four-step process enables this to be carried out in a systematic manner, but the extent to which the steps are carried out will be dependent on the scope of the risk assessment. This can be defined clearly by the risk manager through ongoing dialog with the risk assessor.

Risk assessments provide information for identifying and characterizing food hazards. Risk assessment information is useful in determining which hazards are of such a nature that their prevention, elimination, or reduction to acceptable levels is necessary. The information is also useful in determining the most effective intervention strategies.

At present, there are two long-standing panels that provide advice to Codex, governments, and industry. They are the Joint FAO/WHO Expert Committee on Food Additives and Contaminants (JECFA) and Joint FAO/WHO Meeting on Pesticide Residues (JMPR). In addition, FAO and WHO convene ad hoc expert consultations whenever needed to address specific issues not covered by the permanent panels. In recent years, several expert consultations have been held on microbiological hazards in food, the risk assessment of foods derived from biotechnology and on animal feeding and food safety. FAO and WHO are currently studying the possibility of establishing an overall expert body on food safety risk

 doi:10.1016/B978-0-12-378612-8.00007-X

assessment that would oversee the entire work in this field and ensure the necessary link, synergy, and harmony between the specific expert panels and consultations.

JECFA

The JECFA is an international expert scientific committee that is administered jointly by FAO and WHO. It has been meeting since 1956, initially to evaluate the safety of food additives. Its work now includes the evaluation of contaminants, naturally occurring toxicants, and residues of veterinary drugs in food. To date, JECFA has evaluated more than 1300 food additives, approximately 25 contaminants and naturally occurring toxicants, and residues of approximately 80 veterinary drugs. The Committee has also developed principles for the safety assessment of chemicals in food that are consistent with current thinking on risk assessment and takes account of recent developments in toxicology and other relevant sciences. As of June 2001 the Committee had met a total of 57 times.

JECFA serves as a scientific advisory body to FAO, WHO, and their member governments, and to the CAC. Advice to the CAC on food additives, contaminants, and naturally occurring toxicants is normally provided via the Codex Committee on Food Additives and Contaminants (CCFAC) and advice on residues of veterinary drugs via the Codex Committee on Residues of Veterinary Drugs in Foods (CCRVDF).

All countries need to have access to reliable risk assessments of chemicals in food, but relatively few have the expertise and funds available to carry out separate risk assessments on large numbers of chemicals. JECFA performs a vital function in providing a reliable source of expert advice, and some countries use information from JECFA in formulating their own regulatory programs. In the same way, CCFAC and CCRVDF develop standards for chemicals in food based on JECFA evaluations.

For food additives, contaminants, and naturally occurring toxicants, the Committee does the following:

- elaborates principles for evaluating their safety;
- conducts toxicological evaluations and establishes acceptable daily intakes (ADIs) or tolerable intakes;
- prepares specifications of purity for food additives; and
- assesses intake.

For residues of veterinary drugs in food, the Committee does as follows:

- elaborates principles for evaluating their safety;
- establishes ADIs and recommends maximum residue limits (MRLs); and
- determines criteria for the appropriate methods of analysis for detecting and/or quantifying residues in food.

For food additives, JECFA normally establishes ADIs on the basis of available toxicological and other relevant information. Specifications of the identity and purity are also developed for food additives, which help to ensure that the product in commerce is of appropriate quality, can be manufactured consistently, and is equivalent to the material that was subjected to toxicological testing.

For contaminants and naturally occurring toxicants, levels corresponding to 'tolerable' intakes such as the provisional maximum tolerable daily intake or provisional tolerable weekly intake are normally established when there is an identifiable no-observed-effect level. When a no-observed-effect level cannot be identified the Committee may provide other advice depending on the circumstances.

In the case of veterinary drugs, data on good practice are evaluated and corresponding MRLs in animal tissues, milk, or eggs are recommended. Such MRLs are intended to provide assurance that when the drug has been used properly, the intake of residues of the drug present in food is unlikely to exceed the ADI.

More detailed information on JECFA's work can be found on the dedicated website, available on both FAO and WHO websites.

FAO/WHO JMPR

The JMPR is comprised of the Joint Meeting of the FAO Panel of Experts on Pesticide Residues in Food and in the Environment and the WHO Core Assessment Group. JMPR carries out toxicological evaluation of pesticide residues, normally resulting in an estimate of the ADI. In addition, JMPR proposes MRLs for individual pesticides in or on specific commodities. These MRLs are primarily based on the residue levels estimated in supervised field trials when the pesticide is used according to good agricultural practices (GAPs). In cases where initial estimates indicate that the ADI may be exceeded, more refined intake calculations are performed using national food consumption data and information from pesticide residues monitoring programs.

These Expert Committees establish chemical safety standards based on a review of toxicological studies in the more sensitive test animal species. They factor in an adequate level of safety, use risk assessment procedures, consider use and consumption patterns, and define the specifications of the identity and purity of food grade chemicals to be used.

Microbiological Risk Assessment

Since 1999, and at the request of the CAC, FAO and WHO have initiated a series of joint expert consultations to assess risk associated with microbiological contamination of foods (Joint FAO/WHO Expert meetings on Microbiological Risk Assessment). This followed the adoption by the CAC of the Principles and Guidelines for the Conduct of Microbiological Risk Assessment (MRA).

The aim of these joint expert consultations is to provide a transparent review of scientific data on the state of the art of MRA, and to develop the means of achieving sound quantitative risk assessments of specific pathogen–commodity combinations. The work includes an evaluation of existing risk assessments; a review of the available data and current risk assessment methodologies, highlighting their strengths and weaknesses and how they may be applied; provision of examples; and identification of data and information needs/GAPs. A further aim of these consultations is the development of guidelines relating to the different steps of risk assessment,

such as hazard characterization and exposure assessment. The purpose of such guidelines is to help the risk assessor, the risk manager, and other interested parties to understand the principles and science behind the risk assessment steps.

A series of such consultations has already been organized. They have dealt with the risk assessment of *Salmonella* spp. in broilers, *Salmonella* Enteritidis in eggs, *Listeria monocytogenes* in ready-to-eat foods, *Campylobacter* in broiler chickens, and *Vibrio* spp. in seafood. The work plan and priorities for MRA are established in close collaboration with the Codex Committee on Food Hygiene.

Ad hoc expert advice: FAO frequently carries out expert consultations and meetings, often jointly with the WHO, on a range of issues related to quality and safety of foods. Examples include the FAO Technical Consultation on Food Allergies, the Joint FAO/WHO Consultation on Biotechnology and Food Safety, the Joint FAO/WHO Consultation on Food Safety Risk Management, the FAO Expert Consultation on Animal Feeding and Food Safety, and the FAO/WHO Expert Consultation on Nanotechnology and Food Safety.

Example of Ad hoc Expert Advice: Genetically Modified (GM) Food Safety Risk Assessment

The use of modern biotechnology for the genetic modification of plants, microorganisms, and animals for the production and processing of foods poses additional concerns to certain consumer groups. FAO recognizes that modern biotechnologies have potential to raise agricultural productivity, reduce dependence on harmful chemicals, and increase the nutritional value of foods. However, FAO also acknowledges that there are possible risks to human and animal health and to the environment, which require a case-by-case assessment.

FAO, jointly with WHO, organized a series of expert consultations to consider general safety and nutritional aspects of foods derived from modern biotechnology. The consultations addressed 'Strategies for assessing the safety of foods produced by biotechnology' in 1990, 'Biotechnology and food safety' in 1996, and 'Safety aspects of genetically modified foods of plant origin' in 2000 and 2001. The latter consultations addressed questions specifically on safety that were raised by Codex Intergovernmental ad hoc Task Force on Foods derived from Biotechnology. The 2000 Consultation reframed the concept of substantial equivalence and identified a set of priority issues that are to be addressed in future FAO and WHO consultations. The 2001 consultation revised the international guidelines on the assessment of potential allergenicity of novel recombinant proteins to address broader concerns or critics of the previous approach. A second consultation in 2001 was convened to consider the criteria essential for the risk assessment of food and food ingredients produced with the aid of or containing viable or nonviable GM microorganisms.

The recommendations of Joint FAO/WHO expert committees and ad hoc consultations provide valuable guidance to member countries and also form the basis for intergovernmental discussions within the CAC. The resulting Codex standards, guidelines, and recommendations provide the basis for harmonization of national food safety regulations.

Development of International Food Standards, Guidelines, and Recommendations (Codex Alimentarius)

FAO and WHO are cofounders of the Codex Almentarius Commission, an intergovernmental body entrusted by the FAO Conference (1962) and the WHO World Health Assembly (1963) to develop international food standards, guidelines, and recommendations with the double objective of protecting consumer's health and ensuring fair practices in food trade. FAO hosts the Secretariat of the CAC and provides the necessary technical and administrative support for its smooth running. More details on the role of the FAO/WHO Codex Alimentarius Commission in food safety is provided elsewhere in this encyclopedia.

Provision of Policy and Operational Advice

FAO provides policy orientation and advice on the organization, management, and operation of national food safety and control systems. This is provided either directly to member countries on request, or indirectly through FAO's authoritative publications and reports. Examples of such work include:

- *Food contamination and residues monitoring*: Food contamination by chemical and biological agents continues to be a serious problem around the world. Surveillance and monitoring of contaminants (chemical and biological) in foods is therefore important not only for the protection of public health but also because of its negative economic impact. Excessive levels of aflatoxin or pesticide residues in food raise consumer's concern about their health implications, and are often a cause of food import rejections in international food trade. FAO advises member countries on the establishment and operation of national food contamination monitoring programs to allow a continuous assessment of the food safety situation at national level and enable food safety authorities to take timely, corrective measures whenever a food safety problem is identified. FAO also assists in the analysis of the causes of the contamination problems and in formulating and implementing preventive actions.
- *Food control management, inspection, analysis, and quality control*: Adherence to Codex standards, guidelines, and recommendations and achieving the appropriate level of sanitary and phytosanitary protection related to food safety can only be assured by establishing effective national food control systems. Therefore, technical assistance provided by FAO is directed toward establishing or strengthening the necessary elements of such systems. FAO's technical assistance aims at creating the political will for, and technical understanding of, these elements to enable proper institutional building process.

FAO provides expert advice required for the development and operation of effective national food control systems including food inspection and sampling programs. Advice is also given on food laboratory management and on accurate, reliable, and cost-effective methods of analysis. Organizing

simple but effective systems of food quality control based on the Codex General Principles of Food Hygiene throughout the food chain improves food quality and safety, reduces food losses, and facilitates international food trade.

FAO's manuals and tools related to food safety and quality provide practical guidance for the development and operation of food quality and safety systems. These are aimed primarily at providing advice to developing countries, and document modern approaches for the development and implementation of risk-based food safety programs throughout the food chain. Such an approach is instrumental in facilitating international trade in food. Key titles in the series include: Food Safety Risk Analysis – A Guide for National Food Safety Authorities (2006), Assuring Food Safety and Quality: Guidelines for Strengthening National Food Control Systems (2003), Manual on the Application of the HACCP System in Mycotoxin Prevention and Control (2001), Animal Feeding and Food Safet, (1998), Imported Food Inspection (1993), and Management of Food Control Programmes (1991).

Direct Technical Assistance to Developing Countries

Direct technical assistance, in the form of project formulation, implementation, consultation, training, and/or other advisory services, is provided, at their request, to many developing countries and countries in transitional economies through the FAO Technical Cooperation Program or through other financing sources (FAO/Government Cooperation Program, Trust Fund arrangement; UNDP, and others). The trade in food is, for many countries, a prime source of foreign exchange. The challenge is to meet the appropriate level of sanitary and phytosanitary protection of importing countries. This requires the establishment of effective export food control systems that provide assurance of adherence to Codex/importing country's standards, guidelines, and recommendations by the exporting country. FAO technical assistance is provided to countries in developing effective food import and export controls thereby increasing confidence in the countries' food products and reducing the number of shipments rejected by importing countries. The Codex Committee on Food Import and Export Inspection Certification Systems provides valuable advice and recommendations in this area.

The following are some highlights of a few of these activities that are being carried out at present and which provide a general idea of FAO's work, which is carried out to meet general or specific food control requests from developing countries.

- *Development of national strategies*: Developing an effective national strategy on food quality control and safety should take into account the development needs of the country and contribute to national development programmes, particularly those related to food security. To provide coherence in national food control strategies, FAO assists member countries in reviewing their food control strategies and infrastructure, usually by convening national workshops involving all those directly and indirectly concerned with food safety and quality. More than 100 such workshops or reviews have been held in developing countries, with the participation of Ministries of Agriculture, Health, Commerce, and/or Industry, as appropriate to the existing infrastructure, as well representatives of the industry, consumers, and other interested parties. Weaknesses and strengths are identified and measures are proposed to strengthen the national infrastructure, often with the help of FAO-executed projects.
- *Advice on food legislation*: FAO assists countries in the review and updating of their national food legislation so as to take into account recent developments, including the World Trade Organization Agreements on Sanitary and Phytosanitary Standards (SPS) and Technical Barriers to Trade (TBT). The Model Food Law developed jointly by FAO and WHO and the Codex Alimentarius standards, guidelines, and recommendations constitute unique references in the development and harmonization of food legislation worldwide.
- *Training and manpower development*: Training of governmental and food industry personnel in all aspects of food quality and safety is a major aspect of FAO technical assistance and capacity development work. Emphasis is placed on food inspection, food analysis, certification requirements and procedures for export, application of HACCP systems in food processing and handling establishment, effective participation in Codex standard setting process, food safety management programs at various levels. These training activities are carried out as part of Regular Program activities or under FAO-executed projects.
- *Export and international trade*: Special emphasis continues to be given to improving national export food inspection and certification programs so that exporting countries have confidence that their products are acceptable to import authorities. Projects dealing specifically with this matter have been implemented in many countries including countries with emerging economies.

National and regional workshops on export food control have been organized for many countries to assess the existing situation and develop strategies and actions for the future.

EMPRES Food Safety

The FAO EMPRES Food Safety contributes to global effort for the prevention and control of food safety risks with the double aim of improving food security and protecting public health. EMPRES Food Safety complements and enhances FAO's ongoing work in animal and plant health emergencies. It serves FAO member countries through the three pillars of early warning, emergency prevention, and rapid response.

Early warning is provided through the FAO/WHO International Food Safety Authorities Network operated by WHO. It involves activities in incident scanning, identification, and verification. EMPRES Food Safety is developing an international network to gather information and intelligence data to conduct horizon scanning, involving other FAO units and decentralized offices, other UN agencies, national and regional governmental bodies, universities, research institutes, and related groups.

FAO, in collaboration with WHO, has developed a series of technical tools that provide countries with practical

guidance on food safety emergencies and reinforce emergency preparedness.

In case of a food safety incident, EMPRES Food Safety works with national food safety authorities to conduct an urgent appraisal of the event and mobilize the needed experts. Wherever needed, the input of experts in public health is sought through WHO. Together with national food safety authorities, EMPRES Food Safety determines the best possible emergency response, and assists in its implementation.

Voluntary Standards and Schemes

In recent years, there has been growing consumer interest for food and agricultural products that have specific characteristics regarding the final product or production system. This has led to the development of a number of voluntary standards, certification systems, labels, and regulatory instruments that relate to factors such as preservation of environment, social welfare and equity, traditions and geographical origin, nutritional aspects, etc. FAO's work on voluntary standards and schemes aims at providing the necessary support to relevant institutions value chain actors in interested countries, in setting up and implementing voluntary standards and schemes, taking into account their needs and constraints as well as the international regulatory framework and standards.

INSTITUTIONS INVOLVED IN FOOD SAFETY

World Health Organization (WHO)

J Schlundt, Technical University of Denmark, Copenhagen, Denmark

© 2014 Elsevier Inc. All rights reserved.

Glossary

Hazard A biological, chemical, or physical agent in or property of food that may have an adverse health effect.
Risk A function of the probability of an adverse effect and the magnitude of that effect, consequential to a hazard in food.
Risk analysis Formalized process to assess, manage and communicate risk.
Risk assessment Scientific formalized process to estimate risk and its attendant uncertainties.
Risk communication An interactive process of exchange of information and opinion on risk among risk assessors, risk managers and other interested parties.
Risk management The process of weighing policy alternatives to accept, minimize or reduce assessed risk and to select and implement appropriate options.

Food Safety as a Health Issue

Foodborne disease (FBD) continues to be a major public health issue. Food safety and FBDs have implications both on the health of individuals and the development of societies. Concerned by this, the Sixty-Third World Health Assembly (WHA), the governing body of the World Health Organization (WHO), in May 2010 reminded the Director-General of WHO of the need for efficient gathering and exchange of information in and among countries; and adopted a resolution 'Advancing Food Safety Initiatives (WHO, 2010).' The resolution asked Member States to establish disease burden estimation and surveillance and to contribute to the timely conduct of international risk assessments through the provision of relevant data and expertise. And specifically the resolution called upon the Director-General of WHO to help countries build relevant capacity to improve cross-sectoral collaboration along the whole food production chain and to establish with the International Food Safety Authorities Network (INFOSAN) an international initiative for the collaboration of laboratory partners in support of surveillance of FBD, identification of food contamination, and emergency response, including outbreak investigation.

WHO's Role in the Conceptual Development of Food Safety

WHO's central role in food safety as well as in other public health areas is a normative one and includes the facilitation of risk assessment and international standard setting. The most thorough normative change over the past decades in the food safety area has been the introduction of a formalized system to prepare and utilize science-based risk assessments to improve the safety of food, both at international and national level. For almost 20 years, WHO has promoted the new concept of risk analysis as a framework for the management of food production and food safety. Developed by WHO in collaboration with the Food and Agricultural Organization of the United Nations (FAO), the risk analysis framework and principles are depicted in Figure 1. Within this framework it is important to achieve functional separation of risk assessment (the science) and risk management (the intervention). The final goal of assessment should be to inform risk managers and other stakeholders of the nature, occurrence, and size of the risk in order to improve the quality of risk management decisions.

New concepts were needed because the old food safety systems have failed in the sense that the incidence of FBDs seems to have increased over the past decades in most countries. One of the reasons for this has been the intuitive reliance on testing. It must be realized that safety cannot be achieved by monitoring the presence of pathogens in the end product because it is impossible to test sufficient samples to obtain the necessary degree of statistical power to detect all contaminants at levels that may create unacceptable health risks. Therefore, a proactive approach is required, starting with the producer, including in many cases the primary production sector, ensuring a safe product based on predictive risk assessment and, where relevant, implementation of action plans to lower the prevalence of relevant pathogens.

The main focus of WHO's work in the area has been the development of methods for quantitative microbiological and chemical risk assessment, FBD surveillance, and also the assessment of the safety of new products used in food, including genetically modified (GM) foods. The use of risk assessment to improve risk management decisions and risk communication to enable transparent and proactive interaction between all interested parties, constitute the two other components of the risk analysis framework.

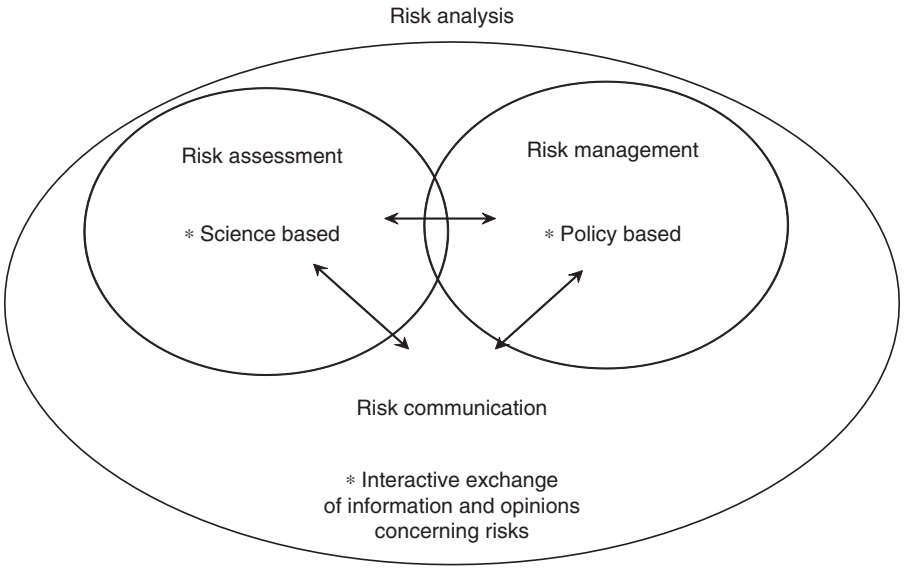

Figure 1 The WHO/FAO risk analysis paradigm, with risk assessment independent from undue influence from risk managers, and with everything floating in a sea of risk communication.

The Structure of WHO Relative to Food Safety Work

WHO's food safety activities extend from the WHO headquarters (HQ) in Geneva, Switzerland, often through six Regional Offices: AMRO (Regional Office for the Americas), AFRO (Regional Office for Africa), EMRO (Regional Office for the Eastern Mediterranean), EURO (Regional Office for Europe), SEARO (Regional Office for South-East Asia) and WPRO (Regional Office for the Western Pacific). The regional structure of WHO stems historically from the creation of WHO in 1948, where the preexisting Pan-American Health Organization was included in WHO as AMRO with an existing, independent governance structure. This independent structure was replicated in the other five regional offices, thereby creating an organization with not one, but seven politically appointed heads. In effect this means that each Regional Director is independently elected, and thus in effect can define policy course on his or her own. The regional offices receive approximately 75% of the WHO's budget and because regional directors are not appointed by or formally responsible to the WHO's Director-General, criticism has been voiced that some of the agency's activities are uncoordinated and not based on the best scientific evidence.

Over the later years, WHO has seen significant cuts in its budget. Therefore, a number of technical departments in the WHO HQ have seen cuts in technical staff. But even before these cuts the technical area of food safety was small in the WHO HQ as well as in regions. At its peak in 2008, the Department for Food Safety and Zoonoses at the WHO HQ included approximately 12–14 scientific staff and 6–8 other staff, whereas the regional offices typically had less than 1 scientific staff in this area. At the third layer of the organization, the country offices, food safety is typically covered by staff, who also cover a number of other technical areas. Nevertheless, the WHO has been able to support significant development in national food safety programs, and shoulder a very significant work load in the area, primarily through the active support of – mostly nationally funded – scientists from all over the world.

Most of the WHO work in the food safety area is conducted in some sort of collaboration with FAO. In the 1990s, the collaborative efforts between the two organizations were somewhat hampered by policy disagreement and to some degree by personal fights between WHO and FAO staff, including staff at senior level. Under the administration of WHO Director-General Dr Gro Harlem Brundtland, WHO in the late 1990s introduced the 'farm-to-fork' collaborative line with FAO, a policy line mirrored by FAO. This did not mean that the two organizations necessarily agreed in all policy areas, but a cooperative effort was underlined in most areas of work. Following the major zoonotic outbreaks in the first decade of 2000, including severe acute respiratory syndrome (SARS), avian influenza, and type H1N1 influenza, the collaboration between FAO and WHO was extended to also include the World Animal Health Organisation (OIE).

Scientific Advice

The collaborative efforts between WHO and FAO in the area of provision of scientific advice include three expert groups with relatively regular meetings. These groups are managed differently, but all in collaboration between WHO and FAO. They are the Joint FAO/WHO Expert Committee on Food Additives and Contaminants (JECFA), the Joint FAO/WHO Meeting on Pesticide Residues (JMPR), and the Joint FAO/WHO Expert Meetings on Microbiological Risk Assessment (JEMRA). For further description of the work of these joint committees, see the article on FAO, or visit:

1. http://www.who.int/foodsafety/chem/jecfa/publications/en/index.html (JECFA).

2. http://www.who.int/foodsafety/chem/jmpr/publications/en/index.html (JMPR).
3. http://www.who.int/foodsafety/micro/jemra/en/ (JEMRA).

In addition to these expert groups, FAO and WHO have hosted a number of ad hoc expert meetings in relation to food safety issues. An example of such an ad hoc expert meeting is the Ad hoc Expert Group on Food Safety Risk Assessment of GM Food, which is described in an other article.

Providing Scientific Advice That Has Not Been Asked For

Whereas the expert groups described above all typically respond to specific requests for scientific advice, in most cases from the FAO/WHO Codex Alimentarius Commission (CAC), WHO has in a number of cases initiated scientific work without such request. The examples are manifold, but three important examples shall be briefly described here.

1. Antimicrobial resistance (AMR) is a global public health issue that is impacted by both human and nonhuman antimicrobial usage. The continuing emergence, development, and spread of pathogenic microorganisms that are resistant to antimicrobials are a cause of increasing concern. WHO's involvement in the containment of AMR due to nonhuman antimicrobial usage dates back to the late 1990s, and includes the hosting of a number of expert meetings from 1997 to this day. Although the other relevant international organizations in this area – FAO and OIE – were not immediately supportive of the suggestions coming out of these expert meetings, through continued efforts from WHO the issue has since 2007 also been included in CAC work. These efforts have led to clear recommendations about prudent use of antimicrobials in animals as well as a description and selection of critically important antimicrobials. Whereas some recommendations have been implemented in some parts of the world, a very significant number of recommendations have not. In most countries, antimicrobials are still used as growth promoters, and veterinarians are still allowed to make profits from selling such drugs.
2. Acrylamide was until 2002 considered an occupational health issue only, as this substance had not been found in food. Therefore, it was considered dramatic news when Swedish researchers in March 2002 unveiled research showing very high concentrations of acrylamide in ordinary food items, such as French fries, bread, and coffee. Although some experts dismissed the importance of these findings – for example, with statements about how 'we have eaten these types of food for centuries' – WHO maintained a serious attitude toward these findings relative to a substance that had been proven carcinogenic in animals. Thus, a WHO/FAO expert consultation was undertaken less than 2 months after the Swedish news. The consultation considered that the available data suggested that toxicological findings in animals should be assumed to be relevant for extrapolation to humans. The consultation also provided a range of recommendations for further information and new studies to better understand the risk to human health posed by acrylamide in food.
3. In September 2008, the INFOSAN Emergency Surveillance System obtained information from the Chinese Ministry of Health (MoH) that a serious and widespread contamination event had occurred in China. The contamination of infant formula with melamine had been spurred by fraudulent use of melamine to disguise the dilution of milk with water. Through further interaction between INFOSAN and MoH the issue of potential other use of the contaminated milk powder as well as parallel (illegal) distribution of contaminated milk powder to other countries was investigated. An INFOSAN Emergency Alert was distributed to the network and subsequently updates were issued regularly during the following months. A WHO Expert Meeting was held in collaboration with FAO a few months after the event unfolded in an effort to elucidate the normal ('baseline') exposure of humans to melamine, as well as suggest relevant tolerable daily intakes of melamine through food.

International Standards and Guidelines

People in ancient times already understood they could get sick from consumption of infected meat, and that keeping their animals healthy and using dedicated methods of food preparation and conservation could improve their health. Maybe the oldest written document about this, 'On Airs, Waters, and Places' is by Hippocrates that describes how human health is influenced by its interaction with the environment. A clear understanding of the importance of food and food safety for health led to the creation of the FAO/WHO Food Standards Programme in 1963, the active arm of which is the FAO/WHO the CAC. The CAC now meets once a year and agrees on food standards, guidelines, and codes of practice, typically developed in one of its 16 committees and task forces. However, the CAC system had become a very heavy system with significant bureaucracy. Realizing this, WHO and FAO in 2001 initiated an evaluation, resulting in some, but not very profound changes, including a higher level of inclusiveness especially toward developing countries. However, the system has also proven a capacity to move fast, even when dealing with politically charged issues. For example, the development of guidelines for the assessment of GM foods was finalized within a time period of only 4 years. When considering that such standards are developed based on several FAO/WHO expert meetings, as well as several task force meetings, many times with the participation of 50–70 countries, this is actually an impressive international achievement.

Because the work of CAC is governed by the member countries, the system typically does not deal immediately with new or upcoming issues, unless key member countries take a direct interest in this. An example of an important food safety issue that has only been taken up reluctantly by CAC is the problem of AMR in microorganisms. Later in this article, forward-looking initiatives by the WHO in this area will be described, but it is noteworthy that it was only in 2007 that

CAC agreed to start an initiative in this area, i.e., the Codex AMR Task Force.

Although CAC standards and guidelines are in effect just voluntary guidance documents, the specific reference to CAC in the World Trade Organization agreements as the 'gold standard' in the food safety area has meant that most countries take CAC guidance seriously. Nevertheless, CAC standards and guidelines have no legal status above this. However, WHO has an international legal instrument that covers certain aspects of food safety, the International Health Regulations (IHR), which is a legally binding agreement for all 194 Member States of the Organization. The aim of these regulations is to help the international community prevent and respond to acute public health emergencies that have the potential to cross borders and threaten people worldwide. Such public health emergencies include risks related to food, because diseases can spread far and wide via international food trade. A health crisis in one country can impact the health, livelihoods, and economies in many parts of the world. The IHR aims to reduce unwarranted interference with international traffic and trade, while ensuring public health through the prevention of disease spread.

The present IHR, which entered into force on 15 June 2007, require countries to report certain disease outbreaks and public health events to WHO. Building on the unique experience of WHO in global disease surveillance, alert, and response, the IHR defines the rights and obligations of countries to report public health events, and establish a number of procedures that WHO must follow in its work to uphold global public health security. Thus, countries have an obligation to inform the global community, through WHO, about any public health risk related to food, which has the potential to cross borders or that are otherwise unique. WHO has created a specific system for the reporting of such food safety events: The INFOSAN, which operates in collaboration with FAO, is described in this article under the section 'Food Safety Emergency Action and Exchange of Experience over Borders.'

FBD Burden

Although important parts of international food safety work involves the collaborative WHO–FAO framework, a number of issues related more specifically to the occurrence, surveillance, and prevention of FBD are primarily supported at the international level by WHO. FBDs result from the ingestion of contaminated foods and food products and include a broad group of illnesses caused by biological and chemical agents, which contaminate food at different points in the food production and preparation process. In work sponsored by the WHO FBD Burden Epidemiology Reference Group (FERG), it was estimated that in 2008, 1.336 million children under the age of 5 years die every year from diarrhea caused by contaminated food or water. Consequently, diarrhea is the second leading cause of death among children after respiratory diseases. In 2009, another FERG-sponsored study estimated that diarrhea-related deaths among adolescents and adults were 1.15 million per year. The total mortality of 2.486 million deaths due to diarrhea is more than deaths due to AIDS, malaria, and measles combined.

As usual the poorest part of the population is at the highest risk: In general, malnutrition can result in a 30 fold increase in the risk for diarrhea-associated death. When considering these estimates of child deaths, it is important to realize that they do not include deaths in other age groups, deaths as caused by foodborne microorganisms not resulting in diarrhea nor the probably very significant disease burden caused by chemical substances, including naturally occurring chemical substances in food. Such chemical substances include aflatoxins caused by fungi growing in food as a result of poor storage conditions, or acrylamide formed in certain foods when heated $>120^{\circ}$C.

Although most diarrheal deaths occur in poor countries, FBDs are not limited to developing countries. It is estimated that, in 2011 in the USA, FBDs resulted in 48 million illnesses (one in six people), 128 000 hospitalizations, and 3000 deaths per year resulting in medical costs and productivity losses in the US$ billions. The full extent of the burden and cost of unsafe food is currently still unknown, but its impact on global health security, trade, and development is considered to be profound. Thus, valid estimations of the real FBD burden are basically nonexistent. Recognizing the current data gap, WHO has launched an Initiative to Estimate the Global Burden of FBDs from all major causes using summary health metrics that combine morbidity, mortality, and disability in the form of the disability-adjusted life year. This has been initiated through the establishment of the FBD Burden Epidemiology Reference Group (FERG). The FERG members are mandated to engage in assembling, appraising, and reporting on currently existing burden of FBD estimates, conducting epidemiological reviews for mortality, morbidity, and disability in each of the major FBD, providing models for the estimation of FBD burden where data are lacking, developing source attribution models to estimate the proportion of diseases that are foodborne, and developing user-friendly tools for burden of FBD studies at country level. Although the work of FERG was originally stipulated to result in (some) global FBD data by 2012, the work is still ongoing, and parts of the work seem hampered by recent funding trouble.

Food Safety Emergency Action and Exchange of Experience over Borders

In 2000, the Fifty-Third WHA recognized the serious threat to public health posed by foodborne illness and called for improved 'gathering and exchange of information in and between countries and regions on matters of food safety'. The Fifty-Fifth WHA in 2002 expressed serious concerns about health emergencies posed by natural, accidental, and intentional contamination, including food contamination, and requested WHO to coordinate the identification of and response to such emergencies.

In 2004, in response to the aforementioned resolutions and in reply to a specific request made by the FAO/WHO CAC, WHO established the INFOSAN, in collaboration with FAO. The network was built to help Member States deal with international food safety incidents and emergencies, and to facilitate communication and information sharing among all food safety stakeholders. Currently, 167 Member States are members of INFOSAN.

The INFOSAN network not only responds to the reporting of human FBD cases to WHO, but also provides information to countries when a food contamination event has the potential to affect human or animal health at a later stage. To promote seamless action throughout the food chain continuum, INFOSAN and the Global Early Warning System (GLEWS) for Major Animal Diseases, including Zoonoses exchange information directly. GLEWS is a confidential early warning network of WHO, FAO, and OIE used to track, verify, and analyze transboundary zoonotic diseases. This network brings together the expertise of the three different organizations to maximize prevention and control of zoonotic diseases. INFOSAN and GLEWS coordinate efforts relative to food safety events linked to animal health (e.g., avian influenza), animal feed (e.g., aflatoxin), or farm practices (e.g., AMR).

In addition to emergency information, INFOSAN facilitates the exchange of food safety information and experience among its members through the publication of INFOSAN Information Notes, in the six official WHO languages. These Notes provide INFOSAN members with summaries on relevant food safety issues. This INFOSAN function is supplemented with capacity building efforts aimed at the building of integrated food safety systems able to manage and monitor events with national or international implications.

Data and Laboratory Networks

WHO has for a number of years hosted the first ever global database for food contamination, focused on chemical contaminants. The Global Environment Monitoring System–Food Contamination Monitoring and Assessment Program (GEMS/Food) was established in 1976 to inform national governments, CAC, and other stakeholders, as well as the public, on levels and trends of chemical contaminants in food and their contribution to dietary exposure. The program operates through a network of WHO Collaborating Centers and national institutions located in approximately 70 countries around the world. National data are submitted to GEMS/Food to conduct international scientific assessments of exposure, as part of chemical risk assessment. In addition, WHO has developed an approach to describe the various diets around the world. The GEMS/Food Consumption Cluster Diets were updated in 2006 and are now used both nationally and internationally for exposure assessment of food contaminants and pesticide residues (Figure 2: WHO GEMS/Food Consumption Cluster Diets).

Recognizing an urgent need for building Member State capacity in surveillance of foodborne and other enteric infections from the farm to the table, the WHO in 2000 initiated the WHO Global Salm-Surv, now called Global Foodborne Infections Network (GFN). The network promotes integrated, laboratory-based surveillance, and fosters intersectoral collaboration and communication among microbiologists and epidemiologists in human health, veterinary, and food-related disciplines. The network has been created with the support of some of the most respected national laboratories in these areas from a long list of WHO Member States, including Australia, Canada, Denmark, France, Germany, Japan, Netherlands and the USA.

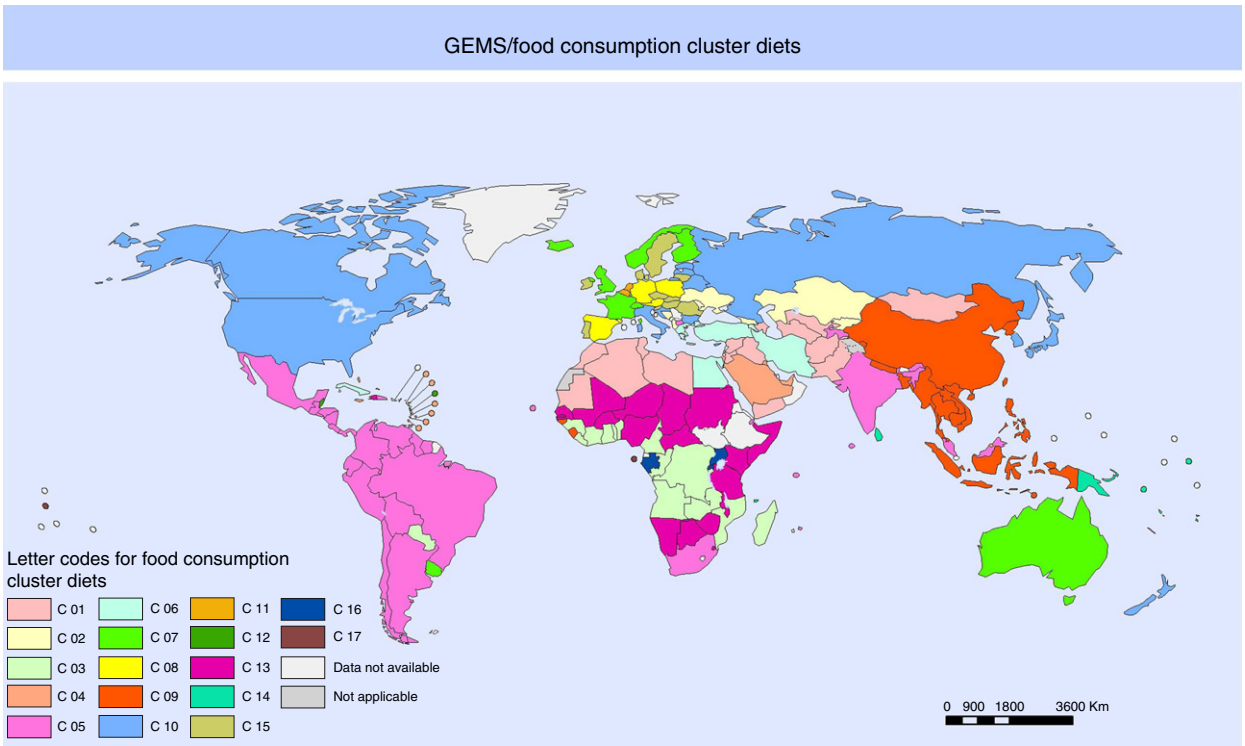

Figure 2 WHO GEMS/Food consumption cluster diets. Reproduced from http://www.who.int/foodsafety/chem/Global_GEMS_CLUSTERS_2012.jpg.

By May 2012 the GFN included 1062 members from 184 Member States, and continuous activities covering: regional training courses on FBD surveillance, risk assessment and epidemiology, external quality assurance programs on microbiology, reference testing of selected foodborne pathogens, and provision of technical information and methodological support for microbiological laboratories. The GFN also hosts a country data bank with data on national *Salmonella* isolates from more than 83 countries comprising approximately 1.5 million human and 360 000 nonhuman isolates.

WHO considers new activities linking databases covering microbiological and chemical contaminants in food in an effort to promote the sharing of food contamination data among countries.

The Future of Food Safety and WHO's Role – Promoting Safer Food and Better Health

The future food safety systems will most likely enable new ways of evaluating disease metrics and attribute such disease directly to food groups. It is likely that new genetic fingerprinting techniques will enable attribution for all pathogenic microorganisms related to food, and new chemical fingerprinting (metabolomics) will enable a significantly better understanding of the effect of chemicals in food. At the same time the new line of risk-based approaches will enable the setting of national – and international – targets for disease reduction, as well as provide the evidence base for such reduction efforts. These approaches will make their way into all parts of the global market, including the developing countries, which are likely to become more and more important agricultural producers and exporters. The introduction of a risk-based framework will enable developing countries to learn from mistakes (and successes) elsewhere. These countries have the potential to 'leap forward' into preventative systems focusing on risks. In addition, at a time where trade restrictions and national/regional protection of the agricultural production through heavy subsidies is likely to come to an end, it will be of paramount importance for the production sector also in developing countries to adapt to the new times. The benefits of improving food safety amount to a 'win-win' situation with improved national health as well as improved export potential. However, it will be crucial for these potential future developments that the developments in new food safety systems is clearly documented and communicated. Such communication has not yet commenced; national authorities as well as international organizations have an important future task in this area.

In supporting such developments, the WHO should focus on its core business. WHO is neither a funding agency nor an implementing agency like United Nations Children's Fund (UNICEF). Instead, it should aim to be the paramount knowledge organization in global health – gathering up the best technical, scientific, and practical information and making it accessible to all countries. This does not mean that WHO products must necessarily only be theoretical analyses aimed at scientific debate. A very significant amount of WHO documentation is directly applicable in national food safety efforts. The information material about GM food ('20 Questions on GM Food'), the exchange of national experience in risk mitigation activities through INFOSAN, or indeed the global spread of the simple WHO message on safe food handling ('Five Keys to Safer Food') all are clear testament to the fact that if the core remains sound science, the application of practical support to countries can take many forms.

WHO should continue to take bold action in support of continuous improvement of national and global food safety. This also means that WHO must remain an impartial and independent broker of sound science. Only thus can WHO contribute to a better – and safer – future for the world.

INSTITUTIONS INVOLVED IN FOOD SAFETY

World Organisation for Animal Health (OIE)

M Thibier and B Vallat, World Organisation for Animal Health, Paris, France

© 2014 Elsevier Inc. All rights reserved.

Glossary

Antimicrobial resistance The resistance of a microorganism to an antimicrobial medicine to which it was previously sensitive. Resistant organisms include bacteria, viruses, and some parasites. The World Organisation for Animal Health (OIE) recognizes that antimicrobial resistance is a global public and animal health concern that is influenced by the usage of antimicrobial agents in humans, animals, and elsewhere. Those working in the human, animal, and plant sectors have a shared responsibility to prevent or minimize pressures for the selection of antimicrobial resistance factors in humans and animals.

Emerging diseases A new infection resulting from the evolution or change of an existing pathogenic agent, a known infection spreading to a new geographic area or population, or a previously unrecognized pathogenic agent or disease diagnosed for the first time and which has a significant impact on animal or public health.

Food safety A scientific discipline describing handling, preparation, processing, and storage of food in ways that prevent foodborne illness. This includes a number of routines that should give assurance that food will not cause harm to the consumer when it is prepared or eaten according to its intended use.

Foodborne hazards A biologic, chemical, or physical agent in, or a condition of, food such as an animal product with the potential to cause an adverse health effect (OIE). Biologic hazards can be posed by parasites, viruses, or bacteria. Chemical contaminants in foods can come from industrial and agricultural sources, from food processing, or from the food itself. Toxic chemicals also come from biological sources such as molds and algae. Foreign objects present in food could constitute a physical hazard to the consumer.

Foodborne illness Also called as foodborne disease and colloquially referred to as food poisoning resulting from the consumption of contaminated food, pathogenic bacteria, viruses, or parasites that contaminate food, as well as chemical or natural toxins such as poisonous mushrooms.

Veterinary Services The governmental and nongovernmental organizations that implement animal health and 'welfare' measures and other standards and recommendations in the Terrestrial Code and the OIE Aquatic Animal Health Code in the territory. The Veterinary Services are under the overall control and direction of the Veterinary Authority. Private sector organizations, 'veterinarians,' 'veterinary paraprofessionals,' or aquatic animal health professionals are normally accredited or approved by the Veterinary Authority to deliver the delegated functions (OIE). The Veterinary Services protect and improve the health and welfare of animals, safe animal products, and veterinary biologics by preventing, controlling, and eliminating animal diseases, and monitoring and promoting animal health, animal welfare, and food safety. The OIE considers the Veterinary Services as a Global Public Good.

Introduction

The goal of Food Safety is that the consumers are able to trust that all food offered for sale is safe for its intended use. The last decades of the twentieth century have been the subject of increased concern in this area, related to numerous factors: changes in the production systems, much wider distances between the sites of breeding, production, and of consuming – particularly in industrialized countries – and occurrences of some new and emerging or reemerging diseases, such as the spongiform encephalopathies in ruminants. This period has stressed the critical importance of animal production and absolute necessity of a holistic approach to food safety and not only on the end products. This underpins the need for an integrated, multidisciplinary approach that covers the whole food chain and even beyond, such as feed for animal products, paradigm summarized with the famous 'from stable to table.'

OIE Involvement: The Animal Production Food Safety Working Group

Basic facts regarding Public Health show the following: 60% of human pathogens are zoonotic, 75% of emerging diseases are zoonotic, and 80% of agents having a potential bioterrorist use are zoonotic pathogens. Similarly, a great proportion of foodborne diseases is due to microbiologic pathogens of animal origin. It was hence recognized essential that the World Organisation for Animal Health (OIE) and the International InterGovernmental Organization (IGO) reference for animal

health and zoonoses gets involved in this area in close cooperation with other IGOs also working on Food Safety, such as the Codex Alimentarius, but from a different angle linked with its global mandate: "The improvement of animal health and welfare all around the world."

The Office International des Epizooties was created through the international Agreement signed on 25 January 1924 following outbreaks of devastating contagious animal diseases and in particular Rinderpest in Europe (nowadays totally eradicated worldwide – official recognition of the eradication in May and June 2011). In 1994, following the Marrakech agreement with the setting of the World Trade Organization (WTO) Agreement on the application of sanitary and phytosanitary measures (SPS), OIE was formally recognized as one reference organization by the WTO–SPS mandate to safeguard world trade by protecting human, animal, and plant health in conjunction with its two 'sister' organizations (Codex Alimentarius Commission (CAC) and International Plant Protection Convention). In 2011, OIE has a total of 178 Member Countries.

The third OIE Strategic Plan (2001–05) identified Food Safety as the first priority and at the 70th General Session in May 2002, the World Assembly of OIE delegates adopted resolutions defining the role of the OIE in this area aiming at strengthening its standard-setting activities in food safety through a new Animal Production Food Safety Working Group (APFSWG). The fourth OIE Strategic Plan (2006–10) supported the continuation of this mandate, recommending that the APFSWG "continue to work with other relevant organizations, especially the Codex Alimentarius Commission, in reducing foodborne risks to human health due to hazards arising from animals."

Hence, the OIE's goal for animal production food safety is to reduce foodborne risks to human health due to hazards arising from animals and hence provide better guarantee of safety of food of animal origin. It should be noted that these hazards include pathogens, which may not cause clinical signs in animals.

After adoption of the 2002 resolution, an ad hoc group of Experts chaired by the President of the CAC, was convened by the Director General in April 2002, and it pursued as a permanent working group of Animal Production Food Safety (APFSWG) in its series of meetings since then.

The terms of reference of this Working Group include among other items, the following:

1. Consideration of all foodborne hazards arising from animals before slaughter;
2. A primary focus on food safety measures applicable at the farm level;
3. Consideration of food safety measures applicable elsewhere, for example, during animal transport and harvesting of wild animals for food; and
4. Work criteria and priorities that take into account global food safety priorities and current work programs of relevant international organizations, especially the CAC.

Within these terms of reference, the role of this working group is to:

1. Provide advice to the OIE Director General on policy and strategic issues relating to the OIE's work on animal production food safety, which has the goal of reducing foodborne risks to human health by preventing, eliminating, or controlling hazards arising from animals before primary processing of animals and animal products and
2. Act in a steering group capacity, as required by the OIE Director General, regarding the work of OIE expert groups:
   a. Giving advice to the Director General on membership, scope, and terms of reference for expert groups and
   b. Reviewing texts arising from relevant expert groups for consideration by the relevant Specialist Commissions.

At its first meeting in November 2002, again chaired by the President of the CAC, the Working Group drew up a detailed work program for the OIE on the development of recommendations on animal production food safety covering pre-slaughter issues and those before the first transformation of the animal products, with the primary focus being on food safety measures applicable at the farm level. The Working Group also reviewed existing OIE Terrestrial Animal Health Code chapters dealing with food safety and zoonoses (brucellosis, tuberculosis, etc.), and recommended necessary changes in standards and additional work in accordance with the overall work program proposed by the Working Group.

A report of their work is delivered each year at the OIE General Session followed by resolutions giving the APFSWG its road book for the year ahead.

Priorities were given along this last decade and include the following:

1. Horizontal issues such as animal identification and traceability, good farming practices, guidelines for animal feeding, ante- and postmortem meat inspection standards, role of Veterinary Services in the reduction of public hazards;
2. Disease-specific OIE texts: Terrestrial Animal Health Code (Terrestrial Code) chapters on brucellosis, salmonellosis in eggs, etc.; and
3. Strengthening relationship between the OIE and the CAC.

Relevant documents were then drafted and later approved by the World Assembly of OIE delegates during various General Sessions this last decade, such as

1. The Guide on Good Farming Practices;
2. Guidelines for the control of hazards of animal health and public health importance through ante- and postmortem meat inspection;
3. Animal identification and traceability later followed by General Principles for identification and traceability of live animals incorporated in the Terrestrial Code (chapter 4.2);
4. Guidelines on the Detection, Control and Prevention of *Salmonella* Enteritidis and *S.* Typhimurium in Poultry Producing Eggs For Human Consumption;
5. Guidelines for the control of Hazards of Animal Health and Public Health importance in animal feed (chapter 6.3. of the Terrestrial Code);
6. Antimicrobial resistance (surveillance programs, chapter 6.7–6.11 of the Terrestrial Code) in coordination with the Codex Task Force;
7. Role and functionality of Veterinary Services throughout the food chain;
8. Review of a paper published on: Priority pathogens for standard setting by OIE.

In addition, the World Assembly of OIE Delegates, during the General Session of 2009 approved in its resolution XXIV, the expansion of the mandate of the Aquatic Animal Health Standards Commission to address Food Safety of products derived from aquatic animals. A first meeting of a working group focused on this issue had met in 2008. At its 2011 meeting, the group finalized the chapter 5.3 of the Aquatic Animal Health Code (Aquatic Code) dedicated to the "criteria to assess the safety of aquatic animal commodities."

Several ad hoc groups also tackle food safety issues in their meetings such as the OIE *ad hoc* groups on identification and traceability of live animal, on animal feeding, on pet food, on trade in animal products, on assessment of food safety related to the use of recombinant vaccines in food-producing animals.

Many seminars under the auspice of OIE and OIE publications, in particular the Scientific and Technical Review, were focused on the benefits for food safety issues to get the OIE and the Veterinary Services widely involved in prevention and control of foodborne diseases.

Among the key documents published by the OIE on food safety those last years, the following can be mentioned:

1. The Guide to good farming practices for animal production. This guide aims at describing a set of generic good farming practices intended to minimize hazards and to recommend good practices to address the listed hazards under six headings: general management, animal health management, etc. with a particular and original focus on animal feeding and watering. Its Appendix 1 is also most valuable as it draws a multientry table of "Hazards and their corresponding control points."
2. Priority pathogens for standard setting by the OIE related to animal production food safety. The authors used expert opinion and a literature review to identify the pathogens that were to be prioritized by the OIE for the development of future standards for animal production food safety. Interestingly, their conclusions were that *Salmonella* (from species other than poultry) and pathogenic *Escherichia coli* were considered as top priorities. *Brucella* spp., *Echinococcus granulosus*, and *Staphylococcus aureus* were also mentioned. The same article also lists the current coverage of farm level control of foodborne disease agents in the OIE Terrestrial Code or OIE guidelines.

OIE Involvement in Food Safety with the Veterinary Services

In addition to the extensive work of APFSWG, the OIE supports the improvement of food safety in the field by, the implementation of the rules to apply for Food Safety via the expertise of the national Veterinary Services. The latter are most often the national key focal points for all food safety issues as a great proportion of reported outbreaks of foodborne diseases is due to contaminations of foods with zoonotic agents, often during primary production. They act in their capacity to prevent and control foodborne zoonosis at the farm level or of other foodborne disease and chemical contamination of foods. They indeed exert their surveillance at all stages of animal production, on farm controls (animal health, feed, use of antimicrobial, identification, and traceability as well as animal welfare) and at the meat inspection level (ante- and postmortem inspections at slaughterhouses). They also provide certification of animal products for international trade.

In this context, the Director General of the OIE asked the OIE Delegates to nominate a national focal point for animal production food safety according to established terms of reference. The OIE also regularly organizes seminars for national focal points to provide information and contribute to capacity building of Veterinary Services.

Further to the implementation of the role of the Veterinary Services in the food chain from stable to table recommended by OIE, the OIE has put some emphasis both on capacity building and veterinary education. Wall stressed the big challenge for Veterinary educators to stimulate interest in public health medicine and make the curriculum relevant to those issues. The OIE in conjunction with the World Veterinary Year 2011 got also involved in trying to standardize the curriculum of veterinary education.

Close Cooperation with the CAC

Since its first involvement in this area, the OIE recognized that the goal to reduce foodborne disease due to hazards arising from animals can only be achieved in collaboration with the World Health Organization (WHO), the Food and Agriculture Organization (FAO), and their subsidiary body, the CAC. This is totally in line with the recent agreements signed between the Directors General of OIE, WHO, and FAO. The FAO–OIE–WHO tripartite strategic alignment recognize that addressing health risks at the human–animal–ecosystems interfaces require strong partnerships among players who may have different perspectives on some issues and different levels of resources.

The OIE has an SPS responsibility for elaborating international standards and related texts for the prevention, control, and eradication of animal diseases and zoonoses, whereas the CAC elaborates standards and related texts for both safety and suitability aspects of food control. CAC and the OIE have strategies and mechanisms in place to coordinate and integrate food safety activities across the production to consumption continuum and so enhance the safety of foods of animal origin on a worldwide basis. In terms of identification and traceability, for example, there is a clear need to strengthen bridges between animal and product traceability.

The terms of reference of the APFSWG include a link at the working level with the CAC (CAC, FAO, and WHO) and the working group has produced a guidance paper on the cooperation between the CAC and the OIE in food safety throughout the food chain. It identified as priorities an examination of the scope to develop joint OIE and Codex standards, address gaps and duplication in standards, and develop procedures for mutual recognition of standards where appropriate.

The cooperation between the CAC and the OIE currently include

1. Cooperation through mutual exchange of information and participation in meetings;
2. The use of a common text in the elaboration of a standard and harmonization of definition;
3. Cross-referencing to the other organization's standards; and
4. The construction of complementary texts taking into account the existing standards.

The next challenge in this cooperation approach is to set common working groups on specific topics, which would set the standards before following the respective procedures of these two organizations for respective official approval.

Conclusion

OIE plays a key role worldwide in Food Safety issues both at the starting points in elaborating and editing Codes of Practices or Standards for specified hazards of biologic origin and on the ground via its guidelines and capacity building to the national Veterinary Services. Through its specific working group APFSWG, the OIE has been an active partner of international organizations, and has been working in close cooperation with CAC, all having complementary functions and sharing the common approach of 'production to consumption' to food control.

INSTITUTIONS INVOLVED IN FOOD SAFETY

Consumer Organizations

E Groth, Groth Consulting Services, Pelham, NY, USA

© 2014 Elsevier Inc. All rights reserved.

Consumer Organizations Involved in Food Safety and Food-Related Issues

Consumer organizations are a prominent sector of civil society; they speak for and represent consumers on a wide range of economic, safety, civil rights, and political issues. Consumer organizations have long been actively concerned with food safety, on scales ranging from local to global. Because they represent consumers and are independent from commercial interests, consumer organizations bring important and generally credible perspectives to food safety policy making.

What is a consumer organization? Consumers International uses this definition to determine eligibility for membership:

- The organization must have members drawn from the general public.
- It must be independent – that is, it should receive neither funding nor tangible support from any commercial entity with an interest in any issue the group addresses.
- It must be transparent – that is, the identities of those who direct and control the organization must be public.
- It must be democratically governed – by a board, a committee, or leaders chosen by its members – and should pursue issues and take positions supported by the members.

Consumer Organizations in a National Food Safety Context

Consumer organizations exist, to varying degrees, in virtually every country of the world. There are hundreds of consumer organizations in the world's 200 or so countries and their food safety interests span a wide spectrum of issues. On the one hand, consumer groups in Mali, Tanzania, and several other African nations have pressed local health authorities in recent years to oversee the safety of street-vended foods. On the other hand, consumer organizations in Europe and North America have lobbied their governments to regulate and label genetically modified foods.

Many consumer organizations, especially in developing countries, are essentially grass-roots community activists with very limited resources. Others, in both developed and developing parts of the world, have scientists and food-safety policy specialists in their staff, and bring professional expertise as well as a strong proconsumer perspective to bear on food safety issues. Some larger consumer organizations operate independent laboratories that test products for quality and safety, and publish magazines to inform consumers of their findings. Such organizations combine a scientific approach to testing, an educational outlook, and a commitment to improve the lot of consumers. This three-part mission is characteristic of consumer nongovernmental organizations (NGOs), both in countries where advanced consumer protection legislation and institutions exist and in nations where that protective framework, largely, still needs to be built.

For more than 50 years, consumer organizations have joined in international alliances, forging broad commonalities of outlook among consumer NGOs worldwide. At the same time, the consumer movement remains quite varied in its political outlook, its choice of issues, and the tactics it uses when pursuing its goals.

Most consumer organizations are concerned with food issues, given the fundamental importance of foods to all consumers. Consumer NGOs may address food sufficiency, nutrition and food quality, trade in foods and food safety; many work on all four. The full scope and diversity of consumer organizations' work on food safety issues cannot be covered in a brief article, but examples from two rather different countries may suggest both the variety of these efforts and some of their common themes.

In the USA, consumer organizations were instrumental in the campaign to pass the first national food safety law, in 1906, and were just as actively involved in the 2010 campaign that led to the passage of major new food safety legislation. One major US consumer NGO, Consumers Union, has worked for stronger food safety standards since 1936. Its recent priorities include regulation and labeling of genetically modified foods, safeguards to keep bovine spongiform encephalopathy out of US cattle herds, and better consumer information about methylmercury in fish. Another US consumer group, the Center for Science in the Public Interest, has created a database of outbreaks of foodborne pathogens for public use, filed numerous petitions with federal regulators to restrict potentially harmful food additives, and taken grocery chains to court for their failure to remove recalled foods from their shelves. Both organizations publish consumer magazines, each is engaged on a much wider range of food safety issues, and of course, these are but two of the many US consumer organizations that address some aspects of food safety.

In India, numerous consumer organizations work on food safety issues. The Voluntary Organization in Interest of Consumer Education (VOICE) has published a guide to food safety for consumers and advocates, tested soft drinks for pesticide residues, lobbied the Indian government for

restrictions on the use of genetically modified crops, and participated in the worldwide campaign for the safety of infant formulas. The Centre for Science and the Environment tested honey and found multiple illegal antibiotic residues. The Association for Consumer Action on Safety and Health (ACASH) promotes breastfeeding and lobbies to strengthen food safety regulations. The Consumer Education and Research Centre (CERC), which operates an independent product-testing laboratory, has found unacceptable levels of arsenic and fluoride in bottled water and widespread microbial contamination of processed foods, such as *Escherichia coli* and *Staphylococcus aureus* in milk and ice cream. These are just a few CERC food test reports available on its website, and these four organizations are but a small sample of the many Indian consumer NGOs working on various aspects of food safety.

Consumer Organizations in an International Food Safety Context

Just as foods and their associated safety issues cross national boundaries, many national consumer NGOs have joined with their sister organizations in other countries to work on food safety at the regional and global levels.

Very similar definitions of consumer organizations (comprised of ordinary citizens, independent, transparent, democratic, and international) are used by the World Health Organization (WHO), the Food and Agriculture Organization (FAO), and the Joint WHO/FAO Codex Alimentarius Commission to determine eligibility for observer status as a consumer international non-governmental organization (INGO). A relatively small number of organizations meet these criteria. Nevertheless, consumer INGOs have participated actively in international food safety deliberations for several decades. Codex has been the primary medium for this consumer involvement, but consumer INGOs have also engaged with WHO, FAO, and the World Trade Organization on food safety issues at the Global Forums on Food Safety, and in other contexts. For brevity's sake, the focus here is on consumer participation in Codex, but the consumer role at other food safety-related intergovernmental bodies has been similar to that in Codex.

In early 2011, there were 199 registered Codex observer organizations. Of those, eight were international consumer-oriented public-interest organizations. Each organization, and the role it has played at international food safety bodies, is described briefly below. The eight organizations are:

- 49th Parallel (49P)
- Bureau Européen des Unions de Consommateurs (BEUC)
- Consumers International (CI)
- Greenpeace International (Greenpeace)
- International Association of Consumer Food Organizations (IACFO)
- International Baby Food Action Network (IBFAN)
- National Health Federation (NHF)
- Pesticide Action Network (PAN)

Several of these consumer observers are essentially single-issue organizations; for example, 49P is concerned almost exclusively with genetically modified foods, and IBFAN works only on infant feeding issues. But at least two consumer observers, CI and IACFO, have broad food safety portfolios and have participated over the years at multiple Codex committees and at other food safety meetings. The breadth and depth of their interests and their highly professional interventions have enabled consumer INGOs to play a more significant role in international food safety deliberations than their small numbers might suggest.

Profiles of Individual Consumer Observer Organizations

Consumer-based Codex observer organizations represent a variety of perspectives, geographical regions, and issue interests. They are listed here in alphabetical order. Further details on each, including their national members where applicable, can be found on the websites listed at the end of this article.

49th Parallel (49P)

49th Parallel is a small organization with membership in the northwestern USA and southwestern Canada (where the 49P the parllel forms the international boundary). 49P's main interest is foods and food ingredients derived from genetically modified organisms. It has attended the Codex *Ad Hoc* Task Force on Foods Derived from Biotechnology, several meetings of the Codex Committee on Food Labeling where international standards for labeling genetically modified foods were being deliberated, and meetings of the Committee on General Principles and the Codex Commission when issues of interest to 49P were on the agenda.

Bureau Européen des Unions de Consommateurs (BEUC)

BEUC, known in English as The European Consumers' Organization, is an alliance of 44 consumer organizations from 31 European countries. BEUC is the European branch of CI. It participates at the Codex Regional Coordinating Committee for Europe, representing CI's European members. At all other Codex bodies and in other international food safety forums, BEUC and its members are usually represented by CI.

Consumers International (CI)

CI is the oldest and largest international association of consumer organizations, with some 220 member organizations in 115 countries in all regions of the world. CI first began participating at the Codex Commission in the 1970s, and has done so more or less continuously since then.

In the 1990s, CI expanded its international food safety work in response to growing member interest in the topic. CI members in the USA, the UK, and several European countries led the effort, assigning their own food safety experts to take part (as CI) at many Codex committees and other international food safety gatherings. At the peak of its activity, CI was engaged in the work of at least 17 different Codex bodies, including the Commission; all six regional Codex coordinating committees; subject committees on Food Labeling, General Principles, Food Hygiene, Food Additives and Contaminants, Pesticide Residues, Residues of Veterinary Drugs in

Foods, Nutrition and Foods for Special Dietary Uses, and Import/Export Certification Systems; and *Ad Hoc* Task Forces on Foods Derived from Biotechnology, and on Management of Antimicrobial Resistance. CI sent experienced delegates to meetings, often submitted detailed written comments on draft documents, and participated in voluntary working groups that met between meetings to draft and revise those documents.

CI also sent delegations to the WHO/FAO Global Forums on Food Safety in 2002 and 2004. Several individuals from CI member organizations have participated as invited experts in joint WHO/FAO expert consultations and similar scientific meetings.

Because of the breadth of its interests, and because its delegates brought expertise on issues, experience in international meetings, and a diplomatic attitude to the table, CI has the played a robust and effective role in international food safety forums for many years.

During the late 1990s, with grant support, CI expanded its presence to include delegates from its members in developing countries. These diversified delegations broadened CI's interactions with national delegations and gave many CI member organizations, new to the process, an opportunity to learn how to participate effectively in global food safety policy making. By building the capacity of its own members, CI also increased its presence at the regional codex coordinating committee meetings, especially those in Africa, Asia, and Latin America.

In recent years, CI's international food safety work has significantly diminished. Key experienced delegates left CI member organizations; grants ran out; and most CI members faced competing needs. As the food-related policy priorities of CI as a whole diversified, an intensive emphasis on Codex-work no longer seemed appropriate, and resources were redirected elsewhere.

Today, CI's involvement in Codex and similar international food safety activities, although still substantial, is a slim shadow of what it once was. CI tracks food safety issues that most concern its members (such as genetically modified foods, safety of infant formulas, and antimicrobial resistance) and attends meetings where those issues are addressed. In recent years, CI's strongest presence has been at the Committee on Food Labeling and the *Ad Hoc* Task Force on Antimicrobial Resistance. CI still attends Codex Commission and General Principles meetings, and keeps its members informed on the status of issues that interest them. CI nowadays is as likely to be represented by someone from Uganda as by someone from the UK, and rarely sends multinational delegations to meetings.

Greenpeace International

Greenpeace International has not often participated at Codex or in other global food safety forums. Greenpeace did join other consumer INGOs attending the 2009 Codex Committee on Food Labeling to lobby in favor of labeling of genetically modified foods.

International Association of Consumer Food Organizations (IACFO)

IACFO was established in 1997; in 2011, it had 12 member organizations in North America, Europe, Asia, and Africa. IACFO is interested in all aspects of international trade in foods, including food safety. IACFO has attended meetings of the Codex Commission and the Committees on General Principles, Food Labeling, Food Hygiene, Residues of Veterinary Drugs in Foods, International Import and Export Certification Systems, and Nutrition and Foods for Special Dietary Uses. IACFO also has participated in deliberations of WHO, FAO, the World Trade Organization, and the Organization for Economic Cooperation and Development (OECD).

In 2004, IACFO created a second global consumer food safety entity called Safe Food International (SFI), described as a project to empower consumer organizations to improve food safety on a global level. SFI developed a set of guidelines for consumer organizations wishing to pursue that goal, and in 2005, organized an international conference at which consumer organizations met with national food safety officials and experts from FAO, WHO, and other intergovernmental bodies.

IACFO's participation in international food safety activities has been led by experts at its US member, the Center for Science in the Public Interest. IACFO has been able to maintain a consumer presence at several critical Codex committees, including Food Hygiene and Veterinary Drugs, after CI could no longer do so, and is probably the most broadly involved consumer organization now working on global food safety issues.

International Baby Food Action Network (IBFAN)

IBFAN is, as its name indicates, concerned with infant feeding issues. Formed in 1979, IBFAN is an alliance of public-interest groups from Africa, Latin America, Asia, Europe, and other regions. As a single-issue organization, IBFAN has interacted with global and regional intergovernmental agencies (such as WHO, United Nations International Children s Fund (UNICEF), and the Pan-American Health Organization (PAHO)) that address infant nutrition policies. At Codex, IBFAN has been involved at the committees on Nutrition and Foods for Special Dietary Uses and on Food Labeling, and participated in the Food Hygiene committee's effort to set microbial safety standards for infant formulas. IBFAN has also attended meetings of the Codex Commission, the Codex Committee on General Principles, and on occasion, some Regional Codex Coordinating Committees.

IBFAN was instrumental in lobbying for the International Code on Marketing of Breastmilk Substitutes, adopted by the World Health Assembly in 1981, helped organize a boycott of Nestle over its infant-formula marketing practices in developing countries, and is currently active in Codex efforts to set standards for the nutrient composition and nutritional labeling of infant formula. Several of IBFAN's member organizations have formed a Codex Working Group to coordinate inputs by the global IBFAN network into the Codex process. The working group has submitted detailed technical comments on some of the Codex drafts, and sent delegates to make expert interventions at Codex meetings.

Because of its single-issue focus, its representation of lower-income consumers from all corners of the earth, the ethical leverage associated with representing babies, and the quality of its experienced, knowledgeable delegates, IBFAN has been one of the most effective consumer INGOs working on global food safety.

National Health Federation (NHF)

NHF is a global association of consumer health advocacy organizations with members in at least 20 countries. First established in 1955 as a national organization in the USA, NHF describes itself as a defender of health freedom. It has participated at the Codex Committee on Nutrition and Foods for Special Dietary Uses, chiefly to oppose standards that it perceives might restrict consumers' rights to buy nutritional supplements. NHF has also joined other consumer observers to support a Codex standard for labeling of genetically modified foods.

Pesticide Action Network (PAN)

PAN is an international alliance of environmental, farm-worker, and consumer advocacy organizations that promotes pesticide safety in a variety of contexts. PAN has been actively involved with the FAO's Agriculture Committee and with the United Nations Environment Program. Pesticide residues in foods are one of PAN's many concerns, and PAN has attended occasional past sessions of the Codex Committee on Pesticide Residues.

Conclusions

The consumer movement is actively engaged in the food safety policy process at all levels, from strictly local to national and global scales. This participation has benefitted consumers and enriched the process. The consumer perspective is independent and often valuable, and sometimes brings substantial insights and expertise to bear on issues that might not have been presented by other stakeholders. Although the intensity of their participation has ebbed and flowed over the years as resources wax and wane, consumer INGOs are a fixture in the world food safety system and are likely to play a significant role in the future.

Glossary

Codex Alimentarius The Codex Alimentarius is a body of standards decided by the Codex Alimentarius Commission to protect the health of consumers and to ensure fair practices in international food trade. The Codex Alimentarius Commission is a joint FAO/WHO organization.

Contaminant Any substance not intentionally added to food, which is present in such food as a result of the production (including operations carried out in crop husbandry, animal husbandry, and veterinary medicine), manufacture, processing, preparation, treatment, packing, packaging, transport or holding of such food, or as a result of environmental contamination. The term does not include insect fragments, rodent hair, and other extraneous matter (definition adopted by Codex Alimentarius Commission).

Genetic modification (GM) A process of altering the genetic makeup of an organism by techniques of modern biotechnology.

Hazard analysis critical control points (HACCP) A system that identifies, evaluates, and controls hazards that are significant for food safety.

Incident Any event which, based on the information available, causes concern about actual or suspected threats to the safety or quality of food that could require intervention to protect consumers.

Rapid Alert System for Food and Feed (RASFF) A notification system for incidents in the EU, which is coordinated by the European Commission.

Overview of the Food Industry Organizations

The Food and Drink Federation (FDF) is the UK representative of FoodDrinkEurope, the confederation of the European food industries (the umbrella trade association for the European food and drink industry). As of January 2010, membership of FoodDrinkEurope was made up of: 26 national federations, including 3 observers, 26 EU sector associations, and 20 major food and drink companies. FoodDrinkEurope aims to promote and represent the interests of the food and drink industry in the EU and beyond. It covers issues such as food quality and safety, nutrition and health, novel foods, labeling, agricultural policy, international trade matters, sustainable development, respect for the environment, and enlargement of the EU. The food and drink industry is one of the Europe's most important and dynamic industrial sectors.

More information on the European food associations and federations that are part of FoodDrinkEurope can be found on the FoodDrinkEurope website. A list of the major associations can also be found on the European Commission, Enterprise, and Industry website.

Below are a few examples of some of the sectoral associations:

- Association of the Chocolate, Biscuit and Confectionery Industries (CAOBISCO) – represents approximately 2000 companies of the chocolate, biscuits, and confectionery sectors of the EU.
- European Sugar Manufacturers Committee (CEFS) – represents all European sugar manufacturers and refiners.
- European Dairy Association (EDA) – represents the European dairy industry.
- European Snacks Association (ESA) – is Europe's trade organization dedicated to advancing the savory snacks industry on behalf of member snack manufacturers and suppliers.
- The Federation of European Union Manufacturers and Suppliers of Ingredients to the Bakery, Confectionery, and Patisserie Industries (FEDIMA) – represents the intermediate products industries for the bakery and confectionery trades.
- Union of European Beverages Associations (UNESDA) – represents the nonalcoholic beverages manufacturers in the EU.

The food industry organizations are structured in a similar way. The common feature of these trade associations is that they have a policymaking body in their structure as well as committees or working groups that discuss specific issues and oversee the day-to-day management of issues. *Ad hoc* groups or task forces can also be set up within a working group or committee to address specific issues. All the businesses are governed by EU legislation. The sectors/associations influence the environment in which their members operate. There are horizontal legislations formed in Brussels and vertical legislations covering products in different sectors. In addition to

legislation, below are some of the aspects addressed by sectors or associations:

- Representing, promoting, and protecting members' interests.
- Policy developments on food safety and quality, nutritional health, sustainability and market management as part of the EU Common Agricultural Policy (CAP), as well as guaranteeing the right to be competitive and innovative.
- Promoting dialogue and exchange of information at technical and legislative levels, for example, on additives, labeling, food quality, environment, nutrition and diet, with the European Commission, European Food Safety Authority (EFSA), national regulators, and other international bodies like Codex.
- Keeping members informed of EU developments.
- Working with legislators and regulators with the aim of improving the workability, proportionality, or enforceability of legislation by consulting and contributing on behalf of members to the setting up or review of European legislation directly affecting members.

An overview of how the national federations within the EU food industry work is reflected in the structure and function of the description given for FDF and its sector associations. The details and exact structures or membership may differ with each national federation, association, or sector within the EU Member States. However, the overall objective is to represent, promote, and protect the particular interests of the members of the concerned sector, association, or federation.

Food and Drink Federation

FDF is the voice of the UK food and drink industry. FDF is a trade organization representing, promoting, and safeguarding the interests of the UK food and drink manufacturing industry in relation to scientific issues and regulatory systems and associated developments which impact on the production and sale of food and drink products.

FDF represents the interests of the UK's food and non-alcoholic drinks manufacturing industry, the largest manufacturing sector in the UK, employing more than 400 000 people. The industry has an annual turnover of £72.8 bn accounting for 15% of the total manufacturing sector. Exports amount to almost £10 bn of which 79.2% goes to EU members. The industry buys two-thirds of all UK's agricultural produce. FDF membership comprises manufacturers of all sizes as well as trade associations dealing with specific sectors of the industry.

Member Services and Sector Groups

FDF is a membership-based organization. Its policies are developed through industry-wide consultation channeled through its governing Council, advised by specialist committees/panels, and informed by sector networking groups. Current FDF membership comprises of 13 associations, 7 sector groups, and other membership organizations (See annex) (Figure 1).

In Scotland, Wales, and Northern Ireland, some government policies and public services are different from those in

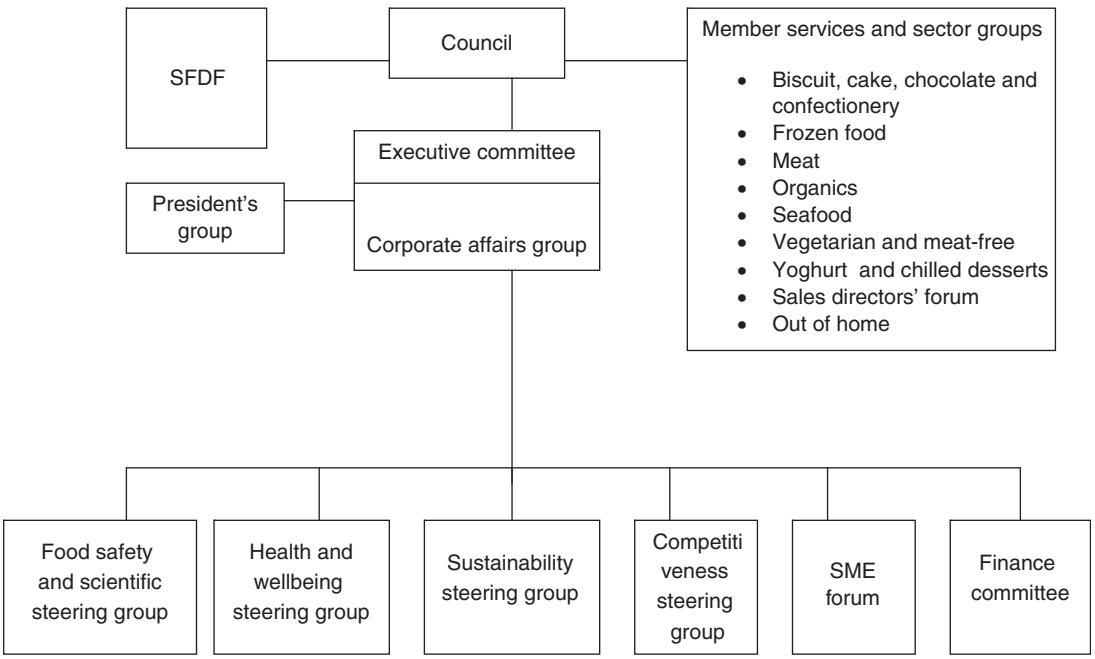

Figure 1 FDF organizational structure. SFDF, Scottish Food and Drink Federation; SME, small- and medium-sized enterprises.

England. Since 1999, the UK central government has given certain powers to devolved governments, so that they can make decisions for their own areas.

Scottish FDF (SFDF) is a devolved division of FDF and is 'the voice' of food and drink manufacturers in Scotland, ensuring the Scottish food industry is heard where it matters in the Scottish, UK, and EU contexts.

Each sectoral organization represents the specific interests of its group. For example the Biscuit, Cake, Chocolate, and Confectionery (BCCC) Group represents the specific interests of UK biscuit, cake, chocolate, and confectionery manufacturing/supplying/marketing companies. The Group is the representative and influential voice of the sector, promoting the industry and representing its viewpoint to the government, to all relevant regulatory, scientific, and enforcement authorities, and other public bodies.

In addition, the Group is the UK representative body on the EU organization representing the product sector, i.e., CAOBISCO, so as to play a full part in influencing EU policy matters which impact on the sector.

Food and Drink Federation Vision and How We Work

The core areas of FDF's work are:

- Food safety
- Promoting the competitiveness of the food and drink industry
- Health and well-being
- Sustainability
- Communications

Food Safety

The overall FDF vision enshrined in its core areas of work is that stakeholders, including government and consumers, trust the UK food and drink industry and have confidence both in the safety of FDF members' products, and from a health and well-being perspective, to see the industry as socially responsible and to know that all products can fit into a balanced lifestyle. The vision from a competitiveness point of view is for stakeholders to understand and value the economic contribution of the UK food and drink sector and for this to be fully taken into account in government policy-making and to realize that the industry is working to improve its sustainability – economically, environmentally, and socially.

The Food Safety and Scientific Steering Group, supported by its committees, is at the core of FDF activities and seeks to ensure that all FDF policies are rigorously science-based, including the scientific underpinning of the work of other divisions in FDF and their activities such as the Health and Well-being, Competitiveness, and Sustainability Steering Groups. The Food Safety and Scientific Steering Group represents, promotes, and safeguards the interests of the UK food industry in relation to scientific issues and regulatory developments. Its role is central to supporting and communicating food safety and science as pillars of FDF's work.

Within the Food Safety and Scientific Steering Group, there are seven issue-led committees to facilitate more detailed discussion of specific issues; these are:

- Food Chain Issues, covering issues relating to the safety of the supply chain in respect of food raw materials and animal feedstuffs, and including the overarching issues of GM, novel foods, and nanotechnology;
- Food Contact Materials, dealing with the safety of packaging materials in immediate contact with food and food ingredients;
- Food Hygiene, including EU food hygiene legislation, hazard analysis critical control points (HACCP), and microbiological food safety;
- Food Ingredients, dealing with developments relating to the use of additives, flavorings, enzymes, and processing aids;
- Food Law and Labeling, covering general food law and food labeling;
- Nutrition, which includes developments in the science in relation to diet and health, obesity strategy, reformulation, portion sizes, nutrition and health claims, and nutrition profiling; and
- Residues and Contaminants, which deals with the safety of raw materials throughout the supply chain in terms of chemical and other contaminations. This includes process contaminants and plant protection products.

Each work area comprises a list of priority topics followed by issues to be monitored, with a view to action if appropriate. A continuing requirement for each committee will be to identify emerging issues and assess the need for action, which may necessitate a revision of established priorities. The work program for each committee is reviewed and updated annually.

All these committees assist FDF members in meeting the requirements of the legislation. In addition, FDF uses the science base to drive development, innovation, and reformulation of products. For example, under nutrition, the science of nutrition and our ability to apply it to drive health and well-being in consumers is seen as a key indicator of whether the food and drink industry is perceived as being one that is responsible and able to move with the times – be these developments in the realms of pure or applied (e.g., social) science.

The roles of the Competitiveness and Sustainability Steering Groups are to provide strategic and proactive leadership on competitiveness issues and lead on sustainability and environmental issues affecting the well-being of the food and drink manufacturing industry, respectively.

From time to time, FDF will also form *ad hoc* technical groups when input is required on particular issues.

FDF's communication programs aim to enhance the industry's reputation as a responsible provider of safe food products and reliable information.

Informing and Consulting Members

FDF ensures that members stay abreast of the advances in science that change our understanding of food safety issues and FDF promotes the need for appropriate risk assessment and reduction strategies by regulators.

FDF enhances the coordination of the industry's approach and response to scientific and regulatory issues, and food safety incidents, by provision of timely information and advice to members, and by undertaking consultation as appropriate.

FDF liaises and develops partnerships, including where appropriate joint positions, with supply chain organizations, including retail, food service, farming, scientific, academic, and other organizations that are part of the food chain including consumer organizations.

Food Safety and Science is Key to Our Work

The safety of food products is the top priority for the food industry and this is reflected in FDF's positions on key issues. As part of their due diligence requirement, manufacturers need to have robust systems in place to ensure that from the time of harvest or slaughter to the time of consumption, product safety is monitored and maintained – whether the potential threat comes from chemical contamination, physical objects, or microbiological infection.

As such FDF ensures that members stay abreast of advances in science that may change FDF policy toward food safety or approach to appropriate risk assessment, risk management, and risk communication by national and European regulators.

It is important to remember that science also brings opportunities for product and process innovation and FDF works with members to develop policy positions to address emerging technologies which explain how these developments can provide real benefits for consumers. FDF's secretariat and committees also work to ensure that regulatory approaches to food information to consumers and nutrition are based on science.

Link with Food Research Organizations

To keep abreast of advances in science, FDF member companies are also members of independent membership-based organizations that carry out research and development for the food and drinks industry worldwide, such as Leatherhead Food Research and Campden BRI. These food research organizations are also affiliate members of FDF.

These food research organizations help the food industry meet their daily and long-term technical, scientific, information, and training needs. They help the industry to innovate and evolve by offering services including market intelligence, food research and analysis, food legislation, business and technical information, and training.

Compliance with Food Legislation

The safety of food and drink products, and their delivery in prime condition along the food chain to consumers, is the key priority of the food and drink manufacturing industry. In this respect, the food and drink industry is highly regulated and carefully monitored to ensure the safety and integrity of the food supply chain.

The Food Safety Act 1990 (as amended) provides the framework for all food legislation in Great Britain – similar legislation applies in Northern Ireland. This is an important act in Great Britain, which updated previous law on food safety and consumer protection. This has been in existence since before the 'General Food Law' Regulation (EC) No 178/2002, which covers EC legislation on general food safety.

According to the General Food Law, in the market, it is prohibited to put food which is unsafe (article 14). The legislation covers hygiene, microbiological contamination, residues, and contaminants. There are also more specific regulations, for example: on food additives, Regulation (EC) No 1333/2008; Enzymes Regulation (EC) No 1332/2008; Flavourings Regulation (EC) No 1334/2008, and Regulation (EC) No 258/97 on novel foods, which is currently under review. These regulations are applicable to the risk assessments of specific ingredients and how they are processed, as appropriate.

Framework Regulation (EC) No 1935/2004 on materials and articles intended to come into contact with food as well as legislation on active and intelligent materials, and articles in contact with food are applicable to packaging material. Compliance with this legislation is necessary to ensure compliance with general food law. There are also commodity specific 'directives' or regulations, for example, on chocolate, jam, etc.

As the body of legislation bearing down on the food industry continues to grow, FDF works closely with its European counterpart, FoodDrinkEurope, and European sector associations, to ensure that the industry's voice is heard in the right places and at the right time within the EU. The industry's input ensures that harmonized legislation is in place in order to ensure the free movement of food and feed in the EU and to comply with international standards where necessary.

The Food Chain

The inherent perishability of food from the time of harvest or slaughter requires food manufacturers to be continually vigilant in maintaining product safety – whether from the threat of chemical, physical contamination, or microbiological infection. FDF's work covers developments and issues that impact on the production and sale of food and drink products, specifically:

- food safety, processing, and composition;
- the labeling and presentation of the final product; and
- nutrition, diet, and health.

This involves a whole food chain approach, constructively influencing the regulatory environment in which the industry operates, working with Government and others to improve confidence in the safety of the food supply, and addressing sustainability and competitive issues in the related regulatory systems.

The food chain encompasses a number of players from primary producers through to consumers. This chain is wide, complex, and global (Figure 2). As such, transparency and compliance with legislation is needed throughout the chain to ensure that food safety is achieved. Hence, responsibility for

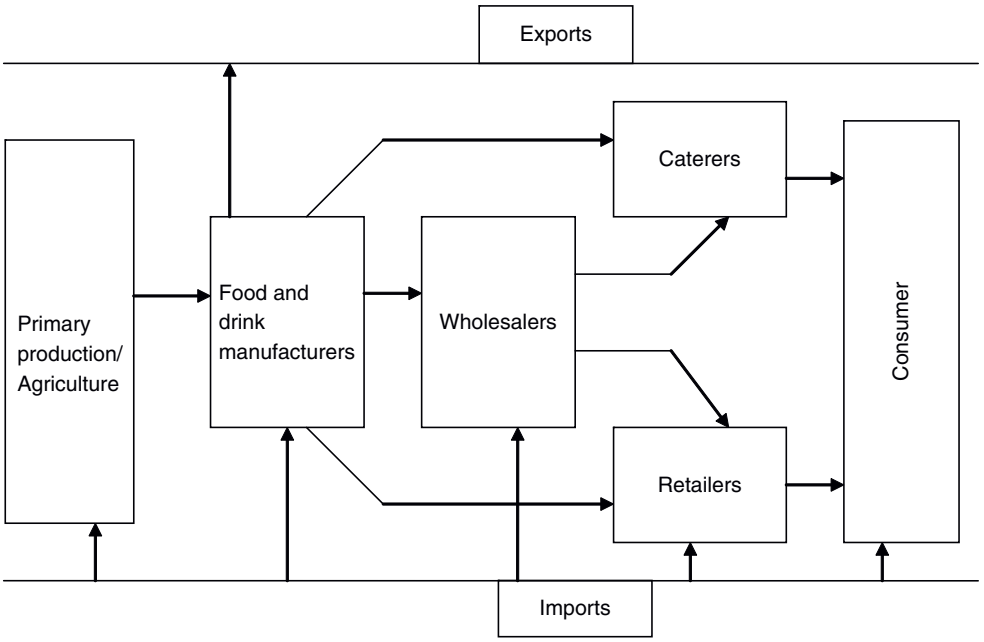

Figure 2 Interaction of the food chain stakeholders. *Source*: Institute of Manufacturing, University of Cambridge, Report to FDF, Value of Food and Drink Manufacturing to the UK, July 2010.

food safety is shared by everyone involved with food, from primary production to consumption, including growers, processors, regulators, distributors, retailers, and consumers.

Responding to Food Incidents

In addition to the objective to seek proportionate and evidence-based legislation that control food, FDF also assists members in the prevention of incidents through the work of the Incident Management Working Group, including identifying the root causes of incidents and horizon scanning for emerging issues. Although the food and drink industry strives to follow and maintain food standards, guides, and codes of practice and legislation along the food chain, incidents do happen now and again. Notable examples of incidents affecting the food industry in recent years are melamine contamination of milk in China, Sudan I contamination of spices originating from India, and dioxins contamination of guar gum from India. With the increasing globalization and complexity of the food chain, trade of food, food ingredients, and agricultural products around the world are continuing to increase; this also increases chances of food incidents happening along the food supply chain. Some of the contaminations are deliberate, i.e., fraud, and some are accidental. As such, FDF promotes and fosters the proportionate handling of food safety incidents at national and EU level.

FDF's Incident Management System assists the food industry in taking prompt action in response to emerging or potential food safety incidents. At national level, the Food Standards Agency (FSA) leads on incidents in liaison with the EU Rapid Alert System for Food and Feed (RASFF), which is managed by the European Commission. FDF helps its members by ensuring that food safety incidents, when they happen, are handled in a proportionate way, at national and EU level, and FDF coordinates an effective industry response to any such incident. FDF assists by cascading information from FSA, FoodDrinkEurope, and the Commission. FDF also consults members for the necessary information that may be required from industry regarding a particular incident.

Partnership

FDF helps its members operate in an appropriately regulated marketplace to maximize their competitiveness. FDF communicates the industry's values and concerns to Government, regulators, consumers, and the media. FDF also works in partnership with key players in the food chain to ensure that our food is safe and that consumers can have trust in it. This involves working with various UK Government departments including FSA, Department for Environment Food and Rural Affairs (Defra), Department of Business, Innovation and Skills (BIS), Local Government Regulation (Enforcement Authority), and others including the European Commission, European Parliament and EFSA, Codex, and FoodDrinkEurope to improve confidence in the safety of the food supply by seeking proportionate and evidence-based legislation.

Annex

The following Associations are members of the FDF:
ABIM Association of Bakery Ingredient Manufacturers
ACFM Association of Cereal Food Manufacturers
BCA British Coffee Association

INSTITUTIONS INVOLVED IN FOOD SAFETY

International Organization for Standardization (ISO)

M Petró-Turza, formerly Budapest Technical University, Budapest, Hungary

© 2014 Elsevier Inc. All rights reserved.

Glossary

Control measure Action or activity that can be used to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

International standard Standard that is adopted by an international standardizing/standards organization and made available to the public.

International standardization Standardization in which involvement is open to relevant bodies from all countries.

Operational prerequisite program (oPRP) PRP identified by the hazard analysis as essential in order to control the likelihood of introducing food safety hazards and the contamination or proliferation of food safety hazards in the product(s) or in the processing environment.

Prerequisite program (PRP) Basic conditions and activities that are necessary to maintain a hygienic environment throughout the food chain suitable for the production, handling, and provision of safe end products and safe food for human consumption. Note: The PRPs needed depend on the segment of the food chain in which the organization operates and the type of organization. Examples of equivalent terms are: good agricultural practice (GAP), good veterinarian practice (GVP), good manufacturing practice (GMP), good hygienic practice (GHP), good production practice (GPP), good distribution practice (GDP), and good trading practice (GTP).

Process An activity using and managing resources in order to enable the transformation of inputs into outputs. Often the output from one process directly forms the input to the next.

Process approach Application of a system of processes within the organization, together with the identification of interactions and the management of these processes.

Standard Document, established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines, or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context. Note: Standards should be based on the consolidated results of science, technology, and experience, and aimed at the promotion of optimum community benefits.

Standardization Activity of establishing, with regard to actual or potential problems, provisions for common and repeated use, aimed at the achievement of the optimum degree of order in a given context. Note: (1) In particular, the activity consists of the processes of formulating, issuing, and implementing standards; (2) important benefits of standardization are improvement of the suitability of products, processes, and services for their intended purposes, prevention of barriers to trade, and facilitation of technological cooperation.

Standardizing body Body that has recognized activities in standardization.

About International Organization for Standardization in General

The International Organization for Standardization (ISO in each language) is the world's largest developer and publisher of International Standards. ISO was the first established international standardizing organization. Officially, ISO began operating in 1947 with 25 national standards institutes as its members (one per country) and at present, the number of its member bodies is 162. The system of this global scale network of national standards institutes is coordinated by the ISO Central Secretariat, located in Geneva, Switzerland.

ISO has more than 3000 technical bodies, among them approximately 200 active technical committees for developing ISO standards; and more than 50 000 experts for participating in its activity. ISO has more than 17 500 International Standards and other types of normative documents in its current portfolio. The technical work of ISO is regulated by a stringent procedure which was developed and continuously improved since ISO's existence. The overall coordination of this technical work is made by the ISO Technical Management Board. The above mentioned data speak for themselves and show that in the past more than 60 years ISO has kept its leading role in international standardization.

ISO deals with the full spectrum of human activity with the exception of electrical and electronic engineering where International Standards are developed by the International Electrotechnical Commission (IEC) as well as the

telecommunication sector, which is the area of International Telecommunication Union (ITU). ISO work program ranges from standards for traditional activities, such as agriculture and construction, through mechanical engineering, manufacturing, and distribution, to transport, medical devices, information, and communication technologies, and to standards for good management practice and services.

Considering the fact that ISO members are not national governments, but the national bodies most representative of standardization in their respective countries, ISO is a non-governmental organization that forms a bridge between the public and private sectors. Many of its member institutes are part of the governmental structure of their countries, or are mandated by their government. Other ISO members have their roots uniquely in the private sector, having been set up by national partnerships of industry associations. Therefore, ISO enables to reach consensus that meet both the requirements of business and the broader needs of society.

ISO standards are voluntary and it does not enforce their implementation. A certain percentage of ISO standards – mainly those concerned with health, safety, and environment – has been adopted in some countries as part of their regulatory framework, or is referred to in legislation for which it serves as the technical basis. However, such adoptions are sovereign decisions by the regulatory authorities or governments of the countries concerned. ISO itself does not regulate or legislate.

Although ISO standards are voluntary, the fact that they are developed in response to market demand, and are based on consensus among the interested parties, ensures their widespread use.

Food Standardization in International Organization for Standardization

Since the beginning, ISO has dealt with food standardization. The majority (70%) of this type of ISO standards specifies analytical or test method. A part of them is suitable for the determination of physical or sensory properties of foods or for the determination of their chemical compound(s); others are used for the measure the extraneous and/or foreign matter content or microbiological contaminations; again others are suitable for the detection and/or determination of toxic materials or genetically modified organisms in food products; whereas other methods are developed for the detection of food adulteration. The suitability of most of the ISO methods is checked by international ring tests. Therefore, many ISO methods are recognized by the Codex Alimentarius Commission.

The second group of ISO food standards (12%) deals with product specifications, majority of them concerns spices and a few concern cereals. The relatively low proportion of this type of ISO standards can be explained by the fact that most of the product specifications are standardized by the Commodity Codex Committees.

There are ISO food standards dealing with storage conditions and transport (9%), whereas others specify sampling procedures (4%). Among the remainder (5%) the group containing vocabularies or nomenclatures is worth highlighting. These International Standards edited trilingually or bilingually are comprehensively used in the world trade and accepted by other international organizations as well.

Food Safety Standards of International Organization for Standardization

As the food safety is a typical area of the Codex Alimentarius Commission, ISO started to deal with this question rather late, in 2001, because of the huge demand of its member bodies. At that time the hazard analysis and critical control point (HACCP) system was already well known and used around the world. Therefore, it is a fair question why does the need for an ISO standard arise?

The main problem with the HACCP system is its general and brief text, which:

- allows various interpretations resulting in huge differences in the implementation and in the acceptance criteria;
- does not give enough help for the food producers in the practical application of the system; and
- does not contain auditable requirements as this Codex document is only a recommended guideline.

Following the success of the ISO 9000 standard series, certified management systems have increasingly become a general requirement for access to both national and international markets. Therefore, many retailer syndicates have prepared food safety auditing standards e.g., the British Retailer Consortium (BRC), the European Food Safety Inspection Service (EFSIS), or the International Food Standard (IFS) developed by German and French companies on the basis of BRC and EFSIS, and require their suppliers to develop food safety management systems and obtain certification to these standards. Although it is stated that these standards do not differ significantly from each other, certification according to one is accepted only in a few cases by another.

The reasons that led to the development of ISO 22000, the basic food safety standard of ISO, can be summarized as follows:

- increasing number and severity of regulations and controls relating to food safety;
- greater extent of customers' requirements (owing to their increased knowledge of the health effects of nutrition and the risks of food safety);
- HACCP systems in place but with differing requirements and implementation in different countries and for different foodstuffs;
- food producers have to comply with different requirements depending on the country and customer; and
- retailers are certifying and inspecting food producers and have set a variety of specific criteria.

The solution to the above mentioned problems was awaited from ISO, as it was the most recognized international standardization organization, which developed the well-known management system standards (ISO 9001, ISO 14001), new ones (e.g., for information security (ISO/IEC 27001), and for supply-chain security (ISO/PAS 28000)).

International Standard ISO 22000:2005, Food Safety Management Systems – Requirements for Any Organization in the Food Chain

In the development of this new ISO standard, experts from more than 40 countries took part and it was published in September 2005. ISO 22000 constitutes an internationally recognized food safety management system allowing an organization to implement and demonstrate compliance with the relevant documents of Codex, thus simplifying/clarifying the customer/supplier relationship. ISO 22000:

- although arranged differently, includes each principle and application step of the HACCP system, so standardizes its implementation and the basic criteria for its acceptance;
- completes HACCP with more detailed instructions regarding its application;
- contains auditable requirement; and
- Annex B contains cross references between HACCP and ISO 22000 to promote the combination of the two systems.

However, ISO 22000 is much more than the HACCP itself, as it combines the HACCP system with the prerequisite programmes (PRPs) and with the quality management system (QMS).

ISO 22000 categorizes the control measures into the following three groups:

- PRPs,
- operational prerequisite programmes (oPRPs), and
- HACCP plan and its critical control points.

PRPs ensure the basic conditions and activities which each member of the food chain should perform. These help in maintaining a hygienic production, processing, and handling environment. PRPs do not need validation but their effectiveness shall be verified periodically.

Both of the other types of control measures are managing control measures identified by the hazard analysis and both shall be validated and verified.

ISO 22000:2005 introduced the new term, oPRP, to handle those control measures that, for any reason, cannot be included or those that it is not necessary to include in the HACCP plan as critical control points. For example, the critical limit of the given hazard cannot be determined, or can be determined but cannot be validated, or the incidence rate of the given hazard is relatively low. This makes it possible to focus the HACCP plan at the most critical hazards, and keep all others under appropriate control.

Among the management system elements of ISO 22000:2005, the following should be highlighted:

- interactive communication (internal and external);
- structured processes/process approach (help to identify and manage numerous linked activities);
- commitment of top management (management responsibility); and
- keeping the system alive (by verification, updating, review, and continual improvement).

ISO 22000:2005 emphasizes the necessity that personnel whose activities have any impact on food safety shall be aware of the relevance and importance of this fact. Therefore, the organization shall provide training or take other appropriate action to ensure personnel have the necessary competencies and awareness. It is important to mention that within the top management responsibilities, the establishment, implementation and maintenance of procedures to manage potential emergency situations and accidents that can impact food safety are also included.

Documentation forms an integral part of management systems. as it has a key role in the case of certification. ISO 22000:2005 deals with the general rules of the documentation in a separate clause, but every clause which specifies any form of documentation draws the attention to it. The Standard differentiates the following types of documents:

- Documented procedures, methods or statements. This means much more than a simple putting down in writing. This type of document shall be developed, implemented, and updated as a part of the food safety management system. Such document is, for example, the food safety policy, the procedure for handling of potentially unsafe products, or the method of hazard analysis.
- Records. The Standard requires this type of document in many cases as they provide evidence of activities performed. Records can be used to demonstrate the suitable operation and the effectiveness of the food safety management system.
- Other documents, for example product specifications.

The main advantages of ISO 22000:2005 can be summarized as follows:

- gives one set of requirements that can be applied to any organization in the food chain in any country;
- internationally recognized;
- auditable, as it contains requirements;
- flexible, organizations can choose which methods and approaches they use to fulfil the requirements of ISO 22000;
- can be applied independently of other management system standards;
- can easily be integrated with existing other management systems and/or with the HACCP method;
- allows small or less developed organizations to implement an externally developed combination of control measures; and
- supported by other ISO deliverables (ISO/TS 22002-1:2009; ISO/TS 22003:2007; ISO/TS 22004:2005; ISO 22005:2007 and *An easy-to-use checklist for small business*).

According to the data of *The ISO Survey of Certifications – 2008* during 3 years, after the publication of ISO 22000, at least 8206 organizations in 112 countries were independently certified to ISO 22000:2005 and their number continuously increases every year.

International International Technical Specification ISO/TS 22004:2005, Food Safety Management Systems – Guidance on the Application of ISO 22000:2005

This ISO document assists the adoption of ISO 22000:2005. As there was a great demand to publish the guidance close to

the date of publication of ISO 22000, it was decided to prepare it as a Technical Specification (TS). In this case, the ISO procedure is shorter; in addition, the required degree of consensus for publication is lower than in the case of an International Standard. ISO/TS 22004 was published in November 2005.

The guidance deals with those parts of the requirements of ISO 22000:2005 which should be handled with special attention. For example, it provides the small and/or less developed organizations with additional information. ISO/TS 22004 helps to avoid misinterpretation of ISO 22000 and to clarify the meanings of its terms. It provides the users with such explanations which were not possible to include in the standard but promoted its application.

International Technical Specification ISO/TS 22003:2007, Food Safety Management Systems – Requirements for Bodies Providing Audit and Certification of Food Safety Management Systems

Certification of the implemented food safety management system (FSMS) is not a requirement of ISO 22000, but – as mentioned before – it is one means of providing assurance that an organization has implemented a system for the management of food safety in line with its policy. Therefore, the number of organizations in the food chain which have certified FSMS continually increases.

ISO/TS 22003 was developed to promote decreasing quality differences among activities of the certification bodies, and giving certification only to those suppliers whose management commitment to food safety ensures that they will operate an effective FSMS.

ISO/TS 22003 was developed in harmony with ISO/IEC 17021:2006, *Conformity assessment – Requirements for bodies providing audit and certification of management systems*, which contains the general requirements for bodies providing audits and certification of management systems.

ISO/TS 22003 defines specific rules applicable for the audit and certification of a FSMS complying with the requirements given in ISO 22000:2005 (or other sets of specified FSMS requirements), and provides the necessary information and confidence to customers about the way certification of their suppliers has been granted.

International Standard ISO 22005:2007, Traceability in the Feed and Food Chain – General Principles and Basic Requirements for System Design and Implementation

The traceability of food products 'from the farm to the fork' is an important requirement of ISO 22000, therefore ISO developed a separate standard for this purpose. ISO 22005 complements the relevant Codex documents and helps food producers and manufacturers to comply with the relevant statutory requirements by providing an internationally recognized approach for designing a traceability system.

ISO 22005:2007 can be applied by an organization operating at any step in the feed and food chain. It is intended to be flexible enough to allow feed organizations and food organizations to achieve identified objectives.

The traceability system is a technical tool to assist an organization to conform to its defined objectives, and is applicable when necessary to determine the history or location of a product or its relevant components.

ISO 22000, *Food Safety Management Systems – An Easy-To-Use Checklist for Small Business – Are You Ready?*

This handbook is a joint publication of ISO and the International Trade Centre (ITC). It is built up as follows: it quotes a part from ISO 22000, and raises a question relating to the quoted part.

- If the reply is 'Yes', it says 'Go to the next question'.
- If the reply is 'No' it says 'See guidance below.'

This structure makes possible to detect each weak and missing point of an existing FSMS in an effective and rapid way, and at the same time offers suitable solution(s) for their elimination.

International Technical Specification ISO/TS 22002-1:2009, Prerequisite Programs on Food Safety – Part 1: Food Manufacturing

This is the newest member of the ISO 22000 standard family and at the same time the first member of a new series, within this family, planned to develop relevant food sectors. ISO/TS 22002-1 were published on 15 December 2009.

The new technical specification applies to all organizations involved in the manufacturing step of the food chain, regardless of size or complexity. It is not a requirement of ISO 22000 and may be used in parts or in its entirety, depending on the nature of food manufacturing operations.

Availability of International Organization for Standardization Deliverables

The hard copy of each member of ISO 22000 standard family can be ordered from ISO national member institutes, and from the ISO Store at the Central Secretariat. The whole ISO 22000 standard family is also available on a CD format (bilingual, English and French).

Glossary

Acceptable daily intake (ADI) Estimate of the amount of a substance in food or drinking water, expressed on a body weight basis, which can be ingested daily of a lifetime by humans without appreciable health risk.

As low as reasonably achievable (ALARA) A risk management approach that aims to keep exposure to a compound at the lowest level that is realistically achievable.

Exposure assessment Assessment of the amount of a particular chemical agent that reaches the target population, organism, organ, tissues, or cells, usually expressed in numerical terms of substance concentration, duration, and frequency.

Genotoxic carcinogen A compound that causes cancer by binding to DNA.

Harmonization Agreement on general principles of food safety standards as well as technical aspects, for example, methodologies, information requirements, or criteria for determining unacceptable risks, by groups representing national and international governmental bodies and others.

Hazard analysis critical control point (HACCP) A system that identifies, evaluates, and controls hazards that are significant for food safety.

Margin of exposure (MOE) The ratio between a reference concentration of a compound (often taken from an animal study and corresponding to the dose that causes a low but measurable response in animals) and the estimated dietary intake in humans.

Probabilistic modeling Use of statistical tools to estimate the likelihood of an event occurring based on historical data.

Risk analysis A discipline comprised of three components: risk assessment, risk management, and risk communication, that is used to provide food safety regulators with the information and evidence they need for effective decision-making to improve public health.

Risk assessment A process intended to calculate or estimate the risk to a given target organism, system, or (sub)population, including the identification of attendant uncertainties, following exposure to a particular agent, taking into account the inherent characteristics of the agent of concern as well as the characteristics of the specific target system.

Purpose and Structure of International Life Sciences Institute

The International Life Sciences Institute (ILSI) is a nonprofit, worldwide organization established in 1978 to advance scientific understanding of nutrition, food safety, toxicology, risk assessment, and the environment. Working through its 15 branches around the world and Research Foundation, ILSI brings together scientists from academia, industry, government, and the public sector for a balanced approach to solving problems of common interest for the health and well-being of the public. Figure 1 provides an organizational chart for ILSI.

The ILSI branches are membership organizations. Food processors, ingredient manufacturers, pharmaceutical manufacturers, agrochemical companies, and others are members of one or more branches. The ILSI Research Foundation does not have members.

All ILSI entities use a tripartite model involving scientists from academia, government, and industry to address scientific questions. ILSI entities address topics of interest through committees, task forces, or working groups made up of experts in the topic. All of ILSI's work becomes public knowledge through publications and meetings.

Each ILSI entity is governed by a group of nonindustry and industry scientists. The ILSI Board of Trustees, a 31-member international body, sets policy for the whole organization. All of the governing bodies are at least 50% nonindustry.

The branches work with their national and regional governmental bodies to ensure that these groups have access to the latest scientific information. For example, ILSI Europe aims to provide scientific information that can support the work of organizations like the European Food Safety Authority (EFSA), the Health and Consumer Protection Directorate-General of the

 doi:10.1016/B978-0-12-378612-8.00394-2

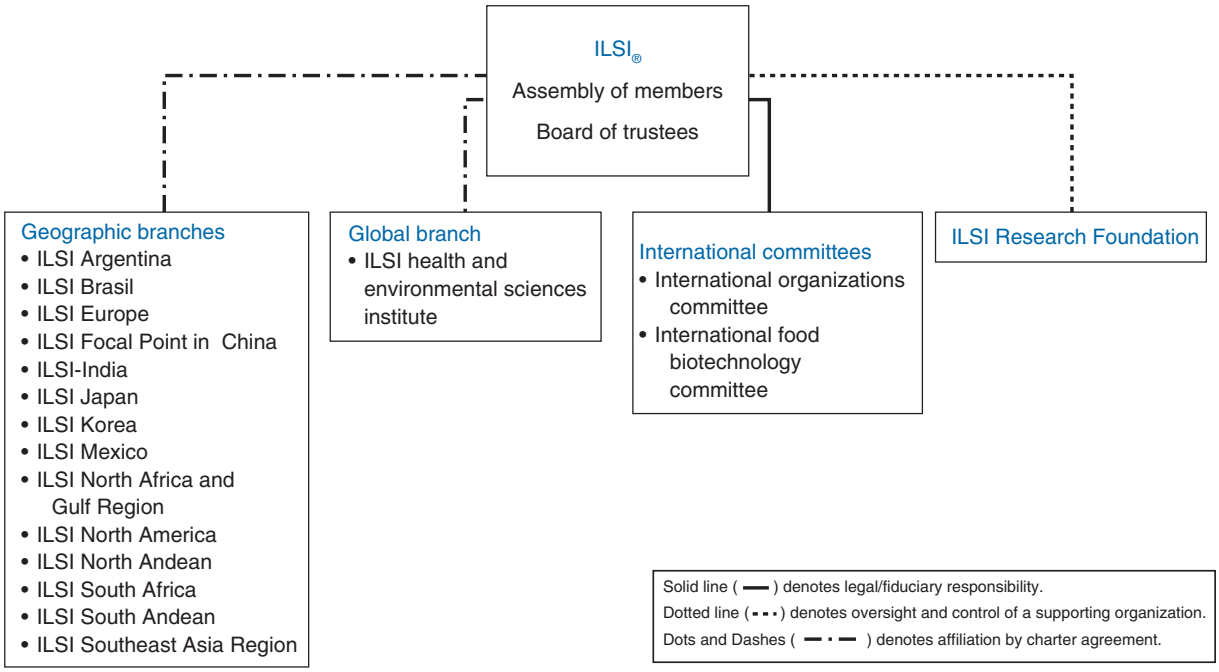

Figure 1 Organizational chart for the International Life Sciences Institute (ILSI). Reproduced from www.ilsi.org, with permission from International Life Sciences Institute.

European Commission (DG SANCO), and the national authorities in Europe. ILSI Focal Point in China provides current scientific information to the Ministry of Health on hot topics in food safety as a reference for their risk-management decisions. ILSI North America has cooperative programs with the US Food and Drug Administration, Centers for Disease Control and Prevention, Department of Agriculture, and other federal food safety agencies. ILSI Southeast Asia (SEA) Region has a long-standing working relationship with the ASEAN Health Authority on capacity building training and harmonization of safety standards. ILSI is also recognized by the World Health Organization (WHO) and the Food and Agriculture Organization of the United Nations (FAO) as a nongovernmental organization.

International Life Sciences Institute's Role in Microbial Safety

ILSI Europe has published an extensive series of monographs on different foodborne pathogens, including their occurrence, toxicity, and mitigation options; the latest edition concerns food-related viruses. Other activities include guidelines on food safety objectives and a monograph on hazard analysis critical control point (HACCP), which is currently in its third edition; the first edition was translated into seven languages.

ILSI North America Committee on Food Microbiology is committed to providing sound science to improve understanding and control of microbial food safety hazards to enable scientifically-informed decision-making. For example, 4 years before the 1993 *Escherichia coli* outbreak in Washington state, the committee recognized the potential public health threat of this emerging pathogen and began supporting research that provided critical data on the prevalence of *E. coli* 015:H7 in retail foods and the development of detection methods still being used today. Data from these research projects were critical to the rapid recognition and control of the 1993 outbreak.

In addition, ILSI North America maintains a reference strain collection, including *Listeria monocytogenes* and *Cronobacter* (*Enterobacter*) *sakazakii*, for distribution to researchers worldwide. Current research priorities include *Salmonella* in low-moisture foods, control of sporeforming bacteria, and foodborne viruses.

International Life Sciences Institute's Role in Chemical Food Safety

Increasing sensitivity of analytical equipment and its concomitant decrease in detection levels result in the identification of low amounts of undesired chemicals in food and beverages, which requires assessment of their risks. Using the Paracelsus theorem which defines chemical substance as a health concern based largely on its dose, ILSI has helped develop the threshold of toxicological concern (TTC) concept, that provides a rationale and decision tree to indicate whether a chemical of known structure and exposure is a potential health concern, or not. The TTC concept is being applied for flavorings and its application for other purposes, such as cosmetic products, is being investigated. This is one example of how ILSI has contributed to scientifically based risk assessment methodologies.

Genotoxic carcinogens, which are chemicals that cause cancer by directly binding to the DNA, are exceptions to this approach. Although from a cell and tissue biology point of view it could be argued that thresholds might exist (e.g., due to DNA repair mechanisms and cell turnover), risk assessment has traditionally assumed the absence of a threshold for these compounds. Thus, it is assumed that any exposure above zero to genotoxic carcinogens could be a concern. Therefore, levels of these compounds must be kept as low as reasonably achievable (ALARA) in food. This ALARA approach, however, does not provide guidance to assess levels of concern and priority setting. Together with WHO and EFSA, ILSI has investigated the use of the margin of exposure (MOE) concept, which determines the ratio between experimentally derived toxicity data and exposure data in humans and can be used for prioritization of risk management actions.

As a result of the data from the ILSI North America Committee on saccharin's 13-year mechanistic research program, the International Agency for Research on Cancer (IARC) downclassified it in a precedent-setting process in its monograph evaluation series in 1999, the National Toxicology Program removed saccharin from its Congressionally-Mandated List of Carcinogens (also a precedent setting event) in 2000, the Joint FAO/WHO Expert Committee on Food Additives (JECFA) increased its temporary acceptable daily intake (ADI) level, and the Canadian Government accepted a reasonable no-effect level for saccharin. Even more importantly, these data have been applied by the US Environmental Protection Agency in developing new guidelines for risk assessment that include the concept of mode of action as a key determinant of risk.

Recently, the ILSI Research Foundation has been exploring how the dose–response relationship at very low doses can be an approach in quantitative risk assessment. The concept of a threshold for adverse effects is fundamental in regulatory toxicology, underlying basic values such as ADI and tolerable daily intake. Analyzing the fundamental biological processes underlying human health effects for chemicals, allergens, pathogenic organisms, and nutrients led to a cross-disciplinary mode-of-action based analytical approach – Key Events Dose–Response Framework – that systematically examines important, required biological and chemical events along the pathway between exposure/intake and the ultimate effect of concern. The approach is described in a series of five papers published in the September 2009 issue of *Critical Reviews in Food Science and Nutrition*.

This new work provides an evidence-based approach and powerful new tool for using our growing understanding of fundamental biology and mechanistic data to reduce reliance on default assumptions, to quantify variability, and to better characterize biological thresholds.

Allergen Safety

Like many other allergens, food allergens are harmless to most people but a significant health risk to a minority, inducing a wide range of effects from mild irritation of the oral mucosa and the skin to anaphylactic shock and death. ILSI-funded research has used clinical data on eliciting allergen doses in combination with the population distribution of allergic individuals for probabilistic modeling of allergen risks. ILSI North America has reviewed a unique set of clinical challenge data for peanut allergens. A dose–response curve for risk characterization of the sensitized population was developed to validate the concept of a threshold level.

Food Safety Training and Education Activities

ILSI Europe organized a continuing education course on TTC at the meeting of European toxicological societies (Eurotox) in 2009. Training programs in collaboration with FAO and WHO to encourage the use of risk assessment in food safety control have been and are being organized in China, Southeast Asia, and Latin America. These workshops address topics such as setting of food safety standards, safety, and exposure assessment of food additives, microbial, mycotoxins, and other contaminants in the food chain. ILSI North America organized and sponsored 52 symposia, technical sessions, and workshops (1993–2009) on emerging global issues in food microbiology through its symposium series with the International Association for Food Protection.

Harmonization across Countries/Regions

Recognizing the difficulty that many countries in Central, Northern, and Southern Eastern Europe experience to harmonize their nutrition and food safety approaches with that of Western Europe, ILSI Europe provides travel grants for scientists from these countries to attend selected scientific events and courses in Western Europe.

In 2001, ILSI SEA Region collaborated with FAO–UN and WHO to establish an ASEAN (comprising 10 countries of the Association of Southeast Asian Nations) Working Group on Food Safety Standards Harmonization. Since then, a series of annual workshops have been conducted to promote scientific understanding and facilitate consensus on the application and implementation of risk analysis, exposure assessment, and harmonization of food safety standards in the region in line with Codex general standard for food additives (GSFA). A database was developed for the working group and the countries to tract the harmonization effort.

ILSI branches in China, Japan, and Korea exchange information on food safety regulations and standards, with the goal of facilitating harmonization these regulations and standards for Asian countries.

Summary Statement of What International Life Sciences Institute as an Nongovernmental Organization has been Able to Accomplish

For more than three decades, ILSI has advocated the use of science in public health decision-making. ILSI has established risk assessment and benefit assessment methodologies for evaluating diet, pharmaceuticals, and chemicals in relation to human and environmental health. Its unique mode of operation that brings together scientists from academia,

government, and industry to address food safety issues has proven effective in generating valuable scientific knowledge applicable for improving human health. The ILSI approach will continue to be relevant in the future for food safety decision-making.

For more information about ILSI and its scientific contributions, please visit the ILSI website (www.ilsi.org). The site has an advanced search function that allows the visitor to retrieve scientific publications sponsored by ILSI. The Scientific Issues section of the website has a subject-matter specific interactive risk assessment diagram that provides information on all ongoing activities in this area.

INSTITUTIONS INVOLVED IN FOOD SAFETY

FoodDrinkEurope

B Kettlitz, FoodDrinkEurope, Brussels, Belgium

© 2014 Elsevier Inc. All rights reserved.

Glossary

Codex Alimentarius (Latin for 'food code' or 'food book') is a collection of internationally recognized standards, codes of practice, guidelines and other recommendations relating to foods, food production, and food safety.

ETP European Technology Platform – A European network bringing together researchers, industry and, other relevant stakeholders in a particular technological field in order to foster European research and development in the concerned area.

European Rapid Alert System (RASFF) European system aiming at providing control authorities with an effective tool for the exchange of information on measures taken to ensure food safety.

FACET Flavors, Additives and Contact materials Exposure Task – European 7th Framework Project.

SMEs Small and medium enterprises – not having more than 250 employees.

Introduction to FoodDrinkEurope (formerly CIAA)

FoodDrinkEurope is the Umbrella Organization of the European Food and Drink Industry. FoodDrinkEurope membership is comprised of 26 national federations, including 3 observers; 26 EU sector associations; 18 major food and drink companies, of which the majority are Small and Medium Sized Enterprises (see Tables 1 and 2).

17 Major Companies

Agrokor, Cargill, Coca-Cola, Danone, Ferrero, General Mills, Heineken, Heinz, Kellogg, Mondelez (formerly Kraft Foods), Mars, Nestlé, PepsiCo, Südzucker, Tate & Lyle, Ülker, and Unilever.

The EU food and drink industry serves almost 500 million consumers with a wide variety of safe and high quality products.

The mission of an industry association is to represent the interests of its members. For FoodDrinkEurope, this means representing their interests at both the European and international institution levels.

FoodDrinkEurope contributes to the development of a legislative and economic framework for the food and drink industry, addressing competitiveness, food quality, and safety, consumer information and respect for the environment.

Access to safe food is an imperative for health, social, and economic reasons.

Although food in Europe is more varied and safer than ever before and the consumer is better informed and more aware of food related issues, consumers still do not appear to have sufficient trust in the supply chain.

FoodDrinkEurope Priorities

One of the key priorities of FoodDrinkEurope and its membership is therefore to increase consumer confidence in the food and drink industry.

To respond to this priority, FoodDrinkEurope is working together with more than 500 industry experts to address challenges related to food safety in the areas of process contaminants, contaminants, ingredients, food contact materials, in addition to novel foods, emerging technologies and others.

Very recently, a nanotechnology expert group was created by FoodDrinkEurope. This is a group in which both expert knowledge and communication skills are necessary to contribute to the public dialogs which are key to establishing trust in the food and drink industry.

Holistic Approach

The food and drink industry has developed an integrated and holistic approach to food safety. Safety is not guaranteed by 'safe' product manufacture – the total chain must be taken into account (see figure below):

- Dietetic products
- Fruit & vegetable juices
- Intermediate producers for bakery & confectionery
- Pasta
- Processed meat
- Sauce & condiments
- Soft drinks
- Spices
- Sugar
- Yeast

Work with Food Chain Partners

As not all food chain partners are members of FoodDrinkEurope, a Food Safety Platform, involving consumer representatives, farmers, feed producers, traders, restaurants and retailers was created at the initiative of the FoodDrinkEurope in 2005. The Platform members strive to exchange information related to the safety of the food chain, emerging issues included.

Emerging Issues

FoodDrinkEurope aims to solve emerging issues. These may be raised by individual members, provided that these are relevant for the entire food industry. The Association also analyses the European RASFFs (Rapid Alerts which aim to provide control authorities with an effective tool for the exchange of information on measures taken to ensure food safety.) which are published on the European Commission website in this respect.

FoodDrinkEurope has put in place an 'Incident Management System', which allows the organization to serve its members immediately, or within 48 h at the latest, by means of establishing appropriate:

- Information networks,
- Links with risk managers, and
- Risk assessors

to address the issue as necessary.

The ultimate aim of the above is the protection of consumer health and the prevention of unnecessary 'scare stories', which naturally have the potential to undermine consumer confidence in the food and drink industry.

The establishment of such a system has been proven to be successful and is appreciated by its members, due to its harmonized approach towards addressing issues and seeking solutions.

Example: Dealing with Emerging Issues

FoodDrinkEurope, together with its members, is also developing tools, such as guidelines for the proper interpretation of new legislation. Examples of these are the 'GMO Guidelines' and the 'Acrylamide Toolbox', the latter of which aims to help producers to find tools to mitigate acrylamide. The Toolbox was last updated in 2011.

Given that the majority of FoodDrinkEurope members are small and medium sized enterprises (SMEs), it is important that relevant information is addressed directly to such enterprises in a clear language and in translated versions. FoodDrinkEurope has for example, provided its members with 'acrylamide pamphlets' which offer 'tools to try' for five different sectors, namely:

- Bread products,
- French fries,
- Potato crisps,
- Biscuits, and
- Breakfast cereals.

These pamphlets have been translated into 22 languages and both the Acrylamide Toolbox and the pamphlets have been recognized by risk managers. Links to the papers are available on the European Commission website.

Joint Industry Groups

Where necessary, FoodDrinkEurope also joins coalitions to address particular issues of temporary concern and seeks the expertise of other industry partners in 'joint industry groups' which are particularly relevant in areas related to the packaging and ink industry.

The role of an industry association is also of course to join research projects where these are relevant to its general work. For FoodDrinkEurope, such a research project concerns refinements of exposure assessments for flavorings, additives and food contact materials, (FACET stands for Flavors, Additives and Contact materials Exposure Task) for instance.

Research and Innovation

Project involvement is of course insufficient to address elements to further improve food safety. The European Technology Platform 'Food for Life' was therefore created in 2005 under the auspices of FoodDrinkEurope. This Platform seeks to deliver innovative, novel, and improved food products for and to national, regional, and global markets in line with consumer needs and expectations.

This Platform offers the unique opportunity to merge academic knowledge with industry needs and, by doing so, to improve the integration of research investments and thereby facilitate competitiveness and wealth creation. Innovation and effective technology transfer will stimulate economic growth.

Stakeholders have been involved in the shaping of a Strategic Research Agenda which also addresses:

- The building of consumer trust in the food chain,
- The support of sustainable and ethical production, and
- The improvement of health, wellbeing, and longevity.

Regulation and Self-Regulation

It is the role of an industry association to react to questions which are integrated within regulatory processes and to proactively address questions which do not yet feature on the radar-screen of policymakers. An industry association will offer assistance in both developing self-regulatory measures or, if necessary, intervene in regulatory processes in order to address industry-specific issues.

Involvement in Global Tasks

In addition to acting at European levels, it is necessary to reach out to global players and therefore to actively contribute to developments within Codex Alimentarius.

In this respect, FoodDrinkEurope also addresses trade-related questions and avails of its networks in order to solve eventual issues either internationally, where new legislation has been introduced, or at European level, where the internal market is at risk of being disturbed due to the incoherent implementation of European legislation.

INSTITUTIONS INVOLVED IN FOOD SAFETY

International Food Information Council (IFIC) and Other Food Information Organizations

DB Schmidt and AP Benson, International Food Information Council and Foundation, Washington, DC, USA

© 2014 Elsevier Inc. All rights reserved.

Glossary

Dietary Guidelines Alliance A private-public partnership among leading food, nutrition and health organizations and societies, food industry organizations and the government, dedicated to providing consumers with science-based, practical advice on how to apply the Dietary Guidelines for Americans to their lives.

Food processor A person, facility, company or machine that transforms raw ingredients into food, or that transforms food into other forms for consumption.

Food safety Assurance that food will not cause harm to the consumer when it is prepared and eaten according to its intended use.

Nutrition The science of how the body uses food.

Risk communication The interactive exchange of information and opinions throughout the risk analysis process concerning risk, risk-related factors and risk perceptions, among risk assessors, risk managers, consumers, industry, the academic community and other interested parties, including the explanation of risk assessment findings and the basis of risk management decisions.

Introduction

Founded in 1985, the International Food Information Council (IFIC) is a nonprofit organization, whose mission is to effectively communicate science-based information about food safety, nutrition and health to health and nutrition professionals, educators, government officials, journalists and others providing information to consumers. Based in Washington, DC, IFIC is supported primarily by the broad-based food, beverage and agricultural industries. The organization does not represent any product or company, nor does it lobby for legislative or regulatory action.

The IFIC Foundation was incorporated as a public education foundation in 1991 and serves as the educational arm of IFIC. The IFIC Foundation is guided by a Board of Trustees, the majority of whom represent public institutions such as universities, governmental bodies, and public foundations.

IFIC participates in, and helps to facilitate cooperation and exchange between the members of an informal network of independent food information organizations in Asia, Europe, New Zealand and South Africa and South America.

Why Do we Need Food Information Organizations?

The food supply chain relies on a complex system involving farmers, growers, ingredient suppliers, food processors, food distributors, food importers, food regulators, and food retailers in many different world regions.

Modern media outlets can transmit news about food safety developments or crises across the world in microseconds. So a crisis in one part of the world has the potential to alarm consumers across the globe.

Technological advances and other new practices in sanitation and detection methods can help reduce potential food safety risks. Yet the task of providing the public with accurate and understandable information to explain these developments remains a daunting one, and it is here that food information organizations play a critically important role.

If the food chain does not function with effective communications among key parties, a potentially disastrous food incident can still result. That is why we need food information organizations, and why their collective reach needs to be local, regional and global.

The Fundamental Underpinnings of Food Safety

Though food safety challenges can be complex, it could be argued that just three key elements constitute the fundamental underpinnings of food safety.

First and foremost is sound science that includes good agricultural and food safety practices, and which has to be a prerequisite. But where science is complex and where the food chain is long, an appropriate level of oversight is clearly necessary.

So the second key element has to be an appropriate level of food safety regulation, together with an adequate measure of regulatory oversight and inspection.

But what happens if key information regarding even basic food hygiene doesn't reach a grower in a developing country, or a food server in a Western quick service outlet? This is the

third key element that underpins food safety, namely effective communications to and from key stakeholders along the length of the food chain.

The IFIC's Food Safety Role

IFIC and its Foundation aim to bridge the gap between science and communications by collecting and disseminating scientific information in a manner consumers can understand, and by working with an extensive roster of experts to help translate research into understandable and useful information and advice for stakeholders, journalists and other opinion leaders and consumers.

In times of a food safety emergency, IFIC plays a key role, briefing the media and informing the public, partner organizations and key stakeholders about important developments that could impact public health and well-being. IFIC serves as a news media resource, and can refer journalists to over 350 independent, credentialed experts on a variety of nutrition and food safety topics.

The Need for International Cooperation

Given the international nature of today's food supply, IFIC recognizes that it is important to disseminate and exchange key information and advice on nutrition and food safety globally.

IFIC participates in and helps to facilitate cooperation and exchange between an informal, global network of independent food information organizations.

Working independently but exchanging knowledge and insight internationally, these organizations all share a common goal of bringing science-based insight and understanding to regional and international food safety and nutrition issues.

Informed decision making by policy makers, stakeholders and consumers helps to maximize levels of food safety, and helps to minimize the consequences of any food safety incident. Informed decision also helps to avoid misinformation and confusion, reducing the risk and the consequences of unfounded public alarm.

Clear and consistent communications – that engage health and nutrition professionals, educators, government officials, opinion leaders and the media – help build broad-based understanding that serves the shared interests of stakeholders and consumers most effectively.

IFIC Collaborations

IFIC has established partnership programs with a wide range of credible professional organizations, government agencies and academic institutions, including a long-standing relationship with the U.S. Department of Agriculture and Food and Drug Administration as part of the Dietary Guidelines Alliance and the *MyPyramid* Food Guidance system, as well as food safety education materials for consumers.

IFIC hosts or participates in major national and international professional conferences and meetings including programs organized by the World Health Organization, the Food and Agriculture Organization of the United Nations, the International Congress of Nutrition and other key international authorities and expert groups.

The IFIC Foundation also participates in a recently formed International Center of Excellence in Food Risk Communication (http://foodriskcommunications.org). The Center is collaborative initiative among global food and health organizations, government agencies, academic institutions, and expert nonprofit communication organizations, founded on the belief that it is important to have a collective international resource of food-specific risk communication materials which are dedicated to enabling informed decision-making to promote global health.

IFIC has helped to develop a number of key training resources for food safety risk communication including *Improving Public Understanding: Guidelines for Communicating Emerging Science on Nutrition, Food Safety and Health* (based on an advisory group convened with Harvard School of Public Health), *A Practical Guide to Risk Communication* (a Continuing Professional Education Module self-study unit developed with the University of Maryland) and *Risk Communicator Training for Food Defense Preparedness, Response and Recovery* (developed through the National Center for Food Protection and Defense).

These and other key resources can be accessed on the IFIC Foundation Web site at www.FoodInsight.org. The IFIC Foundation uses the latest technology, communication tools and interactive formats, including a Blog, a *FoodInsightTV* channel, Web casts, educational videos, a Facebook page and a Twitter account. The popular monthly *Food Insight* newsletter (available online only) helps stakeholders stay on top of the latest research and trends.

IFIC and its Foundation commission primary research on public opinion about food safety and nutrition and shares the results with stakeholders and the public. The *Food & Health Survey* provides information about how Americans connect the food they eat with their health. Recent surveys have explored topics such as food safety, overall diet, physical activity, weight management, dietary fats, functional foods, caffeine, and food allergies.

IFIC (www.ific.us) and the IFIC Foundation (www.foodinsight.org) are headquartered at: 1100 Connecticut Ave, NW, Suite 430; Washington, DC 20036. Tel.: +1 202/296-6540; Fax: +1 202/296-6547.

How Do International Food Information Organizations Cooperate?

The international food information organizations operate autonomously and independently yet they share insight, consumer attitudinal research and best practices in risk communication globally.

The food information organizations realize that, although knowledge and expertise should be shared internationally, communications need to be handled regionally and locally to have the desired impact and effectiveness.

Effective communication organizations need to have the linguistic capabilities to reach stakeholders and consumers in

their regions. But beyond language there are the key questions of credibility and impact.

Who are the trusted authorities in the region? What are the most effective communication channels? What are the regional sensitivities regarding particular food and nutrition issues, and what sort of messaging is needed to communicate accurately, clearly and effectively?

The food information organizations determine locally who have detailed first-hand knowledge of the issues, communications challenges and cultural sensitivities in the region.

So Who are Other Key International Food Information Organizations?

The Asian Food Information Centre (AFIC) was founded in 1998 and registered in Singapore. The AFIC team of scientific, health and communications professionals works in close collaboration with the academic and scientific communities in the region.

AFIC produces and distributes a wide range of science-based, consumer-friendly information on food safety and nutrition through workshops, interviews, articles, information leaflets and multilanguage website. AFIC publications include the *Food Facts Asia* newsletter and an *AFICNews* E-bulletin.

AFIC also conducts research into consumer behavior, perceptions and expectations.

Mailing Address: Shaw Centre #23-14, 1 Scott's Road, 228208 Singapore. Tel.: +(65) 6235 3854; Fax: +(65) 6235 7459. E-mail: info@afic.org. Website: www.afic.org.

The Council for Food Safety and Nutrition Information (CISAN) was newly formed in 2010 and has its operational base in Buenos Aires, Argentina. Its mission is to share science-based information on food safety, nutrition and health with health professionals, communicators and consumers, so as to enhance understanding and enable informed food choices. CISAN is operated as a collaborative initiative between three prestigious institutions, namely the Argentine Nutrition Foundation, the International Life Science Institute of Argentina, and the Argentine Council for Information on Biotechnology.

CISAN's website can be accessed at http://cisan.org.ar. To contact CISAN, please send an E-mail to info@cisan.org.ar.

The European Food Information Council (EUFIC) is a nonprofit organization, which provides science-based information on food safety and quality, and health and nutrition to the media, health and nutrition professionals, educators and opinion leaders, in a way that consumers can understand.

EUFIC's mission is to enhance the public's understanding of such issues and to raise consumers' awareness of the active role they play in safe food handling and choosing a well-balanced and healthy diet.

Information that EUFIC publishes has been subject to a review process by members of its Scientific Advisory Board (SAB). Given the broad range of subjects addressed in EUFIC's popular newsletter, *Food Today*, a dedicated Editorial Board for this publication provides additional insights and feedback.

With its main offices located in Brussels (Belgium), EUFIC counts on and liaises with a European network to enhance the impact and outreach of its communication instruments and programs in other countries.

EUFIC actively participates in European initiatives together with the European Commission Directorate Generals for Research, and for Health and Consumers, where it contributes to a number of projects as dissemination partner.

EUFIC's website is www.eufic.org. To contact EUFIC, please send an E-mail to eufic@eufic.org.

The Food Advisory Consumer Service (FACS) is South Africa's first independent food and nutrition consumer service. First launched in January 1995, its purpose is to provide consumers with information on food and nutrition issues which is both relevant and scientifically correct.

FACS operates a telephone information service, supported by a network of technical experts in food, nutrition and related subjects.

FACS is run by a committee representing SAAFoST, the South African National Consumer Union (SANCU), the Association of Dietetics (ADSA), the Directorate of Food Control of the Department of Health, and professional representatives of other consumer-friendly organizations. FACS has access to information from similar bodies overseas. However, it is committed to offering a comprehensive service in line with South Africa's unique situation. This would include risk groups such as infants, sufferers of malnutrition and others.

FACS has good contact with the media and is a member of the Food Legislation Advisory Group, the body concerned with food legislation in South Africa, and with Codex Alimentarius, the Joint FAO/WHO Food Standards Program.

Website: http://www.foodfacts.org.za/. Postal Address: PO Box 27852, Sunnyside, 0132. Customer Hotline: 012 428 7122 (hotline available from 08:00 to 12:00); Fax: 086 672 8585.

The New Zealand Nutrition Foundation (NZNF) is a professional, nonprofit organization whose members believe all New Zealanders should have access to accurate information to enable them to make informed choices about food and the effect it has on their health. NZNF helps New Zealanders make these choices by providing a balanced viewpoint on important issues around food, nutrition and health.

Founded in 1980, the NZNF was established as a charitable not-for-profit trust, with individual and corporate membership to support its activities. The Foundation's membership includes those working in health, nutrition, education and the food industry, providing the opportunity to co-ordinate and support work between professional groups, food producers and marketers and government agencies.

INSTITUTIONS INVOLVED IN FOOD SAFETY

International Union of Food Science and Technology (IUFoST)

A Mortimer, ABC Blending, Bayswater, VIC, Australia
K Buckle, The University of New South Wales, Sydney, NSW, Australia

© 2014 Elsevier Inc. All rights reserved.

Glossary

Adhering body A representative body of the International Union of Food Science and Technology (IUFoST) from each country, or defined geographical area(s), that has an independent science budget.

What is IUFoST?

The International Union of Food Science and Technology (IUFoST) is the sole global, country member organization that represents more than 200 000 food scientists and technologists (Buckle and Meech, 2003). It is a voluntary, nonprofit association that links the world's food scientists and technologists through international cooperation and exchange of scientific and technical information. IUFoST is a full member of the International Council for Science and works closely with several United Nations agencies such as the Food and Agriculture Organization (FAO), World Health Organization (WHO), Codex Alimentarius Commission, and International Atomic Energy Agency as well as other international organizations to transfer technical knowledge and strategies for basic and applied research for the developing world.

IUFoST sponsors international and regional congresses, conferences, symposia, and workshops that are held in member countries, and promotes a safe, secure, and wholesome food supply for the world's increasing population.

Origin

The profession of food science and technology is generally agreed to have emerged in the USA in the early decades of the twentieth century. The subsequent formation of the (US) Institute of Food Technologists (IFT) in 1939 and its successful development and expansion led to the formation of similar associations in many countries during the following 20 years. In 1960, the UK government and several British scientific societies hosted a conference in London to commemorate the centenary of the UK Food and Drugs Act (1860) and the hundred and fiftieth anniversary of the publication in 1810 of Nicolas Appert's book (*L'art de Conserver, Pendant Plusieurs Années, Toutes les Substances Animals et Végétales*) on heat preservation of foods in sealed containers. In the preceding week, the Glasgow Royal College of Science and Technology (later to become the University of Strathclyde) convened a symposium on recent advances in food science, and discussions between several eminent UK and US food scientists raised the concept of an international food society. The formation of an international organization was discussed at the First International Congress of Food Science and Technology held in London in 1962 and organized by the Food Group of the (UK) Society of Chemical Industry.

Following the Congress, an ad hoc International Committee of Food Science and Technology (ICFoST) was formed with eminent scientists from several countries to promote and foster international cooperation in food science and technology. The Second International Congress of Food Science and Technology was held in Warsaw, Poland, in 1966. By the time the Third International Congress of Food Science and Technology (Science of Survival: SOS/70) was held in Washington, DC, USA, in 1970, ICFoST had developed a constitution and working arrangements for an international union (IUFoST), which was inaugurated on 14 August 1970.

Membership

The founding membership consisted of 20 food science and technology organizations from 20 nations; current membership includes organizations from 69 countries (http://www.iufost.org/adhering-bodies). Under the constitution, membership is open to all countries and consists of one representative body, termed as an 'Adhering Body,' from each country. The term 'country' is understood to be a defined geographical area, or areas, that has an independent science budget. Only one Adhering Body can represent each such area. Adhering Bodies can be a national food science and/or technology group, society or institute composed of food scientists, and food technologists or other professionals engaged in food science and technology; an academy of sciences, national research council, or similar organization of scientists; an intersociety committee or similar group representing two or more

Table 1 IUFoST World Congresses of Food Science and Technology

Congress no.	*Year*	*Location*
1	1962	London, UK
2	1966	Warsaw, Poland
3	1970	Washington, DC, USA
4	1974	Madrid, Spain
5	1978	Kyoto, Japan
6	1983	Dublin, Ireland
7	1987	Singapore
8	1991	Toronto, Canada
9	1995	Budapest, Hungary
10	1999	Sydney, Australia
11	2001	Seoul, South Korea
12	2003	Chicago, IL, USA
13	2006	Nantes, France
14	2008	Shanghai, PR China
15	2010	Cape Town, South Africa
16	2012	Iguazu Falls, Brazil

societies composed of food scientists and technologists; or a national committee representing food scientists, engineers, and technologists working in the field.

Mission and Activities

The IUFoST mission is to promote international cooperation and information exchange, to provide education and training to food scientists and technologists around the world, and to promote professionalism and professional organization among food scientists and technologists.

IUFoST conducts a wide range of activities in order to achieve its objectives of fostering international cooperation and exchange of knowledge and ideas. They are conducted in conjunction with the Adhering Bodies and regional groupings, or with other local, national, and international organizations.

Congresses

From 1962 to 1999, World Congresses of Food Science and Technology were conducted about every 4 years, in conjunction with the Adhering Body of that country. From 2001, they have been held biennially, commencing with the 11th World Congress of Food Science and Technology in Seoul, South Korea (Table 1).

Regional Meetings

IUFoST has been associated with more than 200 conferences, symposia, seminars, workshops, training programs, and short courses since its inception in 1970, covering diverse topics in areas such as food science, technology, engineering, and microbiology; human nutrition; national and international food law; food toxicology; product development; food security; and, in more recent years, especially food safety.

IUFoST Involvement in Food Safety Activities

Committees and Panels

The first formal committee with a brief on some aspects of food safety was set up in 1980 as the Committee on Food Composition and Food Safety, initially chaired by Dr Richard Hall (USA), who was later to become the fourth IUFoST President (1983–87). One of the first food safety activities was the First Asian Conference on Food Safety: The challenges of the 1990s, held in Kuala Lumpur, Malaysia on 2–7 September 1990, organized by the Malaysian Institute of Food Technology, International Life Sciences Institute (ILSI), Malaysian Agricultural Research and Development Institute, Malaysian Ministry of Health, and the WHO in conjunction with the Federation of Institutes of Food Science and Technology in Association of South-East Asian Nations (ASEAN) (FIFSTA)…, FAO, ILSI Australia, and IUFoST.

In 2009, IUFoST established a Food Safety Committee in response to the expressed needs of its Adhering Bodies worldwide, with the objective to advise and act within IUFoST, via the Scientific Council, on emerging and current issues in areas of food safety from the national and regional perspective, in conjunction with IUFoST Expert Panels. The Food Safety Committee consists of representatives from Adhering Bodies, including Regional Groups, together with Academy Fellows, and others. The Expert Panel members are drawn from Fellows of the International Academy of Food Science and Technology (IAFoST), from the Union's worldwide members, and from IUFoST's global partners in Europe, FAO, WHO, ILSI, International Commission on Microbiological Specifications for Foods (ICMSF), and others. The Food Safety Expert Panel advises on aspects of chemical and microbiological food safety, allergies, zoonoses, traceability and food safety policy, and regulation and reports to the Scientific Council.

Declarations on Food Security

IUFoST has long recognized the role of food science and technology in improving food security, including food safety, in the developing world, especially in Africa, Southeast Asia, and Eastern Europe. The Victoria Falls Declaration, supporting the plight of consumers in the developing world, especially in sub-Saharan Africa, was approved by delegates at the IUFoST/Eastern, Central and Southern African Association of Food Science and Technology (ECSAAFoST) joint meeting in 1994, the first International food conference held in Zimbabwe in September 1994. The declaration was based on the original declaration from the FAO/WHO International Conference on Nutrition held in Rome, Italy in December 1992, which was endorsed by 159 states and the European Economic Community.

The following year, the 9th World Congress of Food Science and Technology, held in Budapest, Hungary in July–August 1995, the Budapest Declaration, based on the FAO/WHO and Victoria Falls Declarations, was approved by delegates to the IUFoST General Assembly (http://iufost.org/budapest-declaration). Clause 1 states that IUFoST delegates will "… recognise that access to nutritionally adequate and safe food is the right of each individual…", whereas clause 7 states that IUFoST

identifies "… the following areas as being especially significant: promotion of the safety and quality of all foods…".

Delegates to the General Assembly at the 15th World Congress of Food Science and Technology held in Cape Town, in August 2010 approved the Cape Town Declaration (http://iufost.org/cape-town-declaration), which again reaffirmed IUFoST's commitment to food safety as reflected by the appearance of terms such as 'nutritionally adequate and safe food.' 'safe and wholesome foods,' 'promotion of the safety and quality of all foods,' and 'to ensure food safety.'

Publications

Trends in Food Science and Technology

Published by Elsevier, this publication is the official journal of IUFoST and the European Federation of Food Science and Technology (EFFoST), one of IUFoST's regional groupings. It is an international peer-reviewed journal publishing critical reviews and viewpoints of current technology, food science, and human nutrition.

Newsline

The IUFoST newsletter, first published in 1970, became *Newsline* with the 25th edition in March 1993, when it was first published as part of *Lebensmittel-Wissenschaft und Technologie* (*Food Science and Technology*), the official journal of the Swiss Society of Food Science and Technology and published by Elsevier Science. *Newsline* is now published electronically three times per year and is available on the IUFoST website (www.iufost.org/iufost-newsline). *Newsline* has published many articles on food safety issues, especially from IUFoST-cosponsored seminars/symposia conducted in conjunction with national Adhering Bodies.

The World of Food Science

In 2000, IUFoST and IFT, the US Adhering Body, jointly launched the online electronic magazine *The World of Food Science*, directed at food scientists and technologists worldwide. It was relaunched in October 2006, following the 13th World Congress of Food Science and Technology, in Nantes, France. Volume 3 (February 2008) features articles on food safety (http://www.worldfoodscience.org/cms/?pid=1004439). The Editorial Advisory Board includes members drawn from IUFoST's Adhering Bodies.

Scientific Information Bulletins

IUFoST's Scientific Council has produced several Scientific Information Bulletins (SIBs) on topical issues, including the following on aspects of food safety (http://iufost.org/iufost-scientific-information-bulletins-sib):

- Bovine spongiform encephalopathy (February 2004).
- Safety, risk, and the precautionary principle (August 2007).
- Best practices in risk and crisis communication: Advice for food scientists and technologists (October 2007).
- Equivalence in food safety management (December 2007).
- Chemical hazards in food (October 2008).
- Food allergy (March 2009).
- Trans fatty acids (updated February 2010).
- Biotechnology and food (updated March 2010).
- Acrylamide in foods (updated July 2010).
- Nanotechnology and food (updated August 2010).
- Chemical hazards in food (January 2011).
- Radioactive fallout from the 2011 Japan nuclear plant accident and some recommended precautions and countermeasures (May 2011).
- Shiga toxin producing *Escherichia coli*: Germany 2011 *E. coli* 0104:H4 outbreak linked to sprouted seeds.
- Food traceability (March 2012).

SIBs are prepared by members of the Scientific Council or by selected experts from around the globe.

Conferences, Symposia, and Seminars

IUFoST has collaborated with a variety of Adhering Bodies, and both national and international organizations, to provide a forum for discussions on aspects of food safety. Some examples of such activities over the past 5 years include:

- 15th IUFoST World Congress of Food Science and Technology, Cape Town, South Africa, August 2010, featuring sessions on food safety, risk assessment and contaminants, and food allergens.
- International Forum on Food Safety, Beijing, China, 2010 and 2011, with Chinese Institute of Food Science and Technology.
- IUFoST – Japan Food Safety Symposium, September 2009.
- 14th IUFoST World Congress of Food Science and Technology, Shanghai, China, October 2008, featuring technical sessions on food safety of children's foods; modern food safety control systems; food safety forum; food safety monitoring technology; food safety regulations and standards; hazard assessment and foodborne disease; hot topics in safety of food systems; food genetic engineering and food safety; and biotechnology and food safety.
- IUFoST/Food Ingredients Asia/China Conference on Natural and Safe Food Ingredients, Shanghai, China, March 2007.
- 13th IUFoST World Congress of Food Science and Technology, Nantes, France, September 2006, featuring 10 chapters on food safety in the resultant book entitled *Global Issues in Food Science and Technology* (Barbosa-Canovas *et al.*, 2009).

In addition to the above, IUFoST has collaborated with a number of national, regional, and international organizations, including:

- ICMSF,
- WHO,
- International Union of Nutritional Sciences and
- IUFoST Regional Groupings, including:
  - La Asociación Latinoamericana y del Caribe de Ciencia y Tecnologia de Alimentos (Latin American and Caribbean Association of Food Science and Technology),

- EFFoST,
- FIFSTA, and
- West African Association of Food Science and Technology.

INSTITUTIONS INVOLVED IN FOOD SAFETY

Trust in Animals and Food Safety (TAFS) Forum

U Sperling, TAFS Forum, Bern, Switzerland

© 2014 Elsevier Inc. All rights reserved.

The international forum TAFS (Trust in Animals and Food Safety) is a nonprofit making Swiss foundation founded in 2002 in a response to the urgent need to enhance the communication between scientists and stakeholders of the food chain, food industry, and consumers in relation to the bovine spongiform encephalopathy (BSE) and other transmissible spongiform encephalopathy (TSE) diseases. With improvements in the prevention of BSE, TAFS extended its scope to other transmissible animal diseases such as paratuberculosis and influenza, and aspects of livestock rearing that are of relevance for food safety in general.

TAFS aims to contribute toward global food safety by acting as platform for communication on risks of animal diseases and measures for their management, particularly where important aspects of the scientific basis of animal diseases are still unclear. This is done by:

- monitoring scientific developments and provision of stakeholders with early warning and advanced information on the new scientific findings;
- interpretation of the significance of the scientific findings and possible implications on the regulatory development;
- voicing TAFS' opinion on the safety of animal-derived food and food products;
- making recommendations on voluntary risk management measures for the stakeholders;
- advocacy for regulatory measures;
- identification of gaps in science and possible areas for research.

Recommendations for risk management are nonbinding even for members and are meant as a guideline. Implementation may require adaptation to local requirements and possibilities.

The guiding principles of TAFS are: Personal trust and confidentiality, independence and impartiality, a strong commitment to a science- and fact-based approach, acknowledgment of knowledge gaps and their impact on risk management.

Communication of TAFS occurs through various channels, including international conferences, position papers, and a news stream. TAFS has so far published a number of position papers and suggested risk management plans, particularly on BSE and paratuberculosis. They are available at www.tafsforum.org for download.

TAFS has 21 members (status January 2012) from Europe, North America, and Asia, representing the food industry, regulators, and academia. Consumer views and interests are covered by social scientists. TAFS is generally open to admit new members, provided they commit to the guiding principles and actively contribute to the achievement of TAFS' goals.

INSTITUTIONS INVOLVED IN FOOD SAFETY

Global Harmonization Initiative (GHI)

H Lelieveld, Global Harmonization Initiative (GHI), Vienna, Austria

© 2014 Elsevier Inc. All rights reserved.

Glossary

Food safety Preventing harm from eating food.
Food security Certainty that there is sufficient food.
Global scientific consensus Consensus between scientists (including nutritionists, technologists, and engineers) from all countries of the world.
Harmonized regulations Regulations that are the same and have the same meaning everywhere.
Nutrient security Certainty that there are enough of all essential nutrients.
Sound science Knowledge based on facts that have been accepted by peers and can withstand scrutiny.
Toxic concentration Concentration of a substance in food that upon ingestion causes bodily harm.

Introduction

The Global Harmonization Initiative (GHI) is a global association of individual food scientists (in a wide sense, hence including technologists, nutritionists, and others) with a goal to "Achieving consensus on the science of food regulations and legislation to ensure the global availability of safe and wholesome food products for all consumers." Consensus statements will provide tools for stakeholders to exert pressure on legislators to make them base regulations on sound scientific evidence. Harmonized regulations will reduce the need for destroying safe food for pure differences between regulations. It will also facilitate trade between countries and the acceptance of new products or production methods once proven safe, avoiding testing in many countries with different protocols.

Although the globalization of world trade has created new pathways to economic growth for many nations, the trend toward a 'one-world economy' has also exposed critical differences in international laws and regulations that are designed to protect the world's citizens. Nowhere is this more evident than in the global food supply chain. Gaps in the science used to justify international regulations create confusion for food producers trying to achieve compliance. The result is a world of barriers to achieve food security and effective food safety – and the technological advancements that could ensure both. The need to harmonize global food regulations and laws has never been greater, considering the following challenges.

Food Security and Nutrition

Although the world as a whole produces enough food for everyone, approximately half of the food produced does not reach those who need it. As a consequence, today approximately 'one billion people' suffer from hunger. One of the major reasons is that a significant percentage of the food is destroyed during harvesting, transport, and storage. Much is spoiled before consumption owing to inadequate preservation, but food may also be deemed unfit for consumption – and consequently destroyed unnecessarily – without scientific justification due to laws that have been developed arbitrarily and are not founded on sanitary or other technical (e.g., rights of consumers and fair trade) reasons. In addition, food preserved to prevent microbial spoilage often has a significantly reduced concentration of essential nutrients. This can significantly be remediated by novel technologies, if their applications are not hindered by scientifically unjustified differences in regulations between nations.

Food Safety

Nations enact food safety regulations to protect consumers from foodborne illness. This is needed because some unscrupulous producers and tradesmen are more concerned about making a profit than safeguarding consumer health. Regrettably, significant differences in food safety regulations between nations can, and do, result in situations in which a food that is considered safe in one country is considered unfit for consumption in another country. This, in turn, leads to the destruction of imported foods that are safe but that do not meet regulatory requirements, or prevents countries from exporting food to areas where it is needed. Without globally harmonized, science-based regulations, rules intended to protect consumers from foodborne illness or death merely serve to erect trade barriers that inhibit technologic advancements that ensure public health.

 doi:10.1016/B978-0-12-378612-8.00440-6

Technology and Method Development

New technologies and scientific methodologies may have drawbacks, so there must be proof that such technologies offering beneficial solutions for one problem will not jeopardize other safety aspects. Thus, there is a fair and logical requirement to prove that food produced using a new process is still safe. Defining what constitutes a 'safe' process for ensuring food safety is challenging when the laws and regulations of countries differ, because validation must occur in many countries following different protocols, resulting in significant hurdles to new technology application.

For example, to protect crops against insects and other pests, producers use traditional prevention methods. Clearly, traditional methods work but they do have drawbacks, such as potentially toxic residues, destruction of nutrients, and dramatic losses to crushing or foraging animals. All over the world, scientists and engineers are developing methods that minimize, or even eliminate, such drawbacks. Results include more insect-resistant crop varieties and packaging that effectively protects against mechanical damage and pest infestation. Similarly, to prevent microorganisms from adulterating food preservation methods are developed that need neither heat nor chemicals to stop microbes from doing harm and help retain more of the food's essential nutrients. However, without agreement between countries about the validity of these technologic approaches, neither food producers nor consumers will benefit from the increased food safety and nutritional benefits they can provide.

Testing protocols used to establish the safety of the food itself or validate a preservation process' safety also require harmonization. A case in point is the prescribed testing protocols involving the use of animals, which not only poses serious ethical objections but, for processed food to cross borders, meeting legal requirements can be difficult, costly, and time-consuming. There is increasing evidence that the results of animal testing to determine toxicity of foods, cosmetics, and pharmaceuticals have little or no relevance to humans or human health outcomes. In fact, easy-to-apply alternative methods have been developed. Although these animal-free methods have been shown to return a faster, more accurate speed-to-result, expected financial benefits of their use cannot be realized if the protocols for product safety testing are not globally harmonized.

Historical Background

In view of the above, in 2004, members of the International Division of the Institute of Food Technologists (IFT) and representatives of the European Federation of Food Science and Technology (EFFoST), which is the European branch of the International Union of Food Science and Technology (IUFoST), were motivated to contribute to the harmonization of food safety regulations, globally. This resulted in the formation of the GHI in 2007. Shortly after establishing GHI, many scientific organizations joined the effort, which now boasts a growing, truly global membership dedicated to achieving consensus on the science of food regulations and legislation to ensure the global availability of safe and wholesome food products for all consumers.

Modus Operandi and Activities

From its inception, GHI's strategy has been to provide a networking forum in which food scientists could practice science. Its goal is to foster global scientific consensuses on issues for which globally equal regulations will help strengthen global food safety and alleviate global hunger and nutrition problems. By producing independent, authoritative information based on scientific consensus, GHI hopes to inform the world's regulators and lawmakers so that regulations are based on sound science and not reactionary conclusions after food safety failures. Stakeholders may use GHI's objective consensus documents to provide evidence to their governments that harmonization of food regulations is possible and in their interest.

Finances and Membership

As is explicit in the constitution of the organizations, to protect its impartiality, GHI will not accept funding from industries or governments. Funding is accepted only from scientifically independent organizations. GHI's intention is to involve scientists from all countries and, to achieve this, there is no membership fee. Applicants for membership, however, need to qualify and therefore are required to provide details showing that they are food scientists and experts have to provide evidence of their expertise before being invited to judge concepts of consensus documents.

Awareness

To make colleagues aware of the initiative, GHI has held workshops, courses, and meetings in many countries, which led to the formation of working groups (WGs), focusing on a variety of topics, including *Listeria monocytogenes* in ready-to-eat food, nanotechnology application, high-pressure sterilization, and the toxicity of food ingredients. Each WG's task is to develop a concept document for discussion by experts worldwide, followed by global distribution to food scientists, technologists, and engineers, with the goal of reaching a significant global consensus on the science involved in the specific area of interest.

From the start there has been abundant publicity about GHI. Many articles can be downloaded from the GHI website. In 2010, Elsevier published the book 'Ensuring Global Food Safety – Exploring Global Harmonization,' edited and written by GHI Members from all over the world. GHI has a quarterly newsletter, which can be downloaded from the website. The newsletters are announced in many professional magazines and in emails to the membership.

Structure

The Association has an Executive Committee consisting of at least six members, namely, the president, a general secretary, a

treasurer, and members at large. There is a Supervisory Board with the task to watch that the organization remains impartial at all times. The consensus processes take place in WGs and opinions are sought from members from all countries. To maximize the input of scientists from all over the world, GHI has Ambassadors in many countries, so that issues can be discussed in local languages.

Abbreviation of Selected Organizations Involved in Food Safety

This is a nonexhaustive list of some of the frequently mentioned abbreviation in the Encyclopedia of Food Safety.

CAC	Codex Alimentarius Commission.
CDC	Centers for Disease Control and Prevention (USA).
CI	Consumers International.
EFSA	European Food Safety Authority.
EHEDGE	European Hygienic Engineering and Design Group.
EPA	Environmental Protection Agency (USA).
EC	European Commission (European Union).
FAO	Food and Agricultural Organization of the United Nations.
FDA	Food and Drug Administration (USA).
IARC	International Agency for Research on Cancer.
ICMSF	International Commission on Microbiological Specifications for Foods.
IFIC	The International Food Information Council.
ILSI	International Life Sciences Institute.
ISO	International Organization for Standardization.
IUFoST	International Union of Food Science and Technology.
JECFA	Joint FAO/WHO Expert Committee on Food Additives.
JEMRA	Joint FAO/WHO Expert Meetings on Microbiological Risk Assessment.
JMPR	Joint FAO/WHO Meetings on Pesticide Residues.
OIE	World Organization for Animal Health.
PAHO	Pan American Health Organization.
RASFF	Rapid Alert System for Food and Feed.
UNEP	United Nations Environment Programme.
USDA	United States Department of Agriculture.
WHO	World Health Organization.
WTO	World Trade Organization.

Index

Notes
Cross-references terms in *italics* are general cross-references, or refer to subentry terms within the main entry (the main entry is not repeated to save space). Readers are also advised to refer to the end of each article for additional cross-references – not all of these cross-references have been included in the index cross-references.

The index is arranged in set-put style with a maximum of four levels of heading. Major discussion of a subject is indicated by bold page numbers. Page numbers suffixed by *T* and *F* refer to Tables and Figures respectively. *vs.* indicates a comparison.

Where index subentries and sub-subentries pertaining to a subject have the same page number, they have been listed to indicate the comprehensives of the text.
