To Mary Chase, my wife and best friend, whose support and patience was essential for the completion of this project. Thank you for always being there.

Christopher C.L. Chase

To Drs Michaela Kristula, Billy Smith, and Rob Callan whose tireless attention to detail rubbed off and gave me the tools to complete this project, Dr Tim Holt whose passion is contagious, and to my very encouraging friends and family.

Kaitlyn A. Lutz

Dedicated with gratitude to my husband, David, for his endless love and patience, and his understanding of the demands of academic life.

Erica C. McKenzie

To my families in Morocco and Minnesota, my wife Brigitte for her support, and to all who share their clinical knowledge through books.

Ahmed Tibary

Preface

With production animal agriculture changing at an alarming rate, the individuals who service these animals, producers, and businesses are called upon to remain current in a myriad of areas. Every farm visit confirms the necessity of possessing knowledge beyond traditional medical and surgical techniques. Veterinarians are challenged to advise producers in areas such as advanced reproductive techniques, precision-feeding, farm economics, facility design, governmental regulations, and biosecurity, to name a few. This second edition of *Wiley-Blackwell's Five-Minute Veterinary Consult: Ruminant* is designed to build upon the first edition by providing food animal practitioners, veterinary students, animal scientists, extension specialists, and researchers with concise and timely chapters relevant to these new challenges. The Five-Minute format allows busy practitioners to access up-to-date information in an easy-to-use format when time does not allow for sifting through the literature. The companion website for the second edition also allows for easier access to information in the field and use of full-color illustrations for improved information transfer.

As we see the consolidation of animal agriculture in many parts of the world, we are also seeing a resurgence of smallholder farming in other areas. To this point, food animal practitioners must be well versed in individual animal care as well as herd management recommendations and production parameters. This textbook, like the first edition, comprehensively covers information useful across a variety of production systems and species and strives for global relevance. Although this text focuses on cattle, sheep, and goats, a significant effort has been made to include key information on other ruminant species including bison, water buffalo, yak, and cervidae as well as pseudoruminants, camelids.

The book editors, along with the hundreds of veterinary specialists who contributed to this second edition of *Wiley-Blackwell's Five-Minute Veterinary Consult: Ruminant*, are delighted to provide this updated text. Our sincere hope is that the reader finds this textbook to be a useful reference guide. Many thanks are also due to Scott R.R. Haskell for his dedication to bringing the first edition of this book to fruition.

Kaitlyn A. Lutz
Christopher C.L. Chase
Erica C. McKenzie
Ahmed Tibary

Acknowledgments

Immense gratitude is owed to the contributing authors, who dedicated much time and energy towards updating and rewriting chapters for this edition. Their combined knowledge and expertise spanning a multitude of ruminant topics has resulted in a greatly improved reference for practitioners of ruminant and camelid medicine.

It was through the vision and perseverance of Dr. Scott R.R. Haskell that this series was originally born. Many thanks for the efforts of Scott and his team who worked on the first edition.

The perseverance of Mirjana Misina was integral in seeing this project to completion. The editors extend their fervent gratitude to Mirjana for unwavering professionalism and patience. We would also like to thank Heather Addison, copy editor, for her attention to detail and ability to "catch" the little things. Thank you also to the team of editors at Wiley Blackwell who ensured that this project ran smoothly: Purvi Patel, Nancy Turner, Melissa Wahl Hammer, Susan Engelken, and Erica Judisch.

USA

DUSTY W. NAGY, DVM, MS, PhD
Diplomate ACVIM (Large Animal)
Associate Teaching Professor
Department of Veterinary Medicine and Surgery
College of Veterinary Medicine
University of Missouri
Columbia, MO
USA

REGG D. NEIGER, DVM, PhD
Professor
Department of Veterinary and Biomedical Sciences
Animal Disease Research and Diagnostic Laboratory
South Dakota State University
Brookings, SD
USA

BENJAMIN W. NEWCOMER, DVM, PhD
Diplomate ACVIM (Large Animal)
Diplomate ACVPM (Epidemiology)
Assistant Professor
Department of Pathobiology
College of Veterinary Medicine
Auburn University
Auburn, AL
USA

ANDREW J. NIEHAUS, DVM, MS
Diplomate ACVS (Large Animal)
Associate Professor
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
The Ohio State University
Columbus, OH
USA

JORGE L. NORICUMBO-SAENZ, MS (Animal Science)
Milk Quality Specialist
Tular County, CA
USA

AKINYI C. NYAOKE, BVM, MSc, PhD
Assistant Professor
California Animal Health and Food Safety Laboratory
San Bernardino Branch
University of California, Davis
San Bernardino, CA
USA

LARRY OCCHIPINTI, DVM, MPVM
Owner
Guardsman Veterinary and K9 Reproduction Services
Tidewater, OR
USA

KATE O'CONOR, BS
Consultant at Yodle
Scottsdale, AZ
USA

DUSTIN OEDEKOVEN, DVM
Diplomate ACVPM
State Veterinarian
South Dakota Animal Industry Board
Pierre, SD
USA

ERIK J. OLSON, DVM, PhD
Diplomate ACVP (Anatomic Pathology)
Associate Professor
Veterinary Diagnostic Laboratory and Department of Veterinary Population Medicine
College of Veterinary Medicine
University of Minnesota
Saint Paul, MN
USA

DONAL O'TOOLE, MVB, PhD, DipECVP, FRCPath
Professor
Department of Veterinary Sciences and Wyoming State Veterinary Laboratory
University of Wyoming
Laramie, WY
USA

ZENHWA BEN OUYANG, VMD, MSE
Department of Clinical Sciences
College of Veterinary Medicine and Biomedical Sciences
Colorado State University
Fort Collins, CO
USA

LAUREN PALMER, DVM, MPH
Veterinarian
The Marine Mammal Care Center at Fort MacArthur
San Pedro, CA
USA

LISA K. PEARSON, DVM, MS, PhD
Diplomate ACT
Adjunct Faculty
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
Washington State University
Pullman, WA
USA

KEVIN D. PELZER, DVM, MPVM
Diplomate ACVPM
Professor
Department of Large Animal Clinical Sciences
Production Management Medicine
Virginia Maryland College of Veterinary Medicine
Virginia Tech
Blacksburg, VA
USA

ARUN PHATAK
Nutrition and Reproductive Management Specialist
Reproduction Specialties, Inc.
Modesto, CA
USA

PABLO PINEDO, DVM, PhD
Assistant Professor
Department of Animal Sciences
Colorado State University
Fort Collins, CO
USA

PAUL J. PLUMMER, DVM, PhD
Diplomate, ACVIM (Large Animal)
Diplomate, European College of Small Ruminant Health Management
Associate Professor
Veterinary Diagnostic and Production Animal Medicine;
Veterinary Microbiology and Preventive Medicine
College of Veterinary Medicine
Iowa State University
Ames, IA
USA

ELEONORA PO, DVM, MRCVS, CVA (IVAS)
Resident, ACVIM (LA) Candidate
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois
Urbana-Champaign, IL
USA

SALUNA POKHREL, BVSc & AH, MVSc (Veterinary Parasitology)
Assistant Professor
Department of Veterinary Microbiology and Parasitology
Institute of Agriculture and Animal Science, Tribhuvan University
Nepal

MARIANNE POLUNAS, RPh, PhD
Assistant Research Professor
Department of Pharmacology & Toxicology
Ernest Mario School of Pharmacy
Rutgers University
Piscataway, NJ
USA

KEITH P. POULSEN, DVM, PhD
Diplomate ACVIM
Clinical Assistant Professor
Large Animal Internal Medicine
Section Head, Client Services
Wisconsin Veterinary Diagnostic Laboratory
School of Veterinary Medicine
University of Wisconsin
Madison, WI
USA

EDWARD L. POWERS, DVM, MPVM
California Department of Public Health
Division of Communicable Disease Control
Infectious Diseases Branch
Veterinary Public Health Section
Richmond, CA
USA

MARIA E. PRADO, MV, PhD
Diplomate ACVIM (Large Animal)
Assistant Professor of Practice
Department of Animal Science
University of Tennessee
Knoxville, TN
USA

STEPHEN R. PURDY, DVM
Director, North American Camelid Studies Program
President
Nunoa Project
Peru;
Adjunct Associate Professor
UMass Amherst
Amherst, MA
USA

BIRGIT PUSCHNER, DVM, PhD
Diplomate ABVT
Professor and Chair
Department of Molecular Biosciences
School of Veterinary Medicine
University of California
Davis, CA
USA

MERL F. RAISBECK, DVM, MS, PhD
Diplomate ABVT
Professor Emeritus, Veterinary Toxicology
Department of Veterinary Sciences
University of Wyoming
Laramie, WY
USA

CHELSEY R. RAMIREZ, DVM
Clinical Instructor
Integrated Food Animal Management Systems
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois
Urbana-Champaign, IL
USA

JAMES M. RASMUSSEN, DVM
Senior Veterinarian
Minnesota Zoological Garden
Apple Valley, MN
USA

JIM P. REYNOLDS DVM, MPVM
Diplomate ACAW
Vice President of Consulting
Praedium Ventures
Visalia, CA
USA

JERRY R. ROBERSON, DVM, PhD, ACVIM
Professor Food Animal Medicine and Surgery
Lincoln Memorial University-College of Veterinary Medicine
Harrogate, TN
USA

JENNIFER N. ROBERTS, DVM
Diplomate ACT
Assistant Professor
Department of Large Animal Clinical Sciences
College of Veterinary Medicine
Michigan State University
East Lansing, MI
USA

NICHOLAS A. ROBINSON, BVSc (Hons), PhD, MACVSc
Diplomate ACVP (Anatomic Pathology)
Associate Professor
Cummings School of Veterinary Medicine
Tufts University
North Grafton, MA
USA

JOE RODER, DVM, PhD
Diplomate ABVT
Director
Swine Technical Services
Merck Animal Health
De Soto, KS
USA

FRANCISCO C. RODRIGUEZ, DVM
Associate Professor, Large Animal Medicine and Surgery
Department of Clinical Sciences
School of Veterinary Medicine
St. Matthew's University
Grand Cayman
British West Indies

KEITH A. ROEHR, DVM
State Veterinarian
Colorado Department of Agriculture
Animal Health Division
Broomfield, CO
USA

EMMANUEL ROLLIN. DVM, MFAM
Clinical Assistant Professor, Dairy Production Medicine
Department of Population Health
College of Veterinary Medicine
University of Georgia
Athens, GA
USA

JENNIFER A. SCHLEINING, DVM, MS
Diplomate, ACVS (Large Animal)
Associate Professor
Department of Veterinary Diagnostic and Production Animal Medicine
College of Veterinary Medicine
Iowa State University
Ames, IA
USA

DAVID A. SCHNEIDER, DVM, PhD
Diplomate ACVIM (Large Animal)
Research Veterinary Medical Officer
US Department of Agriculture
Agricultural Research Service
Animal Disease Research Unit
Pullman, WA
USA

CLARE M. SCULLY, MA, DVM, MS
Diplomate ACT
Assistant Professor
Department of Veterinary Clinical Sciences
Louisiana State University School of Veterinary Medicine
Baton Rouge, LA
USA

WILLIAM J. SEGLAR, DVM
Senior Nutritionist/Veterinarian
Global Nutritional Sciences
DuPont/Pioneer Global Forages
Johnston, IA
USA

JAN K. SHEARER, DVM, MS
Diplomate, American College of Animal Welfare
Professor and Extension Veterinarian
Iowa State University, CVM, VDPAM
Ames, IA
USA

CLIFFORD F. SHIPLEY, DVM
Diplomate ACT (Theriogenology)
Associate Clinical Professor
Attending Veterinarian
Agricultural Animal Care and Use Program
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois
Urbana, IL
USA

SUVASH SHIWAKOTI, BVSc & AH, MSc (Microbiology)
Veterinary Officer
Government of Nepal
North Dakota State University
Fargo, ND
USA

EGENDRA KUMAR SHRESTHA, BVSc & AH, MVSc
Associate Academic Director
Associate Professor
College of Agriculture and Veterinary Sciences
Nepal Polytechnic Institute Ltd
Bharatpur-11, Chitwan
Nepal

KATHARINE M. SIMPSON, DVM, MS
DACVIM
Associate Professor
Food Animal Medicine and Surgery
Large Animal Medicine and Surgery Department
St. George's University
School of Veterinary Medicine
True Blue, Grenada
West Indies

BILLY I. SMITH, DVM, MS
Diplomate ABVP (Food Animal)
University of Pennsylvania
School of Veterinary Medicine
New Bolton Center
Department of Large Animal Clinical Studies
Section of Field Service
Kennett Square, PA
USA

JACK D. SMITH, DVM
Diplomate ACT
Associate Professor, Theriogenology
Interim, Associate Dean for Academic Affairs
College of Veterinary Medicine
Mississippi State University
Starkville, MS
USA

JOE S. SMITH, DVM, MPS, DACVIM (LAIM)
Clinician
Food Animal and Camelid Hospital
Department of Veterinary Diagnostic and Production Animal Medicine
College of Veterinary Medicine
Iowa State University
Ames, IA
USA

KEELY A. SMITH, DVM
Private Practitioner
Hudson, FL
USA

JAMIE L. STEWART, DVM, MS
Theriogenology Resident
Department of Veterinary Clinical Medicine
College of Veterinary Medicine
University of Illinois
Urbana, IL
USA

AUDUN STIEN, PhD
Senior Researcher
Norwegian Institute for Nature Research – NINA
Fram Centre
Tromsø
Norway

KELLY M. STILL BROOKS, DVM, MPH
Diplomate ACVPM
Clinical Assistant Professor
Veterinary Diagnostic and Production Animal Medicine
College of Veterinary Medicine
Iowa State University
Ames, IA
USA

RICARDO M. STOCKLER, DVM, MS
Diplomate ABVP (Dairy Practice)
Assistant Clinical Professor of Farm Animal Ambulatory Services
JT Vaughan Large Animal Teaching Hospital
College of Veterinary Medicine at Auburn University
Auburn, AL
USA

CAROLYN L. STULL, MS, PhD
Diplomate ACAN (Animal Nutrition), ACAWS (Animal Welfare Science)
Animal Welfare Cooperative Extension Specialist, Emerita
Department of Population Health and Reproduction
School of Veterinary Medicine
University of California
Davis, CA
USA

JENNIFER S. TAINTOR, DVM, MS
Diplomate ACVIM (Large Animal)
Diplomate ACVSMR (Equine)
Associate Professor
Department of Clinical Sciences
College of Veterinary Medicine
Auburn University
Auburn, AL
USA

RACHEL H. H. TAN BVSc, DVCS, MACVSc, CertVetAc, MS, DipACVIM, GradCertEd
Senior Lecturer, Large Animal
College of Public Health, Medical and Veterinary Sciences
James Cook University
Townsville, Queensland
Australia

AHMED TIBARY, DMV, MS, DSc, PhD
Diplomate ACT
Professor
Department of Veterinary Clinical Sciences
College of Veterinary Medicine
Washington State University
Pullman, WA
USA

FERENC TOTH, DVM, PhD
Diplomate ACVS (Large Animal)
Assistant Professor
Department of Veterinary Population Medicine
College of Veterinary Medicine
University of Minnesota
Saint Paul, MN
USA

ALEX K. TURNER, DVM
Traceability Veterinarian
Colorado Department of Agriculture
Animal Health Division
Broomfield, CO
USA

TORKILD TVERAA, PhD
Senior Researcher
Norwegian Institute for Nature Research – NINA
Fram Centre
Tromsø
Norway

JEFFREY W. TYLER (Deceased)
College of Veterinary Medicine
University of Missouri
Columbia, MO
USA

FRANCISCO A. UZAL, DVM, FRVC, MSc, PhD
Diplomate ACVP
Professor of Veterinary Pathology
California Animal Health and Safety Laboratory System
San Bernardino Branch
University of California, Davis
San Bernardino, CA
USA

MODEST VENGUST, DVM, DVSc, PhD
Diplomate ACVIM (Large Animal)
Diplomate ACVSMR (Equine)
Veterinary Faculty
University of Ljubljana
Ljubljana
Slovenia

PAUL H. WALZ, DVM, MS, PhD
Diplomate ACVIM (Large Animal)
Professor
Department of Pathobiology
College of Veterinary Medicine
Auburn University
Auburn, AL
USA

MUHAMMAD SALMAN WAQAS, DVM, M.Phil
Lecturer
Department of Theriogenology
Faculty of Veterinary Science
University of Agriculture
Faisalabad
Pakistan

MATT G. WELBORN, DVM, MPH
Diplomate ACVPM
Professor
Food Animal Health Management
Department of Veterinary Clinical Sciences
LSU School of Veterinary Medicine
Louisiana State University
Baton Rouge, LA
USA

ASHLEY WHITEHEAD, DVM, BSc, DVSc
Diplomate ACVIM (Large Animal)
Assistant Professor
Department of Veterinary Clinical and Diagnostic Sciences
Faculty of Veterinary Medicine
University of Calgary
Calgary, Alberta
Canada

JEFFREY J. WICHTEL, BVSc, PhD
Diplomate ACT
Professor and Dean
Ontario Veterinary College
University of Guelph
Guelph, Ontario
Canada

AUDREY WIEMAN, DVM
Owner
Ridgeline Veterinary Services, LLC
Lynch, NE
USA

CHRISTINE M. WINSLOW, DVM
Diplomate, ACT
Assistant Professor
Animal Health Institute
Midwestern University
Glendale, AZ
USA

AMELIA WOOLUMS, DVM, MVSc, PhD
Diplomate ACVIM
Diplomate ACVM
Professor
Department of Pathobiology and Population Medicine
College of Veterinary Medicine
Mississippi State University
Mississippi State, MS
USA

ALAN YOUNG, PhD
Professor of Veterinary and Biomedical Science
South Dakota State University
Brookings, SD
USA

About the Companion Website

This book is accompanied by a companion website:

www.fiveminutevet.com/ruminant

The website includes:

- Additional topics not found in the book
- Client education handouts
- The figures from the book in PowerPoint

Contents

Topic	
Abomasal Emptying Defect in Sheep	1
Abomasal Impaction	3
Abomasal Ulceration	5
Abortion: Bacterial	7
Abortion: Bovine	9
Abortion: Camelid	11
Abortion: Farmed Cervidae	13
Abortion: Small Ruminant	16
Abortion: Viral, Fungal, and Nutritional	19
Actinobacillosis: Wooden Tongue	21
Actinomycosis: Lumpy Jaw	23
Acupuncture	24
Acute Renal Failure	26
Agricultural Chemical Toxicities	27
Agricultural Practices Contributing to Disease*	
Agroterrorism*	
Akabane	29
Alternative Medicine*	
Anaphylaxis	31
Anaplasmosis	32
Anemia, Nonregenerative	33
Anemia, Regenerative	35
Anesthesia: Inhalation	38
Anesthesia: Injectable	40
Anesthesia: Local and Regional	43
Anestrus	45
Angular Limb Deformity	47
Animal Disease Traceability (ADT)*	
Animal Welfare*	
Anthelmintic Resistance	50
Anthrax	52
Arsenic Toxicosis	54
Arthrogryposis	56
Artificial Insemination: Bovine	59
Artificial Insemination: Camelid*	
Artificial Insemination: Cervidae*	
Artificial Insemination: Small Ruminant	61

**Published online, see www.fiveminutevet.com/ruminant*

Aspiration Pneumonia 63
Atypical Interstitial Pneumonia 65
Avocado Toxicosis 67
Babesiosis 68
Bacillary Hemoglobinuria 71
Bacterial Endocarditis 73
Bacterial Meningitis 76
Beef Bull Management*
Beef Herd Records*
Beef Herd Reproductive Worksheets*
Biosecurity: Beef Cow/Calf*
Biosecurity: Cervidae*
Biosecurity: Dairy*
Biosecurity: Goats*
Biosecurity: Research Herds*
Biosecurity: Sheep*
Bison: Bacterial Diseases 78
Bison: Clinical Examination and Treatment*
Bison: Management*
Bison: Parasitic Diseases 81
Bison: Viral Diseases 83
Black Locust Toxicity 86
Bloat 87
Blood Chemistry*
Blue-Green Algae Poisoning 89
Bluetongue Virus 91
Body Condition Scoring: Alpacas and Llamas*
Body Condition Scoring: Beef*
Body Condition Scoring: Camels*
Body Condition Scoring: Cervidae*
Body Condition Scoring: Dairy Cattle*
Body Condition Scoring: Goats*
Body Condition Scoring: Sheep*
Border Disease 94
Borna Disease 96
Bovine and Ovine Implants*
Bovine Anthelmintics*
Bovine Dermatology 98
Bovine Digital Dermatitis 100
Bovine Ephemeral Fever 103
Bovine Leukemia Virus 105
Bovine Papular Stomatitis 107
Bovine Petechial Fever 108
Bovine Respiratory Syncytial Virus 109
Bovine Spongiform Encephalopathy 111
Bovine Viral Diarrhea Virus 113
Bracken Fern Toxicity 117

**Published online, see www.fiveminutevet.com/ruminant*

Brain Assessment and Dysfunction*
Brassica spp. Toxicity 119
Breeding Soundness Examination: Bull 122
Breeding Soundness Examination: Camelids 124
Breeding Soundness Examination: Cervidae 128
Breeding Soundness Examination: Small Ruminant 130
Brisket Disease 132
Brucellosis 134
Buckeye (*Aesculus* spp.) Toxicity 136
Burn Management 137
Cache Valley Virus 140
Calf Diphtheria/Necrotic Stomatitis 142
Camel Diseases 145
Camel Management and Health Programs 149
Camelid: Dentistry 152
Camelid: Dermatology 154
Camelid: Gastrointestinal Disease 158
Camelid: Heat Stress 160
Camelid: Parasitology 162
Camelid: Reproduction 165
Camelid: Venipuncture*
Campylobacter 169
Candidiasis 172
Caprine Arthritis Encephalitis Virus 174
Carbamate Toxicity 177
Cardiac Failure 179
Cardiotoxic Plants 181
Caseous Lymphadenitis (CLA) 184
Castor Bean Toxicity 187
Castration/Vasectomy: Bovine 188
Castration/Vasectomy: Camelid 190
Castration/Vasectomy: Small Ruminant 192
Caudal Vena Caval Thrombosis Syndrome 194
Cecal Dilation and Volvulus 196
Cervidae: Captive Management 198
Cervidae: Capture Myopathy 201
Cervidae: Chronic Wasting Disease 203
Cervidae: Game Park Management, Facilities 205
Cervidae Mortality 208
Cervidae: Reproduction 211
Cesarean Section: Bovine 213
Cesarean Section: Camelid 215
Cesarean Section: Small Ruminant 217
Chlamydiosis 219
Cleaning and Disinfection*
Clostridial Disease: Gastrointestinal 221
Clostridial Disease: Muscular 223

**Published online, see www.fiveminutevet.com/ruminant*

Clostridial Disease: Nervous System 225
Coccidioidomycosis 228
Coccidiosis 230
Coenurosis 232
Colic: Bovine 234
Colic: Small Ruminant 236
Colostrum and Milk Replacers*
Common Pharmacologic Therapies: Adult Dairy Cattle*
Congenital Defects: Bovine 239
Congenital Defects: Camelid 241
Congenital Defects: Small Ruminant 243
Congenital Ocular Disorders 245
Contagious Bovine Pleuropneumonia 247
Contagious Caprine Pleuropneumonia 249
Controlled Substances*
Copper Deficiency and Toxicity 251
Corkscrew Claw 255
Corneal Disorders 257
Coronavirus 260
Cow-Calf Management*
Cowpox 263
Cranial Nerve Assessment and Dysfunction*
Cryptococcosis 265
Cryptosporidiosis 267
Cyanide Toxicosis 269
Dairy Cattle Behavior*
Dairy Cow Comfort*
Dairy Economics*
Dairy Heifer Management Program*
Dairy Heifer Nutrition: Basics*
Dairy Informatics*
Dairy Nutrition: Ration Guidelines for Milking and Dry Cows*
Dairy Record Evaluation*
Dairy Reproduction*
Dairy Sheep and Goat Industries*
Death Camas 271
Dehorning/Cornuectomy*
Dermatophilosis 272
Dermatophytosis 274
Diarrheal Diseases: Bovine 276
Diarrheal Diseases: Camelid 278
Diarrheal Diseases: Small Ruminant 280
Disaster and Emergency Preparedness and Response*
Displaced Abomasum 282
Disseminated Intravascular Coagulopathy 285
Down Bovine 287
Down Camelid 289

**Published online, see www.fiveminutevet.com/ruminant*

Down Small Ruminant 292
Drug Hypersensitivities 294
Drug Interactions 296
Drug Residues in Milk*
Drug Storage Requirements and Veterinarian-Client-Patient Relationship (VCPR)*
Drug Toxicities 298
Dystocia: Bovine 300
Dystocia: Camelid 302
Dystocia: Small Ruminant 304
Echinococcosis 306
Economics: Net Present Value*
Economics: Partial Budgeting*
Embryo Transfer: Bovine 308
Embryo Transfer: Camelid 310
Embryo Transfer: Small Ruminant 312
Emesis 314
Employee Management*
Endocrine Disorders 316
Endometritis 318
Enucleation/Exenteration*
Environment and Mastitis*
Enzootic Ataxia 321
Enzootic Pneumonia of Calves 323
Epidemiologic Study Designs*
Epidemiology: Clinical Versus Statistical Significance*
Epidemiology: Diagnostic Test Use*
Epidemiology: Informatics*
Epidemiology of Mastitis*
Epidemiology: Risk Analysis*
Epidemiology: Systematic Approach to Disease Outbreak Investigations*
Epizootic Hemorrhagic Disease Virus 325
Erythrocytosis (Polycythemia) 327
Escherichia coli 330
Esophageal Disorders 332
Estrus Synchronization: Bovine 335
Estrus Synchronization: Small Ruminant 337
Evaluating Corn Silages for Feed Value*
Ewe Flock Nutrition*
Extra-label Drug Use and Compounding*
Failure of Passive Transfer 339
Fatty Liver 341
Feed Additives*
Feeding By-Products to the Beef Cow Herd*
Feeding for Milk Components*
Fescue Toxicity 343
Floppy Kid Syndrome 345
Fluid Therapy: Intravenous 347

**Published online, see www.fiveminutevet.com/ruminant*

Fluid Therapy: Oral 350
Fluoride Toxicity 353
Food Animal Residue Avoidance Databank (FARAD)*
Foot and Mouth Disease 355
Foot Rot: Bovine 357
Foot Rot: Small Ruminant 359
Freemartinism 361
Frostbite 363
Fungal Tremorgens 365
Gaseous Toxicities*
Gastrointestinal Pharmacology*
Gastrointestinal Surgeries: Laparotomy*
Gastrointestinal Surgeries: Rumenotomy/Rumenostomy*
Goat Milk Quality*
Goat Nutrition*
Gossypol Toxicosis 367
Grass Tetany/Hypomagnesemia 369
Grayanotoxin 371
HACCP (Hazard Analysis Critical Control Point)*
Haemonchosis 372
Hazardous Materials Spills Awareness and Response*
Heartwater (Cowdriosis) 376
Heat Stress 378
Heavy Metal Toxicosis 380
Hemorrhagic Bowel Syndrome 384
Hemotropic Mycoplasmas (Formerly Eperythrozoonosis) 386
Hereditary Chondrodysplasia: Ovine 388
Hernia Surgery*
Histophilus somni Complex 390
Hydrometra 394
Hydrops 396
Hypocalcemia: Bovine 398
Hypocalcemia: Small Ruminant 401
Indigestion 403
Induction of Parturition 405
Infectious Bovine Rhinotracheitis 407
Infectious Necrotic Hepatitis 410
Infectious Pustular Vulvovaginitis 412
Infertility and Subfertility Issues 414
Injection Site Lesions 416
Iodine Deficiency and Toxicity 418
Jimsonweed Toxicity (*Datura stramonium*) 420
Johne's Disease 421
Juvenile Llama Immunodeficiency Syndrome 423
Ketosis: Dairy Cattle 425
Lactation Failure (Dysgalactia, Agalactia, Hypogalactia) 428
Lameness: Bovine 430

**Published online, see www.fiveminutevet.com/ruminant*

Lameness: Camelid 433
Lameness: Small Ruminant 435
Laminitis in Cattle 437
Lantana Toxicosis 439
Lead Toxicosis 441
Leptospirosis 444
Leukocyte Responses in Cattle 447
Lightning Strike 451
Listeriosis 453
Liver Abscesses 455
Liver Flukes 458
Low-Fat Milk Syndrome 462
Lumpy Skin Disease 464
Lupine Toxicity 466
Lymphocytosis 468
Lymphosarcoma 470
Maedi-Visna (Ovine Progressive Pneumonia) 473
Malignant Catarrhal Fever 476
Management of Gunshot Wounds 478
Managing Neglect Cases*
Manure Management and Environmental Planning*
Manure Microbiology and Zoonosis*
Mastitis: Bulk Tank Monitoring and Somatic Cell Counts*
Mastitis: Camelids 480
Mastitis: Coliform 482
Mastitis: Fungal 484
Mastitis: Involvement of Milking Equipment and Stray Voltage*
Mastitis: Milking Procedures and Teat Disinfection*
Mastitis: Minor Bacteria 486
Mastitis: Monitoring*
Mastitis: Mycoplasmal 488
Mastitis: No Growth 491
Mastitis: Pharmacology*
Mastitis: Small Ruminant 493
Mastitis: Staphylococcal 496
Mastitis: Streptococcal 498
Melioidosis 501
Metaldehyde Toxicosis 503
Metritis 505
Microbiologic Sampling*
Milk Cow Nutrition Monitoring*
Milk Quality and Composition*
Milk Vein Rupture 508
Milkweed (*Asclepias* spp.) Toxicosis 509
Molybdenum Toxicity 511
Monensin Toxicity 513
Mycoplasma bovis Associated Diseases 516

**Published online, see www.fiveminutevet.com/ruminant*

Mycotoxins 518
Nairobi Sheep Disease 522
Nematodirosis 524
Neonatal Diarrhea 526
Neonatal Septic Arthritis 529
Neonatology: Beef 531
Neonatology: Camelid 533
Neonatology: Caprine 535
Neonatology: Dairy Cattle*
Neonatology: Ovine*
Neosporosis 537
Nightshade (*Solanum* spp.) Toxicosis 539
Nitrate and Nitrite Toxicosis 540
Nonsteroidal Anti-inflammatory Drugs (NSAIDs)*
Nutrition and Metabolic Diseases: Beef 542
Nutrition and Metabolic Diseases: Camelid*
Nutrition and Metabolic Diseases: Cervidae 544
Nutrition and Metabolic Diseases: Dairy 546
Nutrition and Metabolic Diseases: Small Ruminant 548
Nutrition and Metabolic Diseases: Water Buffalo 550
Nutritional Assessment*
Oak (*Quercus* spp.) Toxicity 553
Oestrus ovis Infestation 555
Oleander and Cardiotoxic Plant Toxicity 557
Oral Disorders 560
Orchitis and Epididymitis 562
Orf (Contagious Ecthyma) 564
Organophosphate Toxicity 566
Osteochondrosis 568
Ostertagiasis 570
Otitis Media/Interna 573
Ovarian Cystic Degeneration 576
Ovarian Hypoplasia, Bursal Disease, Salpingitis 578
Ovine Encephalomyelitis (Louping Ill) 580
Ovine Pulmonary Adenocarcinoma 582
Oxalate Toxicity 584
Pain Management*
Parainfluenza-3 Virus 586
Parasite Control Programs: Beef 588
Parasite Control Programs: Camelid 590
Parasite Control Programs: Dairy 594
Parasite Control Programs: Small Ruminant 596
Parasitic Pneumonia 600
Parasitic Skin Diseases: Bovine 602
Parasitic Skin Diseases: Camelid 605
Parasitic Skin Diseases: Small Ruminant 609
Parelaphostrongylus tenuis (Meningeal Worm) 612

**Published online, see www.fiveminutevet.com/ruminant*

Parenteral Nutrition 614
PCR Diagnostics*
Penile Disorders 617
Penile Hematoma 620
Pericarditis 622
Perinatal Lamb Mortality 625
Peripheral Nerve Assessment and Dysfunction*
Peste des Petits Ruminants 628
Petroleum Product Poisoning 630
Pharmaceutical Use: Legal Issues*
Pharmacokinetics and Pharmacodynamics*
Phenoxyl Toxicity 632
Phosphorus Deficiency/Excess 634
Photosensitization 637
Pine Needle Toxicity 641
Plants Producing Acute Respiratory Distress Syndrome 643
Poison Hemlock (*Conium* spp.) Toxicity 645
Polyarthritis 647
Postpartum Disorders 649
Postparturient Hemoglobinuria 651
Postparturient Paresis (Hypocalcemia) 653
Precocious Udder 655
Pregnancy Diagnosis: Bovine 657
Pregnancy Diagnosis: Camelid 659
Pregnancy Diagnosis: Small Ruminant 661
Pregnancy Toxemia: Bovine 663
Pregnancy Toxemia: Camelid 666
Pregnancy Toxemia: Small Ruminant 668
Prolonged Pregnancy 671
Protein Nutrition 673
Prudent Use of Antimicrobials*
Pseudocowpox 675
Pseudorabies 677
Pyelonephritis 679
Pyometra 681
Pyrrolizidine Alkaloids 683
Q Fever (Coxiellosis) 685
Quality Assurance for Meat Goats*
Quality Assurance Programs for Beef and Dairy*
Rabies 688
Reading and Evaluating Scientific Literature*
Rectal Prolapse 690
Reindeer Management: Overview 691
Reindeer Management: Population Dynamics 693
Repeat Breeder Management 695
Reproductive Pharmacology 697
Reproductive Prolapse 700

**Published online, see www.fiveminutevet.com/ruminant*

Reproductive Tumors 702
Reproductive Ultrasonography: Bovine*
Reproductive Ultrasonography: Camelid*
Reproductive Ultrasonography: Small Ruminant*
Respiratory Disease: Bovine 705
Respiratory Disease: Camelid 707
Respiratory Disease: Pharmacology*
Respiratory Disease: Small Ruminant 710
Retained Placenta 712
Rift Valley Fever 715
Rinderpest*
Ringwomb 717
Rodenticide Toxicity 719
Rotavirus 723
Rumen Dysfunction: Alkalosis 726
Rumen Fluid Analysis*

ABOMASAL EMPTYING DEFECT IN SHEEP

BASICS

OVERVIEW
Abomasal emptying defect (AED) is a syndrome of mature Suffolk sheep characterized by chronic, progressive weight loss and abomasal dilatation in the absence of mechanical obstruction.

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
N/A

SYSTEMS AFFECTED
Digestive

PATHOPHYSIOLOGY
• The pathogenic mechanism is unclear. Neurotoxicosis has been suggested.
• The syndrome shares some characteristics with chronic idiopathic intestinal pseudo-obstruction of humans. Affected individuals have clinical signs suggesting partial or complete gastric obstruction, when none is present.
• Morphologic investigations of human patients indicate degenerative changes in the smooth muscle or the tunica muscularis and/or neurons of the enteric plexus.

HISTORICAL FINDINGS
• Condition occurs sporadically, typically affecting a single individual. Flock management is usually excellent despite affected individuals within it.
• Owners may report weight loss in affected animals despite providing extra attention, nutrition, and anthelmintic treatment. Owners may note that the animal appears "bloated" despite inappetence.

SIGNALMENT
• AED affects sheep, with an anecdotal report in a cross-bred dairy type goat.
• Predominantly affects Suffolks; also reported in the Hampshire, Dorset, and Texel breeds.
• Affected animals are typically over 2 years old and of either gender.

PHYSICAL EXAMINATION FINDINGS
• Body temperature is within normal limits unless concurrent disease is present. Heart and respiration rates may be normal to increased. Fecal consistency usually normal, but volume often decreased.
• Abdominal conformation may be normal; bilateral, asymmetrical abdominal distention may occur (distension of the left paralumbar fossa and right ventrolateral abdomen when the animal is viewed from behind); unilateral distension may be present (right ventrolateral aspect of the abdomen).
• Rumen contractions are variable. Rumen hyperactivity can be dramatic in affected sheep and the left paralumbar fossa appears to be in constant motion, reflecting almost constant rumen activity.
• Sheep with AED are in varying stages of cachexia and their abdominal wall feels "thin" due to muscle wasting. Abdominal organs may also lack tone or give the impression of being fluid filled. In some instances, the caudal border of the abomasum may be visible and palpable as it extends beyond the last rib on the ventrolateral aspect of the abdomen. The distended abomasum usually feels fluid filled rather than the doughy or firm consistency often associated with abomasal impaction in cattle.

GENETICS
• Information regarding genetic predisposition is limited. Pedigree analysis of a flock in which 11/92 Suffolks were affected during a 5-month period did not identify a hereditary pattern.

CAUSES AND RISK FACTORS
Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Differential diagnoses for chronic weight loss in adult sheep include caseous lymphadenitis and other chronic infections including scrapie, Johne's disease, malnutrition, dental problems, parasitism, neoplasia.
• Historical and clinical findings are fairly specific to AED.
• Vagal indigestion with resulting ruminal distension is uncommon in sheep.

CBC/BIOCHEMISTRY/URINALYSIS
• Hematology and serum chemistry analysis are usually normal.
• Metabolic alkalosis with hypochloremia and hypokalemia observed with proximal GI obstruction in cattle is not consistently noted with AED.
• Elevations in liver enzymes (AST, SDH, GGT) may be noted.
• Increased intra-abdominal pressure from a distended abomasum may lead to secondary liver congestion and ischemia and can precipitate leakage of hepatic enzymes.
• Urinalysis usually unremarkable.

OTHER LABORATORY TESTS
• Elevated rumen chloride concentration is useful in supporting a diagnosis of AED.
• Normal rumen chloride in sheep is ≤15 mEq/L. Affected sheep will have at least a two-fold increase. Rumen fluid samples are easily obtained by percutaneous aspiration of the rumen from a site in the ventrolateral aspect of the left paralumbar fossa.

IMAGING
• Abdominal radiography may be helpful; however, unless the animal can be positioned for an oblique abdominal radiographic view, results will be difficult to interpret.
• Abdominal ultrasonography may be more useful than radiographic imaging. A 3 to 5 MHz linear or convex array can provide adequate images of the abomasum. When placed on the lower right abdomen, the normal abomasum will not extend beyond the last rib. In animals with AED the abomasum will usually appear 2 to 4 times normal size.

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Gross necropsy reveals a greatly distended abomasum and patent pylorus.
• Abomasal contents are usually liquid but may be dry. Histopathologic changes in the abomasum include smooth muscle degeneration, vacuolation, and varying degrees of necrosis. Degenerative changes have been reported in the celiacomesenteric ganglia.

TREATMENT

THERAPEUTIC APPROACH
• The prognosis for recovery with intensive treatment is variable and dependent upon the duration of abomasal dysfunction and distention. Medical therapy using cathartics and laxatives, and surgical therapy (abomasotomy) have had limited success.
• In animals that are good surgical candidates, abomasotomy followed by metoclopramide and supportive fluid therapy has provided some success.

SURGICAL CONSIDERATIONS AND TECHNIQUES
An abomasotomy is best performed under general anesthesia, although a local line block can be used. The animal is placed in left lateral recumbency and a right paracostal approach provides excellent access to the abomasum. Subsequently the abomasum is opened and its contents removed, and the organ is flushed and closed in a routine manner. Treatment with metoclopramide should be used as an adjunct to the surgery. Concurrent fluid replacement and electrolyte correction therapy is critical to survival and success.

MEDICATIONS

DRUGS OF CHOICE
Metoclopramide (0.1 mg/kg, q8h, SQ) as an adjunct to abomasotomy has been reported to improve abomasal motility. This medication should not be used if GI obstruction is suspected.

A

ABOMASAL EMPTYING DEFECT IN SHEEP (CONTINUED)

Erythromycin (8.8 mg/kg, IM) increased abomasal emptying rate in dairy calves; pre-operative administration (10 mg/kg, IM) increased abomasal emptying after surgical correction of left displaced abomasum in dairy cows. Erythromycin may therefore provide some benefit in treatment of AED.

CONTRAINDICATIONS
Neostigmine should not be used in affected animals since it increases frequency rather than strength of rumen contractions.

PRECAUTIONS
Appropriate milk and meat withdrawal times apply to all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- The earlier that AED is recognized and treated, the better the prognosis; however, prognosis is guarded for long-term recovery regardless.
- In certain circumstances such as a ram completing a breeding season, or a late gestation ewe completing her pregnancy, a fair to good short-term prognosis may be offered if intensive treatment is provided early.

POSSIBLE COMPLICATIONS
- Complications related to abomasotomy: surgical dehiscence of the abomasal incision (especially if the abomasal wall has undergone degenerative changes) and dehiscence of the abdominal incision may occur (more likely in a debilitated patient).
- Once the condition is recognized, if treatment is declined, euthanasia should be offered as a humane resolution.

CLIENT EDUCATION
Owners of Suffolk sheep should be familiar with the breed predisposition for AED and educated regarding the clinical presentation.

PATIENT CARE
If intensive therapy is undertaken, the animal should be observed for attitude, appetite, fecal production, and abdominal conformation. Signs of improvement following abomasotomy and during metoclopramide therapy may include improvement in attitude and appetite, increased fecal production and decreased abdominal distention.

PREVENTION
Because the underlying cause and heritability of AED is unknown, recommendations cannot be made.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Other concurrent conditions may occur with AED. Pneumonia and other organ failure can be secondary to any chronic debilitating disease.

AGE-RELATED FACTORS
AED usually occurs in mature sheep.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
In spite of treatment, pregnant animals may abort. Pregnant animals (especially mid- to late-term) represent an increased surgical risk.

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
AED is usually observed in a single animal from a well-managed flock.

SYNONYMS
- Abomasal dilatation and emptying defect
- Abomasal impaction
- Acquired dysautonomia
- Functional pyloric stenosis
- Ovine abomasal enlargement

ABBREVIATIONS
- AED = abomasal emptying defect
- AST = aspartate transaminase
- GGT = gamma-glutamyltransferase
- SDH = sorbitol dehydrogenase

ABOMASAL IMPACTION

BASICS

OVERVIEW

• Abomasal impaction occurs when there is obstruction to the passage of fluid and ingesta from the abomasum through the pylorus by feed, sand, gravel or other foreign bodies, or as a result of neurologic dysfunction from various conditions.
• Pyloric obstruction from improperly placed percutaneous fixation of left-displaced abomasum ("roll and toggle") can also result in abomasal impaction in cattle.
• Clinical signs can be acute or chronic and are characterized by anorexia, decreased or scant feces, abomasal distension, weakness, dehydration, and signs of abdominal pain.
• Abomasal impaction typically occurs in cattle and occasionally in sheep. It is usually sporadic, but morbidity can be associated with feeding of low-quality forages.
• This disorder has a high mortality rate.
• Abomasal emptying defect (AED) is a disorder that primarily affects Suffolk sheep and is characterized by distension and impaction of the abomasum.

INCIDENCE/PREVALENCE

Low morbidity.

GEOGRAPHIC DISTRIBUTION

Worldwide. Occurs more commonly in regions where low quality roughage or low energy diets are fed.

SYSTEMS AFFECTED

Digestive

PATHOPHYSIOLOGY

• Physical obstruction of outflow from the abomasum into the duodenum occurs. This may be due to packing of straw or other poor-quality roughages, or sand or gravel in the abomasum.
• Damage to branches of the vagus nerve as a result of traumatic reticuloperitonitis, lymphoma or other disorders can decrease the emptying ability of the abomasum.
• Failure of fluid to move from the abomasum into the intestines results in dehydration and starvation.
• Sequestration of hydrochloric acid in the abomasum can result in metabolic alkalosis.
• In sheep, no histologic lesion has been consistently associated with AED, and the etiology is unknown. In one study, histologic examination of celiacomesenteric ganglia from affected sheep revealed scattered chromatolytic or necrotic neurons, without inflammation. Chromatolytic neurons were observed more frequently in AED-affected sheep than in healthy Suffolk sheep. Neuronal necrosis was not observed in any of the healthy sheep. Neuronal lesions of AED resemble dysautonomic diseases of humans and other animals.

HISTORICAL FINDINGS

• Abomasal impaction often affects cattle on poor-quality pasture or that are fed chopped, low-quality forages with low dietary energy, especially in cold weather. Beef cattle are more prone due to management characteristics.
• The disorder may also arise in cattle eating from sand or gravel surfaces, or if excessive gravel from the feed storage area contaminates the feed.
• Animals may also develop the condition as a result of pica.

SIGNALMENT

• This disorder typically affects cattle and sometimes sheep.
• Suffolk sheep may be predisposed compared to other ovine breeds due to the higher prevalence of AED in this breed. Abomasal impaction affects juvenile to adult animals; AED affects sheep >2 years old.
• Abomasal impaction may be more prevalent in pregnant females.

PHYSICAL EXAMINATION FINDINGS

• Anorexia, depression, and decreased rumen motility are typical.
• Distension of the abomasum may be identified by visualization, palpation, and ballottement of the lower right flank.
• Affected animals eventually display weight loss, reduced fecal production, and dehydration.

GENETICS

A hereditary pattern has not been demonstrated for abomasal impaction or for AED.

CAUSES AND RISK FACTORS

• Physical blockage of the abomasum in cattle fed low-quality chopped forages, or consuming sand or gravel.
• As a result of "roll and toggle" sutures inadvertently placed in or near the pylorus.
• From conditions that damage the vagus nerve.
• Late pregnancy may predispose.
• Suffolk sheep with AED are predisposed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Include other disorders that may cause signs of inappetance, scant fecal production, and abdominal distension including abomasal displacement, reticuloperitonitis, lymphoma, and vagal indigestion.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC is usually normal.
• Hypochloremic, hypokalemic metabolic alkalosis may be present in chronic cases.
• Sheep with AED do not typically demonstrate the hypochloremic, hypokalemic metabolic alkalosis commonly found in cattle with outflow obstruction disorders.

OTHER LABORATORY TESTS

Elevated rumen chloride concentrations in sheep (>15 mEq/L) indicate reflux of abomasal contents into the rumen.

IMAGING

• Ultrasonography may be useful to determine distension of the abomasum and to assist detection of potential inciting causes such as traumatic reticuloperitonitis and lymphoma.
• Radiography may be useful to detect traumatic reticuloperitonitis or the presence of excessive sand or gravel within the gastrointestinal tract.

OTHER DIAGNOSTIC PROCEDURES

• Measurement of rumen chloride using fluid samples obtained by orogastric tube or rumenocentesis.
• Laparotomy.
• Abdominocentesis can identify elevated nucleated cell counts, elevated total protein concentration, and/or abnormal cellular morphology in animals with underlying causative disorders that are inflammatory or neoplastic in nature.

PATHOLOGIC FINDINGS

Distension of the abomasum with packing of roughage, gravel or sand is confirmed via laparotomy or necropsy. Concurrent traumatic reticuloperitonitis, lymphoma, and other predisposing causes may also be recognized by these techniques.

TREATMENT

THERAPEUTIC APPROACH

• Surgical therapy likely provides the greatest chance of resolution depending on the underlying cause.
• Medical therapy best accompanies surgical therapy and can consist of administration of cathartics and laxatives daily for 2 to 4 days.
• Correction of metabolic alkalosis may be indicated in severe or chronic disease.

SURGICAL CONSIDERATIONS AND TECHNIQUES

• Impaction may be resolved by abomasotomy with removal of roughage or foreign material. Surgical approaches that allow access to the abomasum include right paracostal, right paramedian and right paralumbar.

MEDICATIONS

DRUGS OF CHOICE

• Cathartics and laxative options include dioctyl sodium sulfosuccinate (50 mg/kg/day), magnesium sulfate (2.5 g/kg/day), mineral oil (8 mL/kg/day), and magnesium hydroxide (1 g/kg/day).

A

ABOMASAL IMPACTION (CONTINUED)

• Metabolic alkalosis can be readily corrected via administration of intravenous sodium chloride preparations.

CONTRAINDICATIONS
• Gastrointestinal motility agents should be considered only after surgical or medical correction of impaction to reduce the risk of abomasal rupture.

PRECAUTIONS
• Lactated Ringer's solution should be used cautiously due to the possibility of inducing or exacerbating metabolic alkalosis.
• Abomasal motility agents (neostigmine, metoclopramide, erythromycin, etc.) should be used with great caution to avoid abomasal rupture.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Grave prognosis. Death from dehydration, metabolic alkalosis or peritonitis if intervention does not occur.

POSSIBLE COMPLICATIONS
Abomasal rupture and peritonitis.

CLIENT EDUCATION
Feed cattle to meet energy requirements and avoid feeding chopped poor-quality forages with low energy, particularly in cold weather.

PATIENT CARE
Affected animals should be assessed for signs of pain and suffering (lethargy, inappetance, signs of abdominal pain), reduced fecal output, hydration status, and electrolyte balance.

PREVENTION
• Feed good-quality, long fiber-length forage with adequate energy supplementation.
• Avoid feeding on sand or gravel.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Reticuloperitonitis, lymphoma, displaced abomasum.

AGE-RELATED FACTORS
More common in adult and pregnant animals, and mature Suffolk sheep.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
Pregnancy predisposes to abomasal impaction as a result of increased energy requirements, appetite, and the possible effect of size and weight of the gravid uterus on abdominal organs.

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
This disorder is largely preventable through appropriate dietary management.

SYNONYMS
Abomasal emptying defect in sheep

ABBREVIATION
AED = abomasal emptying defect

ABOMASAL ULCERATION

BASICS

OVERVIEW

• Abomasal ulceration represents damage to the abomasal mucosa ranging from mucosal erosion to complete perforation. Often subclinical depending on the severity of disease.
• Abomasal ulceration can be classified as type I (nonperforating ulcers), type II (nonperforating with severe blood loss), type III (perforating with localized peritonitis), and type IV (perforating with diffuse peritonitis).
• When present, clinical signs reflect abdominal pain, blood loss, and peritonitis. The etiology is not clear, but may be associated with stress. There is no demonstrated association with specific bacterial pathogens.

INCIDENCE/PREVALENCE

• Low, likely below 1–2%. May be higher in some types of calf raising systems, and in cattle in the first month postpartum, particularly with concurrent disease.
• Rare occurrence in sheep and goats.

GEOGRAPHIC DISTRIBUTION

N/A

SYSTEMS AFFECTED

Digestive

PATHOPHYSIOLOGY

• Injuries to the protective mucosal layer of the abomasum allow gastric acid and pepsin to diffuse into the mucosa.
• Type I nonperforating ulcers have incomplete penetration, little local reaction, and minimal bleeding.
• Type II bleeding ulcers erode into a major blood vessel in the submucosa. There may be distension of the abomasum and reflux of abomasal contents into the rumen. Melena is typically observed.
• Type III ulcers completely perforate the wall with leakage of fluid and local peritonitis. Adhesions form to viscera, localizing the peritonitis.
• Type IV ulcers also completely perforate the wall; however, the subsequent fluid leakage is not contained by adhesions, resulting in generalized peritonitis.

HISTORICAL FINDINGS

Changes in feeding, such as transition from milk to solid feed in calves or change from a high roughage prepartum diet to high concentrate postpartum diets may be involved.

SIGNALMENT

• This disorder affects cattle, and rarely sheep and goats.
• There are no breed or gender predilections; however, dairy cattle may have a higher prevalence.
• Occurs in calves and adults.

PHYSICAL EXAMINATION FINDINGS

• Melena or occult blood is observed in feces.
• Possible distension of the abomasum detected by ballottement of the ventral right abdomen.
• Pale mucus membranes and tachycardia in cases with severe blood loss or septic shock.
• Anorexia, depression, pyrexia, and abdominal pain (bruxism).
• Peracute death common in adult cattle but not calves.

GENETICS

N/A

CAUSES AND RISK FACTORS

• This disorder has been associated with physical irritation from straw ingestion in veal calves and high grain diets in feedlot cattle.
• May be related to postpartum conditions in dairy cattle.
• Not definitively associated with bacteria such as *Clostridium*, *Salmonella* or *Helicobacter* sp. Recent gene pyrosequencing suggests limited involvement of bacteria in abomasal ulcers.
• No association with hairballs in veal calves.
• Risk factors might include sudden transition from milk diet to dry feed in calves, straw feeding in milk-fed calves, high concentrate diets, recent parturition, and peak milk production.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Lymphoma
• Left displaced abomasum
• Abomasal volvulus or torsion
• Intussusception
• Duodenal ulcers
• Hemorrhagic bowel syndrome

CBC/BIOCHEMISTRY/URINALYSIS

• Acute hemorrhagic anemia in cases of severe gastric hemorrhage, elevated fibrinogen, altered total protein concentration.
• Serum chemistry might reflect chronic inflammation in type III and IV ulceration reflected by high total protein concentrations and possibly neutrophilia on CBC.

OTHER LABORATORY TESTS

• Abdominocentesis may identify peritonitis, with increased leukocyte count, phagocytosed or free bacteria, and possibly feed particles in some cases.
• Testing for occult blood in feces may detect blood in the feces before melena is visible.

IMAGING

Ultrasonography may show free fluid and fibrin in the abdomen.

OTHER DIAGNOSTIC PROCEDURES

• Exploratory surgery.
• Peritoneal emphysema may be detected during per rectum examination.
• Positive withers pinch test may be evident (type III and IV).

PATHOLOGIC FINDINGS

• Ulcers are most commonly found along the greater curvature and usually in the fundic area. Ulcers can be a few millimeters to several centimeters in size. They are often filled with debris or clotted blood. Perforating ulcers are usually adhered to the omentum.
• Cattle with bleeding ulcers have signs of anemia with blood in the distal GI tract.
• Diffuse fibrinous peritonitis may be evident with defects in the serosal surface of the abomasum.

TREATMENT

THERAPEUTIC APPROACH

• Treatment is typically unrewarding but should target correction of management issues (dietary, stress related), correction of concurrent disease, and addressing clinical problems related to abomasal ulceration.
• Medical therapy may include provision of antacids to protect the abomasal mucosa, removal of high energy feedstuffs, and stall confinement.
• Blood transfusion may be beneficial if bleeding ceases or can be controlled, and is indicated if hematocrit declines to ≤14%.
• Broad-spectrum antibiotic therapy is indicated to prevent or address septic peritonitis.

SURGICAL CONSIDERATIONS AND TECHNIQUES

Surgical intervention for perforated ulcers might be attempted for valuable cattle.

MEDICATIONS

DRUGS OF CHOICE

• Magnesium oxide (500 g/400 kg body weight daily for 2–4 days), or a kaolin and pectin mixture (2–3 liters twice daily to mature cattle).
• Treatment options in calves include oral administration of antacids (25–50 mL q8h), ranitidine (50 mg/kg q8h) and omeprazole (4 mg/kg q24h).

CONTRAINDICATIONS

NSAIDs that interfere with the production of prostaglandin E series via the arachidonic acid cascade are not recommended, to avoid compromise of the protective coating of the abomasal mucosa.

PRECAUTIONS

• Avoid NSAIDs and corticosteroid drugs, particularly in susceptible populations.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

A

ABOMASAL ULCERATION (CONTINUED)

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Recovery for type I and type III ulcers is considered likely or possible; type II ulcers are fatal if severe hemorrhage occurs; type IV ulcers carry a guarded prognosis.

POSSIBLE COMPLICATIONS
• Septic peritonitis as a result of abomasal leakage or perforation.
• Hepatic lipidosis as a result of anorexia, particularly in cattle in early lactation.

CLIENT EDUCATION
Gradual introduction of dry feed to calves is preferred over abrupt exposure to dry feed during the milk-fed period.

PATIENT CARE
Serial assessments of CBC, anemia, and pain are used to determine recovery over time.

PREVENTION
• Avoid rapid change from liquid to dry feed in calves.
• Avoid excessive concentrate diets in feedlot or dairy cattle.
• Cull animals infected with bovine leukosis virus to eliminate lymphosarcoma as a cause of abomasal ulceration.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Lymphoma

AGE-RELATED FACTORS
Affects all ages

BASICS

OVERVIEW
Pregnancy loss between 42 days and term, caused by bacterial infection

INCIDENCE/PREVALENCE
• Abortion rates depend on the pathogen and immunologic status of the herd.
• Abortion rates range from <10% (serovar Hardjo of *Leptospira*, *listeriosis*) to 50–70% (serovar Pomona of *Leptospira*, *brucellosis*, epizootic bovine abortion).

GEOGRAPHIC DISTRIBUTION
• Worldwide
• Epizootic bovine abortion: California, Nevada, and Oregon

SYSTEMS AFFECTED
• Reproductive
• Other systems depending on cause

PATHOPHYSIOLOGY
• Infection occurs venereally, orally, via inhalation or across conjunctival mucosa.
• Ticks act as vectors for epizootic bovine abortion, *Anaplasma* spp., and *Coxiella burnetii*.
• Conceptus infection via hematogenous spread, ascending infection through the cervix, or descending infection from the abdomen through the oviducts.
• Bacteria may cause placentitis and fetal septicemia via the umbilical veins or by ingestion of amniotic fluid.
• Fetal death occurs secondary to placental insufficiency, fetal septicemia, lysis of the corpus luteum (CL) or failure of the diseased fetoplacental unit to produce progesterone to support pregnancy (after 200 days).
• A delay in fetal expulsion leads to autolysis or maceration.
• Dams may shed bacteria in urine, milk, feces, oronasal secretions, or uterine discharge. The abortus is an important source of infection.
• Gram-negative bacteria causing maternal systemic disease may also lead to abortion associated with luteolysis secondary to endotoxemia.

HISTORICAL FINDINGS
• Abortions
• Inappropriate vaccination
• Introduction of new animals

SIGNALMENT
• Ruminants, bovine (epizootic bovine abortion)
• Breeding age females
• Epizootic bovine abortion more common in naïve heifers

PHYSICAL EXAMINATION FINDINGS
• Physical examination is usually unremarkable.
• Illness and fever may develop secondary to retained fetal membranes (RFM) or a retained macerated fetus and metritis.
• *Campylobacter fetus venerealis*: Infertility, pregnancy loss between 15 and 80 days' gestation, or abortion at 4 to 6 months.
• *Leptospira* spp.: Last trimester abortion, stillbirth, weak calves, and infertility. Severe acute disease with hemolytic anemia, hemoglobinuria, and mastitis with serovar Pomona.
• *Brucella abortus*: Abortion after 5 months' gestation, weak or premature calves, RFM, metritis, infertility, carpal hygromas, regional lymphadenitis.
• *Listeria monocytogenes* and *L. ivanovii*: Abortion in the last trimester, meningoencephalitis, metritis, weight loss, maternal and neonatal septicemia.
• *Histophilus somni*: Pneumonia, arthritis, myocarditis, meningoencephalitis, sporadic abortions in the second half of gestation.
• *Salmonella enterica* serovar Dublin: Enteritis, dysentery, pneumonia, polyarthritis, pyrexia, abortion during the second half of gestation.
• *Trueperella pyogenes* (formerly *Arcanobacterium pyogenes*): Organ abscessation with varying signs, pyometra, abortion at any time.
• *Ureaplasma diversum*: Embryonic death, last trimester abortion, stillbirth, weak calves, neonatal pneumonia, endometritis, granular vulvovaginitis, salpingitis, endometritis.
• *C. burnetii*: late abortions, stillbirth, weak calves.
• *Mycobacterium bovis*: Organ granulomas with variable signs, late abortion, purulent to caseous vaginal discharge.
• *Anaplasma marginale*: Pale mucus membranes, icterus, fever, weakness, abortion during the acute phase of maternal disease.
• *A. phagocytophilum*: Fever, cough, nasal discharge, abortion during the acute phase of maternal disease.
• Epizootic bovine abortion: Last trimester abortion, premature births.
• *Chlamydophila abortus*: Abortions at 6 to 8 months' gestation, stillbirths, weak calves, RFM, mastitis, infertility.

GENETICS
N/A

CAUSES AND RISK FACTORS
Contagious bacteria
B. abortus, C. fetus (subsp. venerealis or fetus), *C. jejuni, Leptospira* spp., *L. monocytogenes, H. somni, Salmonella* spp., *Y. pseudotuberculosis, M. bovis, C. abortus*

Tick-borne infection
C. burnetii, A. marginale, A. phagocytophilum, epizootic bovine abortion

Mollicute infection
M. bovis, M. bovigenitalium, M. canadense, M. leachii, Ureaplasma diversum

Opportunistic bacteria
Bacillus spp., *E. coli, Pasteurella* spp., *Pseudomonas* spp., *Staphylococcus* spp., *Streptococcus* spp.

Mode of infection
• Inappropriate biosecurity measurements and vaccination schedules
• Nutritional, social or environmental stress
• Seasonal presence of ticks and vectors
• Exposure to wildlife and rodents

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Vaginitis, metritis, endometritis
• Other causes of abortion

CBC/BIOCHEMISTRY/URINALYSIS
• Hemolytic anemia and hemoglobinuria (*L. interrogans* serovar Pomona)
• Anemia or leukopenia (*Anaplasma* spp.)

OTHER LABORATORY TESTS
• Bacterial culture from aborted tissues (lung, abomasal contents, placenta) and dam's milk (brucellosis).
• Dam and fetal serology.
• Immunohistochemistry and/or immunofluorescence on fetal tissues (leptospirosis, listeriosis, campylobacter, *C. burnetii*, *C. abortus*).
• PCR on aborted tissues (leptospirosis, *Brucella* spp., *Mycoplasma* spp., *Ureaplasma*, campylobacteriosis, *C. burnetii*, *Anaplasma* spp., *C. abortus*).
• Direct identification on Giemsa-stained blood smears (*Anaplasma* spp.).
• Pathognomonic microscopic lesions in the thymus (epizootic bovine abortion).

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
Fetal necropsy

PATHOLOGIC FINDINGS
• *C. fetus*: Fetal fibrinous pleuritis, pericarditis and peritonitis. Intercotyledonary placentitis, necrotic cotyledons.
• *Leptospira* spp.: Autolyzed and icteric fetus, cholestasis, intercotyledonary edema, diffuse cotyledonary necrosis.
• *B. abortus*: Fetus (autolysis, fibrinous pleuritis, pericarditis, peritonitis, pneumonia); placentitis.
• *Listeria* spp.: Fetus (autolysis, white foci of liver necrosis, abomasal erosions, pneumonia, polyarthritis); multifocal cotyledonary necrosis and intercotyledonary placentitis.
• *H. somni*: Autolytic fetus, necrosis of cotyledons.
• *Salmonella* spp.: Fetus (autolysis, emphysema, liver necrosis); placentitis.
• *T. pyogenes*: Fetus (autolysis), suppurative bronchopneumonia); cotyledonary and intercotyledonary placentitis.

A

ABORTION: BACTERIAL (CONTINUED)

• *Mycoplasma* spp.: Placentitis, fetal bronchopneumonia, and myocarditis.
• *U. diversum*: Fetus (fresh); thickening and fibrosis of the amnion and chorioallantois, mineralization, necrosis, hemorrhage.
• *C. burnetii*: thick leathery intercotyledonary spaces, multifocal mineralization, and pericotyledonary necrosis.
• Epizootic bovine abortion: Fetus (fresh, ascites, excessive fibrin, enlarged liver, spleen and lymph nodes, petechial hemorrhage on mucosal membranes and thymus, focal necrotizing lesions in lymphatic tissues, depletion of cortical thymocytes, and infiltration with macrophages in the thymus).
• *C. abortus*: Fetus (subcutaneous edema, ascites, thymic and subcuticular petechiae, serofibrinous pleuritis and peritonitis, nodular mottled liver, and enlarged lymph nodes); necrotizing placentitis with leathery, reddish, opaque intercotyledonary patches and multifocal cotyledonary necrosis.

TREATMENT

THERAPEUTIC APPROACH
• Treatment of systemic disease, RFM, metritis or hypocalcemia as needed.
• Vaccination can be curative (*Campylobacter* spp.).
• Supportive as needed.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• *H. somnus*: β-lactams, florfenicol, tetracycline, and sulfonamides
• *Leptospira* spp: oxytetracycline, erythromycin, tiamulin, tylosin, tilmicosin, tulathromycin, ceftiofur
• *Listeria* spp.: tetracycline
• *U. diversum* and *Mycoplasma* spp.: tetracycline, tylosin
• *C. abortus*: tetracycline
• Epizootic bovine abortion: chlortetracycline

CONTRAINDICATIONS
N/A

PRECAUTIONS
Milk and meat withdrawal times should be followed.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Infected or exposed cows may develop natural immunity to some bacteria, with lower rates of abortion in subsequent breeding seasons.

POSSIBLE COMPLICATIONS
• Dystocia
• RFM
• Metritis
• Infertility

CLIENT EDUCATION
• Zoonotic potential. Wear protective gloves and clothes when handling aborted tissues and animals.
• Pregnant women, children, elderly and immunosuppressed people should not handle aborting animals or tissues.
• Keep aborted tissues refrigerated and call a veterinarian.
• Proper disposal of aborted tissues.

PATIENT CARE
• Monitor cow for RFM and metritis.
• Monitor herd for further abortions, stillbirths, or birth of weak calves.
• Change silage source (listeriosis).
• Adjust diet to eliminate ruminal acidosis and bacterial translocation.

PREVENTION
• Appropriate immunization program, nutrition, and environmental management.
• Test and quarantine new animals.
• Test and cull positive animals.
• Use virgin bulls and heifers for replacement.
• Use artificial insemination.
• Reduce contact with wildlife and rodents.
• Cure silage properly and avoid feeding spoiled material.
• Use fall calving season to prevent exposure of pregnant cows to ticks.
• Expose cows to ticks prior to breeding to stimulate natural immunity.

BASICS

OVERVIEW
Abortion in cattle is defined as loss of the fetus from 42 days to term. Prior to 42 days, pregnancy loss is considered embryonic mortality.

INCIDENCE/PREVALENCE
• Should be <5% on a herd basis (<1–2% ideal). • Abortion storms may occur in the case of specific infectious diseases. • In a 10-year study on bovine abortions and stillbirths, bacteria were determined to be the cause of 14.49% of the cases. The five bacteria most commonly associated with bovine abortion in the study were *Trueperella pyogenes*, *Bacillus* spp., *Listeria* spp., *E. coli*, and *L. interrogans*.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Reproductive • Other systems depending on cause

PATHOPHYSIOLOGY
• Cattle rely primarily on the corpus luteum (CL) for production of progesterone for the first 180–200 days of gestation, followed by a shift to production of progesterone by the placenta in late gestation. • Abortion may be caused by infectious or noninfectious etiologies. ◦ Infectious causes of abortion include bacteria, viruses, fungi, and protozoa. ▪ Bacteria involved in abortion can be grouped into contagious and opportunistic. ▪ Ability of a pathogen to damage the conceptus is influenced by the dam, stage of fetal development, and virulence of the infectious agent. ▪ The time between fetal death and expulsion may be characteristic for a pathogen. ◦ Noninfectious causes of abortion include nutritional imbalance, exogenous drug administration, malnutrition, stress, environmental toxins, teratogenic compounds, hormone imbalances, and genetic abnormalities. • Abortion may result due to fetal death following: ◦ Invasion by microorganisms through hematogenous spread, ascending infection or presence of organism in the uterus prior to conception. ◦ Placental disease or insufficiency due to hematogenous (umbilical veins) or amniotic fluid (i.e., fungal infections) contamination. Some pathogens may cause severe placentitis leading to fetal hypoxia and death. ◦ Maternal compromise (mastitis, pneumonia, circulatory disorder, hypoxia, endotoxemia, etc.). ◦ Severe congenital malformations in some etiologies.

HISTORICAL FINDINGS
• Introduction of new animals • Return to receptivity after confirmation of pregnancy • Bloody or mucopurulent vaginal discharge in the pregnant cow • Protrusion/expulsion of the placenta or fetus • Premature development of the mammary gland and lactation
A complete history should be taken from each aborting case and include the following information:
• Age, breed, lactation/parity, clinical signs of the aborting female. • Reproductive history (i.e. breeding technique, breeding dates). • Individual case vs herd outbreak ◦ Number of animals ◦ Health problems/body condition ◦ Herd abortion history • Treatments and vaccination administered in the preceding 2 weeks. • Animal movement within the last month. • Previous abortions and any workup performed. • Feeding/nutritional management, quality of pasture (toxic plants). • Layout of the facilities (water sources, proximity to other operations, etc.). • Contact with wildlife or feral cats and dogs.

SIGNALMENT
Females of breeding age

PHYSICAL EXAMINATION FINDINGS
• Physical examination findings and evidence of abortion will depend on the stage of gestation and the cause of abortion. • Clinical examination of the cow(s) should be taken into consideration: ◦ Body condition score. ◦ Thorough physical examination including temperature, pulse, respiration, mucus membrane color, hydration status, presence of vaginal discharge, etc. ◦ Demeanor. ◦ Visual abnormalities.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Causes of abortion can be classified as infectious (viral, bacterial, protozoal, fungal) or noninfectious (iatrogenic, maternal, fetal/placental, nutritional). • Noninfectious causes of abortion may be sporadic or affect several animals in the herd (nutritional deficiencies or administration of certain drugs). Infectious abortions are more likely to affect several animals within the herd simultaneously. • Risk factors include lack of biosecurity measures, presence of vectors or toxins, overcrowding, etc.

DIAGNOSIS

• The etiology of abortion is often difficult to determine and can be frustrating for owners and practitioners. Even when all required samples are submitted, the diagnostic rate is only 30%. • Abortion frequently results from an event that occurred weeks to months prior to the abortion event, making the diagnosis difficult in many cases. • Evaluation should include: ◦ Uterine cytology and culture (indicated in some cases) ◦ Serology ▪ Samples should be taken from the fetus (cardiac blood), from the aborting dam (paired samples) at abortion and 2 to 3 weeks later, and from at-risk pregnant females in the face of an outbreak. ▪ Samples from 10% of the herd will make serological assessment more meaningful. ◦ Bacteriology/Virology ▪ Samples should be taken from the fetus (stomach content, fetal fluids both thoracic and abdominal, kidney, liver, lung, spleen, and thymus), from the dam (vaginal discharge, uterine swab), and from the placenta. ▪ Samples should be collected using aseptic technique into sterile bags, refrigerated, and submitted to the diagnostic laboratory for further evaluation. ◦ Necropsy/Histopathology ▪ Digital photographs are helpful for documenting lesions. ▪ A complete set of tissues should be collected in every case. ▪ Fetal necropsy: Measurement of the crown–rump length and weight. External evaluation of the fetus for developmental abnormalities or lesions and evidence of autolysis, maceration, or mummification. Internal evaluation of the fetus. Either the entire fetus (optimal) or samples from the liver, brain, thymus, heart, spleen, kidney, stomach, lungs, skeletal muscle should be submitted fixed in formalin and fresh chilled to a diagnostic laboratory for further evaluation. Collection of ocular fluid (freeze) for nitrate/nitrite levels. ▪ Placental evaluation: External examination of the chorioallantois (including the cotyledons) and amnion. External examination for signs of placentitis (thickening, degradation, exudate). Examination for developmental abnormalities or lesions of the umbilical cord. Make impression smears of any lesions. Either the entire placenta or samples of both uterine horns and uterine body (cotyledons and intercotyledonary areas), along with any subjective abnormal areas, should be submitted fixed in formalin and fresh chilled for further evaluation.

DIFFERENTIAL DIAGNOSES

Infectious Causes of Abortion
• Viral causes of abortion: ◦ Bovine viral diarrhea virus (BVDV). ◦ Bovine herpesvirus 1 (BHV-1, infectious bovine rhinotracheitis; abortion storms affecting 25–60% in naïve pregnant cattle). ◦ Bovine herpesvirus 4 (BHV-4, often associated with other pathogens). ◦ Bluetongue virus (BTV). ◦ Epizootic hemorrhagic disease virus (EHDV). ◦ Rift Valley fever phlebovirus (RVF; mortality range 10–70% and abortion occurring at any gestational age reaching 80–90%). ◦ Akabane virus. ◦ Schmallenberg virus. • Bacterial causes of abortion: ◦ Brucellosis (*B. abortus*; in susceptible herds, abortion rates may be as high as 70%). ◦ Listeriosis (*L. monocytogenes*, *L. ivanovii*; abortions sporadic and rarely >15%). ◦ Campylobacteriosis (*C. fetus* subsp. *venerealis* (abortions <10% in infected herds), *C. fetus* subsp. *fetus*, *C. jejuni*). ◦ Leptospirosis (*L. interrogans* serovars Hardjo and Pomona most important causes of abortion, losses of

A

ABORTION: BOVINE (CONTINUED)

up to 50% may be experienced in some outbreaks). ◦ Tuberculosis (*Mycobacterium bovis*, *M. caprae*). ◦ Epizootic bovine abortion. ◦ *Histophilus somni* (formerly *Haemophilus somnus*). ◦ *Salmonella* spp. ◦ *Trueperella pyogenes* (formerly *Arcanobacterium pyogenes*). ◦ *Mycoplasma bovis*, *Ureaplasma diversum.* ◦ *Chlamydophila abortus* (lesser extent *C. psittaci.* ◦ *Coxiella burnetii.* ◦ Anaplasmosis (*Anaplasma phagocytophilum* has been known to cause abortion storms during first exposure to infected ticks during late pregnancy). ◦ Other opportunistic bacteria: *Escherichia coli*, *Pasteurella* spp., *Pseudomonas* spp., *Staphylococcus* spp., *Streptococcus* spp., *Bacillus* spp. • Protozoal causes of abortion: ◦ *Neospora caninum* (abortion only clinical sign in cattle). ◦ *Tritrichomonas foetus.* • Fungal causes of abortion: ◦ *Aspergillus* spp. (*A. fumigatus*; reported most common cause of mycotic abortion in cattle). ◦ *Candida* spp. ◦ *Zygomycetes.*

Noninfectious Causes of Abortion

• Iatrogenic causes of abortion: Administration of $PGF2_{\alpha}$ or glucocorticoids. • Maternal causes of abortion: ◦ Stress ◦ Systemic disease ◦ Hormonal imbalances, adrenal gland dysfunction (particularly in fiber-producing animals) ◦ Uterine/cervical pathology ◦ Trauma (hemorrhage during pregnancy). • Environmental/nutritional causes of abortion: ◦ Nutritional/trace mineral deficiencies. ◦ Toxic plants: pine needle; broom snakeweed; locoweeds; hairy vetch (sporadic abortions); poison hemlock (cattle surviving acute poisoning generally abort); high plant estrogens; plants that accumulate nitrates. ◦ Aflatoxins◦ *Fusarium graminearum* (zearalenone) ◦ Organophosphates ◦ Nitrate fertilizer ◦ Vitamin A, selenium deficiency/toxicosis, iodine deficiency. • Fetal/placental causes of abortion: ◦ Twinning ◦ Umbilical cord torsion ◦ Congenital anomalies

CLIENT EDUCATION
• Establish good preventative programs: biosecurity measures, immunization programs, adequate nutrition, parasite control. • Producers should have an intervention plan in case of abortion (isolation of affected females, collection of aborted materials for submission to veterinarian, examination of female and abortus). • Segregation of animals based on sex, age, and pregnancy status may help reduce transmission of infectious organism.

PATIENT CARE
• Dependent on the cause of abortion. • Isolation of affected cow(s) from remainder of the group. • Adequate nutrition, including balanced trace minerals, for the herd is important for elimination of some of the causes of abortion.

PREVENTION
• General prevention program for abortion (guidelines for biosecurity): ◦ Quarantine new animals (4 to 6 weeks) ◦ Nutrition ◦ Immunization program ◦ Keep feed, pasture, and water sources free from contamination ◦ Control rodent, bird, and feral animal populations. • Observe strict hygiene during parturition, keep good calving facilities. • Reduce stress due to poor nutrition, unsanitary environment, crowded conditions.

BASICS

OVERVIEW
Abortion is defined as loss of the fetus from 42 days to term. Prior to 42 days, pregnancy loss is considered embryonic mortality.

INCIDENCE/PREVALENCE
- Pregnancy loss ranges from 2 to 17%.
- Losses of up to 60% may be experienced in some leptospirosis outbreaks (i.e., leptospirosis, brucellosis).
- Loss of 40–50% have been reported in maiden females under some management systems.

GEOGRAPHIC DISTRIBUTION
Worldwide with some regional differences

SYSTEMS AFFECTED
- Reproductive
- Other systems depending on cause and complications

PATHOPHYSIOLOGY
- Camelids rely primarily on the corpus luteum (CL) for production of progesterone and maintenance of pregnancy for the entire gestation.
- Abortion is caused by any factor that causes directly or indirectly luteolysis:
  - Treatment with prostaglandin $F2_{\alpha}$
  - Inflammatory or infectious process
  - Endotoxemia
  - Stress such as heat stress or transport
  - Debilitating diseases
- Abortion can be caused by compromised fetal viability or placental integrity:
  - Placentitis
  - Placental insufficiency (endometrial fibrosis, uterine capacity in maiden females, twinning)
  - Direct insult to the fetus (mechanical or infectious)
  - Fetal malformation/abnormal pregnancy
  - Hormonal insufficiency or imbalance

HISTORICAL FINDINGS
- Presenting complaints may include:
  - Return to receptivity after confirmation of pregnancy
  - Bloody or mucopurulent vaginal discharge in the pregnant female
  - Protrusion/expulsion of the placenta or fetus
  - Premature development of the mammary gland and lactation
- A complete history of the aborting female(s) should include the following information:
  - Age
  - Reproductive history (breeding technique, pregnancy diagnosis, breeding dates)
  - Treatments and vaccination administered in the preceding 2 weeks
  - Animal movement within the last month
  - Possibility of heat stress
  - Feeding management
  - Layout of the facilities (i.e., proximity to stagnant water, run-offs from dairy or swine operations)
  - Contact with wildlife, feral cats

SIGNALMENT
Females of breeding age

PHYSICAL EXAMINATION FINDINGS
- Physical examination findings and evidence of abortion will depend on the stage of gestation and the cause of abortion.
- Anorexia or poor appetite.
- Increased rectal temperature, pulse and respiration are seen in some infectious conditions.
- Signs of colic are often reported prior to abortion particularly in late gestation.
- Emaciated or obese females.
- Mucopurulent or bloody vaginal discharge.

GENETICS
N/A

CAUSES AND RISK FACTORS
- Causes may be infectious or noninfectious (iatrogenic, fetal/placental abnormalities, nutritional, environmental, management).
- Abortion of noninfectious origin is usually sporadic. However, several animals in the herd may be affected in the case of nutritional deficiencies or administration of certain drugs.
- Infectious abortions are more likely to affect several animals within the herd simultaneously.

Infectious Causes of Abortion
- Viral causes:
  - Bovine viral diarrhea virus (most common serotype affecting alpacas and llamas is noncytopathic BVDV-1b)
  - Equine herpes virus-1 (potential)
  - Blue tongue virus (potential)
- Bacterial causes:
  - Brucellosis (*B. meletensis* and *B. abortus*)
  - Listeriosis
  - Chlamydiosis (*Chlamydophila abortus*)
  - Leptospirosis
  - Q fever (*Coxiella burnetii*, well-established cause of abortion in camels)
  - Hemorrhagic disease (*Bacillus cereus*, camels)
- Protozoal causes of abortion:
  - *Neospora caninum*
  - Toxoplasmosis
  - Trypanosomiasis (camels)

Noninfectious Causes of Abortion
- Iatrogenic causes of abortion:
  - Administration of $PGF2_{\alpha}$
  - Administration of corticosteroids (even topical) in the second half of pregnancy
  - Some multivalent vaccines (8-way vaccines against *Clostridium* spp.)
  - Ecbolic drugs
- Maternal causes of abortion:
  - Hypoluteoidism (luteal insufficiency)
  - Stress
  - Systemic disease
  - Hormonal imbalances, adrenal gland dysfunction (particularly in fiber-producing animals)
  - Uterine/cervical pathology
  - Trauma (hemorrhage during pregnancy)
- Nutritional causes of abortion:
  - Nutritional/trace mineral deficiencies (selenium)
  - Toxic plants (limited information available in camelids)
- Fetal/placental causes of abortion:
  - Twinning
  - Umbilical cord torsion
  - Congenital anomalies
  - Placental insufficiency

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Evaluation of the female should include:
- Transabdominal ultrasonography
- Vaginal speculum examination
- Uterine cytology, culture, and biopsy may be indicated in some cases.
- Serology
  - Samples should be taken from the fetus (cardiac blood), from the aborting dam (paired samples) at abortion and 2 to 3 weeks later, and from at-risk pregnant females in the face of an outbreak.
- Bacteriology
  - Samples should be taken from the fetus (stomach content, fetal fluids both thoracic and abdominal), from the dam (vaginal discharge, uterine swab), and from the placenta.
- Necropsy/Histopathology
  - Fetal necropsy:
    - Measurement of the crown–rump length.
    - External evaluation of the fetus for developmental abnormalities or lesions.
    - Either the entire fetus or samples from the liver, brain, spleen, kidney, stomach, and lungs should be submitted fixed in formalin and fresh chilled to a diagnostic laboratory for further evaluation.
  - Placental evaluation:
    - External examination of the chorionic surface for lack of villi (placental insufficiency) or signs of placentitis (thickening, degradation, exudate).
    - The umbilical cord is examined for abnormalities or inflammatory lesions.
    - The entire placenta or samples of both uterine horns and uterine body, along with any abnormal areas, should be submitted fixed in formalin and fresh chilled for further evaluation.
- Endocrinology
  - In cases of habitual abortion, progesterone determination during pregnancy may be indicative of possible luteal insufficiency. Pregnant females with progesterone levels

ABORTION: CAMELID (CONTINUED)

<2 ng/mL should be considered suspicious. However, some females may be able to carry a pregnancy to term even if progesterone levels are 1.5–2 ng/mL.

CBC/BIOCHEMISTRY/URINALYSIS
May be indicated depending on disease condition

OTHER LABORATORY TESTS
See "Diagnosis"

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
See "Diagnosis"

PATHOLOGIC FINDINGS
- Studies on pathological findings in camelid abortion are scarce.
- Placentitis is a common feature in bacterial and fungal abortions.
- Placental insufficiency is often suspected if large avillous areas are seen on the placenta.
- Fetal abnormalities are common.

TREATMENT

THERAPEUTIC APPROACH
- Dependent on the cause of abortion
- Abortion due to hypoluteoidism
  - Requires progesterone supplementation (injections of progesterone or hydroxyprogesterone caproate, norgestomet implant). Altrenogest is not active orally in camelids.
  - Hydroxyprogesterone caproate 250 mg, IM, every 3 weeks with treatment discontinued at 300 days to allow normal parturition.
  - Fetal viability should be monitored regularly if progesterone supplementation is implemented.
- Placental insufficiency
  - Early diagnosis and termination of twins.
  - Early diagnosis of uterine fibrosis (uterine biopsy) and sexual rest.

POSSIBLE COMPLICATIONS
Dystocia, metritis, endometritis, retained placenta, infertility

CLIENT EDUCATION
- Pregnancy should be monitored in the first 60–90 days of gestation.
- Producers should have a plan if an abortion occurs (isolation of affected females, collection of aborted materials for submission to veterinarian, examination of female and abortus).
- Adequate nutrition, parasite control, and immunization programs for the herd are important for preventing some causes of abortion. Segregation of animals based on sex, age, and pregnancy status may help reduce transmission of infectious organism.
- Adequate nutrition, including balanced trace minerals, for the herd is important for elimination of some of the causes of abortion.

PATIENT CARE
- Depends on the cause of abortion and complications.
- Supportive care is important in debilitated animals.

PREVENTION
- Observe strict hygiene in breeding management.
- Set up guideline for biosecurity: quarantine new animals; during movement of animals between shows and ranch, visiting animals for breeding.
- Isolate any aborting female until diagnosis is established.
- Vaccination for leptospirosis (4 times a year in high-risk situations).

BASICS

OVERVIEW
• Definition: Loss of an embryo or fetus
• Causes may be infectious, environmental, congenital or idiopathic

INCIDENCE/PREVALANCE
The incidence of pregnancy loss in farmed deer is relatively low.

GEOGRAPHIC DISTRIBUTION
N/A

SYSTEMS AFFECTED
• Reproductive • Others depending on cause

PATHOPHYSIOLOGY
• Pathophysiology depends on etiology.
• Infectious: organism spreads to gravid uterus and may cause death of the embryo/fetus or placentitis, which leads to placental separation; absorption or expulsion of the conceptus. • Environmental: as in other ruminant species, stress, malnutrition, or toxins can adversely affect oocyte or embryo quality or hormonal regulation in the female.
• Congenital: placental dysfunction or fetal abnormalities usually result, leading to premature expulsion of the fetus.

HISTORICAL FINDINGS
• If fetus is resorbed early in gestation, there may be no findings except missed due date from an expected or confirmed pregnancy. • If pregnancy had been confirmed early in the season, a female may come back into estrus.
• If abortion occurred early in the season, the female may give birth much later than the rest of the herd if re-mating occurred. • If abortion occurred late in the pregnancy, discovery of expulsed fetus. • Female may show signs of imminent parturition (i.e., seeking isolation, restlessness) before expected due date.

SIGNALMENT
• Commonly studied species include those within the genera *Cervus* (red deer, wapiti), *Dama* (fallow deer), *Axis* (chital deer), *Rangifer* (reindeer), *Odocoileus* (white-tailed deer, black-tailed deer, mule deer), *Alces* (moose), *Capreolus* (roe deer), *Ozotoceros* (Pampas deer), *Elaphurus* (Père David's deer), *Rucervus* (swamp deer, Barasingha). • Females of breeding age.

PHYSICAL EXAMINATION FINDINGS
• Likely no visible signs if fetal resorption occurred early in gestation. • If suspected, fetal/embryonic loss can be confirmed by transrectal palpation (in wapiti) or transrectal ultrasonography. • A female with an impending or unobserved late-term abortion may exhibit the following clinical signs:
◦ Bloody or purulent vaginal discharge
◦ Presence of expulsed fetus and/or placenta
◦ Premature udder development and dripping
◦ Nonspecific signs of illness, such as depression, dehydration, pyrexia, anorexia, or weight loss. • An impending late-term abortion may be suspected if the female begins showing signs of imminent parturition before expected due date. • Late-term abortions in cervids may go unobserved if the female eats the placenta and/or a predator consumes the dead fetus. Observation of alternative clinical signs or ultrasound may be able to confirm the loss of a fetus.
• Brucellosis-induced abortion in female reindeer is characterized by a retained placenta and metritis. • Bovine viral diarrhea virus and cervid herpesvirus 2 can both cause ulceration and/or pustules in oral or vulvar mucosa.

GENETICS
N/A

CAUSES AND RISK FACTORS
The major risk factors for abortion are poor herd management ranging from inadequate nutrition to stressful handling to poor biosecurity protocols.

Metabolic Causes
Febrile or severely stressed animals may abort. This may result from factors ranging from environmental (i.e., temperature) to iatrogenic (i.e., excessive handling).

Nutritional Causes
• Inadequate nutrition: Pregnant white-tailed deer females experience a 16% increase in fasting metabolic rates during gestation, 92% of which is in the 3rd trimester in early spring. Females with adequate body condition entering the winter months are more likely to have adequate fat reserves to fulfill gestational requirements in the event of prolonged winter. Females with inadequate fat reserves or that do not receive adequate nutrition in the spring may abort or give birth to nonviable or underweight calves. • Iodine deficiency: Abortion and stillbirth have been reported in cervid species due to iodine deficiency. The deficiency may be caused by insufficient dietary intake, or be secondary to excessive calcium in the diet, ingestion of toxic plants such as *Brassica* spp., gross bacterial contamination of the feed, continuous intake of feeds containing cyanogenetic glucosides (e.g., white clover), or ingestion of canola (rapeseed and canola meal). • Vitamin E and/or selenium deficiency: Congenital white muscle disease has been reported in several deer species and can be fatal to the neonate.

Bacterial Causes
• *Brucella abortus*: Biovars 1 and 4 have been recovered from wild elk in the Yellowstone area of the US. Natural infections have not been reported in axis deer, white-tailed deer, or mule deer, but experimental infections have been established in all three, suggesting potential for interspecies transmission.
• *Brucella suis* biovar 4: Brucellosis is the most common cause of abortion in reindeer and caribou and is endemic in some populations in the Arctic. Natural infection has not been reported in white-tailed deer or mule deer, but experimental infections have been established in both, suggesting possibility for interspecies transmission. • Leptospirosis: Studies in red deer showed reproductive effects, mostly reduced weaning rates, but no reports of abortions. Abortions following experimental inoculation with *L. pomona* have been demonstrated in white-tailed deer, demonstrating its abortigenic potential in cervid species. • Listeriosis: The septicemic form has been reported to cause placentitis and endometritis in farmed red deer, leading to abortion in late-term pregnancy and birth of weak, full-term young. It should be considered as a potential cause of abortion in any cervid species.

Fungal Causes
Incidence of fungal infections in cervid species is very low.

Parasitic Causes
• *Toxoplasma gondii*: Toxoplasmosis has been associated with encephalitis and placentitis in a full-term stillborn reindeer fetus. In red deer, seropositive females experience adverse effects on fetal development. • *Neospora caninum*: Seroprevalence in asymptomatic animals has also been reported in many cervid species; however, there have been reports associated with full-term stillborn Eld's deer and perinatal death in fallow deer and axis deer following suspected vertical transmission.

Viral Causes
• Bluetongue (BTV; orbivirus): Infection of cervid species generally leads to hemorrhagic disease and death. Under experimental inoculation, early embryonic absorption and fetal death were both reported in white-tailed deer. • Epizootic hemorrhagic disease (EHDV; orbivirus): Usually resulting in widespread hemorrhages, dehydration, and sudden death. EHDV has been reported to cause abortion and congenital lesions in cattle and, therefore, cannot be ruled out as a potential cause of fetal death in deer. • Bovine viral diarrhea virus (BVDV; pestivirus): BVDV has been isolated from many cervid species. A wide seroprevalence to BVDV has also been reported in surveys of wild ruminants in North America. Cervid species experimentally inoculated with cattle-derived BVDV experienced mild or no clinical disease. Experimental inoculation with a deer-derived BVDV strain in white-tailed deer resulted in fetal abortion and resorption and establishment of persistently infected (PI) carrier animals, similar to those effects observed in cattle, indicating a potential for natural infection. • Cervid herpesvirus 2 (CvHV-2; Varicellovirus): Endemic in Norway reindeer populations. Reports of vertical transmission and neonatal death in experimentally infected reindeer suggest an abortogenic potential, though this has yet to be reported in naturally occurring abortions.

A

ABORTION: FARMED CERVIDAE (CONTINUED)

Other Causes

• Other causes of abortion or stillbirth include toxicoses, traumatic injuries, congenital abnormalities, and administration of some drugs. • Locoweed causes abortions in sheep and cattle and may be a problem for cervidae as well. • Congenital abnormalities, fetal oversize, or abnormalities of presentation at time of parturition are rare, but may lead to dystocia and subsequent fetal death.
• Prostaglandins and steroids can induce fetal expulsion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Vaginal discharge ◦ Normal term parturition ◦ Vaginitis ◦ Pyometra ◦ Metritis ◦ Uterine trauma or hemorrhage ◦ Uterine or vaginal neoplasia • Missed due date ◦ Infertility, either male or female (if pregnancy was not confirmed) ◦ Incorrect due date • Signs of impending parturition before due date ◦ Isolation: may indicate neurologic disease ◦ Abdominal straining: colic due to bloat (frothy vs. free gas) or other GI disease.

CBC/BIOCHEMISTRY/URINALYSIS

Little data is available on routine analyses but may be extrapolated from domesticated ruminants based on cause of abortion.

OTHER LABORATORY TESTS

Pregnancy Diagnosis and Monitoring

Maternal pregnancy-specific protein B (PSPB): Bovine pregnancy-specific protein B antibody cross reacts with caribou, red, fallow, and white-tailed deer PSPB and, therefore, commercial radioimmunoassay developed for cattle can be used for pregnancy diagnosis and monitoring in cervids.

IMAGING

• Transrectal ultrasonography: Used for early pregnancy detection (30–60 days) and fetal monitoring. • Transabdominal ultrasonography: Can be performed in smaller cervid species as early as 35 days and used to count the number of fetuses if performed within the first 2 trimesters.

OTHER DIAGNOSTIC PROCEDURES

Necropsy and sample collection of aborted fetus and placenta should occur as soon as possible to minimize secondary bacterial overgrowth. It may be difficult to obtain the placenta as the female usually ingests it. In herd outbreaks, it may be worthwhile to sacrifice a female for postmortem diagnosis if fetal tissues are inconclusive. Paired serology that shows rising antibody titers in the female may also be beneficial for antemortem diagnosis in some cases.

Bacterial Abortions

• Brucellosis: Four serological tests available – card test, standard plate agglutination test (SPT), complement-fixation (CF) test, and rivanol test. ◦ Positive serology requires that a confirmatory test be performed. This includes culture and isolation of *Brucella* from tissues, secretions, or excretions. ◦ Test results must be reported to state and federal animal officials.
• Leptospirosis: ◦ Paired serology: Microscopic agglutination test (MAT) and enzyme-linked immunosorbent assays (ELISAs); MAT will evaluate response to a selection of serovars.
◦ Immunohistochemistry (IHC) staining or polymerase chain reaction (PCR) on aborted tissue. • Listeriosis: ◦ In captive species, cerebrospinal fluid analysis can show a markedly elevated protein concentration and neutrophilic pleocytosis. These results combined with neurologic manifestations are almost pathognomonic for listeriosis, though no pre-mortem confirmatory test is currently available. ◦ Anti-Listeria IHC from the brainstem in deceased animals is quick and most effective for verifying the diagnosis.

Parasitic Abortions

• Toxoplasmosis or Neospora: ◦ Serology: Indirect or direct hemagglutination, indirect immunofluorescent antibody test, ELISA. ◦ Real-time PCR or IHC on aborted tissue.

Viral Abortions

• BTV or EHDV: Serology (competitive ELISA, agar gel immunodiffusion, microtiter virus neutralization (MVN)); IHC, PCR, virus isolation of aborted tissue. • BVDV: Paired serology (MVN; ELISA); virus isolation from blood or nasal secretions; IHC of aborted tissue. • CvHV-2: Serology (ELISA); PCR from tissues samples, nasal swabs, trigeminal ganglia samples.

PATHOLOGIC FINDINGS

Depends upon etiology.

Bacterial Abortions

• Brucellosis: Necrotizing placentitis characterized by a thickened placenta covered with a purulent exudate. • Leptospirosis: Gross lesions in aborted white-tailed deer fetuses (following experimental inoculation with *L. pomona*) included swollen, hemorrhagic, pulpy kidneys, liver, and lymph nodes. • Listeria: Evidence of fibrinopurulent to necrotizing placentitis on histopathology; fetuses may have either have no gross lesions or suppurative pneumonia and meningitis.

Parasitic Causes

Toxoplasmosis: Necrotizing placentitis and multifocal nonsuppurative encephalitis of the fetus with presence of tissue cysts histologically in sections of brain and tachyzoites in placenta and myocardium that stain positive with *T. gondii* antibodies.

Viral Causes

• BVDV: Abortion patterns are similar to those observed in cattle with fetal death occurring at variable stages of gestation, resulting in variable autolysis or mummification and a variety of dysplastic lesions. • CvHV-2: No specific gross pathologies have been described in aborted fetuses, but severe autolysis has been noted. Affected reindeer cows have demonstrated mild to moderate interstitial verminous pneumonia.

Fungal Causes

Granulomas (gross), fungal hyphae (histopathology) on affected organs.

TREATMENT

THERAPEUTIC APPROACH

N/A

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

• Dependent upon etiology. • Broad-spectrum antibiotics: Indicated for specific bacterial diseases; long-acting antibiotics require less frequent dosing and will help to minimize stress of handling. • Anti-inflammatories: Flunixin meglumine (1.1–2.2 mg/kg IV) or meloxicam (0.5 mg/kg PO) can be administered once daily.

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Dependent upon underlying cause. • BTV and EHDV are most likely to cause rapid, acute death. • CvHV-2 may become latent and recrudesce during periods of stress.
• BVDV may lead to persistently infected animals that can shed the virus throughout their lifetime.

POSSIBLE COMPLICATIONS

• Decreased fertility, increased morbidity in females • Dystocia, uterine infection

CLIENT EDUCATION

See "Biosecurity" and "Production Management"

PATIENT CARE

• In cases of single abortion, important to watch entire herd to ensure no outbreak ensues. • Appropriate health care should be

provided based on the underlying etiology. • Supportive care (IV fluids, anti-inflammatories ± antibiotics) for systemic illness. • If suspected nutritional issue, have feed analysis performed to determine underlying deficiency or toxicity. Change feed or supplement nutrients as necessary. • If listeriosis or mycotoxins are suspected, make appropriate changes to silage feeding practices.

PREVENTION

Establish a good nutritional and preventive health program.

Brucellosis

• USDA-APHIS have published minimum program standards and procedures to eradicate and monitor brucellosis in farm or ranch-raised deer. Required cervid surveillance identification tests include: ◦ Interstate movement tests: All sexually intact animals 6 months of age or older must test negative for brucellosis within 30 days prior to interstate movement, with a 90-day post-movement test strongly recommended. ◦ Slaughter establishment tests: All test-eligible animals are blood-sampled at slaughter and tested for brucellosis. • Certified brucellosis-free cervid herds are exempt from testing requirements for interstate movement. • In infected herds, test and removal programs may be practical for intensively managed deer farms but not for game or wildlife parks. • No recommended vaccine is currently available for most cervid species. • *Brucella suis* biovar 4 (killed) vaccine has been shown to be useful for providing protection in reindeer.

Leptospirosis

Extra-label use of cattle vaccine available in the US.

Bluetongue and EHD

• Parasite control should be implemented to decrease the number of arthropod vectors (e.g., *Culicoides* spp. or gnats). • Autogenous vaccines are available through Newport Laboratories.

BVDV

Fencing of adequate height and double fencing are recommended in order to prevent direct contact and disease transmission between captive and wild cervids.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Dystocia, infertility

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

Brucellosis, toxoplasmosis, leptospirosis, and listeriosis are all zoonotic diseases; appropriate precautions should be taken when handling fetal or placental tissues.

PREGNANCY

N/A

BIOSECURITY

• Quarantine newly acquired animals for 30 days minimum. • Pre-shipment testing for infectious diseases. • Double fences to minimize direct contact with wildlife species.

PRODUCTION MANAGEMENT

• Monitoring birthweight and growth of young animals and keeping records of previous reproductive performance of females will allow owners to make appropriate herd management decisions. • Habituating animals to gates and chutes makes handling during physical exams and other routine procedures less stressful on the animals. • Adequate nutritional management is crucial. Females should have a body condition score of 3–5 out of 9 to even be considered for breeding. Overweight females may be at increased risk for dystocia whereas underweight females are at an increased risk for abortion. • Close monitoring during gestation will be beneficial in the event of an abortion.

SYNONYMS

A

ABORTION: SMALL RUMINANT

BASICS

OVERVIEW

• Fetal loss, fetal wastage: conceptus loss at any time during pregnancy. • Most commonly observed in the last 2 months of pregnancy.

INCIDENCE/PREVALENCE

• Flock pregnancy loss should be <5% (<2% ideal). • Abortion storms may occur in the case of specific infectious diseases.

GEOGRAPHIC DISTRIBUTION

• Worldwide • Some diseases processes may be regional (presence of vector)

SYSTEMS AFFECTED

• Reproductive • Other systems depending on etiology

PATHOPHYSIOLOGY

• Abortion results from: ◦ Fetal death from invasion by microorganisms or subsequent to placental disease (placentitis, vasculitis) and placental insufficiency. ◦ Fetal expulsion or premature parturition may result from maternal compromise. ◦ Reabsorption, maceration, mummification, and autolysis may be observed in some cases. ◦ Fetal abnormalities are often a feature of some viral infections. • Causes include a variety of infectious and noninfectious agents.
• Infectious causes of abortion are the most economically significant. • Common bacterial causes are *Chlamydophila abortus*, *Coxiella burnetii*, *Toxoplasma gondii*, and *Campylobacter* spp. • Common viral causes include caprine herpesvirus (CpHV-1), bluetongue virus, BDV, Cache Valley virus.

GENETICS

• Angora goat may be a habitual aborter.
• Some breeds of sheep are more susceptible to viral bluetongue (Merino, British breeds).

HISTORICAL FINDINGS

• Introduction of new animals • Repeat breeding or return to estrus • Premature udder development • Presence of expelled fetuses
• Premature/stillbirths • Increased congenital abnormalities in neonates or fetuses

SIGNALMENT

Nonspecific; females of breeding age that were exposed to the male or inseminated.

PHYSICAL EXAMINATION FINDINGS

• Mucopurulent or hemorrhagic vaginal discharge containing fetal membranes in early pregnancy loss. • Signs of abortion: vaginal discharge vulvar edema, retained placenta.
• Systemic signs such as fever, anorexia may be present. • Other signs in flock: abnormal fetuses, sick or ill-thrift lambs and kids).
• Clinical signs in the aborting female vary depending on the cause. • Complications depend on cause (deterioration of health, retained placenta, metritis).

Clinical Signs

• Several infectious abortions are subclinical in the dam (Cache Valley, Border disease, caprine herpesvirus, Schmallenberg, Q fever).
• Bluetongue: Febrile, swollen tongue, ear or face, lameness, ulcerative lesions on month.
• Campylobacteriosis: Aborting goats may show diarrhea. • Chlamydiosis: Pneumonia, keratoconjunctivitis, epididymitis, and polyarthritis. Anorexia, fever, bloody vaginal discharge 2 to 3 days before abortion.
• Brucellosis (*B. melitensis*) in goats: weak kids and mastitis. Aborting goats may experience fever, depression, weight loss, mastitis, and lameness. • *B. ovis* in sheep: Rarely a cause of abortion but is responsible for poor reproductive performance and in the ram contagious epididymitis. • Leptospirosis: Anorexia, fever, marked jaundice, hemoglobinuria, anemia, neurological signs, abortion, occasionally may be fatal.
• Salmonellosis: Abortion, retained placenta, metritis, and various systemic signs (fever, depression, diarrhea). Mostly in overcrowded flocks. • Toxoplasmosis: Generally no clinical signs; immunocompromised females may present a neurologic form of the disease.
• Leptospirosis: Septicemia, fever, decreased appetite, reduced milk production, abortion, and meningoencephalitis. • Mycoplasmosis (goats): Mastitis, arthritis, keratoconjunctivitis, vulvovaginitis, and abortion in the last 3rd of pregnancy.

CAUSES AND RISK FACTORS

• Causes of abortion include: ◦ Viruses: bluetongue, BDV, CpHV-1, CVV, RVF, Akabane, Nairobi, Wesselsbron ◦ Bacteria: *Brucella* spp. (*B. ovis*, *B. melitensis*), *C. fetus* subsp. *fetus*, *C. jejuni* subsp. *Jejuni, Chlamydophila abortus, Francisella tularensis, Leptospira* spp., *Listeria monocytogenes* and *L. ivanovii, Salmonella abortus-ovis* ◦ Rickettsia: *Coxiella burnetii* ◦ Protozoa*: Sarcocystis*, *Neospora caninum*, *Toxoplasma gondii* ◦ Toxic plants: annual ryegrass, *Gutierrezia microcephala* (broomweed, snakeweed), locoweed, subterranean clover, *Veratrum californicum* (skunk cabbage) ◦ Mineral deficiencies: copper, iodine, selenium • Risk factors include: ◦ Lack of biosecurity measures ◦ Vector or reservoir population: bluetongue, CVV, Rift Valley fever, Akabane, Nairobi sheep disease, Wesselsbron disease virus, *Coxiella burnetii* (ticks), *Leptospira* spp., *Neospora, T. gondii* ◦ Overcrowding ◦ Pasture type

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Brucellosis

• Isolation: Best samples are vaginal discharges and milk, stomach contents. • Indirect diagnosis: Complement fixation, agglutination, and precipitation tests may help identify carrier animals.

Chlamydiosis (Enzootic Abortion)

• *C. abortus*, Gram-negative intracellular organism. • Abortion and other clinical signs in neonates. • Aborting females become immune. • Females infected after 100 days of pregnancy may not abort. • Diagnosis: ◦ Generalized placentitis, abortion in the last month of pregnancy, high incidence in newly infected flocks. ◦ Demonstrations of characteristic inclusion bodies on smear from cotyledons, vaginal discharge, fetal stomach content. ◦ Culture from vaginal discharge, placenta and fetal tissue, PCR. ◦ Serology: paired samples from dam and fetal serum. ◦ ELISA or indirect inclusion fluorescence antibody tests (IIFA).

Toxoplasmosis

• Goats more susceptible than sheep
• Diagnosis: ◦ Cotyledons are gray-white to yellow and present small 1–3 mm focal area of necrosis and calcification. Intercotyledonary areas are generally normal. Macroscopic lesions: 2–3 mm necrotic foci on cotyledons, intercotyledonary allantochorion are generally normal. Fetus may be mummified or decomposed. Chalky white necrotic brain lesions. ◦ Samples: placenta, fetal brain, fetal fluids, maternal blood, precolostral blood. ◦ Isolation from cotyledons, brain and fetal fluids, tissues (shipped packed in ice). ◦ Histopathology: fixed cotyledons, fetal brain. ◦ Serology: presence of antibodies in fetal fluids or precolostral serum is the preferred diagnostic technique and indicated transplacental infection.

Q Fever (Coxiella burnetii)

• Placentitis, placental necrosis, thickening of the intercotyledonary areas. Abortion and stillbirth. • Isolation: Placenta, vaginal discharges, fetal stomach content. • PCR techniques are available. • Demonstration of organism by Ziehl-Neelsen staining.
• Complement fixation: Need samples from several animals. • Fluorescent antibody test may be used to identify organism in frozen section of placenta.

Campylobacteriosis

• Campylobacter fetus subsp. fetus, C. jejuni subsp. jejuni, and Campylobacter lari.
• Gram-negative microaerophilic rods.
Symptoms
• Late term abortion, stillbirths and weak lambs, retained fetal membranes. • Placentitis, placental edema. • Fetal lesions: Hepatomegaly, hemorrhagic liver, necrotic foci of 1–3 cm, subcutaneous edema, sero-sanguinous fluid in abdominal and thoracic cavity, bronchopneumonia.
• Histopathology: Necrotic areas of the chorionic villi, arterioles and thrombosis of the hilus of the placentomes.

Isolation and Identification
• Samples: Placenta and vaginal discharges, frozen fetal stomach content (–20°C). • Transport medium required. • Isolation from placenta, vaginal discharge, fetal stomach content.

Salmonellosis
• *Salmonella abortus-ovis, S. barndenburg, S. typhimurium, S. dublin, S. montevideo, S. arizona, S. oranienburg.* • Early, mid or late term abortions, septic metritis, peritonitis in aborting females. Fetuses are often autolyzed. Lambs may be born weak or develop bronchopneumonia. Placentitis, placental edema. • Direct diagnosis: Culture from fetal tissues taken aseptically may be preserved at –20°C, placenta and uterine discharges. • Indirect diagnosis: Seroagglutination.

Listeriosis (Listeria monocytogenes)
• Gram-positive, non-acid-fast facultative microaerophilic organisms. *L. monocytogenes* affects sheep and goats; *L. ivanovii* affects sheep only. • Females may show fever, depression, and anorexia prior to abortion mid to late pregnancy. Stillbirths, birth of weak lambs, and retained placenta are common. Fetuses may be mummified. • Direct diagnosis: Placenta, fetal liver and spleen, fetal stomach content, vaginal discharge within 48 hours of abortion. Samples may be refrigerated if not cultured immediately. • Indirect diagnosis: Histopathology on placenta, fetal liver and spleen- microabscesses (white pinpoint spots), necrosis, and infiltration of macrophages and neutrophils. Gram stain reveals numerous Gram-positive rods.

Leptospirosis
• Sheep and goats are generally less susceptible to leptospirosis than other species. Goats are more susceptible than sheep. • Sheep: mostly *L. hardjo,* sometime *L. pomona*, *L. ballum* and *L. bratislava*, late term abortion, stillbirths, and ill-thrifty lambs. • Goat: *L. icterohaemrrhagiae*, *L. pomona*, *L. grippotyphosa.* • Affected flocks are mostly reared indoors. • Clinical signs in case of acute infection include fever and agalactia. Abortion occurs in late pregnancy. • Direct diagnosis: Fetal tissue, fetal fluids, and placenta. ◦ Isolation is difficult. ◦ Demonstration by dark-field microscopy, immunofluorescence, and silver stain. • Indirect diagnosis: ◦ Serology: macroscopic agglutination test.

Border Disease
• Goats are fairly resistant. • Viremic animals may show fever. Fetal death and resorption when infected in the first 2 months of pregnancy. Infection after 60 days results in fetal death, mummification or abortion, and fetal abnormalities. • Virus isolation (buffy coat) and antigen demonstration: Heparinized blood from dam or hairy shaker lambs, fetal tissue (thyroid, kidney, spleen, cerebellum, placenta), hairy shakers (thyroid, kidney, spleen, cerebellum, intestine, lymph nodes). • Histopathology: Cerebellum (white matter necrosis and gliosis), spinal cord. • Serology: Flood from dam and hairy shakers. • Clinical: Small cotyledon with focal necrosis, hairy shakers.

Bluetongue
• Viral isolation: Blood, semen, fetal brain and spleen. Unlikely cause of abortion in goats.

Akabane Disease
• Fetal malformation, positive antibody titer in liveborn and aborted fetuses.

Cache Valley Virus
• Congenital abnormalities. • Detection of antibodies in fetal fluids or precolostral serum.

Mycoplasmosis
• Mycoplasma abortions (*M. mycoides*, *M. agalactiae)* are significant in goats. • Diagnosis: Culture and serotyping of the isolate from milk, fetal fluids, and placenta.

Noninfectious Causes of Abortion
• Genetic (goat) may be a habitual aborter ◦ Angora goats with fine mohair ◦ Abortion at 100 days ◦ Adrenal dysfunction • Energy protein deficiency • Phenothiazine and levamisole in the last 2 months of pregnancy • Corticosteroids in late gestation • Prostaglandin $F2_{\alpha}$ or analogues (goats) • Plants that accumulate nitrates

CBC/BIOCHEMISTRY/URINALYSIS
May be indicated if aborting dams are clinically sick.

OTHER LABORATORY TESTS
• Sampling is critical for the proper diagnosis of abortion. • Placenta ◦ Ideal for the isolation of most abortion-causing agents. ◦ Ideal for identification using specific staining techniques on histological section or impression smears. ◦ For isolation need 5 or 6 cotyledons and section of intercotyledonary spaces both from healthy appearing and diseased areas. ◦ These tissues may be rinsed with sterile saline. ◦ For isolation need a transport medium ■ Viruses ■ *Campylobacter* FBP/glycerol ■ Leptospirosis 100 mL extender with 1% BSA ◦ For histopathology ■ 0.5 cm section of tissue in 10% formalin 1:10 ◦ For bacteriology ■ Impression smears • Vaginal discharges ◦ Collect in sterile manner ◦ Vaginal/uterine swabs ◦ Use of specific transport medium is preferred if a specific microorganism is suspected. • Fetal tissues ◦ Tissue samples from all fetal organs (spleen, liver, kidneys, brain, lymph nodes, spinal cord) should be taken in an aseptic manner immediately after abortion or death. ◦ Handle in the same manner as for placenta. • Fetal fluids ◦ If fetus is not autolyzed ◦ Stomach content ◦ Peritoneal/thoracic fluids ◦ Blood from the cardiac cavity • Milk ◦ Samples of milk are taken from both glands using aseptic techniques (clean the mammary gland, disinfect teats, and eliminate the first 2 jets). • Blood ◦ For isolation: immediately after/during abortion. ◦ For serology: paired samples immediately after abortion and 2 to 3 weeks later ◦ In case of an outbreak, blood should be collected from aborting females as well as from lambs/kids before colostral intake.

IMAGING
N/A

PATHOLOGIC FINDINGS
Abortion Associated with Deformities
• Bluetongue: Hydranencephaly. • Akabane disease: Arthrogryposis (dystocia), hydranencephaly, and mummification. • Cache Valley virus: Arthrogryposis, brachygnathia, hydranencephaly, microencephaly, spinal cord hypoplasia, and mummification. • Border disease virus: Cerebellar hypoplasia, hydranencephaly, brachygnathia, arthrogryposis. Dark pigmentation of the fleece, hairy shaker. • Toxic plants: Lupine, skunk cabbage, locoweed, and Sudan grass. • Iodine, copper, manganese deficiency.

TREATMENT

THERAPEUTIC APPROACH
Depends on etiology and complications following abortion

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Depends on etiology and complications following abortion. Daily tetracycline treatment of the flock may help with some of the abortion-causing diseases. • Broad-spectrum antibiotics and anti-inflammatory therapy. • *Campylobacter*: Penicillin or streptomycin or tetracycline in feed some strains are resistant. • Chlamydiosis: Tetracycline, Tylosin • Leptospirosis: Tetracycline • Toxoplasmosis: Decoquinate, monensin • Leptospirosis: Tetracycline • Mycoplasma: Tetracycline and tylosin

CONTRAINDICATIONS
Appropriate milk and meat withdrawal times must be followed.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

A

ABORTION: SMALL RUMINANT (CONTINUED)

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Dependent upon underlying cause.

POSSIBLE COMPLICATIONS
Dystocia, retained placenta, metritis, mastitis, male infertility (brucellosis, chlamydiosis), female infertility, poor lactation, neonatal losses.

CLIENT EDUCATION
• Establish good preventive program (biosecurity measures, vaccination, good nutritional programs). • Consider every case of abortion as a possible outbreak. • Act quickly and help collect appropriate samples to be examined by a veterinarian. • Zoonotic risk awareness.

PATIENT CARE
• Frequent monitoring of late term females in the entire herd or flock. • Correct nutritional deficiencies if suspected. • Avoid toxic plants and mycotoxins if suspected.

PREVENTION
• Assess disease risk and set up preventive measures. ◦ Toxoplasmosis: cat population. ◦ Leptospirosis: rodent population, humid hot environment, proximity to dairy and swine operation. ◦ Salmonellosis: source of infection: bird, cattle, wildlife, predisposing conditions: overcrowding, shipping, climatic changes ◦ Chlamydiosis ▪ Infection transmission: placenta, fetal fluids ▪ Pigeon/sparrows are reservoirs, ticks or insects may play a role ▪ Vaginal discharge in goat up to 2 weeks before abortion ▪ Reservoir: young maiden females ◦ Listeriosis ▪ Organisms grow in poorly fermented silage ▪ Can survive in soil and feces for extended period of time ◦ Bluetongue: *Culicoides* gnat (cattle may be a reservoir) ◦ Akabane virus diseases: gnats and mosquito population ◦ Cache Valley virus: mosquitoes • General prevention program for abortion ◦ Quarantine new animals (4 to 6 weeks) ◦ Nutrition ◦ Vaccination: *Chlamydia*, *Campylobacter* (2 months and last month of pregnancy) ◦ Feed chlortetracycline (200–400 mg/head/day), monensin (15 mg/head/day) during gestation ◦ Keep feed, pasture and water source free from contamination by run-off, particularly from cattle and hogs. ◦ Control rat, bird, cat population. ◦ Act quickly on any abortion and assume it is an outbreak. ◦ Submit complete samples. ◦ Separate pre-partum from postpartum females. ◦ Keep good lambing/kidding facilities. • Reduce stress due to poor nutrition, unsanitary environment, crowded conditions.
• Vaccination ◦ Bluetongue: questionable ◦ Akabane virus: effective ◦ Cache valley: effective ◦ *Campylobacter*: helpful ◦ *Chlamydia*: helpful ◦ Q fever: autogenous vaccines in conjunction with chlortetracycline may help ◦ *B. ovis*: poor efficacy of killed vaccine ◦ *B. melitensis*: live attenuated good when permitted ◦ Salmonellosis: autogenous vaccine may be helpful ◦ Toxoplasmosis: may be helpful

Client Education Handout available online

ABORTION: VIRAL, FUNGAL, AND NUTRITIONAL

BASICS

OVERVIEW

Pregnancy loss during the fetal stage, between 42 days and term, caused by viral or fungal infection of the fetus or placenta, or nutritional problems.

INCIDENCE/PREVALENCE

• BHV-1: sporadic abortions in vaccinated or previously exposed herds, up to 60% in naïve herds. • BVDV: up to 40% in susceptible herds. • Fungal: sporadic, <10% of the herd, can vary from 2 to 20% depending on environment and season. • Selenium deficiency: 4–5% of aborted fetuses in a Canadian study.

GEOGRAPHIC DISTRIBUTION

• Potentially worldwide • Seasonal occurrence of bluetongue virus abortions due to vector cycle (late summer and early autumn in temperate areas) • Seasonal occurrence of fungal abortion (winter and spring)
• Seleniferous areas for selenium toxicosis

SYSTEMS AFFECTED

• Reproductive • Other systems depending on etiology

PATHOPHYSIOLOGY

Viral Abortion

• Maternal infection occurs venereally, orally, via inhalation or across conjunctival mucosa. • Vector transmission occurs with BTV (*Culicoides* spp.) and Cache Valley virus (multiple mosquitoes). • Viruses replicate in local lymphoid tissue and spread hematogenously to secondary organs.
• Viruses invade the placenta hematogenously from the dam's systemic circulation and cause fetal infection. • Fetal death occurs secondary to fetal infection and direct organ damage, or placental damage. • Fetal expulsion can occur before or immediately after death, with expulsion of a fresh or live fetus. More commonly, a delay in fetal expulsion leads to autolysis. • Fetal mummification may occur with some viral infections. • In the bovine, fetal infection between 100 and 150 days leads to congenital neurologic abnormalities (BVDV, BTV, BPV). • Fetal infection with noncytopathic BVDV strains between 1 and 4 months' gestation leads to birth of persistently infected immunotolerant calves.
• In small ruminants, infection with BTV and Border disease virus during the first 40 to 60 days results in fetal death and resorption. Later infection results in abortion, weak neonates, and congenital abnormalities (hydranencephaly, retinal dysplasia).
• Depending on the pathogen, dams may shed virus in ocular, oral, nasal, or vaginal secretions. • Latency is established with BHV-1 in the trigeminal nerve or the sacral spinal ganglia. Recrudescence and shedding may occur after stress.

Fungal Abortion

Fungi are thought to cause primary maternal respiratory or gastrointestinal disease and spread to placentomes hematogenously. Fetal infection occurs by extension of amniotic fluid infection.

Nutritional Abortion

• Selenium deficiency results from grazing plants growing in low-selenium soils. Development of congenital white muscle disease is thought to lead to fetal cardiac failure and death. • Ingestion of selenium-accumulating plants or contaminated water in areas with high-selenium soils or with environmental contamination, or iatrogenic overdose or oral or injectable selenium causes toxicosis. The toxic dose of selenium is uncertain, ranging from 2.2 to >20 mg/kg in the literature.
• Iodine deficiency has been associated with premature delivery, weak lambs and kids, and congenital goiter.

HISTORICAL FINDINGS

• A herd history of abortions or maternal and neonatal signs (described above)
• Inappropriate vaccination schedules
• Introduction of new animals to the herd
• Ataxic, blind or small calves in the herd (BVDV)

SIGNALMENT

• Ruminants of all breeds • Breeding age females

PHYSICAL EXAMINATION FINDINGS

• Maternal physical examination is usually unremarkable at the time of abortion.
• Maternal illness and fever may develop secondary to retained fetal membranes (RFM). • BHV-1: Abortion between 4 and 8 months' gestation, usually 2 weeks to 3 months after maternal clinical disease, respiratory disease, fever, conjunctivitis, nasal lesions, encephalomyelitis, neonatal disease, severe and painful pustular vaginitis. • BVDV: Variable depending on host and virus characteristics: infertility, embryonic death, abortion, mummification, small calves, persistently infected calves, congenital defects, fever, ocular and nasal discharge, oral ulcers, diarrhea, decreased milk production, epithelial erosions at the interdigital spaces, coronary bands, teats or vulva, hemorrhagic syndrome. • BTV: Maternal ulcers in mouth, tongue, muzzle and coronary bands, sloughing of hooves, abortion, stillbirth, embryonic death, fetal malformations. • BPV: first and second trimester abortions, congenital malformations, infertility.
• Fungal: abortion between 6 to 8 months' gestation, RFM. • Selenium toxicosis: Abortion, infertility, respiratory distress, lethargy, anorexia, diarrhea, fever, teeth grinding, death. In the chronic form: depression, weakness, anorexia, diarrhea, anemia, hair loss, hoof deformities, lameness.

GENETICS

N/A

CAUSES AND RISK FACTORS

Viral Causes

• Bovine herpes virus 1, 4, and 5, bovine viral diarrhea virus, bluetongue virus, bovine parvovirus. • The most common viral causes of abortion in small ruminants are Akabane, bluetongue, Border disease, Cache Valley virus, caprine herpesvirus-1 (goats).

Fungal Causes

Aspergillus spp., *Mucor* spp. *Absidia* spp., *Rhizopus* spp., *Mortierella* spp., *Candida* spp., *Pseudallescheria boydii*.

Nutritional Causes

Selenium toxicity or deficiency, toxic plants

Risk Factors

• Inappropriate biosecurity measurements and vaccination schedules. • Nutritional, social or environmental stress. • Seasonal presence of vectors. • Poorly ventilated moist environment, high animal density, animal confinement, and feeding moldy hay and feedstuffs (fungal). • Selenium-deficient soil.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Additional viral abortions: Bovine enterovirus, pseudorabies virus, parainfluenza virus 3, lumpy skin capripoxvirus, malignant catarrhal fever, bovine leucosis virus, foot and mouth disease virus; emerging or geographically restricted viruses (Kasba virus in Africa, Asia and Australia, Rift Valley fever in sub-Saharan Africa and Madagascar, Akabane virus in Asia, Australia, Middle East and Kenya, Schmallenberg virus in Germany and the Netherlands, Wesselsbron virus in Africa). • Bacterial abortion: Brucellosis, *Campylobacter* spp., *Leptospira* spp., *Listeria monocytogenes*, *Histophilus somni*, *Salmonella* spp., *Trueperella pyogenes*, *Mycobacterium bovis*, *Chlamydophila abortus*, *Coxiella burnetii*, epizootic bovine abortion, *Mycoplasma* spp., *Ureaplasma diversum*.
• Protozoal abortion: *Neospora caninum*, *Tritrichomonas foetus.* • Toxic abortion: Nitrate/nitrite poisoning, Ponderosa pine, broom snakeweed, sumpweed, moldy sweet clover, locoweed, poison hemlock, annual ryegrass infected with *Clavibacter rathayi*, snakeweed, stinkweed, turpentine weed, wild pea, sweet pea, subterranean clover, skunk cabbage mycotoxins, iatrogenic administration of teratogenic or luteolytic drugs. • Vaginal discharge: Vaginitis, metritis, endometritis, pyometra, hemorrhage.
• Ulcers: Foot and mouth disease, bovine papular stomatitis, vesicular stomatitis.
• Respiratory disease: Bovine respiratory disease complex.

A

ABORTION: VIRAL, FUNGAL, AND NUTRITIONAL (CONTINUED)

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Virus isolation from aborted tissues (lung, liver, spleen, kidney, adrenal glands, placenta). • Virus isolation from maternal or neonatal buffy coat (BVDV). • Antigen detection (ELISA or IHC) or PCR on maternal or neonatal ear skin biopsies, serum, whole blood, milk, and nasal swabs (BVDV). • Dam, fetal or pre-colostral calf serology (BVDV, BTV, BPV). • Immunohistochemistry and/or immunofluorescence on fetal tissues (BHV-1, BVDV). • PCR on aborted tissues (BHV-1, BVDV) or whole blood (BVT). • Gross lesions in fetal skin and placenta (fungal). • Fungal culture from aborted tissues (placenta, abomasal fluid, lung). • Direct microscopic examination of skin or placental scrapings or histopathology (fungal).

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• Fetal necropsy (see finding below) • Determination of selenium content in fetal and maternal liver

PATHOLOGIC FINDINGS
• BHV-1: Autolytic fetus, pinpoint white foci of necrosis in liver, pulmonary and renal hemorrhage and necrosis, diffuse placentitis, and yellow/brown amniotic fluid. • BVDV: Calves with congenital abnormalities (hydranencephaly, hydrocephalus, cerebellar hypoplasia, microphthalmia, retinal dysplasia, cataracts, thymic hypoplasia, hypotrichosis, brachygnathism, arthrogryposis, pulmonary or renal hypoplasia or dysplasia), necrotizing myocarditis, hepatic congestion, ascites. Autolyzed fetuses with rarely recognizable lesions, typically necrotizing inflammation with mononuclear infiltrations and lymphoid depletion, and no placental lesions. • BTV: Congenital abnormalities (hydranencephaly, hydrocephalus). • Fungal: Minimal fetal autolysis with numerous epidermal plaques, emaciation, placentitis with severe thickening of cotyledons and intercotyledonary areas with a leathery appearance; cotyledons may contain attached necrotic caruncular tissue. • Selenium deficiency: Fetal ascites, cardiac dilation and nodular liver, myocardial necrosis and mineralization, necrosis of skeletal muscle.

TREATMENT

THERAPEUTIC APPROACH
• Treatment of systemic disease, RFM, or metritis as needed. • Decrease environmental exposure to fungi by decreasing confinement and cow density, and improving ventilation and feed quality.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUG(S) OF CHOICE
N/A

CONTRAINDICATIONS
Use of modified live virus or attenuated vaccines against BVDV and BTV in pregnant cattle is associated with congenital malformations.

PRECAUTIONS
Latency may result after vaccination with modified live virus or attenuated vaccine against BHV-1.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Infected or exposed cows may develop natural immunity to some viruses, with lower rates of abortion in subsequent breeding seasons. • 25% of cows with *M. wolfii*-associated abortions may develop post-abortion pneumonia with death within 72 h.

POSSIBLE COMPLICATIONS
• Dystocia • RFM • Metritis • Viral spread to herd mates • Infertility • Secondary bacterial infections

CLIENT EDUCATION
• Wear protective gloves and clothes when handling aborted tissues and animals. • Pregnant women, children, elderly and immunosuppressed people should not handle aborting animals or tissues. • Keep aborted tissues (fetus and placenta) refrigerated and call a veterinarian as soon as abortion was noticed for appropriate diagnostic tests. • Remove additional aborted tissues from the pasture to prevent disease transmission. • Work with a veterinarian to design an appropriate biosecurity and vaccination program. • Follow milk and meat withdrawal times if medications are administered.

PATIENT CARE
• The cow should be monitored to ensure the fetal membranes are expelled and metritis does not develop. • Supportive care as needed. • The rest of the herd should be monitored for further abortions, stillbirths or birth of weak or abnormal calves. • Tests dams of PI calves (BVDV). • Prevent feeding moldy hay or low-quality silage to pregnant animals (fungal).

PREVENTION
• Optimize the herd's health status by providing appropriate nutritional, stress and environmental management. • Test and quarantine new additions to the herd. • Buy replacement animals from BVDV-free herds. • Test and cull positive animals for eradication. • Where vaccines are available, vaccinate breeding stock. • Avoid modified live or attenuated virus vaccines in pregnant cattle.

ACTINOBACILLOSIS: WOODEN TONGUE

BASICS

OVERVIEW
Actinobacillosis is caused by *Actinobacillus ligniersii* infection of the soft tissues, usually in the tongue.

INCIDENCE/PREVALENCE
Seen in up to 3% of cattle tongues at slaughter

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
- Digestive
- Musculoskeletal
- Integument
- Hemolymphatic

PATHOPHYSIOLOGY
- *Actinobacillus ligniersii* is a Gram-negative rod, which normally inhabits the alimentary tract of domestic ruminants, and is also found on plant awns.
- Mucosal lesions anywhere on the body, typically in the mouth, can be invaded by these bacteria, causing a localized lesion. Bacteria can also spread to different parts of the body via lymphatic drainage.
- A typical site of bacterial invasion is through small ulcers in the sulcus lingualis at the base of the tongue, leading to hard, painful, diffuse lesions of the tongue interfering with prehension of food, hence the synonym "wooden tongue." The bacteria initially cause an acute diffuse myositis of the muscles of the tongue, followed by development of granules and fibrosis.
- Lesions other than "wooden tongue" are usually uncommon; however, actinobacillosis should be included as a differential diagnosis for cutaneous diseases such granulomatous dermatitis and lymphadenitis.

HISTORICAL FINDINGS
Abrasive feeds and crowded conditions may lead to sporadic herd outbreaks or endemic disease. Lesions outside the oral cavity may be associated with previous wounds or needle punctures.

SIGNALMENT
- Mainly cattle and sheep, occasionally goats
- All ages

PHYSICAL EXAMINATION FINDINGS
Cattle generally present with hypersalivation and tongue may protrude from mouth. Weight loss can be seen in more chronic cases due to inability to prehend feed. Tongue may be diffusely firm and immovable and nodular swellings may be present on the tongue or lips or within the pharyngeal region. If present in atypical sites, signs will vary.

CAUSES AND RISK FACTORS
Caused by infection of soft tissues by *Actinobacillus ligniersii*. Abrasive feeds, crowded conditions, surgical lesions, and other sources of trauma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
- Pharyngeal trauma and abscessation
- Retropharyngeal lymphadenitis or lymphosarcoma
- Oral foreign bodies
- Dental disease
- Parasitic or foreign body granuloma
- Exuberant granulation tissue
- Contagious ecthyma and caseous lymphadenitis in sheep and goats

CBC/BIOCHEMISTRY/URINALYSIS
Chronic inflammatory profile

OTHER LABORATORY TESTS
- Acute lesions: Culture and cytology of aspirates.
- Chronic: Biopsy/histopathology and culture of lesions.
- Microscopic examination of pus compressed between two glass slides shows "sulfur granule" or clublike rosette appearance with a central mass of Gram-negative rods.

PATHOLOGIC FINDINGS
Firm, pale, gritty, granulomatous abscesses with multifocal necrotic foci containing mononuclear cells, neutrophils, eosinophils, and plant fibers.

TREATMENT

THERAPEUTIC APPROACH
- Sodium iodide 20%: 70 mg/kg IV, once, repeat at least once at 7–10-day intervals.
- Organic iodides: 1 oz/450 kg PO daily following first IV administration above.
- Antibiotics may be used alone or in conjunction with iodide treatment for severe cases.
- Use of a soft feed will aid prehension during treatment.

SURGICAL CONSIDERATIONS AND TECHNIQUES
May need surgical debulking of lesions in severe cases; however, note that access to the surgical lesion and close proximity to major vessels limit feasibility in some cases.

MEDICATIONS

DRUGS OF CHOICE
- Sodium iodide IV
- Daily organic iodides PO
- Antibiotics: sulfonamides, tetracyclines, ampicillin, streptomycin

CONTRAINDICATIONS
- Use sodium iodide with caution in pregnant cattle; see "Precautions."
- Extra-label use of sulfonamides is restricted in lactating dairy cattle.
- Streptomycin is not labeled for use in food-producing species in some countries.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals. Consult the Food Animal Residue Avoidance Database (www.farad.org) for current withdrawal times. As of August 2015, suggested Milk and Meat withdrawal times for cattle treated with NaI as above were 96 hours and 1 day, respectively.

PRECAUTIONS
Anecdotal reports of association with abortion in cattle at high doses of sodium iodide.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- Good prognosis if only the tongue is involved and lesions are acute. Expect dramatic response to therapy in this case.
- Fair to guarded prognosis if atypical sites are involved or lesions are chronic.

POSSIBLE COMPLICATIONS
Anecdotal reports of association with abortion in cattle at high doses of sodium iodide. If signs of iodism seen (dandruff, excessive lacrimation, inappetence, coughing, diarrhea), halt therapy until signs disappear.

CLIENT EDUCATION
Make aware of risk factors.

PREVENTION
Reduce access to abrasive feed and pastures with hard penetrating plant awns or thistles.

MISCELLANEOUS

ZOONOTIC POTENTIAL
Bite wounds from ruminants can contain *Actinobacillus ligniersii*, but rarely result in actinobacillosis.

PREGNANCY
Anecdotal reports of association with abortion in cattle at high doses of sodium iodide.

SYNONYMS
- Wooden tongue
- Woody tongue

ABBREVIATIONS
- IV = intravenous
- NaI = sodium iodide
- PO = per os

ACTINOBACILLOSIS: WOODEN TONGUE (CONTINUED)

ACTINOMYCOSIS: LUMPY JAW

BASICS

OVERVIEW
Common, sporadic, chronic granulomatous osteomyelitis of cattle caused by non-spore-forming, filamentous, Gram-positive, anaerobic bacterium *Actinomyces bovis*.

INCIDENCE/PREVALENCE
Common, sporadic

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Musculoskeletal, typically confined to the mandible and maxilla • Potential for hematogenous spread to other organs

PATHOPHYSIOLOGY
• *Actinomyces bovis* is part of the normal flora of the bovine oral cavity. It has low virulence and only causes disease when mucosal barriers are compromised. • Trauma to the oral mucosa from rough feed or foreign objects permits entrance of *Actinomyces* into buccal tissues. The organism may also enter through the dental alveolus. • The organism grows best in anaerobic conditions associated with devitalized tissues where there is a lack of phagocyte delivery. • Disease is typically of the mandible or maxilla, beginning as a painless, hard, immobile swelling. It is possible for teeth to become involved. In the following weeks to months, abscess/granuloma formation with necrotic foci may occur. As the disease progresses lesions may become painful. • Discharge of viscous, sticky, "honey- or whey-like," odorless, yellowish pus from openings may occur. The pus contains sand-like, firm, yellowish granules. The granule contains microcolonies of *Actinomyces* in an eosinophilic, amorphous matrix made of calcium phosphate/antigen-antibody complexes. • Occasional involvement of soft tissues, especially of esophageal groove with spread to lower esophagus, anterior wall of reticulum, may occur. Trauma to the digestive tract could allow for disease in regions distal to the oral cavity. • Hematogenous spread to other organs is rare. • Local lymph nodes are usually not involved. • Severe swelling, particularly of the maxilla, may cause dyspnea.

SIGNALMENT
• Primarily cattle; potentially all ruminant species • Often young with erupting teeth, but may affect any age • No sex or breed predilection

PHYSICAL EXAMINATION FINDINGS
• Hard, immovable swelling of the mandible or maxilla • Draining, fistulous tracts with a yellow, odorless pus • Missing or malaligned teeth with difficulty masticating • Weight loss, intermittent diarrhea, chronic bloat • Dyspnea • Rarely, partial tracheal obstruction, orchitis, brain/lung abscesses

CAUSES AND RISK FACTORS
• Eruption of teeth in young cattle • Rough feeds containing awns, foreign objects • Procedures causing oral lacerations

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Tooth root abscess • Osteomyelitis from cause other than *Actinomyces bovis* • Cheek abscess from cause other than *Actinomyces bovis* (movable, located in soft tissue) • Impacted feed/foreign body between cheek and teeth (soft, movable) • Lymphosarcoma/fibrosarcoma (soft)

OTHER LABORATORY TESTS
• Culture: Deep samples should be taken and placed in anaerobic transport media. • Microscopic examination of purulent debris: mix sample with saline and crush granules between slides. Gram stain will reveal Gram-positive organisms that may be branching, filamentous, coccoid or diphtheroid.

IMAGING
Osteomyelitis of the affected area; teeth may be involved. Important to differentiate from tooth root abscess.

PATHOLOGIC FINDINGS
Osteomyelitis with organisms present

TREATMENT

Difficult to treat. Antibiotics and sodium iodide have been historically used. Surgical debridement and drainage may be necessary.

MEDICATIONS

DRUGS OF CHOICE
• Penicillin, streptomycin, sulfonamides, erythromycin, and isoniazid have been used. • Sodium iodide: 70 mg/kg IV every 3 to 5 days until signs of iodism occur (scaling skin, lacrimation, cough, anorexia).

CONTRAINDICATIONS
• Iodine therapy may cause abortion. • Appropriate meat and milk withdrawal times must be followed for all compounds administered to food-producing animals. • Many historically used antibiotics are no longer approved in the United States.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• If untreated, disease will progress until the animal is no longer able to appropriately prehend food. • Difficult to treat. Early, aggressive treatment provides the best outcome.

POSSIBLE COMPLICATIONS
• Some animals become distressed with iodine infusion (restlessness, dyspnea, tachycardia). • Subcutaneous iodine causes severe irritation.

PATIENT CARE
• Lesions will slowly remodel after successful treatment. The affected areas may never return to normal. • Recrudescence is possible, even after prolonged periods of time.

PREVENTION
• Avoid feeds or procedures that could cause oral lacerations. • Monitor young cattle for swelling of mandible, especially following tooth eruptions. • Isolate cattle with discharging lesions. • There is no vaccine.

MISCELLANEOUS

AGE-RELATED FACTORS
Young cattle with erupting teeth

PREGNANCY
Iodine treatment during pregnancy may cause abortion.

ABBREVIATION
IV = intravenous

ACUPUNCTURE

BASICS

OVERVIEW

• Acupuncture is one of the four branches of traditional Chinese veterinary medicine (TCVM) and has been practiced for over 2,000 years.
• The twelve regular channels and the eight extraordinary channels connect acupoints all over the body. These pathways, known as meridians, relate to different organ systems and conduct the acupuncture signal and life energy, known as Qi.
• Techniques for stimulating acupoints include dry needling, aquapuncture, electroacupuncture, hemoacupuncture, and moxibustion.
• In 1997 the NIH (USA) released a consensus statement stating that acupuncture was proven to be effective for treatment of musculoskeletal pain, some gastrointestinal diseases, pulmonary disease, immunomodulation, and reproductive disorders in humans.
• Acupuncture is appropriate for use in organic production systems which are otherwise limited in their choice of treatment options.
• The practice of veterinary acupuncture is restricted to licensed veterinarians, or under the supervision of a licensed veterinarian, in most states and provinces in the US and Canada.

DIAGNOSIS

OTHER DIAGNOSTIC PROCEDURES

A full Western veterinary physical examination should be performed prior to initiating treatment. Both the Western and TCVM examination results are taken together to formulate a diagnosis. Additional TCVM procedures which are not part of the traditional Western examination can include:
• Determination of the patient's temperament type and element association.
• Inspection of the tongue: Tongue color, coating, and degree of moisture.
• Pulse diagnosis: Relative strength of the pulse at different points. In cattle, the pulse is taken at the coccygeal artery; in small ruminants the pulse is taken from the right and left carotid arteries, allowing for comparison between the two.
• Palpation along the meridians to find areas of sensitivity.

TREATMENT

THERAPEUTIC APPROACH

• Dry needle (DN): Insertion of sterile needles into an acupoint.
• Electroacupuncture (EA): Electrical stimulation of an acupoint; electrical leads are connected to the handles of the metal needles and either low or high frequency current sent into the points and along the associated channels. Provides greater, longer-lasting stimulation of a point or channel than dry needling alone.
• Aquapuncture (AA): Injection of sterile saline, vitamin B12, or the patient's own blood into an acupoint. Provides longer-lasting stimulation of a given point than dry needling alone.
• Hemoacupuncture (HA): Release of blood from an acupoint; the point is pricked with a sterile hypodermic needle and allowed to bleed. Used to release excess heat or relieve stagnation.
• Acupressure: Applying pressure to an acupoint or along a meridian without insertion of a needle or other method of stimulation.
• Moxibustion (moxa): Sticks or cones of dried mugwort are burned and held near an acupoint or touched to a dry needle to stimulate the point. Used to break up stagnation or warm the point.

Protocols

Treatment protocols should take into account the Western diagnosis, TCVM pattern diagnosis, patient's temperament, and the owner's primary concern for each individual case. As such there is no true "cookbook" protocol for any particular condition. That said, the most frequently used points for common Western medical diagnoses are given below along with suggested techniques. For explanation of the channel names and point locations, see "Suggested Reading." It is strongly recommended that one completes a formal training program prior to performing any acupuncture treatment.
Please note that for emergencies (e.g., dystocia) acupuncture should not be used as the sole treatment, and the practitioner must adapt his or her approach as the case develops.
• Anestrus: Bai-hui, Yan-chi, GV-1, GV-2, CV-1, BL-23, BL-26, Shen-shu, Shen-peng and Shen-jiao; can use DN, EA, or moxa.
• Retained fetal membranes: Bai-hui, Ba-jiao, GV-1, BL-31/32/34; EAP recommended daily until resolution.
• Infertility/subfertility: Bai-hui, Shen-peng/shu/jiao, Yan-chi, CV-1; DN, EA, or AA.
• Dystocia: SP-6, BL-60/67 to promote normal labor, add GB-21 for dystocia; DN or AA.
• Resuscitation, esp. of neonates: GV-26; DN.
• Heat stress: Er-jian, Wei-jian, Tai-tang (GB-1), GV-14; DN for GV-14, HA for others; EA between GV-14 and Bai-hui.
• Hemorrhage: Duan-xue (GV-6), Tian-ting; DN or AA; can be administered 2 hours prior to surgical procedures (e.g. castration, enucleation) for prevention.
• Diarrhea: GV-1, ST-36, BL-20/21/25; DN or AA.
• Anorexia: Shan-gen (use hypodermic needle), Mi-jiao-gan, ST-36; DN.
• Calving paralysis: Bai-hui, GB-29/30, BL-54, GV-3 and KID-1; EA or AA.

MEDICATIONS

DRUGS OF CHOICE

Chinese herbal medications are sometimes given as a complement to acupuncture. Because of metabolism in the rumen and first compartment, oral doses should be 2 to 3 times greater than those listed for horses. Alternatively, the equine dose can be administered per rectum as a slurry.

PRECAUTIONS

These medications have not been evaluated by the FDA and there are no established withdrawal times for any food-producing species.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Improvement should be seen by the third treatment. Chronic or severe conditions will often require multiple treatments over an extended period (weeks to months).
• Although acupuncture can be used symptomatically, being able to make a Chinese medical diagnosis allows the practitioner to target the treatment towards the underlying pathologic process and will enhance results.
• Prognosis depends heavily on the severity and chronicity of the disease process, the patient's temperament and demeanor, and the patient's tolerance of acupuncture treatment.

POSSIBLE COMPLICATIONS

• Acupuncture should be used with caution during pregnancy. Avoid points around the abdomen, mid to lower back, and hips. Any points which move blood or Qi should be avoided, as well as potent points such as ST-36, LI-4, BL-67, and SP-6. The CV channel (along ventral midline) should not be stimulated during gestation.
• Very old or debilitated patients (See "Age-Related Factors").
• Although extremely rare, needles can break off and become lodged in the muscle. To prevent breakage, use appropriately sized needles for each point, avoid using hypodermic needles except as a guide or for HA, and do not insert the needle completely up to the handle.
• Concurrent use of sedatives or dexamethasone will blunt the response to acupuncture and should be used only when necessary.

PATIENT CARE

For complicated or severe conditions, multiple treatments over an extended period of time should be expected. As the primary condition improves, other symptoms and disease patterns may become more obvious and treatment protocols adjusted accordingly.

MISCELLANEOUS

AGE-RELATED FACTORS

• Neonates and juvenile patients respond readily to acupuncture and may not need extensive treatment.
• Very old patients may not have enough energy or Qi left to tolerate a full acupuncture session. Since acupuncture moves energy around the body, it may deplete what little is left for these patients, leading to death. Short treatments with very few needles should be used.

PREGNANCY

• Acupuncture should be used with caution during pregnancy (see "Possible Complications"). Points which are both safe to use and can promote a healthy pregnancy include Bai-hui, Shen-peng/shu/jiao, and BL-20/21/22/23/24/25/26.

BIOSECURITY

• Acupuncture needles are single use only and should be disposed of properly in a sharps container.
• Use of blood for AA should only be performed with the patient's own blood, injected immediately after being drawn from the jugular or coccygeal vein.

ABBREVIATIONS

• AA – aquapuncture
• DN – dry needle technique

A

Acute Renal Failure

BASICS

OVERVIEW
Acute renal failure (ARF) is common in ruminants experiencing hemodynamic changes or exposed to nephrotoxins.

PATHOPHYSIOLOGY
• Dehydration, endotoxemia, hemorrhage, and shock could result in ARF due to sustained decrease in renal perfusion (hypoperfusion and ischemia) and release of endogenous inflammatory and pressure mediators. • Infarction of the renal cortex and destruction of the base membrane of tubular cells in cases of decreased renal perfusion results in nephron dysfunction. • Direct injury to tubular cells caused by exposure to nephrotoxins.

SIGNALMENT
There is no predisposition of ruminant species, breed, sex, or age to develop ARF.

PHYSICAL EXMINATION FINDINGS
• Signs of acute renal failure are nonspecific and signs of primary disease may mask renal affection. • Anuria, oliguria, or polyuria may be observed. • Affected animals may present with dehydration, depression, anorexia, and diarrhea. • Oral ulcerations might be observed in uremic animals. • Severe cases develop muscular weakness and recumbency due to electrolyte and acid-base abnormalities. • Rectal palpation in cattle may reveal left renal enlargement.

CAUSES AND RISK FACTORS
• Conditions that result in systemic compromise, dehydration, and hypotension such as diarrhea, septicemia, endotoxemia, disseminated intravascular coagulopathy, and acute blood loss. • Nephrotoxic agents include heavy metals, aminoglycosides and tetracyclines, NSAIDs, toxic plants such as pigweed and oaks, vitamin C and D, hemoglobin, myoglobin, and calcium oxalate among others. • Infectious agents such as *Leptospira* spp. and urolithiasis are less common causes of ARF.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
The nonspecific nature of clinical signs in cases of ARF in ruminants makes it difficult to develop a differential diagnosis list. Many primary disease conditions might result in ARF.

CBC/BIOCHEMISTRY/URINALYSIS
• Azotemia (increased BUN and creatinine). • Isosthenuria in the face of azotemia is a strong indicator of ARF. • Proteinuria, glucosuria, and granular casts may be present in urine. • Metabolic alkalosis, hypochloremia, hyponatremia, hypocalcemia, hyperphosphatemia, and hypermagnesemia are common findings with ARF. • Increased liver enzymes (SDH and GGT) values may be observed.

OTHER LABORATORY TESTS
Fractional excretion of sodium may be evaluated but the test should be compared to a normal animal (e.g., herd mate) of similar age, physiologic state, and nutritional status.

IMAGING
Ultrasonographic evaluation may reveal loss of detail of cortico-medullary junction, dilation of renal pelves and perirenal edema.

DIAGNOSTIC PROCEDURES
• Glomerular filtration rate assessment provides precise information of renal function. • Renal biopsy may provide diagnostic as well as prognostic information in cases of ARF.

PATHOLOGIC FINDINGS
Renal tubular degeneration and necrosis is a consistent histopathologic finding.

TREATMENT

THERAPEUTIC APPROACH
• The animal should be removed from the source of the nephrotoxins or exposure discontinued. • Isotonic, sodium-containing IV fluids with added calcium and potassium are indicated to correct acid-base and electrolyte abnormalities, increase renal perfusion, and promote diuresis. IV fluids should be maintained until the serum creatinine has returned to normal (usually 2–3 weeks). • Oral fluid therapy may be used if IV administration is impractical. • IV or oral fluids should be administered at a rate of two times the adult maintenance rate of 60 mL/kg/day. • Hydration and plasma protein should be monitored to avoid overhydration. • Supportive care should include broad-spectrum antibiotics, rumen transfaunations, and nutritional support.

MEDICATIONS

DRUGS OF CHOICE
• Furosemide (1 mg/kg IV or IM, q12h) administered every 2–3 hours to promote diuresis in anuric animals. • A dopamine drip (2 µg/kg/min IV) should be considered if diuresis is not achieved.

CONTRAINDICATIONS
• With repeated use of furosemide, the patient's serum sodium and potassium must be monitored carefully. • Drug withdrawal times need to be determined and maintained in food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• ARF due to ischemic episodes generally results in a grave prognosis. • Renal failure due to toxic causes may have a more favorable prognosis. • Failure to produce urine in the face of high volume IV fluids and diuretics carries a grave prognosis.

MISCELLANEOUS

ABBREVIATIONS
• ARF = acute renal failure • BUN = blood urea nitrogen • GGT = gamma glutamyl transferase • IM = intramuscular • IV = intravenous • NSAIDs = nonsteroidal anti-inflammatory drugs • SDH = sorbitol dehydrogenase

BASICS

OVERVIEW

• Defined by the 1971 Agricultural Chemicals Regulation Law as "chemical agents such as fungicides and insecticides that are used to control crop-harming organisms (e.g., fungi, nematodes, mites, insects, and rodents) or viruses (hereinafter collectively referred to as 'diseases and pests')." Also included are plant growth regulators and germination inhibitors.
• EPA regulates pesticides in the USA; it must find that a pesticide poses a "reasonable certainty of no harm" before it can be registered for use on food or feeds.
• Residual agricultural chemicals are those remaining in the crops after application. They may become part of livestock feed and end up in meat or milk, harming ruminant animals (fetus and neonates in particular) and human beings.
• Agricultural chemicals are best classified by their specific application target.
  ◦ Insecticides—control pests; includes ovicides and larvicides.
  ◦ Fungicides—control diseases that damage feeds, field crops, and fruit trees.
  ◦ Insecticides/fungicides—act together to control harmful pests and diseases that damage field crops.
  ◦ Herbicides—control weeds; may be selective for a specific plant or group of plants or be totally nonselective.
  ◦ Plant growth regulators—either inhibit or stimulate growth of crops.
  ◦ Attractants—attract insect pests.
  ◦ Repellants—repel birds and small mammals that may damage crops.
  ◦ Spreaders—substances mixed with other chemicals to enhance adherence.
  ◦ Rodenticides—control mice, rats, and other small rodents.
• Ruminants are exposed through ingestion of contaminated feeds, treated seeds, or stored chemicals as well as oral and dermal exposure to recently treated fields or pastures.
• Many banned or cancelled products such as arsenicals and organochlorines may not have been properly disposed of, posing a hazard to ruminants that may ingest them.
• Newer insecticides (i.e., pyrethrins and pyrethroids, fipronil, and neonicotinoids) are safer and have replaced organophosphate and carbamates, but they are not without some harm to animals and the environment.

INCIDENCE/PREVALENCE

Sporadic; may be a single isolated animal or entire herd.

SYSTEMS AFFECTED

• Multisystemic, depending on chemical encountered

PATHOPHYSIOLOGY

• Toxicity:
  ◦ Variable depending on the product.
  ◦ Acute toxicity occurs within a few hours to a day.
  ◦ Chronic toxicity develops over time and is much more difficult to diagnose.
• Systemic absorption may result in accumulation in fat, liver, brain, kidney, and milk; some products result in transplacental transmission.
• Insecticides: Older products
  ◦ Old insecticides such as DDT, most organochlorines, and arsenicals are no longer registered in the USA, but may be used worldwide.
    ▪ Highly toxic; many are carcinogens and some have associated reproductive defects.
    ▪ Primarily lipid soluble, non-biodegradable, and accumulate in fat resulting in contamination of milk and meat.
    ▪ Persist in the environment for very long periods of time.
    ▪ High potential for bioaccumulation (absorption occurs more rapidly than excretion) and biomagnification (tissue concentrations of a contaminant increase as it passes up the food chain).
  ◦ Organophosphate (OP) and carbamate compounds
    ▪ OPs: diazinon, dichlorvos, malathion, parathion, others.
    ▪ Carbamates: aldicarb, carbaryl, carbofuran, methomyl, others.
    ▪ Inhibit the enzyme acetylcholinesterase at cholinergic junction.
    ▪ Many are highly toxic and no longer registered in the USA; still widely used worldwide.
• Insecticides: Newer products
  ◦ Pyrethrins and pyrethroids
    ▪ Cyhalothrin, cypermethrin, deltamethrin, others.
    ▪ Slow the opening of sodium channels causing hyperexcitability.
    ▪ Most are highly lipophilic.
    ▪ Generally safe.
    ▪ Salivation, vomiting, tremors, seizures, dyspnea, prostration, death.
  ◦ Phenylpyrazole (fipronil)
    ▪ Inhibits $GABA_A$ chloride channels resulting in hyperexcitation and neurotoxicity.
    ▪ Generally safe unless exposed to highly concentrated product.
    ▪ Buffalo and their calves may have increased risk of toxicosis.
    ▪ Anorexia, twitching, tremors, ataxia, seizures.
  ◦ Neonicotinoids
    ▪ Acetamiprid, dinotefuran, imidacloprid, nitenpyram, others.
    ▪ Imidacloprid widely used worldwide in crop production.
    ▪ Act on postsynaptic nicotinic receptors in insects CNS; little effect on mammalian receptors.
    ▪ High margin of safety; not carcinogenic, mutagenic, or teratogenic.
    ▪ Adult buffalo and their calves may have an increased risk of toxicity.
    ▪ Lethargy, tremors, ataxia, hypothermia, death with high concentrations.
• Fungicides
  ◦ Less acute toxicity; may be due to decreased oral absorption.
  ◦ Respiratory and ophthalmic irritation from aerosolized products.
• Herbicides
  ◦ Toxicity varies by compound.
  ◦ Dinitro compounds
    ▪ Highly toxic to ruminants.
    ▪ Fever, dyspnea, tachycardia, seizures, death.
    ▪ Methemoglobinemia, intravascular hemolysis.
    ▪ Dinitrophenol compounds may cause yellow staining of the skin, conjunctiva, or hair.
  ◦ Paraquat
    ▪ Highly toxic when wet; very low toxicity once dry and bound to vegetation.
    ▪ Restricted use, nonspecific herbicide that kills all vegetation.
    ▪ Widely used worldwide, less so in USA.
    ▪ Dyspnea, anuria, muscle tremors, ataxia, salivation, recumbency, death.
  ◦ Sodium chlorate
    ▪ Dyspnea, recumbency, seizures, abortion
    ▪ Methemoglobinemia
  ◦ Glyphosate—considered less toxic, but controversial

HISTORICAL FINDINGS

Toxic ingestion may be known or suspected based on thorough history taking.

SIGNALMENT

• Very young and old.
• Neonates without functioning rumen are at a greater risk of toxicity from pyrethroids, OPs, and carbamates.
• Buffalo calves may be more susceptible to fipronil and neonicotinoids (acetamiprid).

PHYSICAL EXAMINATION FINDINGS

• General nonspecific signs include:
  ◦ Anorexia, hypersalivation, decreased rumen motility and bloat, abdominal pain, diarrhea (SLUDGE with OPs and carbamate insecticides)
  ◦ Stimulation or depression; lethargy, ataxia, hyperexcitation, tremors, seizures, recumbency, coma
  ◦ Tachypnea, dyspnea, respiratory arrest (paraquat)
  ◦ Polyuria, anuria (paraquat)
  ◦ Methemoglobinemia (chlorate and nitrate herbicides); cardiac arrest
  ◦ Hypo/hyperthermia
  ◦ Paresthesia, dermal irritation, inflammation (pyrethrins/pyrethroids; paraquat)
  ◦ Ophthalmic irritation (aerosolized products)

AGRICULTURAL CHEMICAL TOXICITIES (CONTINUED)

• See "Pathophysiology" for specific signs.
• Generally occur within 4–24 hours.
• May differ with individual animals, but specific system abnormalities are normally recognized in a herd situation.

CAUSES AND RISK FACTORS
• Improper storage or labeling of chemicals
• Equipment not cleaned well (e.g., ammonium nitrate residue in tank later used to fill water tanks)
• Access to a newly treated pasture or feed batch

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Gastrointestinal—bloat, grain overload, coccidiosis
• Nervous– lead poisoning, nervous ketosis, polioencephalomalacia, rabies (single animal)
• Respiratory—bloat, infectious diseases

CBC/BIOCHEMISTRY/URINALYSIS
Often unremarkable

OTHER LABORATORY TESTS
Gas or liquid chromatography on fresh or frozen samples

OTHER DIAGNOSTIC PROCEDURES
• Variable
• Urine or milk analysis helpful for some exposures

PATHOLOGIC FINDINGS
Often unremarkable, especially with sudden death.

TREATMENT

THERAPEUTIC APPROACH
• Remove animals from suspected source.
• Activated charcoal or mineral oil within 10–12 hours of oral exposure.
  ◦ Contraindicated: digestible oils such as corn oil may increase absorption and should not be used as a cathartic.
• Symptomatic and supportive
  ◦ Dermal exposure— bathe with grease cutting dish detergent (wear gloves)
  ◦ Respiratory exposure—fresh air
  ◦ Seizures —barbiturates, diazepam
  ◦ Methemoglobinemia—methylene blue
  ◦ SLUDGE—atropine; pralidoxime not cost effective for larger animals

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Specific agent and response to therapy guide prognosis.

POSSIBLE COMPLICATIONS
Chronic poor production

CLIENT EDUCATION
See "Prevention"

PATIENT CARE
Milk and meat testing for clearance time

PREVENTION
• Proper labeling and storage of chemicals
• Disposal of older products
• Effective cleaning of multiple use equipment

MISCELLANEOUS

AGE-RELATED FACTORS
Pre-ruminants are more susceptible to chemicals degraded in the rumen.

ZOONOTIC POTENTIAL
• Meat and milk contamination.
• Movement and/or marketing of animals poisoned with agricultural chemicals varies by state; consult with board of animal health or diagnostic laboratory.

ABBREVIATIONS
• CNS = central nervous system
• DDT = dichloro-diphenyl-trichloroethane
• EPA = Environmental Protection Agency
• OPs = organophosphate insecticides
• SLUDGE = salivation, lacrimation, urination, diarrhea, gastroenteritis

BASICS

OVERVIEW
• Akabane virus (AKAV) is an arthropod-borne virus of ruminants.
• The virus is transmitted by small biting midges (or gnats) of *Culicoides*. Some species may carry both AKAV and bluetongue virus.
• AKAV infects a wide range of domesticated and wildlife ruminants. The disease has been reported in cattle, buffalo, sheep, and goats.
• Infection of pregnant animals results in abortion and stillbirth due to variable defects of the fetal nervous system and arthrogryposis, with no clinical signs in the dam.

INCIDENCE/PREVALENCE
• In endemic areas, the disease has a seasonal pattern, with peak vector activity in summer and diagnosis of outbreak made the subsequent winter.
• Most female animals are infected prior to reproductive age.
• Disease is seen in naïve animals which become infected during pregnancy, either due to "spillover" of the vector from its region, or movement of naïve animals into endemic areas.
• Surveys indicate that more than 80% of adult cattle in an endemic area are seropositive for AKAV. However, following years of drought or times of reduced vector populations, native livestock may not be exposed prior to breeding age and therefore become susceptible.
• Data from Japanese and Australian outbreaks suggest that the fetus is infected in 30–40% of pregnant cows which are infected with AKAV.

GEOGRAPHIC DISTRIBUTION
• The virus is widespread throughout Asia, Australia, Africa, and the Middle East.
• The virus is considered a foreign animal disease in the United States.

SYSTEMS AFFECTED
• Reproductive
• Musculoskeletal
• Nervous

PATHOPHYSIOLOGY
• AKAV is a single-stranded negative sense tripartite RNA virus. It is a member of the genus Orthobunyavirus, family Bunyaviridae, and serogroup Simbu. Four genotypes are identified (I, II, III, IV).
• After infection via the *Culicoides* vector, viremia occurs in the host 1–6 days later.
• Antibodies are detectable 14 days after infection.
• The virus crosses the placenta and infects the fetus, leading to the clinical signs.
• A fetus may be infected months prior to abortion, premature birth, or stillbirth.
• Akabane virus is a potent teratogen and affects the limbs (arthrogryposis) and central nervous system (porencephaly, hydranencephaly).
• Type of fetal abnormalities depend on stage of pregnancy. Susceptible periods range from 28 to 56 days in small ruminants and 3 to 6 months in cattle.
• Long-term carriers of the disease are not believed to occur.

HISTORICAL FINDINGS
• Severe epizootics or smaller outbreaks are associated with movement of naïve pregnant animals into an endemic area, or "spillover" of the vector into naïve populations outside the endemic area.
• Abortion outbreak of abnormal fetuses between 4 and 6 months of gestation.

SIGNALMENT
• Disease occurs only in cattle, sheep, and goats but antibodies have been found in several other large animal species.
• Manifestations of infection depend on the gestational age at the time of infection.
• In cattle:
  ◦ Infection between days 79–104 of gestation results in hydranencephaly.
  ◦ Infection between days 103–174 results in arthrogryposis with focal Wallerian-type degeneration of the brain and spinal cord.
  ◦ Infection in late gestation can result in encephalomyelitis.
  ◦ Infection in few postnatal calves and adult cows has been diagnosed in Japan, which manifested as encephalomyelitis.
• In sheep, infection at 32–48 days' gestation resulted in fetal abnormalities.
• In goats, infection at approximately 40 days' gestation resulted in fetal abnormalities.

PHYSICAL EXAMINATION FINDINGS
• Infections in adult ruminants are typically asymptomatic. However, the Iriki strain (Japan and Korea) has been associated with encephalitis.
• The hallmark of AKAV is congenital abnormalities of the neurologic and muscular systems. Effects on the fetus depend on time of infection during gestation.
• One group of investigators divided the gestational effects of AKAV into 5 groups (1 = late gestation infection; 5 = early gestation infection). Group 1 abnormalities included microscopic non-suppurative encephalomyelitis. Group 2 lesions included loss of ventral horn spinal cord neurons and Wallerian-type degeneration of ventral spinal nerves which resulted in ataxia, flaccid paralysis, and mild arthrogryposis. Group 4 lesions included arthrogryposis and hydranencephaly. Groups 3 and 5 were more severe manifestations of group 2 and 4 signs, respectively.
• Dystocia may occur at parturition or abortion due to fetal abnormalities.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Clinical signs of AKAV are caused by exposure of ruminant fetuses to the virus by dam infection via *Culicoides* midges. Outbreaks are related to seasonal factors and vector distribution.
• Exposure of naïve pregnant animals to the virus-borne vector.

DIAGNOSIS

AKAV can be suspected based on clinical appearance of the fetus and knowledge of endemic areas; however, confirmation of the diagnosis by a diagnostic laboratory is required because gross appearance of AKAV is the same as many other vector-borne viruses.

DIFFERENTIAL DIAGNOSIS
• Bluetongue virus
• Bovine viral diarrhea virus
• Border disease virus
• Schmallenberg virus
• Cache Valley virus
• Aino virus
• Toxic, nutritional, or genetic causes of fetal neuromuscular defects

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Serology can be performed in affected dams and precolostral serum of the offspring.
• Collection of fetoplacental tissues at necropsy can be diagnostic via several molecular techniques, including reverse transcriptase real-time PCR, competitive ELISA, and immunohistochemistry/immunofluorescence.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• The most common lesions are arthrogryposis and hydranencephaly.
• Other neurologic abnormalities may include porencephaly and microencephaly.
• In the brain, degenerative and necrotic neurons as well as perineuronal and perivascular edema has been described.
• There may be loss of ventral horn spinal cord neurons and Wallerian-type degeneration of ventral spinal nerves.
• Other findings in calves include: gliosis, demyelination, hepatitis, nephritis, and myodegeneration/polymyositis.
• In sheep, there can be a marked loss of the ventral horns of the spinal cord which leads to hypoplastic spinal cord and muscle atrophy (e.g., torticollis). Pulmonary hypoplasia may also be noted.

AKABANE (CONTINUED)

TREATMENT

THERAPEUTIC APPROACH
• There is no treatment for AKAV.
• Most fetuses born alive die or are euthanized due to effects of the virus.
• Subsequent pregnancies of the dam will not be affected.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
N/A

CONTRAINDICATIONS
N/A

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Most offspring born alive are either euthanized or die shortly after birth.
• Subsequent pregnancies of the dam will not be affected.

POSSIBLE COMPLICATIONS
• Dystocia
• Infertility

CLIENT EDUATION
• In endemic areas, clients should be aware of repercussions of introducing naïve pregnant animals into the herd.
• Vaccination should also be considered in areas where it is available.

PATIENT CARE
• Specific treatment and supportive care if there are any complications following abortion.

PREVENTION
• Prevention of AKAV includes vector control and vaccination.
• Vector control should include elimination of vector breeding sites, and repellents for pregnant animals.
• Naïve pregnant animals should not be introduced during seasons of high vector activity (summer and autumn).
• Naïve animals should be introduced to endemic areas prior to breeding to develop immunity.
• Breeding season may be altered to avoid period of highest risk.
• Live (Japan) and inactivated (Japan, Australia, Korea) vaccines are available for the prevention of AKAV and are to be administered prior to breeding.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Dystocia, retained placenta

AGE-RELATED FACTORS
AKAV affects fetal ruminants.

ZOONOTIC POTENTIAL
There are no indications that AKAV is zoonotic.

PREGNANCY
Effects of AKAV are dependent on the gestational age of the fetus at the time of infection. However, most affected neonates die or are euthanized after birth due to effects of the virus irrespective of time of infection in utero.

BIOSECURITY
Suspected cases or outbreaks of AKAV outside its endemic areas (see "Geographic Distribution") should immediately be reported to the proper governmental veterinary authorities (i.e., state or federal veterinarian).

PRODUCTION MANAGEMENT
• In endemic areas, avoid introduction of naïve pregnant animals in the summer and autumn months.
• Implement vector control programs to reduce potential transmission of AKAV.
• Consider vaccination protocols prior to breeding.

SYNONYM
Arthrogryposis-hydranencephaly syndrome (AH syndrome)

ABBREVIATION
AKAV = Akabane virus

SEE ALSO

BASICS

OVERVIEW
An anaphylactic reaction is a pathologic immune response that occurs following exposure of a sensitized animal to a specific antigen. This exposure results in urticaria, pruritus, and angioedema, followed by vascular collapse, shock and often life-threatening respiratory distress. Anaphylaxis has now been included under type I (immediate) hypersensitivity.

INCIDENCE/PREVALENCE
Sporadic, dependent on exposure to inciting antigen. Tetanus antitoxin is one of the major vaccine antigens associated with anaphylaxis.

SYSTEMS AFFECTED
• Cardiovascular • Respiratory • Urinary • Digestive • Integument

PATHOPHYSIOLOGY
Anaphylaxis is an acute systemic manifestation of the interaction of an antigen (allergen) binding to IgE antibodies, which are bound to mast cells and basophils. This binding of antigens to cell-bound IgE antibodies triggers the release of chemical substances from the mast cells and basophils. The major biologically active mediators produced by mast cells and basophils include histamine, leukotrienes, the eosinophilic chemotactic factor, platelet-activating factor, kinins, serotonins, and proteolytic enzymes. These chemicals directly affect both the vascular system, causing vasodilatation and increased vascular permeability, and smooth muscles, causing contraction of the bronchi and respiratory distress.

SIGNALMENT
Bovine, ovine, and caprine; also reported in many other species of ruminants.

PHYSICAL EXAMINATION FINDINGS
Sudden, severe dyspnea, muscle tremors, anxiety, occurs within a few to 10–15 minutes following exposure to the antigen; muscle tremor may be severe and temperature may rise to 105°F. History of injection in the previous hour. Occasionally profuse salivation, mild bloat, diarrhea, urticaria, angioneurotic edema, and rhinitis. Laminitis rarely occurs in ruminants. Auscultation of the chest—vesicular murmur, crackling if edema is present, and emphysema in the later stages if dyspnea was severe.

GENETICS
There have been reports of higher incidence in certain lines and breeds of cattle (Holstein-Friesian and Angus) and Saanen goats.

CAUSES AND RISK FACTORS
Common agents causing anaphylaxis include blood transfusions, vaccines, horse sera, insect bites, heterologous enzymes and hormones, and certain drugs, such as penicillin and lidocaine. Milk allergy occurs occasionally in cows. This can happen when there is increased intramammary pressure to a point that normally sequestered milk components, notably casein, gain access to the circulation; these "foreign" proteins induce a type I hypersensitivity. Previous exposure to antigens (i.e., previous treatment with blood or blood products or vaccines).

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Acute Bloat • Acute Bronchopneumonia

CBC/BIOCHEMSTRY/URINALYSIS
Increase in PCV, high plasma K^+, neutropenia

PATHOLOGIC FINDINGS
Lungs—severe pulmonary edema in calves and lambs; pulmonary edema and emphysema without blood engorgement.

TREATMENT

THERAPEUTIC APPROACH
• Ancillary support of blood pressure (IV fluids) and respiration may be necessary. • In dairy cattle that have been recently dried off, recovery usually is prompt once the gland is emptied.

MEDICATIONS

DRUGS OF CHOICE
• Anaphylactic shock is treated with an injection of epinephrine. Epinephrine (1/100) subcutaneously or intravenously at a dose of 1 mL per 100 lb. of body weight is the drug of choice and can literally be a lifesaver. A second dose can be given in 15–20 minutes if needed. • In addition, flunixin meglumine (50 mg/mL) can be given at a rate of 1–2 mL per 100 lb. body weight IV or IM as well.
• Corticosteroids potentiate the effects of epinephrine and may be given following the administration of epinephrine.
• Antihistamines have no effect once signs are present.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Animals treated promptly usually return to normal within 12–24 h.

POSSIBLE COMPLICATIONS
Emphysema may result from severe dyspnea and violent muscle spasms. Following anaphylaxis, animals may spontaneously abort.

PATIENT CARE
Animals need to have their respiratory system monitored for the next 24 hours to detect any emphysema.

PREVENTION
Discuss the situation associated with the onset with the producer. Certain products may need to be avoided.

A

ANAPLASMOSIS

BASICS

OVERVIEW
Anaplasma is a hemoparasite of ruminants.

INCIDENCE/PREVALENCE
Anaplasmosis is the most prevalent tickborne disease of cattle.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Hemolymphatic

PATHOPHYSIOLOGY
• *Anaplasma marginale* is the most common cause of clinical disease in cattle; *A. centrale* causes mild disease. *A. ovis* causes mild disease in sheep. • *Anaplasma* is transmitted by many ticks including *Dermacentor* (USA) and *Rhipicephalus* spp. (other regions). • Iatrogenic transmission can occur. • Infected erythrocytes are destroyed by the monocyte macrophage system leading to extravascular hemolysis and anemia.

HISTORICAL FINDINGS
N/A

SIGNALMENT
Clinical disease primarily occurs in cattle over 3 years.

PHYSICAL EXAMINATION FINDINGS
• Calves generally display no clinical signs; cattle 6 months to 3 years of age may have mild to moderate signs. • Cattle over 3 years can have severe clinical disease. • Acute disease provokes fever, lethargy and anorexia. • Anemia results in tachypnea, tachycardia, pallor, icterus, exercise intolerance, ataxia, and death. • Hemoglobinemia and hemoglobinuria do not occur. • Survivors generally become subclinical carriers.

GENETICS
Bos indicus cattle may be more resistant to *A. marginale* infection than *Bos taurus* breeds.

CAUSES AND RISK FACTORS
• Disease is spread naturally by ticks and mechanically by *Tabanid flies*, needles, and blood-contaminated instruments. • Moving naïve adults to endemic areas or carrier animals to non-endemic areas may precipitate outbreaks.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Bleeding abomasal ulcer • Babesiosis • Leptospirosis • Bacillary hemoglobinuria • Hepatotoxic plants • Copper toxicity (sheep)

CBC/BIOCHEMISTRY/URINALYSIS
• CBC shows decline in PCV with regeneration indicated by anisocytosis, basophilic stippling, poikilocytosis, polychromasia, and reticulocytosis. On blood smears stained with Wright's, new methylene blue, or Giemsa stain, organisms will appear darkly stained on erythrocytes. • Increased hepatobiliary values. • No hemoglobinemia or hemoglobinuria.

OTHER LABORATORY TESTS
• cELISA is a widely used serologic test for identifying infected cattle. • Rapid card agglutination and complement fixation tests. • PCR more reliable for diagnosing acute infection.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Pallor or icterus • Splenomegaly • Hepatomegaly • Prominent erythrophagocytosis in reticuloendothelial organs

TREATMENT

THERAPEUTIC APPROACH
• Minimize stress • Blood transfusion if significant signs of anemia and low PCV

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Long acting oxytetracycline 20 mg/kg, IM or SQ, once to twice q 72 h. • Imidocarb efficacious but not approved in Europe or USA.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all pharmaceutical agents administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Mildly affected animals may recover and become carriers. • Severely affected animals often die within hours to days.

POSSIBLE COMPLICATIONS
• Old protocols to clear the carrier state are ineffective. • New carrier state protocols violate AMDUCA. • Clearing carrier animals makes them susceptible to reinfection.

CLIENT EDUCATION
N/A

PATIENT CARE
Monitor for clinical indications that transfusion is required.

PREVENTION
• Arthropod control. • Chemoprophylaxis can be achieved with 20 mg/kg of long-acting oxytetracycline every 21–28 days from the start of the vector season until 30–60 days after vector season ends, or with chlortetracycline in feed at 1.1 mg/kg daily during the vector season. • Live and killed vaccines are variably available, and decrease the severity of clinical signs.

ANEMIA, NONREGENERATIVE

BASICS

OVERVIEW

• Anemia is defined as a decrease in the red blood cell (RBC) count, hemoglobin (Hb) concentration, and/or packed cell volume (PCV)
• Nonregenerative anemia is caused by reduced or defective erythropoiesis.
• Nonregenerative anemia is suspected when signs of bone marrow regeneration (reticulocytosis, polychromasia, and basophilic stippling of RBCs) are minimal to absent.

SYSTEMS AFFECTED

• Multisystemic

PATHOPHYSIOLOGY

• Anemia is characterized by a reduced capacity of the blood to transport oxygen, leading to systemic tissue hypoxia and increased erythropoietin (EPO) production.
• Most clinical signs associated with anemia result from poor tissue oxygen delivery.

Nonregenerative Anemia Caused by Reduced Erythropoiesis

• Chronic inflammation, chronic renal disease, or bone marrow failure can lead to reduced erythropoiesis
• Chronic inflammation is associated with increased liver expression of hepcidin liver, causing alterations in iron metabolism and bone marrow responsiveness to EPO.
• Chronic renal disease can be associated with decreased EPO production by the kidneys.
• Destruction of hematopoietic stem cells due to damage by toxicants, irradiation, immune-mediated mechanisms, or infiltration of the marrow with abnormal cells can lead to bone marrow failure.

Nonregenerative Anemia Caused by Defective Erythropoiesis

• Disorders of Hb or DNA synthesis can lead to defective erythropoiesis.
• Iron (Fe) and copper (Cu) deficiencies can impair Hb synthesis.
• Iron is crucial to Hb synthesis because each Hb molecule is made up of four heme groups, each group being composed of an Fe molecule and a porphyrin.
• Iron deficiency is usually caused by chronic blood loss but can also be secondary to dietary Fe deficiency in young milk-fed animals.
• Copper deficiency can lead to Fe deficiency because several Cu-containing proteins are required for Fe transport.
• Dietary Cu deficiency and/or excessive dietary intake of molybdenum, sulfate, or zinc can cause decreased Cu absorption and lead to Cu deficiency.
• Dietary cobalt (Co) deficiency can cause Co deficiency and lead to vitamin B12 deficiency and defective DNA synthesis

HISTORICAL FINDINGS

• Weakness, lethargy, anorexia, weight loss, exercise intolerance, or syncopes.

SIGNALMENT

Bovine, ovine, caprine, and camelid species.

PHYSICAL EXAMINATION FINDINGS

• Clinical signs are less overt when the anemia progresses slowly.
• Lethargy, weakness, or obtundation.
• Pale mucus membranes.
• Tachycardia and tachypnea.
• Heart murmur (due to reduced blood viscosity).

GENETICS

• Congenital dyserythropoiesis is an autosomal recessive trait in polled Hereford cattle.
• Myelofibrosis is an autosomal recessive trait in pygmy goats

CAUSES AND RISK FACTORS

Nonregenerative Anemia Caused by Reduced Erythropoiesis

• Common causes of chronic inflammation include pneumonia, peritonitis, deep digital sepsis, liver abscesses, paratuberculosis, and lymphoma
• Causes of chronic renal disease include pyelonephritis, urolithiasis, amyloidosis, and glomerulonephritis.
• Causes of bone marrow failure include bracken fern toxicosis, bovine neonatal pancytopenia, irradiation, myelofibrosis, and neoplasia

Nonregenerative Anemia Caused by Defective Erythropoiesis

• Causes of defective erythropoiesis include congenital dyserythropoiesis and deficiencies in Fe, Cu, and Co.
  ◦ Chronic blood loss: GI ulcers, hematuria, hereditary coagulation factor deficiencies, parasitism, dietary Fe deficiency in milk-fed ruminants

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Normocytic, normochromic anemia with normal to increased neutrophil and platelet counts can be caused by chronic inflammation or renal disease.
• Normocytic, normochromic anemia with decreased neutrophil and/or platelet counts can be caused by bone marrow failure.
• Microcytic, hypochromic anemia with variable neutrophil and platelet counts can be caused by iron or copper deficiencies.
• Macrocytic, normochromic anemia with variable neutrophil and platelet counts can be caused by cobalt deficiency or congenital dyserythropoiesis.

CBC/BIOCHEMISTRY/URINALYSIS

• The PCV is the easiest and most accurate method to identify anemia.
• The PVC should be interpreted with consideration of the animal's hydration status and any potential cause of splenic contraction (excitement, exercise, handling, or transportation).

Severity of anemia	*PCV (%)*
Mild	20–26
Moderate	14–19
Severe	10–13
Very severe	<10

• Blood should be analyzed within 30–60 minutes of collection or stored at refrigerator temperature (4°C) and analyzed within 24 hours
• Delayed analysis may result in marked cellular swelling and therefore a false increase in MCV
• Hypochromasia and microcytosis are hallmarks of iron and copper deficiencies.
• Hyperfibrinogenemia, hypoalbuminemia, and hyperglobulinemia are often present in with chronic inflammation.

	Chronic inflammation or renal disease	*Bracken fern toxicosis*	*Iron and copper deficiencies*	*Cobalt deficiency*
Mechanism	Increased hepcidin or decreased EPO production	Cytotoxic damage to bone marrow	Defective	Defective DNA synthesis
Plasma protein	N - ↑	N - ↓	N - ↓	N - ↓
PCV	↓ - ↓↓	↓ - ↓↓	↓ - ↓↓↓	↓ - ↓↓
MCV	N	N	N - ↓	N - ↑
MCHC	N	N	N - ↓	N
Neutrophil count	N - ↑	N - ↓	N - ↑	N - ↑
Platelet count	N - ↑	N - ↓	N - ↑	N - ↑

N = normal, ↓ = slightly decreased, ↓↓ = moderately decreased, ↓↓↓ = markedly decreased, and ↑ = slightly increased

A

ANEMIA, NONREGENERATIVE (CONTINUED)

• Azotemia, hypoalbuminemia, and proteinuria are often present with chronic renal disease.

OTHER LABORATORY TESTS

Chronic Inflammation and Iron Deficiency

	Chronic inflammation	*Iron deficiency*
Serum ferritin	N - ↑	↓
Bone marrow iron content	N - ↑	↓
Total iron binding capacity	N - ↓	N - ↑

N = normal, ↓ = decreased, and ↑ = increased

• Hepatic Fe concentration: <40 ppm on a wet matter basis with Fe deficiency anemia

Copper Deficiency

• Plasma Cu concentration: <0.5 µg/mL
• Hepatic Cu concentration: <35 ppm on a dry matter basis

Cobalt Deficiency

• Serum vitamin B_{12} concentration: <0.2 mg/mL
• Hepatic vitamin B_{12} concentration: <0.2 ppm (dry matter basis)

Parasitism

• Examination of the skin and coat
• Fecal flotation

OTHER DIAGNOSTIC PROCEDURES

• Bone marrow examination is indicated when the cause of a nonregenerative anemia remains undetermined and/or atypical or unexplained immature cells are observed on the peripheral blood smear.

TREATMENT

THERAPEUTIC APPROACH

• Treatment must primarily address the underlying cause(s) of the anemia.
• Blood transfusion is indicated in valuable animals with overt clinical signs of anemia and/or PCV <12%.
• Activity and stress should be minimized.
• Routine care procedures should be delayed (deworming, hoof trimming …).

MEDICATIONS

DRUGS OF CHOICE

• Oral iron supplementation is indicated with iron deficiency anemia.
• Oxygen therapy may be beneficial in hypoxemic animals (PaO_2 <80 mmHg).

CONTRAINDICATIONS

• Iron supplementation is contraindicated in animals with chronic inflammation.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Clinical course and prognosis is dependent on the underlying disease process.

PATIENT CARE

• Heart rate, respiratory rate, mucus membrane color, blood lactate, and arterial blood gas analysis can be used to monitor systemic tissue oxygen delivery.
• CBC or PCV with blood smear examination should be repeated every 1–2 days until evidence of bone marrow regeneration is present.
• Reevaluation is indicated after 7–10 days in stabilized animals.

PREVENTION

• Feeding of trace mineral supplements with label claims for the species that are being supplemented is recommended.
• Diet should contain 4–10 ppm of Cu, 0.1–0.2 ppm of Co, and 30–40 ppm of Fe.
• The dietary copper/molybdenum ratio should be maintained between 5:1 and 10:1.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• A congenital syndrome characterized by dyserythropoiesis and progressive alopecia has been described in polled Hereford cattle.

AGE-RELATED FACTORS

BASICS

OVERVIEW

• Anemia is defined as a decrease in the red blood cell (RBC) count, hemoglobin (Hb) concentration, and/or packed cell volume (PCV). • Regenerative anemia is caused by blood loss and/or accelerated RBC destruction. • Signs of bone marrow regeneration include reticulocytosis, polychromasia, and basophilic stippling of RBCs.

INCIDENCE/PREVALENCE

• Extravascular hemolysis is more common than intravascular hemolysis. • Chronic copper toxicosis occurs most commonly in sheep. • Neonatal isoerythrolysis (NI) has been described in calves born to cows immunized with *Anaplasma* or *Babesia* vaccines. • NI has been described in lambs and kids following ingestion of bovine colostrum.

SYSTEMS AFFECTED

• Multisystemic

PATHOPHYSIOLOGY

• Anemia is characterized by a reduced capacity of the blood to transport oxygen, leading to systemic tissue hypoxia and increased erythropoietin production. • 2–3 days are necessary for signs of bone marrow regeneration to be evident in the blood. • Reticulocytosis usually peaks about 7–10 days after bone marrow stimulation.

Regenerative Anemia Caused by Blood Loss (Hemorrhagic Anemia)

• Causes of blood loss include trauma, surgery, coagulation factor deficiencies, thrombocytopenia, parasitism, and neoplasia. • Regenerative response is usually higher with internal than external hemorrhage because some RBCs are reabsorbed by lymphatics and iron (Fe) is recycled. • Chronic blood loss is usually associated with mild regenerative response and can lead to Fe deficiency.

Regenerative Anemia Caused by Accelerated RBC Destruction (Hemolytic Anemia)

• Accelerated RBC destruction (hemolysis) can occur within the blood vessels (intravascular) and/or outside of the blood vessels (extravascular). • Extravascular hemolysis is more common than intravascular hemolysis. • Reticulocyte counts are usually higher in hemolytic anemias than in hemorrhagic anemias. • Onset of clinical signs is usually peracute to acute with intravascular hemolysis and more progressive with extravascular hemolysis. • Icterus may develop in animals with hemolytic anemia secondary to increased Hb degradation and bilirubin formation. • Intravascular hemolysis is characterized by hemoglobinemia (free Hb in the plasma) that can lead to red discoloration of plasma and/or increased MCHC. • Hemoglobinuria can develop if the plasma free Hb concentration exceeds the capacity of renal tubular reabsorption. • Causes of intravascular hemolysis include bacterial infections, erythrocytic parasites, oxidative damage to the RBC membrane, primary immune-mediated disorders, osmotic lysis, envenomation, and congenital disorders. • Extravascular hemolysis results from sequestration and phagocytosis of RBCs in spleen or liver due to decreased RBC deformability or immune-mediated mechanisms. • Extravascular hemolysis does not cause hemoglobinemia or hemoglobinuria. • Causes of extravascular hemolytic anemias include erythrocytic or endothelial parasites and congenital disorders.

SIGNALMENT

• Bovine, ovine, caprine, and camelid species. • Neonatal isoerythrolysis (NI) can occur in calves born to cows immunized with Anaplasma or Babesia vaccines and in lambs fed bovine colostrum. • Chronic copper (Cu) toxicosis occurs most commonly in sheep • Hereditary factor VIII and IX deficiencies almost always occur in males. • Anaplasmosis and babesiosis occur most commonly in adults.

PHYSICAL EXAMINATION FINDINGS

• Lethargy, obtundation, weakness, or syncopes • Pale mucus membranes • Tachycardia and tachypnea • Heart murmur (due to reduced blood viscosity) • Icterus • Hemoglobinuria (with intravascular hemolysis)

GENETICS

• Hereditary factor VIII deficiency is an autosomal recessive trait in Hereford and Japanese Brown cattle. • Hereditary factor XI deficiency is an autosomal recessive trait in Holstein and Japanese Black cattle. • Hereditary afibrinogenemia is an incompletely dominant trait in Saanen goats. • Hereditary spherocytosis is an autosomal dominant trait in Japanese Black cattle. • Congenital erythropoietic porphyria is an autosomal recessive trait in Holstein cattle.

CAUSES AND RISK FACTORS

Regenerative Anemia Caused by Acute Blood Loss

• Coagulation factor deficiencies
  ◦ Disseminated intravascular coagulation (DIC) ◦ Hereditary afibrinogenemia and factor VIII or XI deficiencies ◦ Moldy sweet clover and rodenticide toxicosis
• Gastrointestinal ulcers
• Hemorrhagic bowel syndrome
• Thrombocytopenia
  ◦ Bovine viral diarrhea virus infection
  ◦ DIC ◦ Snake evenomation
• Trauma
• Surgery

Regenerative Anemia Caused by Chronic Blood Loss

• Gastrointestinal ulcers
• Chronic hematuria
  ◦ Bracken fern toxicosis ◦ Urolithiasis
  ◦ Pyelonephritis
• Hereditary afibrinogenemia and factor VIII or XI deficiencies
• Parasites
  ◦ Internal (*Haemonchus* spp., *Bunostomum* spp., *Eimeria* spp.) ◦ External (blood sucking lice, fleas, ticks)

Regenerative Anemia Caused by Accelerated RBC Destruction

Causes of Extravascular Hemolysis

• Intraerythrocytic parasites
  ◦ *Anaplasma centrale* and *A. marginale* in cattle ◦ *Theileria annulata*, *T. buffeli*, *T. mutans*, and *T. parva* in cattle ◦ *A. ovis* and *T. lestoquardi* in small ruminants
• Epierythrocytic parasites
  ◦ *Candidatus Mycoplasma haemolamae* in camelids ◦ *Mycoplasma wenyonii* in cattle and *M. ovis* in small ruminants
• Extraerythrocytic parasites
  ◦ *Trypanosoma congolense*, *T. brucei*, and *T. vivax* in cattle
• Endothelial parasites
  ◦ *Sarcocystis* spp. in cattle, and small ruminants
• Hereditary RBC membrane defects
  ◦ Hereditary spherocytosis

Causes of Intravascular Hemolysis

• Bacterial infections
  ◦ *Clostridium haemolyticum* in cattle and sheep ◦ *Clostridium perfringens* type A in cattle and sheep ◦ Leptospirosis
• Osmotic lysis
  ◦ Overuse of hypotonic intravenous fluids
  ◦ Water intoxication
• Intraerythrocytic parasites
  ◦ *Babesia bigemina*, *B. bovis*, *B. divergens*, and *B. major* in cattle ◦ *B. motasi* and *B. ovis* in small ruminants
• Oxidative damage
  ◦ *Brassica* spp. ingestion ◦ Chronic Cu toxicosis ◦ Oak leaves and acorns ingestion ◦ Onion or garlic ingestion ◦ Red maple leaf ingestion ◦ Selenium deficiency ◦ Zinc toxicosis
• Primary immune-mediated disorders
  ◦ Neonatal isoerythrolysis ◦ Incompatible blood transfusion
• RBC membrane alterations due to other mechanisms
  ◦ Congenital erythropoietic porphyria
  ◦ Postparturient hemoglobinuria ◦ Snake envenomation

A

ANEMIA, REGENERATIVE (CONTINUED)

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

• The PCV is the easiest and most accurate method to identify anemia. • The PVC should be interpreted with consideration of the animal's hydration status and any potential cause of splenic contraction (excitement, exercise, handling, or transportation).

Severity of anemia	*PCV (%)*
Mild	20–26
Moderate	14–19
Severe	10–13
Very severe	<10

• Blood should be analyzed within 30–60 minutes of collection or stored at refrigerator temperature (4°C) and analyzed within 24 hours. • Delayed analysis may result in marked cellular swelling and a false increase in MCV.

OTHER LABORATORY TESTS

Hemorrhagic Anemia

• Examination of the skin and coat (external parasites) • Fecal flotation (internal parasites) • Fecal occult blood test (gastrointestinal ulcers) • Coagulation tests (coagulation factor deficiencies)

	aPTT	*PT*	*TT*
Afibrinogenemia	↑	↑	↑
DIC	↑	↑	↑
Factor VIII deficiency	↑	N	N
Factor XI deficiency	↑	N	N
Sweet clover toxicosis	↑	↑	N
Rodenticide toxicosis	↑	↑	N

aPTT = activated partial thromboplastin time, PT = prothrombin time, TT = thrombin time, N = normal, and ↑ = increased

Immune-Mediated Hemolytic Disorders

• Positive autoagglutination and direct antiglobulin (Coombs') test

	Acute blood loss	*Chronic blood loss*	*Intravascular hemolysis*	*Extravascular hemolysis*
Plasma protein	N - ↓	N - ↓	N - ↑	N - ↑
PCV	↓ - ↓↓	↓ - ↓↓↓	↓↓ - ↓↓↓	↓ - ↓↓↓
MCV	N - ↑	N - ↓	N - ↑	N - ↑
MCHC	N - ↓	N - ↓	↑	N - ↓
Reticulocyte count	N - ↑↑	N - ↑	N - ↑↑↑	N - ↑↑↑
Neutrophil count	N - ↑	N - ↑	N - ↑	N - ↑
Platelet count	N - ↑	N - ↑	N - ↑	N

N = normal, ↓ = slightly decreased, ↓↓ = moderately decreased, ↓↓↓ = markedly decreased, ↑ = slightly increased, ↑↑ = moderately increased, and ↑↑↑ = markedly increased

Intravascular versus Extravascular Hemolysis

	Intravascular hemolysis	*Extravascular hemolysis*
Hyperbilirubinemia	can be present	usually present
Hemoglobinemia	Yes	No
Plasma color	pink to red	straw to yellow
Hemoglobinuria	usually present	No
Urine color	pink to red	straw to yellow
Blood reagent strip	positive	usually negative
Bilirubinuria	can be present	usually present
RBCs in urine sediment	No	No

• Abnormal RBC morphology or RBC inclusions may suggest the mechanism of hemolysis. • Heinz bodies suggest oxidative damage. • Spherocytes suggest immune-mediated hemolysis. • Keratocytes and schistocytes DIC.

Chronic Copper Toxicosis

• Serum or plasma Cu concentration: >2 µg/mL • Hepatic Cu concentration >350 ppm (dry matter basis) • Renal Cu concentration >100 ppm (dry matter basis) (most reliable)

Lead Toxicosis

• Lead toxicosis should be suspected when basophilic stippling if RBCs is accompanied by signs of inappropriate bone marrow regeneration (minimal polychromasia with nucleated RBCs).

Selenium (Se) Deficiency

• Blood Se concentration <50 ng/mL • Blood glutathione peroxidase (GSH-Px) activity <15 m/min/mg of Hb

PATHOLOGIC FINDINGS

• Extravascular hemolysis is usually associated with splenomegaly.

TREATMENT

THERAPEUTIC APPROACH

• Treatment must primarily address the underlying cause(s) of the anemia. • Blood transfusion is indicated in valuable animals with overt clinical signs of anemia PCV <12%. • Activity and stress should be minimized. • Routine care procedures should be delayed (deworming, hoof trimming ...).

MEDICATIONS

DRUGS OF CHOICE

• Oral iron supplementation is indicated with chronic blood loss. • Oxygen therapy may be beneficial in hypoxemic animals (PaO_2 <80 mmHg). • Fluid therapy is indicated with hypovolemia to support cardiovascular function and with intravascular hemolysis to prevent renal damage.

CONTRAINDICATIONS

• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Clinical course and prognosis is dependent on the underlying disease process. • Return to reference intervals is expected in 1–2 weeks following a single acute blood loss. • Chronic blood loss should be suspected if reticulocytosis persists >3 weeks.

POSSIBLE COMPLICATIONS

• Iron deficiency anemia loss develops more quickly in young milk-fed animals because they have limited Fe stores.

PATIENT CARE

• Heart rate, respiratory rate, mucus membrane color, blood lactate, and arterial blood gas analysis can be used to monitor systemic tissue oxygen delivery. • CBC or PCV with blood smear examination should

be repeated every 1–2 days until stabilization of the PVC. • Reevaluation is indicated after 7–10 days in stabilized animals.

PREVENTION

• Cross-matching is indicated in animals receiving more than one blood transfusion. • Feeding of trace mineral supplements with label claims for the species that are being supplemented is recommended. • Diet should contain 4–10 ppm of Cu and not less than 0.1 ppm of Se. • The dietary copper/molybdenum ratio should be maintained between 5:1 and 10:1
• Prevention programs of vector-borne diseases should be implemented in endemic areas.

A

ANESTHESIA: INHALATION

BASICS

OVERVIEW

• Most ruminants tolerate surgical procedures with appropriate physical restraint, local or regional anesthesia, and sedation (if necessary).
• Inhalational anesthesia requires specialized equipment including: an anesthetic machine, oxygen source, oxygen regulator, oxygen flow meter, agent-specific vaporizer, breathing circuit, and a gas scavenging system.
• Ruminants <60 kg can be anesthetized with a conventional small animal machine. Ruminants 60–250 kg can be anesthetized with a human or small animal anesthetic machine with expanded carbon dioxide absorbent canisters. Ruminants >250 kg should be anesthetized with a conventional large animal anesthetic machine.
• Endotracheal intubation and proper cuff inflation are recommended.
• Inhalational anesthetics do not provide analgesia.
• Inhalant anesthetics are off-label drugs in food-producing animals. These agents are primarily eliminated through the lungs so accumulation within tissues is unlikely.

SYSTEMS AFFECTED

• Nervous
• Musculoskeletal
• Respiratory
• Cardiovascular

PATHOPHYSIOLOGY

• General anesthesia is defined as a state of controlled but reversible depression of the CNS not arousable by noxious stimuli. The sensory, motor, and autonomic functions of the body are attenuated to different degrees based on type of drugs used and the dose administered.
• Inhalant anesthetics are administered and removed primarily through the lungs.
• The mechanism of inhalant anesthetic actions is still largely unknown.

Minimum Alveolar Concentration

• Inhalant anesthetic doses are based on the calculation of MAC in healthy animals anesthetized without other drugs (Table 1).
• MAC is the minimum alveolar concentration of inhalant anesthetic that produces immobility in 50% of patients from responding to a supramaximal stimulus (electrical stimulation of oral mucus membrane). This is equivalent to the ED_{50} and corresponds to a light plane of anesthesia.
• The ED_{95} is equal to 1.2 to 1.4 × MAC_{agent} and corresponds to a moderate plane anesthesia in 95% of patients.
• There is some individual variation in MAC and inhalant dose should be titrated based on evaluation of the patient's monitored anesthetic depth and physiologic parameters.
• If adjunctive anesthetics or analgesics are used, the MAC requirements may be reduced, therefore the inhalant dose should be titrated as stated above.

Table 1

Minimum Alveolar Concentration of Inhalant Anesthetics

Species	*Isoflurane*	*Sevoflurane*	*Halothane*
Cow	1.14	—	0.76
Sheep	1.58	—	0.97
Goat	1.2–1.5	2.33	1.29–1.3

SIGNALMENT

Potentially all ruminant species

PHYSICAL EXAMINATION FINDINGS

• Palpebral reflexes disappear at minimal anesthetic depth in ruminants but corneal reflexes remain intact.
• Cattle demonstrate eye globe rotation at different depths of anesthesia. When awake, the globe is positioned between the eyelids. At induction, the globe rotates ventrally and may be partially hidden below the lower eyelid. As anesthetic depth increases, the globe can be completely hidden under the lower eyelid. At the surgical anesthetic plane, the globe rotates dorsally between the eyelids again.
• Any purposeful movement will indicate an insufficient plane of anesthesia and adjustment should be made as necessary (i.e., administer intravenous anesthetic agent, increase vaporizer setting, administer additional analgesics).

CAUSES AND RISK FACTORS

• Minor procedure or surgery like hernia repair or fracture stabilization.
• Complicated procedures like abdominal exploratory, arytenoidectomy, or bladder repair.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

• May be included as routine preoperative workup.
• Recommended for sick patients with an ASA status of III or higher.

OTHER LABORATORY TESTING

Blood gas analysis (arterial or venous) if suspect respiratory disease or patient is not appropriately fasted.

TREATMENT

THERAPEUTIC APPROACH

Inhalational Anesthetics in Ruminants

• Often not required if adequate restraint plus local or regional anesthesia is provided.
• Fasting is recommended for all ruminants to minimize complications associated with recumbency and general anesthesia (i.e., tympany, regurgitation, aspiration pneumonia, ventilation/perfusion mismatch). The food and water fasting recommendations for calves, sheep, and goats are 12–18 hours and 8–12 hours respectively. The food and water fasting recommendations for adult cattle are 18–48 hours and 12–24 hours respectively. Neonates should not be fasted before anesthesia to avoid hypoglycemia.
• Airway protection with a cuffed endotracheal tube is essential for injectable or inhalational anesthesia. Intubation in adult cattle is usually performed with a blind or digital palpation technique whereas small ruminants and calves can be intubated with a laryngoscope with a 250–300 mm blade.
• The head and neck should be positioned to allow free flow of regurgitation from the mouth.
• Padding and positioning of the patient are critical to prevent complications associated with neuropathy, myopathy, and injuries to the eyes.
• An IV catheter is recommended for administration of analgesic drugs or supplemental injectable drug doses.
• Ruminants usually have smooth, controlled recoveries from inhalational anesthetics as they do not experience emergence delirium like their equine counterparts. Extubation should only take place when swallowing reflexes have returned.

MEDICATIONS

DRUGS OF CHOICE

Isoflurane

• The most common anesthetic agent used today.
• Isoflurane is less arrhythmogenic than halothane and is not dependent on metabolism for elimination.

Sevoflurane

• Currently widely available but not used in food animal anesthesia, often due to cost.
• Sevoflurane is less arrhythmogenic than halothane and is not dependent on metabolism for elimination.

Halothane

• Limited availability but may still be available in some areas.

• Halothane is associated with increased risk of cardiac arrhythmias in patients with high amounts of circulating cathecholamines (i.e., stressed animals, septic shock).
• A preservative, thymol, is added to the halothane to prevent degradation. Thymol can concentrate within a vaporizer over time so frequent cleaning is recommended.

CONTRAINDICATIONS
• Caution in non-fasted animals.
• Caution in patients with compromised airways, respiratory systems, or systemic hypotension.

PRECAUTIONS
Meat and milk withholding: No current published withholding times. Suggested withholding times may be obtained by contacting FARAD.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

CLIENT EDUCATION
Discuss the risks associated with general anesthesia with clients prior to performing on the client's animal(s).

PATIENT CARE
• Ruminants tend to hypoventilate under general anesthesia and require mechanical ventilation for procedures >90 minutes or if hypercapnic and/or hypoxemic.
• Other potential complications include: bradycardia, hypotension, hypothermia, hypoxemia, and hypoventilation. Monitoring for these complications is important, especially in compromised patients, and can be assisted by use of EKG, blood pressure monitoring, thermometer, and arterial blood gas analysis when available.

MISCELLANEOUS

AGE-RELATED FACTORS
• Neonatal and geriatric animals will have exaggerated drug effects if standard drugs are used; therefore it is recommended to reduce the drug doses.
• Both have decreased respiratory and cardiac reserves so support of oxygenation, ventilation, and chronotropic or inotropic support should be expected.

PREGNANCY
• There are several physiologic alterations in pregnant animals including an increase in cardiac output, blood volume, oxygen consumption, and minute ventilation.
• In addition, gastrointestinal motility and esophageal sphincter tone can decrease as well as functional residual capacity.
• Therefore the anesthetist should be prepared to intubate with a cuffed endotracheal tube, ventilate, and support the pregnant animal.

ANESTHESIA: INJECTABLE

BASICS

OVERVIEW
• General anesthesia produces unconsciousness, analgesia, and muscle relaxation for surgical or diagnostic procedures.
• To prevent complications associated with regurgitation, it is important to protect anesthetized ruminants' airways by placement of a cuffed endotracheal tube and positioning the head to allow regurgitant to flow out of oral cavity during lateral or dorsal recumbency.
• Injectable anesthetics may be administered via intravenous (IV) or intramuscular (IM) injection.
• An IV catheter, placed in jugular or auricular vein, is recommended for anesthesia maintained with continuous IV infusion.
• During recovery, ruminants should be placed in sternal recumbency and the endotracheal tube removed with cuff inflated when the patient regains swallowing and coughing reflexes.

MEDICATIONS

DRUGS OF CHOICE

α_2 Agonists (Xylazine, Detomidine, Medetomidine, Romifidine)
• Classified as sedatives/analgesics.
• Produce profound sedation, analgesia and central muscle relaxation by binding to α_2 receptors in the CNS and spinal cord.
• Often use with an injectable anesthetic to produce general anesthesia.
• Ruminants are more sensitive to xylazine's effect and only one tenth of the dose used in horses should be used.
• Doses required for detomidine, medetomidine, and romifidine to produce sedation in ruminants are similar to the doses required for horses.
• At higher recommended doses, α_2 agonists induce analgesia, recumbency, and immobilization suitable for minor procedures.
• Order of breed variation of sensitivity to xylazine in cattle: Brahman > Hereford > Holstein; in small ruminants: goats > sheep; in camelids: llamas > alpacas.
• Recommended dose ranges of xylazine are 0.1–0.2 mg/kg IV for cattle, sheep, and goats, 0.15–0.25 mg/kg IV for llamas and alpacas.
• Recommended dose ranges of medetomidine are 0.02 mg/kg IV for cattle and 0.025–0.05 mg/kg IV for llamas and alpacas.
• A α_2 antagonist (atipamezole, tolazoline, or yohimbine) can be given to reverse an α_2 agonist's pharmacological effect.
• Recommended dose ranges of atipamezole are 0.02–0.06 mg/kg IV for cattle, 0.05–0.2 mg/kg IV for sheep and goats, and 0.125 –0.5 mg/kg IV for llamas and alpacas.
• Recommended dose ranges of tolazoline are 0.2–2 mg/kg IV for cattle and 1–2 mg/kg IV for sheep, goats, llamas, and alpacas.
• Recommended dose ranges of yohimbine are 0.12–0.2 mg/kg IV for cattle and 0.125–0.22 mg/kg IV for sheep, goats, llamas, and alpacas.

CONTRAINDICATIONS
Animals with severely compromised cardiopulmonary functions

PRECAUTIONS
• Side effects: bradycardia, hypotension, decreased respiratory rate, cardiac arrhythmias, decreased gastrointestinal (GI) motility, hypoinsulinemia, hyperglycemia, increased urine output, and oxytocin-like effect.
• Premature parturition has occurred in pregnant ruminants with xylazine during the last trimester.
• Severe hypoxemia and pulmonary edema can occur in sheep.
• In animals with urethral obstruction, rupture of bladder can result from increased urine output.
• Ruminants and camelids are more sensitive to tolazoline's toxicity effect. Low recommended dose and slow IV injection should be used.

POSSIBLE INTERACTIONS
Additive or synergistic effect with other anesthetics.

Benzodiazepines (Diazepam, Midazolam, Zolazepam)
• Primary use for their anxiolytic, anticonvulsant, and central muscle relaxing effects.
• Have little or no analgesic effect.
• Produce minimal cardiovascular depression, used in animals with high anesthetic risk.
• Use with an injectable anesthetic to produce general anesthesia and improve muscle relaxation.
• Diazepam has 40% propylene glycol as solvent in the injectable solution. May precipitate if mix with water soluble solution.
• Midazolam is water soluble with two to three times more potency than diazepam.
• Diazepam or midazolam is used in goats with urethral obstruction, when the effect of increasing urine output is contraindicated.
• Immobilization with good analgesia is produced when diazepam is combined with xylazine in cattle.
• Recommended dose ranges of diazepam are 0.1 mg/kg IV for cattle, 0.23–0.3 mg/kg IV for sheep and goats, and 0.1–0.2 mg/kg IV for llamas and alpacas.
• Recommended dose of midazolam is 0.4 mg/kg IV.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Propylene glycol may cause hypotension if diazepam is administered IV rapidly.

POSSIBLE INTERACTIONS
Additive or synergistic effect with other anesthetics.

Dissociative Anesthetics (Ketamine, Tiletamine)
• Dissociative anesthesia is characterized by unconsciousness while maintaining eye reflexes (palpebral and corneal reflexes) and pharyngeal–laryngeal reflexes (swallowing reflex).
• Dissociative anesthetics cause direct CNS stimulation leading to increased sympathetic outflow and increased heart rate and arterial blood pressures.
• Respiratory pattern is characterized by an apneustic, shallow, and irregular pattern.
• Ketamine is the most popular injectable anesthetic for large animal species.
• Ketamine induces rapid onset and short duration of anesthesia and analgesia. When administered alone, muscle relaxation is inadequate for more painful surgery. Often combine with xylazine or diazepam for their central muscle relaxing effect.
• Subanesthetic doses of ketamine produce profound analgesia by blocking N-methyl-D-aspartate receptors.
• Recommended dose ranges of ketamine are 2.2–4.5 mg/kg IV for cattle, 1–5.5 mg/kg IV for sheep and goats, and 3–5 mg/kg IV for llamas and alpacas.

Table 1

Drugs Used for Injectable Anesthesia in Cattle, Small Ruminants, and Camelids.

	Dosages (mg/kg)			
Drugs	*Cattle*	*Sheep & Goats*	*Alpacas & Llamas*	*Comments*
Diazepam Xylazine	0.1, IV 0.2, IV	—	—	Immobilization with good analgesia for 30 min Total recumbency 60 min
Diazepam Ketamine	0.1, IV 4.5, IV	Mix 1 mL D (5 mg), 1 mL K (100 mg), give 1 mL/18–22 kg, IV	0.1–0.2, IV 4, IV	Anesthesia 10–15 min Total recumbency 30 min
Medetomidine Ketamine	0.02, IV 2.2, IV	0.02, IV 1–2, IV	0.025, 0.035, or 0.05, IM 1–1.5, IM	Anesthesia 70–120 min in calves Light anesthesia for 30–60 min in camelids
Midazolam Ketamine	—	0.4, IM 4, IV	—	Anesthesia 15 min
		Sheep	Alpacas	Anesthesia 30 min
Xylazine Ketamine	0.1–0.2, IV 2, IV	0.1, IV 0.2, IM 2.2, IV 3–5, IM	0.35–0.8, IM 5–8, IM Llamas	Preferred combination for adult large ruminants
		Goats	0.15–0.25, IV 0.25, IM	
Xylazine Ketamine		0.1, IM 3–5, IM	3–5, IV 5–8, IM	
BKX Butorphanol Ketamine Xylazine	0.0375, IM 3.75, IM 0.375, IM	1 mL/23 kg, IM; 1 mL/45 kg, IV	Alpacas: 1 mL/18 kg, IM Llamas: 1 mL/23 kg, IM	Anesthesia 20–30 min Mixture: add 1 ml LA X (100 mg), 1 mL B (10 mg) into 10 mL K (1,000 mg), give 1 mL/20 kg IM
Modified BKX Butorphanol Ketamine Xylazine	—	0.02 mL/kg, IV 0.03, IV 1.6, IV 0.03, IV	—	Mixture: add 8 mg of X, 8 mg of B into 400 mg (4 mL) of K For debudding in young animals
Bovine Triple Drip Xylazine (0.1 mg/mL) Ketamine (1–2 mg/mL) into 5% Guaifenesin	Induction: 0.67–1.1 mL/kg Maintenance: 2.2 mL/kg/hr	Induction: 0.67–1.1 mL/kg Maintenance: 2.2 mL/kg/hr	Induction: 0.67–1.1 mL/kg Maintenance: 2.2 mL/kg/hr	Adjustable dose for induction & maintenance Stable plane of anesthesia Smooth recovery
Propofol	4–6, IV	Induction: 3–4, IV or 4–8, IV Maintenance: 18–40 mg/kg/hr	Induction: 2–3.5, IV Maintenance: 24 mg/kg/hr	Anesthesia 5–10 min, single dose Apnea may occur CRI: 24 mg/kg/hr for maintenance of light anesthesia
Telazol	4, IV	2–4, IV	2, IV or 4.4, IM	Anesthesia 45–60 min Smooth but prolonged recovery
Xylazine Telazol	0.1, IM 4, IM	—	0.25, IV 1, IV	Anesthesia 60 min Standing in 130 min
TKX-Ru Telazol Ketamine Xylazine	1.25–1.5 mL/125 kg, IM for small cattle 1 mL/125 kg IM for large, adult cattle	—	1.25–1.5 mL/kg, IM for smaller patients 1 mL/110–115 kg, IM for larger patients	Mixture: Add 2.5 mL (250 mg) of K and 1 mL (100 mg) of X into 500 mg of Telazol Allow 20 min to reach peak effect Effective for capture wild ruminants Deep sedation, recumbency and chemical restraint in camelids; awake and assume sternal recumbency in 40–60 min

ANESTHESIA: INJECTABLE (CONTINUED)

• Telazol® is a combination of a tiletamine and zolazepam, in a 1:1 ratio by weight base.
• Telazol® comes as 500-mg powder, and is reconstituted with 5 mL sterile water into 100 mg/mL solution. Telazol® can be reconstituted with a smaller volume of sterile water with higher concentration, like adding 2.5 mL sterile water into 500-mg powder, resulting in a final concentration of 200 mg/mL.
• The pharmacologic effect of Telazol® is predominated by tiletamine. Similar to diazepam and midazolam, zolazepam produces minimal cardiovascular depression. Thus, Telazol® anesthesia is characterized by that of ketamine anesthesia, but better muscle relaxation, more profound analgesia, and longer duration of anesthesia.
• Recovery from Telazol® anesthesia tends to be smooth but prolonged in ruminant as a result of slower metabolism and elimination of zolazepam.
• Recommended dose ranges of Telazol® are 4–6 mg/kg IV for cattle, 2–4 mg/kg IV for sheep and goats, and 1–2 mg/kg IV for llamas and alpacas.

CONTRAINDICATIONS
N/A

PRECAUTIONS
• Ketamine increases salivation and mucus secretion in the respiratory tract, which can be reduced by administration of an anticholinergic, e.g., atropine.
• Prolonged recovery may follow Telazol® anesthesia.

POSSIBLE INTERACTIONS
Additive or synergistic effect with other anesthetics.

Guaifenesin (Glycerol Guaiacolate; GG)
• Administered alone, GG produces muscle relaxation, ataxia, and recumbency.
• Minimal changes on respiratory muscle activity and respiratory function at recommended doses of GG. Respiratory muscle paralysis occurs at doses 3–4 times higher than that required to induce recumbency.
• GG can be reconstituted with 5% dextrose to make up 5% or 10% injectable solution.
• Xylazine, ketamine, and GG combination ("bovine triple drip") for induction and maintenance of anesthesia (see Table 1).

CONTRAINDICATIONS
GG does not produce anesthesia or analgesia. It should always be used with an anesthetic.

PRECAUTIONS
Thrombophlebitis can occur with the administration of 5% solution. Hemolysis, hemoglobinuria, and venous thrombosis may occur with a solution of 10% or higher.

POSSIBLE INTERACTIONS
Additive or synergistic effect with anesthetics.

Propofol
• Short-acting hypnotic/anesthetic.
• Propofol is not water soluble, the injectable solution comes as a white, oil-in-water emulsion. This emulsion contains no preservative, the contents should be used or discarded within 8 hours. New formulation, PropoFlo 28, uses 20 mg/mL of benzyl alcohol as preservative, thus the 28 days of shelf life.
• A single dose of propofol induces 10 minutes of general anesthesia. Complete recovery without residual sedation and ataxia occurs within 20 minutes.
• Side effects include absence of analgesic effect at subanesthetic doses, apnea following bolus injection, and hypotension due to peripheral vasodilation.
• Recommended dose ranges of propofol are 4–6 mg/kg IV for cattle, 3–8 mg/kg IV for sheep and goats, and 2–3.5 mg/kg IV for llamas and alpacas.

CONTRAINDICATIONS
• Do not use in animals with preexisting hypotension.
• Cost is prohibitive for most large animal patients.

PRECAUTIONS
Apnea and hypotension may occur after bolus.

POSSIBLE INTERACTIONS
Additive or synergistic effect with other anesthetics.

FOLLOW-UP

POSSIBLE COMPLICATIONS
Severe CNS and cardiopulmonary depression which may result in death if overdose.

PATIENT CARE
Closely monitor vital signs: eye reflexes, heart rate, rhythm, respiratory rate and depth, and arterial blood pressures.

MISCELLANEOUS

PREGNANCY
• Premature parturition has occurred in pregnant ruminants with xylazine during the last trimester.
• Reduced anesthetic requirement in pregnant animals.

BASICS

OVERVIEW

• Local or regional anesthesia with appropriate patient restraint provides the most cost-effective method of humane anesthesia and analgesia in ruminants. Fractious animals may also require sedation.
• Local or regional analgesia causes a reversible loss of sensation to an area without loss of consciousness. Some techniques (i.e., LS epidural) can affect motor function if motor nerves are targeted.
• These techniques should not be used as the sole source of analgesia but can be used in conjunction with NSAIDs and/or systemic opioids for optimal analgesia.

SYSTEMS AFFECTED

• Nervous
• Musculoskeletal

PATHOPHYSIOLOGY

• All LA will block sodium channels and can be infiltrated near a nerve, epidural space, or in areas near planned surgical sites.
• Signs of LA toxicity include sedation, muscle twitching, convulsions, cardiopulmonary depression, coma, and death.

CAUSES AND RISK FACTORS

Variety of procedures from castration or dehorning to abdominal exploratory procedures.

DIAGNOSIS

CBC/CHEMISTRY/URINALYSIS

Routine blood work may be performed but is not commonplace for routine procedures.

TREATMENT

THERAPEUTIC APPROACH

Anesthesia for Dehorning and Castration

It is well documented that LA should be used in conjunction with NSAIDs for optimal analgesia in these procedures.

Dehorning, Bovine

There are 1 or 2 nerves to block in cattle, depending on horn size.
• *Cornual branch of zygomaticotemporal nerve*: 2.5–3.8 cm, 20G needle with 5–10 mL 2% lidocaine injected SQ ventral to the frontal ridge and halfway between the lateral canthus and the base of the horn.
• *Cutaneous branches of the second cervical nerve:* 2.5 cm, 20G needle with 5–10 mL 2% lidocaine injected SQ along the caudal aspect of the base of the horn. *Note*: this is only necessary in adult cattle with larger horns.

Dehorning, Ovine and Caprine

There are two nerves to block in sheep and goats.
• *Cornual branch of the lacrimal nerve:* 2.5 cm, 22G needle with 2–3 mL 2% lidocaine injected SQ halfway between the lateral canthus and lateral edge of the horn base.
• *Cornual branch of the infratrochlear nerve:* 2.5 cm, 22G needle with 1–2 mL 2% lidocaine inject SQ halfway between the medial canthus and the medial edge of the base of the horn.

Castration, Bovine, Ovine, Caprine

Infiltrate LA into the skin at the proposed incision site to desensitize the skin. Inject LA into the center of the testicle until it feels firm to the touch. The LA will migrate into the spermatic cord.

Anesthesia of the Eyelid and Eye

• *Auriculopalpebral block, bovine, ovine, caprine:* 2.5 cm, 22G needle with 5 mL (2 mL in ovine and caprine) 2% lidocaine injected SQ on the dorsal zygomatic arch about 5–6 cm behind the supraorbital process.
• *Retrobulbar block, bovine:* 9 cm, 18 or 20G curved needle with 5–10 mL 2% lidocaine at each of 4 sites. The needle is passed thru the eyelids at the 12, 3, 6, and 9 o'clock positions around the eye. *Ovine and caprine:* 3.8 cm, 20 or 22G needle curved is inserted as above but only at sites (6 & 12 or 3 & 9 o'clock) with 2–3 mL 2% lidocaine per site.
• *Peterson block, bovine:* 10–12 cm, 20G needle with 15–20 mL of 2% lidocaine. The needle is passed in front of the rostral border of the coronoid process of mandible but caudal to the zygomatic arch and supraorbital process. *Ovine and caprine:* 6.3 cm, 20G needle with 3–4 mL 2% lidocaine using the technique described for cattle.

Anesthesia of the Nasal Passages

• *Infraorbital block, bovine, ovine, caprine:* 3.8 cm, 18G needle with 5–10 mL 2% lidocaine is injected SQ at the infraorbital canal. The foramen is located 5 cm above the second premolar.

Anesthesia of the Flank and Paralumbar Fossa

• *Proximal paravertebral block, bovine:* The area should be prepped from the last rib to the TP of L4 about 4–5 cm from midline. A 3.8 cm, 16G needle is used as a guide for a 8.9 cm, 20G spinal needle. The cannula needle is placed thru the skin at anterior edge of TP of L1, 4–5 cm from dorsal midline. The spinal needle is passed until it contacts the L1 TP and walked off the cranial edge; as it passes thru the transverse ligament inject 6–8 mL for the ventral branch. Then withdraw the needle to 2.5 cm over the fascia and deposit an additional 6–8 mL for the dorsal branch. Continue this at the other sites. *Ovine and caprine:* Same technique with a 2.5–3.8 cm, 20G needle with 0.5–1 mL for the dorsal branch and 2–3 mL for the ventral branch with 2% lidocaine. Do not exceed 5–6 mg/kg total.
• *Distal paravertebral block, bovine:* The area of the block is clipped and prepped from T13 to L3 on the lateral aspect. A 3.5–5.5 cm, 18G needle is inserted ventral to the TP and 10 mL of LA is infused in a fan pattern. The needle is then redirected or reinserted dorsally and LA is infused caudally in a fan pattern as well. Repeat at the other sites.

Anesthesia of the Linea Alba and Paramedian Region

• *Cranial (lumbosacral) epidural block*, bovine: Not recommended as LA infiltration will cause motor blockade of the pelvic limbs preventing ability to stand. *Ovine and caprine*: 3.8 cm or 7.5 cm, 20 or 22G spinal needle is inserted on midline between L6 and S1. Confirmation of correct placement is usually done with the hanging drop technique where saline will be pulled by negative pressure into the epidural space. A dose of 0.4–0.6 mL/kg of 2% lidocaine will provide anesthesia up to the navel region.

Anesthesia of Pelvic Area

• *Caudal (sacrococcygeal or intercoccygeal) epidural, bovine*: The space is located between S5-Co1 or Co1-Co2 and is easily palpable while moving the tail up and down. You will feel this as the space between the last anchored and first movable vertebrae. A 3.8 cm, 20 or 18G needle is passed on midline at a slight cranial angle into the vertebral space. Check placement with hanging drop technique. A dose of 0.01–0.02 mL/kg of 2% lidocaine can be used. *Ovine and caprine:* The same technique as above with 2.5 or 3.8 cm, 20G needle at S4-Co1 or Co1-Co2 with an injection volume of 0.01–0.03 mL/kg. The needle is directed at a 45° angle in small ruminants.

Anesthesia of the Teats and Udder

See "Suggested Reading" for these techniques including a ring block, inverted "V" block, and teat sinus infusion blocks. A proximal or distal paravertebral block extending from T13 to L4 can be used to block a majority of the udder.

SURGICAL CONSIDERATIONS AND TECHNIQUES

The type of block used will largely depend on clinician preference, position and temperament of the animal, and length of procedure.

MEDICATIONS

DRUGS OF CHOICE

Lidocaine

• Only approved LA for use in cattle and sheep in the United States and Canada.
• The maximal effect occurs within 2–5 minutes of injection and lasts 90 minutes.

ANESTHESIA: LOCAL AND REGIONAL (CONTINUED)

• The addition of epinephrine (0.01 mg/mL) was found to increase the duration of activity to 304 minutes. However, epinephrine cannot be used in limb blocks or wound edges due to the potential risk of ischemia and tissue necrosis.
• The maximum dose is 6 mg/kg for ruminants.

Bupivacaine and Mepivacaine

• Off-label use
• The maximal effect occurs within 20–30 minutes and lasts 5–8 hours for bupivacaine. Mepivacaine behaves similarly to lidocaine.
• Bupivacaine exhibits the most cardiotoxic effects of all the LA and should be only used for SQ or infiltrative techniques.
• The maximum dose is 2 (bupivacaine) and 5–6 (mepivacaine) mg/kg. No withdrawal times have been established.

CONTRAINDICATIONS

• Regulatory restrictions: See "Suggested Reading" for links to the FDACVM and AMDUCA or recommendations for the use of LA in ruminants.
• Meat and milk withholding: See "Suggested Reading" for the link to FARAD and withdrawal times recommended.

BASICS

OVERVIEW

• Anestrus is the absence of estrus behaviors in female animals.
• Anestrus is physiological before puberty, between estrus periods, for a variable time after parturition or during lactation, during pregnancy, and seasonally in sheep and goats.
• Pathologic anestrus is the absence of estrus during a time when it would normally be expected to occur.
• Pathologic anestrus results from a disruption of the reproductive axis and typically involves the absence of both the behavioral signs of estrus and the underlying normal ovarian events associated with cyclic activity, although follicular waves may still occur.
• The most common clinical manifestation of anestrus is a delayed return to ovular cycles after parturition. Anestrus is also used to describe animals undergoing normal ovular cycles where the signs of estrus are missed, due either to deficiencies in management (unobserved estrus), subtle or absent signs of estrus (silent heat/subestrus), or both. The intensity and duration of estrus behavior may also be reduced or absent altogether at the first postpartum, seasonal or postpubertal ovulation in ruminants.
• Animals experiencing pathologic anestrus are usually anovular though some cases are associated with prolonged luteal function (CL retention).
• Follicular growth may be arrested at any stage of development as reflected in the size of structures found on the ovaries. Growth and persistence of follicular structures beyond the normal ovulatory size and duration is defined as OCD.

INCIDENCE/PREVALENCE

• The incidence of anestrus varies widely with the specific condition on the farm and the species affected.
• In dairy cows, for example, the incidence of delayed return to estrus after parturition in four recent reports ranged from 29 to 54% in primiparous cows and from 15 to 32% in multiparous cows.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Reproductive

PATHOPHYSIOLOGY

• Pathologic anestrus may be the result of a primary disruption or disease at the level of the hypothalamus, pituitary, or ovary.
• Commonly, anestrus is secondary to disease or derangement in some other body system. Examples include nutritional deficiencies, especially energy; chronic severe illness, pain or stress resulting in a loss of body condition; heat stress; and uterine disease with or without retention of a CL.
• The endocrine basis for profound anestrus associated with very small follicles is unclear. Anestrus associated with follicular growth to the point of deviation and beyond appears to be related to inadequate LH pulses for follicular development and the absence of an LH surge sufficient to cause ovulation.
• Anestrus occurring in association with prolonged luteal function is likely the result of inadequate uterine $PGF2_{\alpha}$ production, secretion, or transport to the ovary.
• Management deficiencies related to estrus detection can lead to a mistaken diagnosis of anestrus in otherwise normally cycling animals.
• In high-producing dairy cattle, increased liver metabolic rates related to high feed intake result in lower circulating levels of gonadal steroids with a subsequent depression of the length and intensity of estrus.
• In heat-stressed cattle, follicular steroidogenic capacity is reduced leading to lower blood estradiol concentration and diminished or absent signs of estrus.
• On rare occasion, anestrus in cattle may be iatrogenic due to inadvertent feeding of a progestational agent (e.g., MGA).

HISTORICAL FINDINGS

• Individual animals: Absence of cyclicity (estrus) beyond 60 days postpartum. Absence of estrus after a negative pregnancy diagnosis.
• Herd or flock: Reduced mating activity, decreased pregnancy rates, increased interval from calving to first insemination, poor heat detection.

SIGNALMENT

• Sexually mature (postpubertal) female animals.
• Specific conditions vary with species and breed depending on nutrition, milk production levels, reproductive management systems, suckling intensity, seasonal (photoperiodic) influences, and the occurrence of systemic or uterine diseases.
• Suckled beef cattle will have a postpartum anestrus period 2 to 3 times as long as beef or dairy cattle that are milked.

PHYSICAL EXAMINATION FINDINGS

• Absence of sexually receptive behavior.
• Poor body condition score or other condition preventing expression of estrus.

GENETICS

• Ovarian agenesis, ovarian hypoplasia, and premature ovarian failure are rare examples of profound anestrus conditions and all probably have a genetic basis.
• The role of inheritance in the more common types of anestrus is uncertain.

CAUSES AND RISK FACTORS

• Poor nutritional management, especially in the transition period.
• High milk production and increased feed intake.
• Heat stress.
• Systemic disease.
• Lameness.
• Loss of body condition.
• Postpartum uterine infections (see chapter, Endometritis) can delay the resumption of normal cycles and increase the incidence of OCD.
• Long dry periods.
• Twin calving/Freemartinism.
• Primary uterine or fetal disease (e.g., pyometra, hydrometra [goats], mummified fetus, prolonged gestation).
• Early postpartum ovulation (<25 days) is associated with a persistent or retained CL.
• Rarely, ovarian tumors, segmental aplasia, ovarian hypoplasia, mycotoxins, and micronutrient deficiencies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Physiological anestrus (pregnancy, sexual immaturity, lactation, or seasonal).
• Ruling out pregnancy should be the first consideration, otherwise diagnostic and therapeutic procedures could potentially result in iatrogenic abortion.
• Freemartinism.
• Inadequate estrus detection/reproductive management deficiencies.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Consistently low progesterone concentrations in serum or milk may confirm anovular (lacking ovulation) anestrus.

IMAGING

• Transrectal ultrasonography reveals persistently small inactive ovaries or failure to ovulate when larger follicles or cystic structures are present.
• Repeated examination may be necessary to confirm the diagnosis. A CL will be absent in most cases but, if present, the uterus should be carefully examined for evidence of pyometra or other uterine disease.

OTHER DIAGNOSTIC PROCEDURES

• Records analysis/history.
• Transrectal ultrasonography or palpation per rectum in cattle.
• Serum progesterone analysis.
• Observation for sexual activity as appropriate for each species.

PATHOLOGIC FINDINGS

N/A

ANESTRUS (CONTINUED)

TREATMENT

THERAPEUTIC APPROACH
• Correct nutritional deficiencies or other primary problems (e.g., lameness).
• Hormonal induction of estrus and/or ovulation.
• Heat abatement.

SURGICAL CONSIDERATION AND TECHNIQUE
Ovariectomy in case of GTCT.

MEDICATIONS

DRUGS OF CHOICE
• GnRH or hCG
• PG600 (combination of FSH and hCG) in sheep and goats
• $PGF2_{\alpha}$ for retained/persistent CL, pyometra and hydrometra
• Ovulation synchronization (Ovsynch®) protocol with the addition of a CIDR
• Ovulation presynchronization protocols that include an injection of GnRH before the breeding Ovsynch®.

CONTRAINDICATIONS
$PGF2_{\alpha}$ should not be given to pregnant animals.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Estrous cycles will resume once nutritional, reproductive, and management issues are addressed.
• Delay in initiating treatment increases the risk of culling for reproductive reasons.

POSSIBLE COMPLICATIONS
• Pyometra
• Delayed conception

CLIENT EDUCATION
Use appropriate methods for estrus detection and monitoring of breeding activity.

PATIENT CARE
Monitor body condition score and behavioral activity.

PREVENTION
• Sound nutritional management, especially in the transition period, to avoid excessive loss of body condition.
• Minimize the incidence of dystocia, retained fetal membranes, and metritis/endometritis.
• Heat abatement.
• Decreased dry period length for older cows.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Pyometra
• Endometritis
• Twinning
• Lameness
• Starvation
• Heat stress

AGE-RELATED FACTORS
In cattle, prolonged postpartum anestrus is more common in primiparous than in multiparous cows.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
• Pregnant animals experience a normal, physiological anestrus.
• $PGF2_{\alpha}$ will invariably (goats and camelids) or frequently (sheep and cattle) cause abortion.

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
• Persistently anestrus females in well-monitored operations with strong management and husbandry protocols should be considered for culling.

ABBREVIATIONS
• CIDR = controlled intravaginal drug release device for delivery of progesterone
• CL = corpus luteum
• FSH = follicle stimulating hormone
• GnRH = gonadotropin-releasing hormone
• GTCT = granulosa-theca cell tumor
• hCG = human chorionic gonadotropin
• LH = luteinizing hormone
• MGA = melengestrol acetate
• OCD = ovarian cystic degeneration
• $PGF2_{\alpha}$ = prostaglandin $F2_{\alpha}$

BASICS

OVERVIEW

• Angular limb deformity (ALD; "bent-leg") is a deviation from the normal axis of a limb (in the frontal plane) and is defined by the joint involved and the direction that the distal aspect of the limb is deviated.
  ◦ **Valgus** deformity: The limb distal to the lesion deviates *laterally.*
  ◦ **Varus** deformity: The limb distal to the lesion deviates *medially.*
  ◦ ALDs are further described by the location of the pivot point (axis of deviation) and by the location of the site of defective growth.
• Some ALDs are caused by asymmetrical lesions involving an active growth plate (e.g., distal radius), but growth plate damage is not always the underlying cause.
• Related conditions include flexural deformities, tendon injuries, joint luxations/joint instability caused by laxity of supporting structures, and rotational/torsional deformities.
• Hereditary chondrodysplasia (HC), or spider lamb syndrome, is a hereditary condition in young lambs characterized by a number of skeletal deformities, including angular limb deformities.

INCIDENCE/PREVALENCE

• Valgus and varus ALDs are common and well documented in horses, but are relatively rare in ruminants. • Congenital limb abnormalities are reported to account for 6.9% of all congenital abnormalities in cattle.

GEOGRAPHIC DISTRIBUTION

Worldwide.

SYSTEMS AFFECTED

Musculoskeletal

PATHOPHYSIOLOGY

• ALDs are considered multifactorial in origin and have congenital/perinatal and developmental predisposing factors.
• Congenital ALDs may arise from environmental factors, genetic factors, or both. These include: toxins, placentitis, laxity of periarticular soft tissues, and intrauterine or perinatal physical factors (e.g., twinning, trauma). • Contributions to the formation of ALDs in immature and mature animals can stem from a low plane of nutrition, trauma, and excessive limb loading. • In llamas, the distal ulnar epiphysis fuses with the distal radial epiphysis. This unique development of the distal portion of the ulna is associated with forelimb valgus deformities in crias. The ulnar epiphysis extends distally, crosses the radial physis, and fuses with the radial epiphysis. This early fusion demands synchronous growth to ensure normal limb development. • Most calves have a mild carpal valgus deformity of approximately 7 degrees, which does not require treatment. Varus deformities in cattle are abnormal and often need treatment.

HISTORICAL FINDINGS

A complete history including current age, birthing details, age at which the deformity was noticed, course and progression of the deformity, and diets of affected animal and dam should be obtained.

SIGNALMENT

Species

• Bovine, ovine, caprine, South American camelids (especially llama crias), cervids—including fallow deer (*Dama dama*), red deer (*Cervus elaphus*), white-tailed deer (*Odocoileus virginianus*)—and a single case report of ALD in a giraffe calf (*Giraffa camelopardalis*).

Breed Predilections

• ALDs have been described in many different beef and dairy cattle breeds. • HC primarily affects black-faced breeds of sheep (Suffolk, Hampshire, Southdown, Shropshire, and Oxford). • Varus/valgus deformities have been described in the distal radial physis of yearling farmed male red and wapiti-red crossbred (elk) deer in New Zealand.

Mean Age and Range

• ALDs primarily affect young growing animals up to 7 months of age, but can be seen in older animals (e.g., trauma-induced ALD). • HC has two distinct clinical entities: lambs are either grossly abnormal at birth or develop the abnormal conformation at 4–6 weeks of age. Radiographic changes at birth are similar for both.

Predominant Sex

No apparent sex predisposition.

PHYSICAL EXAMINATION FINDINGS

• Conformation should be assessed first by having the animal stand in a symmetrical manner on a firm, flat surface and observing it from multiple angles. Affected animals may appear to be knock-kneed or bowlegged. All limbs should be palpated and affected limbs should be manually manipulated. Clinical signs such as abnormal bending of the affected limb, increased laxity, muscle atrophy, swelling, heat, pain on manual pressure, abrasions on lateral or medial side of hoof wall, presence of orthopedic injury, and abnormal gait and locomotion are indicative of ALD. • Compensatory deviation (opposite that of the affected limb) is relatively common in the contralateral limb. • If varus deformity is found unilaterally, the contralateral limb should be examined for a significant orthopedic injury as a cause of excessive weight bearing in the deformed limb/joint.
• Since cattle are considered to have a "normal" degree of medial deviation at the level of the carpus and hock, as well as normal external rotation of the lower limb, ALDs tend to be missed in the early stages of development. • Most bovine ALDs occur at the level of the mid-diaphysis of long bones.
• In sheep affected with HC, various degrees of ALDs of fore- and/or hindlimbs will be noted. Other physical examination findings include severe scoliosis/kyphosis of the thoracic spine, pectus excavatum, retarded growth rates, facial deformities such as angular deviation and/or shortening of maxilla, rounding of the dorsal silhouette, and Roman-shaped noses.

GENETICS

• The questions of heritability in ALDs have not been definitively answered; the details of some syndromes are known. • ALDs in Jersey calves are genetically transmitted as a simple autosomal recessive trait. • HC of Suffolk and Suffolk-cross sheep is inherited as a single, autosomal recessive gene that has been localized to the distal end of chromosome 6. A defect in the gene encoding fibroblast growth factor receptor 3 (FGFR3) is suspected. DNA tests (blood or semen) are available to identify homozygous and heterozygous animals.

CAUSES AND RISK FACTORS

• ALDs are often related to asymmetrical growth of the physis, ligament rupture, or orthopedic injuries.

Congenital Predisposing Factors

• Incomplete cuboidal bone ossification (carpal and/or tarsal). • Physiologic immaturity at birth. • Uterine malpositioning. • In utero bending stress and bone remodeling early in gestation. • Twin (or triplet) pregnancy. • Reduced intrauterine space may limit fetal movement and subsequently cause congenital angular and/or flexural limb deformities. • Laxity of periarticular supporting structures.
• Disproportionate osseous growth of medial and lateral aspects of long bones (e.g., distal radius, tibia, metatarsus). • Nutritional imbalance during gestation. • Genetic causes.

Developmental Predisposing Factors

• Conformational defects (causing abnormal weight distribution across a joint).
• Nutritional disorders (e.g., improper dietary calcium and phosphorus ratios; copper, zinc, manganese, iron, and molybdenum concentrations). • External trauma (e.g., compression of or trauma to growth plate; Salter-Harris fractures, malunion of fractures, inflammation of growth plate). • Iatrogenic (e.g., assisted delivery). • Excessive exercise.
• Hematogenous osteomyelitis involving the physeal region. • Rapid weight gain in heavy breeds (high energy rations and rapid growth).
• Often, no specific cause is identified.

Camelids

• May see ALDs (usually carpal valgus) in growing camelids with hypophosphatemic rickets syndrome. • Ill-thrift syndrome in llamas may be associated with ALDs as well as anemia, low serum iron concentrations, and metabolic disorders (hypothyroidism). Underlying cause not established.

ANGULAR LIMB DEFORMITY (CONTINUED)

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Physiologic deformities. • Metabolic bone disease (e.g., rickets). • HC may be confused with arthrogryposis-hydranencephaly syndrome (AHS) in lambs, in which there is characteristic hyperflexion of forelimbs, cranial overextension of hindlimbs, with a corkscrew deviation of the spine. In lambs with AHS, severe deformities result from primary abnormalities of the CNS (including hydranencephaly and others) and not of the skeleton.

Camelids

True ALDs in llamas must be differentiated from valgus deformities of the forelimbs in newborn crias that self-correct without surgical treatment.

CBC/BIOCHEMISTRY/URINALYSIS

• There are usually no associated laboratory abnormalities with ALDs. • HC results in slightly elevated serum alkaline phosphatase activity; insufficient for diagnostic purposes.

Camelids

• Ill-thrift syndrome: Serum vitamin D (25-hydroxycholecalciferol) concentrations are often diagnostic. • May also see hypothyroidism, anemia, erythrocyte dyscrasias, hypophosphatemia, and low serum iron concentrations.

OTHER LABORATORY TESTS

N/A

IMAGING

• Radiographs are critical in diagnosing ALDs—at least two views, 90 degrees apart, should be taken of the affected joint, including joints immediately proximal and distal to the affected joint. • The dorsopalmar/dorsoplantar (DP) view is needed for examination of the anatomical location of the deformity and for measurements. The pivot point is defined as the intersection between lines drawn through the long axis at the center of the proximal and distal long bone using the dorsopalmar view. Location of the pivot point identifies the type of deformity. Measure the angle of deviation with a protractor. • HC: Most consistent lesions include multiple islands of ossification of the anconeal process and malformed, displaced sternebrae. The anconeal lesions of HC are progressive, whereas similar lesions in other skeletal conditions of lambs regress.

OTHER DIAGNOSTIC PROCEDURES

• Bacterial cultures may be indicated in cases of septicemia, arthritis, or osteomyelitis. • Toxicology (heavy metal and mineral analysis) and feed analysis may assist in diagnosis.

PATHOLOGIC FINDINGS

• Histology: Focal or segmental thickening of the physis (expansion of the hypertrophic zone) with extension into the proximal metaphysis; closely resembles physeal manifestations of osteochondrosis. • Histology associated with HC (vertebrae and long bones): Increase in width of the zone of proliferation and hypertrophy and unevenness of growth cartilage; failure to form or maintain orderly columns of chondrocytes.

TREATMENT

THERAPEUTIC APPROACH

• Treatment of neonatal animals with incomplete ossification involves the application of tube casts or splints to the affected limb(s) until ossification is complete (based on repeated radiographs). • Many cases of ALD will resolve without surgery if the underlying cause(s) can be identified and addressed and if the animal does not damage the affected physis or joints with vigorous exercise. • Specific treatment methods are selected on the basis of age, degree of angulation, remaining growth potential of the involved physis, and experience of the veterinarian. • Minor limb deviations may be conservatively treated by manual alignment and external support of the limb (e.g., rigid splinting, bandaging, or casting/tube casts) and/or hoof (claw) trimming. • Hoof manipulations create growth plate response to stress applied opposite the deformity, and self-correction occurs. The hoof tends to turn in the direction of the longer claw or toward the side of the wider wall, resulting in straightening and de-rotation of the limb. • Medial (varus) deformities can be treated by trimming the medial claw shorter than the lateral claw and by placing an acrylic (methyl methacrylate) wing on the weight-bearing surface of the lateral claw (to increase lateral contact with the ground). • Treatment should be directed at the orthopedic injury when varus deformity is present secondary to a contralateral limb injury.

SURGICAL CONSIDERATIONS AND TECHNIQUES

• Surgery is recommended for older animals (near the end of active physeal growth), for those that do not respond to conservative treatments, and for animals with bone malformations that require realignment (via osteotomy). • The choice of surgical technique should take into consideration the economic value and age of the animal, severity of the deformity, and the joint involved.

Treatment Strategies Include the Following:

Growth Acceleration (Periosteal Stripping/ Elevation)

In young calves and lambs with early cases of ALD, surgical growth stimulation via periosteal stripping on the concave aspect (shorter side) of the deformity has been used successfully. Based on the remaining growth potential in the physis, allow the animal to correct the deviation by physeal growth.

Growth Retardation (Transphyseal Bridging)

• Transphyseal bridging is indicated for severe cases of ALD or in animals past the rapid growth phase of the radius and ulna (often recommended for animals older than 5 months of age). • By creating a temporary transphyseal bridge on the convex side of the deformity using staples or screws and wires, limb growth is slowed by restricting growth and allows the other side to continue growing, resulting in limb straightening. • The surgical implants must be removed when the limb achieves normal conformation to prevent overcorrection. This can be used in combination with periosteal stripping to increase the likelihood of full correction in animals with severe deviations.

Corrective Wedge Osteotomy

• This procedure is indicated in mature animals with ALD and in neonates with congenital fracture malunion. If the growth plates are closed or if the growth plate is not involved in an ALD, a corrective osteotomy is recommended. This requires more experience and equipment and often is reserved for valuable animals when response to other therapies has failed. • The site and orientation of the wedge should be determined by clinical and radiographic examination. • The limb needs to be stabilized by internal fixation with a plate and screws for an extended postoperative period.

Camelids

An ulnar osteotomy must be done in conjunction with the periosteal transection because the ulna spans the radial physis.

MEDICATIONS

DRUGS OF CHOICE

Nonsteroidal anti-inflammatory agents (NSAIDs) are recommended to reduce inflammation in some cases of ALD.

CONTRAINDICATIONS

Prolonged NSAID administration has been associated with gastrointestinal (abomasal or C3) ulcers.

PRECAUTIONS

• Many of these affected animals are young; precautions regarding drug choices must take age into consideration. • Appropriate milk

and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Prognosis is guarded, yet reasonable for ALDs associated with growth plate imbalances, such as most valgus deformities. • The prognosis for ALDs secondary to contralateral orthopedic injury (such as most varus deformities) is generally poor because it is usually centered over a joint and is dependent on the prognosis of the primary orthopedic injury. • HC-affected individuals rarely survive the neonatal period. • Camelids: The prognosis for ill-thrift syndrome in llamas is poor; etiologic agent often not identified.

POSSIBLE COMPLICATIONS
• In cases of valgus deformity, efforts should be taken to prevent compensatory varus in the contralateral limb. Persistence of hoof distortion is possible if the angular deformity is not corrected. • Surgical: transphyseal bridging—overcorrection of the physis is possible. Owner cooperation is required to determine when limb has regained its normal conformation. • Possible ALD surgical complications include muscle, tendon, and ligament atrophy/laxity, hyperextension of limbs, fibrous scar tissue development, and postoperative infection.

CLIENT EDUCATION
• Examination and intervention of young animals with congenital ALDs should be done as early as possible. • Due to the possible hereditary link with ALDs, breeding of affected animals is not recommended.

PATIENT CARE
• Severely affected animals may be unable to rise to nurse and require additional supportive care. Protect limbs with thick, soft bandages that fit well. • Care should be taken to maintain a soft (padding), clean, and dry environment and to minimize decubital/pressure sores, open arthritis, muscle atrophy, umbilical infections, and septicemia. • Physical confinement (stall) is recommended for the management of ALDs to limit stresses placed on affected limbs.
• Nutritional imbalances have been implicated, such as ill-thrift in llamas. Treatment for this condition includes appropriate vitamin D supplementation.
• Other dietary imbalances should be corrected while treating cases of ALD.
• Frequent physical monitoring and repeated radiographs should be done to assess the efficacy of corrective measures and to monitor progress. • In cases of transphyseal bridging surgery, owner cooperation is required to determine when the limb has regained its normal conformation, at which time the implants must be removed to prevent overcorrection.

PREVENTION
Avoid breeding affected animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Conditions associated with ALDs include osteochondrosis of the physis, epiphysitis, and incomplete ossification of the cuboidal carpal bones. • Hyena disease (premature physeal closure) has been reported in calves due to overdose of vitamins A, D3, and E.
• Congenital lethal chondrodysplasia in Australian Dexter cattle = "Dexter bulldog calves". • Congenital chondrodysplastic dwarfism in Holstein calves. • Complex vertebral malformation is a familial syndrome of Holstein calves. • Syndrome known as "bentleg" or "bowie" associated with ingestion of *Trachymene glaucifolia* (wild parsnip) by pregnant ewes in Australia and New Zealand.

AGE-RELATED FACTORS
The majority of ALDs occur during the active growth phase of the affected bone/joint.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
• Many of the causes of ALDs are congenital diseases in which the in utero environment is somehow disturbed (hormones, vascular supply, teratogens, mechanical factors, or prenatal viral infections). • Cases of ALDs in goats pregnant with triplets have been reported. • Contributing factors likely include stress and in utero malpositioning.

ANTHELMINTIC RESISTANCE

BASICS

OVERVIEW
Gastrointestinal nematodes are common and may cause pathology that impacts health and welfare of infected animals. Infestation with these nematodes decreases production parameters. Control measures have relied predominantly on periodic administration of anthelmintic drugs to the entire herd or flock. Their continual use has led to the selection of populations of drug-resistant worms worldwide. Multi-drug resistance has now been reported in sheep and cattle. Anthelmintic resistance by *Haemonchus contortus* in sheep has been well documented and in cattle recent reports of resistance in *Cooperia* spp. and to a lesser extent in *Ostertagia ostertagi* are now documented.

INCIDENCE/PREVALENCE
Each farm may have different levels of resistant parasite populations. The level of resistance is dependent on how frequently the herd has been treated with anthelmintics and how effective those compounds have been in reducing luminal burdens.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Gastrointestinal, which may lead to pathology of other organ systems with significant infections.

PATHOPHYSIOLOGY
Individual nematodes that survive an anthelmintic treatment have a reproductive advantage in the absence of competition by susceptible worms in the intestine. This advantage persists until lifecycle features prevail or anthelmintic levels decrease and allow reestablishment of susceptible parasites. Resistant worms transmit their unique, heritable traits to the next generation and by doing so they increase the frequency of their genetic alleles in the general population. Depending upon the parasite, the clinical significance of the infection may be greater than would be present if the treatment was more effective. Resistant worms have no particular advantage until the selection pressure of anthelmintic treatment is applied. Once this happens, a great way to accentuate this advantage is to repeatedly use the same anthelmintic. Individual worms are initially resistant to only one class of anthelmintics, so when "drug A" is used, they survive, but if "drug B" were introduced, the worms would be removed like the rest of the susceptible population. Thus, the reproductive advantage of resistant worms would be favored if "drug A" were used exclusively.

HISTORICAL FINDINGS
Lack of efficacy of anthelmintic treatment evidenced by poor fecal egg count reductions and increased clinical signs of parasitism.

SIGNALMENT
All ruminants may be affected.

PHYSICAL EXAMINATION FINDINGS
The signs of parasitism may be variable depending upon the pathogenicity of the resistant parasites.

GENETICS
All ruminants may be affected, but it is most common to find that 20% of a herd will harbor 80% of the parasites. This fact suggests that a genetic component exists within a population of animals that allows the majority of the herd to have some level of resistance to internal parasites. The issue then becomes identifying those individuals within the herd that are most susceptible to continued infection and providing them with effective treatment.

CAUSES AND RISK FACTORS
Anthelmintic resistance in a nematode population is a phenotypic manifestation of a heritable, genetic trait within that population. The genetic basis and modes of inheritance of resistance are quite complex and differ widely among the various classes of compounds, but positive selection occurs whenever worms carrying resistant alleles are exposed to an anthelmintic to which they have lost their susceptibility.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Any cause of weight loss may be considered as a differential for chronic parasitism. In sheep with *Haemonchus contortus* infections anemia and hypoproteinemia are predominate signs.

OTHER LABORATORY TESTS
The standard by which parasite loads are measured is the assessment of fecal egg counts per gram of feces (EPG). Fecal EPG of cattle tend to be less reflective of the adult worm burden when compared to sheep. This fact leads to a great deal of uncertainty in the detection of anthelmintic resistance in cattle. Resistance can be defined as a measurable decrease in efficacy of a compound against parasitic species and its larval stages that were previously susceptible.

OTHER DIAGNOSTIC PROCEDURES
The use of fecal EPGs on a herd basis is important to obtain knowledge of the efficacy of any anthelmintic. It is important to obtain an adequate sample size, although the number of animals with an adequate infection for enrollment can be limited. Recommendations to minimize diagnostic uncertainty include the use of arithmetic means over geometric means to calculate anthelmintic efficacy, the use of individual based group means with pre- and post-treatment individual fecal egg counts, and the preferred use of diagnostic methods with higher analytic sensitivity to minimize inaccuracies in populations with low baseline fecal egg count.

PATHOLOGIC FINDINGS
The pathology associated with internal parasites is variable and dependent on the genus.

TREATMENT

THERAPEUTIC APPROACH
The key to parasite control is either to prevent egg shedding and/or prevent larval uptake. For the last 50 years we have tried to prevent egg shedding by routine anthelmintic treatments. Managing animals to prevent larval uptake can be accomplished by co-grazing different species, removal of feces or clever use of available pasture lands. The assessment of the drug disposition in the host and increased knowledge of the mechanisms of drug interaction in the targeted parasites has increased our understanding of how these anthelmintics actually work. It is clear that we need additional scientific knowledge on how to improve the use of available molecules to avoid or delay development of resistance.

MEDICATIONS

- See "Follow-Up"
- See chapters, Parasite Control Programs

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
This is a life-threatening aspect of small ruminant production and serious consequences will occur if solutions are not forthcoming.

POSSIBLE COMPLICATIONS
Very limited information is available on the potential additive or synergistic effects occurring after co-administration of two (or more) drugs with different modes of action.

CLIENT EDUCATION
A change in treatment philosophy is necessary to combat or delay the development of anthelmintic resistance in ruminant nematodes. Producers have used dewormers in a very cavalier manner over the past 40

years and been taught that when deworming, all animals in the herd must be treated. New knowledge and evidence point out that this technique has helped to create the resistance that is now present. Educating producers on how to address parasite problems must be done and this knowledge needs to encompass feed stores and pharmaceutical supply houses as well.

PATIENT CARE

The individual monitoring within a herd will be necessary to allow for identification of those that have the highest parasite loads.

PREVENTION

- Integrated management and pharmacologic intervention.
- Treatment targeted at those individuals that harbor the most parasites and are at risk for the development of adverse clinical signs.
- Different pharmacokinetic-based approaches to enhance parasite exposure.
- Mixed-class anthelmintic treatment.

MISCELLANEOUS

PREGNANCY

Chronic parasitism may significantly affect gestating dams, especially in small ruminants infected with *H. contortus.*

BIOSECURITY

Anytime a new animal is brought on to a property they should be evaluated for their internal parasite load. This is especially critical in small ruminant populations with *Haemonchus contortus*. Purchased additions should be screened and quarantined to evaluate their existing infestation and, if they are infected, their response to treatment.

PRODUCTION MANAGEMENT

Production is imperative to success in ruminants and internal parasites are a major contributor to production losses. Control of these parasites is critical for success in rearing young stock.

ABBREVIATION

- EPG = egg count per gram of feces

ANTHRAX

BASICS

OVERVIEW

• Anthrax is a bacterial disease that many animals are susceptible to including humans.
• In ruminants it causes acute bacteremia, septicemia, and usually death. It is caused by *Bacillus anthracis* which is present in the soil.
• It is seen most often in and is highly pathogenic for most wild and domestic herbivores.
• In most areas anthrax is a reportable disease and the regional veterinary authorities should be notified of an outbreak.
• In the USA, *Bacillus anthracis* is listed in the Federal Select Agent Program.

INCIDENCE/PREVALENCE

• Anthrax spores are endemic in parts of the United States, where occurrence of clinical disease is usually sporadic.
• Both sporadic cases and outbreaks are often associated with disruption of the soil.
• Morbidity varies widely but case mortality is 90–95%.

GEOGRAPHIC DISTRIBUTION

• Anthrax is found worldwide but certain regions have higher occurrence of disease.
• Anthrax spores favor areas with neutral to alkaline soils with high levels of calcium and manganese and are organically rich.

SYSTEMS AFFECTED

• Hemolymphatic
• Multisystemic

PATHOPHYSIOLOGY

• Soil-borne spores are the infective form of the bacteria.
• In ruminants the main source of infection is consuming spore-contaminated pasture or feed. However, spores can enter the host via the cutaneous or respiratory systems also.
• Once in the host, the spores germinate and produce the vegetative form of the bacterium which rapidly proliferate.
• These rapidly dividing bacteria produce capsule and toxins. Early in the infection these toxins help the bacteria to evade the immune system resulting in systemic infection. Later in the infection with large numbers of bacteria in the blood, the toxins enter cells of other systems resulting in vascular shock and death.
• Late in the course of the disease and at death all animal excretions contain large numbers of bacteria and sporulate when contacting air. This exposes additional animals and contaminates the environment.

SIGNALMENT

Goats, sheep, cattle, and bison are more susceptible than other species such as horses, pigs, and dogs.

PHYSICAL EXAMINATION FINDINGS

• Commonly animals will be found dead and clinical signs not observed.
• Clinical signs include fever up to 107°F (41.5°C), congested mucus membranes, excitement, depression, stupor, dyspnea, ataxia, muscle tremors, collapse, convulsions, and death. Younger animals will have less severe signs.
• If the animal lives long enough bloody diarrhea, hematuria, and localized swellings maybe seen as well as abortion.

CAUSES AND RISK FACTORS

• Anthrax is caused by *Bacillus anthracis* which is a large (1 μm by 3–5 μm) Gram-positive rod that is rectangular with square ends and commonly forms chains.
• *Bacillus anthracis* exists in two forms: the spore and vegetative cell.
• Once the spore infects the animal it germinates into the vegetative form. The vegetative form in infected tissues of the dead animal only survives up to 1–2 weeks. However, when exposed to air vegetative bacteria will sporulate in several hours. Sporulation is oxygen dependent.
• It is important not to necropsy the carcass to limit the spore formation and therefore keeping contamination of the environment to a minimum.
• Scavengers and biting insects may mechanically disseminate anthrax after feeding on affected carcasses.
• Risk factors include:
  ◦ Animals residing in endemic pastures or range.
  ◦ Exposure to disturbed soil in endemic areas. Disturbances can be due to flooding, excavations, cattle disturbing soil around wet pastures, or shrinking surface water sources.
  ◦ Grazing plants close to the ground, as seen in overstocking range or pasture or drought in endemic areas.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Anthrax, because of the nonspecific history and clinical appearance, can be confused with many other causes of acute death in ruminants including clostridial infections (blackleg, malignant edema), lightning strike, acute toxicosis (cyanobacterium), and bloat.

OTHER DIAGNOSTIC PROCEDURES

• Samples must be submitted for a definitive diagnosis.
• The laboratory should be forewarned of a suspected anthrax case submission due to the zoonotic risk.
• Collections of samples are recommended at or soon after death when bacterial numbers are at their highest.
• Blood is the main and best sample for diagnostic submission. Bloody fluids and tissues are also useful; however, opening the carcass is strongly discouraged.
• To prevent contamination of the environment collection of blood sample from a superficial vein using a large gauge needle and syringe is recommended.
• Microscopic examination of blood smears, bacterial cultures, and PCR are a few of the examinations laboratories use to identify *Bacillus anthracis*.

PATHOLOGIC FINDINGS

• If the carcass is inadvertently opened the lesions are those of septicemia.
• Rigor mortis is commonly not present or incomplete.
• Cattle that die of anthrax decompose rapidly and are found gas distended with bloody exudates coming from any of the body orifices.
• Blood is usually thick and dark red with little or no clotting. Any clotted blood found is not well formed.
• Multifocal hemorrhages are common on mucosal and serosal surfaces as well as subcutaneously.
• Gelatinous fluid accumulates in loose connective tissue and serous cavities and could be blood tinged.
• Parenchymatous organs are congested, swollen, and soft. The spleen can be greatly enlarged and bloody.
• The heart has a dull appearance and is flaccid.
• In cattle the lesions at the site of bacterial entry can be more severe, such as ulcerative hemorrhagic enteritis.
• If the bacteria come in through the oropharynx there will be hemorrhage and swelling of local lymph nodes as well as edema in adjacent connective tissue and throat.
• Likewise if there is a case of pulmonary anthrax in cattle, lesions would be most severe in lung and mediastinum.
• Sheep and goats are more susceptible to anthrax than cattle. The course of the disease is more rapid so some of the lesions maybe less prominent or missing.

TREATMENT

THERAPEUTIC APPROACH

Often no therapeutic approach is available as the disease is peracute. Sick animals are treated with antibiotics (see "Drugs of Choice").

MEDICATIONS

DRUGS OF CHOICE

B. anthracis is generally antibiotic-sensitive but some strains can be resistant to penicillin. *B. anthracis* is susceptible to many antibiotics,

including but not limited to penicillin and tetracycline. However, eliminating the bacteria may not increase survival: once the toxins have entered cells in sufficient quantity, they can still manifest their lethal effects.

CONTRAINDICATIONS
Because the Sterne strain vaccine must replicate to effectively stimulate an immune response, antibiotic treatment should not be given in conjunction with or shortly after the administration of vaccine in healthy animals. However, field conditions may dictate a combination of vaccine and antibiotics as a practical course of action.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
In ruminants the incubation period is 1–5 days and the course of the disease is from hours to 2 days and the usual outcome is death.

PREVENTION
- Affected premises are quarantined to prevent further spread of the disease.
- Consideration should be given to limiting access to suspected sources of exposure in affected herds. This may include moving livestock to a different pasture, fencing livestock away from low-lying water sources, where spores may recently have been exposed due to drought conditions, providing insect control, and proper disposal of affected carcasses.
- Hygiene and carcass disposal are of paramount importance in halting an outbreak and preventing future disease occurrence.
- Autolysis of the carcass destroys the vegetative forms of *B. anthracis* and, therefore, if carcasses are not opened up, the potential for contamination of the environment is minimized.
- Carcasses must be disposed of in accordance with state or local regulations.
- Livestock in endemic areas should be vaccinated with Sterne-strain spore vaccine at least 2–4 weeks prior to the expected seasonal onset. Booster vaccination is given 4–5 weeks following the initial vaccination, and then annually thereafter.
- The vaccine is a live nonencapsulated organism and therefore antibiotics should not be given within 7–10 days of vaccine administration.
- Following vaccination, there is a 60-day withdrawal time for the carcass, and milk should be discarded for at least 72 hours.

MISCELLANEOUS

AGE-RELATED FACTORS
There are some reports of males being more susceptible than females and older animals being more susceptible than young animals, but these probably reflect differences in grazing behavior rather than inherent differences in susceptibility.

ZOONOTIC POTENTIAL
Anthrax can infect humans and precautions should be taken to avoid contamination with infected animal tissues, contaminated animal products, and anthrax spores.

BIOSECURITY
- Once anthrax is diagnosed, the farm will be quarantined. No movement of animals on or off the premises should occur during the quarantine period.
- Animals surviving an outbreak may be moved to uncontaminated pastures or holding pens in order to reduce the possibility of additional cases.
- Scavenger and insect control is important to prevent the spread of the disease.
- All equipment, vehicles, and working facilities used in an outbreak must be cleaned and disinfected.

PRODUCTION MANAGEMENT
Vaccination of livestock is an important consideration in anthrax endemic areas.

ABBREVIATION
PCR = polymerase chain reaction

A

Arsenic Toxicosis

BASICS

OVERVIEW
• Arsenic is the second most common cause of heavy metal intoxication of cattle, after lead.
• Arsenic is still used in herbicides, defoliants, wood preservatives, and other products; however, alternative products with lower toxicity and less environmental persistence are becoming progressively more available.

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Digestive
• Urinary

PATHOPHYSIOLOGY
• Poisoning most often results from exposure to inorganic arsenic compounds contained in commercial products including herbicides, insecticides, and pressure-treated wood.
• Inorganic arsenic products can be trivalent (arsenite) or pentavalent (arsenate), with the arsenites being more soluble and toxic.
• Organic arsenic compounds are aliphatic or aromatic, and aromatic compounds can also be trivalent or pentavalent in nature.
• Ingestion of soluble arsenic compounds results in distribution of arsenic to many organs, with tissues rich in oxidative enzymes being the most vulnerable to damage, including the lungs, liver, kidneys, endothelium, and gastrointestinal tract.
• Mechanism of toxicity and toxic dose depend upon the formulation, route of exposure, and duration of exposure.
• Arsenates uncouple oxidative phosphorylation and trivalent arsenicals disrupt the citric acid cycle, creating damage to metabolically active tissues.

HISTORICAL FINDINGS
Deliberate or incidental exposure to products containing arsenic.

SIGNALMENT
Any ruminant species of any age, breed, or gender can be affected.

PHYSICAL EXAMINATION FINDINGS
• Signs typically reflect acute toxicosis and can include sudden death.
• Signs of acute or subacute toxicosis occur within 3–12 hours of exposure and reflect shock associated with gastrointestinal and cardiovascular damage.
• Colic, dehydration, weakness, anorexia, and severe watery diarrhea, which may be hemorrhagic, are observed.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Exposure or access of animals to arsenic-containing products or residues such as herbicides, insecticides, and the ashes of pressure-treated wood.
• Grazing animals in areas of high environmental contamination which can result from residue from livestock dip, mining waste, and sources of industrial contamination.
• Ruminants are particularly sensitive to the aliphatic arsenicals MSMA and DSMA which are used as herbicides.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Bovine viral diarrhea virus (BVDV) could take out
• Bacterial enteritis *(Salmonella* spp.)
• Organophosphate insecticide exposure
• Other heavy metal toxicoses (lead)
• Urea toxicosis

CBC/BIOCHEMISTRY/URINALYSIS
Changes are not specific to arsenic toxicosis, but are consistent with dehydration, shock, gastrointestinal damage, and hemorrhage.

OTHER LABORATORY TESTS
• Arsenic concentration can be chemically determined in tissues including the liver and kidney (>3 ppm wet weight associated with toxicity); however, tissue concentrations may be normal in animals suffering peracute death.
• Arsenic can be measured in gastrointestinal content and blood for 24–48 hours after poisoning, and for several days in urine.
• Chemical determination of arsenic in water (>0.25 ppm potentially toxic) or feedstuffs can be performed.
• Skin or hair can be tested in animals exposed for more than 2 weeks.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Gross findings include pale, swollen liver and kidneys, and generalized or localized reddening of the gastrointestinal mucosa with hemorrhage, erosions, submucosal edema, and sloughing of the mucosal lining into the gut lumen. In ruminants, the abomasum is often the most severely affected region.
• Peracute cases may have no abnormalities on gross inspection.
• Histopathologic findings include hepatic and renal tubular necrosis; dilation of intestinal capillaries, submucosal congestion and edema, and intestinal epithelial necrosis.

TREATMENT

THERAPEUTIC APPROACH
• Recently exposed animals may benefit from maneuvers to reduce further ingestion and absorption of arsenic from the gastrointestinal tract.
• Effective treatment of clinically affected animals relies on supportive medical care in addition to targeted chelation therapy.
• Fluid support and blood transfusion may be required in severely affected animals.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Absorption from the rumen after recent ingestion may be reduced via administration of mineral oil, or by rumen gavage or rumenotomy.
• Chelation therapy can be attempted using:
  ◦ Thioctic acid (lipoic acid)—50 mg/kg, IM, q8h (20% solution divided into two to three injection sites).
  ◦ Thioctic acid should be used in combination with dimercaprol at 3 mg/kg, IM, q4h for 2 days, q6h on day 3, then q12h for 10 days. Dimercaprol is also known as British anti-lewisite (BAL) and is recommended for treating trivalent inorganic or aliphatic organic arsenic toxicity.
  ◦ Sodium thiosulfate—IV: 30–40 mg/kg; PO: 20–30 g in 300 mL water (cattle) or 5–7.5 g in sheep and goats given q12h or q8h for 3–4 days.
  ◦ d-penicillamine (may be cost prohibitive)—10–50 mg/kg, PO, q8h–q6h for 3–4 days.
  ◦ 2,3-dimercaptosuccinic acid (DMSA, a water-soluble analog of dimercaprol)—10 mg/kg, PO, q8h has been recommended in small animals.

CONTRAINDICATIONS
N/A

PRECAUTIONS
• The source of arsenic exposure should be identified to reduce human risk.
• Carcasses should be disposed of carefully to avoid environmental contamination.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Death can occur within the first 3–5 days of clinical signs; surviving animals may demonstrate slow recovery over several weeks.

POSSIBLE COMPLICATIONS
- Bacteremia/septicemia from severe gastrointestinal damage
- Renal failure

CLIENT EDUCATION
Avoid access by ruminants to heavy metals.

PATIENT CARE
Fluid and nutritional support, and nursing care are indicated to optimize survival.

PREVENTION
Avoid access by ruminants to heavy metals.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Colic
- Renal failure
- Anemia

A

ARTHROGRYPOSIS

BASICS

OVERVIEW

• Arthrogryposis is not a specific diagnosis, but rather a clinical finding of congenital contractures; these may be present in numerous disorders.
• Congenital arthrogryposis ("crooked joint") is defined as a syndrome of persistent joint flexure or contracture present at birth and may involve one or multiple limbs (forelimbs and/or hindlimbs).
• The carpal and phalangeal joints are most commonly affected, followed by metacarpophalangeal and metatarsophalangeal joints.
• Arthrogryposis is often associated with cleft palate and primary CNS lesions such as hydranencephaly and syringomyelia. Severely affected animals may also have scoliosis, kyphosis, and torticollis; with rotation, abduction, or curled limbs.
• The arthrogryposis-hydranencephaly syndrome (AHS) is usually associated with flexural contracture of the limbs rather than angular limb deformities (ALDs).
• In contrast with contracted tendons, arthrogryposis involves improper articular alignment or rotational deformity.
• Crooked calf disease (CCD) is a congenital deformity condition widely recognized in western North America, characterized by arthrogryposis, scoliosis, torticollis, and cleft palate. CCD is observed in calves after maternal ingestion of lupines containing the quinolizidine alkaloid anagyrine during gestation days 40–100.
• Congenital arthrogryposis may be associated with denervation muscle atrophy.
• The terms "arthrogryposis multiplex congenita" and "congenital articular rigidity" have been introduced to describe cases in which the rigidity may be due to lack of extensibility of muscles, tendons, ligaments, or other tissues around the joint, or to deformity of articular surfaces, or to fusion between bones at the articular surface.

INCIDENCE/PREVALENCE

• For CCD, there are reports of up to 40% of calves from a single herd being affected. The incidence of disease varies with year, area, and herd.
• Cattle records reveal that the disease usually affects <10% of a herd.

GEOGRAPHIC DISTRIBUTION

• Arthrogryposis is thought to occur worldwide. Depending on the etiologic cause and based on the distribution of vectors, viruses, and plants, the geographic distribution of individual syndromes may vary (e.g., CCD is most common in western North America).
• Calf arthrogryposis has been reported from most parts of the world and in many breeds of cattle.

SYSTEMS AFFECTED

Musculoskeletal

PATHOPHYSIOLOGY

• Congenital arthrogryposis is considered multifactorial in origin and has multiple predisposing factors and etiologies, including inherited defects. The causes are often not clear.
• Can be caused by a number of etiologic agents including: plant teratogens, spinal dysraphism, prenatal viral infections that affect the nervous system, and in utero hormonal and vascular defects.
• May also be attributed to a decrease or lack of motion of the fetus during critical stages of development, such as malpositioning and overcrowding caused by the size of the fetus relative to the dam.
• Ingestion of teratogenic plants such as *Astragalus* or *Oxytropis* spp. (locoweed); *Verratrum californicum* (skunk cabbage); piperidine alkaloid-containing plants such as *Lupinus, Conium,* and *Nicotiana* species.
  ◦ Repeated dosing or continuous low-level ingestion over time may result in cumulative intoxication and/or teratogenesis.
  ◦ Teratogenic plant alkaloids may be transferred to the placenta and induce a sedative or anesthetic effect in the fetus.
• In CCD, there is often a lesion in the CNS that may result in reduced or absence of movement of the affected body parts in the developing fetus, especially during the period of rapid growth. Alpha-motor neurons in the cervical spinal cord are significantly reduced.
• May cause disruption in normal innervation of muscles leading to paresis and instability of the limb, or may result in hypotonic condition of extensor muscle and dysfunction of the radial nerve.

HISTORICAL FINDINGS

A complete history including age, birthing details, age at which the deformity was noticed, course and progression of deformity, diets of affected animal and dam should be obtained. The animal may be normal at birth and develop the flexural deformity within hours or days.

SIGNALMENT

Species

Bovine, ovine, caprine, and camelid species

Breed Predilections

• Certain syndromes are predominantly reported to occur in certain breeds (e.g., congenital arthrogryposis in Charolais cattle). CCD has been observed in most dairy breeds and in all breeds of beef cattle common to western North America.
• No breed predilection or genetic susceptibility in cattle to the lupine-induced condition has been determined.

Mean Age and Range

• Arthrogryposis tends to affect young, growing animals. The incidence of CCD is highest in heifers at first calving, but the disease has been observed in calves from cows of all ages.
• For each species (cattle, sheep, and goats), there are specific periods of gestation when the fetus is susceptible to plant teratogens. The critical gestational period for exposure of cattle to lupines is 40–70 days with susceptible periods extending to 100 days.

Predominant Sex

No apparent sex predisposition

PHYSICAL EXAMINATION FINDINGS

• The animal's conformation should be assessed first by having the animal stand in a symmetrical manner on a firm, flat surface and observing it from multiple angles.
• Arthrogryposis in CCD is characterized by deformities of the limbs (rigid flexion of elbows and carpal joints) and spinal column (scoliosis, lordosis, kyphosis), and rib cage abnormalities. Affected calves occasionally have torticollis and cleft palate.
• The joints are often flexed and cannot be extended even after the flexor tendons are cut—distinguishing the disease from contracted tendons.

GENETICS

• Some genetic patterns have been worked out, for example, the arthrogryposis multiplex anomaly of Angus cattle is thought to be a simple autosomal recessive pattern.
• Syndromes in the Charolais, Friesian, Swedish, and Red Danish breeds of cattle are consistent with a simple recessive or modified recessive characteristic.
• Dominant defect traits are inherited as well and are sometimes selected for.
• Lambs: A congenital arthrogryposis exists in pedigree Suffolk and Australian Merino lambs as an inherited limb deformity.

CAUSES AND RISK FACTORS

A number of etiologic agents such as intrauterine infection with Border disease virus, BVDV, Akabane virus, Cache Valley virus, bluetongue virus, Aino virus, Kasba (Chuzan) virus, Rift Valley Fever virus, Schmallenberg virus, and Wesselsbron virus, as well as teratogenic plant ingestion have been implicated in the pathogenesis of arthrogryposis in ruminants.

Congenital Predisposing Factors

• Uterine malpositioning
• Genetic causes
• Ingestion of teratogenic plants by pregnant dam such as *Astragalus* or *Oxytropis* spp. (locoweed); *Verratrum californicum* (skunk cabbage); piperidine alkaloid-containing plants such as *Lupinus, Conium,* and *Nicotiana* species.
• Conditions associated with arthrogryposis include CCD/congenital arthrogryposis, HC (hereditary chondrodysplasia or spider lamb

syndrome), ill-thrift syndrome in llamas, metabolic, and neurovascular disorders.
• Leg deformities in young calves are most commonly associated with congenital contraction of the tendons. Flexural deformities involving contracted tendons and ligaments may be seen in many breeds of cattle and small ruminants.

Risk Factors
Predisposing factors for congenital arthrogryposis include male calves, posterior intrauterine presentation, and double muscling.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Arthrogryposis and CCD differ from contracted tendons; in animals with contracted tendons, the joints are usually properly aligned and the legs are not rotated. In calves with arthrogryposis, the articular and osseous changes are usually permanent and worsen as the calf grows.
• Fracture malunion.
• See "Causes and Risk Factors" (viruses and toxic plants).
• Arthrogryposis-hydranencephaly syndrome (AHS) in lambs may be confused with HC.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
• Radiographs can be used to diagnose ALDs; at least two views, 90 degrees apart, should be taken of the affected joint.
• The dorsopalmar/dorsoplantar (DP) view is needed for examination of the anatomic location of the deformity and for measurements. Shoot with radiographic beam in line with the claws.

OTHER DIAGNOSTIC PROCEDURES
• Serology and virologic diagnostic assays may aid in ruling out in utero viral infections (e.g., Cache Valley virus).
• Feed analysis and assessment of the availability of potentially toxic plants in the environment (pasture) may assist in diagnosis.

PATHOLOGIC FINDINGS
• No consistent primary lesion in CCD; a number of varied tissue responses are observed. It is likely that these findings are at least in part due to the animal's inability to stand.
• CCD histology: Few lesions, restricted to muscles of the forelimb, external intercostalis muscle, or radial and femoral nerves—myositis, myodegeneration, muscle necrosis and atrophy, cellulitis, and perineuritis.

TREATMENT

THERAPEUTIC APPROACH
• Severely affected animals may be unable to rise to nurse and require additional supportive care.
• Protect limbs with thick, soft bandages that fit well. Minor deformities may be corrected by manual alignment and external support of the limb (e.g., rigid splinting, bandaging, or casting/tube casts).
• Provide good footing and allow for stretching of flexor tendons.
• Maintain a soft (padding), clean, and dry environment to minimize decubital/pressure sores, open arthritis, muscle atrophy, umbilical infections, and septicemia.
• Restrict activity until it is certain that the deformity is improving; however, some degree of exercise allows for stretching and lengthening of affected limb structures. Weight bearing provides the necessary physical exercise to strengthen and lengthen affected tendons and musculature.
• Dietary imbalances should be addressed while treating cases of arthrogryposis.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Surgery may be required for animals with severe deformities and for animals that do not improve with age or conservative management.
• Treatment of arthrogryposis includes surgery to improve the animal's posture sufficient for it to obtain slaughter weight (a salvage procedure).
• Surgical procedures include transection of flexor tendon and suspensory ligament, joint capsule release, flexor tendon lengthening procedures, and joint arthrodesis.
• May require postoperative splinting or casting for support.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• The prognosis is guarded, depending on the severity of the flexural deformity. Severe deformities requiring surgery often have a poor prognosis.
• For arthrogryposis in cattle, approximately 80% of surgically treated animals can be kept until they reach normal slaughter weight.

POSSIBLE COMPLICATIONS
Some severe cases of arthrogryposis cannot be corrected and full extension may not be possible postoperatively.

CLIENT EDUCATION
• Examination of young animals with congenital arthrogryposis should be done as early as possible to assess the degree of manual correction possible.
• Because of a possible hereditary component associated with some forms of arthrogryposis, breeding of affected animals is not recommended.
• Many affected animals are stillborn or die shortly after birth. Others may fail to thrive and euthanasia should be considered.

PATIENT CARE
Frequent physical examinations and assessing the efficacy of corrective measures should be done to monitor progress.

PREVENTION
• CCD/HC: Avoid breeding affected animals.
• Coordinate grazing times and alter breeding dates to minimize exposure. Avoid grazing potentially teratogenic plants when pregnant cows are at the susceptible stage of pregnancy.
• Control teratogenic plant populations with herbicides.

MISCELLANEOUS

ASSOCIATED CONDITIONS
A syndrome known as "bentleg" or "bowie" has been associated with ingestion of *Trachymene glaucifolia* (wild parsnip) by pregnant ewes in Australia and New Zealand.

AGE-RELATED FACTORS
Majority of cases occur during the active growth phase of the affected bone/joint.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
In cases of congenital arthrogryposis, the teratogenic plants are ingested by the pregnant dam and the compounds are passed to the fetus through the placenta.

BIOSECURITY
N/A

ARTHROGRYPOSIS (CONTINUED)

PRODUCTION MANAGEMENT

• Producers should be aware of the association between certain toxic plants (e.g., lupines) and angular limb deformities such as CCD.
• To reduce the incidence of CCD, graze lupines during their least hazardous growth period and reduce exposure of pregnant cows. Lupines are most hazardous when they are young or in the mature seed stage.
• Fence off heavily infested pasture areas and use intermittent, short-term grazing of lupine pastures.

SYNONYMS

BASICS

OVERVIEW
Artificial insemination (AI) is the aseptic delivery of viable spermatozoa into the female reproductive tract (uterus).

INCIDENCE/PREVELENCE
AI is more prevalent in dairy cattle than beef cattle.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Reproductive

PATHOPHYSIOLOGY
• Improvements in semen extenders, implementation of protocols for estrus synchronization and timed insemination, and availability of sex-sorted semen have increased the use and importance of AI in cattle.
• Advantages of AI over natural service:
  ◦ Efficient use and dissemination of valuable bull genetics
  ◦ Eliminate cost associated with bull maintenance
  ◦ Decreased risk of sexually transmitted diseases
  ◦ Fewer breeding-related injuries
  ◦ Enables evaluation of semen before insemination
• AI success is dependent on semen quality and handling, timing, site of deposition, and female fertility.
• Acceptable fertility in an AI program involves excellent management of all phases of the program.

HISTORICAL FINDINGS
• Estrus synchronization and timed AI
• Cows selected based on estrus detection

SIGNALMENT
Females of breeding age

PHYSICAL EXAMINATION FINDINGS
• Estrus behavior and observations:
  ◦ Standing to be mounted (cardinal sign of estrus)
  ◦ Cervical mucus discharge
  ◦ Mounting other cattle
  ◦ Increased locomotion and vocalization
  ◦ Decreased feed intake/milk production

Semen Collection and Cryopreservation
• Semen used for AI is commonly collected using an artificial vagina (AV) (most common in commercial AI bull centers) or by electroejaculation (custom freezing of bulls not trained to an AV, salvage of genetics from terminally ill bulls).
• Epididymal spermatozoa may be collected to salvage genetics from bulls following catastrophic injury or terminal illness.
• Semen collected with an AV presents better post-thaw motility than semen collected with electroejaculation.
• Although fresh/cooled semen may be used in some ranches, most AI in the bovine uses frozen-thawed semen.
• Semen is frozen after dilution in various commercial extenders in the presence of antibiotics, egg yolk, and glycerol.
• Bovine sperm is usually frozen in 0.25 or 0.5 mL straws. The majority of sex-sorted (gender-selected) semen is packaged in 0.25 mL straws.
• In general, the total dose per straw is 10 to 20 million motile spermatozoa. However, this dose is considerably lower for elite bulls and sex-sorted semen. Higher doses are used for bulls with lower fertility or in custom freezing of beef bulls.
• The cryopreservation process varies slightly depending on extender and technique used.

Factors Affecting AI Success
Quality of Semen
• The quality of frozen-thawed semen depends on initial quality at production, handling during storage, thawing procedures, and interval until deposition into the uterus.
• Quality at production is affected by initial quality of the ejaculate, method of collection used, the inherent freezability, and methods of processing used for cryopreservation.
• Repeated exposure to temperature above −80°C may cause changes in liquid/frozen phase and damage to the sperm membrane. This can occur during handling or transfer of straws between tanks or may be due to faulty tank performance and lack of verification of LN level. To prevent these problems, the following points should be observed:
  ◦ LN tank management:
    ▪ Keep in a cool, dry, well-ventilated area away from direct sunlight.
    ▪ Check LN level frequently. Presence of frost on the surface of the LN tank is a sign of leakage.
    ▪ Place LN tanks on a wooden or plastic dolly above concrete or wet floors to prevent corrosion.
    ▪ Keep a precise inventory for quick identification of straws to be used.
    ▪ Attach LN refill date logs to the tank.
  ◦ Removing straws from the tank:
    ▪ Remove straws quickly without exposing other straws to air.
    ▪ Do not raise canisters higher than 10 cm above the neck of the LN tank; do not raise the top of the goblet in the canister above the frost line in the neck of the tank.
    ▪ Ensure that the goblet is always filled with LN.
    ▪ Always use forceps to remove straws from the goblets.
  ◦ Handling at the time of use:
    ▪ Use recommended thawing temperature and time. Recommendation of the NAAB is immersion in the water bath at 30–35°C for at least 40 seconds. Others recommend thawing at 70°C for 6 seconds or 35–37°C for 30 seconds. Thawing at high temperatures may be very difficult to observe in field conditions.
    ▪ Thawing procedures should be strictly observed.
    ▪ Check water baths for temperature control accuracy.
    ▪ Use a stopwatch for the timing of thawing.
    ▪ In cold areas, it is preferable to keep straws in the water bath, at 35°C, until use.
    ▪ Prevent exposure of the straw to low temperatures after thawing: use a pre-warmed insemination gun; protect prepared gun from exposure to low temperature.
    ▪ Thaw out straws and prepare insemination guns in a sheltered area when ready to inseminate.
    ▪ Clean and dry straws before loading in the AI gun.
    ▪ Straws should be cut using straw cutters to prevent backflow of semen during insemination.
    ▪ Time period from removal of straw from the tank to insemination should not exceed 15 minutes.

Timing of Insemination
• Insemination timing is important to maximize conception rates. Ovulation occurs 28–32 hours after the beginning of estrus. Optimum fertility of the oocyte is 6–12 hours after ovulation and the viable lifespan of spermatozoa in the reproductive tract is estimated to be between 24 and 30 hours.
• The optimal time for insemination is 12 hours after first observed estrus. This has led to the AM/PM rule: if a cow is observed in estrus in the morning she is inseminated in the afternoon, and vice versa.
• Several schemes for timed insemination have been developed.
• Double insemination at a 12-hour interval is sometimes performed in cows with decreased fertility, when using semen straws with lower concentration, or in cows that have been superstimulated for embryo collection.

Insemination Technique
• Semen should be deposited at the proper site without excess manipulation.
• People who inseminate cows periodically cannot achieve a high level of expertise.
• Semen is deposited in the body of the uterus by transrectal manipulation of the insemination gun for cervical catheterization.
• Deep horn insemination may reduce conception rates in the hands of untrained people due to irritation of the uterus.
• Deep uterine insemination may be important when low spermatozoa numbers are used (i.e., sexed semen).
• Good inseminators should be able to pass the cervix rapidly and with a high degree of reliability. Cervical catheterization is particularly difficult in some breeds of cattle (e.g., Santa Gertrudis).

A

ARTIFICIAL INSEMINATION: BOVINE (CONTINUED)

• Strict hygienic measures should be observed during insemination to prevent vaginal or uterine contamination.
• Use a protective plastic sheath (cannula or chemisette) to help prevent contamination.

GENETICS
Semen is selected based on specific selection criteria.

CAUSES AND RISK FACTORS

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Pregnancy rates depend on many factors: breed, quality of semen, site of semen deposition, nutrition, milk production (dairy), environmental conditions, parity, type of synchronization program, and human factors.
• Conception rates following artificial insemination range between 40 and 50% in cows and 60 to 70% in heifers. However, in dairy cattle, pregnancy rates 35 to 40 days following AI are generally between 20% and 30% due to a high early embryonic loss.
• In addition to the factors already mentioned, other factors involved in decreased conception rate in dairy cows are:
  ◦ Insemination of non-estrous cows
  ◦ Heat stress prior to artificial insemination
  ◦ Incidence of postparturient diseases
  ◦ Clinical mastitis

POSSIBLE COMPLICATIONS
Perforation of the vagina or uterus by unskilled or inexperienced technicians.

PATIENT CARE
Appropriate estrus detection and handling to reduce stress.

PREVENTION
N/A

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Normal conception rates have been achieved with as low as 2 million spermatozoa in heifers.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
See "Expected Course and Prognosis"

BIOSECURITY
• Use semen from bulls routinely tested for brucellosis, IBR, BVD, trichomoniasis, and campylobacteriosis, as well as bluetongue virus (Certified Semen Service).
• Bacteriologic quality of semen is ensured by strict hygiene during collection and use of specific guidelines for antimicrobials in the extenders (Certified Semen Service).
• All straws are properly labeled, identifying the semen center, bull, breed, and date on which semen was collected.

PRODUCTION MANAGEMENT
Use a professional inseminator.

ARTIFICIAL INSEMINATION: SMALL RUMINANT

BASICS

OVERVIEW
• Artificial insemination (AI) is used in sheep and goat herds to improve genetics, improve reproductive efficiency of males, reduce disease transmission, and permit out-of-season breeding.
• Success of an AI program is affected by several factors including timing, semen quality, and semen placement.
• For economic reasons, except in a few cases (dairy goat), most AI is performed at a fixed time following synchronization of estrus.

INCIDENCE/PREVALENCE
• AI using fresh or cooled semen is a common procedure in several countries.
• AI with frozen-thawed semen is more common in dairy goats.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Reproductive

PATHOPHYSIOLOGY
• Adequate fertilization rates are achieved when sperm form a reservoir at the level of the isthmus of the uterine tube and remain viable until ovulation occurs.
• Fertilization rates are dependent on quality of semen, adequate transport to the fertilization site, and proper timing in relationship to ovulation.
• In small ruminants, semen is deposited onto the cervix after natural mating. Sperm is selectively transported through the cervix into the uterus and only highly motile, morphologically normal sperm is found in the isthmus.
• With AI the number of sperm used is significantly lower than in natural mating. In addition, processing and cryopreservation reduces sperm viability. Therefore, timing and site of deposition of sperm are critical in achieving acceptable fertilization rates.
• Oocyte viability is extremely reduced beyond 12 hours post-ovulation. AI should be performed within 12 hours after onset of estrus.
• The number of viable spermatozoa per insemination required for adequate fertilization rates depends on quality and site of semen deposition. Ideally, preserved semen (chilled or frozen-thawed) should be deposited into the uterine cavity.
• In sheep and small breeds of goats, TCI is extremely difficult due to the tortuous anatomy of the cervical canal. To bypass the cervix, insemination is performed laparoscopically.

HISTORICAL FINDINGS
• Flock or herd desiring to improve genetics
• Out-of-season breeding

SIGNALMENT
Postpubertal female sheep and goats

PHYSICAL EXAMINATION FINDINGS
• Females to be inseminated should be in estrus.
• Estrus detection may be performed with a teaser male (sheep and goat) or by visual observation (goats).
• Females in estrus will show typical receptive behavior. Does express estrus more intensely than ewes (tail fanning, mounting other females, and standing to be mounted).
• Females in estrus show variable degrees of vulvar swelling and mucus discharge. Mucus is clear and runny at the beginning of estrus and becomes thick and whitish near ovulation.
• On vaginoscopy, the cervix is hyperemic and open.

Artificial Insemination Techniques
Semen Source and Processing
• Semen is collected from selected males using an artificial vagina (preferred) or electroejaculation.
• Only high-quality ejaculates are used. Semen is diluted in one of a variety of available commercial extenders (milk-based, egg yolk-based, or new chemically defined soybean lecithin-based).
  ◦ Milk-based extenders are commonly used for fresh, chilled (4°C) or cooled (15°C) semen insemination. Skim-milk or UHT-treated milk is used in order to remove lactenin which is spermicidal.
  ◦ Tris-based egg yolk extenders are used routinely for cryopreservation. However, egg yolk is toxic to buck semen because of the presence of lipase produced by the bulbourethral gland (*BUSgp60*). Buck semen needs to be washed prior to addition of egg yolk-based extender. An alternative is to use a minimal quantity of egg yolk in the extender.
  ◦ Chemically defined media have been shown to be effective for the cryopreservation of small ruminant sperm. They offer the advantage of not containing any additional animal products, which guarantee its biosecurity for international movement of semen.
  ◦ Additional improvement in preservation of semen has been achieved by addition of antioxidants.
• Small ruminant sperm is cryopreserved in either 0.25 mL or 0.5 mL straws and rarely in pellet form. Semen handling and thawing procedures (time and temperature) are critical for viability.

Timing of Insemination
• Natural estrus: AI is performed 12 hours after detection of estrus. A second insemination is often needed 12 hours later if frozen-thawed semen is used.
• Fixed time after synchronization:
  ◦ TCI insemination: Sheep – 55 hours (1 dose) or 50 and 60 hours (2 doses) after progesterone removal. Goats – 45 to 65 hours (1 dose) or 30 and 48 hours (2 doses) after progesterone removal.
  ◦ Laparoscopic AI: 54 to 60 hours after progestogen removal (6 to 8 hours earlier for frozen-thawed semen) in sheep, and 43 to 46 hours after progesterone removal in goats.

Method of Insemination
• Blind vaginal insemination—At least 400 million sperm are blindly deposited around the external cervical os. This technique is useful only when fresh, extended semen is used.
• Intracervical—At least 200 million sperm are deposited into the cervical canal as far as the AI gun can advance.
• TCI—Between 50 and 100 million spermatozoa are required. TCI is used more in goats as the cervix is more easily catheterized. In sheep, TCI is limited by the morphology of the sheep cervix, which is long, tortuous, and narrow, with nonconcentric rings. However, several techniques have been proposed to improve TCI in sheep; these include the use of special cradles for restraint, and the use of flexible AI guns.
• Laparoscopic—Semen is injected directly into the uterus via laparoscopic portals. Between 20 and 40 million sperm are required (15–20 million if sex-sorted). Drawbacks to this technique include the need for sedation or anesthesia of the animal, laparoscopic equipment, increased labor time and costs, and postoperative monitoring.

GENETICS
AI is the best method for rapid genetic improvement of a flock or herd.

CAUSES AND RISK FACTORS

ARTIFICIAL INSEMINATION: SMALL RUMINANT (CONTINUED)

TREATMENT

THERAPEUTIC APPROACH

• Estrus should be synchronized using approved hormonal methods of synchronization.
• Several treatments (oxytocin, estrogen, ß-adrenergic blocking agents, relaxin, and PGE) have been used in sheep to induce cervical relaxation for TCI but were not very successful.

SURGICAL CONSIDERATIONS AND TECHNIQUE

• Estrus animals displaying systemic illness should not be selected for surgical insemination. Obese and non-fasted animals present surgical challenges.
• Animals should be fasted for 18–24 hours prior to laparoscopic AI (LAI).
• LAI is performed under sedation and local block in sheep. Heavy sedation or general anesthesia is preferred in goats. The animal is placed in dorsal recumbency on a cradle in a Trendelenburg position. The ventral abdomen is clipped and prepared for surgery.
• Two portals are created on each side (about 5 cm) of the linea alba and about 6–10 cm from the cranial border of the mammary gland. The laparoscope is inserted into the abdominal cavity from one portal. The uterus is visualized and the insemination gun is inserted through the other portal using a cannula. The uterine horn is stabbed with the needle of the insemination gun and semen is deposited in the lumen.
• Skin incisions are usually closed with staples or absorbable suture.

MEDICATIONS

DRUGS OF CHOICE

• Sedation and anesthesia: xylazine and ketamine.
• Administration of antibiotics and anti-inflammatories is recommended.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Pregnancy rates depend on many factors: species and breed, type of semen used, extender type, site of deposition of semen, nutrition, season, environmental conditions, parity, the synchronization program used, and human factors.
• Expected conception rates when semen quality and number of spermatozoa are adequate are:
  ◦ Vaginal AI: fresh semen 60–75%; frozen semen 5–30%
  ◦ Intracervical AI: fresh semen 50–80%; frozen semen 35–60%
  ◦ TCI: fresh semen 40–80%; frozen semen 30–70%
  ◦ Laparoscopic AI: fresh semen 40–80%; frozen semen 40–70%.

POSSIBLE COMPLICATIONS

• For surgical complications see "Patient Care."
• TCI in sheep may result in cervical trauma or laceration.

CLIENT EDUATION

• Clients should be aware of factors affecting fertility and the expected pregnancy rates for the type of semen and AI used.

PATIENT CARE

• Animals should be handled with minimal stress.
• After laparoscopic AI, animals should be monitored for complications, including incisional infection or dehiscence, fever, peritonitis, and adhesion formation. Animals should be vaccinated against *Clostridium tetani*. Administration of antibiotics and anti-inflammatories is recommended.
• Pregnancy diagnosis should be performed after an AI program.

PREVENTION

N/A

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

TCI is more difficult in young maiden females.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

BIOSECURITY

• All males used for semen collection and AI should have a health screening and infectious disease testing prior to use.
• Hygienic semen collection and processing of semen should be performed according to guidelines described by the Office International des Epizooties.
• Diseases that can be transmitted by semen include: Bluetongue, Border disease, brucellosis, leptospirosis, paratuberculosis, Q fever, contagious caprine pleuropneumonia, ovine enzootic abortion, Lentivirus infection, peste des petit ruminants, *Salmonella* serotype abortus-ovis, sheep and goat pox.

PRODUCTION MANAGEMENT

• AI with fresh semen allows more efficient use of top sires, particularly after synchronization of estrus.
• Use of frozen semen allows genetic improvement.
• AI after a synchronization program can allow predictable parturition dates and allow segregation of animals on the farm by physiologic status.
• AI can allow for accelerated lambing programs or out-of-season breeding.

SYNONYMS

N/A

ABBREVIATIONS

• AI = artificial insemination
• PGE = prostaglandin E
• TCI = transcervical insemination

BASICS

OVERVIEW
Aspiration pneumonia arises from the inhalation or accidental administration of liquids, pastes, gels or foreign bodies (plant debris, dirt) which can result in inflammatory, gangrenous or granulomatous pneumonia, or in the case of oil aspiration, lipid or lipoid pneumonia. Some substances directly insult the respiratory tissues, while others may induce vigorous inflammatory responses associated with nondegradable foreign material. Secondary bacterial infection is a common sequela.

INCIDENCE/PREVALENCE
Uncommon

GEOGRAPHIC DISTRIBUTION
N/A

SYSTEMS AFFECTED
Respiratory

PATHOPHYSIOLOGY
• The disorder often arises following the accidental or forceful administration of substances and medication by unskilled personnel, or after inappropriate regurgitation/aspiration associated with heavy sedation, anesthesia, or oropharyngeal and esophageal disorders.
• Lung tissue in the cranioventral thorax is most commonly affected after inhalation or instillation of a foreign substance.
• The affected lung tissue is irritated, inflamed, and loses capacity for appropriate clearance, immune function, and oxygenation. Secondary bacterial invasion frequently occurs.

HISTORICAL FINDINGS
Consistent with a primary illness or management activity prompting treatment with oral medications or substances, or preexisting signs of upper gastrointestinal dysfunction.

SIGNALMENT
• Varies with different inciting conditions.
• Young ruminants and crias may suffer aspiration from accidental orotracheal intubation during provision of colostrum or milk; from inhalation of meconium in fetal fluids during difficult parturition; from poorly performed bottle feeding; from congenital disorders such as cleft palate and aortic arch defects; and from acquired disorders such as selenium deficiency and necrotic laryngitis.
• Mature ruminants and camelids may suffer aspiration due to pharyngeal and esophageal dysfunction related to trauma, abscessation, choke, or megaesophagus; infectious diseases (botulism, listeriosis); heavy sedation or anesthesia; toxicities (ingestion of lead, crude oil, fuel oil, natural gas condensate, rhododendron); and from oral medication administration or severe hypocalcemia (lactating cattle).

PHYSICAL EXAMINATION FINDINGS
• Acute-onset depression, tachypnea, coughing, and fever.
• Large volume aspiration can produce dyspnea, tachypnea, tachycardia, nasal discharge, and malodorous breath.
• Thoracic auscultation can reveal adventitious lung sounds, pleural friction rubs, or reduced audibility of ventral lung sounds if pleural fluid accumulates.
• Shock and sudden death may occur.
• Milk or feed material may be seen coming from the nostrils in cases where dysphagia or esophageal disorders are the initiating cause.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Accidental or forceful administration of substances and medication orally or orogastrically by unskilled personnel.
• Heavy sedation or general anesthesia.
• Oropharyngeal and esophageal disorders.
• Submergence dipping of livestock.
• Exposure to poorly cured silage (*Listeria*) or specific toxins in the feed or environment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Acute bronchopneumonia due to infectious agents or causes other than aspiration.
• Systemic sepsis, particularly in neonates.

CBC/BIOCHEMISTRY/URINALYSIS
• Complete blood count may demonstrate leukocytosis or leukopenia with left shift, elevated total plasma protein, and hyperfibrinogenemia.
• Serum chemistry may demonstrate hyperglobulinemia and azotemia, and/or specific electrolyte abnormalities such as hypocalcemia.

OTHER LABORATORY TESTS
N/A

IMAGING
• Radiographs typically show alveolar-interstitial pattern that is most pronounced in the cranioventral lung fields. Pleural fluid lines or pulmonary abscesses may be evident.
• Ultrasonography reveals cranioventral consolidation with or without pleural effusion.
• Pharyngeal abscessation or trauma, and esophageal dilation, stricture or obstruction may be evident on radiographs (contrast enhancement can be performed if indicated).

OTHER DIAGNOSTIC PROCEDURES
• Endoscopic or transtracheal wash can be performed to obtain samples for cytologic examination and aerobic and anaerobic bacterial culture and sensitivity procedures.
• Endoscopy of the upper gastrointestinal tract is appropriate to investigate pharyngeal and esophageal disorders.

PATHOLOGIC FINDINGS
• Reflect acute bronchopneumonia with cranioventral distribution, with or without accompanying fibrinous pleuropneumonia.
• In early disease the main findings may include pulmonary congestion and edema, and the bronchi may be hyperemic and contain froth and potentially foreign material. As disease progresses affected areas of lung become suppurative, necrotic and soft, and fibrinous pleuritis is evident. Chronic cases may have pulmonary abscesses and fibrous adhesions between the visceral and parietal pleura.

TREATMENT

THERAPEUTIC APPROACH
• Commences with identification of the reason or cause for aspiration to protect the airway from further damage, and to determine the prognosis (e.g., treatment may be futile with large volume oil aspiration).
• Treatment is aimed at neutralizing secondary bacterial infection by Gram-positive and Gram-negative aerobic and anaerobic bacterial agents and should start as soon as possible after the aspiration event is recognized, typically regardless of whether clinical signs exist.
• Steroidal and/or nonsteroidal anti-inflammatory agents can be utilized to control shock and inflammation.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Broad-spectrum antibiotic therapy is indicated to cover Gram-positive and Gram-negative bacterial agents. In severe cases anaerobic bacterial coverage is also indicated.
• Appropriate antibiotic coverage can be achieved using combinations of antibiotics, or one antibiotic depending on the desired spectrum and duration of coverage; drugs should be given at recommended doses and dosing intervals.

CONTRAINDICATIONS
Oral administration of medications during treatment is likely contraindicated if deficits in pharyngeal and esophageal function are present.

A

ASPIRATION PNEUMONIA (CONTINUED)

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- Animals with relatively minor aspiration events that receive prompt therapy are expected to survive.
- Aspiration events that are large volume, promote gangrenous pneumonia, have delayed recognition and treatment, or are associated with congenital or poorly reversible disorders have a poor prognosis.
- Fibrosing alveolitis (oil aspiration), pulmonary abscessation, and pulmonary granulomas are chronic sequelae that typically reduce prognosis.

POSSIBLE COMPLICATIONS
- Chronic respiratory disease related to fibrosing alveolitis or ongoing pulmonary inflammation and infection.
- Septicemia and multiorgan failure.

CLIENT EDUCATION
Personnel should be thoroughly instructed in the correct techniques for administering medications by mouth or orogastric tube.

PATIENT CARE
- Monitor for worsening of respiratory function, fever and any other associated clinical signs.
- Provide a soft and palatable ration.
- Intermittent orogastric feeding may be indicated for animals with upper gastrointestinal dysfunction.

PREVENTION
- Education regarding medication administration is the most important method of preventing aspiration events.
- Fasting of animals combined with careful head positioning, ± intubation during sedation and general anesthesia reduces the risk of inducing aspiration.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Young animals are prone to aspiration events associated with feeding management, or with congenital disorders and selenium deficiency.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
N/A

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
- Avoid unnecessary oral medications and instruct personnel to deliver oral medications or drenches at a measured rate to allow the animal to swallow, with the head positioned level or down, and with great caution during periods of struggling and vocalization.
- Caustic or inflammatory substances (calcium chloride, mineral oil) are often best given by orogastric tube versus oral drench.

BASICS

OVERVIEW

• Atypical interstitial pneumonia (AIP) is a loosely defined term that covers a variety of respiratory disorders with different etiologies. These disorders typically present with acute respiratory distress and are characterized by the microscopic findings of pulmonary congestion or edema, hyaline membrane formation, epithelial hyperplasia, and interstitial emphysema.
• Specific causes include intoxication of cattle with 3-methyl-indole (3-MI), 4-ipomeanol (4-IP), and perilla ketone. A form of AIP also affects feedlot cattle, and other potential causes include noxious gases, *Brassica* spp. plants, perennial ryegrass intoxication and lungworm infestation.

INCIDENCE/PREVALENCE

Variable; high morbidity and mortality can occur in cattle herds when AIP is related to toxicity.

GEOGRAPHIC DISTRIBUTION

• Widespread, but specific causes have some degree of regional distribution.
• AIP related to 3-MI toxicity has been reported in the United Kingdom, Canada, and the western United States. Moldy sweet potato toxicity and perilla ketone toxicity occur in southeastern USA. Feedlot cattle in the USA, Canada and other countries can develop AIP of unknown etiology.

SYSTEMS AFFECTED

Respiratory

PATHOPHYSIOLOGY

• 3-MI toxicity results from ruminal conversion of L-tryptophan to 3-MI which is absorbed from the rumen and further metabolized in the lung, resulting in bronchiolar, alveolar epithelial and endothelial damage with pulmonary edema, hyaline membrane formation, alveolar epithelial hyperplasia, and interstitial emphysema resulting in hypoxemia and distress. Most often this arises after movement of cattle from sparse, dry feed, to lush green pastures without significant time for acclimation or feed additives provided to prevent AIP.
• 4-IP toxicity arises with the formation of furanoterpenoid toxins by sweet potatoes infected with the fungus *Fusarium solani*. Ingestion of moldy sweet potatoes by cattle allows these compounds to be absorbed from the rumen and converted in the lungs to toxic metabolites that produce bronchiolar, alveolar epithelial, and endothelial injury by irreversible binding to cellular proteins.
• Perilla ketone toxicity occurs in cattle grazing on sparse pastures in late summer in the southeastern USA (*Perilla frutescens*) and New Zealand (*Perilla maculatta*). The tall, green plants are found along the edge of wooded areas in pastures and grow well in later summer when other plants are dry. Intoxication commonly occurs in drought years when forage is limited. Consumption of volatile oil in these plants, including perilla ketone and two other substituted furans, results in comparable lung injury to 3-MI and 4-IP toxicity.
• AIP in feedlot cattle has not been fully elucidated but typically occurs in the late feeding period when animals have been consuming a high concentrate diet for some time. This is considered a multifactorial condition and specific features of feedlot rations and rumen metabolism may contribute to the formation of 3-MI and other metabolites. Mortality is highest in summer and fall, when on finishing diets. Heifers are far more susceptible than males which may relate to the use of melengestrol acetate to control estrus.

HISTORICAL FINDINGS

• Management factors relevant to these disorders include feeding of moldy sweet potatoes, access to toxic plants, exposure to noxious gases, or finishing stages in a feedlot environment. Pasture-related AIP develops within 2 weeks of sudden movement to a variety of lush pastures.

SIGNALMENT

• Adult cattle are most susceptible; typically brood cows or bulls over two years of age
• Nursing calves are generally not affected and yearlings are less susceptible
• Feedlot cattle, particularly heifers, nearing the end of their feeding period are predisposed

PHYSICAL EXAMINATION FINDINGS

• Sudden onset of severe expiratory dyspnea with open mouth breathing, ptyalism, extension of the head and neck, distress, and anxiety.
• Quiet lung sounds are noted on auscultation; coughing is uncommon.
• Collapse and sudden death can occur with exertion.
• Subcutaneous emphysema may occur.

GENETICS

• No breed predilection.
• Heifers are >3 times as likely to develop AIP in feedlot situations.

CAUSES AND RISK FACTORS

• Movement of cattle from dry summer range onto irrigated or fertilized pastures in fall.
• Feedlot environment and ration.
• Female gender (feedlot AIP).
• Mature age (>2 years).
• Access to toxic plants in times of limited feed availability.
• Consumption of moldy sweet potatoes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Intoxication with 3-MI, 4-IP, and perilla ketone may appear clinically similar to one another but can usually be readily separated on review of management factors.
• Infectious respiratory diseases (particularly bovine respiratory syncytial virus).
• Hypersensitivity pneumonitis of confined adult cattle (extrinsic allergic alveolitis).
• Verminous pneumonia (*Dictyocaulus viviparus*).

CBC/BIOCHEMISTRY/URINALYSIS

Stress leukogram may be evident; however, restraint and sampling can be fatal and is not usually justified.

OTHER LABORATORY TESTS

N/A

IMAGING

Not typically indicated

OTHER DIAGNOSTIC PROCEDURES

Necropsy

PATHOLOGIC FINDINGS

• Typically lesions are confined to the respiratory system. The lungs are heavy, wet and rubbery, and do not float. The lungs may fail to collapse and maintain rib impressions after the thorax is opened. Petechial hemorrhages may be evident in the upper respiratory tract, with foamy fluid in the large airways. Incriminating feedstuffs (Perilla mint, moldy sweet potatoes) may be present in the rumen.
• Microscopic pulmonary lesions include congestion, edema, hyaline membranes, interstitial emphysema, and proliferation of alveolar epithelial cells.

TREATMENT

THERAPEUTIC APPROACH

Largely limited to preventing further exposure to offending pasture, feed, or toxins, and avoiding stress or exertion that exacerbates respiratory distress.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

• Treatment should be considered carefully and performed with caution due to associated stress.

ATYPICAL INTERSTITIAL PNEUMONIA (CONTINUED)

• Furosemide (1 mg/kg IM or IV, q24h or q12h).
• Flunixin meglumine (1.1–2.2 mg/kg IV, q24h or divided q12h).
• Dexamethasone (0.05 to 0.2 mg/kg IM or IV, once or twice).
• Antibiotics may be indicated to prevent secondary bacterial pneumonia.

CONTRAINDICATIONS
N/A

PRECAUTIONS
• Any stress or exertion, including treatment, can precipitate fatal collapse.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Most fatalities from toxic interstitial pneumonia are likely to occur in the first two days of clinical signs. Animals with severe disease may display chronic emphysema or signs of cardiac failure related to cor pulmonale.
• Moderately to mildly affected animals often improve substantially and spontaneously after 72 hours and continue to recover over 10 days.
• Feedlot AIP typically has a poor prognosis.

POSSIBLE COMPLICATIONS
Secondary bacterial pneumonia

CLIENT EDUCATION
Focus on preventive management factors relevant to the various disorders.

PATIENT CARE
• Exertion should be minimized; it is generally best to leave affected animals in their location and to provide alternative sources of safe feed (hay).
• Monitor progression of disease or improvement, so animals in severe distress can be euthanized before undue suffering occurs.

PREVENTION
• Management practices that prevent abrupt exposure of animals to suspect pasture can include gradually increasing pasture time over 10–12 days (commencing with 2 hours/day); strip grazing; or using other species or young stock to graze pasture down before adult cattle. Delaying use of lush pastures until after a hard frost, or cutting and windrowing pasture before turning cattle out is also preventive.
• Prophylactic administration of monensin or lasalocid (200 mg/head/day) for 1 day or 6 days respectively, prior to placing adult cattle on lush pasture can prevent disease if maintained for at least 10 days after introduction to pasture. These drugs reduce the conversion of L-tryptophan to 3-MI.
• Provide sufficient feed and minerals during late summer to limit consumption of toxic plants.
• Do not feed moldy sweet potatoes to livestock.
• Fence off access to toxic plants.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Secondary bacterial bronchopneumonia
• Viral respiratory infections

AGE-RELATED FACTORS
Young animals are resistant.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
N/A

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
Management has the greatest influence on the occurrence of these disorders, hence attention should be paid to minimizing all associated causes and risk factors, or where possible, employing specific preventive strategies.

SYNONYMS
• Fog fever
• Acute bovine pulmonary emphysema
• Pulmonary adenomatosis
• Acute respiratory distress syndrome

AVOCADO TOXICOSIS

BASICS

OVERVIEW

• There are approximately 150 species of avocado (*Persea*). Of these, *Persea americana* and its races and cultivars are of toxicologic importance. Races and cultivars most commonly encountered include Guatemalan and its hybrid ("Fuerte"), Mexican, and West Indies.
• The tree or shrub has a dense crown with brown to gray bark.
• Leaves, fruit, and seeds are toxic with leaves being the most toxic.
• Leaves alternate and crowd near the end of the twig. Leaf blades are ovate-elliptical with single primary vein.
• Flowers are perfect, greenish yellow.
• Fruit are ovoid to pyriform with thick glossy green to dark green skin.
• Seeds are large and light brown.

GEOGRAPHIC DISTRIBUTION

Cultivated primarily in Mexico, California and Florida, but can also be found as an ornamental in the Gulf coast areas.

SYSTEMS AFFECTED

• Mammary
• Cardiovascular

PATHOPHYSIOLOGY

• Suspected toxin is a R-enantiomer of persin. However, the mechanism of action is unknown.
• Toxin targets the mammary gland and myocardium depending on the amount of plant consumed.

HISTORICAL FINDINGS

Exposure to avocado groves

SIGNALMENT

Bovine, ovine, caprine (especially). Goats are highly susceptible to the mammary-induced effects of avocado poisoning, although all lactating animals can develop noninfectious mastitis and agalactia. With respect to cardiotoxic effects of avocado, all animal species are considered susceptible.

PHYSICAL EXAMINATION FINDINGS

• Mammary gland effects present as mastitis 24 hours post-ingestion with a 75% decrease in milk production. Milk appears to be watery and curdled.
• Myocardial effects present as edema of the neck and brisket, infrequent cough, depression, reluctance to move, leading to respiratory distress and cardiac arrhythmias.

CAUSES AND RISK FACTORS

• Presumed exposure to R-enantiomer of persin.
• Toxic dose:
  ◦ Mammary effects are seen with ingestion of 20 g of fresh leaves/ bwt (kg) in lactating goats.
  ◦ Myocardial effects were seen with ingestion of:
    ▪ 30 g of fresh leaves/bwt (kg) in lactating goats
    ▪ 25 g fresh leaves/bwt (kg) for 5 days in sheep (severe signs)
    ▪ 5.5 g fresh leaves/bwt (kg) for 21 days in sheep (chronic signs)
    ▪ 2.5 g fresh leaves/bwt (kg) for 32 days in sheep (mild signs)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of mastitis and cardiac disease

CBC/BIOCHEMISTRY/URINALYSIS

• No characteristic changes on CBC
• Elevation of liver enzymes such as AST and LDH
• Elevated CK

OTHER DIAGNOSTIC PROCEDURES

Finding of plant material within gastric contents on gross pathology

TREATMENT

THERAPEUTIC APPROACH

• Remove from source
• Treatment of mastitis
• Supportive care

MEDICATIONS

N/A

CONTRAINDICATIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Recovery possible
• Death

PREVENTION

Avoid feeding avocado plant material or grazing near avocado trees.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

PRODUCTION MANAGEMENT

Restrict grazing of livestock from avocado groves

ABBREVIATIONS

• AST = aspartate aminotransferase
• CK = creatine kinase
• LDH = lactate dehydrogenase

BABESIOSIS

BASICS

OVERVIEW
• Eradicated from the USA for 60 years, babesiosis remains an important disease in cattle throughout the world where the tick vector is prevalent.
• The causative agent is an intraerythrocytic protozoan that produces intravascular hemolysis in the ruminant host.

INCIDENCE/PREVALENCE
• Widespread in endemic areas.
• Asymptomatic carriers obscure the true prevalence.

GEOGRAPHIC DISTRIBUTION
• Worldwide, eradicated from the USA.
• Endemic in tropical climates where tick vectors flourish.

SYSTEMS AFFECTED
• Hemolymphatic
• Cardiovascular
• Nervous

PATHOPHYSIOLOGY
• Babesiosis is contracted via inoculation of infected blood, principally by tick vectors, and via blood-contaminated needles or instruments.
• The organism is transmitted by several one-host ticks; the genus *Boophilus* is particularly important.
• Female ticks are infected during feeding on infected cattle, with subsequent replication of *Babesia* in the tick's embryos. As the embryos develop into larvae, nymphs, and adults, the *Babesia* persist and can be transmitted to new mammalian hosts during tick feeding. For *B. bigemina,* only nymph or adult ticks are capable of transmitting the disease. The infection does not persist beyond the larval stage in *B. bovis*.
• Although rare, vertical transmission in mammalian hosts has been reported.
• The incubation period is 2–3 weeks.
• In endemic areas, where passive humoral immunity is transferred from dam to offspring, clinical disease is uncommon in cattle <6 months old.
• Immunosuppressed or immunologically naïve individuals are susceptible to parasitemia and clinical signs. If an animal survives initial infection, active immunity rapidly ensues, thereby controlling parasitemia.
• Immunity after natural exposure may last 1–2 years, but may be insufficient to completely eliminate the organism, allowing for persistence without clinical signs of disease (premunition).
• Subclinical "carriers" of *Babesia* serve as a silent reservoir for persistent infection within a herd.
• Carriers also may experience episodic clinical signs of recrudescence as protective immunity and parasitemia wax and wane.
• Some individuals may eventually eliminate the infection; other chronic carriers eventually succumb to the disease.
• Upon inoculation, infective sporozoites enter red blood cells wherein binary fission occurs within 14 days of inoculation. When replication is complete, the organisms are released by erythrolysis to propagate infection in new red blood cells.
• The predominant clinical signs of disease are fever and intravascular hemolysis. Other factors that may contribute to hemolysis include increased red blood cell fragility, removal of infected cells by the mononuclear phagocytic system, and the development of secondary autoimmune hemolytic anemia.
• Anemia develops, and in severe cases, death from hypoxemia may ensue.
• With *B. bovis* infection, release of inflammatory mediators in response to infection may also lead to intense hypotension, cardiovascular shock, and disseminated intravascular coagulation.
• *B. bigemina* may also replicate within the endothelium of the cerebrum, causing local hypoxemia and the development of "cerebral babesiosis," characterized by acute onset of signs of cerebral disease.

HISTORICAL FINDINGS
Concurrent illness; progressive depression, weakness, and lethargy; poor growth; separation from the herd; anorexia; tick infestation; hemoglobinuria; fever; and icterus.

SIGNALMENT
• Cattle and small ruminants are the principal hosts, but cases have been reported in other ruminants, such as water buffalo, reindeer, and the American bison.
• Any age may be affected, but younger calves in endemic areas rarely develop infection prior to 6 months of age due to passive immunity.
• Immunosuppressed, debilitated, stressed, or immunologically naïve adult ruminants are more susceptible to infection and often are more severely affected by the disease.

PHYSICAL EXAMINATION FINDINGS
• Onset of clinical signs depends on the size of the inoculum.
• Signs can develop within 1 week of inoculation, but may not be apparent for 2–3 weeks.
• High fever, depression, anorexia, and progressive weakness occur first.
• The predominant clinical signs develop with the onset of intravascular hemolysis that occurs as reproducing merozoites destroy erythrocytes in the circulation.
• Tachycardia and tachypnea may be profound and depend on the degree and rate at which the anemia develops. A low-grade systolic murmur may be present over the heart base as blood viscosity decreases.
• Hemoglobinemia and membrane pallor precede hemoglobinuria and icterus.
• Pregnant cows often abort.
• In severe cases, death results from hypoxemic shock. If the infected animal survives the initial episode of hemolysis, convalescence is prolonged until anemia has regenerated (weeks to months).
• Emaciation, poor condition, failure to thrive, and the existence of the carrier stage are common developments during convalescence.
• Infection of the endothelium of the central nervous system in cattle with *B. bigemina* may result in clinical signs of cerebral disease, including maniacal behavior, hyperexcitability, seizures, bruxism, opisthotonus, blindness, ataxia, and coma, with a grave prognosis.
• A unique phenomenon of anal sphincter spasm in cattle infected with *B. divergens* may produce the additional clinical sign of pipestream feces.

GENETICS
Zebu, Afrikaner, and Santa Gertrudis cattle are less susceptible to babesiosis than other breeds of cattle.

CAUSES AND RISK FACTORS
• Babesiosis is caused by infection with protozoa from the phylum Apicomplexa, order Piroplasmida, genus *Babesia.*
• At least six species of *Babesia* affect cattle and two species affect small ruminants (see Table 1). *B. bovis* is the most pathogenic; *B. major* and *B. ovate* are less pathogenic to nonpathogenic.
• Immunologically naïve, immunosuppressed, or otherwise debilitated individuals in endemic areas are most at risk for infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Causes of intravascular hemolysis include leptospirosis, bacillary hemoglobinuria, Heinz body anemia (onion, rape, kale toxicity), theileriosis, postparturient hemoglobinuria, and autoimmune hemolytic anemia.
• Causes of extravascular hemolysis should also be considered.
• Copper toxicity should be considered in sheep.

CBC/BIOCHEMISTRY/URINALYSIS
• Regenerative anemia 5–7 days after onset (signs of regeneration include an increased MCV, anisocytosis, polychromasia, basophilic stippling, reticulocytes, Howell Jolly bodies, nucleated red blood cells).
• Hemoglobinemia (pink plasma, increased MCH and MCHC).

Table 1

Distribution and Vectors for *Babesia* in Ruminants

Species	*Geographic location*	*Reported vectors*	*Infective stage of tick vector*
B. bigemina	South America, Europe, Africa, Australia, Middle East, Asia, West Indies	*Boophilus annulatus, B. decoloratus, B. microplus, B. calcaratus, Rhipicephalus evertsi, R. bursa, R. appendiculatus, Haemaphysalis punctata*	Nymphs and adults
B. bovis (also includes *B. berbera,* or *B. argentina)*	South America, Europe, Russia, Africa, Asia, Australia	*B. annulatus, B. microplus, Ixodes* spp., *Rhipicephalus bursa*	Larvae
B. divergens	Europe, Africa	*Ixodes ricinus*	Larvae
B. major	Europe, Russia, North Africa, Middle East	*Haemaphysalis punctata*	Adults
B. jakimovi	Siberia, Asia	*Ixodes ricinus*	
B. ovata	Japan	*Haemaphysalis longicornis*	
B. motasi (sheep and goats)	Europe, South America, Africa	*Dermacentor silvarum, Haemaphysalis, Rhipicephalus bursa*	Adults
B. ovis (sheep and goats)	Europe, Russia, Asia, Middle East	*Ixodes ricinus, Rhipicephalus bursa, Dermacentor reticulatis*	Adults

• Hemoglobinuria (red-brown urine, dipstick positive for blood; positive for hemoglobin with saturated ammonium sulfate test).
• Hyperbilirubinemia (unconjugated).
• Hypokalemia.
• Thrombocytopenia.
• Metabolic acidosis.

OTHER LABORATORY TESTS

• *Babesia* species may be seen within erythrocytes in a peripheral Wright- or Giemsa-stained blood smear. *B. bovis* is often difficult to find in the peripheral blood.
• The organisms are non-pigmented, pyriform to irregular, round or amoeba-shaped.
• Often, the protozoa appear in groups of two, with the "tops" of the pear-shaped organisms joined at an angle to form a "V."
• Parasitemia is often low, or affected cells are removed from circulation, so absence of visible protozoa does not preclude the diagnosis.
• The humoral response to *Babesia* can usually be detected within a week of infection. Many serologic assays exist, but the complement fixation and the indirect fluorescent antibody tests are most commonly used. Other tests include the rapid card agglutination, gel precipitation, latex agglutination, and enzyme-labeling immunoassay.
• Because humoral immunity post-infection is long lived, it may be difficult to distinguish active infection from previous exposure.
• Highly sensitive and specific molecular biology techniques are useful for diagnosis and surveillance of active infection in ticks and cattle. Nested PCR, RTqPCR and reverse line blotting technique are considerably more sensitive at detecting infection than traditional PCR.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

• Depending on the stage of the disease, diffuse pallor of the tissues or icterus is present.
• Splenomegaly, hepatomegaly, edema, body cavity effusion, petechial and ecchymotic hemorrhages on the heart and gastrointestinal tract, thin blood, thrombi, gallbladder distension, and the presence of red-brown urine in the urinary bladder are common.
• In chronically infected cattle, emaciation also occurs.
• *B. bigemina* tends to proliferate in peripheral vessels, whereas *B. bovis* multiplies in visceral blood vessels.
• Direct fluorescent antibody staining and PCR assay of blood or tissues are the most specific tests used to confirm the diagnosis postmortem.

TREATMENT

THERAPEUTIC APPROACH

• If anemia is severe and clinical or laboratory evidence of hypoxemia is evident (intense lethargy or weakness, profound tachycardia or tachypnea, severe anemia, acidosis, increased anion gap), a whole blood transfusion is indicated.
• The normal total blood volume is approximately 8% of the body weight (i.e., 0.08 × body weight in kilograms equals the total blood volume in liters). Typically, transfusing one-fourth to one-third of the total blood volume is adequate.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

• The most commonly used drugs include diminazene diaceturate (Berenil or Ganeseg; 3–5 mg/kg IM), phenamidine diisethionate (Lomadine; 8–13 mg/kg, SQ or IM), imidocarb dipropionate (Imizol; 1–3 mg/kg, SQ or IM), and amicarbalide diisethionate (Diampron; 5–10 mg/kg IM). Imidocarb therapy may prevent reinfection for up to 2 months.
• Concern over tissue residues, particularly with imidocarb, has resulted in withdrawal of some of these products in certain countries.
• Overzealous use of babesiocidal drugs may abruptly reduce parasitemia to a level that is inadequate for establishment of protective immunity.

CONTRAINDICATIONS

N/A

PRECAUTIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

N/A

BABESIOSIS (CONTINUED)

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Carriers are common in endemic areas. Infection with *B. bovis* is generally more severe than infection with other species.
• Cerebral babesiosis warrants a grave prognosis.
• The mortality rate is high in adult immunologically naïve or immunosuppressed individuals.

POSSIBLE COMPLICATIONS

• Death from hypoxemic anemia or cerebral babesiosis.
• Treatment frequently does not eliminate the carrier state.

CLIENT EDUCATION

• See "Prevention."
• Immunologically naïve cattle moving into endemic areas should be vaccinated prior to movement.

PATIENT CARE

Monitor heart rate, respiratory rate, attitude, appetite, PCV, body weight of affected animals.

PREVENTION

• Most control programs are tailored to individual herds.
• Complete eradication from a herd within an endemic area leaves that herd susceptible to future reinfection from surrounding herds.
• Thus most control programs are aimed at balancing infection with an appropriate level of immunity. This is most effectively achieved by reducing the tick population with acaricides and cattle tick vaccines and vaccination with live or live-attenuated *Babesia* organisms produced by either in vivo inoculation or in vitro culture to establish a state of premunition. There is little cross protection between species of *Babesia.* The shelf life of live and live-attenuated vaccines is short (approximately one week) unless ultra-frozen.
• Calves are typically vaccinated between 4 and 10 months of age.
• As older animals are more sensitive to the effects of infection, vaccination with live organisms is often followed with babesiostatic or babesiocidal drugs.
• Newer vaccines using recombinant proteins are promising but not commercially available.
• Selection of cattle that are resistant to the tick vector and/or the disease is another method of control.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Younger cattle in endemic areas are rarely infected.

ZOONOTIC POTENTIAL

Rare. Immunosuppressed humans may be susceptible to infection.

PREGNANCY

Immunization of pregnant cows with live or live-attenuated vaccines may induce neonatal isoerythrolysis.

BASICS

OVERVIEW

• Fatal clostridial disease associated with the proliferation of *Clostridium haemolyticum* (*Clostridium novyi* type D) in the liver as a consequence of hepatic damage induced by parasite larval migration, trauma or abscessation of hepatic parenchyma. The fulminant course of the disease is characterized by toxemia, hemoglobinuria, and sudden death.
• Spores of *Clostridium haemolyticum* are normally found in the soil and gastrointestinal tract, liver, feces, and urine of healthy cattle and sheep and accumulate in the environment as a result of fecal shedding by carrier animals.
• Disease results when a hepatic insult or damage creates an area of anaerobiosis in the liver that promotes spore germination and results in vegetative cell multiplication and toxin production.
• Hepatic insult often results from migration of liver flukes (*Fasciola hepatica, Dicrocoelium dendriticum, Fascioloides magna* or *Cysticercus cellulosae*), trauma (iatrogenic or spontaneous) or abscessation of the liver.
• The disease is usually fatal but recovery after treatment of some cases has been reported.
• Endemic in swampy areas with an alkaline soil pH (~8).
• Organism capable to survive in decomposed carcasses and soil for years.
• Outbreaks are seen in cattle fed hay from infected fields and after flooding.

INCIDENCE/PREVALENCE

Herd mortality rate ranges from 5% to 25% and case fatality rate is 95%.

GEOGRAPHIC DISTRIBUTION

This is a disease that affects cattle and sheep all over the world. In the United States, Red Water is found primarily in the western part of the country and occasionally in the southern states.

SYSTEMS AFFECTED

• Digestive
• Hemolymphatic

PATHOPHYSIOLOGY

• *Clostridium haemolyticum* is transported to the liver from the GI tract and persist in Kupffer's cells.
• Asymptomatic but infected cattle harbor the organism in their GI tract, liver, and tissues and may shed it in feces and urine.
• Anaerobiosis resulting from liver damage causes germination of *Clostridium haemolyticum* spores, vegetative growth, and release of exotoxins.
• The β-toxin (phospholipase C) released by the organism causes extensive hepatic necrosis, vasculitis, and intravascular hemolysis.
• Anemia, icterus, hemoglobinuria, and shock result from release of exotoxins.

SIGNALMENT

• Occurs usually in cattle older than 1 year but it is uncommon in young calves.
• Highly conditioned cattle seem most susceptible.
• Mature sheep affected sporadically.
• Uncommonly elk, other ruminants.
• No sex or breed predilection.

PHYSICAL EXAMINATION FINDINGS

• Short course of clinical disease 12–48 h
• Sudden death/found dead
• Rare to see affected animals alive
• Severe depression/affected animals stand apart from the herd
• High fever (103°F–106°F; 39.5°C–41°C)
• Tachycardia
• Abdominal pain
• Rectal bleeding and bloody feces
• Diarrhea
• Shallow breathing/dyspnea
• Hemoglobinuria/dark red urine
• Icteric or pale mucus membranes
• Progressive anemia
• Weakness
• Recumbency

CAUSES AND RISK FACTORS

• Pasturing cattle in wet and swampy pastures that favor liver fluke survival.
• Geographic areas with high soil pH.
• Irrigated and poorly draining alkaline pastures.
• Hepatic insult(s) caused by larval migration, liver abscesses, septicemia, hepatotoxins, trauma, biopsy, and high nitrate diets which create a state of anaerobiosis and promote germination of *Clostridium haemolyticum* spores and toxin production.
• Unvaccinated cattle and sheep.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Leptospirosis
• Postparturient hemoglobinuria
• Enzootic hematuria (bracken fern toxicosis)
• Acute pyelonephritis
• Chronic copper poisoning
• Black disease
• Hemorrhagic cystitis
• Babesiosis

CBC/BIOCHEMICAL/URINALYSIS

• Anemia
• Leukocytosis or leukopenia with left shift
• Neutrophilia/neutropenia with toxic changes
• Increased values of liver enzymes (SDH, AST, GGT, ALP)
• Increased CK
• Hyperbilirubinemia
• Azotemia
• Hemoglobinuria

OTHER LABORATORY TESTS

• Blood culture.
• Nested PCR of whole blood samples for *Cl. haemolyticum.*
• Identification of large, Gram-positive rods on impression smear from liver, spleen, blood, or abdominal fluid.
• Isolation of *Cl. haemolyticum* from tissue from the edge of liver infarcts and from blood of affected animals.
• Fluorescent antibody test (FAT) on impression smears from liver infarcts, or immunohistochemistry on spleen will be positive for the organism.
• Biochemical and toxin (β-toxin) identification tests.
• Definitive diagnosis by culture and GLC confirmation that isolate is *Cl. haemolyticum.*
• Detection of the flagelin gene (*fliC)* sequence of *Cl. haemolyticum* by nested PCR of whole blood samples of affected animals.
• Caution should be exerted when interpreting Gram stains, culture, or FAT of liver lesions or GI tract as *Cl. haemolyticum* could be found in healthy animals and proliferates rapidly after death.
• Clostridial FAT cross reacts with *Clostridium novyi* type B and C.

IMAGING

Hepatic ultrasound:
• Infarct
• Disruption of normal parenchyma
• Vascular changes

PATHOLOGIC FINDINGS

• Subcutaneous edema, petechial and ecchymotic hemorrhages throughout the body.
• Diffuse hemorrhage in GI tract, respiratory tract, and pericardium.
• Red-tinged abdominal and thoracic fluid.
• Large ischemic hepatic infarct is pathognomonic.
• Usually a single infarct but occasionally multiple of varying size.
• Congestion and hemorrhage of lymph nodes
• Pigmented kidneys (blackened kidney)
• Red urine in kidney and bladder
• Icterus
• Anemia
• Splenomegaly

TREATMENT

THERAPEUTIC APPROACH

• Treatment is rarely effective.
• High doses of penicillin (44,000 IU/kg), intravenously preferred (q6h).
• Tetracyclines, cephalosporins, and ampicillin have also been recommended.
• Blood transfusion(s) as indicated; minimum of 6–8 liters for adult cattle.
• Antitoxic serum, if available.
• Intravenous isotonic polyionic fluids.
• Liver fluke treatment.
• Anti-inflammatory therapy.

BACILLARY HEMOGLOBINURIA (CONTINUED)

MEDICATIONS

DRUGS OF CHOICE
- Sodium, potassium or procaine penicillin
- Oxytetracycline
- Cephalosporins
- Blood transfusion
- Antitoxic serum
- Polyionic fluids

CONTRAINDICATIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- Mortality in treated animals is high.
- Heavy mortalities when naïve, unvaccinated cattle brought onto infected pastures.
- Recovered animals may become poor doers: chronic weight loss, poor production.
- Cattle surviving subclinical attacks of disease may act as immune carriers.

MISCELLANEOUS

ASSOCIATED CONDITIONS
- Toxemia, hypovolemia, and severe anemia
- Renal or pulmonary emboli
- Renal infarcts
- Cardiac arrhythmias
- Pigment nephropathy

PRODUCTION MANAGEMENT
- Cattle should not be grazed on liver fluke-infested pastures.
- Liver fluke control is recommended in endemic areas.
- Prevent acute or sub-acute ruminal acidosis in order to decrease the risk of liver abscess formation.
- Vaccinate young animals with bacterin-toxoids of *Cl. haemolyticum* at 3–4 months of age and revaccinate 21 days later.
- Booster vaccination at weaning and every 6 months.
- Time of vaccination should be dictated by liver fluke season exposure.
- Deworm sheepdogs to reduce *Cysticercus tenuicollis* infection.
- Avoid pasture contamination by properly disposing (burn, deep burial, remove from premises) of decomposing carcasses of affected animals.

SYNONYMS
- Icterohemoglobinuria
- Infectious icterohemoglobinuria
- Red water

ABBREVIATIONS
- ALP = alkaline phosphatase
- AST = aspartate transaminase
- CK = creatine kinase
- FAT = fluorescent antibody test
- GGT = gamma-glutamyl transferase
- GI = gastrointestinal
- GLC = gas–liquid chromatography
- IM = intramuscular
- PCT = polymerase chain reaction
- SDH = sorbitol dehydrogenase

SEE ALSO
- Bracken Fern Toxicity
- Brassica spp. Toxicity
- Copper Deficiency and Toxicity
- Infectious Necrotic Hepatitis
- Leptospirosis
- Liver Flukes
- Postparturient Hemoglobinuria
- Pyelonephritis

BACTERIAL ENDOCARDITIS

BASICS

OVERVIEW

• Bacterial endocarditis is the most common valvular or endocardial disease in cattle. Chronic active infections such as rumenitis, mastitis, metritis, abscesses, foot infection, lead to continual bacteremia which predisposes cattle to bacterial endocarditis.
• Bacterial endocarditis can be an acute, subacute, or chronic infection, usually involving one or more heart valves resulting in variably-sized mass-like lesions. Less commonly, lesions may involve the mural endocardium.
• Initial clinical signs can be vague and variable. As lesions progress, valvular insufficiency can lead to heart failure, but heart failure is observed only in advanced disease.
• Clinical signs related to septic thromboembolism can be observed.
• The most common etiologic agents associated with bacterial endocarditis in cattle are *Trueperella pyogenes* and *Streptococcus* spp.
• Tricuspid valve most frequently and severely affected in cattle, but can also involve mitral, aortic, and pulmonic valves. Valves may be affected singly, or multiple valves can be involved.
• Rarely a curable disease. Long-term antimicrobial and supportive therapy required.
• Prognosis is poor for productivity and long-term survival.

INCIDENCE/PREVALENCE

Prevalence of bacterial endocarditis is estimated from slaughterhouse surveys to range from 0.01% to 0.15%.

GEOGRAPHIC DISTRIBUTION

Worldwide distribution

SYSTEMS AFFECTED

Cardiovascular

PATHOPHYSIOLOGY

• Chronic bacterial infection predisposes to bacterial endocarditis. Endocarditis most commonly occurs secondary to a chronic infection at a distant site that results in a recurrent or sustained bacteremia.
• Whether bacteria directly adhere to undamaged valvular endothelium, gain access to valves through damaged valvular surfaces, or enter hematogenously through capillaries at the base of valve is unknown.
• Bacteria proliferate within valve leaflets. Further endothelial damage by bacteria exposes collagen and enhances platelets and fibrin; fibrin is a major component of the vegetative lesion.
• Certain bacteria can adhere directly to endothelium because of their ability to synthesize polysaccharides (dextrans) and fibronectin, thus enhancing their ability to colonize endothelial surfaces (vascular walls, heart valves).
• Bacteria adhering to valve surface activates coagulation cascade via release of tissue thromboplastin and extrinsic pathway.
• Endothelial surfaces are continuously exposed as a result of persistent bacteremia.
• Heart failure, right-sided more commonly than left-sided, may subsequently develop.
• In cattle, endocarditis most commonly occurs on the tricuspid valve, with the mitral valves the second most common valve affected. If multiple valves, bilateral infection of atrioventricular valves (tricuspid and mitral) is more common.
• Endocardium adjacent to valves can also be affected, especially secondary to congenital heart disease that causes turbulent blood flow.
• Embolic showering to secondary organs is common. Further bacteremia and septic thromboembolism leads to infections in other parts of the body, particularly those sites with high blood flow (lungs, kidney, joints).
• Lesions may be small or can be large enough to occupy most of adjacent heart chamber.
• Three histologic zones in lesions: (1) inner zone composed of fibrous tissue, (2) intermediate zone contains fibrin and bacterial colonies, and (3) superficial zone of fibrin and blood cells.
• Gross necropsy findings: (1) valvular lesions, often vegetative or fibrotic, thickening and distortion of valve leaflet, (2) embolic lesions to other organs, (3) signs of right-sided or congestive heart failure (e.g., hydrothorax, hydroperitoneum, passive congestion of liver, subcutaneous edema).

SIGNALMENT

• Primarily in mature cattle, goats, sheep
• More common in adult than in young
• No sex or breed predilection

PHYSICAL EXAMINATION FINDINGS

• Clinical signs often related to two phenomena: valvular insufficiency and septic thromboembolism.
• Clinical signs are often variable and vague.
• Persistent tachycardia is the most consistent finding in bacterial endocarditis.
• Heart murmur noted in ~50% of cattle cases. Absence of a murmur does not rule out bacterial endocarditis.
• Location, timing, and point of maximum intensity of murmur depends on valve(s) affected. If tricuspid is involved, heart murmur is primarily holosystolic or pansystolic and heard loudest on right side of thorax.
• Frequently, animal has history of temporary remission of clinical signs during antibiotic therapy.
• Ill-thrift, decreased appetite, and weight loss.
• Intermittent or constant fever.
• Lameness, septic arthritis.
• Temporary but dramatic drop in milk production.
• Cardiac arrhythmias (sinus tachycardia, other tachyarrhythmias) in affected cattle.
• Less common signs: weakness, diarrhea, abdominal pain, pale mucus membranes.
• As disease progresses, signs of heart failure, primarily right-sided, develop. Signs of right-sided heart failure include ventral, mandibular, or brisket edema, jugular or mammary vein distention, vein pulsation, tachycardia, hepatomegaly.
• Occasionally, affected cattle die suddenly without observed clinical signs.
• Signs of secondary organ (lung, kidney) involvement (infection, infarction) or embolic disease.

CAUSES AND RISK FACTORS

• Numerous bacterial species have been isolated from cattle with bacterial endocarditis.
• *Trueperella* (formerly *Arcanobacterium*) *pyogenes* is most frequent isolate from bacterial endocarditis cases in cattle with *Streptococcus* spp. second most commonly isolated.
• Other common isolates: *Escherichia coli, Micrococcus* spp., *Staphylococcus aureus, Pseudomonas* spp., *Klebsiella pneumoniae, Proteus mirabilis, Clostridium* spp., *Bacterioides* spp., *Fusobacterium necrophorum.*
• Less common isolates: *Mycoplasma mycoides, Erysipelothrix rhusiopathiae, Helcococcus ovis.*
• Recently, *Bartonella bovis* has been identified with bacterial endocarditis in cattle in the US and Europe. Other etiologic agents will likely be identified with next-generation sequencing technologies.
• Predisposing factors include chronic infection, chronic bacteremia, and underlying damage to valvular or endocardial surface.
• Risk factors include ruminal acidosis (acute, subacute, chronic), thrombophlebitis, distant infection site (mastitis, metritis, septic arthritis, tail infection, pneumonia, omphalophlebitis, abscesses, etc.), hardware disease (traumatic reticuloperitonitis), decubital ulcers, traumatic myocarditis, indwelling intravenous catheter, iatrogenic lesions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Bacterial, viral, or protozoal myocarditis
• Brisket disease
• Cardiac lymphosarcoma or other neoplasm
• Congenital cardiac abnormalities
• Congestive heart failure
• Cor pulmonale
• Dilated cardiomyopathy
• Endocardiosis
• Nutritional myodegeneration
• Parasitic endocarditis
• Septic pericarditis
• Toxic myocardial necrosis (ionophore toxicity, gossypol toxicity, plant toxicosis)

BACTERIAL ENDOCARDITIS (CONTINUED)

CBC/BIOCHEMISTRY/URINALYSIS

• Clinical pathologic abnormalities can assist with diagnosis: Hyperfibrinogenemia and hypergammaglobulinemia due to infectious or inflammatory processes.
• Complete blood count findings may include a nonregenerative anemia, leukocytosis with or without a left shift and monocytosis.
• May have normal leukogram or leukopenia with left shift.
• Cattle have less consistent leukocyte response compared to other species.
• Marked elevation in cardiac troponin I was observed in a case report of bacterial endocarditis, but elevations may also be observed in myocardial disease.
• Serum chemistry panel often reflects accompanying changes in other organ systems, hydration status, or hypophagia.
• Azotemia.
• Elevated GGT.
• Elevated creatine kinase if recumbent.
• Electrolyte abnormalities from anorexia.
• Urinalysis if renal infection or infarct suspected.

OTHER LABORATORY TESTS

• Electrocardiogram if arrhythmia present.
• Transtracheal wash for cytology and microbiologic cultures if signs of pulmonary disease.
• Thoracic radiographs are of limited value in evaluating cardiac disease in cattle.
• Arterial blood gas to evaluate oxygenation status.
• Venous blood gas to evaluate metabolic status.

IMAGING

• Echocardiography is a sensitive diagnostic tool; however, specific criteria to define endocarditis are lacking. Endocarditis lesions appear as echogenic shaggy, smooth, or cystic masses. Vegetative lesion on or around heart valve can be visualized and measured. Valves are thickened with ventricular hyperkinesis.
• For adult cattle, use a 3.5 megahertz (MHz) (or smaller) transducer. 5.0 MHz can be used for young calves or small ruminants. Scan both sides of the chest.
• Echocardiography: Vegetative lesion on or near one or more heart valves, most commonly tricuspid valve, secondary chamber enlargement (right atrial) may be observed.
• Negative study does not rule out diagnosis of bacterial endocarditis.

OTHER DIAGNOSTIC PROCEDURES

• Field diagnosis is based on history (chronic infection) and clinical findings (murmur, persistent tachycardia) consistent with bacterial endocarditis. A murmur heard over the tricuspid valve area in an adult cow is suggestive of bacterial endocarditis.
• A recent meta-analysis identified that positive blood cultures had the highest sensitivity (86.9%) for diagnosis of bacterial endocarditis, followed by echocardiographic identification of valvular lesions (84.3%), presence of tachycardia (79.7%), presence of a murmur (60.3%), presence of fever (45.7%), and presence of lameness/polyarthritis (43.5%). In same meta-analysis, presence of clinical signs of heart failure had a sensitivity of 37.3%.
• Aerobic and anaerobic blood cultures and sensitivity should be attempted for valuable livestock. Blood cultures should be obtained prior to initiation of antimicrobial therapy. A minimum of 10 mL of blood should be collected aseptically, with two to three cultures drawn several hours apart from separate venipuncture sites.
• Culture blood at a 1:10 to 1:20 ratio to broth medium. Incubate at 37°C for 24 hours before plating on traditional blood agar plates.
• Antimicrobial removal device (ARD) should be used if animal previously received antimicrobial drugs. Alternatively, if animal's condition permits, withdraw antimicrobial therapy for 24–48 hours before obtaining blood samples for culture.
• Failure to obtain a positive blood culture does not rule out the presence of bacterial endocarditis.
• Examination of buffy-coat smears or leukocyte monolayer preparation stained with Gram or Giemsa stain.

TREATMENT

THERAPEUTIC APPROACH

• Long-term and often costly; compliance and economic issue provide major disadvantages for treating bacterial endocarditis in ruminants.
• Often palliative rather than curative. The bacteria create permanent damage to valvular endocardium.
• Treatment is aimed at sterilizing lesion, halting spread of infection, managing clinical signs of heart failure.
• Antimicrobial therapy should be ideally based on sensitivity of bacteria isolated from blood culture or other site of infection.
• Parenteral administration of bactericidal antimicrobials required for a minimum of 4–6 weeks and often as long as 8–12 weeks.
• Ideally, initial therapy includes broad-spectrum antimicrobials given intravenously (IV) to achieve increased blood levels.
• In cattle, penicillin and beta-lactam drugs are frequently first-choice therapy due to high percentage of Gram-positive organisms isolated from affected animals.
• Early withdrawal of therapy may result in relapse.
• Extra-label use of antimicrobial is required because current antimicrobials are not labeled for bacterial endocarditis and for the duration of therapy required.
• Anti-inflammatory/antipyretic agents: aspirin, flunixin meglumine.
• Anticoagulants to limit enlargement of vegetative lesions and thromboembolic disease; bovine platelets respond poorly to antithrombotic effects of aspirin.
• If signs of heart failure are present, diuretics are added to the therapeutic plan.
• Maintenance of normal blood electrolyte concentrations, acid-base status, and hydration.
• Appropriate treatment of secondary organ disease or dysfunction.
• Correct hypokalemia, hypocalcemia, and other electrolyte abnormalities associated with anorexia and diuretic therapy.
• Oxygen supplementation if hypoxemic.

MEDICATIONS

DRUGS OF CHOICE

• Drug of choice is based upon information collected from blood culture and sensitivity.
• All medications used for treatment of bacterial endocarditis must be used following AMDUCA guidelines.
• Penicillin: 22,000 IU/kg: Aqueous potassium penicillin IV, q6h or procaine penicillin IM, q12h
• Amoxicillin: 10 mg/kg IM, q12h
• Ampicillin: 20 mg/kg IV, q8h; 10–20 mg/kg IM, q12h
• Anti-inflammatories: flunixin meglumine, aspirin
• Furosemide: 0.5–1 mg/kg IV, q12–24h
• Potassium supplement (50–200 g/day PO) if on potassium-wasting diuretics

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Most cases die or are culled due to poor prognosis and expense of therapy.
• Long-term survival rate and productivity level is not known.
• Prognosis is generally guarded to poor for recovery and productivity.
• Animals diagnosed early and treated aggressively with small or single lesions have a fair to good prognosis.
• Evidence that lesions or disease are resolving include regression of clinical signs, return of fibrinogen and serum protein concentrations to normal, reduction in size of lesion on echocardiographic examination, negative blood cultures 3–4 days after discontinuing antimicrobial therapy.

• Reasons for therapeutic failure include advanced stage of disease at initiation of therapy, premature withdrawal of therapy, ongoing valvular thrombosis due to endothelial damage, bacterial recolonization of valve, and change in sensitivity or type of infecting bacteria.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Cardiac arrhythmias including sinus tachycardia, premature ventricular contractions, and atrial fibrillation.
• Septic arthritis.
• Passive hepatic congestion.
• Congestive heart failure.
• Myocardial disease.
• Most common sequelae include embolic pneumonia, renal infarction, suppurative arthritis, hepatic emboli.
• Less common sequelae: cerebral and adrenal emboli, epididymitis, pleural effusion.

PRODUCTION MANAGEMENT

• Observe appropriate milk and meat withdrawal times for drugs administered.
• Treatment of most animals with bacterial endocarditis is often not undertaken due to costs.
• Genetically valuable animals often treated to enhance options for genetic salvage procedures (e.g., semen collection, embryo collection, cloning).
• Infection results in decreased milk and meat production.

BACTERIAL MENINGITIS

BASICS

OVERVIEW

• Meningitis is defined as inflammation involving one or more layers of the meninges. The meninges function to support, protect, and contribute to nourishment of the brain and spinal cord.
• Bacterial meningitis is more common than viral meningitis and is most commonly seen in neonatal ruminants concomitantly due to bacterial sepsis as a result of poor neonatal colostral intake and/or absorption. Gram-negative enteric bacteria, especially *E. coli,* are the most common pathogens associated with bacterial sepsis and bacterial meningitis.
• Meningitis can also be observed in older animals as a result of osteonecrosis induced by thermal cauterization during dehorning, extension of localized infection from skull fractures or coccygeal vertebrae (poor docking hygiene), or secondary to bacterial endocarditis.

INCIDENCE/PREVALENCE

In general, meningitis is a relatively rare condition in large animals, but is most frequently reported in neonatal farm animals. A recent survey demonstrated that the prevalence of meningitis-meningoencephalitis was 36% in critically ill Piedmontese calves <15 days of age.

SYSTEMS AFFECTED

Nervous

GEOGRAPHIC DISTRIBUTION

Worldwide

PATHOPHYSIOLOGY

• The mechanisms by which bacteria gain entry to the meninges are poorly understood; however, sustained bacteremia in neonatal ruminants may provide a source of bacteria reaching the meninges. This bacteremia, when combined with a highly perfused dural venous system and choroid plexuses, and pathogenic factors including attachment fimbria in some strains of *E. coli*, create an opportunity for bacterial colonization of the meninges.
• Once bacterial colonization occurs, a relative lack of bactericidal and opsonic activities in the CNS allow bacteria to survive and proliferate in the cerebrospinal fluid (CSF).
• The inflammatory response including release of host-derived cytokines and the direct effects of bacterial invasion and replication are responsible for the long-term neurologic sequelae and death associated with bacterial meningitis.
• Defects of CSF drainage occurring secondary to meningeal inflammation lead to hypertensive hydrocephalus.
• Bacterial meningitis can also occur by direct extension of an infectious agent into the calvarium (otitis media, infected skull fracture, sinusitis, thermal osteonecrosis) or by hematogenous spread to the CNS from a distant site (heart valves, lungs, gastrointestinal tract, joints, umbilicus).

SIGNALMENT

Neonates of all species, especially calves

PHYSICAL EXAMINATION FINDINGS

• Earliest clinical signs are often nonspecific.
• Acute meningitis may or may not be accompanied by fever in the neonate. Anorexia and loss of a coordinated suckle reflex in a neonate are common clinical signs.
• Hyperesthesia, stiff neck, depression, seizures, or blindness, with or without a history of another illness, such as enteritis or polyarthritis.
• Depression, omphalophlebitis, polyarthritis, and ophthalmitis are frequent concurrent findings.
• Ataxia, with or without spasticity and mild tetraparesis, depression, wandering, star-gazing, and abnormal vocalization may be seen.
• Lethargy, recumbency, coma, opisthotonus, convulsions, tremors, and hyperesthesia are the common clinical signs in calves with meningitis.

CAUSES AND RISK FACTORS

• Failure in the transfer of maternal antibodies predisposes to hematogenous meningitis.
• *E. coli,* the organism most often associated with neonatal sepsis, is the most common bacterium isolated. Other isolates include *Klebsiella pneumoniae, Salmonella* spp. (*S. dublin* and *S. typhimurium*), *Staphylococcus* spp., *Streptococcus* spp., and *Bacillus* spp. in calves. In sheep and goats, *Klebsiella pneumoniae, Salmonella* spp., *Streptococcus* spp., *Trueperella pyogenes, Erysipelothrix rhusiopathiae,* and occasionally *Leptospira interrogans, Listeria monocytogenes, Mycoplasma* spp., and *Fusobacterium necrophorum* are isolated.
• Both maternal and neonatal factors contribute to the development of sepsis in the neonate. They include bacterial placentitis, perinatal stress, prematurity, dystocia, birth asphyxia, unsanitary or adverse environmental conditions, overcrowding, contamination of the environment with pathogenic bacteria, and the presence of enteritis, omphalitis, or respiratory infections in the neonate.
• There may be a history of trauma, recent dehorning, or tail docking, or there may be information relating to the presence of a wound near the calvarium or vertebrae (usually older ruminants), or an infection of the sinuses, middle ear, or inner ear.
• *Histophilus somni* is a potential cause of meningitis in feedlot cattle.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Cerebral edema
• Encephalitis (e.g., viral)
• Hydrocephalus
• Metabolic disease (e.g., hypoglycemia, hypomagnesemia)
• Toxicity

CBC/BIOCHEMISTRY/URINALYSIS

• Leukocytosis with a left shift is common in calves.
• Respiratory acidosis, hypernatremia, hyponatremia, hyperkalemia, hypomagnesemia, and hypoglycemia may be observed also.

OTHER LABORATORY TESTS

• Low serum immunoglobulin concentrations may be observed.
• In the presence of neurologic signs, a positive blood culture supports a diagnosis of bacterial meningitis secondary to neonatal infection. Other samples, such as synovial fluid, also may culture positive.

IMAGING

Radiographs and/or ultrasound may be indicated when trauma or extension of a localized infection is suspected.

OTHER DIAGNOSTIC PROCEDURES

Definitive diagnosis is based on the presence of a neutrophilic pleocytosis, xanthochromia, turbidity, high total protein concentration in the CSF, and, ideally, positive culture from the CSF. Gram stain and culture should be attempted on CSF.

PATHOLOGIC FINDINGS

On gross necropsy, meningeal vessels appear congested and meninges are swollen and opalescent with petechiae. The CSF is often cloudy and can contain fibrin clots. Microscopic changes can include suppurative inflammation of meningeal vessels with bacterial colonies present in the meninges and brain parenchyma. Hemorrhagic or thrombotic infarcts may also be observed within the CNS.

TREATMENT

THERAPEUTIC APPROACH

• Early diagnosis and aggressive treatment are imperative for a successful outcome. By the time clinical signs are present, treatment is often unrewarding.
• Provision of adequate nutritional support and a clean, comfortable environment; protection from self-inflicted trauma; and maintenance of body temperature, fluid, and

acid-base balance are critical for a successful outcome.
• Treatment may be expensive and mortality rate high despite appropriate therapy.

MEDICATIONS

DRUGS OF CHOICE

Antimicrobials

• Antimicrobial therapy is the treatment of choice but is often unrewarding because course of treatment is begun too late and case fatality rate is high. The blood-brain barrier makes achieving therapeutic levels of drug in the CNS difficult.
• Selection of antimicrobial drugs should be based on either smears stained by Gram stain or culture from CSF. If empirical antimicrobial therapy is chosen, the therapy should include Gram-negative and Gram-positive spectrum.
• No drugs are labeled for treatment of bacterial meningitis; thus, treatment of bacterial meningitis in ruminants constitutes an extra-label use.
• Inflammation markedly enhances CSF concentrations of beta-lactams, particularly cephalosporins, which normally penetrate poorly. Meningitis caused by Gram-negative enteric bacteria can be treated with a third- or fourth-generation cephalosporin.
• Selection of an antimicrobial drug in ruminants should also be based on the pharmacokinetics and pharmacodynamics of the drug in neonates, the likelihood of antimicrobial resistance, and the potential for violative antimicrobial tissue residues.
• Bacteriocidal drugs are superior to bacteriostatic drugs.
• Antibiotics should be administered by intravenous routes to attain maximum peak blood and CSF concentrations.
• There is a lack of CSF pharmacokinetic data in ruminants. Specific antimicrobial therapy could include florfenicol (20 mg/kg, IV, q12h), ceftiofur (must be used at labeled dose levels, frequencies, durations, and routes of administration), and sodium ampicillin (10–20 mg/kg, IV, q8h).
• Relapses may occur as meningeal inflammation subsides and CNS concentrations of (nonlipophilic) antimicrobial drug(s) fall.
• Antimicrobial drug therapy should continue for at least 7 days after resolution of all clinical signs.

Anticonvulsants

The following drug doses for neonatal ruminants have been "guess-estimated", based on recommended doses for equine neonates.
• Diazepam (0.1–0.2 mg/kg, slowly IV, repeated every 30 minutes if necessary) is used for short-term control.
• If two to three doses of diazepam fail to control convulsions, a loading dose of phenobarbital (10–20 mg/kg diluted in 30 mL saline, IV over 15 minutes) should be given. Oral therapy (5–10 mg/kg, q8h to q12h) is then used for maintenance for long-term control.

Other Treatments

• Following rehydration, nonsteroidal anti-inflammatory drugs may be beneficial (flunixin meglumine, 0.5–1.0 mg/kg, IV, q12h to q24h)
• A plasma transfusion may be required.
• Additional therapy may be required to resolve secondary complications (i.e., abomasal ulcers due to NSAID usage, corneal trauma, etc.).

CONTRAINDICATIONS

• Acepromazine should not be used as a sedative due to its ability to lower the seizure threshold.
• Drug withdrawal times must be determined for all drugs used to treat food-producing animals.

PRECAUTIONS

Care should be exercised when dosing anticonvulsant drugs in neonates because of the increased permeability of their blood-brain barrier.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Prognosis in neonatal ruminants with septic meningitis is poor, despite treatment. The key to a successful outcome relies on early recognition of CNS involvement and institution of aggressive, appropriate therapy.

PATIENT CARE

Close monitoring of vital parameters and metabolic indices is warranted during antimicrobial therapy, especially in animals showing seizure activity.

PREVENTION

• The key to prevention of meningitis in neonates is paying attention to the events leading up to and including parturition, and ensuring adequate colostral intake.
• Proper dehorning technique and hygiene during tail docking will decrease the incidence of meningitis in older animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Generalized sepsis typically accompanies septic meningitis in neonates.

PREGNANCY

Diseases affecting the dam during gestation may predispose the neonate to partial or complete failure of passive transfer after birth.

PRODUCTION MANAGEMENT

• Measures taken that reduce perinatal stress will reduce the incidence of septic meningitis in the neonate.
• Proper dehorning technique and hygiene during tail docking will reduce the incidence of septic meningitis in older animals.

ABBREVIATIONS

• CNS = central nervous system
• CSF = cerebrospinal fluid
• IV = intravenous
• PO = per os, by mouth

BISON: BACTERIAL DISEASES

BASICS

OVERVIEW

The bacterial diseases that bison are susceptible to are similar to those found in cattle, and the disease processes in bison mimic those seen in cattle as well. Different bacterial diseases have implications regarding biosecurity, production efficiency, and clinical health of the herds affected. Further in-depth information for each disease can be found in the pertinent chapter (see pertinent chapter; SPC).

INCIDENCE/PREVALENCE

• *Arcanobacter pyogenes*: Uncommon; top differential for localized abscesses. • Actinobacillosis: Pathology found in bison. • Anthrax: Described in bison in the USA and Canada. • Blackleg: Uncommon; unvaccinated bison are susceptible. • Brucellosis: Endemic in Wood Buffalo National Park, Yellowstone National Park, and Grand Teton National Park. • Foot rot: Incidence lower in bison than in cattle. • Hemorrhagic septicemia: Uncommon in bison. • Hemophilosis: Isolated in clinically normal bison. • Johne's Disease: Clinical disease reported in bison. • Leptospirosis: ~ 7% of bison in Yellowstone National Park showed titers to leptospirosis. • Listeriosis: Low incidence in bison. • Mannheimiosis: *M. hemolytica* isolated in clinically affected bison. • Mycoplasma: *M. bovis* thought to be spread from cattle to bison. • Necrotic stomatitis: Sporadic in nature with low prevalence. • Pinkeye: Sporadic in bison, with some herds becoming infected more than others. • TB: Prevalence increases with age in endemic herds.

SYSTEMS AFFECTED

Multisystemic.

PATHOPHYSIOLOGY

• *Arcanobacter pyogenes*: This bacterium (aka *Trueperella pyogenes* or *Actinomyces pyogenes*) is present throughout the environment and in ruminant GI tracts, often taking advantage of breaches in the integument or in the oral mucosa (associated with rough/coarse feed). It can also take advantage of injury to the ruminal mucosa due to acidosis or injury. Abscesses often result, and can happen anywhere in the body. Bison develop subcutaneous, soft tissue, and hepatic abscesses caused by this bacterium. • Actinobacillosis: SPC • Anthrax: *Bacillus anthracis* causes sudden death. Affected bison will be unresponsive, staggering, or reluctant to move. Edematous swellings on the ventrum and serosanguinous fluid seeping from orifices in dead animals can be seen. SPC • Blackleg: *Clostridium chauvei* has been reported to cause this disease in bison. SPC • Brucellosis: *Brucella abortus* biovar 1 (in North America) has been reported to cause disease in bison. Male bison can develop orchitis, seminal vesiculitis, and epididymitis, decreasing/eliminating fertility. Chronic infections in males can cause scrotal/testicular abnormalities. In female bison, placentitis, abortions (less frequent than in cattle), and retained placentas have been seen. Other clinical signs in bison include abscesses, chronic septic arthritis, lameness, and hygromas. Bison vaccinated with the RB51 or Strain 19 vaccines are shown to be more prone to abortion. SPC. • Foot rot: The organisms responsible for foot rot in bison have not been isolated/reported. SPC. • Hemorrhagic septicemia: This disease, caused by *Pasteurella multocida,* has not been reported in bison in the USA in the past 30 years. Disease occurs in explosive outbreaks with high mortalities. Disease often associated with high temperature, humidity, and the rainy season. Most bovids are colonized with small numbers of *P. multocida* serotype B:2 or E:2, which shed in periods of stress. Infection begins at the tonsils/nasopharyngeal tissues, with subsequent bacteremia and multi-organ infection, resulting in large release of endotoxins causing organ failure. The disease has a sudden onset, and clinical signs include excessive salivation, mucus membrane hemorrhage, depressed mentation, severe pyrexia, edema/swelling on the ventral aspect of the body, and labored breathing. Death often occurs within 1 day. • Hemophilosis: *Haemophilus somnus* (*Histophilus somni*) has been associated with bronchopneumonia in recently weaned bison calves in feedlots with minimal clinical signs, though sudden death can occur. Outbreaks are associated with cold weather and stressful situations. Thrombotic meningoencephalitis has been found in weaning bison calves, presenting with depression, recumbency, body temperature extremes, partial/complete blindness, seizures, weakness, ataxia, and proprioceptive deficits; death occurs within 1 or 2 days. SPC • Johne's disease: SPC • Leptospirosis: SPC • Listeriosis: *Listeria monocytogenes* has caused sporadic abortions in bison, usually occurring in the last trimester of pregnancy. SPC • Mannheimiosis: SPC • Mycoplasma: *Mycoplasma bovis* infections have been associated with a pneumonia-polyarthritis syndrome in calves, young adults, and adult bison. Clinical signs include dyspnea, stridor, coughing, lethargy, isolation from the herd, weight loss, lameness, and abortion. Infection with BVDV increases susceptibility. Cases of pneumonia with high morbidity/mortality have been seen in mature bison cows and bulls on pasture. Recovered animals can often show infertility and ill-thrift. SPC • Necrotic stomatitis: SPC • Pinkeye: The causative agent of infectious keratoconjunctivitis in bison is unknown, but thought to be *Moraxella bovis.* Disease is spread by the face fly vector. SPC • TB: *Mycobacterium bovis* infection is characterized by granulomatous lymphadenitis affecting the lymph nodes of the head, thorax, and abdominal cavity. Clinical signs include chronic weight loss, cough, and enlarged lymph nodes. Affected bison also suffer from orchitis, metritis, and abortions. SPC

SIGNALMENT

Plains bison (*Bison bison* subsp *bison*) and woods bison (*Bison bison* subsp *athabascae*)

PHYSICAL EXAMINATION FINDINGS

See SPC

CAUSES AND RISK FACTORS

• *Arcanobacter pyogenes*: Breaches in protective epithelial layer (skin/mucosa) due to coarse feeds/high grain diets causing acidosis. • Actinobacillosis: Breaches in the oral mucosa/tongue epithelium caused from coarse feeds/eruption of teeth. • Anthrax: Ingestions of infective environmental spores. Outbreaks occur during summer months with prolonged wet periods followed by drying conditions. Spores surface after heavy rainfall. • Blackleg: Ingestion of environmental spores, seeding of spores in muscle in combination with muscle injury/bruising. Unvaccinated individuals are at high risk. • Brucellosis: Susceptible animals that come in contact (from ingestion/mucus membrane contact/skin breaches) with infected herd mates/wildlife and their contaminated bodily fluids (blood, urine, milk, semen, vaginal discharges) or aborted fetuses/placentas from positive females. • Foot rot: Abrasions in interdigital space allow bacterial invasion. Wet weather, rough pasture, stony ground, and unsanitary housing conditions can predispose bison. • Hemorrhagic septicemia: Infection occurs by ingestion of contaminated feed/water or contact with infected oral/nasal secretions from carrier animals/diseased animals, with young immunosuppressed/stressed individuals most at risk. • Hemophilosis: Exposure to diseased animals/carrier animals when individuals are immunocompromised. Handling/processing, weaning, and exposure to cattle can predispose individuals. • Johne's disease: Transplacental transmission, or ingestion of contaminated feed/water. Risk factors include exposure to shedding individuals, especially when young. Rain run-off from cattle farms can be a source of infection. • Leptospirosis: Ingestion/contact with contaminated environment/water sources or with contact with urine, vaginal discharge, post-abortion discharge, or a fetus from a *Leptospira*-induced abortion. • Listeriosis: Ingestion/contact with contaminated environment/feed or clinically/subclinically infected individuals. Stress, pregnancy, and feeding of poorly preserved ensiled forages are risk factors. • Mannheimiosis: Immunocompromise increases susceptibility.

Stressful situations (weaning/transport) can predispose. • Mycoplasma: Exposure to infected animals (domestic cattle/bison) through fence line contact, importation of stock, and concurrent infection with BVDV are risk factors. • Necrotic stomatitis: Injuries/abrasions to the mouth/tongue from the use of balling guns or rough/coarse feeds can allow invasion into oral tissues. • Pinkeye: *Moraxella bovis*, spread by the face fly, is thought to be the most likely cause; herds with face fly issues are at risk. Proximity to endemic cattle herds is a risk factor. • TB: Ingestion of contaminated feed/aerosolized infectious particles from infected/shedding individuals can precipitate disease, especially in the immunocompromised.

DIAGNOSIS

OTHER DIAGNOSTIC PROCEDURES

• *Arcanobacter pyogenes*: SPC
• Actinobacillosis: SPC • Anthrax: SPC
• Blackleg: SPC • Brucellosis: A fluorescence polarization assay with high sensitivity/specificity in bison has been developed and shows promise at differentiating antibodies induced by strain 19 vaccination and true infection. SPC • Foot rot: SPC • Hemorrhagic septicemia: Diagnosis is often made on postmortem examination, with submission of tissues for C/I/S. Antemortem diagnosis is done based on history, vaccination status, environmental conditions, and clinical signs/lesions. Blood/tissues from individuals can be sent off for bacterial isolation by PCR.
• Hemophilosis: Diagnosis is difficult in live bison, and most often diagnosed on postmortem examination. SPC • Johne's Disease: Antemortem tests in cattle can be used in bison, but have poor sensitivity. Fecal PCR/culture are the most reliable diagnostic tests. SPC • Leptospirosis: SPC • Listeriosis: An aborted fetus with the placenta must be submitted to a pathology laboratory for histopathology/bacterial culture (to diagnose listeriosis abortion). SPC • Mannheimiosis: SPC • Mycoplasma: *M. bovis* should be considered in herd disease outbreaks with high morbidity and mortality. Lung tissue culture taken from postmortem examination is best way for definitive diagnosis. Histopathologic lesions can ID the organism by IHC or PCR. Affected and exposed bison have high antibody titers. SPC • Necrotic stomatitis: SPC • Pinkeye: SPC • TB: SPC

PATHOLOGIC FINDINGS

• *Arcanobacter pyogenes*: N/A
• Actinobacillosis: SPC • Anthrax: SPC
• Blackleg: SPC • Brucellosis: Arthritis, retained placenta, placentitis, and pyometra. Histopathology includes necropurulent placentitis, bronchointerstitial pneumonia in fetuses/neonates, serous arthritis with thickening/distention of the joint capsule, and seminal vesiculitis/orchitis in bulls. SPC
• Foot rot: SPC. • Hemorrhagic septicemia: Widespread subcutaneous edema, subserosal hemorrhages of organs/body cavities, and edema/inflammation of the lungs.
• Hemophilosis: Hemorrhagic infarcts in the brain/spinal cord found in bison. SPC
• Johne's disease: SPC • Leptospirosis: SPC
• Listeriosis: SPC • Mannheimiosis: SPC
• Mycoplasma: Affected individuals are generally emaciated with severe fibrinonecrotizing pneumonia, fibrinous pleuritis, epicarditis, and/or chronic pleuropneumonia. Widespread dissemination to the tonsils, pharynx, larynx, mediastinal/abdominal lymph nodes, peritoneum, pericardium, liver, spleen, kidney, mammary gland, endometrium, and joints. Lesions in distant locations from lung are characterized by areas of caseous necrosis. Histopathology includes eosinophilic necrosis with ID of the organism on IHC. Liquefactive necrosis in the lung and inflammatory cell infiltrates of the joint capsules are common. SPC • Necrotic stomatitis: SPC • Pinkeye: SPC • TB: Abscesses or granulomas in the lymph nodes of the head, pharynx, thoracic cavity, and abdominal cavity are seen. Some cases only involve a few or a single lymph node. Generalized tuberculosis has occurred. SPC

TREATMENT

THERAPEUTIC APPROACH

• *Arcanobacter pyogenes*: SPC
• Actinobacillosis: SPC • Anthrax: SPC
• Blackleg: SPC • Brucellosis: SPC • Foot rot: SPC • Hemorrhagic septicemia: Antimicrobial treatment is successful if enacted early in the disease. • Hemophilosis: Disturbing newly weaned bison calves to examine/treat is very stressful and can predispose other calves to the disease. Sick calves should be removed from the group, treated, and returned to the group; SPC
• Johne's disease: SPC • Leptospirosis: SPC
• Listeriosis: SPC • Mannheimiosis: Broad-spectrum antibiotics; supportive care (decreasing stress/overexertion, providing high-quality nutrition/free choice water); surveillance of calves at risk with little or no intervention is critical to minimize mortalities; sick calves should be removed from the group, treated, and returned to the group; SPC • Mycoplasma: Recrudesces after cessation of antibiotic therapy, indicating persistent nature of infection; SPC • Necrotic stomatitis: Broad-spectrum antibiotics, anti-inflammatories (to aid respiration); SPC
• Pinkeye: Spontaneous recovery occurs; small volumes of penicillin injected into bulbar conjunctiva/eyelid conjunctiva; not recommended to suture the eyelids closed/use third eyelid flaps, bison will remove these sutures shortly after placement; bison with pinkeye can be very dangerous to themselves and to handlers; SPC • TB: SPC

MEDICATIONS

DRUGS OF CHOICE

Note: No medications have been approved or licensed for use in bison, and minimal efficacy trials performed; all use must be done extra-label and generally at cattle dosages unless otherwise stated. Appropriate milk and meat withdrawal times must be followed for all compounds: contact FARAD. Please follow BQA guidelines regarding injections.
• *Arcanobacter pyogenes*: N/A
• Actinobacillosis: Shown sensitivities to tetracyclines/erythromycin. Sodium iodide at 70 mg/kg as a 10–20% solution must be administered IV, which is problematic in bison. • Anthrax: N/A • Blackleg: N/A
• Brucellosis: N/A • Foot rot: Long-acting antibiotic preparations are the practical choice for bison, SPC • Hemorrhagic septicemia: Sulfonamides, tetracyclines, penicillin, ceftiofur, enrofloxacin, and tilmicosin. Some strains (B:2) show resistance to tetracyclines and penicillins. • Hemophilosis: Long-acting oxytetracycline or florfenicol have been used for neurologic disease. • Johne's disease: N/A
• Leptospirosis: SPC • Listeriosis: Penicillin/oxytetracycline. Frequency of administration of these medications may be prohibitive in bison. • Mannheimiosis: SPC
• Mycoplasma: Oral tetracyclines and tylosin have been used with variable results. SPC
• Necrotic stomatitis: SPC • Pinkeye: SPC
• TB: N/A

FOLLOW-UP

PREVENTION

Note: No vaccinations have been approved or licensed for use in bison, and minimal efficacy trials performed; all use must be done extra-label.
• *Arcanobacter pyogenes*: Feeding high forage/low concentrates, allowing most nutrition to come from pasture/quality hay.
• Actinobacillosis: Pasture grazing/offering quality hay. • Anthrax: SPC. • Blackleg: Recommended to administer a commercial cattle multivalent *Clostridium* vaccination annually to all bison. • Brucellosis: *B. abortus* eradication programs instituted: serologically positive or infected bison are slaughtered. Other surveillance measures include farm testing, slaughterhouse testing, and monitoring movement of bison. Vaccination

BISON: BACTERIAL DISEASES (CONTINUED)

of bison is not recommended (not permitted in Canada). • Foot rot: SPC • Hemorrhagic septicemia: Removal of carrier animals; a formalin inactivated vaccine was developed/used in a Montana herd; control programs in wild herds are not currently in use due to the low disease prevalence. • Hemophilosis: Reduce frequency of elective stressful situations (handling, processing, weaning) in combination with uncontrollable stressful situations (cold weather); recurrence rate in subsequent years is moderate-to-high if disease is found within a herd. Anecdotal evidence suggests that vaccination with a commercially available *H. somnus* cattle vaccine may reduce mortalities in bison calves. • Johne's disease: Fecal cultures/PCR every 6 months, culling of infected animals and their offspring. Depopulating/repopulating with clean stock in the face of severe disease outbreaks. New arrivals to herd should be tested. SPC • Leptospirosis: No vaccinations recommended; practitioner discretion. • Listeriosis: SPC • Mannheimiosis: Decrease stressful situations when weaning calves. • Mycoplasma: Quarantine new arrivals, avoid fence line contact with domestic cattle, routine surveillance in susceptible herds. • Necrotic stomatitis: SPC • Pinkeye: Due to unknown etiologic agent for pinkeye in bison, efficacy of commercial vaccines questionable, though anecdotal accounts of moderate-to-good efficacy with these vaccines. SPC • TB: Acquiring animals from a TB-free herd/having them tested (caudal tail fold tuberculin skin test) prior to arrival into herd; exclusion of wild reservoir hosts (white-tailed deer) from pastures. SPC

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Anthrax: SPC • Brucellosis: SPC • Johne's Disease: SPC • Leptospirosis: SPC • Listeriosis: SPC • TB: SPC

BIOSECURITY

• Anthrax: SPC • Brucellosis: SPC • Tuberculosis: SPC

PRODUCTION MANAGEMENT

• Thought that bison will respond to antibiotics similarly as cattle, but no pharmacologic studies have been performed in bison. Care should be taken when dosages/meat withdrawal times are recommended. • Often best to use a long-acting preparation as first choice when treating bison; daily handling of sick bison increases risk of injury/stress to both handler and animal. Including a few healthy bison in pen with a sick bison can keep the animal calmer due to herd mentality. • Bison mask clinical signs associated with disease, and often don't show clinical signs until just before death; important to be knowledgeable about normal bison behavior in order to remedy stressful situations and catch disease early.

ABBREVIATIONS

BISON: PARASITIC DISEASES

BASICS

OVERVIEW

• Parasitism is common in bison, but its clinical significance must be judged based on overall condition, environment, stocking density, clinical signs, and other factors.
• Parasites found in bison are also found in cattle, and the treatment is often similar between these species. Many of these diseases generate important economic concerns affecting bison production.

INCIDENCE/PREVALENCE

• Anaplasmosis: Depends on location, local reservoirs (i.e., *A. marginale* positive cattle farms), and tick prevalence. 15.7% of wild bison tested in the National Bison Range in Montana were positive.
• Babesiosis: Depends on location, local reservoirs, and tick prevalence.
• Coccidiosis: Common in ranched/farmed bison; uncommon in free-ranging bison.
• Demodecosis: Minor significance.
• Helminthiasis: Common and prevalent anywhere herds reside.
• Hydatid tapeworms: Isolated from bison, no clinical signs/deaths reported (though potential for disease is present).
• Liver flukes: Fluke eggs have been observed in the feces of bison; clinical disease not commonly reported.
• Lungworm: Occurs in the USA and Canada; often not diagnosed until the bison dies due to nonspecific obscure clinical signs.
• *Parelaphostrongylus tenuis*: Uncommon, but should be considered in bison exhibiting neurologic disease.
• Ticks and tick paralysis: Uncommon, reported in bison from Montana.
• Warbles: Isolated in bison in the USA/Canada; may be more common than clinically noted due to the insidious nature of these parasites.

GEOGRAPHIC DISTRIBUTION

Dependent on distribution of management systems, vectors and hosts.

SYSTEMS AFFECTED

Multisystemic

PATHOPHYSIOLOGY

• The specific pathophysiologic processes of most parasitic infections of bison are described in individual chapters throughout this text that address specific parasitic pathogens.
• Anaplasmosis: Acute infections occur; bison remain infective up to 496 days post-infection, suggesting bison may act as reservoirs; bison thought to be more resistant than cattle.
• Babesiosis: *Babesia bigemina* and *B. major* have both been isolated from bison and fatalities reported.
• Coccidiosis: Various *Coccidia* species have been isolated from bison, with no published reports of clinical disease.
• Demodecosis: The causative species of demodex in bison has not been identified. Mites invade hair follicles/sebaceous glands, and create small (7–9 mm) black nodules filled with pus around the eyes, perineum, ventral aspect of tail, neck, flank, and shoulders.
• Helminthiasis: Type II ostertagiosis causes morbidity/mortality in bison. *Cooperia* is commonly identified in bison, but clinical disease has not been seen.
• Hydatid tapeworms: Adult forms of two tapeworms (*Taenia hydatigina* and *Echinococcus granulosis*) release eggs into the feces of carnivores (ex. domestic dogs) which are consumed by secondary hosts (bison); eggs hatch in the intestinal tract, migrate to the peritoneal cavity/liver/lungs, and form cysts (hydatids/cysticerci). Damage occurs with cyst formation, causing organ failure.
• Liver flukes: Bison develop acute/chronic hepatitis with hepatic fluke migration and biliary damage
• Lungworm: Clinical signs are difficult to recognize at pasture, leading to mortalities; disease is commonly seen in late summer.
• *Parelaphostrongylus tenuis*: Documented aberrant migration of larvae in bison cause various neurologic signs.
• Ticks and tick paralysis: *Dermacentor andersoni* has been implicated in tick paralysis of bison calves/yearlings in Montana.
• Warbles: *Hypoderma* larvae are unable to penetrate through the skin and dense hair of bison; however, numerous bison in the western US have been found with dead larvae underneath the hide along their back.

HISTORICAL FINDINGS

N/A

SIGNALMENT

Bison of any age and gender may be affected.

PHYSICAL EXAMINATION FINDINGS

• Dependent on the specific parasite, its pathogenesis, and parasite burden.
• Signs relate to damage of the liver, intestines, lungs, integument, nervous or hemolymphatic systems.

GENETICS

There is gathering evidence that genetic characteristics are important in host resistance/resilience to parasitic infections.

CAUSES AND RISK FACTORS

• Anaplasmosis and babesiosis: Older bison are more susceptible. No deaths have been reported due to *A. marginale* infection in bison.
• Coccidiosis: Poor sanitation, overcrowding, poor pen design, wet conditions, and stress associated with weaning can all precipitate coccidiosis.
• Demodecosis: Immunocompromised individuals are more susceptible.
• Helminthiasis: Risk factors include wet weather, cool summers/warm winters, high stocking rates, and contaminated pastures.
• Hydatid tapeworms: Risk factors include exposure to carnivore feces on pasture.
• Ticks and tick paralysis: Heavy infestation of ticks can cause anemia in young calves due to sheer volume of blood being removed by the parasites. Risk factors include immunosuppression and *D. andersoni* home range overlap.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Differentials should be relevant to the major organ system affected and/or the primary clinical signs displayed.

CBC/BIOCHEMISTRY/URINALYSIS

• Depending on the type of parasite infestation, abnormalities might reflect dehydration, blood loss, protein loss, inflammation, liver damage, etc.

OTHER LABORATORY TESTS

• Fecal analysis by various methods is a useful method for detection of many parasites.
• An array of tests also exists for blood-borne parasites.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

See individual chapters on specific parasites for additional procedures.

PATHOLOGIC FINDINGS

Strongly dependent on the parasite in question and the systems affected.

TREATMENT

See individual chapters on specific parasites for recommendations.

THERAPEUTIC APPROACH

Pharmaceutical intervention, including anthelmintic agents, may be indicated, along with concurrent supportive care measures in clinically diseased animals.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

• No medications have been approved or licensed for use in bison, and minimal efficacy trials have been performed; all drugs are

BISON: PARASITIC DISEASES (CONTINUED)

therefore used in an extra-label fashion and generally at cattle dosages unless otherwise stated.
• See individual chapters on specific parasites for treatment recommendations.

CONTRAINDICATIONS
N/A

PRECAUTIONS
• Appropriate milk and meat withdrawal times must be followed for all compounds.
• Advice is to follow BQA guidelines regarding injections.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
See individual chapters on specific parasites for recommendations.

POSSIBLE COMPLICATIONS
N/A

CLIENT EDUCATION
Should focus on establishing appropriate management and prevention protocols, and judicious use of pharmaceutical or anthelmintic agents where necessary.

PATIENT CARE
N/A

PREVENTION
• See individual chapters on specific parasites for recommendations.
• Demodecosis is not a highly contagious ectoparasite so no control programs are reported.
• Hydatid tapeworms: Prevent contamination of bison pasture/feed areas with carnivore feces; screen and treat suspect domestic carnivores around ranches/farms.
• Liver flukes: Consider treating bison in early spring to reduce contamination of pasture during summer.
• Lungworm: Set up a two-pasture rotation system; administer anthelmintics prior to pasture turnout/rotation; perform surveillance of fecal samples in early spring to identify individuals shedding larvae.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Young and old bison are likely more susceptible to specific parasitic infections.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
N/A

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
• The importance of most gastrointestinal parasites in bison is uncertain, therefore the economic value of routine deworming is questionable. Anecdotal evidence suggests that many of these parasites contribute to poor growth rate and clinical disease in farmed bison.
• Commercially available deworming pellets are not recommended due to the hierarchical structure of bison herds and inability to ensure proper dosing of all individuals. Their use can allow low-level anthelmintic exposure within most individuals in the herd, promoting parasite resistance.
• Delaying spring grazing of infected pastures until overwintered larvae have died on pasture is highly recommended. Pasture rotation and management is crucial in reducing parasite burdens.

BISON: VIRAL DISEASES

BASICS

OVERVIEW

Many of the viral diseases that bison are susceptible to are similar to those found in cattle, and certain viral disease processes in bison mimic those seen in cattle, with a few notable exceptions. Other cattle viral diseases have shown to stimulate bison to produce antibodies against the virus, but clinical disease has not been reported. Different viral diseases have implications regarding biosecurity, production efficiency, and clinical health of the herds affected. Further in-depth information for each disease can be found in the pertinent chapter (see pertinent chapter; SPC).

INCIDENCE/PREVALENCE

• BVDV/Mucosal disease: Acute BVDV has been seen in bison, but none of the other forms (mucosal disease, persistent infection, or thrombocytopenic forms) have been reported in bison. It has been shown that in some herds in the western USA, up to 55% of adult bison were seropositive for BVDV.
• Neonatal viral diarrhea (rotavirus): Not as common as in cattle, but is seen in overcrowded holding pens or overstocked production systems.
• Infectious bovine rhinotracheitis (IBR): Clinical disease in bison is not reported to be common, but up to 44% of bison screened in the western USA and Canada were seropositive for the virus, indicating exposure.
• Malignant catarrhal fever (MCF): Bison are very susceptible if exposed to sheep shedding the virus. Multiple epizootics have been reported in the USA.
• Parainfluenza-3 (PI-3): In Yellowstone National Park, 36% of all bison tested showed antibodies to this virus. No clinical disease has been reported.

SYSTEMS AFFECTED

• Respiratory
• Digestive
• Cardiovascular
• Musculoskeletal
• Reproductive

PATHOPHYSIOLOGY

BVDV/Mucosal Disease

• BVDV is an RNA virus from the family Togaviridae, genus Pestivirus. BVDV is a very complex disease, and its behavior even in cattle has not completely been established, let alone in bison. It is known that not only is it present within bison herds, but it also causes disease—with both non-cytopathic and cytopathic forms. There are various strains within the cattle population that can cause various maladies, but the strains of the virus that are found in bison have not been reported. There are several different manifestations of the disease that have been seen in cattle: acute BVD, fetal infections, mucosal disease, and the thrombocytopenic form of BVD.
• The acute form of BVD occurs in animals that have not been previously exposed to the virus, and can range from an asymptomatic infection to acute diarrhea associated with anorexia and pyrexia. This form of BVDV infection has been seen in bison and has been shown to cause mortality in bison of all ages.
• Fetal BVDV infections have not been reported in bison, but are entirely possible and usually are seen (in cattle) following an acute BVDV outbreak. Fetal infections can cause abortion, stillbirths, weak calves, persistent infection, and fetal abnormalities. Persistently infected calves can occur if the fetus contracts BVDV in the first 40–120 days of gestation. Persistently infected calves are born infected and continue to be a subclinical shedder the remainder of their lives, infecting others (including their own progeny) with the disease. These animals are generally unthrifty and are poorly developed, with low weaning weights. They can develop diarrhea at any time in their life.
• Mucosal disease has not been reported in bison. The disease only occurs in animals (cattle) that are persistently infected and contract another strain of BVDV. It is often fatal, and clinical signs include ulcerations of the mucus membrane, snout, and the feet, with sloughing of the hooves noted in a few cases. They develop diarrhea, pyrexia, and emaciation before death.
• The thrombocytopenic form of BVDV has also not been reported in bison, but in cattle it had shown to cause hemorrhage in all mucus membranes, blood nasal discharges, bloody diarrhea, and coagulopathies. Mortality from this form is extremely high. SPC.

Neonatal Viral Diarrhea (Rotavirus)

• In calves, there are many possible etiologies of diarrhea, which include some viruses such as rotavirus, coronavirus, calicivirus, parvovirus, and BVDV, as well as many bacterial and protozoal etiologies.
• Rotavirus has been associated with neonatal diarrhea in bison. Though not as common as it is in cattle, stress can predispose neonatal calves to this disease and in bison it has been associated with overcrowding.
• The most common clinical sign is a watery diarrhea, which can predispose the calf to becoming dehydrated, weak, and depressed. They often can be seen staggering and remaining recumbent prior to death, though some bison calves hide their clinical signs until the disease is very severe. Observing the perineal area of bison calves and bedding is important to look for signs of diarrhea. SPC.

Infectious Bovine Rhinotracheitis

• IBR is common in cattle, and caused by bovine herpesvirus-1 (BHV-1). It is spread by nasal secretions, semen, and fetal fluids, and can easily be aerosolized from coughing animals.
• Clinical signs have not been described in bison, but are suspected to be similar to those found in cattle: fever, anorexia, reddening of the nasal mucosa, ocular discharge, nasal discharge, increased respiratory rate, and coughing. It can be very contagious and occurs in large outbreaks in cattle.
• Calves who develop symptoms have been associated with a high mortality rate, and cattle <6 months of age can develop neurologic signs from BHV-1 induced encephalitis, also leading to a high mortality rate.
• Abortion can occur in infected pregnant animals, up to 90 days after infection. SPC.

Malignant Catarrhal Fever

• MCF in bison in North America is caused by ovine herpesvirus type 2, which is endemic in both domestic and wild sheep. When a dead-end host, such as a bison, contracts this virus, it can cause severe disease. It is not, however, contagious between bison.
• Numerous reports have discussed this disease in bison, which is almost always fatal. Bison most often develop an acute fatal form of disease where they die 7–10 days after contracting the virus, but they can also develop a chronic fatal form where it may take up to 156 days for them to die.
• Clinical signs include corneal opacity, keratoconjunctivitis, nasal discharge, ocular discharge, excessive salivation, diarrhea, ulceration of the oral mucosa, anorexia, fever, neurologic signs, melena, and hematuria, with the most common signs being anorexia, depression, and bloody diarrhea. They often separate themselves from herd mates, and become depressed.
• In most reports, this disease is seen in winter, but can occur at any time. Herd mortalities have reached 100% in some instances. It is seen more commonly in animals >6 months of age. SPC.

Parainfluenza-3

• PI-3 is a virus seen commonly in respiratory disease complexes of cattle. Though antibodies have been found in the serum of bison (both wild and farmed), no clinical disease or decrease in productivity have been reported. That being said, any stressed bison can be affected by this virus, and measures should be taken to avoid immunocompromise.
• In cattle, clinical signs include nasal discharge, coughing, and pneumonia, often with secondary bacterial infections. SPC.

SIGNALMENT

Plains bison (*Bison bison* subsp. *bison*) and woods bison (*Bison bison* subsp. *athabascae*)

PHYSICAL EXAMINATION FINDINGS

SPC

BISON: VIRAL DISEASES (CONTINUED)

CAUSES AND RISK FACTORS

• BVDV/Mucosal disease: BVDV is spread from animal to animal through secretions and excretions, such as diarrhea. Fomites can also carry the virus from pasture to pasture, and to different farms. It is thought that the virus can spread from infected cattle to bison. Pregnant animals infected with the non-cytopathic strain of the virus within a specific time period (40–120 days) can cause the calf to become persistently infected and shed the virus its whole life. Bison farms adjacent to cattle farms, poor hygiene within bison facilities, and poor biosecurity practices are all risk factors. SPC.
• Neonatal viral diarrhea (rotavirus): Most transmission occurs through the fecal-oral route, often with ingestion of contaminated feed or water. Young animals, immunocompromised individuals, and high stress environments (like overcrowding) can all predispose bison to rotaviral diarrhea. SPC.
• Infectious bovine rhinotracheitis (IBR): Transmission of the virus through aerosolized secretions is the main way this virus is transmitted. It has a high morbidity, and high mortality in young and immunocompromised animals. Young animals and immunocompromised individuals are at high risk of fatal disease. Proximity to cattle herds, overcrowding, high stress situations, and omitting quarantine protocols for newly acquired animals are potential risk factors. SPC.
• Malignant catarrhal fever (MCF): Exposure to animals (generally sheep), transmitted through direct contact, fomite transmission, or contact with discharge/feces from hosts. Bison have contracted MCF when sheep were grazed as far as 3 km away SPC.
• Parainfluenza 3 virus (PI-3): Exposure to infected cattle is most likely the source of exposure to this virus. Stressed bison can potentially become susceptible to the virulent effects of this viral disease that are seen in cattle. SPC.

DIAGNOSIS

OTHER DIAGNOSTIC PROCEDURES

• BVDV/Mucosal disease: In cattle, blood samples for virus isolation or PCR testing can give reliable results. Immunohistochemistry from an ear skin notch can test for a persistently infected individual. Serial BVDV serology can be performed to determine exposure versus infection titer. Postmortem examination and submission of samples can also be done. SPC.
• Neonatal viral diarrhea (rotavirus): Fecal samples can be submitted to diagnostic pathology laboratories for bacterial culture (to rule out other etiologies) and virus isolation. Postmortem samples can be sent off for histopathology and virus isolation. SPC.
• Infectious bovine rhinotracheitis (IBR): The virus can be isolated in swabs taken from nasal and ocular exudate. Postmortem examination with histopathology and virus isolation of aborted fetuses or samples can provide a diagnosis as well. Serial antibody testing can be performed 2–3 weeks apart to detect rising titers to BHV-1. SPC.
• Malignant catarrhal fever (MCF): Diagnosis can be made from blood samples or nasal swabs submitted for PCR testing—though this method is not validated in bison. Serum samples from herds can be used for antibody screening via competitive inhibition ELISA tests. Postmortem examination and submission of tissue samples for PCR is the only validated way to establish a diagnosis—pooled tissue samples are best, as ovine herpesvirus type 2 does not infect all tissues consistently. SPC.
• Parainfluenza-3 (PI-3): Serology is the best test to determine exposure to this virus. Virus isolation from nasal swabs or blood can determine active infection. SPC.

PATHOLOGIC FINDINGS

• BVDV/Mucosal disease: In cattle with mucosal disease, postmortem findings include shallow ulcers in the mouth, pharynx, esophagus, rumen, and omasum. There also can be mucosal erythema and hemorrhage within the gastrointestinal tract. SPC.
• Neonatal viral diarrhea (rotavirus): Dehydration, emaciation, and fluid feces within the intestinal tract are often seen on rotavirus-infected bison calf postmortems. SPC.
• Infectious bovine rhinotracheitis (IBR): The pathologic changes have not been reported in bison, but in cattle the lesions are often focused in the nasal cavities, pharynx, larynx, trachea, and on the muzzle. SPC.
• Malignant catarrhal fever (MCF): Ulcerations of the mouth, esophagus, rumen, abomasum, intestinal tract, and trachea are common. Hemorrhages in the urinary bladder, enlarged lymph nodes, injected conjunctiva, and corneal opacity have also been seen in bison. Widespread necrotizing lymphocytic vasculitis without thrombosis is most often seen on histopathology. There can also be vascular hemorrhages, epithelial degeneration, and lymphoid hyperplasia with invasion of lymphoid cells into nonlymphoid tissues— which can sometimes be seen on the kidney at gross necropsy. SPC.
• Parainfluenza-3 (PI-3): SPC.

TREATMENT

THERAPEUTIC APPROACH

• BVDV/Mucosal disease: There has not been any treatment that has shown to be successful in either bison or cattle. Supportive care is the best option, but often culling infected individuals can decrease chances of spread to other individuals within the herd. SPC.
• Neonatal viral diarrhea (rotavirus): This can be a self-limiting disease, and many bison calves recover spontaneously. Reducing stress and offering supportive care can help, but providing supportive care to bison calves most often results in a calf that must be hand-reared (bison cows will reject the calves after only a few days of separation). Supportive care can include oral or intravenous fluid and electrolyte therapy, correction of acid-base imbalances, and potentially parenteral antibiotics, as the calves can be susceptible to other infections. SPC.
• Infectious bovine rhinotracheitis (IBR): Infected bison should be separated from noninfected bison, and not allowed nose-to-nose contact. No treatment protocols are described, but NSAIDs can potentially lessen the severity of disease. Antimicrobials can help decrease the chances of a secondary bacterial infection. In cattle, vaccinating with a modified-live intranasal vaccine during an outbreak can sometimes help reduce the spread of the disease. SPC.
• Malignant catarrhal fever (MCF): There are no successful treatment protocols established for treating bison, and are usually ineffective. Supportive care can be provided. SPC.
• Parainfluenza-3 (PI-3): No treatment protocols are suggested for bison due to no clinical disease reported. SPC.

PREVENTION

• BVDV/Mucosal disease: In cattle, control of BVDV can be very difficult. Vaccines are available for cattle, but the immunogenicity, safety, or efficacy have not been tested and published in bison. Vaccination may not provide adequate protection against the occurrence of mucosal disease and persistently infected individuals, but may provide adequate protection against acute BVD infection in bison—though none are registered or labeled for use in bison, and should be approached with caution. Certain adjuvants found in killed BVDV vaccines can have unfavorable effects in calves, and modified-live vaccines have shown to not only cause diarrhea in recently weaned bison calves, but also abortion in pregnant beef cattle. Yearling and older adult nonpregnant adult bison have, anecdotally, shown no adverse reactions to these vaccines.
• Neonatal viral diarrhea (rotavirus): At the time of writing, calf scour vaccinations are not generally recommended for use in bison. No studies have been done, and the best prevention is reducing stocking density, increasing facility hygiene, and decreasing sources of stress for neonatal bison calves. SPC.
• Infectious bovine rhinotracheitis (IBR): Currently, there are no approved vaccinations

for use against BHV-1/IBR in bison, though there are multiple available modified-live and killed vaccines for cattle. Properly quarantining new animals and infected animals can help reduce introduction and spread of the disease, respectively. SPC.
• Malignant catarrhal fever (MCF): There are no vaccinations available for this virus. Avoid all contact between bison and sheep/goats as well as wildebeest, and keep a safe distance between pastures of these animals. The mean incubation period following exposure to sheep is reported to be 81 days, range 50–220 days. SPC.
• Parainfluenza-3 (PI-3): Avoiding contact with cattle is the best chance of avoiding exposure to this potential pathogen. Some respiratory vaccines also include this in their coverage, but they have not been approved in bison. SPC.

ABBREVIATIONS

• BHV-1 = bovine herpesvirus type 1
• BVD = bovine viral diarrhea
• BVDV = bovine viral diarrhea virus
• ELISA = enzyme-linked immunosorbent assay
• IBR = infectious bovine rhinotracheitis
• MCF = malignant catarrhal fever
• PCR = polymerase chain reaction
• PI-3 = parainfluenza-3

BLACK LOCUST TOXICITY

BASICS

OVERVIEW

• Black locust (*Robinia pseudoacacia*) may also be known as yellow locust, post locust, locust tree, or false acacia.
• Medium size tree growing up to 80 feet.
• Bark of black locust is dark reddish-brown to black in color. It has an alternate branching pattern with a pair of sharp short thorns at each node.
• Leaves are pinnate, compound measuring approximately 8 to 14 inches in length with 7 to 19 short stalked leaflets. Leaflets are ovoid or oval, 1 to 2 inches long, thin, rough, dull green above and pale below.
• Flowers are creamy white, with five petals arranged in a pyramidal spike, usually blooming in May or June.
• Seeds are produced in a flat, brown to black pod, approximately 2 to 4 inches long with an average of 25,500 seeds per pound.

INCIDENCE/PREVALENCE

Feeding meal composed of 20% locust leaves causes decreased protein digestibility in lambs.

GEOGRAPHIC DISTRIBUTION

• Native to United States from northern Georgia and Alabama to Pennsylvania and westward to Oklahoma but has been transplanted thru much of the US.
• It has been additionally transplanted to areas of Europe, Southern Africa, and Asia.

SYSTEMS AFFECTED

• Digestive
• Cardiovascular

PATHOPHYSIOLOGY

• Toxic compounds include: glycoside robitin, alkaloid robinine, and lectins or toxalbumins robin, ricin, and phasin.
• Toxalbumins inhibit protein synthesis leading to cell death. Rapidly proliferating cells, such as those found within the intestinal wall, are most commonly affected.
• Ricin decreases calcium uptake by the sarcoplasmic reticulum as well as increasing the sodium calcium exchange, leading to a dysfunction of intracellular calcium homeostasis.
• Bark, leaves, and seeds are the primary source of the toxin. Bark is the most toxic. Flowers are nontoxic.
• Toxic dose is not well established; it is approximately 0.5% body weight in cattle.

HISTORICAL FINDINGS

Presence of plant or cuttings of the plant within the pasture.

SIGNALMENT

• Bovine, ovine, caprine, and camelid species.
• Ruminants are one tenth less sensitive than horses.

PHYSICAL EXAMINATION FINDINGS

• Depression; however, cattle can become belligerent
• Anorexia
• Abdominal pain
• Diarrhea (blood may be present)
• Weakness
• Weak pulse
• Congested mucus membranes
• Arrhythmias

CAUSES AND RISK FACTORS

• Gastric irritation and ulceration as a result of toxalbumin effects.
• Cardiac dysfunction as a result of ricin effects on calcium homeostasis.
• Rarely reported intoxication in cattle.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Other causes of gastroenteritis

OTHER DIAGNOSTIC PROCEDURES

• History of exposure to the plant
• Finding of plant material within gastric contents on gross pathology

PATHOLOGIC FINDINGS

Gastroenteritis, reddening, edema, and perhaps small hemorrhages of the mucosa of the stomach and small intestine, although degenerative lesions may be found in other organs.

TREATMENT

THERAPEUTIC APPROACH

• Decrease absorption of the toxin thru administration of charcoal.
• Supportive including gastroprotectants, fluid therapy, and pain management.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Prognosis depends on the amount of the plant that has been consumed and the time of supportive treatment initiation. Recover may take several weeks.
• Death is rare.

PATIENT CARE

• Dehydration
• Fecal consistency and color

PREVENTION

Restrict grazing of livestock from areas where black locust tress grow.

BLOAT

BASICS

OVERVIEW
Gas distension of the rumen and reticulum. Primary or frothy bloat occurs when rumen gas is trapped in bubbles/froth, and cannot be eructated. Secondary or free gas bloat occurs because of physical blockage of the esophagus or from decreased vagal nerve function.

INCIDENCE/PREVALENCE
• Normally very low incidence, generally <1%.
• Incidence of primary bloat may be >25% if animals are grazed on immature legumes/clover or fed excessive amounts of highly fermentable carbohydrates, such as finely ground grains.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Digestive
• Cardiovascular

PATHOPHYSIOLOGY
• Normal rumen bacterial fermentation produces gases that are eructated from the rumen. Primary or frothy bloat occurs when the gas is trapped in bubbles/froth, and cannot be eructated. Immature legumes and clovers are rapidly fermented by rumen microflora, resulting in release of chloroplast particles that trap gas bubbles and prevent their coalescence.
• Additionally, liquid is trapped in the foam, reducing the passage of liquid from the rumen. This serves to enhance bacterial growth and increase gas and foam production. Feeding finely ground grains can also cause frothy bloat.
• Secondary or free gas bloat occurs because of physical blockage of the esophagus (i.e., feed materials such as potatoes/beets) or from decreased vagal nerve function. Decreased vagal nerve function may be caused by mediastinal masses such as tumors from lymphoma, enlarged lymph nodes from tuberculosis and chronic bacterial pneumonia. Expansion of the rumen within the abdominal cavity eventually compresses the diaphragm, decreasing lung volume, oxygenation and the venous return to the post cava, causing hypovolemia.
• Young calves can bloat from fermentation of milk or milk replacer in the rumen.

HISTORICAL FINDINGS
Sheep and cattle grazing on lush pastures, especially young legumes or clovers. High concentrate diets with finely ground grains. History of chronic pneumonia.

SIGNALMENT
Ruminants, especially cattle

PHYSICAL EXAMINATION FINDINGS
• Distension of the left flank from gas accumulation. Tachycardia from hypoxia. Rumen contractions may decrease but often remain normal. Abdominal discomfort is evident.
• Severe cases may show open mouth breathing and staggering. Animal may become recumbent from hypoxia.
• Distension of the dorsal left flank. Cattle with chronic vagal indigestion may have concurrent distension of ventral right flank due to rumen emptying defect ("papple-shape": right side pear/left side apple).
• Tachycardia often present.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Blockage of the esophagus or interference with the vagus nerve.
• Grazing or feeding early legumes or clovers. Feeding finely ground grains or rapidly fermented carbohydrates.
• Inflammation or masses in the mediastinum can affect vagus nerve function. Factors associated with the spread of tuberculosis, bovine leukemia virus, and chronic bacterial pneumonia can impact the vagus nerve.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Ruminants often bloat postmortem. Necropsy signs of antemortem bloat include compression of blood and lymph flow in the neck and thorax, resulting in enlarged cervical vessels and lymph nodes. There is often a visible "white line" demarcation in the esophagus near the thoracic inlet from compression of the distal esophagus and congestion in the proximal esophagus.
• Lymphoma, enlarged lymph nodes from tuberculosis and chronic bacterial pneumonia.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
Passing a stomach tube differentiates primary (frothy) from secondary (free gas) bloat. Esophageal blockages may often be detected while passing the stomach tube.

PATHOLOGIC FINDINGS
• Distension of the rumen and reticulum with gas.
• Congestion of cervical lymph nodes and vessels.
• "White line" demarcation in esophagus at interface of compressed and congested tissue.

TREATMENT

THERAPEUTIC APPROACH
• Depends on the cause and the degree of hypoxia. Severely hypoxic animals should be intubated to relieve the free gas. The tube often plugs with froth or dips below the fluid level in the rumen, requiring clearing the tube by blowing into it or moving the end within the rumen.
• Mild to moderate cases of frothy bloat often respond to oral surfactants such as poloxalene (25–50 g per animal). Mineral or vegetable oils may act as anti-foaming agents.
• In severe cases it may be necessary to place a rumen trocar in the dorsal left flank. Animals may die from cardiac insufficiency due to collapse of splanchnic venous return.

MEDICATIONS

DRUGS OF CHOICE
Poloxalene (25–50 g per animal) for primary bloat

CONTRAINDICATIONS
N/A

PRECAUTIONS
Administer using an orogastric tube rather than oro-esophageal tube to reduce the risk of aspirating surfactant products.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Spontaneous recovery in mild cases and those patients sufficiently relieved by stomach tube/trocar or treated with poloxalene.
• Death from hypoxia or hypovolemic cardiac insufficiency in severe cases.

POSSIBLE COMPLICATIONS
• Physical damage to the vagus nerve or branches of the vagus from excessive rumen distension may result in rumen dysfunction and possible recurrence.
• Trocarization may result in localized or diffuse peritonitis.

PATIENT CARE
Watch for recurrence.

BLOAT (CONTINUED)

CLIENT EDUCATION

• Advise clients about the danger of grazing or feeding immature legumes/clovers especially to hungry animals.
• Discuss the importance of a functional rumen mat in cattle on high concentrate diets.
• Discuss early recognition of bloat and treatments such as poloxalene and stomach tubing.

PREVENTION

• Avoid feeding or grazing high-risk plants such as legumes or clovers. If feeding is necessary, ensure a slow transition and always fill cattle with a high dry matter feed such as straw prior to grazing. Do not overfeed finely ground grain or other highly fermentable carbohydrates.
• Avoid feeding apples, potatoes, or feedstuffs that can lodge in the esophagus and block eructation.
• Prevent infections with bovine respiratory disease complex, bovine leukemia virus, and tuberculosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Lymphoma
• Vagal indigestion
• Tuberculosis

AGE-RELATED FACTORS

Young calves may bloat from fermentation of milk or milk replacer in the rumen.

BLUE-GREEN ALGAE POISONING

BASICS

OVERVIEW

• Over 50 genera of freshwater blue-green algae (also referred to as cyanophytes or cyanobacteria) exist worldwide that produce two major types of toxins: neurotoxic alkaloids, such as anatoxins, and hepatotoxic peptides, such as microcystins.
• Very few cases of anatoxin poisoning (often produced by *Anabaena flos-aquae*) have been reported in cattle with clinical signs resembling organophosphorus insecticide poisoning (depolarizing neuromuscular blocking agent), such as muscle weakness and paralysis.
• Microcystin toxicosis is much more common than anatoxin poisoning and numerous cases have been reported in cattle and sheep worldwide. Therefore, microcystin toxicosis is discussed in detail.
• Microcystins are primarily produced by *Microcystis aeruginosa,* but many other cyanobacteria produce these peptides such as other *Microcystis* spp., *Anabaena* spp., *Oscillatoria* spp., and *Nostoc* spp.
• Microcystins are usually confined within the algal cells and are released only when cells are damaged (e.g., when cells encounter the acidic environment of the stomach).
• Microcystins enter the hepatocytes through a carrier-mediated transport system and cause inhibition of protein phosphatase (1 and 2A) in the hepatocytes. Dissociation and necrosis of hepatocytes lead to intrahepatic hemorrhage and diffuse centrilobular hepatocellular degeneration.
• Sudden death is possible as a result of hemorrhagic shock.
• Death in animals usually occurs within hours to days postexposure.
• Animals that survive the acute phase of poisoning can recover, but may develop clinical signs related to liver disease (e.g., hepatogenous photosensitization; drop in production).
• Respiratory—pulmonary edema and congestion have been reported in acute cases.

SYSTEMS AFFECTED

• Nervous
• Multisystemic

INCIDENCE/PREVALENCE

• Blue-green algae poisoning occurs seasonally during warm weather conditions. The blooms are most common in the summer and fall when bodies of water are stagnant and warm and contain ample nutrients.
• A breeze blowing across the water may help concentrate the organisms near a shore.
• Not all animals in a herd may be affected. Several important factors are related to occurrence of poisoning. Favorable algae growth conditions are usually required to produce sufficiently high concentrations of algae in water. Nutrient pollution of lakes and ponds with phosphorus and nitrogen leads to eutrophication and accelerated algae growth.
• Long periods of sustained sunshine, which produce warm water temperatures, are usually necessary. A breeze blowing across the water has also been identified as critical in some situations for concentrating algae near a shore where cattle congregate on the leeward side during hot weather.
• Microcystins are the most prevalent hepatotoxins and are produced by several cyanobacteria genera including *Microcystis, Planktothrix, Anabaena,* and *Oscillatoria.* Anatoxins are produced mainly by *Anabaena* spp. in addition to *Aphanizomenon, Microcystis,* and *Oscillatoria* spp. Saxitoxin production is associated with a few specific freshwater cyanobacteria species found in the genera of *Anabaena, Aphanizomenon, Cylindrospermopsis, Lyngbya,* and *Planktothrix*.

GEOGRAPHIC DISTRIBUTION

Worldwide

PHYSICAL EXAMINATION FINDINGS

• Animals exposed to blue-green algae toxins are often found dead near water that has a thick algal bloom. Cattle may have algae on their limbs.
• Abrupt onset of apprehension and distress occurs within hours of microcystin exposure.
• This is quickly followed by pale mucus membranes, ruminal atony, diarrhea, weakness, nervousness, ataxia, and anorexia. In severe cases, the animals become recumbent and comatose.
• Death may occur within 24 hours of exposure, but may be delayed several days.
• Animals that survive the initial toxicosis may develop hepatogenous photosensitization.

SIGNALMENT

• All ruminant species are susceptible to blue-green algae toxins. Microcystin poisoning has been reported in cattle and sheep.
• Dead animals are often found close to water bodies that have a "painted green" or "scumlike" bloom.

CAUSES AND RISK FACTORS

• Exposure to water contaminated with toxin-producing cyanobacteria.
• Warm, dry weather and stagnant water and a breeze that blows across water, allowing the organisms to concentrate near a shore.
• High concentrations of nutrients in the water, such as nitrates and phosphates from sewage, detergents, industrial pollution, and fertilizers increase the risk for a blue-green algae bloom.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Other hepatotoxicants—metals (detection in liver and kidney, histopathologic lesions), aflatoxins (detection in feed, often chronic), pyrrolizidine alkaloids (evidence of plant consumption, histopathologic lesions, chronic disease).
• Cardiotoxic plant exposure, such as oleander, milkweed, and azalea—chemical analysis for plant toxins in gastrointestinal contents, history of presence of plants in the environment.
• Cyanide poisoning—mucus membranes are initially bright cherry red, evidence of exposure to cyanogenic plants, chemical analysis for cyanide in gastrointestinal contents, liver, or muscle.
• Electrocution or lightning strike.
• Grass tetany—hypomagnesemia.
• Hepatopathy—serum clinical chemistry and liver biopsy.
• Larkspur poisoning—mainly found in the western US states; bloat is a common finding, evidence of exposure to *Delphinium* spp.
• Nitrate toxicosis—chocolate-colored blood, exposure to nitrate-accumulating plants.
• Organophosphorus or carbamate insecticide exposure—commonly associated with gastrointestinal irritation and neurologic signs, evaluation of cholinesterase activity, detection of pesticides in gastrointestinal contents.
• Lead poisoning—determination of blood lead concentration.
• Neurotoxic plant exposure, such as poison hemlock, water hemlock, tree tobacco, lupine—chemical analysis for plant toxins in gastrointestinal contents, history of presence of plants in the environment.

CBC/BIOCHEMISTRY/URINALYSIS

Increased GGT, AST, SDH, and GLDH

OTHER LABORATORY TESTS

• Direct microscopic examination of water and gastrointestinal contents.
• Detection of microcystins in water or rumen contents by high-performance liquid chromatography/mass spectrometry.
• Mouse bioassay.
• Analysis of suspect water by direct competitive ELISA or protein phosphatase inhibition assay.

PATHOLOGIC FINDINGS

• Postmortem lesions in animals that died of exposure to microcystins include hepatomegaly, congested and hemorrhagic liver.

BLUE-GREEN ALGAE POISONING (CONTINUED)

• Histopathologically, microcystin toxicosis results in centrilobular hepatocellular degeneration and necrosis; dilatation and engorgement of sinusoids; and loss of hepatic cords.
• Postmortem lesions are generally nonspecific in animals that died of exposure to neurotoxic blue-green algae toxins (e.g., anatoxins).

TREATMENT

THERAPEUTIC APPROACH
• Treatment of animals exposed to blue-green algae toxins is primarily supportive and symptomatic. Supportive therapy should include administration of intravenous fluids, corticosteroids, and calcium.
• Poisoned animals should be removed immediately from the source.
• Poisoned animals should be protected from UV exposure to prevent/minimize secondary photosensitization.
• Adsorption of toxins with activated charcoal has been suggested.
• Rumenotomy or a rumen lavage may be considered in valuable animals.

MEDICATIONS

DRUGS OF CHOICE
• No antidote available
• Activated charcoal, mineral oil, or saline cathartics
• Corticosteroids
• Vitamin E and selenium supplementation
• Hepatic uptake blockers, such as rifampicin and cyclosporin A, may be helpful, but their usefulness in the treatment of microcystin-poisoned ruminants has not been evaluated.

CONTRAINDICATIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Animals poisoned with microcystins are often found dead.
• Microcystin poisoning progresses rapidly, and treatment is often too late. If animals exhibit clinical signs of liver failure, the prognosis is poor.
• Animals that survive 24–72 hours after exposure usually survive but may develop clinical signs associated with hepatic failure.

POSSIBLE COMPLICATIONS
Hepatogenous photosensitization

CLIENT EDUCATION
• Create awareness for potential of blue-green algae toxicity, especially during sunny, warm weather and other favorable environmental conditions.
• A heavy water bloom of algae producing a surface scum is usually necessary for poisonings to occur.

PATIENT CARE
• Monitoring of liver enzymes is helpful.
• Monitor serum electrolytes.

PREVENTION
• Keep animals away from water bodies with visible algal blooms.
• Precipitation of algal cells:
  ◦ Lime (100–250 mg/L) to precipitate cells without rupturing them
  ◦ Suspend ferric alum block (1 kg/10,000 L)
  ◦ Suspend gypsum block (50 kg/1000 L)
• Algaecide (lysis of algal cells): Copper sulfate at 20–40 g/50,000 L (target concentration: 0.2–0.4 ppm). After treating water body with copper sulfate, animals must be kept away for approximately 7 days.
• Use of straw bales (100 g/1000 L) to control algal blooms has also been reported. Barley straw seems to be more effective when compared to wheat or other straws.

BLUETONGUE VIRUS

BASICS

OVERVIEW

• Bluetongue (BT) is an arthropod-borne, noncontagious viral infection of domestic and wild ruminants caused by bluetongue virus (BTV).
• Antibodies against BTV have been detected in a wide variety of domestic and wild ruminants.
• In 2006, the spread of the northern European strain of BTV-8 resulted in one of the major outbreaks in the history of BT.
• In some countries, BTV is a reportable disease of significant economic concern and of major importance for the international trade of animals and animal products.
• The Office International des Epizooties (OIE) includes BT in their A list of diseases.

INCIDENCE/PREVALENCE

• Prevalence of serum BTV antibodies in endemic areas ranges from 1% to >80% in domesticated and wild ruminants.
• Clinical disease varies from <5% to 50–75% when the virus is first introduced into a naïve population of sheep, but once the infection becomes endemic, morbidity and mortality may be as low as 1 to 2%.

GEOGRAPHIC DISTRIBUTION

• Bluetongue is enzootic throughout much of a broad belt encompassing subtropical and tropical areas of the world, from latitude approximately 40° North and 35° South, corresponding to the distribution of specific species of *Culicoides* biting midges. In recent years, BT has spread beyond this traditional range.
• Periodic incursions of the infection occur annually or at longer intervals in latitudes as far as 50° North. With the exception of BTV-8, other BTV serotypes do not persist throughout the winter.
• Outbreaks in Northern Europe are almost exclusively caused by BTV-8.
• In the United States, BTV infection is more prevalent in the southern and western parts of the country; and most infections occur in late summer and fall.
• Currently, twenty-six BTV serotypes (BTV-1 to -26), including Toggenburg virus (BTV-25) and a serotype 26 from Kuwait, are recognized worldwide.
• Four serotypes are endemic in the US (10, 11, 13, 17); BTV-2 has been isolated sporadically in the US. Nonendemic serotypes (1, 3, 5, 6, 9, 12, 14, 19, 22, and 24) have been found in the southeastern US since 1999.
• During the last two decades, BT has spread beyond its normal range due to climate change, deforestation, and increased global commerce.

SYSTEMS AFFECTED

• Cardiovascular
• Musculoskeletal
• Reproductive
• Digestive
• Respiratory
• Nervous

PATHOPHYSIOLOGY

• Bluetongue is caused by BT virus (BTV), of the genus *Orbivirus* in the family Reoviridae. The genus also includes epizootic hemorrhagic disease virus (EHDV), equine encephalosis, and African horse sickness (AHS) viruses.
• The BTV genome consists of ten linear segments of dsRNA encoding seven structural (VP1 to VP7) and four nonstructural (NS1 to NS4) proteins.
• BTV serotype is determined predominantly by VP2, which is the main target of neutralizing antibodies.
• Transmission of BTV among susceptible hosts occurs through the bite of certain species of infected *Culicoides* or biting midges.
• The main vector of BTV in the US is *Culicoides sonorensis* (previously known as *C. varipennis*); in Australia, *C. brevitarsis*; in Africa, Asia, and Europe, *C. imicola;* *C. insignis* is the major vector of multiple BTV serotypes in Central and South America. *C. insignis* also is found in the southeastern US.
• Transmission can also occur transplacentally or by semen.
• Viremia is prolonged but not persistent. In cattle, viremia may last 60 days, occasionally up to 100 days. In sheep and goats, viremia lasts 14–54 days and 19–54 days, respectively.
• BTV RNA can be detected by RT-PCR in blood of some infected animals for over 200 days in the absence of infectious virus.
• After entering the body, BTV disseminates to the regional lymph node to commence replication. It then disperses to many tissues throughout the body, and replicates within the mononuclear phagocytic and endothelial cells and lymphocytes. BTV infection of red cells facilitates infection of insect vectors.
• Replication of BTV in endothelial cells leads to cell death and subsequent injury to small blood vessels. This can create thrombosis, tissue ischemia, and hemorrhage. Endothelial damage in vulnerable species (e.g., white-tailed deer) can provoke disseminated intravascular coagulation (DIC).

HISTORICAL FINDINGS

N/A

SIGNALMENT

• BTV infects a wide range of domestic and wild ruminants. Among domestic animals, severe disease occurs almost exclusively in sheep, and particularly those naïve to the infection.
• White-tailed deer, bighorn sheep and pronghorn antelope are highly susceptible. Morbidity and mortality in these species can be as high as 100% and 80–90%, respectively.
• Cattle and goats generally develop subclinical infection; however, during the BTV-8 outbreaks in Western and Central Europe, mortality in cattle reached 26% in some areas.
• European BTV-8 is a particularly virulent strain capable of passing the placenta and infecting the fetus.
• BT with high mortality has been reported sporadically in South American camelids.

PHYSICAL EXAMINATION FINDINGS

• BT clinical signs range from inapparent infection to acute fulminant disease.
• The incubation period ranges from 2 to 15 days.
• Clinical disease in domestic ruminants is largely restricted to sheep; the acute fulminant form is characterized by fever up to 107.6°F (42°C), leukopenia, anorexia, weight loss, depression, edema and swelling of the face, lips, muzzle, and ears, reddening of the oral mucosa, and salivation. Pregnant sheep may abort.
• Crusting and accumulation of mucopurulent discharge in the muzzle and nostrils occurs, and in some cases, the tongue appears edematous and purplish-blue (hence the name of the disease) as a result of cyanosis.
• Hemorrhages, erosions, and ulcers of the gums, cheeks, tongue, and nostrils.
• Lameness and stiffness.
• Laminitis manifests as swelling, hyperemia, and hemorrhage of the hoof laminae and coronary band, and may induce "knee walking" or recumbency.
• Death due to bronchopneumonia or secondary bacterial infections may occur 8–10 days after initial signs.
• BTV infection of pregnant sheep or cattle may result in abortion, stillbirths, fetal malformation, or the birth of live but weak offspring (dummy lambs/calves) with minimal systemic signs in the dam. These negative effects have been linked to the use of modified-live vaccines (MLV) and more recently to BTV-8 infection in Europe.

GENETICS

North European breeds of sheep appear to be more susceptible to BTV-induced disease.

CAUSES AND RISK FACTORS

Ruminants living in areas where the vector *Culicoides* and BTV coexist.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Sheep: Foot-and-mouth disease (FMD), orf, sheep pox, peste des petits ruminants, photosensitization, polyarthritis, foot rot, and also toxic (monensin) and nutritional

BLUETONGUE VIRUS (CONTINUED)

(vitamin E/selenium deficiency) myopathies must be considered.
• Cattle: FMD; vesicular stomatitis; bovine viral diarrhea (BVD); rinderpest; bovine malignant catarrhal fever; Ibaraki disease (in Japan), and photosensitization.
• In white-tailed deer, epizootic hemorrhagic disease (EHD).
• The differential diagnosis for BTV fetal infection, fetal malformations and abortions include infection with Cache Valley virus, Akabane virus, Border disease virus, BVD, Rift Valley fever virus, Nairobi sheep disease virus, Wesselsbron disease virus, and genetic defects, and ingestion of teratogenic plants.

CBC/BIOCHEMISTRY/URINALYSIS
Leukopenia

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• Serologic assays include complement fixation, virus neutralization, agar gel immunodiffusion (AGID), and ELISA. Only the AGID and competitive ELISA (cELISA) are recommended by the OIE for international movement of ruminants.
• Virus isolation can be performed by inoculation of susceptible sheep or embryonated chicken eggs with heparinized blood or homogenized lymph nodes, spleen, or lung. Subsequent adaptation to cell culture and serotyping of the virus may be necessary. Blood and tissue samples for diagnosis need to be preserved at 4°C, and not frozen.
• BTV can be isolated from blood of infected sheep and cattle for up to 54 and 60 days post-infection, respectively. BTV nucleic acids can be detected by reverse transcription-polymerase chain reaction (RT-PCR) for up to 222 days post-infection. However, blood from sheep and cattle is infectious for *C. sonorensis* for only 21 days after infection of the ruminant host.
• Real-time RT-PCR is a commonly used diagnostic test with high sensitivity and specificity; however, a positive RT-PCR result does not indicate the presence of infectious virus.

PATHOLOGIC FINDINGS
• Grossly, BTV infection in sheep may result in extensive vascular injury that leads to congestion, edema, hemorrhage, disseminated intravascular coagulation, and tissue necrosis.
• Affected animals may have hyperemia and edema of the eyelids, ears, intermandibular area, muzzle, and other areas of the skin.
• Laminitis and coronitis.
• Lips, gums, and tongue may be edematous, congested, or cyanotic, with ulcerations and hemorrhages of the tongue, oral mucosa, hard palate, dental pad, and sometimes fore-stomachs and intestine.
• Subcutaneous and intramuscular edema and hemorrhages.
• Superficial lymph nodes may be enlarged and edematous.
• The most consistent lesion in sheep is hemorrhage in the tunica media at the base of the pulmonary artery and less often aorta, epicardium, endocardium, and myocardium.
• Pale areas in skeletal and cardiac muscles.
• Pulmonary congestion and edema.
• Pneumonia due to secondary bacterial infections.
• Fetal infection during the first trimester results in hydranencephaly, porencephaly, retinal dysplasia, and/or arthrogryposis.
• Microscopically, affected animals have vascular thrombosis with congestion, edema, hemorrhage, and ischemic necrosis.
• Myofiber necrosis (infarcts) of the left ventricular papillary muscles and other areas of the myocardium.
• Hemorrhages and myodegeneration and necrosis of skeletal muscles.
• Ulceration and crusting of the gastrointestinal tract.
• Pneumonia.

TREATMENT

THERAPEUTIC APPROACH
There are no specific treatments for BT.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
Broad-spectrum antimicrobials are often used to treat secondary bacterial infections.

CONTRAINDICATIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
The majority of infections are subclinical, but mortality can be high in sheep with severe disease.

POSSIBLE COMPLICATIONS
• Secondary bacterial infections.
• DIC

CLIENT EDUCATION
N/A

PATIENT CARE
Affected animals should be protected from the environment, and provided with clean water and good-quality feed.

PREVENTION
• Both modified-live virus (MLV) and inactivated BTV vaccines are available in some parts of the world for use in sheep and sheep and cattle, respectively.
• MLV vaccines have side effects, including reduced milk production in lactating ewes, and pregnancy loss and fetal teratogenesis when pregnant females are vaccinated during the first half of gestation.
• Recombination of viral genes between vaccine and BTV field strains and reversion to virulence are concerns with the use of BTV MLV vaccines.
• In the US, an MLV vaccine containing serotype 10 is available. In addition, MLV vaccines containing serotypes 10, 11, or 17 can be obtained in California.
• Lambs can be vaccinated close to weaning, and breeding stock 3 weeks before breeding or after lambing. Pregnant animals should not be vaccinated with MLV vaccines.
• To induce protection, the BTV serotype of the vaccine must correspond to the serotype of the virus in the region.
• Monovalent inactivated vaccines directed against serotypes 2, 4, 8, 11 and 16 and a bivalent vaccine directed against serotypes 2 and 4 induce neutralizing antibodies in sheep and in most cases prevent both viremia and clinical disease.
• Autogenous BTV inactivated vaccines have been used successfully in Europe.
• Limiting vector exposure by housing susceptible animals during peak feeding times (from dusk to dawn) may reduce the risk of exposure, but vectors may be active during daytime when overcast.
• Methods of controlling the vector population include approved low-toxicity insecticides, such as synthetic pyrethroids (deltamethrin, cyfluthrin, permethrin, and fenvalerate), housing livestock in enclosed buildings, and making vector habitat unsuitable.
• Many countries impose restrictions to the movement of livestock and germplasm from infected areas.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Abortion and fetal malformation.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY

• Modified-live BTV vaccines may cause pregnancy loss and teratogenesis.
• Infection with BTV-8 results in abortions and fetal malformations.

BIOSECURITY

Sheep and cattle whose blood contains BTV nucleic acid detected by RT-PCR, but which have no infectious virus detected by virus isolation, are unlikely to play an important role in the epidemiology of BTV.

PRODUCTION MANAGEMENT

See Prevention.

BORDER DISEASE

BASICS

OVERVIEW

• Congenital disease of sheep resulting from viral infection of the dam during pregnancy. The virus crosses the placenta and infects the fetus.
• Caused by Border disease virus (BDV), a pestivirus closely related to classical swine fever virus (CSFV) and bovine viral diarrhea virus (BVDV).
• Affected lambs are often referred to as "hairy shaker" lambs due to characteristic coat changes and the presence of ataxia or muscle tremors, particularly in the hindlimbs.

GEOGRAPHIC DISTRIBUTION

Worldwide in almost all major sheep-producing countries.

SYSTEMS AFFECTED

• Reproductive
• Musculoskeletal
• Nervous

PATHOPHYSIOLOGY

• Infection of susceptible dams prior to 80 days' gestation with noncytopathic strains of the virus may result in persistent infection in the fetus.
• Persistently infected (PI) animals do not mount an immune response to the virus and consistently shed high levels of virus throughout their lifetime.
• PI animals serve as the main reservoir for the virus.

SIGNALMENT

• Sheep are primarily affected. Goats are affected less commonly.
• Clinical signs in lambs are evident at birth.
• Clinical manifestations in the fetus depend on the stage of gestation when infection occurs. Signs are generally present in neonates at the time of birth but resolve gradually over time so that animals may be clinically normal after 3–6 months of age.
• No breed or sex predilections are described.

PHYSICAL EXAMINATION FINDINGS

• Infection in nonpregnant adult and adolescent sheep is generally subclinical.
• Viral infection in susceptible pregnant sheep results in placentitis and potential infection of the fetus.
• Fetal infection may result in abortion, stillbirth, mummification, and congenital malformations.
• Clinical manifestations in the fetus depend on the stage of gestation when infection occurs. Gestational infections before development of fetal immunocompetence (<80 days' gestation) may result in PI lambs. These lambs are permanent carriers and shedders of the virus, but do not always develop clinical signs of disease.
• Surviving fetuses infected <80 days' gestation that do not become PI may develop the characteristic clinical signs of border disease.
• The fleece of affected lambs appears hairy due to long fibers rising above the fleece. The coat may also be pigmented. Skin and coat changes are apparently absent in coarse-fleeced breeds of sheep and goats.
• Mild muscle tremors to tonic-clonic contraction of skeletal muscles of the body and head.
• Affected lambs may have lower birth weights and decreased crown–rump lengths and may be weak at birth.
• Deficiency of T_3 and T_4 thyroid hormones has been demonstrated in affected lambs.

CAUSES AND RISK FACTORS

The disease is caused by BDV. The main source of infection is the asymptomatic, PI sheep. These animals shed the virus in saliva, respiratory secretions, urine, feces, or semen throughout their lifetime. Transmission occurs across mucus membranes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Other causes of abortion such as enzootic abortion (ovine chlamydiosis), toxoplasmosis, listeriosis, salmonellosis, and bluetongue.
• In lambs, other neurologic conditions such as enzootic ataxia (swayback), bacterial meningoencephalitis, focal symmetric encephalomalacia. Caprine arthritis and encephalitis (CAE) infection should be considered in affected kids.
• BVDV infection can present with similar clinical signs in sheep.

OTHER DIAGNOSTIC PROCEDURES

• Presumptive diagnosis often made based on clinical signs. Confirmation through detection of the virus or viral antigen and/or histologic demonstration of pathognomonic lesions of the central nervous system.
• Virus isolation from tissues or blood. Leukocytes in the blood buffy coat are recommended sample. Precolostral samples are preferred; colostral antibody can mask virus for up to 2 months.
• RT-PCR also used to detect viral RNA.
• Fluorescent antibody tests for viral antigens performed on tissues of affected lambs. Tissues to be collected for biopsy include: abomasum, pancreas, kidneys, thyroid, testicles, and skin.
• PI animals are seronegative. Serology on dams of affected lambs generally demonstrates high antibody titers. Seronegative dams should be sampled for detection of virus or viral antigen.
• Serology is of limited diagnostic value for abortions as clinical signs generally lag several weeks behind infection. Seropositivity does not indicate the virus as the cause of abortion; seronegativity rules out a diagnosis of BDV unless the dam is persistently infected.

PATHOLOGIC FINDINGS

• Abnormal "hairy" appearance of birth coat due to enlargement and relative increase in primary hair follicles.
• Cerebellar dysplasia or hypoplasia.
• Hydranencephaly or microcephaly.
• Abnormal skin pigmentation.
• Placentitis and placental necrosis can occur.
• Gross findings may be normal.
• Histopathologic findings may include white matter lesions in the CNS, spinal cord and CNS hypomyelinogenesis. An increase in interfascicular glial cells with myelin-like lipid droplet accumulation.

TREATMENT

THERAPEUTIC APPROACH

No specific or effective treatment. Supportive care for affected lambs although production potential is poor.

MEDICATIONS

DRUGS OF CHOICE

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Affected lambs that survive the first few months will show gradual resolution of neurologic signs and fleece abnormalities. Permanent identification of affected lambs is recommended as lambs may no longer be clinically recognized as infected after a few months of age.

PREVENTION

• Stimulation of herd immunity and prevention of exposure during pregnancy are keys to prevention.
• To prevent exposure, PI lambs should be identified and culled promptly.
• Not all PI lambs exhibit clinical signs. Routine serologic surveillance in endemic areas or on farms with history of disease is recommended. Seropositive animals are not PI and are immune to further challenge with homologous viral strains. Seronegative animals should be screened to determine PI status.
• There are no approved vaccines for use against Border disease virus in the United States. Field strains of BDV are antigenically distinct from most BVDV strains and, thus, cattle BVDV vaccines are generally not effective for use against BDV in sheep.

• Recovered lambs can be commingled with the herd prior to breeding as a means of natural immunization. Such lambs should be removed from the herd prior to breeding and, if not removed from the farm, quarantined from contact with pregnant animals.
• Serologic monitoring of bulk tank milk samples can be performed in dairy sheep herds.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• BVDV and CSFV are closely related pestiviruses found primarily in cattle and swine, respectively. Similar clinical signs may be seen in sheep naturally infected with either BVDV or BDV.

AGE-RELATED FACTORS

Age at time of infection determines clinical signs in the individual. Persistent infection only results from congenital infection; exposure to the virus at other times results in subclinical disease except in pregnant animals when infection may result in abortion.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

• Infection of sheep and goats during pregnancy may result in abortion.
• Clinical disease or death in lambs is the result of infection of the dam during gestation.

BIOSECURITY

• Biosecurity is most critical for pregnant ewes during the critical period for formation of PI lambs.
• PI lambs should be identified and removed from the herd prior to the breeding season.

PRODUCTION MANAGEMENT

Affected lambs should not be kept as replacement animals.

ABBREVIATIONS

• BDV = Border disease virus
• BVDV = bovine viral diarrhea virus

BORNA DISEASE

BASICS

OVERVIEW
Borna disease (BD) is sporadic, transmissible, progressive encephalitis. The virus does not have a direct cytopathic effect. Virally infected cells initiate a T-cell immune response, which leads to tissue destruction.

INCIDENCE/PREVALENCE
Up to 20% of a flock can develop the disease. The incubation time is several weeks, and the duration of disease is around 4–10 days, with around 90% mortality.

GEOGRAPHIC DISTRIBUTION
Borna disease was historically endemic to areas of Germany and Switzerland. Confirmed outbreaks of the disease have generally been in middle and eastern Europe and in horses in the Middle East. Clinically normal animals have tested positive for the RNA virus responsible for the disease in many areas of the world including the United States.

SYSTEMS AFFECTED
Nervous

PATHOPHYSIOLOGY
• BDV is neurotropic, with a particular predilection for neurons of the limbic system. The virus ultimately spreads throughout the central, peripheral and autonomic nervous systems infecting astrocytes, Schwann cells and ependymal cells in the central nervous system (CNS); sensory and autonomic ganglia; and nerves to organs. Viral transport is presumably axonal and transsynaptic.
• Following intranasal infection, viral antigen is detected sequentially in olfactory receptor cells, olfactory nerve fibers, cells of the olfactory bulb and olfactory tract. In the hippocampus, viral antigen is localized in axon terminals, which form synaptic contacts with cortical area 1 (CA1) pyramidal cell dendrites, prior to appearing in pyramidal cell bodies.
• Borna disease is an immune-mediated multiphasic syndrome where the immune response to viral antigens after BDV infection does not elicit protective immunity but rather an immunopathologic reaction where T cells play an important role in causing disease. The critical role of T cells in the pathogenesis of BD was demonstrated in adoptive transfer experiments: transfer of BDV-specific major histocompatibility complex class II-restricted TH 1 cell lines resulted in acute meningoencephalitis and disease. Consequently, conventional immunization with inactivated virus preparations or purified virus-specific antigens did not confer protective immunity against clinical BD, despite detectable levels of virus-specific antibodies after immunization.

SIGNALMENT
• Natural infections occur in sheep and horses. Goats and cattle are rarely affected.
• BDV has been experimentally transmitted to a wide range of animals including chickens, rabbits, rats, guinea pigs, and monkeys.
• BDV antibodies have been identified in monkeys, humans, and birds.

PHYSICAL EXAMINATION FINDINGS
• Borna disease is a progressive neurologic disease.
• Initial signs in sheep are generally nonspecific including social behavioral changes, apathy and may include anorexia, fever, excessive salivation, yawning, and chewing movements. Early neurologic signs include hyperesthesia, ataxia, head pressing, head tremors, muscle contractions, and depression. Transient signs of irritability, kicking, biting or compulsive movements may occur.
• In later stages of disease, animals may lean against objects or maintain a sawhorse stance. Convulsion or coma is possible. Nystagmus is observed in terminal cases.
• As the disease progresses, decreased feed intake, bruxism and gait disturbances including circular movement are seen. Finally, in some cases paresis or paralysis occurs.
• The incubation time is several weeks, and the duration of disease is around 4–10 days, with around 90% mortality.
• Besides the initial reports of BD in cattle, demonstrated by transmission of the disease to laboratory animals, there seems to be only sporadic occurrence in cattle. Hence, BDV infection of cattle has been considered as a rare event.

CAUSES AND RISK FACTORS
• The etiologic agent of BD, Borna disease virus (BDV), is an enveloped, non-segmented, negative-stranded RNA virus with a genomic size of approximately 9 kb and a nuclear site for replication and transcription. The genomic organization is similar to that of other members of the Mononegavirales order; therefore, BDV is the prototype of the new family *Bornaviridae* within this order. The Mononegavirales also include *Filoviridae* (e.g. Ebola viruses), *Paramyxoviridae* (e.g., rinderpest, bovine respiratory syncytial virus, Newcastle disease virus), and *Rhabdoviridae* (e.g., rabies, vesicular stomatitis virus).
• Actively infected, convalescent, and immune carrier animals shed the virus in nasal secretions, saliva, urine, or milk. Infection often occurs due to contaminated food and water. The virus moves to the CNS by intra-axonal transport via nerves in the nose and throat area. Disease outbreaks are more commonly seen in spring and early summer.
• The virus is transmitted between birds by the tick *Hyalomma anatolicum*. An arthropod vector is not necessary for transmission in other species. An outbreak of disease in horses in the Middle East was associated with a dense population of infected wild birds. Rodents have also been suspected as a source of infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• CNS tumor
• Metabolic or digestive disorders—milk fever, nervous ketosis
• *Oestrus ovis* infestations in sheep
• Pseudorabies
• Rabies
• Scrapie, bovine spongiform encephalopathy, chronic wasting disease in elk and deer

OTHER LABORATORY TESTS
In some cases, serum and CSF may contain antibodies to BDV.

OTHER DIAGNOSTIC PROCEDURES
Polymerase chain reaction (PCR) viral amplification and in situ hybridization have been used to demonstrate viral RNA in peripheral blood mononuclear cells (PBMC) neurons, astrocytes, Schwann cells, and ependymal cells.

PATHOLOGIC FINDINGS
• There are no characteristic gross lesions.
• On histologic examination, inclusion bodies in neuronal nucleus known as Joest or Joest-Degen bodies are found in ganglion cells of the hippocampus and olfactory lobes of the cerebral cortex. They are considered pathognomonic for Borna disease.
• Other histologic lesions are characteristic of encephalitis including perivascular cuffing, ganglion cell degeneration, and gliosis.
• Neuronophagic nodules may be found.
• Lesions are typically found in gray matter of the cerebral hemispheres and brainstem. The most severe lesions are found in the olfactory bulbs, caudate nucleus, and hippocampus.

TREATMENT

THERAPEUTIC APPROACH
• No specific treatment is available.
• Supportive therapy with mannitol may temporarily relieve cerebral edema. Anti-inflammatory medications may reduce discomfort.

MEDICATIONS

No specific medications

(CONTINUED) BORNA DISEASE

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Unlike other viral encephalitides, the incubation period can vary from 3 weeks to months or possibly years. The average incubation period is usually 2–3 months. Duration of clinical illness is normally 1–3 weeks.
• Mortality rates can range from 60% to 95% in animals exhibiting clinical signs. Surviving animals may remain permanently neurologically impaired.

PATIENT CARE

Surviving animals may have permanent neurologic deficits.

PREVENTION

There is no vaccine.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• The viruses of Borna disease and Near Eastern encephalitis are indistinguishable.
• BD is serologically distinct from the viruses that cause West Nile virus (WNV), Eastern equine encephalitis (EEE), Western equine encephalitis (WEE), Venezuelan equine encephalitis (VEE).

ZOONOTIC POTENTIAL

BDV antibodies have been found in humans with various neuropsychiatric disorders such as schizophrenia. Although most reports of an association between infection and disease have focused on unipolar depression, bipolar disorder or schizophrenia, BDV has also been implicated in an improbably wide range of disorders, including chronic fatigue syndrome, acquired immune deficiency syndrome (AIDS) encephalopathy, multiple sclerosis, motor neuron disease, and aggressive brain tumor. The actual significance of BDV in these disorders has yet to be determined.

BIOSECURITY

Animals coming into BD areas should not be fed and watered together in large numbers and should be kept separate from horses and sheep. Incoming animals should be quarantined for 2 months due to the long incubation period of the disease, and tested twice during this period for the presence of antibodies. BDV is resistant to drying and other adverse environmental conditions.

ABBREVIATIONS

• AIDS = acquired immune deficiency syndrome
• BD = Borna disease
• BDV = Borna disease virus
• CA1= cortical area 1
• CNS = central nervous system
• CSF = cerebrospinal fluid
• EEE = Eastern equine encephalitis
• PBMC = peripheral blood mononuclear cells
• PCR = polymerase chain reaction
• TH 1= T helper 1 cells
• VEE = Venezuelan equine encephalitis
• WEE = Western equine encephalitis
• WNV = West Nile virus

SEE ALSO

• Bovine Spongiform Encephalopathy
• Cervidae: Chronic Wasting Disease
• Hypocalcemia: Bovine
• Ketosis: Dairy Cattle
• *Oestrus ovis* Infestation
• Pseudorabies
• Rabies
• Scrapie

BOVINE DERMATOLOGY

BASICS

OVERVIEW
• The most important skin diseases of cattle are those that are contagious, zoonotic, and/or affect production or animal welfare. • The most common problems are external parasites, bovine papilloma virus, udder cleft dermatitis, digital dermatitis, dermatophytosis, and dermatophilosis.

INCIDENCE/PREVALENCE
Varies depending on the disorder and management factors; contagious disorders can achieve high prevalence in herds.

GEOGRAPHIC DISTRIBUTION
Worldwide; regional distribution varies for specific ectoparasites and infectious disorders.

SYSTEMS AFFECTED
Integument

PATHOPHYSIOLOGY
• Dermatologic disorders cause disease through a variety of mechanisms which can be distinguished to some degree by clinical presentation. • Any dermatologic disorder has the potential to adversely impact animal welfare and productivity which may be reflected by changes in behavior, production variables, and visible alterations to the skin or hair. • Ectoparasites can also facilitate transmission of a variety of infectious disorders including babesiosis, heartwater, and infectious keratoconjunctivitis. • Pruritic conditions create damage due to inflammation associated with the causative agents (typically ectoparasites performing feeding and development activities), compounded by self-trauma. • Nodules or masses may reflect edema/inflammation from allergic response, infestation with particular ectoparasites (*Demodex, Hypoderma*), and cellular proliferation associated with specific viruses (poxviruses) or neoplastic processes. • Papules, pustules, and/or vesicles on the skin often form as the result of allergic or immune conditions, viral or bacterial infections of the skin, and ectoparasite activity. • Ulceration or erosions of the skin arise from a wide range of disorders, some of which are infectious and potentially reportable. • Many infectious and noninfectious disorders can cause scaling and crusting of the skin. Dermatophytosis and dermatophilosis are two of the more significant causes in cattle.

HISTORICAL FINDINGS
• Vary with etiology; however, defining the history of skin disease within the herd, and any relevant treatment or management procedures, is important. • A description of skin lesion appearance and duration, number of animals affected, and the presence or absence of pruritis are important historical factors.

SIGNALMENT
All breeds of cattle, of any age, are at risk of dermatologic disease.

PHYSICAL EXAMINATION FINDINGS
• Many disorders can be diagnosed by lesion characteristics and location on the body; these should be carefully annotated during examination. • The skin should be closely evaluated for characteristics that include sensitivity/pruritis, alopecia, excoriations, lumps, vesicles, and other anomalies. • Signs of anemia or related infectious diseases may be observed. • Ticks and lice are often readily visible on close examination of the skin. • Udder cleft dermatitis is identified by necrosis of skin between the udder and hind leg or between quarters of the udder. Secondary bacterial infection leads to a foul odor and severe cases have skin sloughing and erosion into vessels resulting in hemorrhage. • Photosensitization following ingestion of specific plants or chemicals or secondary to liver disease tends to most severely affect white-haired areas exposed to sunlight. Affected skin appears erythematous, thickened, necrotic, and may slough. • Rain rot (*Dermatophilus congolensis*) typically affects the dorsum; however, any part can be affected if subjected to prolonged or repeated moisture. Lesions are palpable as thick, usually circular, crusts under the hair. When crusts are removed the skin and removed hair form a paintbrush shape. • Dermatophytosis in cattle often invokes circular lesions with alopecia and scaling. Lesions most often affect the face, especially near the eyes and are generally nonpruritic.

GENETICS
• Individual breed differences exist in susceptibility to specific infectious disorders associated with ectoparasite vectors. • Individual breed differences exist in susceptibility to squamous cell carcinoma (Hereford cattle predisposed).

CAUSES AND RISK FACTORS
• The presence of specific parasitic or infectious agents in the region. • Overcrowding and poor nutrition. • Lack of control and treatment procedures for external parasitism. • Udder rot is more prevalent in older or high-producing animals, and is often associated with udder edema. • Dermatophilosis manifests when the hair coat is frequently moist such as during rainy seasons, or in summer if sprinklers are used for cooling. • Lice infestations are more prevalent/problematic in winter.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Pruritus
• Lice • Ticks • Mites (*Psoroptes, Sarcoptes, Chorioptes*) • Migrating helminths (*Strongyloides*, *Pelodera*) • Flies (*Musca*, *Stomoxys calcitrans*, *Culicoides*, *Tabanus*)

Pustular/Papular/Vesicular Lesions
• Impetigo (*Staphylococcus*) • Contagious ecthyma • Pemphigus foliaceus • Capripox virus (lumpy skin disease) • Foot and mouth disease • Papillomas (bovine papilloma virus) • Hypersensitivity lesions

Nodules with or without Ulcers
• Demodicosis • Staphylococcal dermatitis • Warble flies (*Hypoderma*) • Mycetoma (fungal tumors) • Abscesses: foreign bodies, *Staphylococcus*, *Streptococcus*, *Corynebacterium pseudotuberculosis*, *Trueperella* • Neoplasia: squamous cell carcinoma (SCC), cutaneous lymphosarcoma, fibroma/fibrosarcoma • Tuberculosis • Epidermal inclusion cyst • Cryptococcosis

Erythema and/or Sloughing
• Sunburn • Frostbite • Ergot toxicity • Photosensitization • Vasculitis

Ulcerations, Erosions
• Hypersensitivity • Adverse drug reaction • Contact irritants • Photosensitivity • Vasculitis • Udder cleft dermatitis • Dermatophilosis • *C. pseudotuberculosis* • Viral infections: herpes viruses, malignant catarrhal fever, vesicular stomatitis • Squamous cell carcinoma (SCC)

Scaling, Crusting
• All pruritic disease can cause scaling • Dermatophilosis (*D. congolensis*) • Dermatophytosis (*Trichophyton verrucosum*, *T. mentagrophytes*) • *Staphylococcus* pyoderma • Stephanofilariosis • Nutritional (zinc deficiency) • Iodism • Immune mediated

CBC/BIOCHEMISTRY/URINALYSIS
Relevant in specific conditions such as when liver disease might be contributing to photosensitization conditions (serum biochemistry can provide supporting evidence of liver damage).

OTHER LABORATORY TESTS
• Bacterial culture and sensitivity are relevant in infections of the skin or ear canals. Avoid surface contamination and obtain samples from underneath crusts or from fresh pustules or vesicles. • Cytologic examination (including Gram stain) can be performed on impression smears of lesions or exudates. *D. congolensis* forms typical "railroad track" cocci, or mincing crusts will reveal filamentous Gram-positive branching organisms.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• Skin scraping or microscopic evaluation of crusts can provide a positive diagnosis and species identification in mange mite conditions. • Potassium hydroxide preparation (10–20% KOH), allows identification of dermatophytes from skin

scrapings or minced crusts. • Dermatophyte culture. • Skin biopsy is the most effective diagnostic aid for skin diseases where the diagnosis cannot be made clinically or with other diagnostic tests.

PATHOLOGIC FINDINGS
Histologic findings in skin biopsies vary substantially depending on the underlying cause of disease (see individual conditions in this text for more details).

TREATMENT

THERAPEUTIC APPROACH
• Udder rot can be addressed by cleaning the region with mild soap and water and applying a drying agent. Systemic antibiotics may be indicated if there is deep infection, fever, or maggot infestation. Diuretics may help if udder edema is a factor. • Dermatophilosis can be treated by removing crusts and washing animals with iodine-based scrub; systemic antibiotics may be required. • Photosensitization is addressed by discontinuing exposure to plants or chemicals containing primary photodynamic agents, or determining if liver disease is causative. Animals should be provided shade or moved indoors, and monitored for skin necrosis. • Dermatophytosis is usually self-limiting in 1–4 months; however, topical treatment with dilute bleach (1:10) and other solutions has been used. • Ectoparasites can be treated with topical or parenteral treatment with insecticides provided via ear tags, residual livestock sprays, pour-on formulations, dust bags, back rubbers, oilers, or wipe-ons. • Animals should be supported via good management, adequate nutrition, and where relevant, good hygiene procedures. • For reportable conditions, contact appropriate state, provincial, or government bodies to determine specific quarantine requirements and treatments.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Skin biopsy is a quick and relatively painless procedure that can be achieved using a 6 mm skin biopsy punch with no preceding preparation of the skin or local anesthesia to avoid lesion disruption and artifact. • Do not clean or clip biopsy site; leave crusts in place. • Take biopsies at a border with normal tissue, without local anesthesia if possible. • Biopsy sites can be left to heal by granulation but should be protected from invasion by external parasites. • Warts can be crushed and pinched off with hemostats or pliers if small, or removed with cryotherapy or surgical excision.

MEDICATIONS

DRUGS OF CHOICE
• Topical insecticide (permethrins or macrocyclic lactones) every 2 weeks for 2 or 3 treatments will treat and prevent lice infestation if bedding, grooming equipment and other fomites are cleaned as well. • Diazinon, pyrethroids, carbaryl or tetrachlorvinos might be indicated for other ectoparasite disorders. • Dermatophilosis responds to parenteral penicillin or tetracycline. • Corticosteroid agents (dexamethasone, methylprednisolone) are indicated for immune-mediated or hypersensitivity disorders.

CONTRAINDICATIONS
• Corticosteroids should not be used in pregnant animals. • Topical ectoparasiticides that fall under the jurisdiction of the EPA rather than the FDA in the USA cannot be applied in an extra-label manner.

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Depends upon the causative agent; however, most disorders of the integument cause production loss but carry a good to excellent prognosis for recovery and survival.

POSSIBLE COMPLICATIONS
• Secondary bacterial infection and toxemia
• Cutaneous myiasis

CLIENT EDUCATION
Focus on methods of control and prevention to reduce disease related to ectoparasites and infectious disorders.

PATIENT CARE
N/A

PREVENTION
• Quarantine new animals before introduction into the herd, with close inspection for skin lesions. • Remove wet, rotting organic matter to reduce habitat for fly larvae; dragging pastures to break up manure masses is also helpful. • Vaccination for specific disorders (such as papillomas) is possible but might require construction of autogenous vaccine products. • Ensure cleanliness of equipment used in routine procedures such as foot trimming, ear tagging, grooming or tattooing.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Secondary infection • Cutaneous myiasis

AGE-RELATED FACTORS
• Warts typically occur in cattle <2 years of age. • Dermatophytosis is more common in young animals.

ZOONOTIC POTENTIAL
Sarcoptes scabiei, contagious ecthyma, dermatophilosis, dermatophytosis, and some pox viruses, including some other dermatologic disorders, are potentially zoonotic.

PREGNANCY
N/A

BIOSECURITY
• Quarantine new animals before introducing into the herd/flock. • Isolate affected herd members or whole herds during testing and treatment. • Contact regulatory bodies if reportable conditions are suspected. • Crusts from *D. congolensis* infected animals are a source of contagion, so should be disposed of with caution. • Potential fomites such as grooming equipment and blankets should be cleaned and disinfected between animals. • Limit exposure and mingling of young naïve animals with older stock.

PRODUCTION MANAGEMENT
• Diseases which cause lameness, pruritis or pain can reduce production and diminish welfare of cattle. • Many of these diseases are contagious and are important to detect when issuing health certificates or screening entrants to fairs or shows.

SYNONYMS
• Dermatophytosis: ringworm
• Dermatophilosis: rain rot, rain scald, mud fever • Mange: mite infestation • Cutaneous myiasis: fly strike • Udder cleft dermatitis: udder rot, udder scald, intertrigo (intertriginous dermatitis)

ABBREVIATIONS
• EPA = Environmental Protection Agency
• FDA = Food and Drug Administration
• KOH = potassium hydroxide

SEE ALSO
• Dermatophilosis • Dermatophytosis
• Lumpy Skin Disease • Orf (Contagious Ecthyma) • Parasitic Skin Diseases: Bovine

BOVINE DIGITAL DERMATITIS

BASICS

OVERVIEW

• Digital dermatitis [DD] has been a well-recognized cause of lameness in dairy cattle for several decades, and is becoming increasingly recognized as a major cause of lameness in feedlot cattle. It is an extremely painful condition associated with severe lameness and reduced milk production.
• DD is highly contagious and can spread rapidly through a herd. Management practices have been developed that aid control and reduce lameness; however, the majority do not eradicate disease. Most herds with DD remain chronically infected.
• Discussion of the condition is hampered by the great variety of names that are used to describe DD (see "Synonyms").
• Affected cattle are often lame and tend to walk on the toes of the feet with lesions.
• Lesions occur most commonly on the plantar surface of the rear feet, adjacent to the interdigital cleft or ridge.
• DD is an important animal welfare concern.

INCIDENCE/PREVALENCE

• Anecdotally, infection spreads rapidly in susceptible cows once introduced into a naïve herd; however, more recent controlled experiments suggest that lesions may require 3–4 months to develop to mature lesions.
• In dairy herds, DD often affects the majority of cows within the first year of infection. Prevalence in endemic herds can vary from <5% to >70% depending on conditions and control programs.
• In feedlots, DD-associated lameness often increases in prevalence when cattle are heavy and close to slaughter.

GEOGRAPHIC DISTRIBUTION

• Worldwide.
• Reports of a similar process in sheep and goats (contagious ovine digital dermatitis) have been confined to Europe but are likely present in other regions.

SYSTEMS AFFECTED

• Integument
• Musculoskeletal

PATHOPHYSIOLOGY

• DD is polybacterial in nature, meaning that no single bacterial organism has been identified as an etiologic agent. Disease occurs when there is an appropriate consortium of organisms present. Mature lesions are predominantly infected with *Treponema* spp. bacteria, however earlier lesions have small numbers and different species of treponemes, suggesting that this family is not exclusively causal for the disease. Viral and fungal etiologies are not considered important.
• Transmission of DD is believed facilitated by constant moisture (hydropic maceration) and low oxygen tension (anaerobic bacterial involvement is suspected).
• Early lesions vary from small, localized focal to multifocal or coalescing lesions that involve the majority of the plantar skin adjacent to the interdigital cleft. The transition to more mature lesions is characterized by the presence of an ulcerated, hyperemic circular lesion that has the roughened "strawberry-like" appearance of a classical DD lesion. More chronic lesions can become proliferative and papillomatous.
• Most active lesions are 2–6 cm in diameter, circular to oval in appearance, and have clearly demarcated borders with ulceration.
• Lesion borders are often surrounded by true hairs that are 2–3 times the length of normal hairs.
• Chronic lesions may have filiform papillae varying in length from 1 mm to >2 cm (hence, the name "hairy footwarts"). Lesions without the filiform papillae can have a thickened granular appearance.
• Washed lesions vary in color from bright red to gray or brown and are generally very painful to touch or when exposed to water jets.

HISTORICAL FINDINGS

• The main sign of DD is severe lameness (often non-weight-bearing) in one or more limbs.
• The disease is highly contagious and outbreaks are common, with lameness being the predominant herd sign, with multiple cows walking on their toes.

SIGNALMENT

• Digital dermatitis has been reported in all breeds of cattle including dairy and beef breeds.
• Holsteins appear to have a higher incidence among the dairy breeds.
• In dairy herds DD can occur in all ages of cattle. In some cases there is an increased recognition of disease in fresh heifers.
• In feedlots DD is most likely to result in lameness in heavy cattle. Dairy steers, presumably due to exposure prior to entry into the feedlot, may develop lesions earlier in the feeding period than other breeds.
• Sheep and goats in Europe have been reported to suffer from a very similar condition termed contagious ovine digital dermatitis.

PHYSICAL EXAMINATION FINDINGS

• Affected cows may have "club feet" (i.e., longer heels, since they are reluctant to put weight on their heels).
• The classical lesion is found on the caudal aspect of the skin above the heel at the interdigital cleft and may extend to the interdigital skin.
• Lesions are typically on the midline between the heel bulbs and below the accessory digits (dew claws) and are covered in a friable layer of gray, fibrin like material.
• The area should be carefully cleaned to remove any debris so that the lesion can be clearly examined; cleaning should be attempted with great care, as the lesion is extremely painful. In some cases IV and/or regional anesthesia may be necessary.
• Although the majority of cases affect the heels, lesions may occasionally be found on the skin in the interdigital cleft, on the heel bulbs, or on the coronary band on the abaxial aspect of the foot.
• Regardless of the position of the lesion, the characteristic lesion appearance is most diagnostic.

GENETICS

A genetic predisposition has not been clearly established; however, a higher incidence may occur in Holstein cattle.

CAUSES AND RISK FACTORS

• DD is highly contagious between cattle. It is typically brought into a herd through the purchase of an affected animal. However, veterinarians or lay foot trimmers may also play a role in transmission through contaminated hoof trimming equipment.
• Once DD is in a herd it is thought to spread through unsanitary conditions in the barn.
• Muddy or wet conditions and purchasing animals from off-premises locations are the two most common risk factors.
• Poor freestall and bedding management will exacerbate problems since cows will spend more time standing in manure slurry, not allowing the feet to dry out periodically.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Few conditions can be confused with DD; however, laminitis, foot rot, interdigital dermatitis and heel horn erosion, interdigital fibroma, traumatic injury, and thin soles from excessive wear or improper hoof trimming might be considered as causes of lameness.
• DD should also be differentiated from heel erosion ("slurry heel"), interdigital fibroma, traumatic injury to the distal limb, and foot rot (interdigital necrobacillosis).

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

• In most cases, the clinical signs of DD are considered diagnostic.
• Definitive diagnosis can be achieved by biopsy using a skin biopsy punch.
• Histopathology using an appropriate stain can demonstrate the presence of spirochete bacteria within the tissue.

• Given the polybacterial nature of the disease, bacterial culture is not widely practiced and is not generally beneficial for diagnosis.

PATHOLOGIC FINDINGS

• Histopathology is helpful but not necessary for diagnosis. Histopathologic findings include a combination of ulcerative and proliferative changes consisting of ulceration of tips of dermal papillae, epidermal hyperplasia with parakeratosis and hyperkeratosis, colonization and invasion by profuse numbers of spirochetes (*Treponema* spp.), and inflammation.

TREATMENT

THERAPEUTIC APPROACH

• One should approach the treatment of DD from two different standpoints: (1) treatment of individual animals that are clinically affected and in severe discomfort, and (2) treatment of the entire herd, which likely contains a large number of subclinically affected individual.
• For individual animals, the affected area should be thoroughly cleaned and the hooves trimmed to ensure no other causes of lameness exist. Hoof testers can be used to ensure that lameness is not due to a claw disorder prior to direct topical treatment of the lesion.
• Herd treatment can be performed via footbath.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

• Tetracycline derivatives are considered ideal for topical treatment. Most reports show no benefit of systemic antibiotics in therapy and control of DD.
• Individual lesions can be treated with topical oxytetracycline (either 3 mL injectable oxytetracycline or a small volume of tetracycline or oxytetracycline soluble powder) applied topically. No difference in treatment outcomes were observed when comparing lesions treated with a wrap to those with the drug applied as a paste and no wrap. Data suggest that while lesions change appearance shortly after treatment, the majority do not completely heal after a single application and repeated treatments are often necessary.
• Herd treatment of DD can be performed via footbath using formalin (3–5%), copper sulfate (5%) or a wide variety of commercially available products, with cattle forced to walk through the solution. Fecal contamination of footbaths can result in decreased efficacy and therefore baths should be drained, cleaned, and refilled every 100–300 cow passages depending upon the degree of organic contamination of feet on the dairy.
• Herd treatment using solutions consisting of either 25 g/L oxytetracycline (made using water additive powder) or 8 g/L of lincomycin or a combination lincomycin/spectinomycin (Linco-spectin water-soluble powder) may be prepared and applied to the heels of all cattle using a "garden sprayer." To be effective, the feet should first be cleaned using a high-pressure hose.
• In severe cases, clinicians may consider the use of systemic NSAIDs if severe discomfort is displayed by affected individuals.

CONTRAINDICATIONS

N/A

PRECAUTIONS

• Drugs used for treating DD are not licensed for this use. Appropriate milk and meat withdrawal times must be followed.
• When using aqueous antibiotic sprays in the parlor, care must be taken to avoid spraying the udder or milking machine to avoid violation residues. Antibiotic residues have not been reported from treatment.
• Great care must also be taken to ensure that cattle do not drink footbath solutions as this can also result in residue violations and possible toxicity.
• Copper and zinc are problematic to the environment due to their heavy metal content and formalin is a carcinogen and respiratory irritant.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Animals typically show increased discomfort immediately after treatment but lameness should resolve almost fully within 48 hours.
• In some cases the disease will affect exposed corium and interfere with normal horn production. A non-healing claw lesion usually results, requiring antibiotic therapy before healing can resume.

POSSIBLE COMPLICATIONS

Some DD lesions will undermine the horn of the heel or wall, which will necessitate removing the loose horn overlying the active lesion and treating it with topical antibiotics.

CLIENT EDUCATION

Clients should be educated regarding this disease, and associated risk factors, and treatment strategies.

PATIENT CARE

• Most individual lame animals treated with topical antibiotics will show rapid improvement in lameness within 24–48 hours. Animals that still have significant lameness after 72 hours should be reexamined for an additional cause of lameness.
• Animals should be monitored for recurrence and retreated as necessary.

PREVENTION

• Due to the high costs associated with DD, prevention is the goal (see "Biosecurity").
• Once DD has become endemic within a herd, good hygiene within the barn (regular scraping of passageways and maintaining clean, dry stalls) will minimize spread.
• Recurrence is common, so control must be ongoing. Monitoring herd prevalence will help to determine how aggressive the control program needs to be.
• It may also be necessary to use prophylactic footbath treatments on a regular basis, and footbaths must be maintained appropriately to keep the treatment solution clean and active.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Lameness, decreased milk production, decreased longevity in the herd.
• Erosive form: A reddened raw area of granulation tissue.
• Proliferative form: In some chronic cases, there may be proliferation of the epithelial tissue to form hairy, frondlike projections.

AGE-RELATED FACTORS

Generally a disease of maturing or mature animals

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

BIOSECURITY

• Introduction of DD to a group commonly occurs with purchase and introduction of new animals to a herd or feedlot. For this reason, it is prudent to inquire and evaluate potential animals for purchase specifically for the presence of DD prior to introduction.
• Any personnel involved in bovine foot care should ensure equipment is suitably disinfected between farm visits.
• DD-free herds should not buy replacement animals from other premises.

PRODUCTION MANAGEMENT

• Recommendations that pertain to cow comfort, including well-designed and bedded freestalls or open housing, are important.
• Prompt and aggressive treatment of active lesions will help control DD.

SYNONYMS

• Hairy heel warts
• Mortellaro's disease
• Papillomatous digital dermatitis
• Strawberry foot rot

BOVINE EPHEMERAL FEVER

BASICS

OVERVIEW

Bovine ephemeral fever (BEF) is a seasonal, arthropod-transmitted, viral disease of cattle and water buffalo that occurs in the subtropics or temperate regions of Africa, Australia, and Asia.

INCIDENCE/PREVALENCE

Morbidity rates can be very high (approaching 100%) and mortality rates are typically low (<1%). Typically, most cases are asymptomatic. However, recently, there have been reports from several countries of alarmingly high case-fatality rates, sometimes exceeding 20%. It is not unusual for serologic surveys to have prevalence rates of 70–80%. In some cases, the prevalence of BEFV antibodies in African wildlife including a number of ruminants and also hippopotamus and elephants was quite high (>60% of animals tested), suggesting they may serve as natural reservoirs of infection in which the virus cycles during inter-epizootic periods.

GEOGRAPHICAL DISTRIBUTION

• Since BEFV is recognized as an arthropod-borne virus (arbovirus), geographic distribution is dependent on the presence of competent insect vectors.
• BEF has a wide distribution over subtropics or temperate regions of Africa, Australia, and Asia. It occurs from the southern tip of Africa to the Nile River Delta, across the Middle East through South and South-East Asia, into northern and eastern Australia, and throughout most of China, extending into Taiwan, the Korean Peninsula and southern Japan.
• BEFV does not occur in the islands of the Pacific, Europe (other than in the western regions of Turkey) or in the Americas where, for quarantine purposes, it is considered an important foreign animal disease.

PATHOPHYSIOLOGY

• Inflammation and fever are hallmark features of acute BEF.
• Bovine ephemeral fever virus (BEFV) is not cytolytic so cellular death and necrosis are not responsible for the inflammatory response.
• The direct induction of proinflammatory cytokines by BEF virus is believed to play a significant role in the pathogenesis and clinical expression of the acute disease. The virus uses the cell's signaling pathways to induce high levels of the proinflammatory cytokines, interleukin-1 beta (IL-1β) and interleukin-6. IL-1β is associated with high febrile responses and IL-6 is a major chemotactic cytokine for initiating innate immune responses.
• Interestingly, BEF infection does not induce the other major proinflammatory cytokine, tumor necrosis factor-alpha (TNF-α), and it also induces the anti-inflammatory cytokine, IL-10. This production of anti-inflammatory cytokine IL-10 may explain the biphasic nature of the febrile response.

SIGNALMENT

• Bovine and water buffalo.
• BEF is a seasonal disease whose severity varies from year to year and region to region. Epidemics may occur periodically and are characterized by rapid onset within days or a few weeks in many animals in a region.
• Ephemeral fever is most prevalent in the wet season in the tropics and in summer to early autumn in the subtropics or temperate regions when conditions favor the presence of biting arthropods. BEF disappears abruptly in winter.
• Morbidity may be as high as 80%; overall mortality is usually 1–2%, although it is higher in well-conditioned cattle (10–20%).

PHYSICAL EXAMINATION FINDINGS

• The clinical signs occur suddenly and vary in severity. They include biphasic or polyphasic fever, shivering, inappetence, lacrimation, serous nasal discharge, drooling, dyspnea, atony of the fore stomachs, depression, stiffness and lameness, and a sudden decrease in milk yield. Cattle may also become recumbent and paralyzed for 8 hours to >1 week.
• After recovery, milk production often fails to return to normal levels until the next lactation.
• Abortion, with total loss of the season's lactation, occurs in ~5% of cows pregnant in months 8 and 9 of the last trimester.
• Bulls, market cattle, and heavily producing dairy cows are the most severely affected, but even so, spontaneous recovery usually occurs within a few days.

CAUSES AND RISK FACTORS

• The disease is caused by ephemeral fever virus, a Rhabdovirus (single-stranded, negative sense RNA in the same family as rabies virus). BEFV displays typical rhabdovirus bullet-shaped morphology, although appears to be more tapered at one end than the rounded forms that are observed for vesicular stomatitis virus (VSV) or rabies virus (RABV). The 14.9 kb BEFV genome is much larger and more complex than those of VSV or RABV. Since the G protein is a major antigenic determinant there is only a single serotype. The G gene is a useful genotyping marker as it displays reliable alignment with adequate sequence variation to obtain precision and resolution, and the absence of genetic recombination suggests it is likely to be is representative of the entire genome. Using the G gene ectodomain, three lineages have been identified: East Asia, Australia, and Middle East.
• The major transmission route of BEFV is by hematophagous insects. The virus has been recovered from some *Culicoides* (biting midge) and mosquito species (*Anopheles, Culex*, and *Culicine* spp.) collected in the field and has been shown to multiply in *Culicoides* and *Culex* mosquitoes in the laboratory. The role of the insect in biologic transmission appears to be very limited as only a small proportion of insects become infected (~20%) and the virus does not survive in them for more than 10 days. The virus can be mechanically transmitted by IV inoculation of blood from infected viremic cattle to susceptible cattle.
• Transmission by contact or fomites does not occur, and the virus does not appear to persist in recovered cattle.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Parturient paresis (milk fever, hypocalcemia)

CBC/BIOCHEMISTRY/URINALYSIS

Clinical cases have a neutrophilia with bands.

OTHER LABORATORY TESTS

Viral serum neutralization, complement fixation, and the blocking ELISA tests are used for serology. Virus isolation can also be done but isolation usually requires mouse inoculation.

OTHER DIAGNOSTIC PROCEDURES

• Diagnosis of BEF is usually based on history and clinical signs (rapid onset of febrile signs for 2–5 days with spontaneous recovery).
• The clinical outbreak is confirmed by serology in paired serum samples collected during illness and 2–3 weeks later with a fourfold rise in antibodies.

PATHOLOGIC FINDINGS

• The gross lesions of BEF include polyserositis affecting joint, pleural, and peritoneal surfaces. Some lung edema is evident, atelectasis, cellulitis, and focal necrosis of skeletal muscle. The lymph nodes are edematous.
• The histologic findings include neutrophilia, leukocytosis, and high fibrinogen deposition.
• Hemosiderosis of the lymph nodes and spleen from loss of erythrocytes early in infection has been observed.
• The venules and capillaries of the tendon sheath, synovial membranes, muscle, and fascia have perivascular neutrophilic infiltration, focal or complete necrosis of vessel walls, thrombosis, and perivascular fibrosis.

TREATMENT

THERAPEUTIC APPROACH

• Complete rest is the most effective treatment, and recovering animals should not be stressed or worked because relapse is likely.

BOVINE EPHEMERAL FEVER (CONTINUED)

• Isotonic fluids can be administered IV to treat dehydration. Oral dosing should be avoided unless the swallowing reflex is functional.

MEDICATIONS

DRUGS OF CHOICE

• Anti-inflammatory drugs can be given early and in repeated doses for 2–3 days.
• IV or subcutaneous administration of calcium borogluconate has been found to be beneficial in some animals.
• Antibiotics can be administered to prevent secondary bacterial infections.

CONTRAINDICATIONS

During acute illness, no oral therapy should be given, to avoid inhalation pneumonia due to the inability of the animal to swallow.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

A complete recovery occurs in 95–97% of cases. BEF virus infection confers life-long immunity to cattle.

POSSIBLE COMPLICATIONS

Pneumonia, mastitis, hindlimb paralysis, abnormal gait, abortion in late pregnancy, and temporary (up to 6 months) infertility in bulls.

PATIENT CARE

• Animals should be encouraged to stand within 2–5 days. The animals should be rolled over several times a day to help avoid loss of circulation to the underside limbs, which will result in permanent muscle damage.
• The heavier the animal is, the more critical it is to get it back on its feet as quickly as possible.

PREVENTION

A modified-live vaccine is available that confers good protection. An inactivated vaccine is also available but it gives only 6 months of protection.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Pneumonia, mastitis, hindlimb paralysis, abnormal gait, abortion in late pregnancy.

PREGNANCY

Infection in the last trimester can result in abortion.

BIOSECURITY

The virus cannot be spread by direct animal-to-animal contact. However, it can be spread from infected animals to susceptible animals by injection, so single-use needles should be used.

BOVINE LEUKEMIA VIRUS

BASICS

OVERVIEW

Bovine leukemia virus (BLV) is the causative agent of enzootic bovine leukosis (EBL), which is a chronic progressive lymphoproliferative disease of cattle.

INCIDENCE/PREVALENCE

• In the United States, approximately 80% of dairy herds have some level of BLV infection and 30–50% of all US dairy cattle are infected. Approximately 40% of beef cow/calf herds have some level of BLV infection. Incidence of new cases within a herd is highly dependent on current within-herd prevalence and management conditions. The cumulative incidence of lymphoma among infected cattle is estimated to be 1–2% per year, but may reach 5% in high-prevalence herds.

GEOGRAPHIC DISTRIBUTION

• BLV is present on all continents and is endemic in many countries where control programs have not been implemented. In the European Union, 21 countries are officially BLV free; 3 have BLV free regions. New Zealand and Western Australia have eliminated BLV from their dairy herds, though it is still present in low levels in beef herds.

PATHOPHYSIOLOGY

BLV is a delta retrovirus which preferentially infects B lymphocytes. Like other retroviruses, infection is persistent and life-long. Transmission occurs through transfer of lymphocytes with integrated provirus from infected to susceptible animals. There are 4 stages of infection.

• Primary infection: Upon initial infection there is a short period of virus replication during which the virus infects new B lymphocytes. Infected cattle may experience flu-like symptoms. As the immune system responds to infection, expression of virus particles ceases and further expansion of the population of infected lymphocytes occurs via polyclonal proliferation.

• Aleukemic (AL) infection: The majority (50–70%) of animals will remain subclincally infected with normal lymphocyte counts. Immune dysregulation occurs which makes animals susceptible to a variety of infections and impairs their response to vaccination.

• Persistent lymphocytosis (PL): Approximately 30–50% of infected cattle will develop persistent lymphocytosis, with circulating lymphocyte levels elevated above normal physiologic levels. These animals are immune suppressed and prone to opportunistic infections.

• Lymphoma: <5% of infected animals will eventually develop lymphoma. Tumors occur in a variety of organs, most commonly the superficial, visceral and retrobulbar lymph nodes, heart (right atrium), abomasum, uterus, liver, spleen, kidneys, and extradural spine.

SIGNALMENT

• Natural infection has been confirmed in *Bos taurus* and *Bos indicus* cattle, and in water buffalo. Experimental infection has been induced in many other species, most notably sheep.

• Infection is more common in dairy cattle than in beef cattle. Animals can be infected at any age. Decreased milk production and increased premature culling are more common in dairy cows in their second and later lactations. Lymphoma is typically seen in cattle >3 years of age.

PHYSICAL EXAMINATION FINDINGS

• No physical examination findings are specific to the AL or PL stages. However, nonspecific clinical signs associated with immune dysregulation may be present, including: weakness, more frequent infections, delayed recovery from infections, decreased milk production, and increased premature culling.

• Physical examination findings due to lymphoma include enlarged lymph nodes and palpable masses, variable signs of organ dysfunction depending on the organs involved, and generalized weakness and loss of body condition. Signs of organ dysfunction that may be noted include: jugular pulses, tachycardia, murmurs, and/or arrhythmias; dyspnea and/or tachypnea; anorexia, constipation, and/or diarrhea; pelvic limb weakness or paralysis; jaundice; keratitis and/or proptosis. Splenic lymphoma can result in rupture and sudden death.

GENETICS

• There is a genetic component to BLV susceptibility and disease progression. The major histocompatibility complex of cattle—bovine leukocyte antigen (BoLA)—is highly polymorphic. Certain polymorphisms in the genes for BoLA have been associated with higher risk of seropositivity, resistance/susceptibility to PL, the number of BLV-infected peripheral B lymphocytes, and high/low proviral load.

• The genetics of BoLA are complex and may potentially be linked to genes controlling milk production, therefore the utility of genetic selection for BLV control is limited.

CAUSES AND RISK FACTORS

• Purchase of infected animals is the main risk factor for introduction of BLV into a previously negative herd.

• Risk factors for new infections of individual animals within an infected herd include: calves born to a positive dam; feeding of fresh, raw colostrum and milk from infected cows to calves; shared use of blood-contaminated equipment including dehorners, tattoo pliers, needles, and rectal palpation sleeves; bull breeding; lack of fly control; and use of milking machines.

• The relative importance of various risk factors and the mechanisms by which they result in transmission are not completely understood and are an area of ongoing research.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• For opportunistic infections in AL/PL stages: Various primary infections, unrelated to underlying BLV.

• For lymphoma: Visceral lymphoma may feel similar to abdominal fat necrosis on rectal palpation. Keratitis due to retrobulbar lymphoma should be differentiated from pink eye. Pelvic limb weakness or paralysis due to extradural spinal lymphoma may mimic nerve damage from calving. Lumpy jaw (*Actinomyces bovis*) causes hard swellings on the jaw and neck, similar to enlarged lymph nodes. Other tumors of affected organs can be differentiated based on histology. Sporadic lymphoma can only be differentiated from BLV-induced lymphoma by PCR.

CBC/BIOCHEMISTRY/URINALYSIS

Cows with PL will have an increased absolute lymphocyte count. Biochemistry and urinalysis may reflect dysfunction of lymphoma-affected organs.

OTHER DIAGNOSTIC PROCEDURES

• AGID and antibody capture ELISA are commercially available for antibody detection; however, ELISA is the test of choice for routine diagnosis of BLV. ELISA tests have higher sensitivity than AGID and can be performed on milk as well as serum. Sensitivity and specificity of commercially available ELISA tests vary from 97–100% and 78–100%, respectively. These tests will miss early infections, prior to onset of antibody production, and cannot differentiate between maternal antibody and active immunity in calves <6 months of age. ELISA can be performed on pooled milk samples for screening, and is used on bulk tank milk for herd-level screening in many countries with control programs.

• RT-PCR for provirus can be used to identify early infections and to differentiate between maternal antibody and true infection in young stock. PCR can also be used to confirm infection in cases where ELISA results are equivocal. PCR may be used as a tool to identify highly infectious animals within herds for disease control protocols. PCR on lymphoma tissue is necessary to definitively differentiate between BLV-induced lymphoma and sporadic lymphoma cases.

BOVINE LEUKEMIA VIRUS (CONTINUED)

PATHOLOGIC FINDINGS

• Grossly, lymphoma can be suspected when tumors of the visceral lymph nodes, uterus, abomasum, heart (especially right atrium), liver, spleen, and kidneys are found. These tumors are usually soft and gray-white, and can include friable areas of necrosis.
• Microscopically, massive lymphoid cell infiltration is observed in the affected organs as they replace normal cells. Histopathology cannot differentiate between BLV-associated lymphoma and sporadic lymphoma.

TREATMENT

THERAPEUTIC APPROACH

Infections are life-long. There is no specific treatment.

MEDICATIONS

DRUGS OF CHOICE

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Progression from AL to PL occurs in 30–50% of infected animals, and <5% develop lymphoma. Lymphoma develops more commonly in PL animals; however, PL is not a prerequisite for the development of lymphoma.
• Prognosis for AL and PL animals is fair, though the productive lifespan is shortened by premature culling.
• Prognosis for lymphoma cases is poor. Once lymphoma is clinically apparent it is fatal, typically within months of diagnosis.

PREVENTION

• Prevent introduction of BLV into previously negative herds by keeping closed herds, or testing all additions—including breeding bulls.
• Minimize spread of BLV to negative animals within a positive herd by implementing a control program for the herd which may include some combination of routine screening of animals, strict management protocols, segregation, and/or culling of infectious animals.
• Management protocols to minimize transmission of BLV have been successful in reducing within-herd prevalence, but have not been demonstrated to be capable of completely eliminating BLV from a herd without some selective culling. These protocols may include: using single-use needles for injection, single-use sleeves for rectal palpation and AI, heat treating and/or freezing colostrum and milk to be fed to calves, fly control, exclusive use of AI breeding, dehorning via cautery, and cleaning/disinfection of any blood-contaminated equipment.
• There are no commercial vaccines currently available. A promising vaccine is currently in experimental trials.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Sporadic bovine leukosis (SBL) also results in lymphoma, but is not associated with BLV infection.

AGE-RELATED FACTORS

A minority of calves born to infected dams are infected at birth. Incidence of infection increases as heifers enter the milking herd. Lymphoma occurs mainly in cattle 3 years of age and older.

ZOONOTIC POTENTIAL

While some studies have demonstrated an association between BLV exposure and human breast cancer, there is no evidence that BLV plays an etiologic role in human disease.

PREGNANCY

Lymphoma of the reproductive tract can result in reproductive failure. About 10% of calves born to infected cows are infected in utero or perinatally.

BIOSECURITY

• Biosecurity for BLV includes keeping a closed herd and implementing management described under "Prevention."
• Virus is cell-associated and does not survive well outside the host in most environmental conditions. Infected cells can survive outside the host in milk and blood. Infected cells are sensitive to freezing, heat, and UV light.

PRODUCTION MANAGEMENT

• BLV infected dairy cows are estimated to have an average loss of 950–1050 kg of milk per cow per year. Given the high prevalence in many herds and the life-long course of the disease, this can be a significant financial loss over time. BLV-infected dairy cows have shortened productive lifespans within the herd, resulting in a lower return on the investment in raising those animals to the age when then enter the milking herd. Similar production measures are currently being studied in beef cow/calf herds. Lymphoma is the largest single reason for cattle carcass condemnation at slaughter in the US, accounting for 13.5% of beef condemnations and 26.9% of dairy cattle condemnations.
• The later stages of BLV infection are characterized by a slow deterioration of condition and may be a significant source of animal distress. Efforts should be made to identify and cull or euthanize animals before disease results in suffering.

BOVINE PAPULAR STOMATITIS

BASICS

OVERVIEW
Bovine papular stomatitis (BPS) is a mild viral disease of calves characterized by proliferative lesions around the mouth and head caused by bovine papular stomatitis virus (BPSV), a Parapoxvirus. Infections are usually asymptomatic, but raised papules may be observed on nasal planum, hard palate, nares, and occasionally on the esophageal or ruminal mucosa. There are no lesions at the coronary band. Bovine papular stomatitis virus, like other parapoxviruses, can be zoonotic.

INCIDENCE/PREVALENCE
Worldwide distribution

SYSTEMS AFFECTED
Integument

PATHOPHYSIOLOGY
• Viral infection results in early hyperemia and inflammation in focal regions of the nares and mouth. Secondary lesions may occur for up to 4 months. Histopathologic evaluation of lesions demonstrates degeneration of epithelial cells and eosinophilic inclusions in degenerated cells. Hyperplasia of the papillae of the lamina propria is observed. Ulceration of lesions is accompanied by bacterial infection and sloughing of the epithelium.
• A chronic form of BPS has been described associated with more severe clinical signs (salivation, diarrhea, anorexia, and fever). The ulcers in chronic cases become encrusted with an exudate.
• Similar to contagious ecthyma and pseudocowpox in sheep and goats, bovine papular stomatitis is zoonotic and common in veterinary personnel.

SIGNALMENT
• Young dairy calves, feedlot calves shortly after arrival. Commonly observed in calves 1–12 months of age. Rare in adult cattle.
• Also has been seen in sheep and goats.

PHYSICAL EXAMINATION FINDINGS
• Acute lesions consist of 2–4 mm macules on the nares and muzzle that progress rapidly to papules with raised periphery and depressed center. Lesions later develop in the oral cavity. Lesion size may increase to 1 cm in diameter or greater (coalescence of multiple lesions) and regress within several days to weeks. Lesions are not found at coronary band.
• Most animals are afebrile, eat normally, and have no clinicopathologic alterations associated with viral infection.

GENETICS
No association with breed or genetics observed. Commonly observed in dairy calves and recent arrivals in feedlots.

CAUSES AND RISK FACTORS
• The disease is caused by infection with a parapoxvirus, bovine papular stomatitis virus.
• Calves born to cows affected by BPSV when young.
• Adult cows may serve as reservoir for future calf infection.
• Recent introduction of naïve animals to feedlot.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Bovine virus diarrhea virus/Mucosal disease
• Foot and mouth disease
• Pseudocowpox
• Vesicular stomatitis

CBC/BIOCHEMISTRY/URINALYSIS
No abnormalities consistently associated with viral lesions

OTHER DIAGNOSTIC PROCEDURES
Polymerase chain reaction, electron microscopy, and histopathology are useful in the diagnosis of BPS.

TREATMENT

THERAPEUTIC APPROACH
Symptomatic treatment of severely affected animals

MEDICATIONS

N/A

FOLLOW-UP

PREVENTION
Prevention can focus on biosecurity and production of vaccines using locally obtained viral strains.

MISCELLANEOUS

ZOONOTIC POTENTIAL
Bovine papular stomatitis virus, like other parapoxviruses, can be zoonotic. Lesions are usually confined to the hands and have been reported on farm workers who are milkers.

ABBREVIATIONS
• BPS = bovine papular stomatitis
• BPSV = ovine papular stomatitis virus

SEE ALSO
• Bovine Viral Diarrhea Virus
• Foot and Mouth Disease
• Pseudocowpox
• Vesicular Stomatitis

BOVINE PETECHIAL FEVER

BASICS

OVERVIEW
Bovine petechial fever (Ondiri disease) is an infectious disease of cattle in East Africa characterized by petechial and ecchymotic hemorrhages on mucosal membranes. The disease has not been reported in North America.

SYSTEMS AFFECTED
Hemolymphatic

HISTORICAL FINDINGS
Affected animals have a fluctuating fever. The most consistent signs are petechiation and ecchymosis of mucus membranes. Unilateral conjunctival edema, hyphemia, epistaxis, and anemia are present in some severe cases. Dairy cattle imported into endemic areas often exhibit a profound drop in milk production.

SIGNALMENT
There is no sex or age predisposition. *Bos taurus* breeds are more susceptible than *Bos indicus.*

CAUSES AND RISK FACTORS
• The cause is *Ehrlichia* (*Cytoecetes*) *ondiri*. The organism is endemic in wild animals, particularly the bushbuck (*Tragelaphus scriptus*) of highlands above 5000 feet in East Africa. Cattle acquire the disease when grazing on edges of thick, humid forests particularly when they are grazed in these areas at the end of the dry season.
• Bovine petechial fever is common in cattle that have been recently introduced to these areas while indigenous cattle appear to acquire resistance.
• The disease is thought to be transmitted by an arthropod vector. The vector has yet to be identified, but epidemiologic findings suggest a tick vector. Grazing in or adjacent to thick, high elevation East African forests and the presence of the bushbuck, the reservoir of the organism, are important risk factors. Recently introduced animals are more susceptible.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Bracken fern poisoning.
• Trypanosomiasis occurs in the tropics where the vector, the tsetse (*Glossina* spp.) fly is found.
• Theileriosis is also common in areas where the tick vector *Rhipicephalus* spp. is present.

OTHER LABORATORY TESTS
Ehrlichia ondiri is diagnosed on demonstration of the organism in peripheral blood monocytes and granulocytes after Giemsa staining, but cannot be cultured.

TREATMENT

THERAPEUTIC APPROACH
Tetracyclines are effective as a treatment. Recovered animals are immune to reinfection for at least 2 years.

MEDICATIONS

DRUGS OF CHOICE
Tetracyclines are effective as a treatment.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Prognosis is guarded. The mortality is up to 50% in affected animals.
• The disease is important in imported animals introduced into risk areas where significant losses are recorded.

MISCELLANEOUS

PRODUCTION MANAGEMENT
• Bovine petechial fever is common in cattle that have been recently introduced to infected areas, while indigenous cattle appear to acquire resistance.
• Grazing in or adjacent to thick, high elevation East African forests and the presence of the bushbuck, the reservoir of the organism, are important risk factors. Recently introduced animals are more susceptible.

BOVINE RESPIRATORY SYNCYTIAL VIRUS

BASICS

OVERVIEW
Bovine respiratory syncytial virus (BRSV) induces a mild to severe lower respiratory tract disease in cattle. This viral infection is one of the pathogens associated with bovine respiratory disease complex.

INCIDENCE/PREVALENCE
• BRSV is endemic in cattle.
• Seroprevalence in herds is often >90%.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Respiratory

PATHOPHYSIOLOGY
• BRSV induces damage to the respiratory epithelium with a concomitant influx of inflammatory cells (neutrophils and lymphocytes) and production of proinflammatory cytokines (IL-6, IL-8) and often also T helper type 2 cytokines, such as IL-4. Arterial oxygen is often reduced by 30–40%.
• Production of anti-BRSV IgE antibodies has been associated with the most severe clinical and pathologic disease.
• The damage to epithelium coupled with inflammatory changes increases the susceptibility of the lung to secondary bacterial infection. Concomitant infection with *Histophilus somni* has been shown to cause synergistic upregulation of inflammatory cytokines and increased severity of disease.
• Severe BRSV infections can cause severe damage to bronchiolar and alveolar epithelial tissue resulting in the formation of bullae and interstitial emphysema.

SIGNALMENT
• Bovine, ovine.
• BRSV is seldom seen in calves <2 weeks of age, and is most prevalent and severe in animals between 1 month and 8 months of age.
• BRSV disease is rarely seen in cattle >9 months of age. Adult cattle can occasionally experience severe disease.

PHYSICAL EXAMINATION FINDINGS
• BRSV infection results in respiratory signs. These respiratory signs can be mild, with increased respiratory rate and increased harshness in respiratory sounds, to severe, with dyspnea, forced expiration, and open-mouth breathing. In severe cases wheezing can be heard on thoracic auscultation.
• Spontaneous cough is always present and induced cough can usually be precipitated by tracheal palpation; cough can vary from dry and nonproductive to moist.
• Nasal discharge can vary from none to serous to mucopurulent.
• Conjunctivitis and lacrimal discharge are seen infrequently. There is an increased rectal temperature (104–108°F; 40–42°C), depression, and decreased feed intake.
• Secondary pneumonia with bacterial pathogens (*Mannheimia haemolytica, Pasteurella multocida, Histophilus somni*) or *Mycoplasma bovis* is a frequent sequela.

GENETICS
Recent studies are showing associations between immune response genes and BRSV resistance.

CAUSES AND RISK FACTORS
• BRSV is an enveloped, negative, single-stranded RNA virus in the pneumovirus group of the paramyxovirus family. The virus is easily inactivated by desiccation, heat, and disinfectants.
• Stress (weaning, shipping, etc.) will increase the risk. Excessive levels of dust have been reported to increase clinical BRSV.
• Maternal antibody will inhibit vaccine response but will not prevent infection. However, it will lessen the clinical course of disease.
• Concurrent infection with other viral agents, particularly bovine viral diarrhea virus (BVDV), exacerbates BRSV clinical disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Bovine herpesvirus 1 (BHV-1) is associated with rhinotracheitis and upper respiratory disease. BHV-1-infected calves frequently have mucopurulent discharge and conjunctivitis.
• BVDV is associated with oral ulcers, mucopurulent discharge, and upper respiratory disease.
• Bovine parainfluenza-3 virus (PI-3) infection is usually a mild lower respiratory disease.
• Bovine coronavirus (BCV) has also been associated with respiratory disease. In younger calves, it is seen in calves suffering from enteritis and diarrhea. BCV in 5- to 13-month-old cattle causes symptoms of dyspnea, nasal discharge, and increased respiratory rate.
• Atypical interstitial pneumonia (AIP) is characterized by sudden onset of disease with subsequent death. AIP animals have labored breathing with loud expiration, frothing at the mouth, and open-mouth breathing. They have harsh respiratory sounds with crackles and rhonchi. These animals usually have a recent history of grazing lush pastures or having a ration change in a feedyard.

CBC/BIOCHEMISTRY/URINALYSIS
BRSV causes a slight lymphopenia 3–10 days post-infection.

OTHER DIAGNOSTIC PROCEDURES
• BRSV is a very difficult virus to detect by virus isolation. Animals need to be sampled in the incubation or acute phase of infection (3–7 days).
• BRSV can often be detected on nasal swabs by quantitative RT-PCR (qPCR) between 4 to 7 days post-infection. Transtracheal washes have also been successful in PCR detection of BRSV. Antigen detection kits have been developed and can detect BRSV antigen.
• Other procedures that have proved useful in detection of BRSV antigen are fluorescent antibody tests of fresh tissue and immunohistochemistry staining of cell cultures or formalin-fixed paraffin-embedded tissues. Staining of lung tissue from cases necropsied late in infection (after day 7) will often be negative for viral antigen.
• Paired serum samples can be used in the diagnosis of BRSV infection. However, the antibody titer of animals with well-developed clinical disease may be higher in acute samples than the samples taken 2–3 weeks later.
• BRSV antibody response often develops rapidly, and clinical signs follow virus infection by up to 7–10 days.
• Single serum samples showing high antibody titers from a number of animals in a respiratory outbreak may be useful in making a diagnosis if coupled with clinical signs.
• Younger calves infected with BRSV in the presence of maternally acquired antibody may not seroconvert.

PATHOLOGIC FINDINGS
• Gross lesions include a diffuse interstitial pneumonia with subpleural and interstitial emphysema along with interstitial edema. These lesions are similar to and must be differentiated from AIP.
• Regional suppurative bronchopneumonia of bacterial origin is usually present.
• Histologic examination reveals necrotizing and proliferative bronchiolitis with alveolitis that is sometimes proliferative along with hyaline membrane formation and edema.
• Syncytial cells are present in bronchiolar epithelium and lung parenchyma.

BOVINE RESPIRATORY SYNCYTIAL VIRUS (CONTINUED)

TREATMENT

THERAPEUTIC APPROACH
The therapy for BRSV is supportive. See "Patient Care" for additional information.

MEDICATIONS

DRUGS OF CHOICE
• Corticosteroids or nonsteroidal anti-inflammatory drugs (NSAIDs) may have some benefit to lessen the severity of BRSV disease.
• Antimicrobial treatment is utilized to reduce secondary bacterial infections.

CONTRAINDICATIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Uncomplicated BRSV infections will resolve in 10–14 days.
• Animals that have secondary infections usually will develop bronchopneumonia with varying levels of morbidity and mortality.

POSSIBLE COMPLICATIONS
• Some formaldehyde-inactivated BRSV vaccines have been shown to increase the severity of BRSV disease. This method of inactivation is not currently used for commercial vaccines.
• Maternal antibodies in calves interfere with development of an effective BRSV immune response with MLV vaccines.

CLIENT EDUCATION
Minimize handling of animals, decrease animal exposure to high levels of dust, and use preventive vaccines.

PATIENT CARE
• Respiratory characteristics along with rectal body temperatures should be frequently monitored to assess BRSV clinical progression and also the development of secondary bacterial infections that would result in bovine respiratory disease complex (BRDC).
• Severely diseased animals that are dehydrated may receive oral and/or intravenous fluids.
• Handling of BRSV-infected animals should be minimized to decrease the risk of secondary bacterial infections.
• Concentrate and silage should not be fed to severely diseased animals.

PREVENTION
• Both modified-live virus (MLV) and inactivated virus BRSV vaccines are available.
• Vaccination is an important part of a BRSV control program.

MISCELLANEOUS

ASSOCIATED CONDITIONS
BRDC is a frequent sequela to BRSV infections.

AGE-RELATED FACTORS
Younger animals (between 1and 8 months of age) are usually affected.

BIOSECURITY
• BRSV survives very poorly in the environment and is susceptible to UV light, desiccation, heat, and disinfectants. The virus will survive better in the winter.
• Animals exhibiting clinical signs of BRSV should be isolated from other cattle as transmission of BRSV occurs by the oronasal route.
• In pens of animals that have had a BRSV outbreak, it would be prudent to clean the water sources.

PRODUCTION MANAGEMENT
In herds with a history of BRSV in their calves, a BRSV vaccine program should be implemented.

ABBREVIATIONS
• AIP = atypical interstitial pneumonia
• BCV = bovine coronavirus
• BHV-1 = bovine herpesvirus 1

BOVINE SPONGIFORM ENCEPHALOPATHY

BASICS

OVERVIEW
Bovine spongiform encephalopathy (BSE) is a progressively fatal, neurodegenerative disease of cattle and is a type of transmissible spongiform encephalopathy (TSE).

INCIDENCE/PREVALENCE
• BSE is an OIE-reportable disease.
• Since the inception of the feed ban, there have been noticeable reductions in the incidence of typical BSE diagnosis.
• The incidence of atypical BSE has not changed significantly, further indicating the potential for a spontaneous origin.
• In 2014, a total of 13 cases of BSE were reported among member countries worldwide.
• As of 2014, 11 countries are listed as having a "controlled BSE risk," with a significantly larger number having a "negligible risk." Canada is currently listed as having a controlled BSE risk, with a 2014 incidence rate of 0 cases per million cattle. The United States is listed as having negligible risk. The highest incidence rate in 2014 was 1.2 cases/million cattle, as compared to peak incidence rate of over 6000 cases/million in the United Kingdom in 1992.

GEOGRAPHIC DISTRIBUTION
Infected indigenous cattle have been reported in most countries in Europe and North America, as well as Brazil and Southeast Asia. The majority of recent cases appear to be of the "atypical" form of the disease, and may be spontaneous in nature.

SYSTEMS AFFECTED
Nervous

PATHOPHYSIOLOGY
• Since its first diagnosis in the UK in 1986, different theories about the origin of BSE have been proposed, generally involving the feeding of an initial new "strain" of the prion agent to cattle.
• Addition of rendered material from affected cattle carcasses to make meat and bone meal amplified the agent.
• Origins for the original source case include a single mutated form of sheep scrapie, a spontaneous case of atypical BSE, or contamination with additional prion-contaminated material into the food chain from additional sources.
• A complete ban on the feeding of ruminant-derived products back to cattle has effectively controlled the majority of cases of BSE; however, it appears that there are at least two "types" of apparently spontaneous BSE that may occur, similar to several classical human prion diseases.
• Unlike TSE diseases in other species, there is no significant involvement of the lymphoreticular system in cattle.
• Unlike other TSEs, there appears to be a single "strain" of conventional BSE that is capable of significant cross-species infection. Atypical BSE (classified as either "H" or "L"-type) may be spontaneous in origin, and differs in both age of onset and molecular signature.

HISTORICAL FINDINGS
Usually an insidious onset of neurologic signs in cattle >2 years of age.

SIGNALMENT
• Cattle, bison.
• Generally affects cattle between 3 and 6 years of age and the incubation period ranges from 2 to 12 years.

PHYSICAL EXAMINATION FINDINGS
Slowly progressive, degenerative neurologic disease. Cattle will often be ataxic, primarily on the hindlimbs with hypermetria. They will also have hyperreflexia, muscle fasciculation and tremors, fall down, and behavior changes such as nervousness and frenzy. Over time, the animal will become anorexic and lose weight and body condition; dairy animals will have decreased milk production.

GENETICS
• Offspring of BSE-infected cattle seem to have an increased risk of developing BSE but exact etiology is unknown at this time.
• Vertical or venereal transmission has not been proven, although it may have been demonstrated in transgenic mice using the BSE agent.
• There is no clear genetic linkage to the development of conventional BSE; however, atypical BSE may be partially linked to unique genetic signatures within the bovine prion (PRNP) gene.

CAUSES AND RISK FACTORS
• BSE and other TSEs are believed to be caused by a pathogenic effect on neurons of an abnormal isoform of a host-encoded glycoprotein, the prion protein.
• The pathogenic form of this protein appears to be devoid of nucleic acids and supports its own amplification in the host through conversion of the secondary structure of host prion protein to the pathogenic protein structure. TSEs in animals primarily occur by transmitting the etiologic agent within a species, either naturally or through domestic husbandry practices. A notable exception among the TSEs is the apparent ability of BSE to effectively cross species barriers, affecting most mammalian species including humans (variant Creutzfeldt-Jakob disease; vCJD).
• Cattle consuming prion-infected meat and bonemeal or other ruminant by-products that may be contaminated with the BSE agent. No horizontal transmission has been reported.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Hypomagnesemia
• Intracranial tumors
• Lead poisoning
• Listeriosis
• Nervous ketosis
• Polioencephalomalacia
• Rabies
• Spinal cord trauma

CBC/BIOCHEMISTRY/URINALYSIS
There is no antemortem test for BSE as the host does not mount an immune response to the agent.

PATHOLOGIC FINDINGS
• Gross lesions are restricted to carcass changes such as emaciation and damage to the hide from ataxia and nervousness.
• Histopathologic detection of neurodegeneration lesions in the brain (bilaterally symmetrical spongiform changes in the gray matter) will help confirm the diagnosis. Immunohistochemistry, immunoblotting, and ELISA to demonstrate accumulations of the prion (PrP^{res}) protein are needed for definitive diagnosis.

TREATMENT

THERAPEUTIC APPROACH
There is no treatment for this disease.

MEDICATIONS

DRUGS OF CHOICE
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
This is a progressively fatal neurodegenerative disease and 100% of the cases will die.

PREVENTION
Do not feed ruminant products to ruminants. Restrictions have been put in place in many countries that preclude the feeding of ruminant products back to ruminants, but clients should be made aware of this as a risk factor and prevent contamination of any cattle feed on their farms.

MISCELLANEOUS

AGE-RELATED FACTORS
Most often seen in cattle between 2 and 10 years of age.

BOVINE SPONGIFORM ENCEPHALOPATHY (CONTINUED)

ZOONOTIC POTENTIAL

• There is evidence to suggest that persons consuming BSE-contaminated products may develop a disease called variant Creutzfeldt-Jakob disease.
• The exact incubation period for vCJD is unknown but it is thought to be decades. It too is a progressively fatal neurologic disease with 28 years of age being the mean age at death of those affected.
• Since the first discovery of vCJD in 1996 through November 2006, there have been 200 cases worldwide, with the majority in the UK (164) and France (21). The US has reported 3 cases, but the patients had resided in the UK (2) and Saudi Arabia (1) the majority of their lives.
• There are recommendations regarding blood donations, surgical equipment, and organ transplants from countries where vCJD has been diagnosed, to prevent further spread of this disease.

PREGNANCY

Vertical transmission of BSE has not been documented but offspring of BSE-infected cattle are at higher risk for developing the disease; offspring are usually culled.

SYNONYM

Mad cow disease

BOVINE VIRAL DIARRHEA VIRUS

BASICS

OVERVIEW

• Bovine viral diarrhea (BVD) is a viral infection of cattle.
• BVD is caused by the virus bovine viral diarrhea virus (BVDV).
• BVDV is capable of infecting and causing disease in other ruminant species (sheep, goats, camelids, cervids) and swine.
• BVDV is capable of causing pathology in many different organ systems.
• Cattle can become acutely infected with BVDV at any age. This is also referred to as primary infection or transient infection.
• Fetal infection prior to day 125 of gestation can result in the development of immunotolerance to the BVDV and the development of a persistent infection (PI) with the virus. Camelids and cervids can also develop PI.
• Cattle persistently infected with BVDV shed large amounts of virus during their lifetime. They are the major source of virus spread within and between farms.
• Cattle persistently infected with BVDV can develop a fatal form of BVD called mucosal disease.

INCIDENCE/PREVALENCE

BVDV is a ubiquitous pathogen of ruminants with high seroprevalence worldwide. Infections with BVDV are endemic in many countries and are often associated with severe economic losses for the cattle industry. Prevalence of cattle persistently infected with BVDV is low, estimated at generally <0.05% of the cattle population.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

• Digestive
• Hemolymphatic
• Nervous
• Respiratory
• Reproductive

PATHOPHYSIOLOGY

• Two main methods of virus transmission include postnatal horizontal transmission and gestational vertical transmission from a viremic dam to her fetus. Transmission may occur by aerosols, nose-to-nose contact, and via semen.
• Following infection with BVDV, a short incubation period of 3–7 days is followed by viremia, which generally lasts for 1–4 days but may persist for 15 days (Figure 1).
• BVDV can result in immunosuppression (leukopenia, hypoimmunoglobinemia, neutrophil dysfunction, decreased antigen presentation) following acute infection resulting in secondary infections caused by opportunistic pathogens. BVDV has been implicated most often as an immunosuppressive component of the bovine respiratory disease complex.
• Following BVDV infection in pregnant animals the virus infects the fetus, resulting in one of several outcomes: early embryonic death occur with infections in the first 45 days of gestation; abortions can occur following infection at any stage of gestation; persistent infection occurs with fetal infection between day 45 and 145; congenital defects can occur with infections in the 2nd and 3rd trimester of gestation and include cerebral hypoplasia, retinal atrophy, cataract, growth retardation, arrested bone development, and pulmonary hypoplasia. Congenital infections are defined as those occurring late in gestation and characterized by the presence of virus-neutralizing antibodies at birth. These congenital infections can result in increased neonatal disease, later sexual maturity and reduced fertility (Figure 1).
• Persistently infected (PI) animals shed high levels of virus in all their secretions, feces, and semen (Figure 2). PI animals are much more efficient transmitters of BVDV than transiently infected animals because they shed large amounts of virus for a long period of time.
• PI animals typically have reduced lifespan with >80% of PI animals dead by 2 years of age.
• The most common sequelae in PI animals is mucosal disease. Mucosal disease is the result of a PI animal developing a superinfection with cytopathic (CP) BVDV (see "Causes and Risk Factors") and results in high mortality. The superinfection is often the result of mutation of the noncytopathic (NCP) BVDV from the PI animal becoming a CP mutant. The superinfection can also be the result of the vaccination of PI animals with a CP modified live virus (MLV) BVDV vaccine.

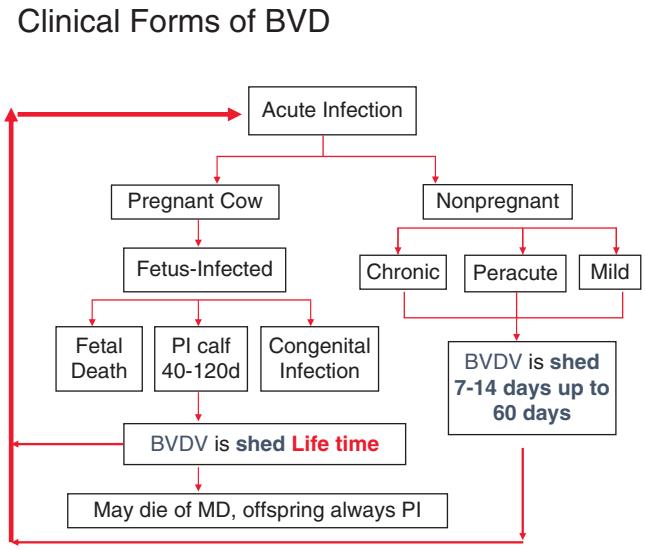

Figure 1.

Outcomes of BVDV Infections.

SIGNALMENT

BVDV is capable of infecting other ruminant species (sheep, goats, camelids, cervids) and swine. It can cause PI in alpacas, white-tailed deer, camels, llamas, and other wild ruminants

PHYSICAL EXAMINATION FINDINGS

• Acute infections are mostly subclinical in nature.
• Severe acute infections may be characterized by fever, leukopenia, thrombocytopenia, and hemorrhagic disease.
• Other manifestations of acute BVDV infection may include enteric disease, respiratory disease, and immunosuppression. The severity of disease depends upon host and viral factors.
• Reproductive outcomes following fetal infection can include transient infertility, early embryonic death, abortion, congenital defects, congenital infections, and persistent infection.
• A mild, biphasic elevation in body temperature and leukopenia may be evident.
• Lactating cattle may have an associated decrease in milk production.
• Mucosal disease occurs in cattle persistently infected with BVDV and is characterized by fever, anorexia, depression, profuse salivation, nasal discharge, severe diarrhea, hemorrhages and erosions in gastrointestinal tract, and a very high case fatality rate.
• BVDV genotype 2 is usually involved in severe acute BVD characterized by severe thrombocytopenia with hemorrhages (prolonged bleeding from venipuncture sites; hemorrhages on sclera of eye and inner surface of eyelids; hemorrhages on mucosal

BOVINE VIRAL DIARRHEA VIRUS (CONTINUED)

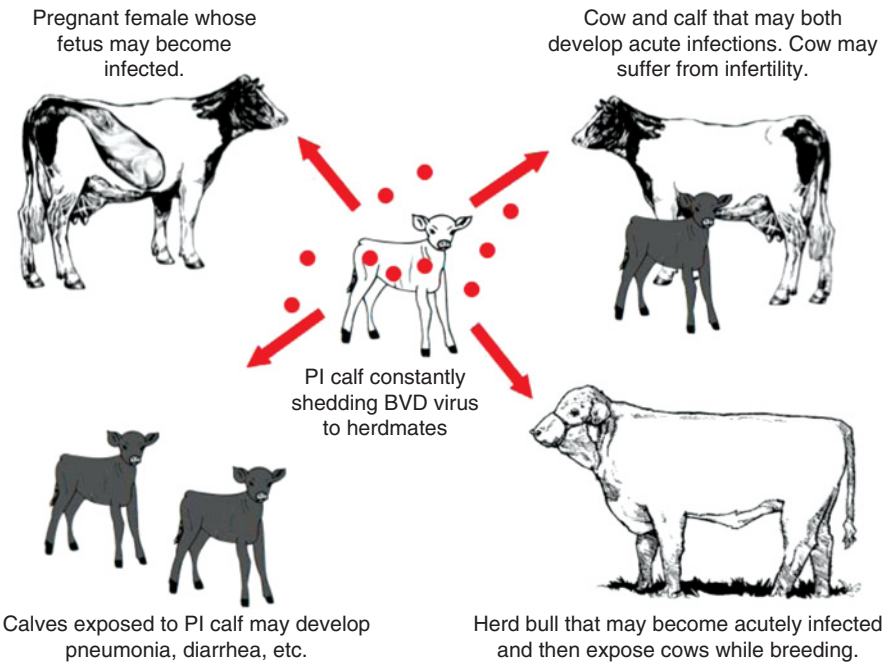

Figure 2.

Effects of a PI in the Herd.

surfaces of cheeks, lower gingiva, tongue, and soft palate), fever, pneumonia, diarrhea, and sudden death in 10–100% of infected animals.
• In calves: Pyrexia, leukopenia, anorexia, diarrhea, immunosuppression with secondary infections.
• In pregnant animals: Early embryonic death occurs with infections in the first 45 days of gestation; abortions can occur following infection at any stage of gestation; persistent infection occurs with fetal infection between day 45 and 145; congenital defects can occur with infections in the 2nd and 3rd trimester of gestation and include cerebral hypoplasia, retinal atrophy, cataract, growth retardation, arrested bone development, and pulmonary hypoplasia. Congenital infections are defined as those occurring late in gestation and characterized by the presence of virus-neutralizing antibodies at birth.

CAUSES AND RISK FACTORS

• BVDV is an RNA virus and a member of the genus *Pestivirus* in the family Flaviviridae.
• The BVDV is antigenically related to classical swine fever virus (CSFV) of pigs and Border diseases virus (BDV) of sheep.
• BVDV is further divided into genotypes (1 and 2) and sub-genotypes (a, b, c . . .). The most common sub-genotypes in the USA include BVDV 1a, BVDV 1b, BVDV 2a, and BVDV 2b.
• BVDV can be further divided into two biotypes; cytopathic (CP) or non-cytopathic (NCP). This differentiation is based on the ability to cause cell cytopathology in cell culture. Only noncytopathic BVDV has been associated with persistent BVDV infection.
• The major risk factor for BVDV being introduced into a farm is the acquisition of new cattle, specifically cattle persistently infected with BVDV. Other risk factors include sharing of pastures with other cattle (direct or fence line) and lack of a BVDV vaccination program.
• The virus is shed in most secretions and excretions of infected animals including tears, milk, saliva, urine, feces, nasal secretions, and semen.
• Virus can survive for several days in a cool, protected environment and hence fomites (nose tongs, halters, etc.) can play a role in virus transmission.
• Flies can also transmit the virus.
• The virus can be present in milk and colostrum.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Differential diagnosis for calves with diarrhea as the result of BVDV includes any pathogen known to cause diarrhea in neonatal calves. In adult cattle, differential diarrheal diagnoses would include winter dysentery and salmonella.
• Differential diagnosis in white-tailed deer includes epizootic hemorrhagic disease of deer and bluetongue.
• Differential diagnosis for abortions caused by BVDV includes BHV-1, Neospora, leptospirosis, and brucellosis.
• Differential diagnosis for thrombocytopenia induced by BVDV includes sweet clover poisoning, coumarol poisoning, and vitamin K deficiency.

CBC/BIOCHEMISTRY/URINALYSIS

• Severe leukopenia is characteristic in the early stages of acute BVD, with total leukocyte count in the range of 1,000–5,000/μL being common.
• Isolates of BVDV associated with hemorrhagic BVDV can result in severe thrombocytopenia and subsequently anemia.

OTHER DIAGNOSTIC PROCEDURES

• Acute infections can be identified by virus isolation from serum, whole blood, nasal swabs, or lymphoid tissue; RT-PCR on serum, whole blood, nasal swabs, or lymphoid tissue; identification of a fourfold increase in virus-neutralizing antibody titers in acute and convalescent serum samples.
• Persistent infection with BVDV can be diagnosed by serial identification of virus 3 weeks apart using virus isolation, antigen detection ELISA, or RT-PCR, in serum, whole blood, milk or skin, or identification of BVDV antigen in skin samples (ear notch biopsies) by immunohistochemistry.
• Because of the high analytical sensitivity of RT-PCR, it can be used on pools of individual samples to reduce costs. Individuals in positive pools are then retested to identify positive animals.

• Herd screening for BVDV infection can be done by testing bulk milk for antibody or virus. Identifying BVDV neutralizing antibodies in young cattle 6–12 months of age that have not been vaccinated for BVDV is highly correlated with virus circulation in the herd. Precolostral screening of newborn calves for BVDV neutralizing antibodies has also been demonstrated to be highly correlated with virus circulation in the herd.

PATHOLOGIC FINDINGS

• In most cases, acute BVDV presents with no gross lesions that are specific.
• Cattle acutely infected with BVDV may have lesions similar to those found with mucosal disease including erosions in the oral cavity, esophagus, rumen, abomasums, and small intestine, especially over areas of the Peyer's patches.
• Widespread petechial and ecchymotic hemorrhages may be present in cattle suffering from hemorrhagic syndrome.
• No specific lesions are seen in aborted fetuses.
• Cerebellar hypoplasia can be seen grossly in congenitally affected calves.
• Histopathologic findings following acute BVDV infections include lymphoid depletion of the Peyer's patches, lymph nodes, spleen, and thymus.
• In PI animals, BVDV immunohistochemistry (IHC) will demonstrate BVDV antigen in all organs. On histologic examination, hair follicles have high levels of BVDV antigen. Ear notches containing hair follicles have been used in IHC assays to identify PI animals.

TREATMENT

THERAPEUTIC APPROACH

• Cattle acutely infected with BVDV typically recover over time.
• In severe cases, supportive therapy is indicated.
• There is no treatment for cattle persistently infected with BVDV.

MEDICATIONS

DRUGS OF CHOICE

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Most cattle recover within 10–14 days.

POSSIBLE COMPLICATIONS

• The use of modified-live vaccines against BVDV in pregnant cattle is contraindicated unless specified by the product manufacturer.
• Modified-live vaccines may be immunosuppressive and therefore should be used with caution.

CLIENT EDUCATION

• Clients should be educated about the importance of biosecurity in the prevention of BVDV entering an operation.
• Clients should understand the significance of cattle persistently infected with BVDV in bringing the virus onto a farm and serving as the major virus reservoir.
• Clients should understand that vaccination is an important tool in controlling BVDV. However, because of the antigenic diversity of the virus, control programs should not rely on vaccination alone, but should include the implementation of appropriate biosecurity as well.

PREVENTION

• Implementation of a whole-herd vaccination program against BVDV is recommended.
• Vaccinations should include antigens against both type 1 and type 2 BVDV.
• Newly acquired cattle should be quarantined for a minimum of 3 weeks and screened for persistent infection.
• Vaccination of breeding age females is important for reducing the risk of fetal infections and subsequent adverse outcomes, most importantly the birth of calves persistently infected with BVDV.
• Vaccination of young stock is important for reducing risk of syndromes associated with acute infections including respiratory disease and hemorrhagic disease.
• Effective vaccines against infectious agents must account for both antigenic and genetic diversity, and they should provide fetal protection.
• Both modified-live (MLV) and killed vaccines are available.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• BVDV infection frequently is a predisposing factor to bovine respiratory disease (shipping fever).
• Mucosal disease occurs in cattle persistently infected with BVDV following a superinfection with an antigenically related cytopathic BVDV strain.
• Cytopathic BVDV may also arise by mutation of the infecting noncytopathic virus.

AGE-RELATED FACTORS

Colostral antibodies can protect newborn calves for 2–4 months.

ZOONOTIC POTENTIAL

BVDV is not considered a zoonotic agent.

PREGNANCY

• Infections during gestation can result in early embryonic deaths, abortion, congenital defects, persistent infection, or congenital infection. The result of fetal infection is dependent on the virus strain, biotype, and the stage of gestation when fetal infection occurs.
• In utero infection of the fetus with noncytopathic BVDV prior to 125 days' gestation leads to immune tolerance and the birth of persistently infected (PI) calves that are usually unthrifty and poor doers and act as a source of virus for the rest of the herd.

BIOSECURITY

• Biosecurity is a central pillar in the prevention of BVDV in a cattle operation. This includes quarantine and testing of animals prior to entering the herd.
• Purchased pregnant animals are a huge threat to introduce BVDV through the birth of a PI calf. There is no simple test of the pregnant animal that can be used to detect a PI calf in utero.
• The role of wild ruminants as a reservoir host or as a dead-end host in BVDV epidemiology is not clear. Controlling contact between cattle and wildlife is advisable if possible.

PRODUCTION MANAGEMENT

• Vaccination is an important tool in controlling BVDV. To be the most successful at preventing PI animals, animals need to be vaccinated prior to breeding.
• Because of the antigenic diversity of the virus, control programs should not rely on vaccination alone, but should include the implementation of appropriate biosecurity programs as well as monitoring and testing for BVDV PI.
• Purchased pregnant animals pose a large threat to any BVDV prevention program. Their offspring need to be immediately tested for PI following calving.

BRACKEN FERN TOXICITY

BASICS

OVERVIEW

• All ruminant species are at risk of developing toxicosis. Most cases of poisonings have been reported in cattle.
• Bracken fern (*Pteridium aquilinum*) is a native perennial fern found throughout the United States and is the source of intoxication. *Pteridium* species in other parts of the world have also been shown to contain the toxic principle.
• Disease in ruminants is generally seen following ingestion of high quantities of the plant over a period of several months.
• Diseases reported in ruminants include bone marrow suppression, bovine enzootic hematuria, bladder and gastrointestinal neoplasias, and progressive retinal degeneration.
• Key to controlling the disease is prevention. Bracken fern is susceptible to a wide variety of herbicides.

INCIDENCE/PREVALENCE

Sporadic and relatively uncommon

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

• Hemolymphatic
• Digestive
• Nervous
• Urinary

PATHOPHYSIOLOGY

• Ptaquiloside is the main toxic principle. Other toxic metabolites include quercetin and shikimic acid. The species of animal exposed, and the dose and duration of exposure, are thought to be the determining factors in which clinical syndrome is observed.
• Bone marrow suppression has been observed in clinically affected animals; there is suppression of all cell lines (radiomimetic effect).
• Clinically affected animals generally present with signs associated with thrombocytopenia and neutropenia; anemia may occur as a result of blood loss or later as the red cells disappear from circulation (longer lifespan).
• Toxicosis is often complicated by bacteremia. Neutropenia due to myelosuppression allows bacterial invasion through ulcerations of the gastrointestinal (GI) tract and may result in infarction of the liver or other bodily organs.
• Under alkaline conditions, ptaquiloside is converted to dienone, an active carcinogen, which alkylates DNA and leads to tumor formation. Because ruminant urine is usually alkaline, tumors are commonly found in the bladder and result in bovine enzootic hematuria.
• Quercetin and papilloma virus type 4 act as co-carcinogens to produce malignant tumors in the upper GI tract, most commonly from the tongue to the rumen.
• Bracken fern also contains a thiaminase which rarely results in clinical signs in ruminants, given the ample production of thiamine by the ruminal microflora. However, intoxication results in neurologic disease more commonly in monogastric species.

SIGNALMENT

• Cattle are most commonly affected; but there are reports of sheep, llamas, and other ruminants being affected.
• All ruminants appear susceptible; most poisonings have been reported to occur in cattle. Natural outbreaks have occurred in sheep. Monogastric livestock species (horses and swine) may also be affected.
• Enzootic hematuria and tumors are generally observed in older animals, following months or years of exposure. The toxin is excreted in the milk and suckling animals may be affected secondarily.

PHYSICAL EXAMINATION FINDINGS

• Cattle afflicted with bone marrow suppression generally present with bloody nasal discharge, petechiation and ecchymoses, and weakness. Thrombocytopenia may result in hyphema or bleeding from the external orifices. Hemorrhagic diarrhea, melena, and hematuria may also be present.
• Secondary bacterial infections are common (e.g., lung), and signs of dyspnea, decreased appetite, and hyperthermia can be observed.
• Bovine enzootic hematuria ("red water") has been reported in cattle chronically exposed to bracken fern. This syndrome is linked to the development of bladder lesions, some of which are neoplastic. Bovine papillomavirus types 2 and 4 may play a role in the development of neoplastic lesions.
• Red to brown urine is a common sign in those cattle suffering from enzootic hematuria.
• Experimentally, bracken fern exposure for 4–12 months has been associated with progressive retinal degeneration in sheep. Sheep suffering from retinal degeneration show bilateral pupil dilatation and have a glassy-eyed appearance ("bright blindness").

CAUSES AND RISK FACTORS

• Bracken ferns (*Pteridium* spp.) are perennial ferns found throughout much of the world, 1–6 feet tall, with triangular, coarse, pinnately compound fronds. Other species of fern may also contain ptaquiloside.
• Bracken fern has a deep-seated, black, elongate, branched, hairy, horizontal rhizome. Spores develop late in the summer and are found rolled under the blade edges.
• Poisonings can occur as a result of grazing the fresh plant (thought to be unpalatable) or following chronic consumption of contaminated hay.
• The plant is toxic green or dry; the most toxic parts of the plant are the young developing fronds (fiddleheads or crosiers) and rhizomes.
• The plant prefers moist to dry woods and open slopes, with good drainage. It tends to occur naturally in very dense stands.
• Clinical disease is generally seen when animals consume significant amounts of plant material (up to 20% of their diet) for 30 days or more.
• Clinical cases may continue to emerge for up to 6 weeks after cessation of exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Other hemorrhagic diseases of cattle include anthrax, BVDV infection, furazolidone poisoning, sweet clover intoxication, and radiation injury.
• Cases of bovine enzootic hematuria need to be differentiated from other causes of hematuria such as cystitis, pyelonephritis, and other toxicants.

CBC/BIOCHEMISTRY/URINALYSIS

• Thrombocytopenia and leukocytosis; polymorphonuclear leukocytes are the most severely affected.
• The presence of anemia depends on the stage of disease and the amount of blood loss by the patient.
• Inflammatory leukogram, hyperproteinemia, elevated fibrinogen can be due to secondary infectious processes.
• Hematuria and the increased presence of epithelial cells may be seen on urinalysis.

OTHER LABORATORY TESTS

• Prolonged bleeding times
• Normal prothrombin times

OTHER DIAGNOSTIC PROCEDURES

• Bone marrow biopsy may reveal pancytopenia. Caution is warranted as this procedure is not without risks in compromised patients.

PATHOLOGIC FINDINGS

• Petechiation and ecchymoses, multiple hemorrhages throughout the tissues, pale bone marrow, edematous and ulcerated GI tract.
• Numerous neoplastic conditions of the GI and urinary tracts—papillomas, transitional cell carcinomas, squamous cell carcinomas, adenocarcinomas, hemangiomas.
• Retinal degeneration in affected sheep.

TREATMENT

THERAPEUTIC APPROACH

• No primary treatment.
• Supportive care includes removal of the animal from contaminated pastures or

BRACKEN FERN TOXICITY (CONTINUED)

forages, broad-spectrum antibiotics, blood transfusion, and good nursing care.
• Most animals respond poorly to treatment. Animals with neoplastic changes should be culled or humanely euthanized.

MEDICATIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Animals suffering from bone marrow suppression almost never recover.

POSSIBLE COMPLICATIONS

N/A

PATIENT CARE

• Monitor platelet, neutrophil, and red blood cell values.
• Check for onset of secondary infections.

PREVENTION

• Recognition of bracken fern in the field or in hay.
• When removal of exposure is not possible, avoid excessive grazing and provide alternate feedstuffs to limit intake.
• Herbicide application can be successful in eliminating the plant.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Monogastric animals exposed to bracken fern suffer from thiamine deficiency due to thiaminases present in bracken fern.

ZOONOTIC POTENTIAL

Since ptaquiloside is a direct-acting carcinogen, people conceivably can be affected through direct consumption of the plant or ingesting milk from exposed animals.

PRODUCTION MANAGEMENT

• Avoid grazing in bracken-dense areas, provide adequate forage, and instill appropriate stocking densities.
• Avoid feeding contaminated hay.

SYNONYMS

• Bovine enzootic hematuria
• Bright blindness

ABBREVIATIONS

• BVDV = bovine viral diarrhea virus
• GI = gastrointestinal

BRASSICA SPP. TOXICITY

BASICS

OVERVIEW

• Forages, seeds, and the roots of plants of the genus *Brassica* (e.g., kale, rape, turnips, mustards, cabbage, Brussel sprouts) contain S-methyl-L-cysteine sulfoxide (SMCO), a rare sulfur-containing amino acid, and glucosinolates which upon metabolism yield toxic principles.
• Syndromes associated with *Brassica* poisoning in ruminants include congenital hypothyroid goiter (enlarged thyroid), enteritis, Heinz-Ehrlich body anemia, polioencephalomalacia (PEM; "rape blindness"), nitrate poisoning, photosensitization, hypotrichosis, decreased libido in bulls, delayed estrus in cows, and acute bovine pulmonary emphysema and edema (ABPEE).
• Severe hemolytic anemia is associated with SMCO intake. Although the SMCO content in culinary vegetables is too low to induce hemolysis, ill-thrift is commonly observed.
• Dependent on their composition, glucosinolate metabolites will become either intestinal irritants (isothiocyanates) or goitrogens (thiocyanate ion and thiones such as vinyloxazolidine-2-thione).
• Isothiocyanate, a metabolite of the mustard oil contained in plant seeds, causes enteritis.
• Thiocyanate ions cause goiter when small amounts are chronically ingested along with iodine-deficient forages. *Brassica* plants also tend to be iodine-deficient. This syndrome is iodine-responsive.
• Thiones also arise from the seeds and are more potent than thiocyanates. They interfere with T4 formation and are unresponsive to iodine therapy. Treatment with iodine is clinically ineffective.
• Instead of being a direct cause of ABPEE, it is believed that fog fever is precipitated by the intake of *Brassica* spp.

INCIDENCE/PREVALENCE

Outbreaks of glucosinolate poisoning vary with the weather, variety, and growth stage of the plants. Grazing of SMCO-containing plants yields high morbidity and case fatality rates.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

• Digestive
• Hemolymphatic
• Integument
• Nervous
• Reproductive
• Respiratory

PATHOPHYSIOLOGY

• Hemolytic anemia usually develops 1–3 weeks after exposure and occurs as a result of the conversion of SMCO to dimethyl disulfide (DMDS) by rumen microbes. Irreversible oxidization and denaturation of hemoglobin leads to Heinz body formation which, concurrent with membrane phospholipid peroxidation, contributes to cell lysis.
• Glutathione reductase (GR) deficiency in cattle, and reduced erythrocyte glucose-6-phosphate dehydrogenase (G6PD) activity in some sheep breeds, contribute to cell fragility.
• Thiocyanates are released by both plant and rumen microbial enzymes during mastication and fermentation, respectively, and are five times more concentrated in the smaller younger leaves than the larger more mature ones. Reduced iodide uptake and hence tyrosine iodination within the thyroid of the developing fetus results in the birth of goitrous neonates which exhibit signs of hypothyroidism. In Japan, the calves of gestating beef cows fed iodine-deficient forages and water concurrent with cruciferous plants alternatively developed diffuse hyperplastic goiter.
• Thiones interfere with the incorporation of iodine into thyroxine (T4) precursors and block its secretion from the thyroid gland.
• "Rape blindness," which is believed to be either a mild form of PEM or hepatotoxicity, is hypothesized to be the result of sulfate poisoning.
• The mechanism of photosensitization remains unclear.

HISTORICAL FINDINGS

• Animals will quickly ingest large quantities of highly palatable *Brassica* spp. which are used to supplement pastures in poor growth.
• Poisonings are more likely to occur when rumen microbes have had little time to adapt.
• Chronic ingestion by pregnant dams in iodine-deficient settings gives rise to a high incidence of neonatal goiter.
• Except for rape, all other varieties of kale yield high concentrations of rumen thiocyanate.
• Drought or high inorganic fertilizer content will amplify clinical signs.

SIGNALMENT

• Bovine, caprine, and ovine.
• Sheep and cattle breeds deficient in G6PD and GR activity, respectively, are especially susceptible to SMCO toxicosis.
• Goiter and clinical hypothyroidism are observed in neonates.
• Heinz body anemia is more likely to occur in ruminating animals.

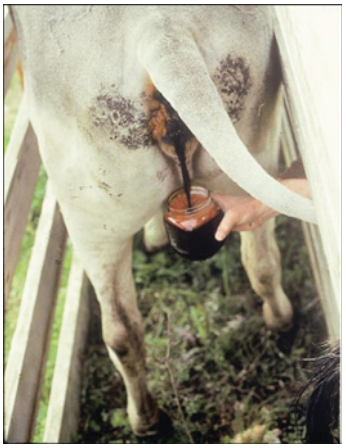
PHYSICAL EXAMINATION FINDINGS

• Outbreaks of *Brassica*-induced hypothyroidism are characterized by abortions, stillbirths and the prolonged parturition of weak, lethargic and recumbent goitrous newborns with varying degrees of hypotrichosis. Kids are often more severely affected than lambs.
• A "thyroid thrill," the result of increased vascularity, is often palpated and auscultated within the jugular furrow.
• Neonatal mortality rates tend to be high during inclement weather.
• Clinical disease is rare in adults, despite palpably enlarged glands.
• Hypersalivation, colic, diarrhea, dysentery, and occasionally scant and sticky feces are observed in cases of rapeseed poisoning.
• Animals in hemolytic crisis may exhibit lethargy, pallor, icterus, dyspnea, coffee-colored urine (Figure 1a), hypoxic abortion, shock, and death.
• Erythema, edema, vesicles, and blindness may develop in photosensitive animals.
• Animals may develop methemoglobinemia and other signs of acute nitrite poisoning post-exposure. Stillbirths and stunted neonatal growth occur with chronic ingestion.
• Severe dyspnea and subcutaneous emphysema are signs of ABPEE.

CAUSES AND RISK FACTORS

• *Brassica* poisoning is possible whenever ruminants consume either *Brassica* plants or their by-products.
• Although glucosinolates are present in all plant components, seeds are the most toxic.
• SMCO content is highest in seeds, flowers, and secondary growth.
• Lightly pigmented animals are likely to develop photosensitivity after ingesting mature plants.
• During droughts and fertilizer overuse, higher levels of nitrates accumulate in *Brassica* leaves.

DIAGNOSIS



DIFFERENTIAL DIAGNOSES

• Nutritional iodine deficiency and the ingestion of couch grasses (*Cynodon aethiopicus*, *C. nlemfuensis*) or white clover (*Trifolium repens*) also result in goiter.
• Hemolytic anemia secondary to immune-mediated disease, onion or red maple toxicosis, chronic copper poisoning, hemo-parasites, leptospirosis, and bovine postparturient hemoglobinuria, should be considered.
• Viable alternatives for enteritis include infectious agents and the ingestion of oak and oleander species.
• Plants such as St John's wort and blue-green algae also cause photosensitization.

CBC/BIOCHEMISTRY/URINALYSIS

Results vary with the observed syndrome and include leukopenia, macrocytic, hyperchromic anemia with Heinz bodies in up to 100% of erythrocytes; elevated serum GGT and bilirubin; bilirubinuria and hemoglobinuria.

BRASSICA SPP. TOXICITY (CONTINUED)

(a)

(b)

(c)

Figure 1.

Rape and Kale Poisoning. (a) Passage of Dark Urine (Hemoglobinuria) (b) Jaundiced Liver (c) Pale Jaundiced Heart. Reproduced with permission of Elsevier.

OTHER LABORATORY TESTS
- Blood glucosinolate assay.
- Determination of milk, serum or plasma iodine to assess T4 status.
- Chromatographic detection of blood dimethyl disulfide.
- Arterial blood gas and pulse oximetry.

OTHER DIAGNOSTIC PROCEDURES
Skin and liver biopsy

PATHOLOGIC FINDINGS
- Goiter; mean fresh thyroid weight is 6.5 g and 2 g in full-term calves and lambs, respectively.
- Thyroid follicles are infolded, depleted of colloid, and lined with columnar epithelium.
- Pallor, jaundiced organs (Figures 1b, 1c; see www.fiveminutevet.com/ruminant), darkened kidney, and hypoxia-induced hepatocellular necrosis.

TREATMENT

THERAPEUTIC APPROACH
- In all cases, further access to *Brassica* spp. should be restricted; provide shade and apply balm to skin lesions as needed.
- Iodine supplementation of pregnant dams is key in cases of thiocyanate-induced neonatal goiter.
- Supportive therapy may include colostrum administration and warmth to weak newborns, blood transfusions, and fluid and electrolyte therapy.

MEDICATIONS

DRUGS OF CHOICE
- Methylene blue
- Zinc-containing ointments

PRECAUTIONS
Adhere to appropriate milk and meat withdrawal times.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Fair to guarded if exposure is restricted.

PREVENTION
Control livestock access to *Brassica* plants and by-products. Iodine supplementation either in the form of potassium iodide or weekly applications of tincture of iodine inside the flank of animals, has been effective.

MISCELLANEOUS

PREGNANCY
Feeding *Brassica* spp. to pregnant dams predisposes neonates to goiter.

PRODUCTION MANAGEMENT
The ingestion of *Brassica* plants and feedstuffs must be closely monitored.

BREEDING SOUNDNESS EXAMINATION: BULL

BASICS

OVERVIEW
• The aim of a breeding soundness examination (BSE) is to identify satisfactory potential breeding males and to remove unsatisfactory breeding males from the herd.
• Major emphasis is placed on physical attributes that affect the bull's ability to locate females in estrus, mount, achieve intromission, and deliver good-quality semen.
• Libido or serving capacity testing is sometimes included as part of a BSE.

INCIDENCE/PREVALENCE
Common procedure in beef bulls

SYSTEMS AFFECTED
• Reproductive
• Musculoskeletal
• Ophthalmic
• Behavioral

GEOGRAPHIC DISTRIBUTION
Worldwide

PATHOPHYSIOLOGY
N/A

HISTORICAL FINDINGS
• General history should include purchase/travel, health/nutritional, and vaccination and deworming.
• Reproductive history should include previous BSE findings, breeding records for previous breeding seasons, and the breeding management of the farm.

SIGNALMENT
• BSE should be performed prior to the breeding season, prior to sale, for insurance purposes, or as part of a herd fertility investigation.
• BSE is particularly important in young bulls prior to their first breeding season.
• Standards set forth by the SFT for minimum scrotal circumference to be classified as a potential satisfactory breeder are based on a minimum age of 15 months.
• Bulls should be examined annually.

PHYSICAL EXAMINATION FINDINGS
• BCS: Bulls should be slightly overconditioned heading into the breeding season. Bulls that are thin may not be able to maintain condition throughout the breeding season and bulls that are obese may experience reduced fertility due to impaired thermoregulation of the testicles from increased fat deposition within the scrotum.
• Eyes: Normal eyesight is required; bulls primarily use eyesight to detect cows in estrus.
• Conformation: A bull must be able to cover large distances to search out and find cows in estrus. Serving capacity is reduced by lameness or pain. Breeding bulls should be free of heritable conformation abnormalities.
• Reproductive examination should include:
  ◦ Evaluation of the scrotal contents and palpation of the testes/epididymides
    ▪ Visual inspection of the scrotum for symmetry, size, and shape. The scrotum should have a distinct neck above the testes to allow for adequate thermoregulation.
    ▪ The scrotal skin should be free of dermatitis or frostbite lesions.
    ▪ The testes should be equal in size, shape, and consistency. They should be freely movable within the scrotum and turgid/resilient on palpation.
    ▪ The epididymides should be palpated for symmetry and any abnormalities including enlargement, heat, or pain. The head of the epididymis can be palpated on the craniodorsal aspect of the testis and the tail of the epididymis can be palpated at the ventral aspect of the testis.
  ◦ Scrotal circumference
    ▪ SC is measured at the greatest diameter by grasping the neck of the scrotum and firmly pulling the testes down into the scrotum. Care should be taken not to place the thumb or fingers between the spermatic cords, which can falsely enlarge the SC diameter.
  ◦ Penis and prepuce
    ▪ The prepuce should be palpated from the base of the scrotum to the preputial orifice. Special attention should be paid to the reflection of the prepuce onto the glans penis, as this is a common site of preputial injury.
    ▪ The penis should be thoroughly evaluated during exteriorization at the time of semen collection.
  ◦ Transrectal palpation
    ▪ The internal genitalia that are readily palpated transrectally consist of the pelvic portion of the penis, body of the prostate, ampullae, and seminal vesicular glands. The bulbourethral glands are imbedded in the urethralis muscle and cannot be palpated.
    ▪ Abnormalities are most commonly detected in the seminal vesicular glands (i.e., acute or chronic seminal vesiculitis).
    ▪ Enlarged inguinal rings may predispose a bull to development of a scrotal hernia.
• Serving capacity/libido test
  ◦ Serving capacity/libido test is not always included as part of a BSE.
  ◦ Bulls are exposed to restrained, estrus cows for a specified time period and observed for sexual behavior and mating activity.

GENETICS
• Onset of puberty and testicular size are age and breed dependent.
• SC is correlated with age at puberty of bull half-sib females and daughters.
• Some spermatozoa abnormalities are hereditary.

CAUSES AND RISK FACTORS
N/A

DIAGNOSIS
• Bulls are classified as satisfactory, unsatisfactory or deferred potential breeders, based on physical examination, scrotal circumference size, progressive motility, and morphology. Any bull with abnormalities of the physical examination should be considered unsatisfactory or deferred.
• Satisfactory potential breeder
  ◦ Scrotal circumference: ≥30 cm at <15 months; ≥31 cm at 15–18 months; ≥32 cm at 18–21 months; ≥33 cm at 21–24 months; ≥34 cm at ≥24 months
  ◦ Progressive motility: >30%
  ◦ Normal morphology: >70%
• Unsatisfactory potential breeder
  ◦ Scrotal circumference: <30 cm at <15 months; <31 cm at 15–18 months; <32 cm at 18–21 months; <33 cm at 21–24 months; <34 cm at ≥24 months
  ◦ Progressive motility: <30%
  ◦ Normal morphology: <70%
• Deferred
  ◦ A "deferred" classification may be assigned if the bull does not meet the standards but is likely to improve.
  ◦ Bulls classified as deferred should be retested at a later date, typically 60 days, but often earlier based on the judgment of the veterinarian performing the examination.

DIFFERENTIAL DIAGNOSES
N/A

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
Semen Collection
• The most common methods for semen collection in bulls in practice are electroejaculation or transrectal massage of the ampullae.
• Semen can also be collected by an artificial vagina in trained bulls.
• Post-mating aspiration from a cow is rarely performed.

Semen Evaluation
• Volume is variable, in the range 1–12 mL.
• Color varies from gray to milk white depending on concentration. Some ejaculates may be yellow (presence of riboflavin).
• Consistency: Ejaculates should be homogeneous.
• Motility: Mass motility or individual motility should be evaluated using clean warm equipment (Table 1).
  ◦ Motility is reduced if semen is contaminated with urine, blood, or purulent material.
  ◦ A minimum of 30% progressive motility is required for a classification of satisfactory potential breeder.

(CONTINUED) # BREEDING SOUNDNESS EXAMINATION: BULL

Table 1

Evaluation of Motility		
Mass motility	*Description*	*Individual motility*
Very good	Rapid dark swirls	>80%
Good	Slower swirls and eddies	50–69%
Fair	No swirls, individual motility	30–49%
Poor	Little or no individual motility	<30%

• Morphology is assessed on eosin–nigrosin stained smears under oil (1000× magnification) or on formalin-fixed samples under phase contrast (wet mount).
  ◦ A minimum of 70% morphologically normal spermatozoa is required for a classification of satisfactory potential breeder.
• Cytology of the ejaculate is assessed using a differential stain or Wright-Giemsa stain to identify any leukocytes. Presence of PMNs should alert the examiner to the possibility of seminal vesiculitis.

Semen Culture and Sensitivity
May be indicated when disease is suspected.

IMAGING
Testicular or transrectal ultrasonography may be performed if abnormalities are identified. This examination is not part of a routine BSE.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
Abnormalities detected during a BSE are numerous and may include (but are not limited to): immaturity, poor semen quality, reduced scrotal circumference/testicular size, penile/prepucial injury or abnormality, congenital reproductive anomalies (e.g., persistent penile frenulum), testicular degeneration, infectious processes involving the reproductive tract, lameness, poor or excessive body condition, and ophthalmic abnormalities.

CLIENT EDUCATION
Bulls should be submitted for BSE annually.

PATIENT CARE
Breeding activity should be monitored during the mating season.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Young males (<15 months) often fail the BSE because of abnormal morphology due to immaturity.

ZOONOTIC POTENTIAL
Brucellosis

PREGNANCY
Early pregnancy diagnosis is helpful for monitoring breeding activity and fertility of bulls.

BIOSECURITY
Quarantine all new bulls and those returning from shows for a determined period of time to protect herd health.

PRODUCTION MANAGEMENT
• In herds with short breeding and calving seasons, bull BSEs are vital to productivity and economic success.
• Bulls should have a BSE prior to the breeding season.
• BSE is particularly important in young virgin bulls.
• BSE should be performed at least 2 months prior to the intended breeding season to allow for replacement if unsatisfactory. For bulls intended for sale, the BSE should be within a month prior to auction.
• Bull to cow ratio should be 1:25.

BREEDING SOUNDNESS EXAMINATION: CAMELIDS

BASICS

OVERVIEW
• Male breeding soundness examination (BSE) is performed as a routine management procedure, for pre-purchase or work-up of cases of infertility.
• BSE is not a measure of fertility but helps identify males with reproductive problems.
• The male camelid reproductive system presents several anatomic and physiologic peculiarities, making some aspects of the BSE unique.

INCIDENCE/PREVALENCE
• Common procedure in alpacas and llamas.
• The procedure is not yet well established in camels (except for highly valuable racing dromedaries).

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Digestive
• Reproductive
• Multisystemic

PATHOPHYSIOLOGY
• Male fertility is the culminating point of intricate endocrine and physiologic events regulating the behavior and function of the reproductive system.
• Testes are in scrotal position at birth. However, they may not be visible or palpable in camels until 1 year of age.
• Rise in testosterone determines onset of sexual behavior and maturation of the reproductive system (detachment of the penis from the prepuce).
• Spermatogenesis is initiated after puberty (15–18 months SAC, 2–4 years in camels).
• Camels are seasonal breeder but SAC can breed all year around. However, semen quality in SAC is lower in hot summer months. Rutting season in camels is signaled by increased poll gland secretions, marking behavior, and exteriorization of the soft palate (dulla).
• Camelids mate with the female sitting in a sternal position.
• Mating lasts 5–20 minutes in camels and 5–60 minutes in SAC.
• Erection is achieved by extension of the sigmoid flexure which is cranial to the scrotum. The penis penetrates through the cervix and semen is deposited deep into the uterine horns.
• Ejaculation occurs throughout the mating period in a dribbling manner. The ejaculate is very viscous and composed of spermatozoa and secretion from the bulbourethral glands and prostate (camelids do not possess seminal vesicles).
• Seminal plasma contains ß-nerve growth factor which, combined with uterine inflammation caused by mating, induces ovulation in the female.

GENETICS
Some defects may have genetic origin (e.g., testicular hypoplasia, cryptorchidism, cystic rete testis).

HISTORICAL FINDINGS
• Selection of male for breeding
• Neonatal examination of a male
• Infertility or abnormal behavior

SIGNALMENT
• Differences exist among the four domesticated species of camelids: dromedaries (*C. dromedaries*), Bactrian (*C. bactrianus*), alpaca (*Vicugna pacos*), and llama (*Lama glama*).
• BSE should be performed on animals that have reached the appropriate age for breeding (3 year for alpacas and llamas, 4–5 years for camels).
• Age, origin, breeding records, and previous health problems should be recorded.
• Reasons for examination should be clearly stated.
  ◦ Define exactly the problem(s) to be addressed: existence of visible lesions, suspicion of infertility due to many unsuccessful breedings, or a change in the reproductive behavior (reduced libido).
  ◦ An approximate date of the onset of the problem should be obtained as well as conditions: did the problem appear suddenly or was it a slow, progressive process?

PHYSICAL EXAMINATION FINDINGS
• Reproductive performance can be affected by diseases of other systems. Prolonged febrile conditions or debilitating diseases affect spermatogenesis.
• Clinical signs depend on the reason for examination.
• A general physical examination should be performed including general appearance and BCS. Attention should be given to contagious diseases and presence of congenital or potentially heritable conditions.
• Prepuce and penis
  ◦ Prepuce abnormalities such as pendulous, edema, laceration, and prolapse should be noted. Sedation may be required for further evaluation.
  ◦ Penile attachment to the prepuce is normal in young, prepuberal animals but can signal the presence of adhesions in the mature male. In SAC, the penis should be completely free at 3 years of age.
• Scrotum and testes
  ◦ The scrotal region is examined from a distance to evaluate testicular descent and integrity of the skin in the area. Lacerations due to bites are common.
  ◦ Both testes should be present and visible within the scrotum in the perineal region. One of the testicles is usually situated slightly more ventral than the other but both should be nearly equal in size (difference less than 15%).
  ◦ In older males, the scrotum may sometimes be pendulous.
  ◦ Palpation of the scrotum and its contents is necessary to appreciate the regularity of the contour of the testes as well as their consistency.
  ◦ The surface of the testes should be smooth and regular. The testes are normally resilient. They become hard and fibrotic or very soft in the case of degenerative changes.
  ◦ The scrotal sac should be free from fluid.
  ◦ The tail of the epididymis is palpable as a small hard nodule.
  ◦ Testicular length and width should be determined using precision calipers. In the llama, length should be least 1.1 cm in a yearling and 3.2 cm by 2–3 years of age. In alpacas the testes long axis should be at least 3.5 cm in order to achieve good fertility in a herd. The length and width of the testicle in adult males should be 5–7 cm and 3–4 cm respectively in llamas and 4–5 cm and 2.5–3 cm respectively in alpacas. In camels, the adult testis during the rutting season should be at least 4 cm in width and 7 cm in length.
• Examination of the accessory sex glands is not performed as a routine.
• Evaluation of mating behavior
  ◦ Mating ability of the male is observed in the presence of a receptive female.
  ◦ The succession of normal behavioral patterns as well as the times needed for each step (chasing, flehmen response, forcing down, mating, intromission, and duration of copulation) are recorded.
  ◦ Behavioral problems at mating can be due to shyness, inexperience, or lack of libido.

CAUSES AND RISK FACTORS
• Infertility in male camelids is primarily due to inadequate sperm production or sperm quality (impotentia generandi) and inability to physically complete mating (impotentia coeundi).
• Impotentia generandi is primarily due testicular hypoplasia, degeneration, fibrosis, or neoplasia. Testicular degeneration occurs following severe loss of body condition, persistent high fever, or direct trauma to the testis.
• Impotentia coeundi is primarily due to penile adhesions, musculoskeletal disorders, or debilitating diseases.

DIAGNOSIS

Diagnosis of causes of infertility requires complete physical examination and systematic evaluation of all the reproductive organs and semen.

(CONTINUED) # BREEDING SOUNDNESS EXAMINATION: CAMELIDS

DIFFERENTIAL DIAGNOSIS

• Scrotal enlargements may be due to edema, hydrocele, orchitis, testicular hemorrhage or neoplasia. Differential diagnosis requires imaging and further testing.
• Inability to exteriorize the penis may be due to adhesions.

CBC/BIOCHEMSTRY/URINALYSIS

Baseline CBC, biochemistry, and urinalysis are highly recommended in valuable males and for prepurchase examinations.

OTHER LABORATORY TESTS

• Fecal analysis for parasites.
• Testing for contagious diseases: Tuberculosis, brucellosis, BVD, trypanosomiasis where endemic.
• Endocrine evaluation
  ◦ Information on endocrinologic evaluation of the infertile male camelid is scarce.
  ◦ Presence of testicular tissue in bilaterally cryptorchid male or castrated males suspected to be cryptorchid is ascertained if there is at least a twofold increase in serum testosterone level within 8–24 hours after IV administration of hCG (3000 IU for alpacas, 5000 IU for llamas, 10,000 IU for camels).

IMAGING

• Ultrasonography of the testis is highly recommended to differentiate among causes of testicular enlargement and to evaluate the testicular parenchyma. The parenchyma should be homogeneous and the rete testis hyperechoic. Cystic rete testis is common in alpacas.
• Transrectal ultrasonography may be indicated in some cases in order to evaluate the bulbourethral glands, pelvic urethra and penis, and prostate.

OTHER DIAGNOSTIC PROCEDURES

Semen Collection

• Semen collection is challenging due to the nature of copulatory behavior and the slow (dribbling) process of ejaculation.
• Use of an AV is possible but requires training and the use of a specially designed dummy mount fitted with a collection apparatus. Modified ruminant AVs work well if they are adapted to camelid by simulating the presence of cervical rings.
• Electroejaculation, using ram probes in SAC and bovine probes in camels, is possible under general anesthesia.
• Response to the electrical stimulus varies greatly from one individual to another.
• The ejaculate obtained by electroejaculation is often of poor quality and contaminated with urine and cellular debris.
• Postcoital vaginal aspiration is commonly used in general practice in SAC. The male is mated to a receptive female. Upon completion of the mating an infusion pipette is introduced vaginally and the seminal fluid is aspirated using a 12 mL syringe.

Semen Evaluation

• The major problem in interpreting semen analysis in the camelid is the lack of standard methods for collection and for examination.
• Ejaculate volume varies greatly depending on the method of collection used, duration of copulation, and male variation.
• Ejaculate volume is in the range 0.4–12.5 mL. Postcoital aspiration yields volumes in the range 0.25–0.5mL in SAC.
• Ejaculates are gray to creamy white depending on sperm concentration. Ejaculates collected by vaginal aspiration may be pink or red because of contamination with blood from the cervix.
• Ejaculate may be heterogeneous with some translucent material mixed with cloudy areas. This is due to its viscous nature.
• Camelid semen is viscous and requires time to liquefy. The degree of viscosity depends on the individual male and on the proportion of seminal plasma, which tends to decrease with number of ejaculates.
• The time required for liquefaction varies from one male to another and from one ejaculate to another. Viscosity is attributed to the presence of secretions of the bulbourethral glands.
• Liquefaction of camelid semen can be obtained by addition of collagenase to the ejaculate.
• Concentration of semen is best estimated after liquefaction using a hemocytometer.
• Sperm concentration is highly variable ($82{,}000–250{,}000/mm^3$) and is affected by age, method of collection, and ejaculate rank.
• The pH of semen varies between 7.5 and 8.1. Semen pH is affected by method of collection and rank of ejaculate.
• Motility of semen is appreciated on nondiluted samples (mass activity) and on diluted samples (individual sperm motility). Mass activity is generally poor in camelid semen unless the ejaculate is constituted exclusively by the sperm-rich fraction. In fresh nondiluted samples, only oscillatory movements are observed. Initial motility is very low (5%) and increases as the ejaculate liquefies. Progressive motility can only be estimated after liquefaction and dilution with a suitable extender. Normal males should have at least 50% oscillatory or progressive motility.
• Morphology of the spermatozoa can be evaluated on smears stained with eosin–nigrosin stain or DiffQuick® (Giemsa) stains.
• A total of at least 200 sperm cells from different fields should be evaluated from each sample. Morphological evaluation is done under phase contrast microscopy (1000×) as for other species. The morphologic abnormalities should be reported according to type and location.
• Effect of various types of abnormalities on fertility has not yet been determined. Total abnormalities should not exceed 50%.
• The most common abnormalities are proximal and distal droplets, knobbed or swollen acrosome, mid-piece reflex, and coiled tails.

Testicular Biopsy

• Testicular biopsy should be considered in subfertile males and in cases of testicular asymmetry or abnormal testicular ultrasonography that is not consistent with hematoma or orchitis. This technique is useful for diagnosis of spermatogenic arrest, oligospermatogenesis, hypogonadism, inflammation, and neoplasm.
• Several techniques of testicular biopsy have been described.
  ◦ *Wedge biopsy:* An incisional or open biopsy requires general anesthesia. After surgical preparation of the scrotum, an incision (0.5 cm) is made over the skin, parietal vaginal tunic and the exposed tunica albuginea avoiding vascular areas. Testicular tissue allowed to protrude from the rent in the tunica albuginea is ablated using a scalpel blade. The tunica albuginea, parietal vaginal tunic, and the scrotal skin are closed with absorbable suture.
  ◦ *Tru-Cut:* Use under sedation or anesthesia. After surgical preparation of the testicles, the scrotum is incised using a sterile #10 surgical blade (alpacas) or #11 scalpel (llamas). The trucut (14 gauge self-firing) biopsy needle is inserted in the testicle through the tunica albuginea. The scrotum is closed with two skin sutures using 2-0 Vetafil®. Results obtained with this technique are more reliable but hemorrhage at the biopsy site is more frequent.
  ◦ *"Core" biopsy:* A needle "core" biopsy can be performed using a $1\frac{1}{2}$ inch 16 gauge needle after heavy sedation of the animal. After surgical preparation of the scrotal skin, the needle is introduced into the testicular parenchyma and redirected by a gentle push-pull movement into two different sites. The needle is retracted from the tissue while a finder is placed over the hub to maintain the core sampled. A direct smear is prepared from the sample obtained.
  ◦ *Fine-needle aspirate:* Fine-needle aspirate cytology is a commonly used technique for the evaluation of azoospermia and testicular neoplasm in humans. It is rapid, simple, and inexpensive. Testicular tissue is aspirated with a 20-gauge needle and 12 mL syringe. A puncture is made and aspirates are taken in three to four directions making sure not to include the epididymis. Cytologic smears stained with DiffQuick® are interpreted based on the different types of spermatogenic cells.
• Interpretation
  ◦ Interpretation should be done by an individual familiar with the technique and histology of camelid testis.
  ◦ Fine-needles aspirates are difficult to interpret. The relative frequency of cell

BREEDING SOUNDNESS EXAMINATION: CAMELIDS (CONTINUED)

types provides a differential diagnosis between hypospermatogenesis, spermatogenic arrest, and normal spermatogenesis. A fine-needle aspirate from azoospermic animals consists of Sertoli cells alone, a few mature spermatozoa, and scant cell material or spermatid but no spermatozoa.
  - Tru-Cut or self-firing biopsy instruments are safe and provide a good amount of tissue for examination of seminiferous tubule spermatogenic activity. Presence of normal spermatogenic activity in cases of azoospermia may suggest the presence of segmental aplasia or other forms of obstructive azoospermia. Atypical spermatogenic cells are usually associated with testicular neoplasm (seminoma). No spermatogenic cells are obtained from atrophic testicles.
- Complications
  - Hematoma or hemorrhage.
  - Adhesions and inflammation.
  - Autoimmune reactions (development of antisperm antibodies).
  - Degeneration of germinal epithelium and tubules.
  - Transient decrease in sperm output that lasts for several months.
  - Wedge biopsy is the most unsafe of all methods.
  - Complication risk increases if the technique is not performed correctly and quickly.

PATHOLOGIC FINDINGS

- Penile/preputial disorders
  - Prolapse prepuce, penile-preputial adhesions
  - Phimosis
  - Persistent frenulum
  - Abscesses
- Testis
  - Testicular hypoplasia or degeneration
  - Segmental aplasia of the epididymis
  - Epididmal cysts or rete testis cysts
  - Orchitis/epididymitis
  - Testicular degeneration/fibrosis and calcification of the testicular parenchyma
  - Testicular trauma or neoplasia
  - Cryptorchidism

TREATMENT

THERAPEUTIC APPROACH

Treatment depends on the complaint and diagnosis. It is important to note that restauration of normal testicular function is very difficult.

SURGICAL CONSIDERATIONS AND TECHNIQUES

- Surgical correction of preputial prolapse.
- Hemicastration in cases of acquired testicular pathologies (orchitis, hemorrhage, neoplasia).
- Males with congenital defects should be castrated.
- Camels with impacted dulla should undergo palatectomy.

MEDICATION

DRUGS OF CHOICE

- GnRH (camels 100 μg, IM; SAC 50 μg, IM) prior to breeding to increase libido
- Other depending on underlying condition

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed.
- Testosterone should not be used to increase libido.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Males with congenital defects or abnormal development of the reproductive organs should be eliminated (castrated or culled) from reproduction.
- Fertility prognosis is good after hemicastration in unilateral acquired conditions of the testis.
- Poor fertility prognosis in cases of testicular degeneration or severe musculoskeletal impairment.

POSSIBLE COMPLICATIONS

Urinary complications (urethral or bladder rupture) in cases of preputial trauma/adhesion.

CLIENT EDUCATION

- Introduction of breeding males constitutes one of the major biosecurity breaches for the herd.
- BSE should be performed on all males prior to breeding.
- BSE should be performed annually.
- Detailed breeding records should be kept including behavior and pregnancy results of bred females.
- Handling techniques should be implemented to ensure safety for personnel and females.

PATIENT CARE

- Dependent on condition.
- Breeding males, particularly camels, can be dangerous during the rutting season. Exercise should be provided. Male should be in separate enclosure to avoid fighting and accidental injuries.
- Weight loss is common during the breeding season. Males should be supplemented accordingly nda special attention should be given to trace mineral supplementation.
- Avoid obesity and emaciation.

PREVENTION

- Prevention of acquired disorders of the reproductive tract relies on good management practices and biosecurity measures.
- Breeding males should be in top health at all times. Vaccination and deworming program should be designed appropriately.
- Routine wellness checks should be performed including dental and foot care.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Infertility, behavioral problems

AGE-RELATED FACTORS

Breeding schedule should take into consideration age and testicular size.

ZOONOTIC POTENTIAL

Brucellosis is a major concern when collecting semen.

PREGNANCY

Early pregnancy diagnosis allows monitoring of male fertility.

BIOSECURITY

- Test all males for contagious diseases and diseases that can spread by vectors.
- Provide a quarantine area for outside female breeding.
- Quarantine males that have traveled to shows.

PRODUCTION MANAGEMENT

- Breeding male management requires special attention in order to avoid loss of fertility.
- Males should be easy to handle and undergo BSE every year.
- Males should be in top health condition before the breeding season.

BREEDING SOUNDNESS EXAMINATION: CERVIDAE

BASICS

OVERVIEW

• BSE in cervids is used to select breeding animals or to investigate herd or individual fertility problems.
• Chemical (sedation, anesthesia) and/or physical (squeeze chute) immobilization is necessary. This presents several inherent risks that must be considered.
• A complete BSE includes the following:
  ◦ Physical examination for anatomic and structural soundness (eyes, mouth, feet, legs, external genitalia, body condition, and overall wellness)
  ◦ In the male, a reproductive evaluation includes
    ▪ Testicle palpation and scrotal circumference (SC) measurement
    ▪ Exteriorization and evaluation of the penis
    ▪ Collection of a semen sample for sperm motility and morphology assessment
  ◦ In the female, transrectal ultrasonography (US) or laparoscopic evaluation of the uterus and ovaries may be necessary.

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Reproductive

PATHOPHYSIOLOGY

Male Reproductive Function and Infertility

• Seasonality is pronounced in most species. BSE should be performed early in the breeding season. Atrophy of the testes (i.e., SC can decrease by up to 50%) with a decline in sperm quality occurs outside of the breeding season.
• SC varies with species and age. It is strongly correlated with sperm production and quality.
• Endocrine regulation of seasonality is similar to sheep and goats with increasing luteinizing hormone (LH) and testosterone (T) production as day length decreases.
• Libido is almost completely absent outside the breeding season (exception: *Axis*, which manifest a strong sex drive and produce sufficient sperm to impregnate females regardless of season).
• Male infertility may be due to congenital (hypoplasia), inflammatory (orchitis, epididymitis), degenerative (testicular degeneration or atrophy) or neoplastic processes.

Female Reproductive Function and Infertility

• Most species are seasonally polyestrous. Females breed in the autumn and give birth in the summer. Exceptions include tropical species (i.e., *Axis*), which are reproductively active year-round, and *Capreolus*, which are monovulatory.
• Hormonal control of the estrous cycle and ovulation is similar to that of small ruminants.
• Estrous cycle length varies by species, but tends to average around 18–24 days.
• Monotocous species include those that are larger-bodied, longer-living, and later-maturing, such as those within the genera *Cervus* (red deer, wapiti), *Dama* (fallow deer), *Axis* (chital deer), and *Rangifer* (reindeer, caribou).
• Polytocous species include those that are smaller-bodied, shorter-lived, and early-maturing, such as those within the genera *Odocoileus* (white-tailed deer, black-tailed deer, mule deer), *Alces* (moose), and *Capreolus* (roe deer).
• Female infertility may be due to severely pathologic processes. Freemartinism, gonadal hypoplasia, nabothian cysts in the cervix, cystic ovarian disease, pyometra, and metritis have all been reported as causes of infertility in various cervid species and may be detected with a thorough physical examination.

HISTORICAL FINDINGS

• Lack of sexual activity during the breeding season
• Excessive return to estrus
• Poor pregnancy rate
• Poor birthing rate

SIGNALMENT

• The family Cervidae represents close to 40 species and 200 subspecies.
• Commonly studied species include those within the genera *Cervus* (red deer, wapiti), *Dama* (fallow deer), *Axis* (chital deer), *Rangifer* (reindeer, caribou), *Odocoileus* (white-tailed deer, black-tailed deer, mule deer), *Alces* (moose), *Capreolus* (roe deer), *Ozotoceros* (Pampas deer), *Elaphurus* (Père David's deer), *Rucervus* (swamp deer, Barasingha).

PHYSICAL EXAMINATION FINDINGS

Male Reproductive Anatomy and Examination

• Scrotum is extra-abdominal, bifurcated, symmetrical, and similar in tone, shape, location, and function to that of domestic ruminants. An exception is the Pampas deer, whose scrotum is located in the inguinal region.
• Each testicle should be palpated to check for orchitis, epididymitis, masses, hypoplasia, or degeneration.
• In general, SC >18 cm in an adult male during the breeding season is indicative of normal sized testicles in white-tailed deer and mule deer.
• The penis is fibroelastic and held within the prepuce by the retractor penis muscle. The sigmoid flexure, if present, can readily be palpated through the skin posterior to the scrotum. The sigmoid flexure is not present in some species, such as *Cervus* and *Ozotoceros*. The penis should be exteriorized to inspect for adhesions, ulcerations, masses, or other pathologies that may prevent normal intromission.
• In species that display "thrash urination" during rut (e.g., *Cervus, Elaphurus*), the position of the urethral orifice is more dorsal on the glans to allow for upward expulsion of urine and sperm onto the ventral abdomen, neck, and throat. The glans varies, depending on species, from blunt and rounded to narrow and tapered.
• Though the anus and rectum are too small to allow for thorough manual palpation of the internalized reproductive organs, prominent abnormalities of the prostate and seminal vesicles may be palpable with a gloved, lubricated finger. If indicated, transrectal US may also aid in evaluation of the accessory sex glands.

Female Reproductive Anatomy and Examination

• Reproductive anatomy and function is similar to that of domestic ruminants. Similar protocols in evaluating reproductive fitness apply.
• Most females have 4 teats. There are reports of congenital absence of active teats, which should be suspected if sudden neonatal death occurs in a maiden female. Teats should also be inspected for signs of mastitis.
• A vaginal speculum can be used on medium and large cervid females to evaluate the vestibule, vagina, and caudal cervix for pathologies.
• The anus and rectum are too small to allow manual palpation of the internal reproductive organs except in the larger cervids; however, transrectal US may be employed for evaluation of the uterus and ovaries.

GENETICS

There are species differences.

CAUSES AND RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Differential diagnosis of poor reproductive performance requires a thorough evaluation of breeding record and examination of the males and females.

CBC/BIOCHEMISTRY/URINALYSIS

May be indicated in specific cases.

OTHER LABORATORY TESTS

Serology, bacteriology, and biopsy (endometrial and testicular) may be indicated in specific cases.

(CONTINUED) # BREEDING SOUNDNESS EXAMINATION: CERVIDAE

IMAGING
• Trasrectal US is indicated for the evaluation of ovarian function and uterine health.
• In the male, testicular US and transrectal evaluation of the accessory sex gland may be helpful.

OTHER DIAGNOSTIC PROCEDURES
Semen Collection and Evaluation
• Methods of collection include EE, AV, and manual stimulation. Higher quality samples are obtained using AV; however, due to the need for chemical or physical immobilization, EE is most common.
• Fractionation of the ejaculate is difficult but should be attempted to minimize the amount of seminal plasma and avoid urine contamination.
• Volume varies with relative size of species (e.g., *Odocoileus* 0.5–2 mL*; Rucervus* 1–2 mL; *Rangifer* 3–5 mL, *Elaphurus* 6–10 mL).
• Concentration ranges from 1.5 billion to 4 billion spermatozoa per mL (e.g., *Elaphurus, Rucervus, Odocoileus*).
• Overall sperm motility should be 30–50% at minimum.
• Morphologic defect classifications are similar to those of domestic ruminants. There should be a minimum of 80% normal sperm to be classified as reproductively sound.

ZOONOTIC POTENTIAL
Many reproductive diseases are zoonotic. Care should be maintained when collecting and processing semen.

PREGNANCY
Herd fertility should be closely monitored using an early and accurate method of pregnancy diagnosis

BIOSECURITY
CWD, TB, and brucellosis

PRODUCTION MANAGEMENT
• Decreased fertility or serving capacity of the buck can have drastic economic implications in affected herds.
• Tropical species have longer breeding seasons than cold-adapted species and may reproduce year round (e.g., *Axis*).
• In temperate environments, allowing tropical species to birth during the winter months may result in high perinatal mortality. Mating management should be employed to ensure birthing in the spring or summer, when there are optimal pasture conditions.

BREEDING SOUNDNESS EXAMINATION: SMALL RUMINANT

BASICS

OVERVIEW

• Breeding soundness examination (BSE) is a screening method to identify satisfactory potential breeding males.
• It is not a measure of fertility.
• The BSE is a quick, inexpensive screening test which can help identify unsuitable breeding males for a herd or flock.
• Animals should be presented at least 2 months prior to the intended breeding period such that identification of any abnormalities in the spermiogram may be addressed prior to breeding. Animals which are found unsatisfactory and for which treatment is not available or elected can be replaced.
• BSE in sheep includes four classifications: excellent, satisfactory, questionable, and unsatisfactory. There are no standards for goats; however, the sheep requirements are often used (minimum scrotal circumference, sperm motility and morphology, and physical examination findings).

INCIDENCE/PREVALENCE

10–20% of males are eliminated from breeding.

GEOGRAPHIC DISTRIBUTION

Worldwide.

SYSTEMS AFFECTED

• Reproductive
• Multisystemic

PATHOPHYSIOLOGY

• Ram/buck fertility depends on normal spermatogenesis, sperm production ability, and delivery.
• Sperm production is positively correlated to testicular volume.
• Sperm production is compromised if the male is in poor health or due to local pathologic processes such as degenerative or inflammatory changes.
• Semen delivery to the female can be hindered by poor health, poor vision, lameness, or penile and preputial abnormalities.

HISTORICAL FINDINGS

• History of the male should include purchase/travel history, general health history, vaccination and deworming history, and details of the nutritional program.
• Reproductive history should include previous BSE findings, results of previous breeding seasons (pregnancy rates), and the breeding management of the farm (multiple or single male herds/flocks).

SIGNALMENT

• Rams and bucks of breeding age.
• The BSE should be performed on all males prior to joining, or on any male for which a herd reproductive problem is identified (i.e., poor pregnancy rates or high rate of return to estrus).
• Prospective sires should be examined prior to or at weaning for major abnormalities (cryptorchidism, split scrotum, etc.). The first BSE should be performed at 6–8 months of age, prior to introduction to females.

PHYSICAL EXAMINATION FINDINGS

Physical Examination

The physical examination should include specific attention to the following:
• Teeth – There is an association between dental health and BCS in breeding rams. Animals with poor dentition may not be able to maintain weight during the breeding season.
• BCS – Males should be slightly overconditioned heading into the breeding season (BCS 3.5–4). Obese animals may have reduced fertility due to fat deposits causing increased temperature of the scrotum. Thin animals may not be able to maintain condition to serve females.
• Eyes – Normal eyesight is required of breeding males.
• Conformation –It is important that correct traits are passed to future generations. Any conformational defects may hinder the male's ability to serve females.
• Feet – males should be checked for common causes of lameness.
• Males should also be examined for any evidence of contagious diseases (mange, contagious lymphadenitis).

Reproductive Examination

The reproductive examination should include the following:
• Palpation of the scrotal contents. Males with enlarged, thickened tails of the epididymis should be suspected of epididymitis, sperm granuloma, or other pathology.
• Palpation of the testes. Outside of the breeding season, testes may palpate smaller or softer than normal. There can be up to 30% seasonal variation in testicular volume. In the breeding season, the testes should be turgid and resilient on palpation.
• Measurement of the scrotal circumference. Minimum circumference is required for satisfactory classification.
• Examination of the prepuce. Ulcerative balanoposthitis (pizzle rot) is a common finding, particularly in males on a high concentrate, high protein diet.
• Examination of the penis. The penis may be exteriorized prior to semen collection with the ram seated, or may be examined during electroejaculation for any pathologies.

Semen Collection and Evaluation

• Semen is collected by electroejaculation unless the male is trained to serve an artificial vagina.
• The volume, color, and consistency are noted. The color and consistency can give a rough idea of the concentration of spermatozoa per mL (thick and creamy > 1 billion, milky 0.5–1 billion, watery <0.5 billion).
• Motility can be assessed by either mass motility (on a scale from 0–5) or by individual motility (as a percentage).
• Morphology is assessed on eosin-nigrosin stained smears under oil (1000x magnification) or by examination of formalin-fixed samples under phase contrast (wet-mount).
• Cytology of the ejaculate is assessed using a differential stain or Wright-Giemsa to identify any leukocytes. Presence of PMNs should alert the possibility of infection with *B. ovis* in sheep.

GENETICS

In goats, the polled characteristic is associated with abnormalities of the reproductive tract.

CAUSES AND RISK FACTORS

• There are multiple causes of infertility or poor reproductive performance in the male. BSE is not intended to make a diagnosis but to screen males and eliminate those that are not suitable for breeding.
• Risk factors for infertility include general poor health, specific reproductive infectious diseases, and poor nutrition.

DIAGNOSIS

• There are four classifications for rams, based on scrotal size, sperm motility, and morphology. Any rams positive for *B. ovis* are automatically unsatisfactory. Bucks are considered satisfactory with a minimum of 30% motility and 70% normal morphology, with scrotal size dependent on breed.
• The classifications are as follows:
  ◦ Excellent
    ▪ Scrotal circumference: >35 cm for adults; >33 cm for rams < 1 year of age
    ▪ Sperm motility: >50%
    ▪ Sperm morphology: >90% normal
  ◦ Satisfactory
    ▪ Scrotal circumference: >33 cm for adults; >30 cm for rams < 1 year of age
    ▪ Sperm motility: >30%
    ▪ Sperm morphology: >70% normal
  ◦ Questionable
    ▪ Scrotal circumference: <33 cm for adults; <30 cm for rams < 1 year of age
    ▪ Sperm motility: <30%
    ▪ Sperm morphology: <70% normal
  ◦ Unsatisfactory
    ▪ Scrotal circumference: <33 cm for adults; <30 cm for rams < 1 year of age
    ▪ Sperm motility: <30%
    ▪ Sperm morphology: <50% normal

DIFFERENTIAL DIAGNOSIS

N/A

CBC/BIOCHEMISTRY/URINALYSIS

N/A

(CONTINUED) BREEDING SOUNDNESS EXAMINATION: SMALL RUMINANT

OTHER LABORATORY TESTS
Serologic testing for *Brucella ovis* should be included as part of the ram BSE.

IMAGING
• Testicular ultrasonography may be performed if abnormalities of the scrotum are identified. This examination is outside of the BSE.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FIDINGS
• In a study of more than 11,000 rams, 20.7% were classified as excellent, 50.4% as satisfactory, 10.8% as questionable, and 18.1% as unsatisfactory.
• The most common reasons for unsatisfactory classification were poor semen quality (43.8%), inflammatory causes (20%), physical abnormalities (15.5%), emaciation (14.2%), and ulcerative posthitis (4.6%).

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Males classified as questionable should be reexamined within 30–60 days.
• Prognosis for fertility is favorable if the diagnosed condition is treatable.

POSSIBLE COMPLICATIONS
N/A

CLIENT EDUCATION
• Clients should present the male for BSE annually prior to the joining period, and if any abnormalities are noted (decreased pregnancy rates in the flock, abnormalities of the scrotum or prepuce, etc.).
• All new rams to a flock should be tested for *B. ovis.*

PATIENT CARE
• Breeding activity should be monitored using marking harnesses.
• The diet should be monitored such that males do not lose too much body condition over the course of the joining period. The protein content should be reduced in males that have a history or diagnosis of ulcerative balanoposthitis (pizzle rot). Obesity should be avoided.

PREVENTION
N/A

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Contagious epididymitis is due to *B. ovis.*
• Polled character is associated to segmental aplasia and spermastasis in goats.

AGE-RELATED FACTORS
• Testicular degeneration can occur in older males or which have sustained thermal injury (high fever or hyperthermia).
• In one large study, 36.7% of rams >6 years were unsatisfactory, which was significantly higher than all rams <6 years of age.

ZOONOTIC POTENTIAL
B. ovis is not zoonotic.

PREGNANCY
Early pregnancy diagnosis on joined females provides more accurate information on male fertility.

BIOSECURITY
All rams or bucks introduced into a flock/herd should be quarantined prior to introduction to the resident population. They should also be screened for infectious diseases, vaccinated, and treated with antiparasite medications.

PRODUCTION MANAGEMENT
• Producers should have all males examined at least 2 months prior to the intended breeding period in order to find replacements for any unsatisfactory animals, or to treat any that may subsequently become satisfactory (cases of ulcerative posthitis, inappropriate body condition, etc.).
• All females joined to the male should be examined for pregnancy. The male should be examined annually.
• All rams positive for *B. ovis* should be culled.

SYNONYMS
N/A

Brisket Disease

BASICS

OVERVIEW

Brisket disease is a form of right-sided heart failure that affects susceptible cattle grazing at high elevations (>2,000 m). Synonyms are: bovine pulmonary hypertension, high mountain disease, high-elevation disease, and *cor pulmonale*. A similar disease affects captive exotic species maintained at high elevation, and includes maras (*Dolichotis patagonum*), cotton-top tamarins (*Saguinus oedipus oedipus*), capybaras (*Hydrochaeris hydrochaeris*), Bennet's wallaby (*Macropus rufogriseus*), nilgai antelope (*Boselaphus tragocamelus*), and scimitar-horned oryx (*Oryx dammah*).

INCIDENCE/PREVALENCE

• The disease is common and well-recognized at elevations >2,000 m.
• Prevalence tends to be herd-specific. It can be as high as 5%. It is higher when susceptible animals, including breeding stock, are introduced from low elevations. A low annual incidence (0.5%) is more common. Sporadic cases can continue to occur even when the bull battery is PAP (pulmonary arterial pressure)-tested annually and only bulls with low m-PAP scores are retained.
• Introduction of carrier bulls will increase the incidence of the disease.
• Large numbers of cases can be seen when non-acclimated cattle from predisposed pedigrees are moved from lowland to montane zones.

GEOGRAPHIC DISTRIBUTION

• Elevations >2,000 m. This cut-off is not absolute. Low rates of brisket disease are seen at or below elevations of 1,500 m.
• The disease occurs worldwide wherever domestic cattle are raised at high elevations. Most published accounts of brisket disease originate from affected areas of the United States (esp. Wyoming, Utah, New Mexico, and Colorado), and from Peru.
• Unexplained cases of brisket disease-like syndromes occur in feedlots in the American Midwest. At least some of these appear to represent animals that entered the feedlot in the early clinical stages of the disease, since they originated in high altitude herds.

SYSTEMS AFFECTED

• Cardiovascular
• Respiratory
• Digestive

PATHOPHYSIOLOGY

• Susceptible cattle at high elevations develop an inappropriate (high) pulmonary vasopressor response to alveolar hypoxia, leading to hypoxic arteriolar vasoconstriction. This is attributed in part to the relatively small size of the lungs relative to body weight in cattle. Increased vascular resistance results in pruning of portions of the pulmonary capillary bed, muscular hypertrophy of pulmonary arterioles, thickened tunica adventitia of small and medium caliber pulmonary arteries, and varying degrees of pulmonary thrombosis. The result is pulmonary hypertension. Increased vascular load leads to compensatory right ventricular hypertrophy. If this pulmonary hypertension is sustained, cattle develop right-sided heart failure.
• The disease has a distinct yet poorly defined inherited component. Inheritance is thought to involve a small number of dominant genes.
• Progression to clinical disease is accelerated by cold ambient temperatures, toxic plants such as *Astragalus* and *Oxytropis* spp. (locoweeds), and intercurrent pneumonia. A relationship exists between elevation (e.g. 2,000 m vs. 3,000 m) and likelihood of developing the condition.

HISTORICAL FINDINGS

Chronic poor-doing, heavy cattle at high altitude.

SIGNALMENT

Brisket disease is a syndrome of older calves and yearlings.

PHYSICAL EXAMINATION FINDINGS

• Cattle present with clinical signs typical of right-sided heart failure: enlarged jugular veins with or without jugular pulse; palpably large subcutaneous abdominal veins; hepatic enlargement that extends beyond the posterior costochondral margin (chronic passive congestion); lethargy and anorexia (terminally); weight loss; subcutaneous edema of the brisket area and submandibular tissue; tachycardia, often with cardiac murmur; weakness and collapse, especially when trailed; bulging eyes.
• Some degree of ascites is present. It may not be obvious clinically. Pleural or pericardial effusion is generally present.
• A common terminal event is diarrhea, associated with ascites, hepatomegaly, and mesenteric-mesocolonic edema.

GENETICS

• There is an appreciable genetic component. At the time of writing, no genetic test is available to identify carriers and to facilitate culling.
• All domestic cattle breeds are susceptible. It is sometimes stated that Angus cattle are particularly predisposed. This is probably related to the current predominance of the breed in the Rocky Mountain area of the United States.

CAUSES AND RISK FACTORS

• Disease is due to a combination of genetic predisposition, combined with residence at high elevation. The higher the elevation, the more rapid the onset. Contributing factors are cold temperatures, some toxic plants (esp. locoweeds), and (in feedlots) feeding for rapid weight gain.
• There is a strong suspicion that animals on high carbohydrate rations, including cattle at low elevations, are more prone to develop brisket disease.
• Cattle with naturally high pulmonary blood pressure. Cattle of any age with an mPAP of 49 mmHg at any elevation are at high risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Other causes of heart failure in cattle <1 year old. Common rule-outs are interventricular septal defects, other major congenital cardiac defects, bacterial valvular endocarditis, heart failure due to chronic bacterial papillary myocarditis, and pericarditis (e.g., due to traumatic reticulopericarditis).

CBC/BIOCHEMSTRY/URINALYSIS

Hepatic enzyme concentrations are elevated. Terminally, myocardial necrosis develops, resulting in elevated myocardial enzyme activities.

OTHER LABORATORY TESTS

• PAP testing
• The sensitivity of PAP testing depends on the altitude at which it is performed, combined with the experience of the veterinarian who performs the test. The higher the altitude, the greater the sensitivity of the test. This creates a dilemma for vendors living at low elevations: they may not wish to risk moving valuable bulls to high elevations so that they can be tested, as brisket disease may develop. Some veterinarians in Wyoming, Colorado, Utah, and New Mexico are proficient at performing PAP tests on bull batteries, and this constitutes a sizable portion of their practice.
• There is a need to develop a validated genetic test for one or more dominant genes thought to predispose cattle to brisket disease.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

Thorough physical examination with focus on cardiac auscultation.

PATHOLOGIC FINDINGS

• Grossly, HMD is characterized by myocardial hypertrophy affecting the free wall of the right ventricle and atrium, combined with dilation of the pulmonary trunk. The heart is abnormally globular. Serous atrophy of fat is generally present systemically in chronic cases. Fibrin tags on the epicardial surfaces are common. Associated lesions are hepatomegaly with chronic passive congestion ("nutmeg liver"), ascites, and edema of mesentery, mesocolon, and perirenal adipose tissue. The name "brisket disease"

notwithstanding, and although subcutaneous edema over sternum is found at necropsy, swelling of the brisket may not be clinically prominent in affected cattle. Many animals develop anteroventral pneumonia, most often due to *Pasteurella multocida* and other members of the bovine respiratory disease complex.

• Confirming the diagnosis at necropsy is straightforward. Dissect free the right and left ventricular myocardial free walls, along with interventricular septum (i.e., remove and discard atrial tissues and the great vessels). Separately weigh the right and left ventricular walls, and interventricular septum. The following ratio is found in healthy cattle: RVFW/(RVFW + LVFW + IVS) = 0.25 (i.e., the right ventricular free wall is no more than one-quarter the combined weight of ventricular muscles). By contrast, in brisket disease the ratio is >0.30, and in typically chronic terminal cases it is 0.40–0.50. Ventricular ratios, determined by weight, are more reliable than ventricular wall thickness.

• A definitive diagnosis can be made postmortem. If histologic confirmation is desired, the diagnostic laboratory should receive, at a minimum, samples of the following: lung (non-pneumonic); right and left ventricular free wall (separately identified); and liver. Pathologists who are inexperienced in the appearance of pulmonary arteries and arterioles in brisket disease should consult a standard veterinary textbook for the characteristic lesions. These can be missed, particularly when concurrent pneumonia is present in the submitted samples of lung. If in doubt, submit the entire pluck unfixed on ice packs for the laboratory pathologist to examine. Cardiocyte hypertrophy is diffuse in the right ventricular myocardium, so that measurements of their diameter—and comparison with those of left ventricular myocardium—may be needed to diagnose hypertrophy histologically.

TREATMENT

THERAPEUTIC APPROACH

• Some affected cattle early in the clinical course may be salvaged by moving them to lower elevations.

• Cattle with brisket disease should not be exercised or excited unnecessarily, or trailed long distances.

• Supportive treatment of affected animals may include diuretics, thoracocentesis, vitamin B complex (appetite stimulant), ± antimicrobial therapy.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUG(S) OF CHOICE

• Furosemide and digoxin
• Vitamin B complex

CONTRAINDICATIONS

Overdosing or chronic use of diuretics can cause electrolyte disturbances and dehydration.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• The prognosis for cattle with advanced heart failure is poor. Some can be salvaged by a combination of furosemide treatment and movement to low elevations.

• Some producers are proficient at recognizing affected cattle early in the clinical course. Such animals can be sold, on the principle of caveat emptor, thereby introducing the disease and its susceptibility trait(s) into other herds.

POSSIBLE COMPLICATIONS

N/A

CLIENT EDUCATION

Brisket disease is a herd problem. The best management tool at present is to use sires with low PAP scores (bulls with mPAP of <42 mmHg). Control is by testing introduced pedigrees for pulmonary arterial pressures.

PATIENT CARE

N/A

PREVENTION

• Exercise care when introducing pedigrees of unknown PAP status to high elevation operations.

• Trailing calves long distances (classically, from Forest Service land in late summer, to native range) is a common situation in which brisket disease is recognized. Producers performing necropsies themselves may diagnose the problem to their veterinarians as an outbreak of "peritonitis," due to fluid effusion in the abdomen.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Pneumonia (of any cause) precipitates clinical onset of terminal brisket disease.

AGE-RELATED FACTORS

Disease is typically seen in cattle <1 year of age.

ZOONOTIC POTENTIAL

No risk

PREGNANCY

N/A

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

• Obtain PAP measurements of all incoming bulls. Use only bulls that have a mPAP of <42 mmHg.

• If AI is used, solicit from vendors where the bulls were PAP-tested and use test results as part of sire selection.

SYNONYMS

• High-altitude disease
• *Cor pulmonale*
• Bovine pulmonary hypertension

ABBREVIATIONS

• AI = artificial insemination
• HMD = high mountain disease
• mPAP = mean pulmonary arterial pressure
• PAP = pulmonary arterial pressure

BRUCELLOSIS

BASICS

OVERVIEW

• Brucellosis refers to disease states induced by infection with one of several *Brucella* species.
• Economic losses in livestock are associated with reproductive failure in both males and females.
• In much of the world brucellosis remains an economic and public health concern.
• Zoonotic concerns have led to eradication or control programs in many developed countries.
• Efforts to prevent and/or control infection can impact regional and international trade.
• *Brucella* are Gram-negative bacteria and infect a wide range of mammalian hosts.
• Brucellosis is a cause of abortion in females and infertility in males.

INCIDENCE/PREVALENCE

• In much of the world, *Brucella* infection in domestic ruminant species is common.
• Targeted control programs have reduced the incidence of bovine brucellosis due to *B. abortus.*
• *B. abortus* is uncommon in North America, northern Europe, Australia, New Zealand, and Japan.
• Bison and elk in Yellowstone National Park remain infected with *B. abortus.*
• *B. abortus* control programs rely on widespread surveillance, slaughter, and herd-level eradication.
• Similar control and eradication programs have reduced *B. melitensis* in some developed countries.
• *Brucella ovis* infections occur in sheep-producing areas of the world.
• In North America *B. ovis* infection is most common in western range flocks.

GEOGRAPHIC DISTRIBUTION.

• Ruminant brucellosis has historically been seen worldwide.
• Control and eradication programs implemented to reduce human exposure have reduced the incidence of *B. abortus* and *B. melitensis* in many developed countries.
• *B. melitensis* is uncommon in North America and Northern Europe.

SYSTEMS AFFECTED

• In ruminants, infection commonly affects the reproductive system.
• Pregnant females often abort.
• Infectious organisms are shed in milk.
• Infection in males can result in epididymitis and orchitis.
• Arthritis and diskospondylitis occur less commonly in ruminants than in dogs and pigs.

PATHOPHYSIOLOGY

• Transmission of most ruminant *Brucella* species occurs through direct contact.
• Ingestion and aerosol exposure are efficient methods of transmission.
• Infectious organisms are most often ingested.
• Fluids or tissues associated with abortion or infected neonates are infectious.
• Placental tissues and fetal fluids are particularly heavily contaminated.
• Vertical transmission occurs through the milk of infected females.
• Following transmission, *Brucella* spp. establish long-term infection in many tissues.
• Recrudescence of infection with bacteremia is a hallmark of the disease.
• Localization of infection in the gravid uterus may be followed by abortion or delivery of a weak neonate.

HISTORICAL FINDINGS

Endemic herd infection is characterized by poor reproductive performance.

Brucella abortus

• Causes epizootic and endemic abortion in cattle.
• Abortion, weak neonates, retained fetal membranes, and reduced milk production are characteristic.
• Abortion due to *B. abortus* in cattle occurs in the second half of gestation.
• Epidemic abortion (*abortion storms*) can follow introduction of infection in a naïve herd.

Brucella melitensis

Abortions in goats usually occur from 4 months until term.

SIGNALMENT

• All ruminant species and many nonruminant species are susceptible.
• No breeds are considered resistant or immune.
• Disease is usually recognized in adult animals.
• *B. melitensis* infection occurs in goats and less commonly in sheep and cattle.
• *B. ovis* causes epididymitis and orchitis in rams and less commonly goats and cattle.

PHYSICAL EXAMINATION FINDINGS

Brucella abortus:

• Late-term abortion is associated with severe placentitis and retention of fetal membranes in cattle.
• Cotyledonary and intercotyledonary necrosis are typical findings but not pathognomonic.

Brucella melitensis:

• Infection in goats closely resembles *B. abortus* infection of cattle.
• Least species specific of the classical *Brucella* species.

Brucella ovis:

• Principally manifests as infectious epididymitis in breeding-age rams.
• Epididymitis is a serious cause of reduced fertility in endemic flocks.
• Occasional cause of abortion in the ewe.

GENETICS

• No breeds are resistant to infection.
• Host-adapted species create persistent reservoirs of infection.
• Infections with non-host-adapted species occur when multiple species are maintained in close proximity.

CAUSES AND RISK FACTORS

• Infection with various *Brucella species* follows contact with fluids, discharges, fetal membranes from infected females, and aborted fetuses or infected neonates.
• Group housing of rams is a risk factor for *B. ovis* infection.
• Vertical transmission occurs following ingestion of milk from infected animals.
• Venereal transmission is rare in cattle.

Brucella abortus:

Following an abortion, infected females may carry subsequent pregnancies to term, shedding infectious organisms at each parturition.

Brucella melitensis:

• Naïve herds are most often infected by introduction of an infected animal.
• Infected females efficiently transmit disease at the time of abortion or subsequent parturitions.

Brucella ovis:

Infection in ewes is not considered a major factor in persistence of flock-level infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Other infectious causes of abortion
  ◦ In cattle, *Leptospira* spp., *Campylobacter fetus*, *Listeria monocytogenes, Trueperella pyogenes, Histophilus somni,* epizootic bovine abortion, mycotic abortion, bovine herpesvirus 1, bovine viral diarrhea virus, bluetongue virus, *Neospora caninum, Tritrichomonas foetus,* others
  ◦ In sheep, *Campylobacter fetus, Campylobacter jejuni, Chlamydophila abortus*
• Noninfectious causes of abortion
  ◦ Stress
  ◦ Toxins
  ◦ Heritable anomalies
• Other causes of epididymitis and orchitis: e.g., *Histophilus somnus, Actinobacillus seminis*

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

• Bacterial culture provides definitive diagnosis.
• Serologic tests are commonly used for diagnostic screening and for surveillance programs.
• The Milk Ring Test provides a convenient method of screening dairy herds.

(CONTINUED) BRUCELLOSIS

• Various confirmatory serologic tests are run by accredited diagnostic laboratories.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• Serologic testing at the time of abortion is valuable. Paired serology is not usually required.
• Serologic screening of cattle entering commerce and the Milk Ring Test often detect infected herds.
• Bacteriologic culture of fetal tissues, associated membranes and vaginal discharges confirm infection.

PATHOLOGIC FINDINGS
• Severe placentitis is common in cattle and most other species.
• Placentitis following *B. melitensis* abortion in goats is reportedly less severe.
• Aborted fetuses often have bronchopneumonia.
• Epididymitis and orchitis in males.

TREATMENT

THERAPEUTIC APPROACH
B. abortus:
• Regulatory programs require slaughter or euthanasia of infected animals.
• Treatment is not allowed.
• Clearing a herd from quarantine requires serial whole-herd testing.

B. melitensis:
• Treatment not recommended.
• Quarantine and serial testing similar to *B. abortus* control necessary to clear a herd/flock infection.

B. ovis:
• Treatment of infected rams is seldom recommended.
• Success is limited and infected animals are the major reservoir.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
N/A

CONTRAINDICATIONS
N/A

PRECAUTIONS
• Bovine brucellosis is a reportable disease in the United States.
• State and federal animal health agencies must be notified following diagnosis.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
N/A

POSSIBLE COMPLICATIONS
N/A

CLIENT EDUCATION
See "Prevention"

PATIENT CARE
N/A

PREVENTION
• Avoid introduction of disease into uninfected herds/flocks.
• Maintain closed herds when possible.
• Test and isolate herd additions.
• Prevent interaction with established wildlife reservoirs.
• Vaccination of calves limits disease in cattle but will not replace appropriate biosecurity.
• Vaccination of adult bovines in infected herds requires regulatory approval.

MISCELLANEOUS

AGE-RELATED FACTORS
• Disease (abortion) is seen in adults.
• Infection at a young age may be followed by abortion many months later.

ZOONOTIC POTENTIAL
• Brucellosis is a major zoonotic infection seen worldwide.
• Brucellosis in humans can be associated with consumption of unpasteurized milk products.
• Contact with aborted fetuses, placentas, and uterine discharges can result in human infection.
• Human disease can be debilitating if not recognized and treated.
• Cattle and wild ruminants are the principal reservoirs for human infection with *B. abortus.*

PREGNANCY
Abortion is a common result of infection in ruminants.

BIOSECURITY
• Effective biosecurity protocols are necessary to prevent introduction into uninfected herds and flocks.
• Surveillance by regulatory agencies is a necessary part of an effective control or eradication program.
• Mandatory testing of animals at the time of slaughter is required in many countries.
• Routine milk testing using the Brucellosis Ring Test readily detects infection in dairy herds.

PRODUCTION MANAGEMENT
• In cattle, vaccination of female calves can be useful to increase herd resistance and marketability.
• In much of the world, RB-51 *B. abortus* vaccine has replaced Strain 19 as the vaccine of choice in cattle.
• Calfhood vaccination is allowed only in females between 4 and 12 months of age in the United States.
• Vaccination is regulated by the government in many countries.
• Vaccination of adult cattle is allowed only in special circumstances and only carried out by regulatory officials.
• *B. melitensis* Rev 1 vaccine for sheep and goats is available in some countries.

BUCKEYE (*AESCULUS* SPP.) TOXICITY

BASICS

OVERVIEW
• Approximately 13 species with the most commonly encountered being:
  ◦ California buckeye (*A. californica*)
  ◦ Sweet or yellow buckeye (*A. flava*)
  ◦ Western, white, Ohio, Texas, or fetid buckeye (*A. glabara*)
  ◦ Red buckeye (*A. pavia*)
  ◦ Georgia or painted buckeye (*A. sylvatica*)
  ◦ Horse chestnut (*A. hippocastanum*).
• Deciduous tree or shrub.
• Bark is gray or dark brown and can be either rough or smooth. It has an alternate branching pattern with a pair of sharp short thorns at each node.
• Leaves are palmate, compound, and opposite with 5 to 11 serrated leaflets. Blades of leaves are elliptical to ovoid, pinnate venation, and acute to acuminate apices.
• Flowers are white, yellow or red with four petals that are free and clawed, usually blooming in May or June.
• Seeds are glossy brown, bearing a large conspicuous, light-brown scar, approximately 2.5 cm in diameter.

GEOGRAPHIC DISTRIBUTION
• Throughout the United States.
• It is also native to Greece, Balkans, the Caucasus mountains, and northeast Turkey.
• It has been cultivated throughout Europe.

SYSTEMS AFFECTED
Nervous

PATHOPHYSIOLOGY
• Toxic compounds include: alkaloids, glycoside (aesculin), and saponins (escin).
• Aesculin or esculin, a lactone glycoside, is additionally a derivative of coumarin.
• Escin is a mixture of various saponins and has neurotoxic as well as hypoglycemic effects.
• Presumed neurotoxin is aglycone, which is a result of the hydrolysis of escin.

SIGNALMENT
• Bovine, ovine, caprine, and camelid species.
• Ruminants are most sensitive likely as a result of the reducing environment of the rumen.

PHYSICAL EXAMINATION FINDINGS
• Sawhorse stance
• Reluctance to move
• Incoordination, stilted gait
• Seizure and collapse

CAUSES AND RISK FACTORS
• History of exposure to the plant.
• Nuts or seeds, dried fruit, bark, leaves, flowers, and young growth including stump sprouts are the primary source of the toxin.
• Presence of plant or cuttings of the plant within the pasture.
• Toxic dose is not well established, it is approximately 1% body weight.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Botulism.
• Gossypol toxicity.
• Hypocalcemia, hypomagnesemia, and hypokalemia: There is a decreased chance of an acute outbreak involving multiple animals with a deficiency of calcium, magnesium or potassium.
• Monensin/other ionophore toxicities.
• Organophosphate and carbamate toxicity.
• Chlorinated hydrocarbon organochlorine insecticides.
• Other neurologic disorders, e.g., tick paralysis, paralytic rabies, louping ills, West Nile virus (sheep and goats), and other encephalitic agents.

CBC/BIOCHEMISTRY/URINALYSIS
• No characteristic changes.
• Hyperglycemia in experimentally induced toxin in calves.

PATHOLOGIC FINDINGS
No lesions but finding of plant material within gastric contents on gross pathology.

TREATMENT

THERAPEUTIC APPROACH
• Decrease absorption of the toxin thru administration of charcoal.
• Clinical signs are usually self-limiting.
• Recovery occurs within a few days.
• Supportive care required for severe cases.

MEDICATIONS

DRUGS OF CHOICE
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Recovery usually within 12–48 hours post-exposure.
• Death is rare.

PREVENTION
Avoid feeding buckeye plant material or grazing near buckeye trees.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

PRODUCTION MANAGEMENT
Restrict grazing of livestock near buckeye trees.

SEE ALSO
• Carbamate Toxicity
• Gossypol Toxicosis
• Grass Tetany/Hypomagnesemia
• Hypocalcemia

BURN MANAGEMENT

BASICS

OVERVIEW

• Burns in livestock are one of the most devastating forms of trauma:
  ◦ Thermal—fire (barn, brush, forest), heat (heat lamps, heating pads), hot solutions
  ◦ Electrical—lightning, electrocution
  ◦ Frictional—rope burns, abrasions
  ◦ Chemical—caustic agents, topical medications
  ◦ Ultraviolet—sunburn
  ◦ Radiation
  ◦ Freeze "burns"
• Burns in livestock commonly occur over back, face, udder, and teats, and over ventrum with brush fires.
• Classification of burns is based on depth to which burn penetrates skin and extent of body surface involved.
  ◦ First-degree burn involves superficial layers of epidermis; characterized by erythema, transient edema, and pain, and generally heals without complication or extensive scarring. Prognosis is good.
  ◦ Second-degree burn: Partial-thickness burns involving all epidermal layers but sparing hair follicles and sweat glands; characterized by erythema, pain, and vesicles (blisters), necrosis, and sloughing with superficial and eschar with deep second-degree burns; usually re-epithelialized with proper care, some scarring.
  ◦ Third-degree burn: Full thickness burns involving entire epidermis, dermis, and appendages and exposing deeper structures; local blood vessels and hair follicles destroyed; characterized by necrosis, ulceration, anesthesia, eschar, and extensive scarring. Require extensive wound care ± skin grafting.
  ◦ Fourth-degree burn involves entire skin, subcutis, underlying fascia, muscle, and tendon.
• The full extent of the thermal burn is difficult to predict immediately after injury.
• Burns are usually complex with body areas being affected to different degrees.
• The development of blisters, fluid separation of epidermis and dermis, and eschars may not appear for several days.
• Thermal injuries caused by fire are often associated with more than skin pathology:
  ◦ Fluid shifts, hypovolemia
  ◦ Electrolyte abnormalities (especially sodium)
  ◦ Hypoproteinemia (loss of plasma is maximal in first 12–24 hours)
  ◦ Extreme stress
  ◦ Smoke inhalation
  ◦ Immune suppression
• Extracutaneous complications of burns may be cardiopulmonary, ocular, hematologic, and renal.
• Animals suffering burns and/or smoke inhalation need to be closely monitored and repeatedly examined as signs and lesion development may be delayed. This is especially so with fluid therapy, which may precipitate pulmonary edema with fluid overload.
• Wound or burn infection is common in cattle and *Pseudomonas aeruginosa* is the most common organism to establish infection.
• Infection under eschars is a common problem.
• Animals with second-degree and third-degree burns over 50% of their body have a guarded prognosis.
• Poor prognosis if second-degree and third-degree burns affect more than 10–15% of body surface.
• Sequelae to burn injuries:
  ◦ Hypoproteinemia from protein exudate from wounds
  ◦ Progressive edema
  ◦ Hyperkalemia
  ◦ Burn-induced immunosuppression
  ◦ Progressive anemia
  ◦ Secondary infections; pneumonia, skin infections
  ◦ Multiple system involvement, i.e., renal shut down, eye damage
  ◦ Scarring
  ◦ Damage to eyelids, conjunctiva, cornea, anterior uveitis, exfoliation of lens capsule
• Sunburn
  ◦ White and light-skinned animals, lateral aspects of teats, ears, nose, areas covered with little hair are most susceptible to ultraviolet light, 290–320 nm.
  ◦ White-faced sheep, especially ears and face.
  ◦ Exposure to sunlight is associated with skin tumor development, especially on udder of white goats.
  ◦ Erythema, pain, swelling, blisters, erosions.
• Complications of teat burns include obstruction of teat orifice, distorted teats, and mastitis.

INCIDENCE/PREVALENCE

Usually sporadic

GEOGRAPHIC DISTRIBUTION

N/A

SYSTEMS AFFECTED

• Integument
• Musculoskeletal, depending on degree of burn

PATHOPHYSIOLOGY

• Thermal burns can result from scalding with hot liquids, contact with hot objects, or exposure to flames or radiant heat (sunburn).
• The three zones of a burn are the zones of coagulation, stasis, and hyperemia respectively. The zone of coagulation is the point of maximum damage. There is irreversible tissue loss due to coagulation of the constituent proteins. The zone of stasis has decreased tissue perfusion. The tissue in this zone is potentially salvagable. The goal in burn resuscitation would be to increase tissue perfusion to prevent any damage becoming irreversible. Pathology resulting from prolonged hypotension, infection or edema can convert this zone to an area of complete tissue loss. The zone of hyperemia is the outermost zone where tissue perfusion is increased. This tissue invariably recovers unless there is severe sepsis or prolonged hypotension.
• The release of cytokines and other inflammatory mediators at the site of the injury usually can have a systemic effect when approximately 30% or more of the body surface area is affected.
• Cardiovascular changes: Capillary permeability is increased, leading to loss of intravascular proteins and fluids into the interstitial compartments.
• Metabolic changes: The basal metabolic rate can increase up to 3 times the original rate. Without intervention there will be increased catabolism and compromise of the gut integrity.
• Respiratory changes: Inflammatory mediators cause bronchoconstriction which can result in respiratory distress.
• Immunologic changes: Nonspecific downregulation of the immune response, affecting both cell-mediated and humoral pathways.
• Electrical injuries: The current will travel from one point of the body to another, creating an entry and exit point. The tissue between these two points can also be damaged by its passage. The amount of heat generated is dependent on the voltage the animal is exposed to.
• Chemical injuries: They tend to be deep, as corrosive agents continue to cause coagulative necrosis until completely removed. Alkalis tend to penetrate deeper and cause more severe burns than acids.

HISTORICAL FINDINGS

Source of trauma is not always known and thorough history should be taken in order to better treat and provide an accurate prognosis.

SIGNALMENT

• No age, sex, or breed predilection
• Sunburn: light-skinned or white animals, white-faced sheep

PHYSICAL EXAMINATION FINDINGS

• Severity of burn determines signs present and may range from mild erythema and superficial scabbing to extensive tissue damage and necrosis with severe protein exudation.
• Wool is fire-retardant; burns on sheep most commonly found on legs and around face.
• Goats and cattle are likely to have burns on any part of body.

BURN MANAGEMENT (CONTINUED)

- Signs of sunburn:
  - Erythema, swelling, crusting of skin
  - Headshaking, pruritus
  - Discomfort during milking or nursing if udder or teats burned.
- Teat burns:
  - Mild burns: erythema, sloughing of outer, white, paper-thin tissue; areas of sloughing, crusting, and discoloration of tissue; milk appears normal; teat pliable on palpation.
  - Severe burns: teats tend to be dull brown or black, dry, and often corrugated; thick layer of tissue is sloughed, underneath is red hemorrhagic tissue; teat is leather-like and lacks pliability ± distorted.
- Healing lesions may be very pruritic causing animals to scratch or lick at affected sites.
- Non-dermatologic signs occur about 7 days after the onset of skin lesions: pyrexia.

TREATMENT

- Initial overall assessment of survivors—recumbent, severely burned animals who are suffering should be euthanized.
- Evaluation of animal's systemic and local injuries is essential. The main aim is to control decreasing circulatory volume.
- Repeat examination is necessary to determine response to therapy and development of delayed signs and lesions.

THERAPEUTIC APPROACH
Treatment is aimed at care of initial injuries, cardiovascular support, respiratory support, and prevention of secondary infection. The goal of treatment is epithelialization of the wound. First- and mild second-degree burns should heal well by epithelialization, while severe second-degree and most third-degree burns may require skin grafts. Burn patients are extremely heterogeneous with significant inter and intra-patient variation with regard to treatment and drug choice. Below are general guidelines for treatment of burn patients.

- Cool affected body areas to reduce heat retention and limit necrosis.
  - Hosing with cool water for 15 minutes (also removes burnt hair, crust, and debris)
  - Wet cool towels.
- Burn wound care:
  - Thorough cleaning with irrigation or dilute chlorhexidine solution (controversial); repeat 2 or 3 times daily.
  - Daily hydrotherapy.
  - Topical antimicrobial; use water-soluble emollient antimicrobial cream, silver sulfadiazine (Silvadene).
  - Use of hydrogel and nonadherent, absorbent dressings, which are not constrictive, may be indicated in some cases but must be kept clean and changed at appropriate intervals.
  - Avoid occlusive dressings, which produce a closed wound with bacterial proliferation and delayed healing.
  - Eschar over large second- or third-degree burns should be left undisturbed until natural sloughing occurs or if infection develops under eschar.
  - Blisters should be allowed to remain in place for 1–2 days on second-degree burns.
  - Wound debridement after 24–36 hours if necessary.
  - Wound allowed to heal by granulation.
- Systemic support:
  - Analgesia as needed—nonsteroidal anti-inflammatory drugs (concern these may delay healing).
  - Correct hypovolemia: rule of thumb—give 3–4 mL/kg of body weight for each percentage body surface involved. Very important to not overhydrate as it can precipitate development of pulmonary edema or generalized edema.
  - Maintenance of electrolyte and acid-base balance.
  - Plasma administration if severe hypoproteinemia.
  - Tetanus booster if indicated.
- Eye damage:
  - Cornea and eyelid damage are of particular concern.
  - With burns on face, cornea should be treated with artificial tears.
  - Gently remove debris from eye with saline-soaked cotton swab.
  - Inspect and fluorescein stain eye for ulcers.
  - Apply topical antibiotics with atropine.
  - Third eyelid flap if necessary to protect eye.
- Teat burns
  - Soothing, softening burn ointments, lanolin ointments, aloe vera
  - Antimicrobial ointment if skin surface sloughs
  - Maintain open teat orifice.
  - Healing is slow, takes many weeks to months.
- Sunburn
  - Remove from exposure to sunlight.
  - Provide shelter.
  - Soothing burn ointments, topical human sunburn medications, or aloe vera, topical steroids.
  - Application of pigmented teat dips.
  - Contamination of milk should be avoided.
  - For secondary bacterial infection, use topical or systemic antimicrobial agents.

SURGICAL CONSIDERATIONS AND TECHNIQUES
Third-degree burns may require skin grafting.

MEDICATIONS

DRUGS OF CHOICE
Many different medications and products are used in wound management and their use is highly case dependent and dependent on clinician preference. See "Therapeutic Approach."

CONTRAINDICATIONS
Systemic antimicrobials fail to penetrate local burn wound infections and may permit growth of resistant organisms; therefore, they should be reserved for use when there is documentation of a secondary site of infection (e.g., pneumonia).

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Lesions can persist for up to 12 weeks.

POSSIBLE COMPLICATIONS
- Complications will vary depending on specific etiology and location.
- Infections beneath eschars are common in cattle secondary to burn wounds.
- Chronic mastitis or teat obstruction may occur after damage to the skin of teats. When the face is involved, chronic vision impairment due to corneal opacity is possible.
- In general, complications are more common with severe burns where systemic support and further surgical interventions are required.

CLIENT EDUCATION
Advise clients of preventive measures (i.e., proper chemical storage, electrical safety, etc.) as well as the possible secondary wound complications.

PATIENT CARE
Monitor for signs of secondary infection and systemic involvement. See "Associated

Conditions" for information on fire-related burns specifically.

PREVENTION

See "Production Management"

MISCELLANEOUS

ASSOCIATED CONDITIONS

Smoke Inhalation

Involves carbon monoxide toxicity and smoke toxicity.

Three Mechanisms of Injury to Respiratory System

- First stage: Heat damage to upper respiratory tract, injury from toxic chemicals in smoke and carbon monoxide toxicity; usually signs within first 6 hours.
  - Inflammation, edema, and necrosis of nasal passages, pharynx, and larynx lead to airway obstruction ± laryngospasm.
  - Bronchoconstriction of lungs; inhalation of soot, noxious gases.
  - Carbon monoxide toxicity: hypoxemia and tissue hypoxia in all organs, especially brain; level above 10% carbon monoxide is consistent with toxicity.
  - Shock.
- Second stage: Formation of pulmonary edema
  - Within 12–72 hours after exposure.
  - Damage due to inflammatory mediators (cytokines, proteolytic enzymes, oxygen free radicals).
  - Obstruction of small airway from deposition of smoke material and inflammatory debris.
- Third stage: bronchopneumonia
  - Result of impaired immune system and exposure to pathogens.
  - May occur within 24–48 hours or 1–3 weeks after initial injury.

Clinical Signs

- Many signs may not be apparent for 1–2 days after fire.
- Oral burns, nasal mucosal swelling, pharyngeal swelling, laryngospasm, conjunctivitis.
- Hoarseness, expiratory wheezes, cough, stridor, tachypnea.
- Tachycardia.
- Bright mucus membranes with carbon monoxide toxicity may mask cyanosis.
- ±Cyanosis.
- Signs of hypovolemia.
- Signs of shock.
- Depression, disorientation, irritability, ataxia, or even comatose.
- ± Signs of septicemia or pneumonia.

Treatment

- Depends on stage and severity of injury.
- Oxygen support.
- Maintenance of airway: Tracheotomy if upper airway obstruction.
- Keep airways clean.
- Bronchodilators to counteract bronchoconstriction.
- Diuretics and anti-inflammatory agents (nonsteroidal anti-inflammatory drugs) to reduce edema and inflammation. Use of corticosteroids is controversial.
- Analgesics.
- Fluid therapy if hypovolemic, electrolyte imbalances, or acid-base derangements. Caution not to fluid overload if ongoing protein loss through burns or from vasculature.
- Plasma therapy if hyperproteinemia.
- Strict hygiene, nursing care, and optimal nutritional support.
- Appropriate antimicrobials based on culture and sensitivity from documented site of infection. Prophylactic antimicrobials are not recommended.

PRODUCTION MANAGEMENT

- Recovery time is prolonged with teat burns and extensive burns.
- Need to determine which animals to be euthanized or culled due to poor prognosis for successful recovery:
  - Animals with second- and third-degree burns over extensive area.
  - Burnt teats that will not withstand milking; mastitis is inevitable.
  - Badly burned feet may slough claws.
  - Facial burns involving cornea may lead to permanent stromal opacities.
- Teat burns:
  - Mild lesions have good prognosis.
  - Severe lesions have variable prognosis due to mastitis and secondary occlusion of teat canal and distortion of teat.
  - Mature adult cows are more likely to return to full function than heifers.
- Prevention of sunburn:
  - Gradual acclimation to exposure to sunlight.
  - Provide shade.
  - Application of sun blocking screens or ointments; use sunblocks with highest SPF available and those that are suitable for use in children; avoid PABA as it is not recommended as safe in children and little is known about its safety in animals.
  - Iodophor teat dips.
  - Pet animals may wear fly nets on ears, or hats or bonnets.

ABBREVIATION

PABA = para-aminobenzoic acid

CACHE VALLEY VIRUS

BASICS

OVERVIEW
• Cache Valley virus (CVV) is an arthropod-borne viral infection that belongs to the genus *Orthobunyavirus* in the family Bunyaviridae. CVV afflicts a variety of domestic and wild ruminants, and humans.
• The majority of CVV infections in ruminants are subclinical; however, embryonic mortality, fetal teratogenesis, and stillbirth occur in sheep, goats, and possibly other ruminants.
• Infected deer have 1–3 days of viremia and are considered amplifying hosts.
• In the southwestern United States, lambs and goat kids born in December, January, and February are more likely to show CVV-induced teratogenesis. This period coincides with increased rainfall and mosquito activity during the breeding season.
• Fetal susceptibility to CVV-induced pathology in sheep is higher when infection occurs during the first 48 days of pregnancy.

INCIDENCE/PREVALENCE
Serologic surveys in North America show widespread prevalence of CVV antibodies in domestic and wild ruminants.

GEOGRAPHIC DISTRIBUTION
CVV is endemic throughout the United States, Canada, Mexico, and some countries of Central America.

SYSTEMS AFFECTED
• Nervous
• Musculoskeletal

PATHOPHYSIOLOGY
• The CVV genome is composed of three negative sense, single-stranded RNA segments: large (L), medium (M), and small (S).
• CVV transmission to vertebrates occurs via the bite of infected mosquitoes, including several species of *Aedes, Psorophora, Anopheles, Coquillettidia, Culex,* and from *Culiseta inornata.*
• The virus circulates in an enzootic cycle involving mammal-biting mosquitoes and deer hosts.
• After infection, there is transient viremia, during which the virus can cross the placenta, inducing embryonic mortality or fetal malformation in small ruminants.
• Fetal malformation in experimentally CVV-inoculated pregnant ewes occurs during a narrow window of susceptibility before the ovine fetus becomes immunocompetent, an event which occurs at approximately 70–75 days of gestation.
• Infection of pregnant ewes before 32 days of pregnancy results in early embryonic death. Infection between 32 and 37 days causes musculoskeletal and CNS lesions. Infection between 37 and 48 days results mainly in musculoskeletal lesions.
• After 60 days of pregnancy, fetal infection results in production of fetal neutralizing antibodies and innate immune responses that clear CVV without malformation.
• There is no cross-protection against other related orthobunyaviruses.
• Ewes that are CVV seropositive at breeding are resistant to reinfection with CVV.

HISTORICAL FINDINGS
N/A

SIGNALMENT
• CVV infects a variety of wild and domestic ungulates and other animals, including sheep, goats, deer, cattle, pigs, horses, raccoons, woodchuck, mouflon, caribou, turtles, rabbits, and foxes.
• In sheep there is a positive relationship between seropositivity to CVV and age.
• In pregnant sheep and goats, CVV can cross the placenta causing embryonic death, mummification, or fetal malformation.
• No gender or breed predilection to infection.

PHYSICAL EXAMINATION FINDINGS
• In most adult animals, CVV infection is subclinical.
• In pregnant sheep and goats, CVV infection may result in embryonic mortality, fetal mummification, and various musculoskeletal or central nervous system anomalies.
• Dystocia may occur in ewes that deliver full-term malformed offspring.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Excessively wet summers preceded by years of drought result in high vector populations and outbreaks of CVV-induced fetal malformation.
• Ecologic modification of the environment, such as constructions of dams or the presence of rice fields, has been associated with an increased risk of vector-borne viral infections.
• The prevalence of CVV antibodies in sera of animals increases with age and reduces the risk of fetal malformation occurring in pregnant ewes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Main Drain, La Crosse, and San Angelo viruses induce similar fetal pathology.
• Bluetongue virus (BTV) serotype 8 or BTV of vaccine origin, and Border disease virus also may result in CNS malformations in sheep.
• Schmallenberg virus, Akabane, Rift Valley fever, Nairobi sheep disease, and Wesselsbron viruses are exotic to North America, but may cause similar fetal pathology.
• Other causes of teratogenesis include ovine hereditary chondrodysplasia (spider lamb syndrome) and teratogenic plants (*Lupinus, Oxytropis, Astragalus*).

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• CVV can be isolated from the blood of infected animals during acute viremia, though viremia is short-lived and in most cases virus isolation is unsuccessful.
• CVV serum antibodies can be demonstrated by serum neutralization, ELISA, complement fixation, and hemagglutination-inhibition.
• In adult animals, serum antibodies indicate previous exposure, but do not provide information regarding the infectious status of those individuals.
• Malformed fetuses that survive in utero for some time develop neutralizing antibodies and eliminate the virus. In these cases, assaying pre-colostral fetal serum for CVV antibodies establishes the diagnosis.
• In experimentally infected fetuses, CVV can be isolated up to approximately day 69 of pregnancy.
• In full-term malformed fetuses or neonates, virus isolation is always unsuccessful; however, viral nucleic acid can be detected by real-time PCR for some time after clearance of infectious virus.
• Lack of CW antibodies in sera of ewes lambing malformed fetuses rules out CVV as the cause.
• A recent duplex real-time RT-PCR for the California serogroup viruses serogroup and CVV has been reported but has not been validated.

PATHOLOGIC FINDINGS
• CVV infection of ewes during early pregnancy may result in embryonic mortality, fetal teratogenesis, stillbirth, and/or oligohydroamnios (deficiency of amniotic fluid).
• Congenital abnormalities of the fetus include arthrogryposis, hydranencephaly, hydrocephalus, microcephaly, porencephaly, cerebellar hypoplasia, scoliosis, torticollis, and lordosis.
• In multiple pregnancies, the degree and type of fetal pathology may be different in each fetus. In some cases, one fetus may be normal while others may have malformations.
• Fetal mummification occurs in some infected fetuses.
• In other ruminants, fetal abnormalities caused by CVV are less well documented.
• Histologic lesions are more frequently observed in the brain, spinal cord, and skeletal muscle of malformed fetuses.

(CONTINUED) CACHE VALLEY VIRUS

• Multifocal areas of necrosis with accumulation of necrotic debris are seen in the gray matter of the brain of affected fetuses.
• Brain cavities containing blood and evidence of neurophil rarefaction and malacia may be present.
• In the spinal cord, there is progressive cellular and parenchymal loss with micromyelia.
• Skeletal muscles of CVV-infected fetuses with arthrogryposis show loss of myofibers with scattered inflammatory infiltrates.
• Affected lambs often have meconium in pulmonary alveoli due to intrauterine stress.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Affected fetuses are born dead or die shortly after birth.

POSSIBLE COMPLICATIONS
N/A

CLIENT EDUCATION
N/A

PATIENT CARE
N/A

PREVENTION
• There are no vaccines available.
• Ewes and does seropositive to CVV at the time of breeding are protected from subsequent infection and its adverse effects on pregnancy; however, they are susceptible to infection by bunyaviruses of different serogroups, some of which may induce similar fetal pathology.
• Insect control is difficult because of the wide range of mosquito vectors and vertebrate hosts, and because insecticides may not be ecologically admissible.
• Breeding ewes or does after the first frost of the fall or early winter once mosquitos subside reduces the risk of fetal infection.
• The use of insecticide ear tags and topical permethrin reduces insect blood feeding in experimental sheep.
• Other insect control methods such as removing standing water sources may reduce abundance of vectors.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Developing fetuses are most susceptible to clinical disease with infection.

ZOONOTIC POTENTIAL
• CW is an indirect zoonosis; humans are infected by infected mosquitoes, but not directly from infected vertebrate animals.
• Infection can occur through accidental puncture with infected needles.
• The great majority of CVV infections in humans are subclinical; however, fever, myalgia, chills, headache, vomiting, and death occasionally occur. At least three cases of CVV-associated neurologic disease have been reported in humans.
• There is no conclusive evidence that CVV infection in humans causes fetal malformation.

PREGNANCY
Infection during pregnancy may result in embryonic death, abortion, and fetal malformation in ruminants.

CALF DIPHTHERIA/NECROTIC STOMATITIS

BASICS

OVERVIEW

• Necrobacillosis is a term used to describe any lesion associated with the Gram-negative, strictly anaerobic bacterium *Fusobacterium necrophorum*, including hepatic abscesses in cattle, foot abscesses, and infections of the oral cavity.
• Oral necrobacillosis is a term used to describe infections of the mouth and larynx with *F. necrophorum*.
• This includes "necrotic stomatitis" in which the lesions are restricted to the oral cavity and "calf diphtheria" in which the lesions are largely confined to the larynx, buccal, and pharyngeal mucosa.
• *F. necrophorum* is a ubiquitous bacterial organism commonly found in the environment (soil); and it is considered part of the normal flora of the oral cavity, respiratory tract, gastrointestinal tract, and urogenital tract of many omnivores and herbivores. The organism is commonly isolated from the soil of feedlots.
• Because of the lack of availability of suitable immunoprophylaxis, the control of *F. necrophorum* infection has depended mainly on the use of antimicrobial agents and management strategies.

INCIDENCE/PREVALENCE

• Sporadic, often with a higher incidence in fall and winter.
• Feedlot cattle are estimated to have a prevalence of 1–2%.

GEOGRAPHIC DISTRIBUTION

• Worldwide.
• More common in countries where animals are housed indoors in the winter (confined quarters), maintained in feedlots, or housed in unsanitary environments.

SYSTEMS AFFECTED

• Digestive
• Respiratory

PATHOPHYSIOLOGY

• *F. necrophorum* is a Gram-negative, non-spore-forming anaerobe that is a normal inhabitant of the respiratory and alimentary tracts of many species of animals.
• Two types of *F. necrophorum*, subspecies *necrophorum* (biotype A) and subspecies *funduliforme* (biotype B), have been recognized. These two biotypes differ morphologically, biochemically, and biologically. Subspecies *necrophorum* is more virulent in nature.
• Injury to the mucosa of the oral cavity, pharynx and larynx allows *F. necrophorum* to invade and infect the tissues. Inflammation, necrosis, and edema can subsequently constrict the larynx, causing dyspnea and painful swallowing.
• *F. necrophorum* is encountered frequently in mixed infections and, therefore, synergism with other pathogens may play an important role in infection.
• Laryngeal contact ulcers provoked by a variety of respiratory pathogens (viral and bacterial) might serve as an important factor in laryngeal invasion.
• Several toxins produced by *F. necrophorum*, including leukotoxin, endotoxin, hemolysin, hemagglutinin and adhesin, have been implicated as virulence factors.
• Leukotoxin and endotoxin are believed to be particularly important in overcoming the host's defense mechanisms and allowing infection to establish.
• Leukotoxin is known to be cytotoxic and causes vascular thrombosis.
• Infection leads to localized inflammation and edema of the laryngeal mucosa and cartilage; however, bacteremia and dissemination of organisms to the liver and other organs can occur in some cases.

HISTORICAL FINDINGS

Intensively managed cattle consuming rough or abrasive feeds, exposed to unsanitary feeding areas or feeding practices, or receiving recent oral bolus medication are at risk.

SIGNALMENT

• Necrotic stomatitis tends to occur in calves <3 months of age, most commonly between 2 weeks and 3 months of age.
• Necrotic laryngitis typically affects cattle <3–18 months of age.

PHYSICAL EXAMINATION FINDINGS

• Fever: temperature tends to be higher for calf diphtheria (106°F), and moderately elevated for necrotic stomatitis (103–104°F).
• Swollen (edematous) and hyperemic oral, pharyngeal, and/or laryngeal mucus membranes.
• The pharyngeal region may be painful on external palpation.
• The laryngeal opening is often reduced by edema and inflammation.
• Inspiratory dyspnea progressing to open-mouth breathing and stertor with extended head and neck.
• Necrotic erosions and ulcers (with diphtheritic membranes) are usually visible in the larynx/pharynx.
• Other signs include painful or difficult swallowing, salivation, a moist cough, anorexia, and depression. Fetid breath and bilateral nasal discharge might be noted.
• Chronic cases of laryngitis may display roaring respiration and a harsh, dry cough.

GENETICS

N/A

CAUSES AND RISK FACTORS

• The etiologic agent is *F. necrophorum*, though many cases involve mixed infections.
• *F. necrophorum* invades into abraded or damaged mucosa of the oral cavity, larynx or pharynx.
• Risk factors include rough or abrasive feeds, unsanitary conditions, administration of oral bolus medications, and infection with viral or bacterial respiratory pathogens.
• The incidence of disease tends to be highest in groups of animals that are kept in confined quarters under unsanitary conditions (housed cattle and feedlot cattle).
• Cattle <18 months of age are at higher risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Pharyngeal trauma, cellulitis or abscessation
• Severe viral laryngitis/tracheitis (e.g., BVD, IBR)
• Aspiration
• Actinobacillosis
• Pharyngeal neoplasia
• Mycotic stomatitis
• Dental abscess
• Maxillary or mandibular fracture
• Foreign body

CBC/BIOCHEMISTRY/URINALYSIS

CBC changes can include leukopenia resulting from neutropenia in acute cases; or leukocytosis with neutrophilia, monocytosis, and hyperfibrinogenemia in chronic cases.

OTHER LABORATORY TESTS

• Bacterial cultures can be obtained from deep within the oral and laryngeal lesions.
• Most specimen cultures contain a single *Fusobacterium* species (usually *F. necrophorum*).
• Specimen cultures will also commonly contain other obligate anaerobes together with facultative and obligate aerobes.

IMAGING

• Direct examination of the oral cavity can be aided with use of an oral speculum and a good light source.
• Laryngoscopy or endoscopy of the pharynx allows visual observation of the pharynx and larynx to identify inflamed and necrotic mucosa, but may exacerbate respiratory distress.
• Radiography or ultrasonography of the pharynx might also be useful to delineate differential diagnoses.

OTHER DIAGNOSTIC PROCEDURES

Postmortem examination of affected animals is recommended to confirm diagnosis and to rule out other diseases.

PATHOLOGIC FINDINGS

• Acute cases typically display edema and hyperemia of the larynx and/or pharynx which may surround centers of necrotic mucosa.
• Lesions are typically identified at the vocal processes and medial angles of the arytenoid cartilages. They may extend along the vocal folds and into the dorsal laryngeal musculature.

• The tongue, buccal mucosa, pharynx, cheeks, gums, palate, and trachea may also be involved.
• The regional lymph nodes may be swollen and/or hyperemic. May see necrosis of the palatine and pharyngeal tonsils.
• Chronic cases may present with tissue tracts extending into regions of necrotic cartilage, and may have deformed or misshapen arytenoid cartilages.
• On histopathology, areas of coagulation necrosis are surrounded by a zone of vascular reaction, leukocytes, and granulation tissue.
• The bacteria are typically arranged in long filaments (sometimes as rods or cocci), but are relatively difficult to demonstrate in tissue sections.

TREATMENT

THERAPEUTIC APPROACH

• Affected animals are typically treated with antibiotics and supportive medical care, which is best instituted early in disease to optimize success.
• Broad-spectrum systemic antimicrobial therapy should be provided for several days using short- or long-acting preparations according to acceptable standards for food animal practice.
• Cases with significant dyspnea may require tracheotomy.
• Fluids and nutritional support may be necessary for particularly compromised and valuable animals.

SURGICAL CONSIDERATIONS AND TECHNIQUES

• In severe cases, a tracheotomy can be performed if necessary to obtain a patent airway.
• Severe, chronic cases may require surgical debridement to remove necrotic and/or granulation tissue and to drain laryngeal abscesses.
• Subtotal arytenoidectomy may be indicated in severe cases involving chronic chondritis (inflammation of the cartilage).

MEDICATIONS

DRUGS OF CHOICE

• Antibiotic options include:
  ◦ Procaine penicillin: 22,000 U/kg, IM, q24h or q12h
  ◦ Oxytetracycline: short-acting preparation: 11 mg/kg, IV or SC, q24h; long-acting preparation: 20 mg/kg, SC, q72h
  ◦ Sulfonamide agents: Sulfamethazine - initial/loading dose of 140 mg/kg IV, followed by 70 mg/kg IV q24h OR 150 mg/kg PO q24h for 3–5 days. Treatment not to exceed 5 days.
• Nonsteroidal anti-inflammatory drugs can reduce fever, inflammation and pain; options include aspirin (100 mg/kg, PO, q12h); flunixin meglumine (1.1–2.2 mg/kg, IV, q24h or divided q12h); or ketoprofen (3 mg/kg, IM or IV, q24h).
• In significantly dyspneic animals, a single dose of dexamethasone (0.05–0.2 mg/kg, IV or IM) may help to reduce laryngeal edema.
• The use of mild topical disinfectants and antiseptics (e.g., Lugol's or povidone iodine) has been described.

CONTRAINDICATIONS

Oral medications should be avoided initially if possible to prevent additional damage to the irritated oropharynx and larynx and because affected animals have reduced ability to swallow.

PRECAUTIONS

Appropriate milk and meat withdrawal times must be followed for all pharmaceutical compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• If the condition is detected early and treated aggressively, the prognosis is guarded to good. Case mortality has been reported as approximately 15–20%.
• The disease course for acute cases is in the range of 7–10 days, but may be as long as 2–3 months for chronic cases.
• Severe complications can occur, especially if diagnosis is delayed. Several reports suggest that approximately 20% of affected animals progress to chronic disease. The prognosis for chronic cases (especially cases with bilateral involvement) is guarded to poor.
• Untreated calves tend to die from toxemia, upper airway obstruction/asphyxia, and pneumonia, usually within 2–7 days.
• A 60% success rate for surgical intervention in severe and chronic cases has been reported.
• Involvement of the laryngeal cartilage (ulcers and necrosis) often leads to a delay in healing or failure to recover.
• It is recommended that chronic, unresponsive cases be culled.

POSSIBLE COMPLICATIONS

• Systemic toxemia and disease.
• Chronic infection of the laryngeal cartilages leading to chronic coughing.
• Pneumonia (aspiration or hematogenous spread).

CLIENT EDUCATION

• Provide good-quality forage and minimize abrasive materials such as sticks and cockleburs in hays and pastures.
• Keep feed areas, mangers, and feeding equipment clean.
• Early recognition is essential for successful treatment.

PATIENT CARE

• Monitor the ability to breathe and swallow appropriately while diseased.
• Provide soft and palatable food sources, water, and shelter from the elements.

PREVENTION

• Maintain sanitary feeding areas and equipment (minimize exposure to dust and inhaled irritants).
• Avoid rough feeds.
• Apply control measures for viral and respiratory pathogens.
• Identify infected animals early to prevent spread.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Aspiration pneumonia

AGE-RELATED FACTORS

Most commonly cattle 3–18 months old are affected, with necrotic stomatitis usually observed in calves <3 months and necrotic laryngitis in calves >3 months.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

BIOSECURITY

• Although the organism is fairly ubiquitous, measures to control other respiratory diseases may reduce the incidence of necrotic laryngitis.
• Proper hygiene precautions and disinfection of potential fomites in calf pens and feeding/drinking places.

PRODUCTION MANAGEMENT

• Observation and early diagnosis of cases is critical to minimize the impact on a feedlot.
• Preventive measures and early treatment can reduce the total number of animals affected.
• Management of feeding protocols and practices, and control of respiratory pathogens in intensively managed cattle, can be used to reduce the incidence of this disease.
• This disease is usually sporadic in nature and the economic losses are primarily due to reduced live weights, inefficient feed conversion, expensive treatments, and fatalities.

SYNONYMS

• Necrotic/necrotizing stomatitis, necrobacillary stomatitis, oral necrobacillosis.
• Calf diphtheria, necrotic/necrotizing laryngitis, laryngeal necrobacillosis.

CALF DIPHTHERIA/NECROTIC STOMATITIS (CONTINUED)

• *Fusobacterium necrophorum* was previously named *Sph(a)erophorus necrophorus*, *Actinomyces necrophorus*, *Corynebacterium necrophorum*, and *Fusiformis necrophorus*.

ABBREVIATIONS

• BVD = bovine viral diarrhea
• IBR = infectious bovine rhinotracheitis

BASICS

OVERVIEW

• With a few exceptions, camel diseases are similar those of domestic ruminants. Diagnostic approach is also similar, although physical examination and interpretation of laboratory data may present some challenges for veterinarians not familiar with these species. • Some diseases of critical importance to camel production are region specific (e.g., trypanosomiasis, theileriosis, hemorrhagic disease, tuberculosis, brucellosis, camel pox).

INCIDENCE/PREVALENCE

• Incidence of various infectious diseases in countries where camels are important production animals shows that the most important are: trypanosomiasis, brucellosis, camel pox, gastrointestinal and external parasites, hydatidosis, caseous lymphadenitis (*Corynebacterium pseudotubeculosis*), clostridial diseases, mastitis, and tuberculosis. • Neonatal and juvenile disorders are dominated by infectious enteritis (collibacillosis, salmonellosis), respiratory disorders (pasteurellosis), and parasite infestation (coccidiosis). • In a Jordanian study, intestinal parasite ova were detected in 98% of camels; one or more species of external parasites were found on the skin of all camels; 33% of animals had nasal myiasis; and hydatid cysts were identified in 44% of the slaughtered animals. Sarcoptic mange (*Sarcoptes scabiei* var. cameli) and trypanosomiasis were diagnosed in 83% and 33% of examined camels, respectively. Rabies virus was detected in eight camels by fluorescent antibody examination. • Noninfectious diseases are dominated by nutritional deficiencies (selenium deficiency, energy and protein deficiency) and foreign body accumulation within the first and second stomach compartments.

GEOGRAPHIC DISTRIBUTION

• Worldwide, specific diseases vary depending on environment and management. • Regional differences exist and depend on environment, type of management (nomadic vs. sedentary), and epidemiologic situation.

SYSTEMS AFFECTED

Multisystemic

PHYSIOPATHOLOGY

Pathophysiologic processes for specific disease are similar to those described for ruminants.

HISTORICAL FINDINGS

• The ability to obtain a thorough history depends on the type of management. Nomadic herds are particularly challenging. Individual animals or specialized operations (dairies, individual pleasure animals, racing animals) may have a more complete history. • History should take into account any animal movement, environment and management.

SIGNALMENT

• Both species of *Camelus* (dromedary camel or *C. dromedarius*, Bactrian camel or *C. bactrianus*) are affected by the same diseases. • Racing animals are more predisposed to gastrointestinal and renal disorders as well as musculoskeletal problems. • Dairy camels are more predisposed to hypocalcemia, mastitis, and postpartum disorders. • Neonates and juvenile animals are predisposed to infectious or gastrointestinal problems.

PHYSICAL EXAMINATION FINDINGS

Physical examination is similar to that of other large animal species. The process starts with a thorough history, signalment, and management.

Temperature

• Camel body temperature is affected by ambient temperature, state of hydration, and seasonal variations. • Morning rectal temperature may vary between 35.5 and 37.5°C while afternoon temperature varies between 38.5 and 41°C. • Young camels (<6 months) have a 0.5 to 1.0°C higher rectal temperature than adults. • Temperatures >39°C should be considered suspect and indicative of fever on cool days or when taken in the morning.

Respiratory Frequency

• Determined by visual observation, palpation of the chest or flank or auscultation. • In cool environments respiratory frequency is 5 to 8 breaths per minute. • On hot summer days respiratory frequency increases to 10 to 12 per minute.

Pulse

• Heart rate is best determined by auscultation. • Normal resting heart rate is 30 to 36 beats per minute. • Heart rate may increase to 40 to 44 bpm in excited animals. • Heart rates above 45 bpm are significant findings in febrile animals or animal with severe pain or intoxication.

CRT and Mucus Membrane Color

Evaluated similarly to ruminants. It may be difficult to appreciate in pigmented animals.

Lymph Nodes

The major lymph nodes can be palpated for reaction as in cattle. The palpable external lymph nodes include the parotid, maxillary, prescapular (superficial cervical), inferior cervical, thoracic, cubital, ilial, and popliteal.

Symptoms

• A systemic disease state may be suspected if the animal has poor appetite and reduced activity. • Specific clinical signs depend on the disease, but sick camels often display a depressed look and prolonged sternal or lateral recumbence. Increased lacrimation is often observed.

GENETICS

There are differences in disease incidence between dairy camels and racing or riding camels.

CAUSES AND RISK FACTORS

Common causes of disease in camels include • Viral (camel pox, rabies) • Bacterial (brucellosis, hemorrhagic disease, anthrax, salmonellosis, tuberculosis, caseous lymphadenitis) • Parasites (trypanosomiasis, coccidiosis, echinococcosis, helminths) • Nutritional: selenium deficiency
Risk factors include
• Geographic location, age, type of management, animal concentration

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Abdominal Pain (Colicky Syndrome)

• Abdominal pain is recognized by behavioral changes such as excessive rolling, kicking at the belly, stretching or overextension of the hind legs, loss of appetite or selective eating and vocalization. • Severe pain is generally accompanied by an increased heart rate and reluctance to rise or move. • The most common reasons for abdominal pain in camels include: ◦ Impeding abortion, parturition or dystocia (uterine torsion) ◦ Gastrointestinal obstruction; can occur at any level of the GI tract (e.g., sand impaction, fecolith/enterolith, intestinal torsion, volvulus or intussusception) ◦ Gastric ulcers ◦ Traumatic reticulitis/pericarditis ◦ Rumen acidosis/grain overload ◦ Rumen tympany, bloat ◦ Enteritis ◦ Peritonitis ◦ Nephritis ◦ Urolithiasis (males)

Abortion and Early Pregnancy Loss

• Trypanosomiasis • Brucellosis • Q-fever • Chlamydia • Toxoplasmosis • Neosporosis • Twining • Starvation • Iatrogenic (prostaglandin F 2 alpha, steroidal anti-inflammatory drugs) • Trauma

Anemia

• Heavy parasitism (e.g., coccidiosis, trypanosomiasis, haemonchosis, tick infestation) • Theileriosis • Chronic illnesses such as paratuberculosis and neoplasia • Bleeding disorder; ulcers, trauma, coagulopathy

Coughing/Dyspnea

• Dust • Respiratory viral infection/influenza • Pneumonia (bacterial or aspiration) • Camel pox • Hemorrhagic disease • Lung worm • Melioidosis • Tuberculosis • Soft palate trauma, impaction • Nasal bots • Toxoplasmosis • Pneumothorax • Cardiac dysrhythmias

Diarrhea, Adult

• Stress, nervous camels • Dietary • Internal parasites • Paratuberculosis • Salmonellosis

CAMEL DISEASES (CONTINUED)

• Trypanosomiasis (some countries)
• Hemorrhagic septicemia (clostridial)

Diarrhea, Young Animal

• Neonatal viral diarrhea (i.e., rotavirus, coronavirus) • Colibacillosis • Dietary (poor quality milk replacer) • Salmonellosis • Coccidiosis • Internal parasite

Dysphagia

• Tongue laceration • Fractured mandible • Tooth abscesses • Lump jaw (actinomycosis) • Soft palate impaction/trauma in rutting male • Cranial never paralysis • Rabies • Pharyngitis

Head Tilt

• Ear infections • Wry neck (torticollis, often traumatic) • Head injuries

Lacrimation/Photophobia

• Keratoconjunctivitis • Corneal ulcers • Myasis • Occluded nasolacrimal duct

Lameness

• Arthritis (common in old animals particularly in wet areas) • Upward fixation of the patella • Racing or riding camel myopathy • White muscle disease • Sole ulcers • Pododermatitis • Cracked or worn foot pads • Fractures • Tendonitis (racing or working camels)

Nasal Discharge

• Nasal bots, rhinitis • Camel pox • Head trauma • Hemorrhagic disease

Neurologic Signs

• Polioencephalomalacia • Hemorrhagic disease • Head trauma • Meningitis • Envenomation • Anthrax • Botulism • Rabies

Skin Diseases

• Contagious ecthyma • Camel pox • Various ectoparasite (mange, tick infestation) • Dermatophilosis • Ring worm • *Corynebacterium pseudotuberculosis* abscesses

Sudden Death

• Heart failure • Vitamin E/selenium deficiency • Monensin toxicosis • Anaphylaxis • Enterotoxaemia • Botulism

Weight Loss/Failure to Thrive

• Failure of passive transfer • Malnutrition • Vitamin E/selenium deficiency • Heavy parasitism • Chronic diseases (paratuberculosis, renal failure) • Dysphagia (due to swollen soft palate or teeth abscesses, broken jaw)

Common Infectious Diseases

• Rinderpest • Rift Valley fever • Pasteurellosis • Rabies • Anthrax • Tuberculosis • Camel pox • Contagious ecthyma • Ringworm • Staphylococcal dermatitis (contagious skin necrosis) • Dermatophilosis • Hemorrhagic disease (*Bacillus cereus* intoxication) • Tetanus • Lymphadenitis (*Corynebacterium pseudotuberculosis*) • Brucellosis (abortion, orchitis) • Leptospirosis • Q fever

Common Parasitic Diseases

• Mange • Tick infestation (tick paralysis) • Lice • Nasal bots (*Cephalipina titilator*) • Lungworms (*Dictyocaulus* filarial, *D. viviparous*) • Hydatidosis (echinococcosis, hydatid cysts) • Coccidiosis

Common Nutritional/Metabolic Disease

• Hypocalcemia (retained placenta, uterine prolapse) • Grain overload/acidosis • Hyperlipemia (pregnancy toxemia) • Vitamin A deficiency • White muscle disease (selenium and vitamin E deficiency) • Hypomagnesemia • Cooper deficiency

CBC/BIOCHEMSTRY/URINALYSIS

• Blood samples can be easily collected from the jugular vein. • Interpretation of CBC and blood biochemistry should take into account age and state of hydration of the animal (see Table 1 for reference ranges). • Urine production is highly variable. Samples are collected by free catch in males or females or by catheterization in the female. ◦ Urine is clear and pale yellow. ◦ Specific gravity varies from 1.020 to 1.070 and depends on the degree of hydration. ◦ Urine pH ranges from 6 to 7 in resting animals and 8 to 9 after effort (work, racing). ◦ Other constituents: Urea 0.18 to 3.6 g/dL (1.95±0.38 g/dL), uric acid 60.41 ±10.46 mg/dL, creatinine 0.58 ± 0.128 g/L, chloride (4.5 ± 1.3 g/dL), phosphate (1.71 ± 0.22 mg/dL), sulfate (77.6 ± 12.4 mg/dL). ◦ Protein is low (1+) but increases after prolonged exercise. ◦ Calcium oxalate, calcium hydrogen phosphate, ammonium urate, and triple phosphate may also be present in up to 30% of the samples.

OTHER LABORATORY TESTS

• Fecal analysis: Fecal balls should be well-formed, shiny and free of mucus. Diarrhea may be a response to high stress or training. ◦ Obstruction should be suspected if no feces are produced in a 24 hour period. ◦ Fecal sample should be taken from a fresh defecation or removed from the rectum. ◦ Feces can be analyzed for parasite eggs using the standard methods. • Serology and microbiology are indicated if specific infectious diseases are suspected.

IMAGING

• Transabdominal ultrasonography is very helpful in colic or reproductive problems. • Percutaneous flank ultrasonography for renal disorders. • Percutaneous thoracic ultrasonography for lung evaluation. • Transrectal ultrasonography for urogenital and caudal GI evaluation. • Radiography, computed tomography, and ultrasonography are used for musculoskeletal disorders.

OTHER DIAGNOSTIC PROCEDURES

• Serology for disease testing • Skin biopsy

PATHOLOGIC FINDINGS

Pathologic findings depend on cause and course of the disease.

TREATMENT

THERAPEUTIC APPROACH

Depends on the diagnosis but is generally similar to that applied to bovine and other camelids.

SURGICAL CONSIDERATIONS AND TECHNIQUES

Depends on the diagnosis but is generally similar to that applied to bovine and camelid with some adjustment of medication choices and doses.

MEDICATIONS

• Information on the pharmacokinetics of common veterinary drugs in camels is limited. • There are no established withdrawal times for pharmaceuticals used in camels. It is important to keep in mind that camels are food-producing animals (milk and meat) in many areas of the world.

Antimicrobials

• Most antimicrobials used in veterinary medicine have been used in camels without any overt adverse effects. • In general the route of administration and dosage are based on recommended guidelines for the bovine. • Sulfonamides are safe in the camel due to the lower degree of acetylation compared with domestic ruminants. Sulfadimidine or sulfamethoxypyridazine are used at the dose of 55–70 mg/kg bw IV q24h. • Penicillin G dosage: 10,000–20,000 IU per kg bw, SQ or IM, q24h. • Long-acting penicillin (Procaine penicillin 150 mg/mL and benzathine penicillin 115 mg/mL) 20–30 mL/500 kg q72h. • Ampicillin: 4–8 mg/kg bw IV, q24h. • Enrofloxacin 1.6–3 mg/kg bw, q12h (oral solution is used at 2.5 mg/kg). maximum dose of 5 mg/kg is used in cases of pasteurellosis or salmonellosis. • Oxytetracycline: 5–10 mg/kg bw IM q24h; long-acting tetracycline can be used at 20 mg/kg q48h. • Chloramphenicol: 10–30 mg/kg bw IM, q12h (not approved in many countries; illegal in Canada and the United States). • Streptomycin: 8 mg/kg bw IM, q12h. • Rifampin and erythromycin have also been used in camels for specific conditions at the same dosage and length of treatment as equines. • Gentamycin 3–4 mg/kg bw IM, q12h. Gentamycin is known to be extremely nephrotoxic in young camels and dehydrated animals. • Tylosin 10 mg/kg bw q8h. • Metronidazole: 5–10 mg/kg • Griseofulvin: 0.25 g/45 kg (not available in some countries; illegal for use in Canada and US). • Trimethoprim (2.7 mg/kg bw)/Sulfadiazine (13.3 mg/kg bw) daily IM or IV.

(CONTINUED) CAMEL DISEASES

Phosphorus (mg/dL)	—		3.9–6.8
Sodium (mmol/L)			129–161
Potassium (mmol/L)	—	—	2.9–5.9
Chloride (mmol/L)	—	—	114–120
pH	—	—	7.3–7.8

Anthelmintics and Other Antiparasitic Drugs

• All types of bovine anthelmintics can be used safely in camels at the same or slightly higher dosage. • Levamisole has been reported ineffective and possibly toxic in camels. • Oral: albendazole 7.5 mg/kg, oxfendazole 5–7.5 mg/kg, fenbendazole (6–7.5 mg/kg, morantel tartrate 35 g/500 kg bw). • Subcutaneous: ivermectin (0.2 mg/kg), moxidectin 0.15 mg /kg bw (helminths, suckling lice, and mange mites). • Pour On: ivermectin 5 mg/10 kg bw. • Monensin is very toxic and can be fatal in camels.

Antiinflammatory Drugs

• Methylpredinosolone: 200 mg IM for allergic reactions in adult camel; can cause abortion in the last half of pregnancy. • Dexamethasone: same dose as the bovine. Do not use in pregnant animals. • Flunixin meglumine: 1 mg /kg IV q24h. • Phenylbutazone: use with care in food-producing animals.

Hormones

• Progesterone: 100 mg/day for synchronization of follicular waves (14 days) and for maintenance of pregnancy (throughout pregnancy). • HCG: induction of ovulation 1,500–3,000 IU IV. • $PGF2_\alpha$ and analogues: dinoprost (25–35 mg, IM), cloprostenol (500–750 µg, IM). • Oxytocin: 5–20 IU for milk letdown, 20–40 IU for retained placenta, IM or IV. • GnRH: buserelin 10 µg, for induction of ovulation.

Sedatives and Anesthetics

• Propofol: 2 mg/kg alone or 0.25–1 mg/kg if premedicated with xylazine and valium. • Detomidine: 0.01–0.08 mg/kg bw, IM or slow IV. • Ketamine: 2–5 mg/kg in association with xylazine. • Reserpine for long-distance transport 1.5–2 mg initially and then on alternate days. • Xylazine: 0.2–1 mg/kg (reversed by yohimbine hydrochloride 0.125 mg/kg IV mixed with 4-aminopyridine 0.3 mg/kg).

Other drugs

• Polysulfated glycosaminoglycan, glucosamine, chondroitin: see horse dosage. • Vitamin B complex for polioencephalomalacia, same dosage as for the bovine. • Anti-diarrhea agents: use same product and dosage as for the bovine. • Laxatives: methylcellulose, magnesium sulfate, same dosage as for the bovine. • Diuretics: furosemide 0.25–1 mg/kg in the adult. • Topical ointments: similar dosages as in cattle. • Buparvaquone, treatment of theileriosis (125 mg/kg bw, IM repeat in 48–72h if necessary). • Trypanocide: bis(aminoethylthio)-4 metaminophenylarsine dihydrochloride (Cymelarsan®): 25 mg/100 kg bw IM, safe in pregnant animals.

CAMEL DISEASES (CONTINUED)

CONTRAINDICATIONS
• Appropriate milk and meat withdrawal times must be followed. • Levamisole has been reported ineffective and possibly toxic in camels. • Ionophores (monensin) are toxic to camels.

PRECAUTIONS
• Be aware of nephrotoxic drugs. • Individual reactiosn have been observed with some antibiotics and trypanocides.

POSSIBLE INTERACTIONS
Depend on drugs

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Varies depending on disease. Prognosis is often guarded in major outbreaks of camel pox, trypanosomiasis, brucellosis, and tuberculosis. • Herd nutritional and parasite problems have a favorable prognosis if treatment plan and corrective measured are developed early. • Individual cases may justify advanced medical treatment when animals are very valuable (breeding males, racing animals, embryo transfer donors).

POSSIBLE COMPLICATIONS
Dependent on disease

CLIENT EDUCATION
• Proper nutrition and health care • Early recognition of signs of illness

PATIENT CARE
Dependent on disease or disorder

PREVENTION
• Major contagious disease should be monitored by regular testing and elimination of positive animals. • Implement a thorough herd health, nutrition and immunization program that is appropriate for the region. • Regular deworming and treatment against external parasites.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Depends on disorder

AGE-RELATED FACTORS
• Depends on disorders

ZOONOTIC POTENTIAL
Brucellosis, Q fever, rabies, anthrax, camel pox, toxoplasma, *Salmonella* spp., contagious ecthyma, ringworm, and tuberculosis are zoonotic diseases.

PREGNANCY
• Methylprednisolone causes abortion in the last half of pregnancy. • Dexamethasone: Do not use in pregnant animals.

BIOSECURITY
• Testing and quarantine of new animals • Segregation of breeding stock from performance or show animals • Regular testing of farm hands (tuberculosis) • Reduce movement of animals and humans between herds

PRODUCTION MANAGEMENT

CAMEL MANAGEMENT AND HEALTH PROGRAMS

BASICS

OVERVIEW

• Camels belong to the family Camelidae, genus: *Camelus*, species *C. dromedarius* (dromedary camel) and *C. bactrianus* (Bactrian camel).
• Some *C. bactrianus* populations or subspecies are endangered.
• *C. dromedarius* and *C. bactrianus* can interbreed and produce a fertile first generation.
• Mature weight in males and females varies from 600–750 kg and 450–650 kg, respectively.
• Birthweights vary according to breeds (dromedary: 30–45 kg, Bactrian: 35–55 kg).
• Camel production systems include intensive sedentary and nomadic herds. Milk, meat, hair, and hide are the main products. Camels are also used for draught, transportation, and riding. Camel racing is a highly specialized business in the Middle East.
• Dairy camels can produce 3–10 kg of milk/day with some breeds in intensive production systems reaching 25 kg/day. Lactation length varies between 300 and 450 days with a total production of 2,500–5,000 kg (8,000–10,000 in high-producing breeds).
• Carcass dressing percentage averages 40% (some breeds may reach 77% at young age).
• Fiber production: 2.5–4.5 kg/year for dromedaries, 5–15 kg/year for Bactrians.

INCIDENCE/PREVALENCE

Incidence of disease depends on region and production system.

GEOGRAPHIC DISTRIBUTION

• Dromedary: Northern and Saharan Africa, Middle East, India, Pakistan, and Australia (feral).
• Bactrian camel: Central Asia and Iran.

SYSTEMS AFFECTED

Multisystemic

PATHOPHYSIOLOGY

• Production camel medicine is an evolving field as production systems are changing from nomadic production to intensive sedentary production.
• Herd production medicine approach is similar to beef cattle for camel meat production and dairy cattle for dairy camels.
• Herd preventive medicine has focused on immunization against the major infectious diseases and preventive treatment against internal and external parasites. Nutritional requirements have not yet been fully studied and adapted to production systems.
• The major production-limiting diseases are: neonatal losses, trypanosomiasis, brucellosis, tuberculosis, camel pox, nutritional deficiencies, and poor reproductive performances (infertility and abortion).

Nutritional Requirements

• Camels are browsers
• The voluntary food intake of camels is about 50–75% that of cattle.
• Dry matter intake is 1.5–1.7% of body weight per day.
• Maintenance energy requirements are estimated to be 75–90 kcal ME per $kg^{0.75}$ daily.
• Maintenance protein requirements are estimated to be 320–370 mg DP per $kg^{0.75}$ daily.
• Camels have an extremely efficient urea recycling ability and they are better equipped than other ruminants to handle protein-deficient diets.
• To allow for energy-protein interactions, the recommended "allowances" for maintenance would be 104 kcal ME and 368 mg DP per $kg^{0.75}$ daily.
• Various feed sources have been used in camels including green alfalfa, barley, Rhodes grass, commercial pellets and mixed grains.
• Traditional systems are based mainly on pasture with a little supplementation with grass or alfalfa hay.
• Grass and alfalfa hay mix is sufficient nutritionally provided that animals have access to mineral and vitamin supplementation.
• Intake should be increased by 25% during the last 3 months of pregnancy and the first 8 weeks of lactation.
• Working camels (600 kg) in traditional management (India) generally receive 9–18 kg of green feed, 7 kg of straw or hay, and 2 kg of grain per day.

Minerals, Trace Elements, and Vitamins

• Copper deficiency has been reported. Normal plasma level is comparable to cattle (70–120 mg/100 mL). Camels are more tolerant to copper excess than sheep and goats. However, death has resulted following intakes of 200 mg of copper daily for 8 days.
• Camels appear to maintain lower zinc levels than other ruminants (<60 μg/100 mL).
• Zn and Cu requirements can be maintained by as little as 15–20 mg $CuSO_4$ and 18–20 mg of $ZnSO_4$. However, up to100 mg $CuSO_4$ and 750 mg of $ZnSO_4$ has been suggested by some authors.
• Vitamin E and selenium deficiency (white muscle disease) can be a serious problem in camels. Daily allowance should be 100 mg for vitamin E and 0.1–0.5 mg/kg of diet for selenium.
• Camels appear to be more sensitive to iodine deficiency than domestic ruminants.
• Crystalline salt is often fed ad lib (120–150 g per day).
• No data is available for cobalt status in camels.
• Thiamine deficiency/polioencephalomalacia have been described.

Reproductive Management

• Camels have a slow reproductive rate due to a delayed age at puberty (2 and 3 years of age for females, 3 and 4 years of age for males) and a long lactation anestrus (one year if the calf is not weaned).
• Breeding season depends on nutrition in both the female and the male and on temperature in the male. Males enter the rutting season in the fall through the spring.
• Male to female ratio ranges from 1:15 to 1:50.

Calf Management

• In nomadic herding systems, calves wean themselves at 15–18 months of age. Calves are generally allowed to nurse (in a controlled manner) so that the female can also be used for human milk supply.
• Early weaning, at 3 months, is used in some areas to increase reproductive ability (i.e., decrease the length of lactational anestrus).
• Weaning can be done as early as 2 days postpartum and calves are raised on milk replacers. (The author has used equine and bovine milk replacers successfully.)
• Calves should be introduced to solid food by 4 weeks of age. Creep feeding should contain 12% good-quality hay.

HISTORICAL FINDINGS

Poorly managed herds present the following features:
• Poor reproduction rate: <70% calving rate due to infertility, early or late pregnancy loss
• Poor weaning rate and weight: Neonatal losses >10% (may reach in some instance up to 50%)
• High morbidity and mortality
• Poor BCS

PHYSICAL EXAMINATION FINDINGS

• Docile/trained adult camels may be examined in horse stocks and will tolerate with minimal discomfort procedures such as transrectal palpation.
• Untrained animals should be examined while hobbled in a sternal (cush) position. Sedation may still be required for some procedures.
• Young calves (<6 months) can be restrained by two persons.
• Sedation: Xylazine, detomidine or xylazine and butorphanol. Combination of xylazine with ketamine is useful in untrained or feral animals.
• Vaginal examination or minor surgeries (e.g., draining abscesses, castration, vulvar sutures, and suture of superficial lacerations) require a combination of sedation and physical restraint.
• In the dromedary a simple method for estimation of body weight is:
  ◦ Weight (kg) = height at the shoulder (m) × chest girth (m) × body girth at the hump (m) × 50
• Management and examination of the camel neonate is similar to other domestic species.

CAMEL MANAGEMENT AND HEALTH PROGRAMS (CONTINUED)

- ◦ Normal birthweights vary from 26 to 52 kg depending on the breed of camel and nutrition.
- ◦ Camel calves should be able to stand and nurse on their own within the first hour after birth.
- ◦ Urination and passage of meconium should be observed in the first 24 hours after birth.
- ◦ Colostrum (10–15% of body weight) should be taken in the first 18 hours of life. Passive transfer can be verified by camelid RAPD or by total protein.
- ◦ Administration of vitamin E and selenium is recommended at 3 days of age and again at weaning.

Common Physical Findings in Neonates

- *Congenital defects:* goiter, umbilical hernia, angular limb deformities, atria ani, ventricular septal defect, cleft palate
- *Common problems of the first 48 hours:*
  - ◦ Prematurity (extreme laxity, small birthweight)
  - ◦ Inability to nurse (dysmaturity "dummy")
  - ◦ Hypothermia (exposure, hypoglycemia, weak calf, septicemia)
  - ◦ Hyperthermia (exposure, septicemia)
  - ◦ Colic (meconium impaction, atresia coli, ruptured bladder)

Physical Findings in Lactating Females

- In traditionally managed herds the interval between calving is in the range 18–36 months (average 2 years).
- Early weaning reduces the calving interval by decreasing lactational anestrus.
- Agalactia is seen sometime in maiden females.
- Mastitis is a major production disease. Diagnosis and treatment are based on the same principles used in cattle.

GENETICS

Dairy camels are more susceptible to postpartum disorders (hypocalcemia, uterine prolapse, retained placenta) and mastitis.

SIGNALMENT

N/A

CAUSES AND RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Herd disease investigation requires a systematic approach based on historical data, clinical signs, and epidemiology of specific diseases in the region.

CBC/BIOCHEMSTRY/URINALYSIS

CBC and biochemistry on a subset of animals may be helpful in detection of trypanosomiasis and severe mineral deficiencies.

OTHER LABORATORY TESTS

- Periodic fecal analysis for parasitology
- Serology for the major diseases (brucellosis, trypanosomiasis, camel pox, chlamydiosis, Q fever)
- Neonates: IgG or total protein for determination of passive transfer of immunity
- Lactating animals: California mastitis test (CMT) and somatic cell count to monitor mastitis

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Depend on disorder investigated

TREATMENT

THERAPEUTIC APPROACH

- External and internal parasites can be controlled or prevented using the same strategies devised for domestic ruminants.
- Strategies should be developed for the specific geographic region.
- Most drugs used in cattle can be used at the same dosage in camels for the control of most parasites.
- Injectable ivermectin is efficacious on most external and internal parasites in camels, but injection site reactions are common.
- Ionophores are very toxic in camelids.

SURGICAL CONSIDERATIONS AND TECHNIQUES

- The most common surgical technique in camels is castration. It may be performed as early as 6 months of age but most breeders will wait until 2 years. Standing and recumbent techniques are used depending on tractability. Methods of castration are similar to those used in the bovine for calves or equine for adults.
- Racing intact males are subjected to palatectomy (surgical excision of the soft palate) to improve breathing. Surgery is performed under heavy sedation or injectable anesthesia with xylaxine and ketamine.
  - ◦ The oral cavity is washed with a weak antiseptic solution and a mouth gag is placed with the tongue exteriorized to one side.
  - ◦ The soft palate is grasped with long forceps and exteriorized, then clamped as close to the base as possible. Large blood vessels are cauterized and the soft palate is excised.
  - ◦ Postoperative care includes long-acting antibiotics (3–4 days), anti-inflammatories and fasting for 24 hours. Soft feed (mash or chopped fresh alfalfa) is given for 2–3 days. Animals should be monitored for a few days for dysphagia.

MEDICATION

DRUGS OF CHOICE

- Sedation and anesthesia
  - ◦ Xylazine 0.25–0.5 mg/kg IM (0.1–0.25 mg/kg IV)
  - ◦ Ketamine (3–5 mg/kg, IV) with xylazine
  - ◦ Detomidine (25–75 μg/kg, IV)
  - ◦ Butorphanol (0.05–0.1 mg/kg, IM).
- Antiparasites: similar to bovine, do not use ionophores.
- Antibiotics: similar to bovine, avoid aminoglycosides.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for food-producing animals.

PREVENTION

Mandatory Vaccines

- Clostridial vaccines (*C. tetani, C. perfringens* types A, B, C, D, *Cl. chauvoei, septicum, novyi*) initially given at 2–3 months of age, booster 4 weeks later and then annual re-vaccination is recommended.
- *C. perfringens* types C and D and *C. tetani* (tetanus toxoid) (combined as CDT vaccine) should be given to pregnant females 4–6 weeks prior to parturition.
- Rabies vaccination at 3 months, booster in 4 weeks, then annual re-vaccination is recommended.
- Anthrax (*Bacillus anthracis*) at 2–3 months and then annually in endemic countries **(considered a foreign disease in some countries)**.
- Camel pox (Orthopoxvirus): Vaccinate at 6 months of age and booster 4 weeks later. Adults are given 2 injections before 4 years of age. Lifelong immunity develops **(considered a foreign disease in some countries)**.

Optional Vaccines

- Leptospirosis (5-way) may need to repeat vaccination 3–4 times per year.

• *E. coli* (for calf diarrhea), oral for calves in the first 10 days of life, pregnant females 6–8 weeks prior to parturition.
• Salmonella: oral for calves in the first 10 days of life; pregnant females 6–8 weeks prior to parturition.
• Neonatal viral diarrhea (i.e., rotavirus, coronavirus): Dams are vaccinated 4 and 2 weeks before parturition.
• Botulism (*Clostridium botulinum* types C and D) may be indicated.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
• MERS (Middle East respiratory syndrome) due to coronavirus
• Brucellosis (*B. meletensis* and *B. abortus*)
• Q fever (*Coxiella burnetii*)
• Tuberculosis
• Anthrax

PREGNANCY
• Pregnancy diagnosis is performed by teasing at 14 days post breeding.
• Pregnancy length varies from 340 to 412 days (majority between 375 and 395 days).
  ◦ The factors affecting pregnancy length are season and nutrition.
  ◦ Adjusting nutrition in the last trimester of pregnancy and booster vaccination improves neonatal survival.

BIOSECURITY
• Test personnel for tuberculosis (dairy camels).
• Avoid comingling with unknown herds.
• Quarantine all newly introduced animals.
• Separate performance animals from breeding stock.
• Regularly test for trypanosomiasis, brucellosis, and tuberculosis.

PRODUCTION MANAGEMENT
• Working camels (600 kg) in traditional management (India) generally receive 9–18 kg of green feed, 7 kg of straw or hay, and 2 kg of grain per day.
• External and internal parasites can be controlled or prevented using the same strategies devised for domestic ruminants.
• Strategies should be developed for a specific geographic region and based on the most commonly found parasite using suitable pharmaceuticals.

CAMELID: DENTISTRY

BASICS

OVERVIEW
Camelids suffer an array of dental diseases, and require routine care. Retained deciduous incisors, incisor malocclusion, and tooth root abscess are more common anomalies. Trimming of fighting teeth in males is a common routine procedure.

INCIDENCE/PREVALENCE
Tooth root abscesses are a common occurrence, particularly in aged camelids. Mandibular molars 1 and 2 are most often affected and maxillary teeth are rarely affected. The incidence in canine teeth appears to be decreasing with change in methods for trimming fighting teeth.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
- Digestive
- Musculoskeletal

PATHOPHYSIOLOGY
- The adult camelid dental formula is: (I 1/3, C 1/1, PM 1-2/1-2, M 3/3) × 2 for 30 to 32 teeth.
- The upper incisors are found caudally in the region of the canine teeth.
- Cheek teeth can be numbered from 1 to 5 (rostral to caudal), or labeled according to the dental chart (PM 1 and PM 2, M 1 to M 3).
- The upper premolars have three roots each; the lower have two roots each.
- The upper molars have four roots each; lower M 1 and M 2 have two roots, M 3 has three roots, but two are fused.
- Dental points on the buccal side of the maxillary cheek teeth and the lingual side of the mandibular cheek teeth are normal due to the orientation of the maxilla and mandible. These are rarely a problem and should not be reduced.
- Retained deciduous incisors occur when eruption of the permanent incisor is misaligned and fails to push out the deciduous tooth. Typically, retained teeth are smaller and rostrally located.
- Incisor malocclusion occurs when the mandibular incisors fail to meet the dental pad. Malocclusion may cause abnormal prehension and abnormal wear of the molars.
- Tooth root abscesses can arise from tooth fracture, gingival penetration, or infundibular decay and infection. Often the source is unknown.
- Periostitis and osteitis of the mandible secondary to tooth root abscesses can spread extensively along the mandibular canal.
- Fighting teeth; the upper I 3 and canine, and lower canines in males, are sharp and used as weapons. Routine trimming is performed to reduce risk of trauma to other animals.

HISTORICAL FINDINGS
N/A

SIGNALMENT
All camelids can be affected; however, retained deciduous incisors are commonly noted in young animals with erupting teeth; incisor malocclusion is most common in adults; and tooth root abscesses rarely occur in animals <12 months of age (median age 5 years).

PHYSICAL EXAMINATION FINDINGS
- Retained deciduous incisors present as smaller incisors located rostral to the permanent teeth.
- Incisor malocclusion creates protrusion of the upper lip and incisors do not meet the dental pad.
- Tooth root abscesses may produce firm swelling of the jaw, drainage of exudates from the mandible or maxilla, reluctance to eat, quidding, abnormal chewing, weight loss, and nasal discharge if the sinus is affected.

GENETICS
N/A

CAUSES AND RISK FACTORS
Tooth root abscesses can arise after tooth fracture, gingival penetration, or infundibular decay and infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Differentials are most relevant to tooth root abscesses, in which case other possibilities include mandibular osteitis/osteomyelitis, subcutaneous abscessation/cellulitis, fracture, sinusitis, neoplasia, actinomycosis, salivary gland disease, and casesous lymphadenitis.

CBC/BIOCHEMISTRY/URINALYSIS
Mild elevation in white blood cell count may occur in severe chronic tooth root abscesses with chronic periostitis/osteitis.

OTHER LABORATORY TESTS
Culture of exudates may rule in or out other causes of facial swelling in cases of suspected tooth root abscess.

IMAGING
- Radiography or computed tomography (CT) can be used to evaluate bony anomalies of the jaw, including suspected tooth root abscesses. Contrast agent may be injected into a draining tract if the affected root is not obvious, or can be given IV (during CT).
- Imaging helps determine the severity and extent of disease and identifies how many and which specific teeth are involved. Relevant findings can include bone lysis, periodontal sclerosis, abscesses, and fistulous tracts.
- Adequate imaging is particularly critical if surgical interventions are anticipated.

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
At necropsy, localized purulent exudates, necrotic bone and alveolus, fistulous tracts, loose teeth, and bony proliferation may be apparent in affected areas.

TREATMENT

THERAPEUTIC APPROACH
Medical therapy alone can suffice for treatment of tooth root abscesses; however, surgical interventions are often needed for dental disorders of camelids.

SURGICAL CONSIDERATIONS AND TECHNIQUES
- Retained deciduous incisors are resolved by extraction of the retained teeth. If they are loose they can be readily pulled. Teeth that are more firmly attached may require sedation/anesthesia and the use of a periosteal elevator.
- Incisor malocclusion is resolved by trimming incisors to meet the dental pad. This is best accomplished with a rotary trimmer, and may require sedation.
- Tooth root abscesses can be addressed with medical care, or with surgical intervention followed by medical care. Oral extraction may be appropriate for premolars, canines, and incisors; however, elevation from the alveolus may be difficult via an oral approach due to the limited excursion of the jaws in these species.
  - Some curettage of the alveolus will help remove necrotic bone.
  - Repulsion of the cheek teeth has also been recommended.
  - Care must be taken due to the fragility of the mandible and maxilla, which can be easily fractured.
  - Motorized burr has been successful for removal of affected teeth, especially mandibular teeth.
  - Incision is made along the ventral or ventrolateral aspect of the mandible, resecting draining fistulas if possible.
  - Periosteum and overlying musculature are elevated along the lateral aspect of the mandible to the level of the gingival attachment.
  - Following removal of the overlying bone, the tooth and roots are carefully elevated and removed.
  - In some cases, resection of the single affected root using the burr can be effective in resolving the problem without complete extraction.
  - A ventral opening in the incision is left for drainage, closing the remainder of the incision.
  - The empty alveolus can be packed with gauze or acrylic if desired, which may be necessary in the maxilla, but is not necessary in the mandible.

- Following surgery, flushing of the tract with dilute chlorhexidine solution can help remove food particles.
- Diet changes are not necessary and most animals will begin eating within hours of anesthetic recovery.

• Fighting teeth should be trimmed leaving 2–3 mm above the gum line, which is most safely accomplished with a rotary trimmer and may require sedation.

MEDICATIONS

DRUGS OF CHOICE

• Tooth root abscesses are often treated with anti-inflammatory medications and long-term antibiotics.
• Anti-inflammatory medications can include flunixin meglumine 1.1 mg/kg IV q24h, typically for postsurgical pain.
• Antibiotics that might be appropriate for tooth root abscesses include procaine penicillin G (20,000 U/kg IM, q12h for 5–10 days or longer if indicated); oxytetracycline (200 mg/mL formulation, 18 mg/kg SC, q48h for 5–10 days); ampicillin (11 mg/kg IM, q24h for 5–10 days); and florfenicol (20 mg/kg SQ, q48h for 10 days of treatment).

CONTRAINDICATIONS

• Wire saws can generate excessive heat and damage the pulp cavity of teeth, particularly the incisors.
• Cutting tools may fracture teeth and predispose to tooth root abscesses.
• Nephrotoxic drugs (flunixin, oxytetracycline) are contraindicated in dehydrated or azotemic animals.

PRECAUTIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Retained deciduous incisors, incisor malocclusion, and routine trimming of fighting teeth carry an excellent prognosis.
• Tooth root abscesses often heal over several weeks, though the presence of significant bony infection can reduce the success rate. Surgical removal of an infected tooth generally results in a good prognosis, particularly in short-term disease, though additional abscesses can arise at adjacent teeth if the extent of the disease was not accurately identified at the initial examination.

POSSIBLE COMPLICATIONS

Tooth root abscesses can be affiliated with ongoing osteitis, discomfort, and drainage in spite of treatment.

CLIENT EDUCATION

Instruct clients on signs of dental disease, and good herd management.

PATIENT CARE

Provide a high-quality, palatable diet.

PREVENTION

Avoiding stemmy hay and foxtail contamination may be helpful for tooth root abscesses.

CAMELID: DERMATOLOGY

BASICS

OVERVIEW

• A variety of diseases of the skin have been described in camelid species, and they vary in presentation with respect to their inciting cause. Parasitic, infectious, nutritional, idiopathic, neoplastic, and congenital diseases have all been reported.
• Parasitic: Biting and sucking lice both affect camelids; biting lice are thought to be more common. Mites are also common in camelids.
• Viral: Bluetongue virus, vesicular stomatitis virus, contagious ecthyma, papilloma viruses, and papilloma viruses have all been described in camelid species.
• Bacterial: Dermatophilosis and folliculitis are commonly encountered skin diseases in camelids.
• Fungal: Dermatophytosis ("ringworm") has been described in camelid species.
• Neoplastic: Squamous cell carcinoma, fibrosarcoma, papilloma, fibropapilloma, fibroma, melanocytoma, hamartoma, and mast cell tumors have all been described in camelid species.
• Congenital ichthyosis (excessive dry skin scaling) has been reported in llamas.
• Camelid skin can be organized into several layers:
  ◦ Stratum corneum: The thickest, outermost layer, composed of the remnants of keratinized cells pushing outward from lower layers.
  ◦ Stratum lucidum: An eosinophilic layer immediately below the stratum corneum.
  ◦ Stratum granulosum: Keratinocytes migrating from underlying layers develop in this layer. They have distinct keratohyalin granules that are thought to bind keratin filaments together.
  ◦ Stratum spinosum: Composed of polyhedral keratinocytes, the cells of this layer are active in synthesizing proteins which ultimately contribute to the desmosomes that arise from between adjacent keratinocytes.
  ◦ Stratum basale: This layer is composed of what are considered the stem cells of the epidermis.
• There are several large glands that are normal anatomic features in camelid species, but which are absent or less pronounced in traditional ruminants.
  ◦ Metatarsal gland: Oval-shaped glands located on both the medial and lateral aspects of the metatarsus of the pelvic limbs. Glandular secretions can accumulate and flake off from these glands.
  ◦ Interdigital gland: Found in the interdigital space of all four feet.
  ◦ Poll gland: A feature of old world camelids. This scent gland is used for marking by bulls in rut.

INCIDENCE/PREVALENCE

Varies by inciting causative agent. Contagious disorders can achieve high prevalence within a group.

GEOGRAPHIC DISTRIBUTION

Worldwide; regional distribution influenced by causative agent and relevant management factors.

SYSTEMS AFFECTED

Integument

PATHOPHYSIOLOGY

• Bacterial disorders:
  ◦ Dermatophilosis ("rain rot") is caused by *Dermatophilus congolensis*, a Gram-positive coccoid organism that can appear in branching filaments. The causative organism requires a break in the skin and moisture to spread.
  ◦ Folliculitis is most commonly caused by *Staphylococcus intermedius.*
• Fungal:
  ◦ Multiple fungal species have been described as causing dermatophytosis in camelids, predominantly *Trichophyton* and *Microsporum*.
• Parasitic:
  ◦ Chewing lice (*Damalinia breviceps*) feed on debris of the superficial skin.
  ◦ Sucking lice (*Microthoracius* spp.) feed on blood and lymph fluid.
  ◦ Mites (mange) cause clinical signs by several mechanisms. The action of burrowing into the skin leads to thickening and reduced local immune response. Some mites stimulate an immune response with their mouthparts that leads to serum loss at the bite sites.
  ◦ *Psoroptes* mites, most commonly found in the pinna and ear canal, induce head shaking due to local irritation.
  ◦ *Chorioptes* mite (*C. bovis*) infestation is common and may be asymptomatic or create pruritis and alopecia of the feet and tail base.
  ◦ *Sarcoptes scabiei* var *auchinae* can cause severe pruritis, particularly in fiberless areas.
• Idiopathic:
  ◦ Munge, or "idiopathic hyperkeratotic dermatitis," is assumed to have an underlying immunodeficiency as the cause.
• Neoplastic:
  ◦ Pathophysiology varies by tumor type.
• Burns:
  ◦ Thermal burns: Severity can range from reddened skin (first-degree burn) to swelling and blistering (second-degree burn) to tissue charring and deep damage (third-degree burn). The pathophysiology of burn injuries is a combination of thermal destruction of tissues, decreased resistance to infection of damaged skin, as well as loss of fluid and protein (albumin) through damaged skin.
  ◦ Chemical burns: Vary considerably depending on the agent involved. Where possible contact the local Poison Control Center or National Poison Control Hotline (1-800-222-1222 in the USA) for information about specific chemical agents.
• Viral:
  ◦ Several parapox viruses can cause skin lesions in camelid species. Contagious ecthyma ("orf") and camel pox have been observed in camelids. Cowpox virus, an orthopoxvirus, has also been noted. Immunosuppression is thought to play a role in the development of clinical cases.
• Zinc-responsive dermatosis:
  ◦ As a significant trace element, zinc plays a role in modulation of the immune response as well as management of inflammation.
  ◦ Disease can arise as a result of poor absorption, binding of zinc with other minerals (calcium), or decreased dietary zinc in the ration. Phytases present in grains may limit zinc absorption in some cases.

HISTORICAL FINDINGS

• Vary with the underlying etiology but defining the history of skin disease within the herd, and any relevant treatment or management procedures, is important.
• A description of skin lesion appearance and duration, number of animals affected, and the presence or absence of pruritis are important historical factors.

SIGNALMENT

All species and breeds of camelids, of any age or gender, are at risk of dermatologic disease.

PHYSICAL EXAMINATION FINDINGS

• Vary depending on the inciting cause of disease.
• Dermatophilosis is most commonly observed on the dorsum, ears, feet, and neck. Lesions can be non-pruritic or pruritic, and erythema may be noted on affected skin.
• Dermatophytosis tends to affect the legs, perineum, and head. Lesions tend to be hyperkeratotic crusts that are not pruritic.
• Lice typically cause pruritis with affected camelids exhibiting scratching, traumatic loss of fiber, excoriation, and restlessness.
• Mange
  ◦ Affected skin may be reddened, or potentially moist from serum leakage.
  ◦ Head shaking and incoordination have been reported as signs of psoroptic mange.
  ◦ Sarcoptic mange is typically localized to the thorax, ventrum, limbs, perineal region, and interdigital space; regions with limited fiber.
  ◦ *Chorioptes* commonly affects the feet and tail base, but can become more extensive.
• Munge is most common in animals <2 years of age and is reflected by crusting and hyperkeratosis of the muzzle, eyes, and ears.
• Neoplasia can present as skin thickening, cutaneous nodules or masses, or superficial ulceration of affected regions.
• Parapox viruses typically cause disease at mucocutaneous junctions, most commonly on the lips. Painful, clumped, raised, alopecic,

crusty, and ulcerated masses in younger animals are suggestive.
• Signs of zinc-responsive dermatosis are most notable on the muzzle, pinnae, neck, ventrum, and thighs where thickening of the skin, alopecia, and scaling may be noted. Hyperpigmentation may occur in chronic cases.

GENETICS
There are few known dermatologic conditions of camelids with a genetic basis. Crooked nails, teat abnormalities, aural hematomas, rolling or "wrinkled" skin, and chondritis are all thought to have a genetic component or to occur more commonly in certain breeding lines.

CAUSES AND RISK FACTORS
• Increased stocking density is likely a risk factor for parasitic skin disease.
• Fiber and skin color may be associated with increased risk of zinc-associated dermatitis.
• Dermatophilosis typically occurs in areas with high rainfall where the fiber of camelids is moist frequently or for extended periods of time.
• Operations with poor biosecurity, management and parasite control measures may be predisposed to contagious, parasitic or nutritional dermatologic disorders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Differential diagnoses encompass all of the listed disorders; another approach is to consider possible differentials based on the anatomic region in which lesions occur:
• Heavily fleeced areas: Lice, dermatophilosis, neoplasms, shearing injuries ("clipper burn").
• Lightly fleeced areas: Dermatophytosis, mange, photosensitization, folliculitis, hyperkeratotic disorders, coccidioidomycosis, and solar dermatitis should all be considered.
• Mucocutaneous junctions: Contagious ecthyma, parapox virus infections (camel pox, cowpox), and skin neoplasms should be considered.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Bacterial culture can be performed directly on skin swabs or on skin biopsies. Susceptibility testing should also be considered to guide antimicrobial selection. Contact the laboratory to determine what antibiotic trays will be used for sensitivity: some laboratories use default trays containing drugs that are not available in a formulation suitable for camelids.
• Cytologic examination of smears of exudates or lesions can help distinguish bacterial, fungal, and neoplastic etiologies.
• Gram staining of roll smears and cytology samples can aid antimicrobial selection in pyoderma and folliculitis.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• Skin biopsies can be obtained for histologic examination and/or bacterial culture.
  ◦ Collection of several samples from an affected animal is recommended, ideally with healthy and affected skin contained within each sample.
  ◦ Select fully developed lesions without secondary trauma or infection.
  ◦ Avoid disturbing the skin surface; rigorous preparation of the skin can disrupt cellular architecture.
  ◦ The skin should be undermined with 1–2 mL of local anesthetic solution if necessary.
  ◦ 4–8 mm biopsy punches can be utilized with care: roll the punch in one direction (instead of alternating back and forth) during sample collection to minimize crush artifact.
  ◦ The sample should be lifted off the biopsy punch with a needle or iris scissors to avoid crush artifact and immediately placed in a fixative, such as 10% buffered formalin, since architectural changes will begin shortly after collection.
• Fiber microscopy using a light microscope can help identify *Demodex* mites adhered to the hair follicle or lice eggs attached to the fiber. If the end of the hair shaft appears to be broken, or sharply cut, this suggests a pruritic lesion.
• Fungal culture can be achieved using commercial Dermatophyte Test Media "DTM" culture kits.
  ◦ When dermatophytes metabolize the culture medium, an alkaline pH is created that will turn the phenol red dye in the medium red.
  ◦ False positives can occur with benign fungal species; after they metabolize the carbohydrates in the medium, they will break down the protein components of the medium, which will shift the pH to alkaline. The color of the media should therefore be recorded when the colony is first noted to avoid false-positive results.
  ◦ The media should be stored loosely to allow for aeration, as well as at room temperature, and examined daily. Black or greenish-black colonies should be regarded as contaminants since dermatophyte colonies typically appear fluffy and light colored.
  ◦ *Trichophyton verrucosum* and some other species do not grow on DTM media.
• Plasma zinc can be measured on blood collected into a lithium heparin ("green top") tube, kept upright, and immediately spun down and plasma removed. Hemolysis or use of tubes with zinc in the container or stopper can artificially elevate concentrations.
• Skin scraping is useful for diagnosis of *Psoroptes, Sarcoptes, Chorioptes,* and *Demodex* infections.
  ◦ A no. 10 scalpel blade can be used; excessive damage to the skin can be prevented by dulling the blade by passing it over a hard surface several times.
  ◦ Several drops of mineral oil are placed on the dulled blade, a microscope slide, and the areas of the skin to be scraped.
  ◦ The dull blade is scraped over the sampling area and the debris is placed on the mineral oil on the microscope slide. The sample can then be viewed with a coverslip. Care should be taken not to press the blade into the skin as this may cause a laceration.
  ◦ Since false-negative scrapings are common, samples should be taken from multiple sites. It is often necessary to scrape deeply enough to draw blood to achieve a diagnostic sample.
  ◦ Digestion with potassium hydroxide may be necessary to clear debris from the visual field.
  ◦ Mites may be visualized at lower magnification, but 100× is often required for identification; 400× may be required for *Psoroptes*.
  ◦ Alternatively an acetate tape test may be useful for identifying surface mites, but will not be effective for mites that burrow into the skin.
• Skin surface cytology
  ◦ Samples can be gathered by directly pressing the slide onto the lesion, aspiration of pustules, rubbing the slide on the interdigital space, or rolling a sterile swab on the lesion.
  ◦ Cytology samples can be heat fixed and stained (Gram stain or Diff-Quick) for improved visualization of cellular changes and structures.
• Wood's lamp visualization
  ◦ When dermatophytes are suspected, lesions can be screened with a 253.7 nm wavelength ultraviolet light (Wood's lamp). Due to the reaction of the light with a tryptophan metabolite, some species of dermatophytes will fluoresce under the lamp.
  ◦ A negative Wood's lamp screening does not verify absence of dermatophytes as numerous species do not fluoresce and false-positive results can occur in previously treated animals.
  ◦ Battery-powered lamps may not have sufficient power to cause fluorescence, so where possible, lamps that draw outlet power should be utilized.

PATHOLOGIC FINDINGS
• Dermatophilosis causes infiltration of the skin with neutrophils, hyperkeratosis, and a "railroad track"-appearing double chain of Gram-positive coccoid organisms.
• Ichthyosis appears as hyperkeratinization on biopsy with minimal to no inflammation.

CAMELID: DERMATOLOGY (CONTINUED)

- Zinc-responsive dermatosis
  - Plasma zinc concentration <0.5 mg/dL may be suggestive. Clinically affected animals can have normal plasma zinc concentrations.
  - Biopsy demonstrates hyperkeratosis, potentially with perivascular infiltrates of white blood cells.
  - Often a diagnosis of exclusion and response to supplemental zinc.

TREATMENT

THERAPEUTIC APPROACH

- There are no labeled drugs for use in camelid species. As such, in some countries treatment of camelid conditions is considered "extra-label" drug use and may come with additional restrictions or responsibilities for the prescribing veterinarian.
- Whenever possible evidence-based approaches utilizing the current literature should be employed for therapy considerations.

SURGICAL CONSIDERATIONS AND TECHNIQUES

Neoplastic lesions including fibromas, fibrosarcomas, fibropapillomas, and papillomas may be managed by surgical excision. Where possible wide surgical excision, with margins checked for completeness, should be employed. Clients should be aware that regrowth is a possibility with surgical removal of these lesions. Surgical excision appears to be curative for mast cell tumors, hamartomas, and melanocytomas.

MEDICATIONS

DRUGS OF CHOICE

- Coccidioidomycosis (systemic) has been treated with fluconazole (2.27 mg/kg, PO). For topical infection, agents such as nystatin or thiabendazole may be useful.
- Dermatophilosis responds to ceftiofur, penicillin, or oxytetracycline given for a minimum of 5–7 days. Topical cleaning of crusts with disinfectants such as dilute chlorhexidine (25 mL per liter of saline) can also be performed.
- Dermatophytosis is primarily managed with shearing affected regions to increase air flow and light exposure, after which, treatment with topical antiseptics such as chlorhexidine (scrub solution or shampoo), iodine (2%, or 0.5% povidone), captan, lime sulfur, or a topical antifungal cream such as clotrimazole or miconazole can be tried. Topical treatments may need to be applied once to several times daily for up to 2 weeks or longer.
- Lice are responsive to macrocyclic lactone compounds (ivermectin, moxidectin, doramectin, eprinomectin). Topical livestock products can be useful; pyrethrin or permethrin compounds are safer than carbamate or organophosphate compounds. Lice burden can be further reduced by shearing and exposure to sunlight.
- Munge has been addressed using combination therapies ("Witches Brew"), typically involving a mixture of mineral oil, dimethyl sulfoxide (DMSO), gentamicin and ivermectin (e.g. 317 mL of mineral oil, mixed with 95 mL of DMSO, 8 mL of ivermectin, and 5 mL of 50 mg/mL gentamicin. The solution can be applied every 3 days for 2–3 weeks, and clients should wear gloves.
- *Psoroptes*: Ivermectin (eardrop) and fipronil spray to the affected pinnae.
- *Sarcoptes*: Ivermectin (0.2 mg/kg, SQ) is often required as topical treatment and is often ineffective.
- *Demodex*: Ivermectin (parenteral), permethrin (topical), fipronil spray (total dose not to exceed 2–3 mL/kg of 2.5% solution), and lime sulfur (2% topical) can be used.
- *Chorioptes*: Ivermectin and topical therapies as described for other mites.
- For squamous cell carcinoma, cisplatin injections as well as topical 5-fluorouracil have been reported along with cryotherapy.
- Antiviral drugs are not indicated for parapox or orthopox viruses. Treatment should focus on supportive care with analgesics, anti-inflammatories, and potentially antibiotics to treat or manage secondary infections.
- Zinc-responsive dermatosis has been treated by ensuring dietary zinc at 100–200 parts per million of the ration, or supplemental administration of oral zinc methionine (4 grams/day) or oral zinc sulfate (2 g/day). Supplementation with zinc methionine is thought to reach greater tissue concentrations, and treatment may be necessary for 60 days or longer.

CONTRAINDICATIONS

Corticosteroids should not be used in pregnant female camelids.

PRECAUTIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Topical ectoparasiticides that fall under the jurisdiction of the EPA rather than the FDA in the USA cannot be applied in an extra-label manner.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Varies depending on cause.
- Most skin diseases take several weeks to resolve once therapy is initiated.

POSSIBLE COMPLICATIONS

Secondary infection

CLIENT EDUCATION

Focus on methods of control and prevention to reduce disease related to ectoparasites and infectious disorders.

PATIENT CARE

- Mange: Follow-up may be required for weeks to months to monitor for recurrence.
- Neoplasia: Camelids with neoplastic masses should be observed for regrowth, and where possible screened for potential metastasis.

PREVENTION

- External parasites can be prevented by decreasing stocking density, shearing fiber, dusting, minimizing sharing of brushes and coats, as well as monitoring frequently.
- Quarantine new animals before introduction into the herd, with close inspection for skin lesions.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Younger animals are more prone to munge, contagious ecthyma, and ichthyosis.

ZOONOTIC POTENTIAL

- Dermatologic diseases in large animals should be considered zoonotic until proven otherwise. Clients should be advised to wear gloves and other barrier clothing when handling animals with a potential zoonosis.
- Dermatophytes, *Dermatophilus*, *Sarcoptes*, contagious ecthyma, camel pox, cowpox, and other skin disorders are all considered potential zoonoses.

PREGNANCY

N/A

BIOSECURITY

- Several mite species can persist in the environment. Common items such as brushes, blankets, and halters should not be shared between individuals when an animal is suspected of having an infectious condition.
- For the disinfection of facilities where dermatophytosis is suspected, chlorhexidine or bleach can be used.

PRODUCTION MANAGEMENT

While the majority of skin conditions are not immediately-life threatening, these conditions can contribute to decreased fiber yield and quality, as well as decreased reproduction.

SYNONYMS

Munge: idiopathic nasal dermatitis or hyperkeratotic dermatitis

ABBREVIATIONS

- DMSO = dimethyl sulfoxide
- DTM = Dermatophyte Test Media
- EPA = Environmental Protection Agency
- FDA = Food and Drug Administration

CAMELID: GASTROINTESTINAL DISEASE

BASICS

OVERVIEW
• New world camelids (NWC) or South American camelids (SAC) include the guanaco, llama, alpaca, and vicuna.
• NWC can subsist on a lower plane of nutrition than other domestic herbivores due to unique gastric anatomy and physiology permitting utilization of less digestible feedstuffs.
• Common GI diseases of camelids include third compartment (C3) ulceration, dental disease, enteritis, peritonitis, intestinal accidents, parasitism, and neoplasia.
• Assessment of body condition, ration analysis, and herd management procedures are important in preventing GI disease in NWC.

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Digestive

PATHOPHYSIOLOGY
• Camelids are considered pseudo-ruminants with three stomach compartments: C1, C2, and C3.
• C1, the largest compartment in the adult, contains 83% of the content and lies predominantly on the left side of the abdomen. While C1 is analogous to the true rumen given its role is fermentation, it contains a homogeneous mixture of partially digested feed, while the rumen is stratified and contains a fluid layer, topped with a fibrous mat and gas cap.
• C2 is much smaller and primarily involved in mixing and fermentation.
• C1 and C2 contain saccules that secrete bicarbonate to buffer the environment for resident microorganisms.
• C3 has two functional parts: the proximal 4/5^{ths} controls absorption of nutrients and the distal 1/5th is glandular and secretes acid.
• Camelids absorb most nutrients in the small intestine and form fecal pellets in the large intestine. They have a spiral colon, which is a common site for obstruction.
• GI disease in camelids can result from parasitism (nematodes, protozoa, helminths, flukes), intestinal obstruction (bezoar, gastroliths), compartment ulceration (C1, distal C3), neoplasia (adenocarcinoma, lymphosarcoma, round cell tumor, squamous cell carcinoma), infection (*Streptococcus zooepidemicus* peritonitis or abdominal abscess; viral and bacterial enteritis), esophageal dysfunction (megaesophagus, vascular ring anomalies; VRA), and other disorders.

HISTORICAL FINDINGS
Signs of colic, weight loss, tenesmus, or abnormal fecal passage or consistency are common complaints.

SIGNALMENT
• Any age, species, gender of camelid.
• Neonatal alpacas are most likely to present with VRA.
• Young camelids are more likely to have bezoars.

PHYSICAL EXAMINATION FINDINGS
• Vary depending on the disorder.
• Salivation, regurgitation, or staining around the mouth may indicate oral or esophageal disease.
• Unusual esophageal activity (fluctuations, billowing, distension) can occur with esophageal disorders.
• Signs of colic reflected by abnormal cush, restlessness, lateral recumbency; vocalization and rolling if severe pain occurs.
• Abdominal distension.
• Empty rectum or diarrhea on digital rectal examination.
• Tachycardia: Usually indicates shock or hypovolemia rather than pain.
• Poor body condition suggests chronic disease or poor management.

GENETICS
N/A

CAUSES AND RISK FACTORS
Poor management procedures related to hygiene, nutrition and parasite control.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Enteritis (viral, bacterial, parasitic)
• Ileus or atony
• Toxicity (rhododendron or other)
• GI obstruction (bezoar, intussusceptions, adhesions)
• Peritonitis
• Compartment ulceration
• Neoplasia
• Mesenteric root torsion

CBC/BIOCHEMISTRY/URINALYSIS
• Neutrophilia or neutropenia reflect inflammatory or infectious disease.
• Hypoalbuminemia suggests parasitic disease.
• Hypochloremic metabolic alkalosis can occur in GI obstruction located near the pylorus or duodenum.
• Increased gamma-glutamyltransferase (GGT) and aspartate aminotransferase (AST) activity may be noted in animals with hepatic disorders or secondary lipidosis due to reduced feed intake.
• Elevations of nonesterified fatty acids and beta-hydroxybutyrate may occur in animals with anorexia and can be used to determine the need for supplemental nutrition.

OTHER LABORATORY TESTS
Fecal samples can be submitted for bacterial culture, parasite detection, and virus detection if indicated.

IMAGING
• Ultrasonography is excellent for imaging the abdomen of camelids and can often be achieved by applying alcohol and spreading the fiber without clipping.
• Radiography is useful to evaluate esophageal disorders and to detect gastroliths.
• Computed tomography 3 hours after orogastric administration of contrast agent (± IV contrast) provides an excellent abdominal study to identify obstruction, neoplasia, and other anomalies.

OTHER DIAGNOSTIC PROCEDURES
• Abdominocentesis can be readily performed in the right paracostal region ~ 2–3 cm caudal to the last rib and level with the costochondral junction. Fluid total protein should be <2.5 g/dL and total nucleated cell count <3,000/µL.
• Exploratory laparotomy may be necessary when uncontrollable pain or diagnostic procedures do not identify the problem, but should be avoided if possible due to risk and the low likelihood of a surgically amenable issue in the vast majority of cases.

PATHOLOGIC FINDINGS
Vary with underlying cause

TREATMENT

THERAPEUTIC APPROACH
• Most GI disease in camelids is medical in nature, and the underlying issue should be correctly identified and addressed as promptly as possible.
• Intensive supportive care may be needed which can include delivery of fluids, nutrition, pain relief, and specific therapeutic medications; this must be balanced against the stress of handling and medicating these animals.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Most GI disorders in camelids are medical in nature.
• Surgery should only be performed where surgical intervention is confirmed to be appropriate (bezoar or other obstruction), or surgical exploration is considered a necessary diagnostic step.
• C3 is highly vascular with an extensive anastomotic capillary network at the luminal surface. Branching vessels provide extensive collateral circulation. Incisions into C3 should be oriented parallel to the longitudinal plane.

(CONTINUED) CAMELID: GASTROINTESTINAL DISEASE

MEDICATIONS

DRUGS OF CHOICE

• Nonsteroidal anti-inflammatory drugs provide analgesia in camelids; flunixin meglumine is often used (1.1 mg/kg IV, q24h or q12h).
• Opioids including morphine (0.05–0.2 mg/kg IV), butorphanol (0.05–0.1 mg/kg IM or IV), buprenorphine (5 –10 µg/kg IM), and fentanyl (1–5 µg/kg IV) or fentanyl (1–2 µg/kg/hr via transdermal patch) are analgesic but have variable adverse effects on GI motility.
• Constant rate IV infusion of lidocaine, butorphanol, or ketamine have been used to control severe discomfort.
• Orally administered proton pump inhibitors and H-2 receptor antagonists are ineffective in camelids. Pantoprazole (1 mg/kg IV or 2 mg/kg SC, q24h) is effective at increasing the pH of C3.
• Partial parenteral nutrition can be provided by supplementation of isotonic crystalloid fluids with dextrose (1–2%) and amino acids.
• Thiamine (10 mg/kg, q24h) is indicated in animals with prolonged anorexia.
• Provision of 500 mL of fresh rumen fluid via orogastric tube once or twice daily is helpful in anorexic animals unless the procedure causes excessive distress.
• Plasma transfusion (5–10 mL/kg of llama plasma) is indicated for severe hypoproteinemia (albumin ≤1.5 mg/dL, total protein ≤3.5 mg/dL).
• Mineral oil can be given by orogastric tube as a mild laxative (5–10 mL/kg).

CONTRAINDICATIONS

Nephrotoxic drugs should be avoided in dehydrated, azotemic animals.

PRECAUTIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

Variable by underlying disease

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Renal failure
• Peritonitis
• Septic shock

AGE-RELATED FACTORS

Young camelids are more likely to have congenital disorders or bezoar obstruction.

ZOONOTIC POTENTIAL

Some causes of enteritis in camelids are potentially zoonotic, including *Salmonella*, *Giardia,* and *Cryptosporidium.*

PREGNANCY

N/A

BIOSECURITY

Careful hygiene precautions and potential isolation procedures are recommended for infectious disorders and zoonotic pathogens.

PRODUCTION MANAGEMENT

N/A

SYNONYMS

• Colic
• Diarrhea
• Endoparasitism

ABBREVIATIONS

• C1, C2, C3 = compartments of the stomach
• NSAIDs = nonsteroidal anti-inflammatory drugs
• NWC = new world camelids
• SAC = South American camelids
• VRA = vascular ring anomaly

CAMELID: HEAT STRESS

BASICS

OVERVIEW
Disease syndrome in South American camelids exposed to excessively high ambient temperature or combined high ambient temperature and high humidity.

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
Heat stress can occur in any part of the world where ambient temperature rises above 80°F (27°C).

SYSTEMS AFFECTED
- Cardiovascular
- Respiratory
- Digestive
- Hemolymphatic
- Urinary
- Reproductive
- Nervous

PATHOPHYSIOLOGY
- The preoptic area of the anterior hypothalamus receives and processes information from thermosensors throughout the body.
- Hyperthermia arises from thermoregulatory malfunction. In heat stress, malfunction arises due to an elevated thermal burden that the body is incapable of handling.

HISTORICAL FINDINGS
High environmental temperatures ± high humidity prior to the animal displaying signs suggestive of heat stress.

SIGNALMENT
Typically adult camelids in full fiber.

PHYSICAL EXAMINATION FINDINGS
- Signs vary depending on severity.
- Typically there is an elevated rectal temperature that may vary with ambient temperature. If animals are examined early in the course of disease or at a cooler time of day, rectal temperature may not be excessively high.
- Tachycardia and tachypnea.
- Sweating and open mouth breathing are common as disease progresses. Weakness and incoordination occur and can progress to recumbency.
- Ventral edema, particularly scrotal edema in males, is common in affected individuals.
- In severely affected animals, petechial and ecchymotic hemorrhages are associated with disseminated intravascular coagulation (DIC), and a uremic smell to the breath and ulcers in the mouth can occur with secondary renal failure.
- Cyanosis, droopy lip with froth at the commissures, depression, marked weakness, colic, and multi-organ failure (kidney, liver) may occur.

GENETICS
N/A

CAUSES AND RISK FACTORS
- Failure of thermoregulatory function due to exposure to high heat ± high humidity combined with a variety of factors.
- Environmental factors include temperature, humidity, and air movement.
- Animal factors include dehydration, exertion, heavy dark fleece, obesity, pregnancy, lactation, and current or recent illness.
- Nutritional factors include high concentrate diet, high protein hay, selenium-deficient diets, and vitamin- and mineral-deficient diets.
- Management factors include availability of fresh drinking water, shade, and cooling water as well as the presence of fans and the timing of stressful activities.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Vary depending on the observed clinical signs, and can include:
- Infectious diseases that generate fever
- Polioencephalomalacia
- Tick paralysis
- Parelaphostrongylosis
- GI causes of colic
- Urethral rupture (animals with severe ventral edema)
- Testicular abscess or hydrocele (males with scrotal swelling)

CBC/BIOCHEMISTRY/URINALYSIS
- CBC often shows a mature neutrophilia; platelet count may decrease with time.
- Biochemistry abnormalities depend on the organ systems involved. Increases can occur in creatinine, urea nitrogen, AST, CK, bilirubin, and SDH. Hypoproteinemia may be present. Serum sodium and chloride may be decreased. Whole body potassium is often depleted; however, serum concentrations may be elevated in the presence of metabolic acidemia. Metabolic and respiratory acidosis also may be present.
- Urinalysis: Initially increased specific gravity that may become isosthenuric if renal failure ensues; tubular casts may be present in individuals with severe disease; blood and protein also may be present.

OTHER LABORATORY TESTS
Clotting times (may be increased)

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
CSF analysis can be performed to rule out other neurologic diseases.

PATHOLOGIC FINDINGS
- Gross necropsy identifies autolysis that is advanced with respect to the time of death; hemorrhages and other findings consistent with DIC might be present, and serous atrophy of fat.
- Histopathologic changes include renal and hepatic necrosis, coagulative necrosis of neurons, and vascular congestion in the lungs, liver, spleen, and myocardium.

TREATMENT

THERAPEUTIC APPROACH
- Animals should be cooled to achieve a normal rectal temperature, but with caution as they may lack the ability to warm themselves if overcooled. Cooling efforts should focus on the ventral body surface where evaporative cooling is optimal. Intact fleece will help insulate the animal even when wet, so water must soak through to the skin, and shearing can be performed to improve heat loss if shearing is not unduly stressful.
- IV fluids are indicated for correction of dehydration, electrolyte disturbances, and acidosis. Adult camelids require 30–40 mL/kg/day of fluid and crias require 80–120 mL/kg/day. Camelids are prone to pulmonary edema with rapid infusion rates, so administration rate should not exceed 20 mL/kg/h.
- Intranasal oxygen if indicated.
- The extent of body system damage is dependent upon the severity of the exposure.
- Animals that have undergone prolonged severe heat stress may have systemic complications that far outlast the inciting hyperthermic incident.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
- Anti-inflammatory agents
  - Corticosteroids can be given to address shock, including dexamethasone (0.05–0.1 mg/kg, IV or SQ, q48h for 2 treatments) and prednisolone sodium succinate (0.5–1.0 mg/kg IV or SQ, q12–24h).
  - Flunixin meglumine (1.1 mg/kg): should be used cautiously because many heat-stressed animals have renal compromise at presentation.
- Antimicrobial agents to prevent secondary infection
  - Ceftiofur hydrochloride: 2.2 mg/kg IM or SC, q24h; ceftiofur sodium can be used IV at the same dose, q12h.
  - Ampicillin trihydrate: 10 mg/kg IM q24h; sodium ampicillin can be used q8h at the same dose.

- Penicillin: 22,000 IU/kg IM or SC, q12h; potassium penicillin can be used IV q6h at the same dose.
- Antioxidant agents
  - Vitamin E provides immediate antioxidant activity: 1 mL/100 lbs SC or IM (of 300 IU/mL formulation).
  - Selenium (antioxidant activity will take 7–10 days for effect): Bo-Se® at 1 mL/50 lb or Mu-Se® at 1 mL/200 lb.

CONTRAINDICATIONS
NSAIDs and other nephrotoxic drugs are contraindicated in animals with severe renal compromise.

PRECAUTIONS
- Even after regaining normal rectal temperature, heat-stressed animals may have ongoing poor thermoregulation and may be more susceptible to heat stress in future.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- None of the drugs listed are approved for use in camelids and none have established withdrawal times.

POSSIBLE INTERACTIONS
N/A

FOLLOW UP

EXPECTED COURSE AND PROGNOSIS
- Prognosis varies from good to grave depending on presenting condition.
- Early heat stress with no systemic complications will often resolve with cooling and several days in a cooler environment.
- Individuals with organ failure and other serious manifestations may not survive despite aggressive therapy.

POSSIBLE COMPLICATIONS
- Affected animals are more predisposed to heat stress in the future.
- Infertility:
  - Male—excessive heat is spermicidal to primary spermatocytes.
  - Female—ovarian activity will decrease in times of high heat.
- Pregnancy loss.
- Congenital abnormalities in the fetus.

CLIENT EDUCATION
Management steps to reduce the risk of heat stress during hot weather in problematic climates.

PATIENT CARE
- Rectal temperature should be monitored regularly (every 30 mins) until stable, then several times daily.
- Serum biochemistry should initially be monitored every 1–2 days depending on severity of disease to assess progress and provide a basis for alteration in fluid therapy.
- Limit exertion as muscle activity increases heat production.

PREVENTION
- Clients should be educated on risk factors and prevention techniques as well as early recognition of affected animals.
- Use the comfort index (CI; ambient temperature + % humidity) to anticipate problems.
  - CI <120—Problems are unlikely.
  - CI 120–180—Caution. Problems are possible.
  - CI >180—Danger. Problems are likely, observe animals closely.
  - Shear animals prior to hot humid months.
- Adequate access to clean drinking water.
- Adequate access to a mineral and salt supplement.
- Provide shade, fans, and other cooling mechanisms for animals during high heat and humidity.
- Observe animals and institute immediate treatment at signs of trouble.
- It is important to avoid overfeeding as it predisposes to obesity and the necessity to process the excess energy at a metabolic level.
- High-quality forages should be fed during warmer times of the year to decrease the heat increment of digestion.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS

CAMELID: PARASITOLOGY

BASICS

OVERVIEW

• Camelids are susceptible to strongyle-type nematodes, coccidia, protozoa, cestodes, trematodes, and a range of ectoparasites, like other ruminants. *Haemonchus contortus* (barberpole worm) and *Parelaphostrongylus tenuis* (meningeal worm) are economically important nematode parasites of llamas and alpacas in North America. Monthly systemic doses of ivermectin to prevent CNS damage associated with migrating *P. tenius* larvae is thought to contribute to anthelminthic resistance exhibited by *H. contortus* and other gastrointestinal nematodes. Other disease-causing parasites seen in adult camelids include *Nematodirus* sp, *Marshallagia* sp, and *Eimeria macusaniensis*. *Lamanema chavezi*, a nematode of NWC, was identified in an animal from an Oregon herd. In dromedaries and Bactrian camels, *Trichuris* sp. can cause weight loss, ill health, and even death in severe cases. Other parasites such as *Monezia* (tapeworm) are less frequently associated with disease or clinical presentation in adult animals. Nonetheless, as in other ruminants, any one parasite may reduce productivity or cause disease.
• Where trematodes are present, *Fascioloides magna*, *Fasciola hepatica* and *Dircocoelium dendriticum* can infect new world camelids. The latter two are associated with pathology.
• In young camelids, coccidia, *Giardia, Cryptosporidium* and *Mycoplasma haemolaema* can be associated with illness. *Eimeria macusaniensis* is a coccidian that can infect and cause disease in all ages.

INCIDENCE/PREVALENCE

• Nematode parasitism is common wherever camelids are pastured.
• *Mycoplasma haemolamae* infections are most commonly subclinical, with varying incidences in individual herds. In one Ohio herd, 40/100 males housed on pasture containing a mud bottom pond were blood PCR positive. On this same farm, the breeding female herd had a blood PCR positive rate of 18%. Other studies indicate infection prevalence rates of 10–20%.

GEOGRAPHIC DISTRIBUTION

• Worldwide for most nematodes, trematodes, and coccidia.
• *P. tenuis* is found in the Eastern USA and Canada where white-tailed deer and the molluscan intermediate hosts reside.
• *Lamanema chavezi* is common in South America. Recent descriptions of this parasite in Oregon and in New Zealand herds suggests it may parasitize NWCs outside South America.

SYSTEMS AFFECTED

• Digestive
• Hemolymphatic
• Nervous

PATHOPHYSIOLOGY

• *Haemonchus contortus* adults are blood feeders, causing anemia and loss of iron into feces, leading to hypoferremia. As with other ruminant gastrointestinal nematodes, hypobiosis may occur with its importance to the pathophysiology of nematodiasis to be determined in the camelid. *Trichuris* pathophysiology has been described in camelids; the morbidity and occasional mortality is associated with host inflammatory responses to parasites (larval and adult) interwoven within the cecum and large bowel. This response is commonly associated with diarrhea. The importance of trichuroids in camelids is suggested by the requirement for higher dosages of avermectin-type anthelmintics and susceptibility to fenbendazole.
• *Parelaphostrongylus tenuis* causes inflammatory tracts within the CNS. For greater detail, see chapter, *Parelaphostrongylus tenuis* (Meningeal Worm).
• Liver flukes cause cirrhosis, abscesses, and granulomas. Reports of *F. magna* are not common whereas *F. hepatica* or *D. dendriticum* can develop into acute and chronic forms and potentially fatal forms of infection.
• Pathology associated with coccidian parasites occurs in association with the reproductive stages occurring within the gastrointestinal cells causing their rupture and cellular death. As parasite multiplication within hosts progress, hemorrhagic enteritis with diarrhea may result. In severe cases, denudation of the intestinal epithelia may result in anemia and hypoproteinemia.
• *Giardia*, as in other host species, may cause a malabsorptive and maldigestive disorder due to the physical presence of the protozoa on the small intestinal microvilli and the influx of lymphocytes due to small intestinal barrier dysfunction associated with enterocyte apoptosis and disruption of epithelial tight junctions.

SIGNALMENT

• Nematodes are most common in pregnant and nursing dams due to periparturient immunosuppression.
• Coccidial species are most common in juvenile crias in confinement.
• *P. tenuis* can be found in any grazing animal cohabiting with white tail deer.

PHYSICAL EXAMINATION FINDINGS

• *Haemonchus contortus:* Anemia, hypoproteinemia, weakness, weight loss, sire's inability to breed, malnourished cria of nursing dam, and death.
• *Lamanema chavezi:* Anemia, eosinophilia, and focal granulomatous liver lesions.
• *Parelaphostrongylus tenuis:* Ataxia, progressive paralysis (rear limb generally), and recumbence.
• *Fasciola hepatica:* Anemia, progressive weakness, and hypoproteinemia.
• Neonatal GI protozoal disease*:* Diarrhea, anorexia, dehydration and weakness.
• *Eimeria macusaniensis* and other coccidia: lethargy, anorexia, weight loss, sudden death, and mild catarrhal to hemorrhagic diarrhea.
• *Mycoplasma haemolaema:* Hypoglycemia, anemia, seizures, and death.

GENETICS

N/A

CAUSES AND RISK FACTORS

• *Haemonchus contortus:* Overstocking, frequent use of systemic or low-dose anthelmintics, warm wet seasons. Periparturient females from approximately 2 weeks before to 8 weeks after parturition have a clinically significant suppression in immunity to GI nematodes and may shed elevated levels of nematode eggs.
• *Trichuris:* Often associated with paddock/dry-lot confinement after prolonged accumulation of ova. Severe infestations (particularly in old world camelids) can occur after prolonged use of individual paddocks with accumulation of eggs.
• *Lamanema chavezi:* Younger animals are reported to be at greater risk.
• *P. tenuis*: Areas where white-tailed deer and the mollusk intermediate hosts are present.
• Trematodes*:* The life cycle is indirect. For *Fasciola hepatica,* it involves the intermediate host, Lymnaeid snails, and a competent definitive host to shed the trematode ova. The snail sheds the infective form which encysts on aquatic plants and is then ingested. In contrast, *D. dendriticum* is shed by snails, ingested by ants whereby the fluke infective stage will encyst within an ant, later to be ingested by a grazing ruminant. Trematodes require multiple factors for their transmission.
• *Coccidia,* including *E. macusaniensis,* and *Giardia*: Contaminated facilities and environment. The reservoir for coccidiosis and gastrointestinal protozoa are primarily younger animals although adults can be a source of contamination.
• *Mycoplasma haemolaema:* In utero transmission and low concentration or drop in protective maternal antibodies acquired through passive transfer. In other species of *Mycoplasma* biting flies and contaminated needles will transmit these agents.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• *Haemonchus contortus: Mycoplasma haemolamae*, acute or chronic hemorrhage, neoplasia

• *Lamanema chavezi: Mycoplasma haemolamae*, acute or chronic hemorrhage, neoplasia
• *Parelaphostrongylus tenuis:* Trauma, cerebrocortical necrosis, listeriosis
• *Fasciola hepatica:* Hepatic lipidosis
• *Coccidia* and neonatal GI protozoal disease: Viral, bacterial or other protozoal infections; sepsis, hypernatremia hyperosmolar syndrome, selenium deficiency
• *Mycoplasma haemolaema:* Sepsis, cerebrocortical necrosis, listeriosis

CBC/BIOCHEMISTRY/URINALYSIS
Anemia, hypoproteinemia, electrolyte and acid-base abnormalities, azotemia, or hepatic and biliary enzyme elevation may be present depending on etiology.

OTHER LABORATORY TESTS
• Fecal examination for nematode, trematode, and protozoa stages.
• Fecal occult blood positive for coccidia.
• CSF analysis for eosinophilic pleocytosis.
• Blood smear for *M. haemolaema* in acute cases, PCR for survey or more chronic cases.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• *Haemonchus contortus:* Double centrifugation (sucrose; >1.26 specific gravity) fecal flotation for strongyle-type ova, followed by fluorescent peanut lectin staining. Larval cultures to identify and distinguish the first stage larvae. PCR is available through specialized diagnostic laboratories.
• *Lamanema chavezi:* Double centrifugation (sucrose; >1.3 specific gravity) fecal flotation for yellow-brown, cylindrical eggs with parallel sides and rounded poles measuring 170 µm × 73 µm, similar to *Marshallagia* except *Lamanema* are often yellow-brown.
• *Parelaphostrongylus tenuis:* Cerebrospinal fluid with eosinophilia.
• *Fasciola hepatica:* Detection of fluke ova can be problematic. Fecal sedimentation of ova or fecal flotation using a high specific gravity (1.30–1.45) can be used.
• *Coccidia* and *Giardia:* Centrifugation fecal flotation analysis to recover ova and cysts. *Giardia* antigen-based detection kits are available but have not been validated for use in camelids. Sugar solutions with specific gravity of 1.27–1.30 or magnesium chloride at 1.30 can be used to recover coccidian oocysts.
• *Mycoplasma haemolaema:* Peripheral blood smears stained with Wright/Giemsa stains to visualize the 2–3 µm cocci-shaped organisms on the peripheral edges of the red blood cells. PCR is also available through specialized diagnostic laboratories.

PATHOLOGIC FINDINGS
Dependent upon the parasite and organ system infected.

TREATMENT

THERAPEUTIC APPROACH
• Anemia, hypoproteinemia: Blood transfusion, iron supplementation, colloid therapies
• Rehydration, replacement/correction of electrolyte and acid-base abnormalities
• Supportive care: Rest, low stress environment; physical therapy with *P. tenuis*
• Selective chemotherapy to remove parasites (requires parasite identification)
• Analgesia, anti-inflammatories

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE

Nematodes
• Fenbendazole 10–20 mg/kg PO
  ◦ 20 mg/kg PO for 3 consecutive days if *Trichuris*
  ◦ 20 mg/kg PO for 5 days if *Nematodirus*
• Albendazole 10 mg/kg PO (**given only once**)
• Ivermectin 0.2–0.3 mg/kg PO; 0.4–0.6 mg/kg if whipworms present
• Levamisole 5–8 mg/kg PO once
• Pyrantel pamoate 25 mg/kg PO for 3 days

Cestodes
• Fenbendazole 50 mg/kg PO for 5 days
• Praziquantal 2–5 mg/kg PO
• Pyrantel pamoate 25 mg/kg PO for 3 days
• Albendazole 10 mg/kg PO (**given only once**)

Trematodes
• Clorsulon 7 mg/kg PO
• Albendazole 10 mg/kg PO (**given only once**)

Coccidia
• Treatment
  ◦ Sulfadimethoxine 55 mg/kg orally on day 1, followed by 22.5 mg/kg PO once daily for 5 days
  ◦ Ponazuril 20 mg/kg PO once (reportedly used 3 days in a row)
  ◦ Toltrazuril 20 mg/kg PO once (metabolized to ponazuril)
• Prevention
  ◦ Amprolium 5 mg/kg diluted in water for 21 days
  ◦ Decoquinate 0.5 mg/kg orally in feed for 28 days

CONTRAINDICATIONS
Albendazole should not be used in juveniles <6 months of age, pregnant animals or females within 30 days of breeding.

PRECAUTIONS
• Dewormers should be used judiciously and in association with appropriate husbandry and herd management strategies to decrease risk of infection in order to lower risk of increased resistance.
• Albendazole and levamisole have low margins of safety and therefore accurate weight estimation is important.

POSSIBLE INTERACTIONS
Amprolium administration has been associated with development of polioencephalomalacia, although the risk appears to be very low.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Blood feeding gastrointestinal parasites may produce acute or more gradual onset of weakness, weight loss, and loss of condition depending upon number of parasites. These clinical signs often go unnoticed until animal becomes recumbent. A hungry cria not gaining weight should trigger evaluation of its dam.
• Cestodes are not associated with obvious clinical signs. Rarely, intestinal impactions may occur associated with routine deworming of younger stock.
• Whipworms and perhaps *Nematodirus* ova in fecal samples should be considered significant in camelids (especially when associated with clinical signs: diarrhea, hematochezia, colic in herds that routinely administer avermectin-type anthelmintics).

POSSIBLE COMPLICATIONS
Nematode-resistant population to common dewormers such as ivermectin and benzimidazoles.

CLIENT EDUCATION
Clients should be made aware of the major parasite risks in their specific geographic location as well as the seasonality and appropriate management practices necessary to decrease risk. Education on proper anthelmintic usage and resistance is also vital.

PATIENT CARE
N/A

PREVENTION
• Periodic fecal egg count reduction tests to monitor the development of nematode resistance. Maintenance of drug-susceptible nematode refugia population.
• Trematodes: Drain or fence off swampy areas.

MISCELLANEOUS

AGE-RELATED FACTORS
Age resistance may develop to some parasites such as coccidia, nematodes, and cestodes.

CAMELID: PARASITOLOGY (CONTINUED)

Significant susceptibility to nematode infection remains throughout their life.

ZOONOTIC POTENTIAL

Minimal potential and generally only associated with protozoa such as *Cryptosporidium* or *Giardia*.

BASICS

OVERVIEW

• Camelid reproductive anatomy and physiology present many peculiarities compared to other domestic species.
• Knowledge of these differences is required in order to provide a comprehensive reproductive medicine and surgery service.

INCIDENCE/PREVALENCE

Congenital abnormalities of the reproductive system are relatively common in SAC.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Reproductive

PATHOPHYSIOLOGY

Reproductive function is affected by genetics, nutrition, general health, and management.

Female Reproduction

• Puberty: Range is 4–8 months in alpacas, 8–12 months in llamas, 12–24 months in camels. Age at puberty is affected by genetics, nutrition, and early life health and development. • Recommended age at first breeding: 12–15 months in alpacas, 15–18 months in llamas, and 36–48 months in camels. Females should not be bred until they reach 65% of adult weight and height.
• Female camelids are not seasonal if they are in good body condition. • Camelids are induced ovulators. Spontaneous ovulation is very rare (1–5%) and occurs mostly in the postpartum. • Ovulation is induced by seminal plasma (ß nerve growth factor) and uterine inflammation. • In absence of copulation, there is a succession of overlapping follicular waves from both ovaries. Each follicular wave spans 12–23 days and has one or two dominant follicles. Follicles establish dominance when they are 7 mm in diameter in SAC and 8–9 mm in camels. Dominant follicles grow 12 mm in SAC and 25 mm in camels. Dominant follicles regress and become atretic in most cases. In camels, in 25–45% of cases dominant follicles continue to grow and form large anovulatory/hemorrhagic follicles, that may persist for a long time. Anovulatory hemorrhagic follicles may become luteinized and produce progesterone. • In presence of a sterile mating, the preovulatory follicle (7–12 mm in alpacas, 8–13 mm in llamas, 9–25 mm in camels) ovulates 30–48 hours in response to an LH surge which occurs within 30 minutes of copulation. Double ovulations are common. The corpus hemorrhagicum develops into a functional CL over a period of 5–6 days. The CL reaches its maximum diameter (peak progesterone production) by 8 days post-mating. The luteal phase is very short. $PGF2_{\alpha}$ is released by 10 days and another period of receptive behavior starts by 14 days. The left uterine horn secretes $PGF2_{\alpha}$ systemically whereas from the right uterine horn $PGF2_{\alpha}$ secretion is more localized. In ovulating nonpregnant camelids the cycle length (from mating to another period of receptivity with possibility of ovulation) is 12–14 days.

Reproductive Function in the Male

• Penile-preputial adhesions prevent extension of the penis in the first year of life in SAC and for two years in camels. Preputial detachment is a good indicator of sexual activity. Spermatogenesis is initiated at 12 months in SAC but sexual maturity may not be reached until 2 and 3 years in some males. • Camels reach puberty between 3 and 4 years of age. Testicular size continues to grow until 4 years of age. • Sexual maturity is reached at 5 years of age. • Male camels are seasonal breeders and testicular size decreases during the nonbreeding season (dry/summer season).
• Mating behavior ◦ Marking behavior in camels is characterized by smearing poll gland secretion and urine spraying. In SAC marking is limited to rubbing and dusting. ◦ Camels exteriorize the soft palate and produce a metallic sound by grinding their teeth during the rutting season. ◦ Males seek receptive females by smelling their urine, feces, and perineal area. All camelids display flehmen behavior. ◦ Females are chased by the male and forced down by mounting (SAC) or neck pressure (camels). ◦ Receptive females sit in the normal sternal position (cush) which is also the mating position. Female receptivity is not always correlated with follicular activity. Females that sit on their side may be submissive rather than receptive.
◦ Copulation lasts 5–60 minutes in camelids (average 13–24 minutes). During copulation the male will display characteristic behavior (orgling sound in SAC, metallic teeth grinding and soft palate exteriorization in camels). ◦ Semen is deposited in utero in a dribbling manner throughout copulation.

Reproductive Failure in the Female

• Females bred three times to a fertile male without resulting pregnancy should undergo complete evaluation for reproductive function. • The most common manifestations of reproductive disorders in the open female:
◦ Repeat breeding ▪ Females without follicular activity can display receptivity. Anestrus can be caused by nutritional deficiencies (poor body condition), lactation or development abnormalities. Hypothyroidism and pituitary dysfunction are possible but difficult to diagnose.
▪ Ovulation failure: poor follicular development, incomplete mating, lack of LH surge, pituitary or hypothalamic disorders, hypothyroidism. Some males may be at increased risk of failing to induce ovulation.
▪ Fertilization failure: caused by a disorder of gamete transport or survival, developmental abnormalities (persistent hymen, segmental aplasia, double cervix, hydrosalpinx), endometritis, vaginal, cervical or uterine adhesions, endometritis. ▪ Early embryonic death generally caused by uterine disorders, luteal insufficiency, chromosomal abnormalities. ◦ *Absence of receptivity*
▪ Congenital (intersex, gonadal dysgenesis).
▪ Painful conditions, persistent hymen, vaginal or cervical adhesions, acquired anestrus). ▪ Persistent luteal function (persistent CL). ▪ Some females with normal follicular development may continue to refuse the male (behavioral problem). ▪ Immature or small male may be rejected by mature aggressive female. ◦ *Visible abnormalities of the genital tract* ▪ Congenital: persistent hymen with mucometra, vulvar hypoplasia or aplasia, intersex conditions, elongated clitoris.
▪ Acquired: bloody or mucopurulent discharge before or after mating due to uterine infection, vaginal adhesions, stenosis.
◦ *Male-like behavior* ▪ Female camelids may display normal homosexual behavior during the period of receptivity. ▪ Clucking, orgling, and aggressive behavior toward the male may be seen in some androgenized females or in females with gonadal development abnormalities. ▪ *Females with male-like behavior* should be examined for presence of granulosa-theca cell tumor (GTCT).
• Complaints in the pregnant female:
◦ *Repeat pregnancy loss* ▪ Incidence is relatively high in the first 60 days of pregnancy. Very young maiden females and females with previous reproductive problems are at risk. Most common causes are poor development (maiden), uterine fibrosis/inflammation, iatrogenic, poor luteal function, congenital abnormalities (uterus unicornis). ▪ Infectious or noninfectious abortion. ◦ Vaginal prolapse ▪ Generally older or obese females ▪ Occurs in the last trimester of pregnancy ◦ *Uterine torsion* • Occurs in the last 2 months or at term • Common in llamas and alpacas
◦ *Pregnancy toxemia/hepatic lipidosis* ▪ Often a complication of a stressful condition with development of anorexia • Postpartum disorders: ◦ *Retained placenta* ▪ The placenta is considered retained if not delivered 6 hours after parturition. ▪ Predisposing causes include hypocalcemia, uterine inertia, dystocia, selenium deficiency, uterine tears.
◦ *Traumatic injuries to the reproductive tract*
▪ Perineal laceration and rectovaginal tear occurs following dystocia and require surgical correction. ▪ Vaginal tears are often due to prolonged manipulation. Many females develop a severe necrotic vaginitis and vaginal adhesion. ▪ Cervical tears due to poor cervical dilation or early intervention. ◦ *Postpartum metritis* ▪ Severe puerperal metritis may develop after dystocia or prolonged untreated retained placenta. ▪ Endotoxemia may develop. ▪ May be complicated by hepatic lipidosis in anorexic females. ◦ *Postpartum*

CAMELID: REPRODUCTION (CONTINUED)

hemorrhage ■ Rupture of the cranial or caudal (vaginal) branch of the uterine artery during parturition (can be fatal). ◦ *Agalactia* ■ Poor lactation is seen in primiparous females and following dystocia. ■ Obese females are at risk. ■ Fescue toxicosis is suspected to be a cause in SAC.

Reproductive Failure in the Male

• Reproductive disorders in the male should be approached using a thorough breeding soundness evaluation. • The most common complaints are ◦ Poor libido ■ Age and inexperience ■ Musculoskeletal disease ■ Painful conditions of the prepuce, penis (urethra), and testis ■ Pain due to urolithiasis ■ Systemic diseases ■ Megaesophagus in alpacas and llamas may be a major component due to the discomfort caused by orgling (the call of the male). ◦ *Erection failure* ■ Persistent peno-preputial attachment ■ Persistent frenulum ■ Preputial adhesions ■ Neurologic damage to the sacral nerve ■ Sequelae of neurologic diseases (meningeal worm) ■ Sequelae of debilitating diseases ◦ *Ejaculation failure* ■ Improper mating conditions: female position or receptivity, failure of cervical dilation, pneumovagina, urovagina ■ Damaged cartilaginous process of the penis ■ Painful condition ◦ *Oligo- or azoospermia* ■ Incomplete ejaculation ■ Immaturity ■ Testicular hypoplasia ■ Testicular cysts ■ Testicular degeneration ■ Heat stress ■ Orchitis/epididymitis ■ Testicular neoplasia ◦ *Teratozoospermia* ■ Immaturity ■ Testicular degeneration ■ Testicular insult

HISTORICAL FINDINGS

Depends on complaint

SIGNALMENT

Domestic camelids include alpacas (*Vicugna pacos),* llamas *(Lama glama*), dromedary (*C. dromedarius*), and Bactrian camel (*C. bactrianus*).

PHYSICAL EXAMINATION FINDINGS

• History is critical for the diagnosis of all reproductive disorders. • Management is a common underlying problem in many reproductive disorders. • Physical examination findings depend on the complaint.

GENETICS

Some reproductive parameters may be affected by breed.

CAUSES AND RISK FACTORS

Risk factors for reproductive disorders include age, poor management, poor nutrition, and systemic diseases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Differential diagnosis of the cause of infertility in females requires an evaluation combining clinical (palpation and ultrasonography per rectum, vaginal examination), histopathologic (uterine cytology and biopsy), microbiologic (uterine culture), and endocrinologic (hormone assays) techniques. • Differential diagnosis of the cause of infertility in males requires a complete breeding soundness evaluation including clinical (palpation and ultrasonography of the testis), semen collection and evaluation, histopathologic (testicular biopsy), and endocrinologic (hormone assays) techniques. • Other techniques such as hysteroscopy, laparoscopy, exploratory laparotomy, and cytogenetics may be indicated in some cases.

CBC/BIOCHMESTRY/URIANALYSIS

• In the female, CBC and serum biochemistry are indicated if the health of the patient is compromised (uterine torsion, suspected hepatic lipidosis, abortion, postpartum metritis) or the female appears debilitated (downer animals). • In the male, CBC and serum biochemistry are indicated if the male presents for an emergency scrotal or preputial swelling or dysuria.

OTHER LABORATORY TESTS

Serology

Testing for brucellosis, BVD, trypanosomiasis

Bacteriology and Virology

• Diagnosis of uterine infection • Diagnosis of infectious causes of abortion

Endocrinologic Evaluation

Progesterone

In the absence of luteal tissue, serum progesterone should be <1 ng/mL. Concentrations of 1–2 ng/mL are difficult to interpret but suggest presence of luteal tissue. Concentrations >2 ng/mL suggest presence of a normal CL.

• Occurrence of ovulation: samples taken 8 days after mating. • Pregnancy diagnosis: samples taken 14 days and 3 weeks after mating. • Pregnancy loss: luteal insufficiency. Samples <1.5 ng/mL in females confirmed pregnant by ultrasonography are arbitrarily considered suspect for luteal insufficiency.

• Accuracy is affected by: ◦ Laboratory errors, sensitivity of method used ◦ Sample handling errors ◦ High progesterone may indicate persistent CL function or presence of luteinized anovulatory follicles.

Estrogens

• Determination of estradiol 17β or estrone sulfate. • Determination of follicular activity. Not as accurate as ultrasonography.

• Pregnancy: Ultrasonography is easier and more accurate.

FSH Challenge

Administration of FSH or FSH-like hormones (eCG) may be used to determine whether the female is capable of growing follicles (differentiates acquired anestrus from congenital ovarian hypoplasia).

LH or GnRH Challenge

• Administration of LH in the form of hCG or GnRH allows verification of the ability of the female to ovulate. • Administration in males followed by determination of testosterone levels allows verification of presence of testicular tissue (cryptorchid, intersex).

Inhibin and Anti-Mullerian Hormone

• In the male: diagnosis of cryptorchidism

• In the female: diagnosis of GTCT

Testosterone

Presence of testicular tissue (cryptorchid) or interstitial cell tumors

Thyroid Function Evaluation

Testing for hypothyroidism is indicated in cases of absence of ovarian activity, recurrent pregnancy loss, or poor spermatogenesis.

Cytogenetics

• All camelids have 74 chromosomes.

• Karyotyping and chromosome banding is indicated in all cases of congenital abnormalities or in females born co-twin to male (rare but possible). • Cytogenetic abnormalities include: 73 XO, 74XX/73XO, 74XX/73XY, 75XXX, 74XX sex reversal, 74XY testicular feminization. • A minute chromosome has been reported in llamas and alpacas and has been found in females with ovarian dysgenesis.

Semen Collection and Evaluation in Males

See chapter, Breeding Soundness Examination: Camelids.

Trace Mineral Analysis

Trace mineral status should be evaluated in all cases on unexplained infertility, abortion, and recurrent pregnancy loss.

IMAGING

• Ultrasonography ◦ In the female: Transrectal ultrasonography (linear 5 or 7.5 MHz transducer) is an important part of any reproductive evaluation of the open or early pregnant female. Transabdominal ultrasonography (3.5 MHz linear or sector transducer) is performed at any stage of pregnancy to determine fetal and placental health in females with compromised health. Transabodminal ultrasonography may be used for the diagnosis of other ovarian and uterine disorders not visualized on transrectal ultrasonography. ◦ In the male, ultrasonography is important for the evaluation of testicular parenchyma, and verification of presence of abdominal or inguinal testes. • Radiography ◦ Fluoroscopy should be considered for the evaluation of cervical patency.

OTHER DIAGNOSTIC PROCEDURES

• Vaginal examination ◦ Indicated for all open females, pregnant females with abnormal vaginal discharge. ◦ Use mare tube speculum for camels and llamas, and human sigmoidoscope for alpacas. ◦ Look for congenital or acquired vaginal and cervical

abnormalities, origin of discharge. • Uterine culture and cytology ◦ Indicated for all females with a history of infertility or presence of abnormal uterine content or vaginal discharge. ◦ Use mare double-guarded swabs for bacteriology and cytobrush for endometrial cytology. ◦ Ideally done when female is receptive (cervix open). ◦ Samples should be taken from the uterine cavity (not the cervix). ◦ Combined bacteriology and cytology are very good for the assessment of uterine infection. • Endometrial biopsy ◦ Considered the gold standard for prognostication of the ability of a female to maintain a pregnancy to term. ◦ It should be performed in all cases of chronic infertility or recurrent pregnancy loss. ◦ For camels and llamas, use mare biopsy forceps; use heifer or human rectal biopsy forceps (Turell) for alpacas and llamas.
• Laparoscopy/exploratory laparotomy ◦ Use techniques similar to sheep and goats for llamas and alpacas. ◦ Laparoscopy is difficulty in camels, exploratory flank laparotomy is preferred. ◦ Use for the confirmation of abnormalities suspected on palpation and ultrasonography: ▪ Periuterine adhesions ▪ Ovarian abnormalities (dysgenesis, tumors, cystic structures, adhesions) ▪ Segmental aplasia ▪ Verification of uterine tube patency.
• Hysteroscopy ◦ Indications: abnormal echotexture of the uterus, severe bleeding following mating, unexplained infertility. ◦ Alpaca and llamas: use pediatric gastroscope. ◦ Camels: use adult gastroscope. ◦ Animals should be sedated. ◦ Each uterine horn should be examined all the way to the uterotubal junction. ◦ Findings: uterine tears, intraluminal adhesions, neoplasm, cysts, foreign objects.

PATHOLOGIC FINDINGS

• Ovarian abnormalities include hypoplasia or dysgenesis, ovarian neoplasia (GTCT and teratomas) • Congenital (infantilism, uterus unicornis, mucometra) or acquired uterine abnormalities (fibrosis, inflammation, pyometra, intraluminal adhesions, uterine cysts) • Congenital (cervical aplasia, stenosis) or acquired cervical abnormalities (cervical lacerations, fibrosis, adhesions) • Congenital (duplication, persistent hymen, stenosis) or acquired (adhesions) vestibulo-vaginal abnormalities • Testicular and penile abnormalities in males

TREATMENT

THERAPEUTIC APPROACH

• Treatment protocol depends on the complaint. • Animals with congenital defects should be removed from breeding.
• Treatment of endometritis requires uterine lavage followed by proper antimicrobial therapy for 4–5 days. • Acquired ovarian disorders are treated by proper hormonal management, adjustment of nutrition or surgically.

SURGICAL CONSIDERATIONS AND TECHNIQUES

• In the female ◦ Unilateral ovariectomy (laparoscopy or via flank laparotomy) for all acquired ovarian and bursal disorders that cannot be managed by hormonal therapy. ◦ Vulvoplasty in cases of postpartum perineal laceration. ◦ Uterine torsion may require surgical correction via laparotomy. • In the male ◦ Castration (normal) or cryptorchidectomy (parainguinal or laparoscopy-assisted) for nonbreeding quality males. ◦ Unilateral castration for unilateral acquired testicular disorders.

MEDICATIONS

DRUGS OF CHOICE

• Hormones
◦ Oxytocin (IM): (5–10 IU in llamas and alpacas, 20–40 IU in camels) for retained placenta
◦ $PGF2_{\alpha}$ (Dinoprost tromethamine IM, 5–10 mg in SAC, 20–35 mg for camels) or analogs (Cloprostenol IM, SAC 250 µg, camels 500–750 µg) for retained CL or luteal structures and induction of parturition or abortion.
◦ PGE (misoprostol): Cervical dilation within 30–120 minutes after local application of 500 µg–1 mg of PGE in gel.
◦ Progesterone for maintenance of pregnancy: natural progesterone daily (50 mg in SAC, 150 mg in camels) or hydroxyprogesterone caproate (250 mg every 3 weeks in alpacas).
◦ Human chorionic gonadotropin (hCG) IV, 500–750 IU for SAC, 1,500–3,000 IU for camels for induction of ovulation.
◦ GnRH or analogs IM (50 µg in SAC and 100 µg in camels) for induction of ovulation or to increase libido in males.
• Antibiotics
◦ Postpartum metritis: Systemic antibiotics.
◦ Uterine lavage (make sure that there are no traumatic lesions to the uterus and cervix).
◦ Endometritis
▪ Uterine flushing with a buffered solution.
▪ Intrauterine infusion of antibiotics based on culture and sensitivity for 3–5 days.
▪ Some antibiotics such as ceftiofur can be used systemically.

CONTRAINDICATIONS

• Appropriate milk and meat withdrawal times must be followed for food-producing animals. • Anti-inflammatory steroids are contraindicated during pregnancy, particularly in the last half. • Estrogens should not be used to enhance cervical dilation. • Testosterone or anabolic steroids should not be used in breeding males. • Progesterone therapy is contraindicated in cases of uterine infection.

PRECAUTIONS

• Toxicity (respiratory distress) has been reported with high doses of $PGF2_{\alpha}$.
• Aminoglycosides are nephrotoxic.

POSSIBLE INTERACTIONS

• Maintenance of pregnancy with exogenous progesterone may result in failure of cervical dilation. • Progesterone therapy should be stopped at 300 days' gestation in SAC.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Prognosis for fertility: Good for uterine infections and unilateral ovarian disorders with proper treatment and management of breeding. • Prognosis is poor for females with severe chronic uterine disorders, cervical or vaginal adhesions. Assisted reproductive biotechnologies may be the only course of action. • Prognosis for fertility in males is good if affection is unilateral and no other complications are observed.

POSSIBLE COMPLICATIONS

• Mucometra and pyometra are common complications of congenital abnormalities and severe vaginal or cervical adhesions.
• Peritonitis and periuterine adhesions may occur following ovariectomy or laparoscopy.
• In males, complications of castration.

CLIENT EDUCATION

• All breeding animal should undergo a BSE before initiation of mating. • Animal with congenital defects should be removed from the breeding pool. • Breeding animals should be in top health (adequate nutritional and preventive program). • Females should undergo postpartum examination before rebreeding. • Breeding management practice: Avoid excessive mating.

PATIENT CARE

Varies depending on complaint and diagnosis

PREVENTION

• Prevention of acquired infertility relies on a sound herd health program and good management practice. • Practice strict measures of biosecurity and hygiene in breeding animals, particularly if outside animals are bred.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Varies according to complaint. • Poor nutrition and contagious infectious diseases may be the underlying cause of infertility.

CAMELID: REPRODUCTION (CONTINUED)

AGE-RELATED FACTORS

• Congenital defects should not be overlooked in young/maiden animals. • Senile changes include poor ovarian activity, uterine degenerative changes in the female, and poor libido and testicular degeneration in males.

ZOONOTIC POTENTIAL

Many abortive diseases are potentially zoonotic.

PREGNANCY

• The left uterine horn is almost always the fetal horn in camelids. • Maintenance of pregnancy relies exclusively on ovarian progesterone. • Administration of $PGF2_{\alpha}$ or analogs at any stage results in loss of pregnancy.

BIOSECURITY

• Quarantine all breeding animals from other herds and animals participating in shows or other off-farm activity. • Fencing is extremely important when herds are in proximity to each other. • Contact with other ruminants should be monitored and limited.

PRODUCTION MANAGEMENT

• Free mating systems: Practiced in large herds with one male or several males in a group. It does not allow precise record keeping for breeding dates and early identification of infertile males or females. Pregnancy diagnosis is scheduled periodically. Prediction of parturition date requires estimation of gestation age. • Controlled field mating: The male is introduced at a specific time of the day and observed for breeding activity. Some males may display complete breeding behavior but do not complete penetration. Pregnancy diagnosis is scheduled at specific dates after mating. • In-hand mating: This system is commonly used for breeding valuable animals and has several advantages: breeding records and pregnancy stages are more precise.
• Controlled breeding: Females are presented to the stud only after veterinary verification of follicular status. This system is recommended for efficient use of males and management of infertile females or visiting females.

BASICS

OVERVIEW

• *Campylobacter* are Gram-negative, microaerophilic, curved or spiral rods in the family Campylobacteriaceae.
• *Campylobacter jejuni* (formerly known as *C. fetus* subsp. *jejuni*) and *C. coli* are associated with enteritis in domestic animals. *C. fetus* subsp. *fetus* is found in cattle, sheep, and goats. *C. fetus* subsp. *venerealis* is found in cattle.
• *C. jejuni*, *C. fetus* subsp. *venerealis*, and *C. fetus* subsp. *fetus* (also known as *C. fetus* subsp. *intestinalis* and *Vibrio fetus var intestinalis*) cause infertility and abortions in sheep, cattle, and goats.
• An additional subspecies of *venerealis* was identified as biotype *intermedius* (*C. fetus venerealis intermedius*) which has also been shown to cause fertility issues in cattle.
• *C. fetus* subsp. *fetus* is occasionally isolated from humans with septicemia.
• *C. lari, C. hyointestinalis,* and *C. upsaliensis* have been reported to cause disease but seem to be of minor importance in domestic animals.
• *C. jejuni* can be shed for as long as 2–7 weeks in untreated infections and *C. fetus* subsp. *fetus* can be shed for several days to several weeks.

INCIDENCE/PREVALENCE

• Incidence of *C. jejuni* and *C. coli* enteritis and resultant diarrhea is variable and oftentimes these organisms can be isolated from healthy animals with no apparent signs of disease.
• Bovine infections with *C. fetus* subsp. *fetus* do occur but are considered to be much more sporadic in occurrence in comparison to sheep.

GEOGRAPHIC DISTRIBUTION

• Campylobacteriosis exists worldwide including South-America, Africa, Asia, North America, Europe, and New Zealand.
• The true prevalence of *Campylobacter* in some countries is still questionable due to lack of reporting and reliable testing.

SYSTEMS AFFECTED

• Reproductive
• Digestive

PATHOPHYSIOLOGY

• *C. fetus* subsp. *fetus* is transmitted primarily by ingestion in cattle, sheep, and goats.
• Oral transmission of *C. fetus* subsp. *fetus* occurs and results in bacteremia and subsequent colonization of the gall bladder and intestines of sheep and cattle leading to systemic infections: enteritis, hepatitis and late-term abortion, still births, mostly in sheep and goats and sporadically in cattle.
• Transmission can also occur following contact with contaminated feed, water, feces, vaginal discharges, aborted fetuses and fetal membranes.
• Venereal transmission of *C. fetus* subsp. *venerealis* as well as an additional subspecies of *venerealis* biotype *intermedius* (*C. fetus venerealis intermedius*) can occur.
• Genital *C. fetus* infections can be spread on fomites including contaminated semen, contaminated instruments and bedding.
• Cattle are considered the primary reservoir of *C. fetus* subsp. *venerealis* and bulls may transmit *C. fetus* for several hours after being bred to an infected cow; some bulls and cows can become chronic or persistent carriers, respectively.
• During coitus contaminated semen gains entrance to the vagina and can live in the cervical mucus for 3 weeks to 3 months.
• The organism can grow and thrive on the penis and prepuce of the bull with the correct microenvironment.
• *C. fetus* subsp. *venerealis* and *C. fetus venerealis intermedius* are confined to the epithelial surface of the glans penis, prepuce, and the urethra.
• Infection is often manifested as infertility, embryonic and fetal death, metritis, placentitis, salpingitis, pyometra, and abortion.

HISTORICAL FINDINGS

In herds with venereal disease, poor conception rates or birth rates may be the first sign noticed.

SIGNALMENT

• Naïve, pregnant ruminants are most often severely affected by *C. fetus* subsp. *venerealis* and *C. fetus* subsp. *fetus.*
• *C. jejuni and C. coli* will affect naïve animal populations as well.

PHYSICAL EXAMINATION FINDINGS

• Enteritis, diarrhea, and dehydration are seen in *C. jejuni* and *C. coli* infections.
• Infertility, placentitis, salpingitis, embryonic and fetal death, abortion, stillbirths, vulvar discharge, metritis, reduced lamb and kid crops, and calf crop, and reduced weaning weights are seen in *C. fetus* subsp. *venerealis* and with *C. fetus* subsp. *fetus*.

GENETICS

N/A

CAUSES AND RISK FACTORS

• Exposure of naïve populations to *C. fetus* subsp. *fetus* and *C. fetus* subsp. *venerealis* is a risk factor.
• Widespread contamination of feed and water troughs and pastures increases the chances for exposure and infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• There are a number of diseases in sheep and goats that result in abortion infertility and have similar signs such as trichomoniasis, bluetongue, BVDV, with many being zoonotic including: *Brucella melitensis* (goats), *Brucella ovis* (sheep), *Coxiella burnetii*, *Chlamydophila abortus, Leptospira* spp., *Listeria monocytogenes, Toxoplasma gondii,* and Rift Valley fever.
• The differentials list for enteritis and diarrhea is a long one and includes: toxic insults, nutritional disturbances, *E. coli* and *Salmonella*, Border disease, BVDV, corona- and rotaviruses, and many others.

CBC/BIOCHEMISTRY/URINALYSIS

• Neutrophilia with a high firbrinogen due to local and systemic infection is often found.
• The hematocrit may be decreased or falsely elevated due to dehydration.

OTHER LABORATORY TESTS

• Fecal and blood cultures may be run on sick animals.
• Uterine/vaginal swabs taken within 3 days of abortion.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

• *Campylobacter* spp. have an "S," "spiral," or "seagull" shape.
• In order for *Campylobacter* to be detected on culture, it must be incubated at 37°C for at least 3 days in a micro-aerobic atmosphere.
• Discrimination between species and subspecies requires additional biochemical or molecular methods (i.e., PCR).
• A presumptive diagnosis can be made utilizing dark field or phase contrast microscopy if characteristic darting motile organisms are seen.
• Whole or partial placentas are optimal for submission for culture and analysis.
• Acute (at the time of abortion) and convalescent (2–3 weeks post-abortion) serum titers are an important indicator of current and past exposure and can reflect ongoing bacteremia or viremia.
• Diagnosis via collection of cervical mucus from infected cows and heifers at 3 weeks to 3 months post-infection can be made.
• If cervical mucus is collected in metestrus, false-positives can occur at a higher rate.
• Culture results, vaginal mucus agglutination tests, and fluorescent antibody tests can all be questionable so confirmatory PCR is being looked to as a more reliable diagnostic of herd infection.
• Bulls: Preputial scraping or preputial wash performed twice, one week apart, or testing of contaminated semen via culture, fluorescent antibody, and PCR.
• It is imperative that the sample be inoculated into Clark's media soon after collection to allow for maximum survival of the organism.
• The organism can survive for approximately 6–8 hours following collection but when placed in Clark's media it will allow for a longer period of survival up to 48 hours.

CAMPYLOBACTER (CONTINUED)

PATHOLOGIC FINDINGS

• Whole or partial placentas are optimal for assessment of pathology.
• Abortion, metritis, endometritis, salpingitis, and enteritis can all be seen in the dam during and after infection.
• The fetus may have bronchopneumonia, pleuritis, hepatitis, or peritonitis and may even present as an autolyzed fetus in *C. fetus* abortions in sheep.
• Necrotic yellow to orange foci in the liver, mild placentitis with hemorrhagic cotyledons, and edematous "leathery" intercotyledonary areas may be seen.
• Histologically areas of vasculitis and necrosis are seen.
• Fetal and placental lesions may also be absent.
• The aborted fetus is the best sample for diagnosis of *C. fetus* subsp. *fetus*.
• The aborted fetus and preputial washes are the most likely samples from which to isolate *C. fetus* subsp. *venerealis.*

TREATMENT

THERAPEUTIC APPROACH

• *C. fetus* subsp. *fetus* abortion storms in sheep can be treated with tetracyclines, penicillin, or streptomycin.
• Supportive care including fluids, antibiotics, and anti-endotoxin drugs may be necessary in cases of *C. jejuni* and *C. coli* enteritis.
• Whole herd treatment of *C. fetus* is considered to be impractical due to the lack of overt clinical signs at the initiation of the disease process.
• Bulls may be treated with extra-label administration of one to two treatments of streptomycin given subcutaneously at a dose of 20 mg/kg along with administration of a topical suspension containing 5 g streptomycin to the prepuce and penis for three consecutive days, but resistant strains have been reported.
• Prevention of venereal diseases in the herd is the most practical approach to dealing with *C. fetus*.

MEDICATIONS

DRUGS OF CHOICE

• Tetracyclines, penicillins, and streptomycin.
• Streptomycin is the drug of choice for *C. fetus* subsp. *venerealis* infections but resistance has been reported.

CONTRAINDICATIONS

All animals receiving drugs must undergo the determined milk and meat withdrawal times prior to the meat or milk from the animal entering the food supply.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Mortality is low in adult sheep and cattle.
• Morbidity may be up to 90% in outbreaks in sheep but is usually around 5–50%.
• For sheep flocks, there will be some level of convalescent immunity which will decrease infections and abortions for a few years but subsequent abortions and fertility problems will again occur.
• Most cows will clear the infection in approximately 3–6 months and have some immunity to *C. fetus* subsp. *venerealis.*
• Bulls will often develop a chronic infection and carrier state with *C. fetus* subsp. *venerealis* infections due to the organism thriving in the microenvironment of the bull's prepuce and penis.
• Herd immunity can reduce the significant economic losses associated with *Campylobacter* infections but, due to short-lived immunity, losses will continue if strict prevention and control measures are not instituted.

POSSIBLE COMPLICATIONS

Additional complications may include endocarditis, pericarditis, pneumonia, thrombophlebitis, peritonitis, or meningoencephalitis.

CLIENT EDUCATION

See "Biosecurity"

PATIENT CARE

Appropriate monitoring and treatment of all sick animals as well as isolation from other pregnant animals is indicated.

PREVENTION

• Control measures include utilization of AI with non-contaminated semen, testing and culling of infected animals, and vaccination of all bulls, cows, and heifers.
• Utilization of AI exclusively for two breeding seasons is suggested in infected herds.
• The use of AI is impractical in range cattle but most producers utilize management (cull problem cattle and use virgin bulls) and vaccination as their primary means of prevention and control.
• The recommendations for vaccination by the World Organisation of Animal Health (OIE) include vaccination of all infected herds: all breeding animals should be vaccinated twice prior to the breeding season.
• Cows and heifers are often administered an additional vaccine in the middle of the breeding season to enhance their immunity.
• Vaccination reduces the length of the infection but carrier cows may still infect susceptible bulls.
• It has been suggested that bulls should be given double the dose of vaccine at each of two vaccinations annually to assist in terminating established infections.
• Noninfected herds: Bulls should at least be vaccinated initially with two doses given 3–4 weeks apart with the last dose approximately 30 days prior to the start of the breeding season.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Bacteremia, septicemia, hepatitis, dehydration, and death can all be associated with infections.

AGE-RELATED FACTORS

Older flocks and herds might have some protection from previous exposure or vaccination.

ZOONOTIC POTENTIAL

• *Campylobacter* species are readily transmitted between animals or from animals to humans.
• Organisms are present in feces, vaginal discharges, and the products of abortions and can be spread by direct contact, on fomites, and by arthropods acting as mechanical vectors.
• The consumption of raw milk and contaminated meat are the primary sources of infection in humans.

PREGNANCY

Female ruminants may become pregnant but sporadically abort in the case of *C. fetus* subsp. *fetus* and *C. fetus* subsp. *venerealis* results in early embryonic death and repeat breeder syndrome as well as abortion in sheep and cattle.

BIOSECURITY

• Isolation and testing of sick animals and any replacements is necessary to prevent disease transmission to herd animals.
• Disinfectants can be utilized to kill *Campylobacter* species and 1% sodium hypochlorite, 70% ethanol, 2% glutaraldehyde, iodine-based disinfectants, phenolic disinfectants, and formaldehyde are efficacious against the organism.
• Disinfectants have been used to kill *C. jejuni* and *C. fetus* in drinking water.
• Moist heat, dry heat, and gamma irradiation and UV radiation can also kill *C. jejuni* and *C. fetus.*

PRODUCTION MANAGEMENT

• Isolation and testing of sick animals along with vaccination during abortion storms seems the most effective against *C. fetus* subsp. *fetus* abortion storms.
• Use of virgin bulls that are tested negative for *Tritrichomonas* and *Campylobacter*.
• Culling carrier bulls.
• Utilization of AI with antibiotic extenders for 2 years due to the chance of a bull breeding a chronically infected cow.
• Follow guidelines for vaccination.

(CONTINUED) CAMPYLOBACTER

SYNONYMS

Vibriosis

ABBREVIATIONS

- AI = artificial insemination
- BVDV = bovine viral diarrhea virus
- PCR = polymerase chain reaction

CANDIDIASIS

BASICS

OVERVIEW
• *Candida* is not highly pathogenic and rarely causes disease in healthy animals.
• Various *Candida* species are normal microflora of intestinal, oral, upper respiratory, and reproductive tracts of mammals and are commonly found in feces.
• Causes opportunistic disease in various body systems, especially in immunocompromised or malnourished animals or those that have been extensively treated with antibiotics.

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
Candida spp. are found worldwide.

SYSTEMS AFFECTED
• Integument
• Digestive
• Reproductive
• Respiratory

PATHOPHYSIOLOGY
• *Candida* spp. are yeasts that propagate by budding.
• Cells are round to oval, 3.5–6 × 6–10 µm and buds are single or multiple.
• Form blastoconidia, pseudohyphae, and true hyphae in culture and in tissues.
• Form mycelium or pseudomycelium when invading tissue.
• *Candida* spp. produce acid proteinases and keratinases, which degrade the stratum corneum, and phospholipases, which aid in penetration of tissues.
• In systemic mycosis, the alimentary tract is the most common route of entry of the organism, which then spreads hematogenously.

SIGNALMENT
• Cattle, camelids, sheep, and goats.
• Most common in neonatal, debilitated or immunocompromised animals.
• Occurs as a complication of polyantimicrobial therapy.

PHYSICAL EXAMINATION FINDINGS
• Depends on organ systems affected.
• Dermatitis
  ◦ Reported in cattle, camelids, sheep, and goats.
  ◦ Chronic moisture and skin maceration predispose to yeast invasion.
  ◦ Cattle: Ulceration, erosion, scaling, crusting, papules, pustules, and secondary alopecia.
  ◦ Goats: Nonpruritic exfoliative dermatitis with alopecia, scales, crusting, greasiness, and lichenification.
  ◦ Evaluate affected goats for protein deficiency or trace mineral deficiency.
  ◦ Camelids: Nonpruritic crusting, papule formation, and epidermal hyperplasia.
• Alimentary
  ◦ Reported primarily in cattle.
  ◦ Calves: Oral candidiasis (thrush) is characterized by white pseudomembranous plaque and ulcers over tongue and gingiva.
  ◦ Mycotic pharyngitis and gastroenteritis in calves results in white pseudomembranes at back of pharynx and extending down to forestomachs.
  ◦ Diarrhea in young calves following prolonged use of antimicrobials.
  ◦ Adult cattle: Mycotic omasitis, rumenitis, and enteritis reported; forestomach lesions include acute hemorrhagic mucosal necrosis.
  ◦ Cattle with GI candidiasis may show nonspecific signs including lethargy, hypophagia, milk drop, decreased GI motility, ± fever, ± low-grade abdominal pain.
• Abortion
  ◦ Rare cause of abortion in cattle and goats.
  ◦ Abortion at 6–8 months' gestation in cattle.
  ◦ Abortus may have patchy alopecia and/or felted appearance.
• Mastitis
  ◦ Reported in cattle, sheep, and goats.
  ◦ Milk drop, increased SCC and hard, swollen udder usually resolve spontaneously after 5–6 days.
  ◦ Organisms are shed in milk for 1–5 weeks; SCC remains increased for up to 2 months.
  ◦ Fever (104–107°F; 40–40.5°C) may be seen acutely.
  ◦ May become chronic.
• Pneumonia
  ◦ Reported in cattle and sheep.
  ◦ Seen in calves and lambs raised indoors.
  ◦ Feedlot cattle may show chronic pneumonia, pulmonary abscesses, dyspnea, fever, brownish nasal discharge, diarrhea, and lacrimation; outbreaks have been reported.
• Systemic candidiasis
  ◦ Reported in cattle, sheep, goats, and camelids.
  ◦ Peracute septicemic infections reported in newborn calves.
  ◦ May affect lungs, GI tract, brain, kidney, liver, heart, pancreas, udder, and reproductive tract.
  ◦ Signs depend on system(s) affected; fever (104–107°F; 40–40.5°C) may be seen.

CAUSES AND RISK FACTORS
• Prolonged antibiotic therapy, especially if administered orally.
• Immunocompromised.
• Glucocorticoid or immunosuppressive therapy.
• Malnutrition.
• Exposure to chronic moisture.
• Feeding of poorly formulated artificial diets to sucklings.
• Use of intramammary infusions may be a risk for development of mastitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
• Other fungal, bacterial or parasitic skin infections.
• Other systemic mycoses.
• Common causes of diarrhea, mastitis, or pneumonia in ruminants.

CBC/BIOCHEMISTRY/URINALYSIS
No specific clinicopathologic changes have been noted.

OTHER LABORATORY TESTS
• Isolation of organism from infected material plus histologic evidence of invasion is the gold standard.
• Culture of skin biopsy, lesion swab or feces: Sabouraud dextrose agar incubated at 30°C; also grows readily on potato dextrose agar and blood agar.
• Colonies are white to cream, shiny, convex, 3–5 mm diameter and smell "beery."
• Skin scraping for cytology, impression smears taken from the edge of the lesion, or direct fecal smears: Budding yeast or pseudohyphae may be seen.
• Scrapings/smears may be viewed with 10% KOH, Diff-Quick, Gram or new methylene blue stains.
• Periodic acid-Schiff, Gridley or Gomori methenamine silver techniques make organisms visible in tissue biopsies or necropsy specimens.
• In systemic cases, polymerase chain reaction, immunohistochemistry or serology may be useful.

OTHER DIAGNOSTIC PROCEDURES
• Direct smear or scraping: Cytology of lesion exudate.
• Culture of lesion exudate, tissue or feces.

PATHOLOGIC FINDINGS
• Dependent on system affected.
• Yeasts, pseudohyphae or hyphae demonstrated as invading tissue.

TREATMENT

THERAPEUTIC APPROACH
• Treatment of underlying or predisposing condition.
  ◦ Withdrawal of immunosuppressive drugs.
  ◦ Withdrawal of antibiotics, if possible.
  ◦ Provide adequate and balanced nutrition.
  ◦ Treat underlying disease process if present.
  ◦ Remove from excessive moisture.
• Dermatitis:
  ◦ Focal lesions: clip, dry, and apply topical medication.
  ◦ Topical therapies for dermatitis:
    ▪ Nystatin (100,000 U/g).
    ▪ 2% Miconazole.

- 1% Clotrimazole (over-the-counter vaginal cream).
- Potassium permanganate (1:3000 in water).
- Enilconazole 0.2% solution.
- Apply 2–3 times a day until lesions are healed.
- Only use approved drugs in food animals.

◦ Treatment for severe dermatitis may require administration of oral or parenteral antifungal agents; however, no protocols have been validated.
- No systemic antifungal agents are approved for use in food animals.
- Efficacy of oral antifungals in ruminants is not known.

• Alimentary:
◦ Oral candidiasis: No validated treatment regimens. Human recommendations include nystatin or 1% gentian violet mouthwash.
◦ Enteric candidiasis: No validated treatments. Transfaunation may be of benefit.
• Abortion:
◦ No treatments have been reported.
• Mastitis:
◦ Most cases are self-limiting.
◦ No antifungal agents are labeled for intramammary infusion.
◦ Chronic cases should be culled.
• Pneumonia:
◦ No treatments have been reported.
◦ If attempted, systemic antifungals should be used.
◦ None labeled for food animals.
• Systemic mycosis:
◦ No successful treatments reported for systemic candidiasis.
◦ Doses must be extrapolated from other species (usually dogs).

MEDICATIONS

DRUGS OF CHOICE

• Systemic mycosis:
◦ No successful treatments reported for systemic candidiasis.
◦ Doses must be extrapolated from other species (usually dogs).
- Amphotericin B 0.6–1 mg/kg/day IV (human dose).
- Fluconazole 5–10 mg/kg PO, q12h.
- Itraconazole 5–10 mg/kg PO, q12h.
- Ketoconazole 5–10 mg/kg PO q24h.
- IV azole formulations exist, but no pharmacokinetic data in food animals.

• Up to 10% of *Candida* isolates may be azole-resistant.

CONTRAINDICATIONS

• Many of the suggested drugs for therapy are not approved and therefore should not be used in food animals.
• Confirm safety of drugs in species to be treated before initiating therapy.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Dermatitis usually resolves with appropriate therapy.
• Alimentary candidiasis often resolves in calves but guarded prognosis in adults.
• Chronic *Candida* mastitis is considered incurable.
• No information on future breeding success following *Candida* abortion.
• *Candida* pneumonia or systemic disease cases usually die despite treatment.

POSSIBLE COMPLICATIONS

• Hematogenous spread of fungus.
• Adverse reaction to antifungal therapy.

PATIENT CARE

• If underlying condition is an inherent immunodeficiency, prognosis is guarded to poor.
• Poor prognosis for systemic mycosis.

PREVENTION

• Avoid long-term or high-dose glucocorticoids.
• Avoid polyantimicrobial therapy, especially oral.
• Provide an adequate plane of nutrition.
• Prevent chronic exposure to moisture or wet conditions.
• Use appropriate hygiene when administering intramammary infusions.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Immunocompromise
• Malnutrition

AGE-RELATED FACTORS

Disease is more severe in neonates.

ZOONOTIC POTENTIAL

Not zoonotic; *Candida* spp. are normal human flora.

PREGNANCY

Abortion in the third trimester has been seen in cattle and goats.

PRODUCTION MANAGEMENT

• Provide adequate and appropriate nutrition.
• Avoid the use of moldy or musty hay or straw.
• Keep animals in a dry environment.
• Avoid prolonged or inappropriate use of antimicrobial agents and corticosteroids.
• Use appropriate hygiene when infusing intramammary medications.

SYNONYMS

• Candidosis
• Moniliasis
• Thrush

ABBREVIATIONS

• PO = per os, by mouth
• SCC = somatic cell count

SEE ALSO

• Abortion: Bovine
• Abortion: Camelids
• Abortion: Small Ruminant
• Mastitis, fungal

CAPRINE ARTHRITIS ENCEPHALITIS VIRUS

BASICS

OVERVIEW

• Caprine arthritis encephalitis (CAE) is characterized by chronic degenerative polyarthritis, chronic indurative mastitis, and/or chronic pneumonia in adult goats, and less frequently by acute paralysis in young kids.
• It is one of the most important diseases of dairy goats in industrialized countries.
• The disease is caused by caprine arthritis encephalitis virus (CAEV), a member of the small ruminant lentiviruses (SRLVs) group that also includes maedi visna virus (MVV). Currently, the term SRLVs is widely used to refer to CAEV and MVV.
• Epidemiologic studies have shown that goats comingled with MVV-infected sheep can get infected with MVV and vice versa.
• Cross-species transmission between goats and sheep is influenced by type of farming practiced and is common in places where goats and sheep are raised together in close confinement.
• Economic losses are associated with decreased productivity as a result of clinical disease. Diminished production is related to secondary infections, animal deaths, and the potential loss of international markets due to trade barriers.

INCIDENCE/PREVALENCE

• In the United States, seroprevalence of CAEV antibodies ranges from 38% to 81% in dairy goat herds.
• The prevalence of CAE in some European countries has declined drastically as a result of eradication programs.
• Switzerland started a CAEV eradication program in 1984 and the prevalence has been reduced from 60–80% to <1%; currently cases of clinical disease are rare. However, seroconversions still occur regularly and SRLV has been isolated from different goat and sheep flocks. The main circulating viruses in these goats belong to subtypes A4 and A3, and appear to be of low virulence, with no cases of clinical disease except some cases of mammary gland inflammation.
• In some developing countries, CAE prevalence is high in imported European breeds, but nonexistent in native goats.

GEOGRAPHIC DISTRIBUTION

CAE is widespread among dairy goat herds in most industrialized countries but rare among native goat breeds of developing countries.

SYSTEMS AFFECTED

• Musculoskeletal
• Mammary
• Respiratory
• Nervous
• Hemolymphatic

PATHOPHYSIOLOGY

• CAEV is a *Lentivirus* in the family Retroviridae, subfamily Orthoretrovirinae.
• The genome of CAEV is single-stranded RNA. After infection, the CAEV genome is reverse transcribed into a double-stranded DNA copy that integrates into the host DNA, persisting in infected goats for life.
• SRLV isolates are classified into five main phylogenetic clusters. Genotypes A and B are widely distributed throughout the world, whereas genotypes C–E are geographically restricted.
• Genotype A includes MVV-like strains and genotype B comprises CAEV-like isolates originally isolated from sheep and goats, respectively, from across the world.
• Genotype C includes isolates originally detected in Norway; isolates from Switzerland and Spain are grouped in genotype D. More recently Italian SRLVs isolated from the Roccaverano goat breed have been designated as genotype E.
• Groups A, B and E can be further subdivided into a number of subtypes.
• Group A is highly heterogeneous and contains at least fifteen subtypes (A1–A15), while group B is less complex and contains three subtypes (B1–B3). Group E contains two subtypes (E1 and E2) and has been detected only in Italy.
• SRLVs from groups B–D and most of the group A subtypes (A1–A6, A9, A11–A13) can infect both sheep and goats. The other SRLV groups and subtypes have so far only been described either in sheep (A15) or in goats (A7, A8, A10, A14, E1, and E2).
Co-infection with more than one SRLV strain may occur and can result in recombination to form new CAEV-MVV strains.
• Small ruminant lentivirus quasi-species are continuously generated through mutation, recombination, and selection pressure by the host immune system.
• Ingestion of CAEV-contaminated colostrum or milk by neonates is the most common form of transmission.
• Feeding pooled colostrum or unpasteurized milk and bad hygiene practices during milking increase the risk of transmission.
• Transmission by close contact between infected and noninfected goats, particularly during lactation and parturition, may also occur.
• Vertical intrauterine transmission of SRLVs occurs in a small percentage of animals.
• CAEV has been demonstrated in semen, but venereal transmission does not appear an important route of transmission.
• Transmission by contaminated milking machines or buckets is possible.

HISTORICAL FINDINGS

Herd history of disease or introduction of new stock is relevant.

SIGNALMENT

• Goats are the natural host of CAEV, but sheep can also be infected.
• CAE infection rates among meat and hair goat breeds in North America is low. This may reflect differences in management practices between dairy and meat/hair goats that prevent transmission.
• Clinical signs manifest more often in goats ≥2 years of age. Paralysis with a rapid clinical course occurs in kids 2–6 months of age.
• Chronic paralysis has been occasionally described in adult goats.

PHYSICAL EXAMINATION FINDINGS

• In the majority of goats, infection is subclinical.
• In ~25% of seropositive goats, arthritis, mastitis, and/or pneumonia manifest several years after infection. More than one clinical manifestation may be observed in the same animal. Chronic weight loss is common.
• Chronic, proliferative arthritis ("big knee") in mature goats is the most common clinical manifestation and is characterized by swelling of the joints, particularly the carpi and less frequently other joints. The onset of arthritis is insidious. Affected animals show pain, decreased range of articular motion, stiff gait, "knee walking," and chronic weight loss.
• The majority of CAE arthritic female goats also show chronic indurative mastitis ("hard bag"). The udder is firm and symmetrically enlarged. There may be reduction of milk production or agalactia.
• Some CAEV-infected goats develop chronic nonsuppurative interstitial pneumonia with dyspnea, cough, and weight loss.
• Adult goats with CNS involvement show slight aberration in gait, progressing to complete paralysis over the course of several months.
• Once CAEV-infected goats show clinical signs of the disease, death, months or years after primary infection, results from secondary infections.
• A rapid clinical course and afebrile paralysis in kids 2–6 months of age has been described. Paralysis starts in the rear legs and progresses to paresis and quadriplegia. Some kids show head tilt, tremors, and ataxia. Affected kids continue to be alert and eat if hand-fed.

GENETICS

• CAE is more common in dairy goats.
• Host genetics may influence the clinical outcome of CAEV infection.

CAUSES AND RISK FACTORS

• Large herd size, high stocking density, increased age, extended exposure to infected animals, prevalence of bacterial mastitis, high somatic cell counts in milk, and intensive rearing systems are risk factors.
• Close contact with SRLV-seropositive sheep is highly correlated with seroconversion in SRLV-seronegative goat herds.

(CONTINUED) # CAPRINE ARTHRITIS ENCEPHALITIS VIRUS

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Caseous lymphadenitis, paratuberculosis (Johne's disease), chronic parasitism, and malnutrition.
• Bacterial, chlamydial, mycoplasma polyarthritis, and mastitis (contagious agalactia).
• Bacterial and verminous pneumonia and lung abscesses.
• Trauma or abscesses in the brain or spinal cord, meningitis, parelaphostrongylosis, vitamin E and selenium deficiency; copper deficiency, listeriosis, scrapie, and rabies.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• Serum antibodies can be detected as early as 3–6 weeks after exposure. Some infected goats may remain seronegative for several months in spite of being virus positive.
• The agar gel immunodiffusion (AGID) test and the enzyme-linked immunosorbent assay (ELISA) are the most commonly used assays. None of these tests are standardized across laboratories, and their sensitivity and specificity vary widely. Confirmation is achieved with Western blot and radioimmunoassay.
• A competitive ELISA (cELISA) with high sensitivity and specificity is commercially available in the US. Several commercially available CAE ELISA tests are available in other countries.
• Goat kids that have received heat-treated colostrum with CAEV antibodies can test positive by serologic methods for several months due to the passive transfer of maternal antibodies.
• Virus isolation has low sensitivity.
• Although PCR is a highly sensitive technique, its usefulness for the detection of CAEV in clinical samples from naturally infected goats still needs validation.
• The sensitivity and specificity of serologic tests and PCR are strongly influenced by the CAEV strains circulating in a particular herd or region.
• A combination of ELISA and real-time PCR increases the likelihood of detecting infected animals.
• Some serologic tests or molecular techniques with high sensitivity and specificity in one country may have lower sensitivity and specificity in another due to genetic and antigenic variability of SRLV subtypes.

PATHOLOGIC FINDINGS
• Gross necropsy findings may include emaciated body condition and swelling of the carpi and less frequently stifle, hock, hip, and atlantooccipital joints in goats with arthritis. In early stages, synovial fluid is increased but remains translucent. Later, fibrin or hard white grains of inspissated fibrin ("rice grains") are evident. Mineralization of periarticular tissues and erosion of articular cartilage are found in advanced cases. Cystic subcutaneous hygromas may be found in the carpi.
• The udder of goats with mastitis is symmetrically enlarged and firm.
• In goats with pulmonary involvement, there is diffuse interstitial pneumonia characterized by firm, gray-pink lungs with numerous 1–2 mm gray-white foci.
• The draining lymph nodes may be enlarged.
• In the neurologic form, there may be asymmetric brown-pink swollen areas in the posterior brain and spinal cord.
• Microscopically, the joints of goats with arthritis exhibit subsynovial infiltration of lymphocytes, plasma cells, and macrophages; formation of lymphoid follicles with germinal centers, and villous synovial hyperplasia. As the disease progresses, there is degeneration of the articular cartilage and mineralization of the joint capsule.
• In the mammary gland, there is infiltration of lymphocytes and plasma cells in the interstitium surrounding lobular ducts.
• Pulmonary lesions consist of lymphoid interstitial pneumonia with mononuclear cell aggregates and lymphoid follicles adjacent to bronchioles and small blood vessels.
• In the neurologic form, there is chronic, nonsuppurative leukoencephalomyelitis in the posterior brain and spinal cord characterized by perivascular infiltration of lymphocytes, macrophages, and demyelination.

TREATMENT

THERAPEUTIC APPROACH
There are no treatments.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
Broad-spectrum antibiotics are indicated for treating secondary bacterial infections.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Infected goats remain infected for life.
• Goats often die months or years after initial clinical signs appear.

POSSIBLE COMPLICATIONS
Secondary bacterial infections

CLIENT EDUCATION
Focus on managing the major methods of transmission; colostrum management in newborn kids is particularly critical.

PATIENT CARE
N/A

PREVENTION
• There are no vaccines available.
• Control of CAE depends on limiting transmission and culling infected animals.
• CAEV-free accreditation programs are in existence in some European countries.
• Serologic testing and segregation of positive reactors reduces prevalence and in some cases facilitates eradication of the disease.
• Retesting every 3–6 months and elimination of new positive reactors is necessary until 3 to 5 consecutive tests result in 100% of goats being negative, following which, yearly testing and acquisition of replacements from CAEV-free herds are recommended.
• Reappearance of occasional positive reactors years after eradication has been documented.
• The use of heat-treated colostrum (56–59°C for 1 hour) to raise goat kids from CAEV-infected goats reduces lactogenic transmission, but does not eliminate the risk of transmission.
• Reporting requirements for CAE differ between countries.
• Good biosecurity and hygiene practices should be adopted to minimize transmission of CAEV by contaminated equipment and other sources.
• Lentiviruses are susceptible to environmental factors and are destroyed by disinfectants.

MISCELLANEOUS

ASSOCIATED CONDITIONS

CARBAMATE TOXICITY

BASICS

OVERVIEW

• Carbamates are anticholinesterase insecticides derived from carbamic acid commonly found in crop and animal insecticides.
• The binding of carbamates is reversible and temporary, unlike the mechanism of another class of anticholinesterase insecticide, the organophosphates, which is irreversible.
• Most intoxications are a result of accidental ingestion of insecticide or indirect exposure to plants or water source sprayed by carbamate.

SYSTEMS AFFECTED

• Nervous
• Digestive
• Respiratory
• Musculoskeletal
• Cardiovascular

PATHOPHYSIOLOGY

Anticholinesterase insecticides bind with and inhibit acetylcholinesterase, the enzyme that breaks down the neurotransmitter acetylcholine. These compounds cause acetylcholine to accumulate at nerve junctions and cause excessive synaptic activity. The effects are in the parasympathetic nervous system and at neuromuscular sites.

SIGNALMENT

Any animal can be exposed to toxic levels of carbamate insecticides and all ruminants are susceptible.

PHYSICAL EXAMINATION FINDINGS

Muscarinic Symptoms

Result from stimulation of the parasympathetic nervous system and are described by the acronym SLUD:
• Salivation
• Lacrimation
• Urination
• Defecation

Other Possible Muscarinic Signs

• Vomiting—rare
• Miosis
• Bradycardia
• Dyspnea
• Bloating
• Transient diarrhea

Nicotinic (Neuromuscular) Signs

• Muscle tremors
• Twitching of facial muscles and eyelids
• Hyperthermia
• Ataxia
• Progressive paresis to paralysis
• Tetany

Central Nervous System Signs

• Depression
• Seizures
• Behavioral changes

CAUSES AND RISK FACTORS

• Domestic animals are usually exposed to carbamate insecticides due to accidental ingestion, or improper treatment by owners. Carbamate insecticides are used primarily on crops and other plants but can be used as topical insecticides on animals. They were previously commonly used for ectoparasite control.
• Carbamates are anticholinesterase insecticides commonly found in insecticides.
  ◦ Carbaryl—LD50 in rats is 250 mg/kg orally and >2000 mg/kg dermally.
  ◦ Carbofuran—Minimum toxic dose in sheep and cattle is 4.5 mg/kg, becoming lethal for sheep at 9 mg/kg and for cattle at 18 mg/kg.
  ◦ Methomyl (Golden Malrin)—LD50 in rats is 50 mg/kg orally.
  ◦ Propoxur—LD50 in rats is 0.8 mg/kg orally and in goats is >800 mg/kg orally.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Gastrointestinal causes of diarrhea
• Metabolic disturbances such as nervous ketosis
• Nonprotein nitrogen toxicosis
• Numerous plant toxicities cause tremor or ataxia
• Other pesticides including organophosphates, rodenticides
• Other toxins such as strychnine or lead
• Rabies

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

• Prompt testing is necessary due to the temporary binding of carbamate toxins. Cholinesterase activity may return to normal before or during laboratory testing.
• Cholinesterase activity in whole blood, retina, or brain that is 25–50% of normal for the species being tested indicates cholinesterase inhibitor toxicosis. If <25% of normal, clinical correlation of symptoms is required for diagnosis.
• Half of the brain should be submitted for homogenization, as cholinesterase activity varies in different brain regions.

OTHER DIAGNOSTIC PROCEDURES

Diagnosis is often based on known exposure to carbamate and response to treatment with atropine.

PATHOLOGIC FINDINGS

None

TREATMENT

THERAPEUTIC APPROACH

• Provide supportive care for SLUD or secondary clinical signs such as dehydration.
• Wash the animal with soap and water if dermal exposure occurs, to decrease absorption. Clipping may be advisable in long-haired animals.
• Administer activated charcoal PO at a dose of 1–2 lb per 500 kg body weight.
• Atropine injection
  ◦ Atropine sulfate L.A. 15 mg/mL
  ◦ Cattle: 30 mg per 100 lb body weight or 0.1 mg/kg SC to standing animals or for recumbent animals 1/3 dose IV and the remainder SC.
  ◦ Sheep and goats: 50 mg per 100 lb body weight or 0.3 mg/kg SC to standing animals or for recumbent animals 1/3 dose IV and the remainder SC. Give 1/4 of the initial dose IV (watch the pupils and see if they start to return to normal) and the rest SC or IM.
  ◦ Dosage can be repeated in 4–8 hours if clinical signs recur.

MEDICATIONS

DRUGS OF CHOICE

• Activated charcoal.
• Atropine is the primary drug of choice and always should be used first.

CONTRAINDICATIONS

• Oximes such as pralidoxime chloride (2-PAM) that are used to release the acetylcholinesterase-organophosphate bond are *not* used due to the reversible nature of carbamate binding to acetylcholinesterase.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Good prognosis if treated promptly

POSSIBLE COMPLICATIONS

Bloating, inhalation pneumonia

PATIENT CARE

• Heart rate
• Respiration
• Fluid and feed intake

CARBAMATE TOXICITY (CONTINUED)

PREVENTION

• Closely follow instructions for dilution and application found on carbamate insecticide label.
• Premises should be washed and contaminated soil removed. Runoff can poison fish and aquatic animals.
• Avoid use of carbamate insecticides for ectoparasite control, especially on sick or debilitated animals.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Carbamate toxicity is not a transmissible disease; however, humans are also susceptible to toxic exposures.
• Follow labeled instructions and precautions when handling carbamate insecticides.
• Use caution when washing poisoned animals.

ABBREVIATIONS

• 2-PAM = pralidoxime chloride
• SLUD = salivation, lacrimation, urination, defecation

CARDIAC FAILURE

BASICS

OVERVIEW

• Cardiac failure can result from primary cardiomyopathy (myocardial disease and dysfunction) typically characterized by cardiac dilation, or secondary to other cardiovascular and respiratory disorders that ultimately produce congestive heart failure (CHF).
• Causes include viral, bacterial, and parasitic pathogens; acquired and congenital cardiac and respiratory disorders; genetic disorders; nutritional deficiencies; toxicants; and neoplasia.
• CHF reflects the terminal endpoint of many cardiac disorders, where the heart can no longer effectively circulate blood to organs and peripheral tissues, resulting in congestion and edema.

INCIDENCE/PREVALENCE

• Uncommon and sporadic.
• Inbred Holstein-Friesian cattle have a 3–5% incidence of hereditary cardiomyopathy.
• Cattle have ~ 4% prevalence of tricuspid valve endocarditis.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

• Cardiovascular
• Respiratory
• Digestive

PATHOPHYSIOLOGY

• Dependent on the primary disease; however, progressive reduction in myocardial contractility leads to decreased cardiac output.
• Compensatory changes in blood volume and blood pressure occur, and constant sympathetic stimulation of the heart causes arrhythmias and myocyte death.
• Renin-angiotensin-aldosterone release causes vasoconstriction and retention of sodium and water.
• Cumulatively these changes result in dilatation of cardiac chambers and atrioventricular rings, increased ventricular mass, reduced myocardial contractility, and decreased systolic function.
• Signs of CHF develop as disease progresses, with left heart failure reflected by tachypnea, coughing, dyspnea, and exercise intolerance; and right heart failure by submandibular, brisket, or ventral edema, jugular and mammary vein distention, and pleural and peritoneal effusion.
• Cardiomyopathy can be inherited, idiopathic, or secondary to ingestion of ionophores, gossypol, *Cassia occidentalis*, and *Phalaris* spp.; to deficiency of vitamin E, selenium or copper; to cardiac lymphoma; and from myocardial fibrosis.
• Infectious endocarditis is also a common cause of CHF in cattle, and typically affects the tricuspid valve, producing right heart failure.
• Restrictive cardiomyopathy characterized by impeded diastolic relaxation and reduced left ventricular filling can occur secondary to pericardial diseases.

HISTORICAL FINDINGS

Vary with cause, but historical assessment should consider management factors, toxicants, nutritional status, and other relevant topics.

SIGNALMENT

• Congenital cardiac anomalies most commonly affect neonates or juveniles.
• A heritable cardiomyopathy linked to the red gene causes cardiac failure in Holstein cattle 2–7 years of age.
• A heritable cardiomyopathy causes cardiac failure in Japanese Black cattle and Australian polled Herefords in the first weeks to months of life. In Herefords the disorder is associated with a dense, tight, curly haircoat.
• Other causes are more common in mature animals.

PHYSICAL EXAMINATION FINDINGS

• Depend on the primary cause and the severity and duration of cardiac disease.
• Primary cardiac signs include cardiac arrhythmias, murmurs, tachycardia, and muffled heart sounds.
• Secondary signs of cardiac failure include peripheral edema, venous distension, abnormal thoracic auscultation (pulmonary edema and/or pleural fluid), and abnormal abdominal contour and percussion (ascites and hepatomegaly).
• Other findings may reflect causative disorders and include fever, anorexia, stiffness or reluctance to move, signs of thoracic or abdominal pain, and sudden death.

GENETICS

Inherited cardiomyopathy disorders in Holstein-Friesians, Australian polled Herefords, and Japanese Black cattle are autosomal recessive traits.

CAUSES AND RISK FACTORS

• Genetic predisposition
• Stress can precipitate clinical signs
• Pericarditis
• Cardiac lymphoma
• High altitude
• Nutritional deficiency
• Toxicity

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Ionophore toxicity
• Gossypol toxicosis
• Selenium deficiency
• Primary or secondary copper deficiency
• Myocarditis
• Endocarditis
• Traumatic reticuloperitonitis/pericarditis
• Cardiac neoplasia
• Idiopathic pericardial hemorrhage
• Cor pulmonale (high altitude or chronic respiratory disease)
• Parasitism

CBC/BIOCHEMISTRY/URINALYSIS

Unremarkable, or findings reflect inflammation (leukocytosis, high total protein), heart failure, reduced feed and water intake, and primary disease, represented by increased liver or muscle enzymes, metabolic alkalosis, low serum electrolytes, and azotemia.

OTHER LABORATORY TESTS

• Cardiac troponin I
• Bovine leukemia virus: AGID, ELISA or PCR
• Whole blood selenium concentration or glutathione peroxidase activity (low in deficiency)
• Serum and urine transferrin concentrations (increased in cattle with dilated cardiomyopathy)

IMAGING

Ultrasonography of the thoracic and abdominal cavities is ideal for evaluating severity of cardiac disease and delineating causes and consequences.

OTHER DIAGNOSTIC PROCEDURES

• Pericardiocentesis
• Feed or rumen content can be tested for ionophores

PATHOLOGIC FINDINGS

• Myocarditis may have minimal gross lesions; histopathologic examination may identify fibrosis, necrosis, or inflammatory cell infiltrates within the cardiac muscle.
• Cardiomyopathy is identified by enlargement of cardiac chambers and the pulmonary artery. Generalized edema, cavity effusions, and vascular congestion of the lung, liver, and spleen can occur. Microscopically myocardial vacuolation and degeneration with necrosis and fibrosis is appreciated.
• Interstitial nephritis has been reported in Holstein-Friesian cattle with dilated cardiomyopathy.
• Other lesions can reflect precipitating causes including muscular lesions with selenium deficiency, pericardial lesions in traumatic reticuloperitonitis, etc.

TREATMENT

THERAPEUTIC APPROACH

• Treat precipitating disorders if feasible.
• Treatment of CHF is palliative and short term, culling is appropriate.
• Supportive care, diuretics, restriction of salt intake, and potentially cardiac medications can transiently reduce severity of clinical signs.

CARDIAC FAILURE (CONTINUED)

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Furosemide: 1.0 mg/kg IV or IM, q12h.
• Digoxin (positive inotrope) must be given IV in ruminants, and requires intensive monitoring. Can be dosed at 0.86 μg/kg per hour (valuable hospitalized animals) or at 3.4 μg/kg IV every 4 hours (greater risk of digoxin toxicity).
• Potassium chloride: 5–10 g per day PO in older calves; 50–200 g daily PO for adult cow/bull.
• Vitamin E/selenium, if indicated, at label dose.

CONTRAINDICATIONS
Digoxin is contraindicated in ionophore toxicosis.

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Mortality is inevitable long term.
• Short-term prognosis depends on the primary disorder, duration, and severity of disease; severe clinical signs have a guarded short-term prognosis and sudden death is likely.
• Holsteins with hereditary cardiomyopathy may survive 6–7 years, whereas Japanese Black cattle usually die by 1 month of life and Australian polled Herefords by 3 months of life.

POSSIBLE COMPLICATIONS
N/A

CLIENT EDUCATION
• Breeding selection for hereditary disorders
• Provision of safe feed supply with minimal foreign bodies and toxicants
• Appropriate infectious disease protocols to minimize relevant disorders (BLV)

PATIENT CARE
• Restrict exertion.
• Monitor heart rate, rhythm, perfusion and hydration.
• Monitor changes in body condition, edema, and venous distension.
• Measurement of plasma/serum digoxin concentrations is indicated to monitor for toxicity in treated animals.

PREVENTION
• Gossypol toxicity can be avoided by not feeding cottonseed meal or choosing meal with a low gossypol content, especially when feeding pre-ruminants. Concentrations of gossypol should be ≤1–2 g/kg of feed for adult cattle and ≤0.5–1 g/kg of feed for immature cattle.
• Ionophore-containing feeds should be mixed at approved facilities.
• Breeding stock should be selected to avoid propagating heritable diseases.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Cardiac arrhythmias
• Congestive heart failure
• Diarrhea
• Digoxin toxicity

AGE-RELATED FACTORS
Congenital disorders and specific heritable diseases are often clinically evident early in life, while most other disorders present in mature animals.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
N/A

BIOSECURITY
Relevant to specific disorders such as BLV.

PRODUCTION MANAGEMENT
• Avoid using suspected or known carriers of heritable traits in breeding programs.
• Maintain safe feed supply.
• Selenium supplementation of feed or by injection of neonates is recommended in deficient regions.

SYNONYMS
N/A

Author Keith P. Poulsen
Consulting Editor Erica C. McKenzie

BASICS

OVERVIEW

A large group of unrelated plants can be cardiotoxic to livestock; the majority contain cardiac glycosides. Other cardiotoxic plants that have resulted in livestock poisoning include yew (*Taxus* spp.), grayanotoxin-containing plants, death camas (*Zigadenus* spp.), avocado (*Persea* spp.; see chapter, Avocado Toxicosis) and oleander (*Nerium oleander*).

INCIDENCE/PREVALENCE

Cardiac Glycoside–Containing Plants

• Plants containing cardiac glycosides include oleander (*Nerium oleander*), summer pheasant's eye (*Adonis aestivalis*), foxglove (*Digitalis purpurea*), lily-of-the-valley (*Convallaria majalis*), dogbane (*Apocynum* spp.), and some species of milkweed *(Asclepias* spp.).
• Oleander is cultivated widely in the southern United States and is most commonly associated with plant poisonings in livestock. This plant is common in Florida and widely planted in California. Therefore, oleander is discussed in detail as a representative of plants containing cardiac glycosides.

Death Camas

Many species of death camas occur across the US and are seasonal with the greatest abundance being in the spring.

Grayanotoxin-Containing Plants

• Plants containing grayanotoxins include *Rhododendron* spp. (rhododendron, azalea, rosebay), *Kalmia* spp. (mountain laurel, sheep laurel, lambkill, sheepkill, dwarf laurel, calico bush), *Pieris* spp. (Japanese pieris, mountain pieris), *Leucothoe* spp. (dog hobble, dog laurel, fetter bush, black laurel), and *Lyonia* spp. (fetter bush, maleberry, staggerbush).

Yews

Yews are popular shrubbery used as a hedge or foundation planting. Several *Taxus* species are found in the US with *T. baccata* (English yew) and *T. cuspidata* (Japanese yew) most commonly reported in poisonings. However, all species of *Taxus* including *T. brevifolia* (Pacific or western yew) should be considered toxic.

GEOGRAPHIC DISTRIBUTION

See "Incidence/Prevalence"

SYSTEMS AFFECTED

Cardiovascular

PATHOPHYSIOLOGY

Cardiac Glycoside–Containing Plants

Cardiac glycosides cause poisoning by inhibiting the cellular membrane Na^+/K^+-ATPase, which results in an indirect increase in intracellular Ca^{2+} concentrations, intracellular sodium, decreased intracellular potassium, and a subsequent positive inotropic effect. In addition, direct effects on the sympathetic nervous system are seen.

Death Camus

Death camas contains steroidal alkaloids, such as zygacine and zygadenine. The alkaloids decrease blood pressure, slow the heart rate, and lead to respiratory depression.

Grayanotoxin-Containing Plants

Grayanotoxins are diterpenes that exert their toxic effect by binding to sodium channels in excitable cell membranes. The resulting increase in membrane permeability to sodium ions maintains excitable cells in a state of depolarization. Accumulation of intracellular sodium results in an exchange with extracellular calcium and plays an important role in the control of transmitter release. The membrane effects caused by grayanotoxins account for the observed responses of skeletal and myocardial muscle, nerves, and central nervous system.

Yews

Yews contain taxine alkaloids (major alkaloids are taxine A and taxine B) that cause an increase in cytoplasmic calcium by interfering with both the calcium and the sodium ion channel conductance across the myocardial cells. This results in the depression of cardiac depolarization and conduction of the heart.

SIGNALMENT

Cattle, sheep, goats, llamas, alpacas, deer

Cardiac Glycoside–Containing Plants

All species are susceptible to cardiac glycoside-containing plants. Oleander poisoning is commonly seen in llamas and alpacas. Severe losses have also been reported in cattle.

Death Camas

Sheep are at highest risk, especially when hungry, because they are most likely to eat the death camas in early spring when little alternative forage is available. However, cattle have also been poisoned.

Grayanotoxin-Containing Plants

Grayanotoxin poisoning has been reported in cattle and sheep, but most reports of poisoning involve goats.

Yew

Most poisonings with yew have involved cattle, but sheep, goats, and wild ruminants are also susceptible. Deer are able to tolerate considerable amounts of yew during the winter months, probably because of lower concentrations of taxine alkaloids in newly grown shoots.

PHYSICAL EXAMINATION FINDINGS

• Animals exposed to cardiotoxic plants are often found dead.
• If animals are presented alive, clinical signs of colic (abdominal pain) are often seen within hours of exposure. Progression of disease is rapid and animals develop weakness, tremors, excessive salivation, incoordination, dyspnea, and sometimes convulsions.
• In cardiac glycoside poisonings, animals often have an irregular, fast pulse with tachycardia, ventricular arrhythmias, or gallop rhythms.
• Animals exposed to avocado develop subcutaneous edema of the neck and brisket, submandibular edema, respiratory dyspnea, and cardiac arrhythmias. Lactating animals exposed to a low dose of avocado develop noninfectious mastitis and agalactia within 24 hours of exposure.

CAUSES AND RISK FACTORS

• Ingestion of cardiotoxic plants presents a great risk to ruminants. Plants most commonly associated with acute poisoning are oleander, yew, and rhododendron.
• Hungry animals are most likely to receive toxic exposures.
• Young and rapidly growing plants often contain highest concentrations of toxins.
• Fresh plant material of cardiotoxic plants is often considered to be of low palatability. However, animals frequently eat the leaves readily, if no other forage is available.

Cardiac Glycoside–Containing Plants

• The median toxic dose of oleander leaves in cattle is 45 mg of plant material per kg body weight or approximately 12 averaged-sized leaves or approximately 15–25 grams of dry leaves.
• In sheep, one to five grams is toxic, or 2 or 3 leaves.
• All parts of oleander are extremely toxic, whether the plant is fresh or dried. Ingestion of dried oleander clippings is a common source of poisoning in livestock.

Death Camus

• Leaves during the early stages of growth pose the greatest risk for poisoning. Seeds and fruits as well as the dried plant in hay are also toxic.
• The minimum lethal dose of the green plant in sheep is approximately 1% of the animal's body weight, but serious illness may be seen with as little as ingestion of 0.2% of an animal's body weight. Cattle are equally or possibly more susceptible than sheep.

Grayanotoxin-Containing Plants

• Toxicosis usually occurs when animals are offered plant trimmings or stray into wooded areas during adverse weather conditions and little else is available to eat.
• In cattle and sheep, ingestion of 0.2–0.6% of an animal's body weight is considered toxic. Goats can be poisoned by the ingestion of fresh foliage in the amount of 0.1% of the animal's body weight.

CARDIOTOXIC PLANTS (CONTINUED)

Yew

• All parts of the plant, green or dried, with the exception of the red fleshy part surrounding the seed (aril portion), are toxic. Ingestion of yew clippings is most often the cause of poisonings.
• The minimum lethal dose in adult cattle is estimated to be approximately 200 g of dried leaves.
• Green foliage is toxic to ruminants at 0.5% of body weight.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Avocado toxicosis.
• Cyanide poisoning—mucus membranes are initially bright cherry red; evidence of exposure to cyanogenic plants, chemical analysis for cyanide in gastrointestinal contents, liver, or muscle.
• Grass tetany—hypomagnesemia.
• Ionophore antibiotics—history of ionophores (e.g., monensin) in the feed ration, detection of toxic concentrations of ionophores in the feed, histologic lesions.
• Larkspur poisoning—mainly found in the western states; bloat is common finding, evidence of exposure to *Delphinium* spp.
• Lead poisoning—determination of blood lead concentration.
• Exposure to neurotoxic plants, such as poison hemlock, water hemlock, tree tobacco, lupine—chemical analysis for plant toxins in gastrointestinal contents, history of presence of plants in the environment.
• Nitrate toxicosis—chocolate-colored blood, exposure to nitrate-accumulating plants.
• Organophosphorus or carbamate insecticide exposure—commonly associated with gastrointestinal irritation and neurologic signs, evaluation of cholinesterase activity, detection of pesticides in gastrointestinal contents.
• Exposure to the plant "fly poison" (*Amianthium muscaetoxicum*)—found only in the eastern United States, most commonly seen in the spring, history of presence of plants in the environment.
• Exposure to star-of-Bethlehem (*Ornithogalum* spp.)—mainly found in the Northeast and Midwest, severe diarrhea, history of presence of plants in the environment.
• Nonprotein nitrogen (NPN) toxicosis—history of NPN supplements in the feed ration, detection of toxic levels of ammonia in rumen content and blood.

CBC/BIOCHEMISTRY/URINALYSIS

• Serum chemistry changes are limited.
• Myocardial damage may result in hyperkalemia, and elevated LDH, CK, and AST activities.

OTHER LABORATORY TESTS

• Detection of oleandrin, gitoxin, digitoxin, grayanotoxins, strophanthidin, or other cardiac glycosides or aglycones in blood, rumen, cecal, or colon contents, and liver.
• Detection of taxine alkaloids in rumen contents.
• Visual and microscopic examination of rumen or intestinal contents for plant fragments.

PATHOLOGIC FINDINGS

• In peracute cases, no lesions are found.
• Postmortem lesions are generally nonspecific in animals that died of exposure to cardiotoxic plants. Lesions include reddening of the mucosa of the gastrointestinal tract and congestion of organs.
• Cattle with oleander poisoning have evidence of fluid in the bowel and thrombosis and hemorrhage in the heart.
• There are no or very few lesions in cases of yew, grayanotoxin, or death camas poisoning.
• Avocado poisoning can result in fluid accumulation in the pericardial sac and in the thoracic and abdominal cavities. Edema of the gallbladder and perirenal tissues and a flabby, pale heart have been observed. Mammary glands are edematous with clots in the large ducts.

TREATMENT

THERAPEUTIC APPROACH

• Immediate removal of the toxic plant material to prevent further exposure. Provide the animals with good-quality feed.
• Treatment of animals exposed to cardiotoxic plants is primarily supportive and symptomatic. Supportive therapy should include administration of intravenous fluids, antiarrhythmics, and antibiotics if indicated.
• Adsorption of toxins with activated charcoal has been suggested.
• Rumenotomy may be considered in a valuable individual animal if ingestion is known and clinical signs have not yet developed.
• Passing a stomach tube, if necessary, should relieve bloat.
• Any possible stress or trauma should be avoided.
• If edema is present in avocado poisoning, administration of diuretics is recommended.
• Atropine should be considered in cases of severe bradycardia. Additionally, it may be warranted in severely poisoned animals that do not respond to decontamination procedures and fluid therapy alone.

MEDICATIONS

DRUGS OF CHOICE

• Lidocaine, phenytoin, or propranolol to treat tachyarrhythmias
• Atropine to treat bradyarrhythmias
• Activated charcoal
• Alternative drug: Anticardiac glycoside Fab antibodies have been used in humans and small animals, but their usefulness in the treatment of cardiac glycoside-poisoned ruminants has not been evaluated.

CONTRAINDICATIONS

• Do not administer potassium in fluids if hyperkalemia is present.
• Avoid calcium-containing solutions and quinidine.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Animals poisoned with cardiotoxic plants are often found dead.
• Cardiotoxic plant exposure progresses so rapidly that treatment is often too late. In most cases, the affected animals have a poor-to-grave prognosis.
• If treatment is initiated promptly after the onset of clinical signs, the prognosis is fair.
• Animals that survive the acute poisoning may suffer from myocardial damage and may be more prone to stress.

PATIENT CARE

Monitor progression of clinical signs.

PREVENTION

• Prevent hungry animals from accessing new pasture, especially in the spring when only limited (and often toxic) forage is available.
• Animals should be denied access to landscaped yards and discarded clippings.
• Suspect forage should be inspected for the presence of cardiotoxic plants before allowing ruminants to graze.
• Hay should be inspected carefully for weeds, as many cardiotoxic plants remain toxic when dried (oleander, death camas, yew).

MISCELLANEOUS

PRODUCTION MANAGEMENT

In lactating animals poisoned with avocado, the milk production remains reduced even after the mastitis has been controlled.

Caseous Lymphadenitis (CLA)

BASICS

OVERVIEW
Caseous lymphadenitis (CLA) is an endemic, contagious disease caused by *Corynebacterium pseudotuberculosis*, characterized by caseous abscessation of internal and external lymph nodes and visceral organs of sheep, goats, and rarely camelids.

INCIDENCE/PREVALENCE
• Common worldwide in small ruminants
• Flock/herd prevalence may exceed 75% in adults if no control program
• Flock/herd incidence varies depending on management and surveillance, but likely >15%
• Abscesses estimated to affect 17–24% of adult sheep at abattoirs
• Important cause of carcass condemnation and trim

GEOGRAPHIC DISTRIBUTION
• Widely distributed in North America
• Mostly in terminal sire flocks in the UK

SYSTEMS AFFECTED
• Hemolymphatic
• Respiratory

PATHOPHYSIOLOGY
• Bacteria invade via wounds, unbroken or abraded skin, or mucus membranes and can be contracted through contaminated fomites (particularly water, feed, soil, or housing), directly from animals with draining abscesses, or from pulmonary abscesses via coughing.
• Bacteria travel through lymphatics or blood to local lymph nodes and organs.
• Phospholipase D (PLD) exotoxin, secreted by the bacteria, disrupts endothelium and is leukotoxic, facilitating spread of the bacteria through tissues.
• The cell wall is thick with high lipid content, enabling bacteria to resist phagocytosis.
• Abscesses generally form first in the lymph node(s) draining the site of initial infection, but may form anywhere in the body.
• Abscesses may rupture (through skin or into bronchi) or regress. New abscesses may form months later in the same or different location.

HISTORICAL FINDINGS
• Typically producers report a lump under the skin or a ruptured abscess.
• Abscesses can be missed in long wool or hair; it is common to identify lesions during shearing.
• Occasionally, adults may present with chronic weight loss and no external evidence of disease.
• Less commonly, respiratory difficulty or regurgitation may arise from enlarged retropharyngeal nodes or from pulmonary involvement.
• Rarely, animals may present acutely anorexic with cellulitis at the site of primary infection, or can be found dead with no previous signs of disease (though there is usually a history of CLA in the group).
• Although the disease usually does not adversely affect general health, owners may be concerned with the negative esthetics of abscesses, particularly in show sheep and goats.

SIGNALMENT
• Domestic and wild sheep and goats, and llamas and alpacas.
• Can affect lambs and kids as young as 6 weeks of age but usually animals >3 months, and more often adults than young stock.

PHYSICAL EXAMINATION FINDINGS
• Affected animals are generally bright, alert, and afebrile, with good appetite.
• External abscesses are initially discrete, cool, and firm, but become soft as they mature.
• Prior to rupture, hair is lost from the center of the lesion and the overlying skin thins and darkens.
• Purulent matter expressed from the abscess is thick, cream colored to slightly green, and odorless. In sheep it is often inspissated and may have concentric layers like an onion skin (this feature is absent in goats).
• Internal abscessation can result in nonspecific signs such as weight loss, variable appetite often without fever. Coughing may occur but even with severe pulmonary involvement, there are often no signs referable to the respiratory system.
• Rarely, acute swelling and pain with high fever (>40°C) can occur with initial infection, potentially attributable to PLD exotoxin.
• At the flock level, decreased weight gains and wool growth have been reported.
• In housed sheep and goats in North America and Europe, CLA most commonly affects the parotid, submandibular, and cervical lymph nodes, as well as the respiratory system.
• In range flocks in Australia, CLA usually affects the respiratory system (parenchyma and mediastinal lymph nodes) and popliteal lymph nodes.
• Less commonly abscesses may affect the prescapular, prefemoral, or mammary nodes; or occur in the liver, kidney, adrenals, pituitary, or vertebrae.

GENETICS
N/A

CAUSES AND RISK FACTORS
• *C. pseudotuberculosis* is a small, Gram-positive, facultative intracellular rod that produces PLD exotoxin.
• Two biotypes are classified on nitrate requirements: nitrate-negative types cause CLA and some cases of ulcerative lymphangitis in cattle; nitrate-positive isolates cause ulcerative lymphangitis in horses but do not cause disease in ruminants.
• The bacteria can survive several days in water, several weeks on fomites such as wooden feeders, and several months in soil. Cool, moist conditions improve its survival.
• Gathering sheep for shearing allows transmission by coughing from animals with pulmonary abscesses, or via skin contamination when abscesses are nicked during shearing. Shearers that do not clean equipment or clothing between flocks can bring the disease to unaffected flocks.
• Broken or abraded skin, which can occur during shearing, increases the risk of transmission, although the bacteria can penetrate unbroken skin.
• Draining abscesses that contaminate feed, water, and feeders are an important source of infection. "Keyhole" type feeders can be particularly problematic for spreading the disease in herds or flocks where lesions occur in the parotid and submandibular lymph nodes.
• Fighting between rams or bucks can also transmit the bacteria.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Many bacteria cause abscesses that may or may not be associated with a lymph node. In small ruminants, these often occur in the cheek or jaw, associated with trauma from feed or other insults. A variety of bacteria have been isolated from these including anaerobes (e.g., *F. necrophorum*), *Mannheimia haemolytica, S. aureus*, many species of streptococci, *T. pyogenes*, and *E. coli.* These abscesses may have a watery content, with or without gas, a foul odor, and often do not involve a lymph node.
• Sterile abscesses occur in about one third of animals recently vaccinated with a multivalent clostridial vaccine.
• Abscesses on the back of the neck are often caused by sheep crawling under wooden feeders that then become infected secondarily with *S. aureus.*
• Chronic wasting can arise from conditions affecting a few individuals in the group such as dental disease, competition, paratuberculosis, ovine progressive pneumonia (maedi visna), caprine arthritis encephalitis (goats), and scrapie. Gastrointestinal parasitism and nutritional deficiency should be considered if a large proportion of the group has weight loss.
• Bacterial pneumonia, lungworm (*Dictyocaulus filaria* or *Muellerius capillaris* in goats only), sheep pulmonary adenomatosis, and transmissible nasal adenocarcinoma can cause weight loss.
• Lymphosarcoma may present as external and/or internal masses, cause chronic wasting, and/or be space occupying in the thorax.

CBC/BIOCHEMISTRY/URINALYSIS
Generally, no specific abnormalities

OTHER LABORATORY TESTS

• Culture abscesses prior to rupture by performing sterile aspiration or by lancing with a sterile blade and collecting material into a sterile container. Animals which have had lesions sampled or lanced should be isolated from others until completely healed.
• A variety of serologic tests detect antibodies to important antigens. Most commonly the tests detect antibody to PLD, including the synergistic hemolysin inhibition (SHI) test and different ELISA tests. Sensitivity on a flock basis is good, but only fair on an individual animal level, likely because the bacteria are walled off after initial infection. Titers may be higher and more persistent in goats than in sheep. Vaccines that contain PLD toxoid interfere with interpretation (i.e., reduce specificity).
• IFN gamma ELISA. Using whole blood, this assay detects cell-mediated immunity. Response does not appear to decrease with time post-infection and vaccination will not interfere with interpretation. This test is not widely available on a commercial basis in the US.

IMAGING

In cases of chronic wasting or respiratory disease: Ultrasound or radiographs of the thorax can identify the number and size of abscesses affecting the respiratory system. In cases of upper respiratory stridor or regurgitation, radiographs of the pharyngeal area can identify large retropharyngeal nodes. Computed tomography can be very useful to identify number and size of internal abscesses.

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

• Abscesses may occur in any lymph node or visceral organ and are grossly evident. Bacterial culture will determine whether *C. pseudotuberculosis* is the causative agent.
• In cases of sudden death, cut down the trachea and bronchial tree to check for evidence of an abscess rupturing into and occluding an airway.

TREATMENT

THERAPEUTIC APPROACH

• Response to therapy is variable at best.
• Many months or years may pass between abscess events in an animal, but once an animal exhibits an abscess, it should generally be considered infected for life.
• Although the bacterium is sensitive to many antibiotics, including penicillin, abscess formation hinders effective therapy.
• One prospective randomized clinical trial compared three treatment options for heavily infected herds: (1) Lancing, flushing, and SC penicillin; (2) Closed-system lavage and intralesional tulathromycin; and (3) Closed-system lavage with SC tulathromycin. There was no statistically significant difference in outcomes between treatments. However, use of the drugs in this manner constituted extra-label usage and would require veterinary oversight with extended withdrawal times prior to meat or milk consumption.
• To hasten recovery and prevent contamination of the environment, isolate animals with abscesses until healed. Isolation facilities should have the following features:
  ◦ No shared water or feed source with other animals
  ◦ Ideally, separate air space
  ◦ Pen must be dedicated to housing animals with abscesses (e.g., not used for lambing or for housing animals with other diseases).
• Lance abscess with sterile blade when it becomes soft. Wear disposable gloves. Catch all material in a container to prevent environmental contamination. Clean wound with iodine or chlorhexidine. Repeat twice per day until wound is scabbed and dry. In cases of chronic and/or repeated episodes of abscess development, strongly consider culling to reduce the risk of infection to the rest of the flock or herd.

SURGICAL CONSIDERATIONS AND TECHNIQUES

• Retropharyngeal abscesses may be surgically drained under anesthesia if animal value warrants it.
• Surgical removal of external nodes can be performed in select cases.

MEDICATIONS

DRUGS OF CHOICE

Antibiotic treatment is controversial and not widely practiced. Herd-level use is not appropriate. However, treatment with penicillin or tulathromycin may be useful in individual animals (see "Therapeutic Approach"). Use of both drugs in this manner constitutes extra-label drug use and requires veterinary oversight with extended withdrawal times for meat and milk.

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Most infected animals do not experience severe disease.
• The disease is more important at the herd level where it can cause chronic wasting, sudden death, premature culling, carcass condemnation and trim, and restriction of movement of animals.

POSSIBLE COMPLICATIONS

N/A

CLIENT EDUCATION

Focus on what a positive diagnosis means to the flock or herd so that control measures can be instituted quickly if relevant using prevention measures (see "Prevention").

PATIENT CARE

• If the owner elects not to cull, animals should be checked at least once a month for new abscesses.
• Animals should be kept in isolation until abscesses are healed.

PREVENTION

A control program is based on the following.

Reduction of Environmental Contamination with the Bacteria

• Routine palpation of external nodes whenever animals are handled.
• Isolation of affected animals and appropriate treatment.
• Disinfection of shearing blades and pieces whenever an abscess is nicked.
• Routine washing of hands with chlorhexidine soap when handling infected animals.
• Use feeders that reduce contact of the head and neck with the feeder (e.g., bars or keyhole feeders).
• Cull all affected animals if economics allow.
• Cull all repeat offenders.

Reduction of Risk of Transmission to Uninfected Animals

• Rear young stock away from adults (e.g., remove at birth and rear artificially in another barn).
• Shear young sheep first and older and infected sheep last.
• Milk affected does last and wash down parlor with disinfectant afterward.
• Purchase breeding stock from flocks with known health status.
• Shearers should wear clean clothing (including footwear) that has not been worn to another flock without laundering. Ideally, producers should purchase their own shearing equipment.
• Treat all shearing wounds immediately with iodine or other topical disinfectant.

Improve the Immune Status of Uninfected Animals

• Commercial vaccines that contain PLD toxoid and some cell components are licensed for use in sheep. The vaccines are marketed as a combined clostridial-CLA vaccine.
• In the US there is one conditionally licensed vaccine (must be approved by the state animal health board for use in that state) for use in healthy, nonpregnant and nonlactating goats

CASEOUS LYMPHADENITIS (CLA) (CONTINUED)

3 months of age or older. Vaccines approved for sheep have been reported to cause adverse reactions in goats that are already infected, so extreme caution should be used when vaccinating with sheep vaccines.
• The vaccines work best if administered before chance of infection and after colostral immunity has waned (around 3 months of age).
• A vaccination program involves vaccination of young stock with a primary series (e.g., vaccinate at 3 and 4 months of age) and an annual booster.
• For breeding ewes, the booster can be administered 1 month prior to lambing, to optimize transfer of colostral immunity to offspring. Use of the goat vaccine in pregnant animals is not approved and has not been tested.
• The vaccine will not cure existing infection and works best when combined with other control measures as it will reduce risk of infection but will not totally prevent. Routine vaccination, when combined with culling of affected sheep, can reduce flock prevalence to <2%.
• Vaccine efficacy may be improved by increasing the frequency of vaccination to every 3–6 months, particularly if sheep and goats are housed all or part of the year.
• Autogenous vaccines have been employed, but if the PLD toxin is not totally inactivated, severe illness and death may occur.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
C. pseudotuberculosis infection of humans is uncommon. Suppurative granulomatous lymphadenitis may occur secondary to wound contamination when treating or handling infected animals or contaminated materials. It is important to wear gloves when lancing abscesses and to wash hands with chlorhexidine soap after treating this disease.

CASTOR BEAN TOXICITY

BASICS

OVERVIEW

• Castor bean, *Ricinus communis*, is considered to be a native of northern Africa. In the United States it is commonly grown as an ornamental plant.
• Commercially, castor bean is used in the production of castor oil. This oil has been used for centuries for medicinal purposes. It is used in cosmetic products and as an industrial lubricant.
• The entire plant is toxic. The primary toxic principle is ricin and is found in highest concentration in the seeds. Ricin is not found in castor oil.
• Ricinin is another toxin in the castor bean plant. It is concentrated in the leaves.
• A by-product of castor oil manufacturing is castor oil cake. This has been fed to livestock as it is high in protein. It must be heat treated prior to feeding in order to destroy the ricin.
• The castor bean plant is a large, robust erect annual woody herb reaching up to 15 feet in height. Large, serrated leaves are alternate and palmate with 5 to 11 lobes. Leaves range in size from 4 to 36 inches. Fruits are three-lobed, spiny capsules with three seeds. The seeds resemble an engorged, female *Ixodes ricinus* tick.

INCIDENCE/PREVALENCE

• Relative to the availability of the plants.
• Castor bean toxicity is not a common intoxication of ruminants.

GEOGRAPHIC DISTRIBUTION

Castor bean is found throughout the world, primarily in tropical, but also in temperate environments. It is found in the southern portions of the U.S.

SYSTEMS AFFECTED

• Digestive
• Nervous
• Multisystemic

PATHOPHYSIOLOGY

• Ricin is a large molecular weight protein and classified as a toxalbumin.
• After ingestion, ricin is absorbed from the gastrointestinal tract into the blood and is transported to the liver and other organs/tissues to a lesser degree.
• After entering a cell, it inhibits cellular protein synthesis, resulting in cell death.

SIGNALMENT

All ruminants are susceptible to castor bean.

PHYSICAL EXAMINATION FINDINGS

• Clinical signs from ricin intoxication range from a few hours to 2–3 days. The delay may be due to the time necessary for cells to die.
• Anorexia, fever and abdominal pain
• Vomiting and profuse, watery, hemorrhagic diarrhea with subsequent dehydration and hypovolemic shock
• Depression
• Terminally, collapse, convulsions, and death
• Clinical signs in animals from ricinin including weakness, and ataxia are usually short-lived and recovery is seen in a few hours.

CAUSES AND RISK FACTORS

Ricin is concentrated in the seeds. They have a hard shell, making it somewhat difficult to break when chewed. If the seed is unbroken when swallowed, it will pass through the digestive tract intact and will not cause any adverse effects to the animal.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Other causes of enteritis and hemorrhagic diarrhea
• Bovine viral diarrhea virus
• Mucosal disease
• Salmonella
• Winter dysentery

CBC/BIOCHEMISTRY/URINALYSIS

• Elevation of hepatic enzymes: AST, LDH
• Increase in BUN

OTHER LABORATORY TESTS

Evidence of plant consumption in gastrointestinal contents

PATHOLOGIC FINDINGS

• Hemorrhagic gastritis and enteritis
• Edematous mesenteric lymph nodes
• Swelling of the liver and kidney may occur.

TREATMENT

THERAPEUTIC APPROACH

• Supportive: good nursing care
• Symptomatic: correct dehydration and electrolyte abnormalities

MEDICATIONS

DRUGS OF CHOICE

• Activated charcoal:2–5 g/kg given orally to control absorption of toxins from the gastrointestinal tract (1 g charcoal per 5 mL water).
• Mineral oil administered orally to more rapidly transport plant materials through the gastrointestinal tract.
• Generally, it is considered best to use either activated charcoal or mineral oil, but not both at the same time.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Dependent upon amount of seeds/plant material ingested.
• Ruminants are less susceptible to the effects of ricin.

PREVENTION/AVOIDANCE

Prevent animals' access to plants.

MISCELLANEOUS

PRODUCTION MANAGEMENT

Restrict grazing of livestock near castor beans or feeding castor bean plant materials.

ABBREVIATIONS

• AST = aspartate aminotransferase
• BUN = blood urea nitrogen
• LDH = lactate dehydrogenase

SEE ALSO

• Bovine Viral Diarrhea Virus
• Salmonellosis
• Winter Dysentery

CASTRATION/VASECTOMY: BOVINE

BASICS

OVERVIEW
• Castration is a husbandry practice used to remove males from the genetic breeding pool and eliminate aggressive behaviors associated with testosterone during the feeding period prior to animal harvest.
• Unilateral castration may be used in breeding males with acquired unilateral testicular disease.
• Vasectomy preserves testosterone production and creates "teaser" bulls that are used for heat detection in females that will undergo breeding by artificial means and is covered elsewhere in this textbook.

INCIDENCE/PREVALENCE
• Castration of calves is a common procedure in many countries.
• Castration may not be acceptable in some countries.
• Vasectomy is not as common.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Reproductive

PATHOPHYSIOLOGY
• The major aim of castration is to eliminate behavior and physiologic changes associated with testosterone period.
• Castration improves feed efficiency and reduces risk of accidents to humans or other animals.
• This can be accomplished using bloodless techniques. Elastrator bands cause an ischemic, avascular necrosis followed by sloughing of the distal tissues. Emasculatome applied to the spermatic cord cause atrophy of the testes but preserves the scrotal skin.
• Early (prepubertal) castration is the standard management technique.
• Vasectomized males will retain their male behavioral and anatomic characteristics but will be sterile. Spermatogenesis may continue for a long time but viable sperm disappears from the ejaculate within 2–3 weeks.

HISTORICAL FINDINGS
N/A

SIGNALMENT
• Castration
  ◦ Routine management: young calves 2–4 months of age.
  ◦ Mature breeding bulls with acquired unilateral testicular disorders.
• Vasectomy: Yearling with normal reproductive tract development and behavior.

PHYSICAL EXAMINATION FINDINGS
• Routine castration and vasectomy are performed on healthy animals.
• Unilateral castration: Animal may have testicular abnormalities.

GENETICS
N/A

CAUSES AND RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
N/A

CBC/BIOCHEMISTRY/URINALYSIS
Indicated for complicated unilateral castration and cryptorchidectomy

OTHER LABORATORY TESTS
N/A

IMAGING
• Ultrasonographic evaluation of the scrotal content is indicated prior to emergency unilateral castraction in a breeding bull with sudden increase in scrotal size.
• Transabdominal (inguinal) and transrectal ultrasonography are used to identify cryptorchid testes.

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Unilateral castration: Pathologic finding of diseased testicle (orchitis, periorchitis, inguinal hernia, neoplasia).
• Vasectomy: Histology performed on the excised tissue to ascertain that it is the vas deferens.
• Cryptorchidectomy: Histopathology confirms lack of spermatogenesis and may reveal neoplastic changes.

TREATMENT

THERAPEUTIC APPROACH
• Sedation and analgesia: Bloodless castration techniques are performed on very young animals without analgesia.
• Premedication with antibiotics and post-surgical pain management are required for adult castration and cryptorchidectomy.
• Anti-tetanus prophylaxis is important.

SURGICAL CONSIDERATIONS AND TECHNIQUES

Castration
• Castration is best performed in young animals <3 months of age. At this age, the testicles are smaller, animals are easier to handle, there is less stress when the calf can return to the cow, and there are fewer complications associated with the procedure. Castration can be performed with either open or closed methods. Attention to the animal's environment, fly control, vaccination status, facilities, and cleanliness of the procedure is warranted to minimize risk of postoperative morbidity.
• *Open castration*
  ◦ Restraint: Calf chute or, if the animal is small enough, in lateral recumbency.
  ◦ Local anesthesia: 2% lidocaine can be used in a pistol grip syringe to accommodate rapid injection of 4–5 mL of anesthetic into the base of the scrotum and 2 mL into each spermatic cord.
  ◦ Scrotal incision: Various methods are used. The use of a Newberry castration knife is common. The testicles are displaced proximally into the neck of the scrotum with one hand.
  ◦ The Newberry Knife is applied with the other hand in the frontal plane of the scrotum, closed, and forcefully pulled distally to incise both sides of the scrotum at the same time. If a local block in the spermatic cords was used, both testicles should descend through the incisions.
  ◦ An alternative method is to grasp the base of the scrotum with one hand or a surgical instrument (e.g., Allis Tissue Forceps) and transect it using a scalpel blade. The advantage of using the Newberry Knife is that the operator's hands are out of the way of the sharp instrument if the calf kicks during the incision.
  ◦ Removal of the testes. The operator grasps one testicle (potentially two if the animal is very small), and place gentle, steady traction on the testicle(s) with one hand while stripping fascial attachments proximally with the other hand. An emasculator or other instrument, such as the Henderson Bloodless Castration Tool, is applied to emasculate the cord and provide hemostasis of the testicular vessels. Alternatively, a transfixation ligature of appropriately sized absorbable suture material can be used. Because of the increased amount of time and expense in using suture material, this is often not done in practice for routine castrations.
  ◦ In young calves, the cords may be stretched until they break. The vas deferens may need to be transected with a scalpel. This technique is less desirable because of the increased incidence of postoperative bleeding, greater discomfort to the animal, and a higher potential of bleeding into the abdomen.
  ◦ Any adipose tissue or extraneous fascia should be sharply removed from the surgical site.
• *Closed castration*
  ◦ Emasculotomes (Burdizzo) should be the appropriate size for the age of the animal and size of the scrotum.
  ◦ The emasculotome is applied across each spermatic cord separately in the neck of the scrotum with two applications of the crush approximately 2 cm apart. It is important that the tension of the emasculotome is set

appropriately to effectively crush the cord within the scrotum without damaging the scrotal skin. The instrument should not be applied across the entire neck of the scrotum as this will cause crushing of the blood vessels that supply the scrotum, resulting in postoperative development of a large, necrotic, painful mass.
◦ Advantage: No postoperative monitoring required.
◦ Disadvantage: The scrotum remains intact, which may lead people to believe that the calves are still intact.
◦ Closed castration may be achieved with tight rubber band (e.g., Callicrate Bander) placed around the neck of the scrotum. This method is popular for castration of large bulls in a feedlot. Disadvantages include a higher degree of pain and development of severe scrotal edema and/or clinical tetanus. The entire scrotum and its contents often fall off within 7–10 days.

Vasectomy

• Restraint: Standing or in lateral recumbency. The incision site is blocked with lidocaine.
• A 2 cm vertical incision is made in the caudomedial aspect through the skin and parietal layer of the tunica vaginalis just above the vascular cone. The ductus deferens is identified by palpation and isolated by blunt dissection. A 3–4 cm segment is ligated and removed. The skin is closed with absorbable suture. The procedure is repeated on the other side.

MEDICATIONS

DRUGS OF CHOICE
Meloxicam (1 mg/kg PO) should be considered to reduce inflammation.

CONTRAINDICATIONS
Appropriate meat withdrawal times must be followed.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Vasectomized males should undergo semen collection and evaluation 2–3 weeks after surgery to make sure that there are no viable spermatozoa in the ejaculate.

POSSIBLE COMPLICATIONS
• Hemorrhage and wound infection, especially at the peak of the fly season or when muddy or very dry, dusty conditions exist.
• Clinical tetanus can be a complication of closed castration.

CLIENT EDUCATION
• Welfare issues regarding castration
• Use proper technique

PATIENT CARE
Patients should be closely monitored for the first 24–48 hours for lethargy, inappetence, fever, and/or severe swelling of the surgical site.

PREVENTION
• Proper technique insuring both testicles are within the scrotum distal to the band.
• Avoid banding the sigmoid flexure of the penis.
• Appropriate restraint, environmental control, and good vaccination protocols.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Testicular disorders

AGE-RELATED FACTORS
Choice of castration technique depends on age of animal

ZOONOTIC POTENTIAL

CASTRATION/VASECTOMY: CAMELID

BASICS

OVERVIEW
• Castration or orchiectomy is the most common method to remove males from the genetic pool.
• Vasectomy is often considered when the male is intended as a teaser for heat detection or to induce ovulation in a sterile mating (mostly for research purposes).
• Other methods for sterilization, including immunologic castration by GnRH vaccine, have been examined but results are variable.
• Unilateral castration is required for the removal of a diseased testicle in a breeding male.

INCIDENCE/PREVALENCE
Castration is the most common surgical procedure in camelid practice.

GEOGRAPHIC DISTRIBUTION
Worldwide distribution

SYSTEMS AFFECTED
Reproductive

PATHOPHYSIOLOGY
• Male aggression is often a problem when a large group of males is housed together. Additionally, intact males are often poor fiber producers (alpacas and llamas) and are not suitable for riding or work (camels).
• Male sexual behavior is more pronounced in camels than in alpacas or llamas, and includes extrusion of the soft palate, tail flapping, secretion from the poll glands, and aggression (which may become directed at humans).
• Male camelids can become very aggressive towards humans, particularly if they were bottle raised (berserk male syndrome). In llamas, castration was shown to decrease human-directed aggression in 73% of cases.
• Castration also removes the source of testosterone, and therefore the majority of sexual behaviors. However, some behaviors may persist, particularly after castration of a sexually mature, breeding male. These may include interest in females, and ability to achieve intromission.
• Vasectomy allows sterilization of males while preserving the ability to mate and induce ovulation.

GENETICS
• Unilateral cryptorchid males and males with congenital testicular disorders should be eliminated from breeding.
• Bilateral cryptorchidism is associated with cytogenetic and developmental abnormalities.

SIGNALMENT
• The current recommendations are to castrate a male after puberty (12–15 months in SAC, 2 years in camels). Prepubertal castration can result in orthopedic disorders.
• Camels intended for food may be castrated earlier. However, testicular descent is often delayed in some individuals, making early castration difficult.

HISTORICAL FINDINGS
• Castration or vasectomy may be elective procedures.
• Treatment of testicular pathologies in breeding males (hemicastration).

PHYSICAL EXAMINATION FINDINGS
• For elective procedures, the animal should be healthy, with no clinical signs of disease.
• Animals submitted for castration should be examined for the presence of both testes in the scrotum.
• Unilateral cryptorchidism and ectopic testis are not uncommon in alpacas and llamas. The abnormal testicle should be removed before the normally descended testicle.

CAUSES AND RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Differential diagnosis between abnormal male behavior in a gelding and cryptorchidism can be achieved by testing for testosterone levels.

CBC/BIOCHEMISTRY/URINALYSIS
May be indicated in breeding males undergoing emergency unilateral castration or before cryptorchidectomy.

OTHER LABORATORY TESTS
• Serum testosterone levels may indicate presence of testicular tissue in cases of cryptorchidism or intersex.
• A rise in testosterone levels is observed within 8 hours of IV administration of hCG (3000 IU for SAC; 10,000 IU for camels).

IMAGING
Percutaneous, transabdominal, or inguinal ultrasonography may help locate retained testes in cryptorchid animals.

DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
The most common reasons for unilateral castration are orchitis, neoplasia (seminoma), testicular hemorrhage/trauma.

TREATMENT

THERAPEUTIC APPROACH
• Animals should be fasted if general anesthesia is considered.
• Tetanus toxoid vaccination prior to surgery.
• Perioperative antimicrobials and anti-inflammatory medications.

SURGICAL CONSIDERATIONS AND TECHNIQUES

Castration
• Castration can be performed in the standing, sedated animal (camels, llamas) or under injectable anesthesia.
• Combinations of xylazine, butorphanol, and ketamine are often used for sedation and anesthesia.
• Two techniques have been described: A prescrotal technique with primary closure, or scrotal technique, with placement of the incisions directly over the testes, and healing by second intention.
  ◦ For both techniques, the testis is removed through the skin incision. Fascia is stripped away from the spermatic cord. A transfixation ligature may be placed around the spermatic cord. Emasculators or crushing forceps are used to achieve hemostasis and the testis is removed. The procedure is repeated on the other side, removing the testis from either the same incision (prescrotal) or an additional incision (scrotal).
  ◦ Closed or open castration may be performed.
  ◦ Analgesia may be enhanced by intratesticular injection of lidocaine or bupivacaine.
  ◦ Animals which have second intention healing should be monitored for fly strike, particularly in hot weather.

Cryptorchidectomy
• Removal of abdominally retained testes may be performed via an abdominal parainguinal approach or laparoscopic assisted technique under general anesthesia with the animal placed in dorsal recumbency.
• For a parainguinal approach, a skin incision is made parallel to the external inguinal ring and the abdominal cavity is penetrated by blunt dissection of the abdominal wall. The testis is retrieved using a spay hook and excised after placement of a transfixation ligature.
• For the laparoscopy-assisted approach, a laparoscopic portal is created at the umbilical scar. A second grasping instrument portal is created parainguinal on the side of the retained testis. The testis is visualized, grasped, and elevated to the second portal, which is enlarged for exteriorization. The testis is excised as already described.

Vasectomy
• Vasectomy is performed under general anesthesia.
• Two techniques have been described: a laparoscopic, intra-abdominal approach, and a prescrotal, extra-abdominal technique.
• For the laparoscopic approach, the ductus deferens is identified using a laparoscope and long-handled forceps. For the prescrotal approach, it is found after dissection between

the external inguinal ring and the scrotum. In both cases, a 2–4 cm segment is removed.
• For the prescrotal approach, the ductus deferens may be ligated after folding over the incised aspect, to reduce risk of sperm granuloma formation at the incision site.
• Intradermal skin sutures at the incision sites remove the need to handle the animals for suture removal.

MEDICATIONS

DRUGS OF CHOICE
• Standing castration sedation: Xylazine (0.2 mg/kg IM) and butorphanol 0.1 mg/kg IM
• Field anesthesia:
  ◦ Llamas and alpacas: Xylazine (0.22–0.55 mg/kg), butorphanol (0.08–0.11 mg/kg) and ketamine (0.22–0.55 mg/kg IM) in combination for llamas and alpacas.
  ◦ Camels: Xylazine (0.25 mg/kg IV or 0.35 mg/kg IM), ketamine (5–8 mg/kg IM, 3–5 mg/kg IV)
• Broad-spectrum antimicrobials

CONTRAINDICATIONS
• Unhealthy animals should not be submitted for surgery.
• Appropriate meat withdrawal times must be followed.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Following castration, serum testosterone levels drop to baseline within 24 hours. However, sexual behaviors may persist in some males.
• Semen samples collected at 15 and 30 days postoperatively had non-viable spermatozoa present.
• Vasectomized males have been successfully used for several years postoperatively with no alterations in sexual behavior. Postmortem examination demonstrated small sperm granulomas at the incision site of the ductus deferens but no other abnormalities.

POSSIBLE COMPLICATIONS
• Castration: Complications are possible, particularly in older males or those with diseased testes, and include surgical site infection, scirrhous cord, and hemorrhage.
• Cryptorchidectomy: peritonitis.
• Vasectomy: Surgical site infection. Excision of the vas deferens should be verified by histology in order to avoid fertility.

CLIENT EDUATION
Clients should be aware that males which undergo vasectomy will still maintain male sexual behavior and be able to achieve intromission in females.

PATIENT MONITORING
Animals should be monitored postoperatively for complications, including fever, inappetence, and incisional infection, dehiscence, or seroma formation. For incisions left to heal by second intention, monitoring for swelling, edema, hemorrhage, and fly strike should be performed.

PREVENTION
N/A

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Testicular disorders
• Abnormal behavior

AGE-RELATED FACTORS
• Males which are castrated too young have been shown to develop orthopedic disorders.
• Males which are castrated after sexual maturity and breeding activity may continue to display those behaviors after castration.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
Pregnancy may occur if vasectomy is not performed correctly.

BIOSECURITY
Vasectomized males can still transmit disease through intromission. Males should be examined for general health prior to use in a breeding program.

PRODUCTION MANAGEMENT
• Vasectomized males may be used to detect estrus in females.
• Castrated males are often used as guard animals for the herd.

SYNONYMS
• Orchiectomy
• Deferentectomy

CASTRATION/VASECTOMY: SMALL RUMINANT

BASICS

OVERVIEW
• Castration is the most common management surgical procedure performed in small ruminants.
• Castration improves fiber production and carcass yield.
• Castration age may be delayed in show or pet animals to avoid risk for urolithiasis.
• Most castrations are performed by the producers themselves except for adult or complicated cases.
• Castration techniques may be bloodless (elastrator bands and Burdizzo emasculatome); alternatively there is surgical excision.
• There is increasing concerns about the welfare of lambs and kids when castration is used without pain management.
• Unilateral castration may be performed on breeding animals to remove a diseased testicle and preserve breeding ability.
• Vasectomy is the bilateral excision of a portion of the vas deferens. It is used to sterilize males for use as estrus teasers. Epididymectomy (cauda epididymis excision) is an alternative but is not as esthetic.

INCIDENCE/PREVALENCE
Common in sheep and goat production

GEOGRAPHIC DISTRIBUTION
In some areas of the world castration is not acceptable for religious reasons or consumer preference.

SYSTEMS AFFECTED
• Reproductive
• Urinary

PATHOPHYSIOLOGY
• The major aim of castration is to eliminate behavior and physiologic changes associated with testosterone during the postpubertal period. In goats, castration eliminates male odor (male taint of meat).
• Bloodless techniques such as elastrator bands cause an ischemic, avascular necrosis followed by sloughing of the distal tissues. An emasculatome applied to the spermatic cord causes atrophy of the testes but preserves the scrotal skin.
• Surgical techniques are preferable in adult males in order to reduce complications.
• Early castration has been associated with increased risk for urolithiasis due to poor development of the penis and small diameter of the urethra.
• Vasectomized males retain their male behavioral and anatomic characteristics but are sterile. Spermatogenesis may continue for a long time but viable sperm disappears from the ejaculate within 2–3 weeks. Development of sperm granuloma is common in vasectomized males.

HISTORICAL FINDINGS
N/A

SIGNALMENT
• Males of various age
• Unilateral castration: Valuable males with acquired testicular disorders

PHYSICAL EXAMINATION FINDINGS
Routine castration is performed on healthy animals.

DIFFERENTIAL DIAGNOSES
N/A

CBC/BIOCHEMISTRY/URINALYSIS
Indicated for complicated unilateral castration and cryptorchidectomy

OTHER LABORATORY TESTS
N/A

IMAGING
Transabdominal ultrasonography to identify cryptorchid testes

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Unilateral castration: Orchitis, periorchitis, neoplasia.
• Vasectomy: Histology performed on the excised tissue to ascertain that it is the vas deferens.
• Cryptorchidectomy: Histopathology confirms lack of spermatogenesis and may reveal neoplastic changes.

TREATMENT

THERAPEUTIC APPROACH
• Sedation and analgesia: Bloodless castration techniques are performed on very young animals (24 hours to 1 week) without analgesia.
• Premedication with antibiotics and post-surgical pain management are required for adult castration and cryptorchidectomy.
• Anti-tetanus prophylaxis is important.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Elastrator bands
  ◦ Usually performed on kids and lambs <1 week of age but can be used up to 4 months of age.
  ◦ Very young animals: Restrained physically by one person. The elastrator band, previously soaked in an antiseptic, is placed around the neck of the scrotum, making sure that both testicles are distal to the band.
  ◦ Sloughing of the scrotum and its contents occurs 7–10 days later.
• Burdizzo emasculatome is used to crush the testicular cord.
  ◦ The emasculatome is applied to each testicular cord separately at different levels if the scrotal skin is to be preserved.
  ◦ This technique has been shown to be less stressful than surgical excision.
  ◦ Reduction of pain may be achieved by administration of bupivacaine in the spermatic cord.
• Surgical excision
  ◦ Sedation and local anesthesia is a subject of debate but it is required in animals 6 weeks or older.
  ◦ General anesthesia is recommended in adult rams and bucks.
  ◦ A crude technique of cutting off the bottom of the scrotum and forced rupture of the testicular cord by traction is commonly used by producers.
  ◦ Alternately, the bottom third of the scrotum is removed with a scalpel or transected with a Newberry knife. The testes are exteriorized. The testicular cord is ligated by transfixing using absorbable suture, then transected with a scalpel or an emasculator.
• Unilateral castration in breeding animal
  ◦ Animal is placed under general anesthesia in lateral or dorsal recumbency.
  ◦ The scrotum is clipped and prepared for surgery.
  ◦ A longitudinal elliptical incision is made on the lateral aspect of the scrotum and continued through the subcutaneous tissue. For closed castration the vaginal tunic is left intact. The cord is ligated with a circumferential suture proximal to a transfixation suture using absorbable #1 or #2 suture material. The testis is removed using an emasculator.
  ◦ The elliptical incision allows removal of as much skin as possible. The subcutaneous tissue is closed with absorbable material to eliminate dead space and the skin is closed using a Ford interlocking pattern.
• Crypotorchidectomy
  ◦ This surgery is often considered for pet animals.
  ◦ The retained testis is removed under general anesthesia following laparotomy or laparoscopy-assisted technique.
  ◦ Food is withheld for 24–36 hours depending on size of the animal.
  ◦ The abdomen is prepared for surgery. The abdominal cavity may be explored through a flank laparotomy. The retained testis is identified by following the vas deferens as it crosses the ureter.
  ◦ Laparoscopy: A laparoscope portal is placed either in a paramedian site or at the umbilical scar. Another portal, to introduce

grasping forceps, is placed parallel to the inguinal canal ipsilateral to the retained testis or paramedian to the penis in bilateral cases. The retained testis is identified, grasped, and lifted toward the portal, then exteriorized and excised after transfixing ligation of the vascular cone and the gubernaculum separately.

- Vasectomy
  - Bilateral vasectomy is the preferred method for preparation of teaser animals under field conditions.
  - The procedure is done under sedation, general or lumbosacral anesthesia. Caudal epidural may be helpful.
  - The animal is placed in a cradle or in a sitting position. A 3–4 cm skin incision is made on the medial aspect of the spermatic cord proximal to the vascular cone. The incision is continued through the vaginal tunic and the vas is identified by palpation and lifted using a hemostat or a spay hook.
  - A 4 cm portion of the vas deferens is isolated and transected after ligation.
  - The skin is closed using subcuticular suture with absorbable material.

MEDICATIONS

DRUGS OF CHOICE
- Sedation: Butorphanol, xylazine
- Local analgesia: Lidocaine or bupivacaine
- Post-surgical anti-inflammatories: Flunixin meglumin
- Antibiotic therapy: Penicillin

CONTRAINDICATIONS
Appropriate meat withdrawal times must be followed.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- Semen evaluation should be performed 60–90 days after surgery in unilaterally castrated breeding males. Fertility is generally not affected but male to female ratio should be adjusted.
- Vasectomized males should undergo semen collection and evaluation 2–3 weeks after surgery to make sure that there are no viable spermatozoa in the ejaculate.

POSSIBLE COMPLICATIONS
- Error in placement of bands or Burdizzo may result in crushing the penis, severe hematoma (crushing of testis), or maintenance of male characteristic if testes are proximal to crushing site or band.
- Clostridial infections (*Cl. tetani*).
- Excessive traction on the testicular cord may cause herniation.
- Adult castration may result in excessive swelling and scirrhous cord.
- Hemorrhage and peritonitis are the main complications of cryptorchidectomy.

CLIENT EDUCATION
- Welfare issues regarding castration
- Use proper technique

PATIENT CARE
- Animals undergoing general anesthesia and abdominal surgery should be fasted.
- Antimicrobial and anti-inflammatory medication should be administered to males undergoing crypotorchidectomy or unilateral castration.
- Older animals should be monitored for any signs of surgical site infection or hemorrhage.

PREVENTION
- Vaccination against clostridial infections or administration of tetanus antitoxin and tetanus toxoid at the time of castration.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Testicular disorders

AGE-RELATED FACTORS
Choice of castration technique depends on age of animal.

ZOONOTIC POTENTIAL

CAUDAL VENA CAVAL THROMBOSIS SYNDROME

BASICS

OVERVIEW
• Caudal vena caval thrombosis syndrome represents a metastatic pneumonia characterized by multifocal abscessation, caused by septic emboli that originate from a septic thrombus typically located in the caudal vena cava.
• The septic thrombus may occasionally be located in the cranial vena cava.
• Septic thrombi in the vena cava are most often a sequela of liver abscesses arising from ruminal acidosis.
• Other less common causes of liver abscesses include septic conditions such as foot rot, mastitis, metritis, and jugular phlebitis.

INCIDENCE/PREVALENCE
A large feedlot survey revealed that this syndrome represented 1.3% of feedlot necropsy diagnoses, with 1.6–7.3 cases per 100,000 head on feed. It was also reported that 68% of cases occurred during the first 90 days of feeding.

GEOGRAPHIC DISTRIBUTION
Influenced by distribution of feedlot and dairy management systems

SYSTEMS AFFECTED
• Digestive
• Respiratory

PATHOPHYSIOLOGY
• Feedlot and dairy cattle that are fed rapidly fermentable high-carbohydrate grain diets commonly experience ruminal acidosis.
• Acidosis of the rumen promotes damage to ruminal epithelium.
• Bacteria including *Fusobacterium necrophorum* and *Trueperella pyogenes* penetrate the damaged ruminal epithelium and are transported to the liver in the portal bloodstream.
• Bacteria are filtered in the portal circulatory system resulting in hepatic abscessation.
• A liver abscess may erode through into the caudal vena cava resulting in formation of a septic thrombus.
• Septic emboli detach from the thrombus and metastasize to the lungs through the pulmonary arterial system.
• Emboli lodge in the arterioles where they cause thromboembolism, arteritis, endarteritis, and pulmonary abscesses.
• Arteritis and endarteritis, in combination with pulmonary hypertension, result in the formation of aneurysms.
• A perivascular abscess in the lung may erode both the pulmonary arterial wall and a bronchial wall and cause rupture of the aneurysm.
• Blood from the ruptured aneurysm is channeled into the bronchus resulting in hemoptysis, and rupture of aneurysms may result in pulmonary hematomas; both contribute to anemia in affected animals.
• Large emboli may block lobar and larger arteries, causing acute hypoxemia and death.

HISTORICAL FINDINGS
• Chronic history of weight loss
• Coughing
• History of episodes of epistaxis
• May exhibit acute respiratory distress
• May be found suddenly dead

SIGNALMENT
The syndrome typically occurs in young feedlot cattle and adult dairy cattle consuming high energy rations. It is uncommon in cattle <1 year of age.

PHYSICAL EXAMINATION FINDINGS
• Tachypnea
• Dyspnea
• Tachycardia
• May be febrile
• Thoracic pain on deep palpation of the sternum and intercostal spaces
• Mild expiratory grunt
• Epistaxis
• Hemoptysis
• Pale mucus membranes due to anemia
• Heart murmurs
• Coughing
• Melena caused by coughing up and swallowing of blood
• Subcutaneous emphysema
• Widespread wheezes on auscultation of advanced cases
• Many cases may die suddenly because of acute hemorrhage from the respiratory tract.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Causative bacteria can include
  ◦ *Fusobacterium necrophorum*
  ◦ *Trueperella pyogenes*
  ◦ *Staphylococcus* spp.
  ◦ *Streptococcus* spp.
  ◦ *Escherichia coli*
• Highly fermentable carbohydrate-based diets
• Sudden increase in the proportion of grain in the diet
• Thrombi may also originate from other sites of infection, such as jugular phlebitis, mastitis, metritis, foot rot.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Interstitial pneumonia
• Anaphylaxis
• Hypersensitivity pneumonitis
• Lungworm
• Suppurative bronchopneumonia
• Aspiration pneumonia

CBC/BIOCHEMISTRY/URINALYSIS
• Changes are nonspecific but anemia and neutrophilic leukocytosis with a left shift may be observed on CBC.
• Hypergammaglobulinemia due to chronic infection.
• Chronic liver congestion results in elevation of serum liver enzyme activities.

OTHER LABORATORY TESTS
N/A

IMAGING
• Ultrasonography is the most reliable method of diagnosing a thrombus of the caudal vena cava.
• Normally, the caudal vena cava appears triangular in cross-section but, with thrombosis, the vein is oval to circular and dilated.
• Although a rare occurrence, detection of a thrombus in the caudal vena cava via ultrasonography is diagnostic.
• Ultrasonography may reveal ascites in some cases.
• Comet tail artifacts and pulmonary abscesses may be observed on thoracic ultrasonography.
• Thoracic radiographs often reveal increase in lung density. Distinct opacities related to embolic infarcts may be evident, and bullae and abscesses may be observed.

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Hepatic abscesses
• Thrombus in caudal vena cava
• Hepatomegaly
• Ascites
• Multiple pulmonary abscesses
• Intrapulmonary hemorrhage
• Swallowed blood evident in rumen

TREATMENT

THERAPEUTIC APPROACH
• The case fatality rate is close to 100% so treatment is rarely indicated.
• Salvage is typically the only realistic option although condemnation of the carcass is highly likely.
• Euthanasia should be considered.
• Antibiotic therapy is largely unsuccessful, but slaughter withdrawal times should be observed if antimicrobials are used.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Most cases are fatal so the prognosis is grave and euthanasia or slaughter recommended.

POSSIBLE COMPLICATIONS
Death typically relates to acute hemorrhage and hypoxemia.

PATIENT MONITORING
N/A

CLIENT EDUCATION
Discuss potential risk factors and evaluate reasons for the occurrence of ruminal acidosis to try to prevent additional cases.

PATIENT CARE
N/A

PREVENTION
- Slowly adapt ruminants to high-carbohydrate rations.
- Utilize ionophores in rations to modulate feed intake and control acidosis.
- Antimicrobial feed additives such as tylosin, virginiamycin, chlortetracycline, or oxytetracycline have been used to prevent liver abscesses. Changes in regulations may now affect their use.
- Appropriate milk and meat withdrawal times must be followed for all pharmaceutical agents administered to food-producing animals.
- Vaccines for *F. necrophorum* may lower the incidence of liver abscesses.

CECAL DILATION AND VOLVULUS

BASICS

DEFINITION
• Cecal dilation is primarily a disease of adult dairy cattle occurring within the first 1–2 months postpartum.
• It is believed to share similar epidemiologic and physiologic characteristics as abomasal dilation and displacement.
• Cecal dilation is also reported in calves <4 months of age, the majority of which are fed high-concentrate diets for purposes of early slaughter.

INCIDENCE/PREVALENCE
Cecal dilatation is thought to occur with similar prevalence as abomasal displacements.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Digestive

PATHOPHYSIOLOGY
Cecal Dilation
• The presence of excess gas from the digestion of fermentable substrates and decreased intestinal motility may cause cecal dilation. Experimental models have also implicated motility aberrations in the proximal loop of the ascending colon as a possible cause.
• Diets high in concentrates and with inadequate roughage produce high levels of fermentable carbohydrates that pass into the lower intestine. Lower intestinal flora digest the excess carbohydrates into volatile fatty acids (VFAs), methane, and carbon dioxide. Increased VFAs present in the cecum and ascending colon are believed to cause a reduction in intestinal motility.
• Decreased intestinal motility may also result from decreased levels of ionized calcium.

Cecal Torsion
Cecal torsion is present if a twist of the cecum occurs along its longitudinal axis, leading to increased tension of the ileocecal fold. This then leads to compromised blood flow and innervation of the cecum. The exact cause of cecal torsion is unknown; however, it is believed to be predisposed by, and therefore a sequela to, the occurrence of cecal dilation.

HISTORICAL FINDINGS
• Cattle suffering cecal dilation typically present with mild to moderate anorexia and decreased milk production.
• Cattle suffering cecal torsion typically demonstrate abrupt anorexia, rumen stasis, and significantly decreased milk production.

SIGNALMENT
Predominantly dairy breeds, adult female cattle within 2 months postpartum

PHYSICAL EXAMINATION FINDINGS
• Cattle with cecal dilation have an area of increased resonance ("ping") that is auscultated over the right paralumbar fossa. The right paralumbar fossa may be distended, and cattle may exhibit mild to moderate signs of abdominal pain.
• Fecal output is normal to decreased and fecal consistency is typically more fluid.
• During rectal examination, a gas-distended cecum is usually palpable with the apex located in or near the pelvic inlet.
• Cattle with cecal torsion have moderate to severe abdominal pain and are often tachycardic and tachypneic, with little to no fecal production and a precipitous drop in milk production.
• Rectal examination usually reveals a markedly distended cecum containing both gas and fluid. The apex of the cecum is often not palpable as it is positioned cranially. The area of resonance in the right paralumbar fossa is generally much larger than that noted with simple cecal dilation. Increased resonance may even be noted over the caudal dorsal left paralumbar fossa.

GENETICS
N/A

CAUSES AND RISK FACTORS
Postpartum cattle fed low-roughage, high-concentrate diets, and those suffering from hypocalcemia, metritis, mastitis, or indigestion that could result in gastrointestinal ileus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Right displaced abomasum, abomasal displacement with volvulus, small intestinal obstructions, and intussusception.

CBC/BIOCHEMISTRY/URINALYSIS
• Serum biochemical profile, blood gas analysis, and complete blood count are typically unremarkable, though a stress leukogram may be observed in cecal dilation cases.
• Depending on the severity and duration of cecal torsion, cattle may present with moderate to severe acid-base and electrolyte derangements. Hypochloremic, hypokalemic metabolic alkalosis is most commonly observed, but circulatory compromise is rarely observed. Urinalysis is typically within normal limits.

OTHER LABORATORY TESTS
N/A

IMAGING
Ultrasonography via the right abdominal wall at the level of the tuber coxae may be useful in the diagnosis.

OTHER DIAGNOSTIC PROCEDURES
Rectal palpation is a reliable diagnostic procedure for cecal dilatation coupled with percussion auscultation of the right flank. The distended, displaced, or twisted cecum can be palpated at rectal examination in most affected animals. In the case of a simple dilatation, the cecal apex is easily recognizable as a rounded, dome-shaped structure, with a diameter of approximately 15 cm, extending into the pelvic inlet. If retroflexion is present, the body of the cecum, but not the apex, can be palpated as a large, rounded, tense structure in front of the pelvis. Rectal palpation alone does not always allow for differentiation of cecal dilatation with retroflexion from right abomasal displacement or volvulus. The appearance of the dilated cecum during ultrasound examination from the right flank has been described.

PATHOLOGIC FINDINGS
N/A

TREATMENT

THERAPEUTIC APPROACH
• Cecal dilation in the early stages of the disease, when the general condition of the affected animal remains good, and when some feces are still being passed, can be managed by conservative treatment with prokinetic drugs, purgatives, along with intravenous fluids. Administration of neostigmine (87.5 mg in 5–20 L of isotonic saline solution supplemented with 5% dextrose as a continuous intravenous infusion at a rate of 1–2 drops per second) or bethanechol (0.07 mg/kg subcutaneously, q8h for 2 days) has been advocated. Intravenous or subcutaneous calcium borogluconate solutions (20 g in 500 mL) can be useful in lactating cows. Mineral oil (3 L) or sodium sulfate (300 g in 10 L water) administered per stomach tube have been described as adequate purgatives for conservative or postoperative treatment of cecal dilatation. Large volumes (20 L) of oral fluids containing electrolytes (8 oz NaCl, 2 oz KCl), calcium (12 oz calcium propionate), and cathartics (12 oz Mg-hydroxide, Mg-sulfate) can also be given q12h or q24h.
• Transfaunation with rumen liquor (10–20 L) can be used to stimulate rumen motility and appetite.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• In cattle with recurrent cecal dilation, preventive typhlectomy may be indicated.
• Cattle with cecal torsion typically require surgical intervention along with appropriate fluid therapy to correct fluid, acid-base, and electrolyte abnormalities. A standing right paralumbar approach is typically used. Decompression via typhlotomy may be

necessary to remove excess fluid and gas and to facilitate correction of a volvulus. In the event that ischemic necrosis is severe, a typhlectomy may be required.

MEDICATIONS

DRUGS OF CHOICE

Management of electrolyte and mineral imbalances is important. Antibiotics should be administered preoperatively when decompression of the cecum is necessary as abdominal contamination may occur during the procedure.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- For patients with normal heart rate, some manure production, a small appetite, no dehydration, and minimal abdominal distension, medical treatment is usually successful.
- Patients with high heart rate, dehydration, and colic signs, are surgical candidates.

Post-surgical prognosis is dependent on the degree of ischemic compromise to the cecum and adjacent bowel, successful corrections of acid-base and electrolyte derangements, and appropriate surgical technique.

POSSIBLE COMPLICATIONS

Cecal torsion leading to rupture and peritonitis in severe untreated cases.

CLIENT EDUCATION

Warranted in cases that are induced by inappropriate diet.

PATIENT CARE

Increased appetite and milk production with manure production are all good signs that treatment is working.

PREVENTION

Pre- and postpartum management of dairy cattle to maximize adequate intake of a forage-based diet, minimize infections of the uterus and vagina by calving in a clean environment, and minimizing the risk of gastrointestinal upset.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Mastitis, metritis, hypocalcemia, inappetence

PREGNANCY

Generally, a postpartum condition

PRODUCTION MANAGEMENT

Management of at-risk cattle to maximize intake of a forage-based diet, and minimize the risk of gastrointestinal upset.

CERVIDAE: CAPTIVE MANAGEMENT

BASICS

OVERVIEW

• Elk (*Cervus canadensis*), red deer (*Cervus elaphus*) and their hybrids are commonly farmed cervid species in North America, Europe, and New Zealand. There are also significant numbers of white-tailed deer (*Odocoileus virgninianus*) which are farmed or kept on hunting preserves. These species are well adapted to North American climate, pasture rearing, and the stress of handling. They also have strong herding instincts and are relatively disease resistant.
• Other deer species that are farmed include fallow deer (*Dama dama*), sika (*Cervus Nippon*), chital (*Axis axis*), rusa (*Cervus timorensis*), sambar (*Cervus unicolor*), and reindeer (*Rangifer tarandus*).
• Cervid species vary in size from the approximately 8 kg pudu to moose that can exceed 800 kg. The males of all but two species of cervids grow antlers, as do females of the genus *Rangifer*.
• The species selected should be based upon the farmer's experience, farm size, handling facilities, and production goals.
• In the United States, deer are marketed mostly for their venison and antlers/velvet.
• In Asian countries, antlers/velvet are used for medicinal products.

CAUSES AND RISK FACTORS

Morbidity and mortality in the herd may be due to noninfectious or infectious causes.

Noninfectious Causes

• A good nutrition program is essential to maintain healthy animals and reduce morbidity and mortality.
• Overcrowding, poor handling facilities, and failure to remove antlers and antler stubs can result in trauma.
• Consideration must be given to the farm's layout, stocking densities, handling facilities, and time of year (rutting season).
• Conditioning animals to the handling facilities will keep stress levels down when performing routine procedures.

Infectious Causes

• Significant infectious diseases of deer can be divided into bacterial, mycobacterial, viral, prion, and parasitic etiologies.
• Bacterial diseases of significance in deer include: *Mycobacterium bovis* (tuberculosis), *Mycobacterium avium paratuberculosis* (Johne's disease), brucellosis, clostridial agents, leptospirosis, yersiniosis, and rarely salmonellosis.
• Malignant catarrhal fever (MCF), a viral infection carried by sheep and goats, can be highly fatal in cervids.
• Other viral diseases of concern include: rabies, bovine viral diarrhea, bluetongue, Eastern equine encephalitis, epizootic hemorrhagic disease, and foot and mouth disease.
• White-tailed deer are asymptomatic carriers of *Babesia odocoilei*, a tick-borne hemoprotozoal parasite that can be fatal in reindeer and other ungulates. They also are the natural host of the meningeal worm *Parelaphostrongylus tenuis* which can cause morbidity and mortality in other cervid and ungulate species.
• CWD is has been identified in white-tailed deer, black-tailed deer, elk, red deer, and moose. It is endemic in wild deer and elk populations in some regions of the US and Canada. It has also been identified in a number of captive cervid herds and there are governmental programs in place to prevent its spread in both captive and wild populations.
• Deer are also susceptible to a number of nematode and trematode infections.
• *Dictyocaulus viviparus*, the lungworm, can cause significant loss of condition in young animals and sometimes death.
• Parasitic gastroenteritis occurs in herds in which stocking densities are too high.
• Ectoparasites such as lice and ticks can cause poor coat condition and weight loss as animals become too pruritic to graze. Ticks and other arthropods are capable of transmitting blood parasites such as babesiosis and anaplasmosis. Maggot infestations can also lead to animal discomfort and subsequent losses from decreased feeding.
• Fecal analysis, strategic deworming, and vector control will help minimize the effects of parasitic infections.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

• Facility design is essential for safe and efficient handling and care of animals (see chapter, Cervidae: Game Park Management, Facilities).
• Drugs may be administered via hand syringe, pole syringe, or immobilization dart.
• There are large differences between species of cervid in their sensitivity to anesthetic agents.
• Excited animals require higher dosages of anesthetics so it is important to keep animals as calm as possible prior to drug administration. During field anesthesia or manual restraint, placing a towel or other cover over the animal's eyes and minimizing noise reduces stimulation and stress for the animal.
• Potent narcotics such as carfentanil, etorphine, and thiafentanil have been successfully used for immobilization of deer, elk, and moose. They provide rapid immobilization but poor muscle relaxation when used as the sole anesthetic agent. The addition of a small amount of xylazine provides better muscle relaxation, but in some species such as moose it needs to be used cautiously as it increases the likelihood of regurgitation and aspiration pneumonia.
• Disadvantages of using potent narcotics include cost, legal requirements, and safety concerns for humans.
• Ketamine/medetomidine or other dissociative/alpha-2 agonist combinations have been used successfully in cervids, but they have a slower onset of action. This is not a significant consideration in a captive situation compared to wildlife immobilization.
• During anesthesia, animal positioning is important to minimize the risk of bloat or regurgitation and aspiration. Sternal

positioning while keeping the neck and head elevated and nose down is safest.
• Upon completion of procedures, the narcotic agents and alpha-2 agonists should be reversed with appropriate antagonists such as naltrexone and atipamazole or tolazoline.
• If IV access is available, ketamine/diazepam or Telazol® works well for short procedures. IV administration may be possible once an animal is in a squeeze chute or alternatively it is possible to condition animals for voluntary blood collection or drug administration. Facilities should be designed appropriately to protect a person doing voluntary injections.
• Smaller animals can also be masked down with inhalant anesthetics once they have been properly restrained.
• Hypoventilation and hypoxemia are not uncommon during anesthesia so it is important to monitor and have supplemental oxygen available. For longer procedures, animals may be intubated and placed on inhalation anesthetics. The injectable agents may be reversed at this point or may allow for a lower concentration of inhalational agent.
• It is beneficial to restrict food intake for 24–36 hours and water intake for 12–24 hours prior to chemically restraining adult cervids, to reduce the likelihood of bloating and regurgitation.

CLIENT EDUCATION
N/A

PATIENT CARE
• Good nutrition is essential for reproductive success, calf survival, and disease resistance. Nutrition also plays a key role in maximizing profits from velvet and venison production.
• The natural diet of cervids of the genus *Cervus* (e.g. elk, red deer) consists of a large proportion of grasses, but they also eat browse. Other cervid species such as moose are primarily browse feeders. Browsers require specially formulated diets or access to adequate browse to provide optimal nutrition and health.
• In general, grazing species do well on good-quality pasture or mixed grass/alfalfa hay. Mineral/vitamin supplementation or addition of a pelleted ration may be necessary depending on forage, environmental conditions, and health status of the animal.
• Weighing animals regularly helps farmers meet target weights and make ration adjustments as necessary.
• Winter feeding helps desensitize deer to the presence of the handlers and makes it easier to work them. While grain supplementation is often required, it should be introduced slowly to reduce risk of acidosis.
• Feed analysis and consultation with an animal nutritionist should be done so that the farmer knows when and with what to supplement. Mineral and trace element supplements can be provided either in concentrate rations or as a free choice block.
• During the fall rut, stags eat little and lose weight. They are much more susceptible to winter mortality than hinds. It is important that stags have access to an adequate amount of appropriate diet following the rut.

PREVENTION
• Herd health programs should increase profits by reducing disease incidence and enabling the farmer to meet and exceed production goals.
• Knowledge of the geographic area and good medical records help the veterinarian and farmer decide which vaccinations and dewormers to administer and when to give them.
• The veterinarian and farm manager should review the feeding program, past production levels, reproductive efficiencies, losses, and other management issues and implement changes if indicated.
• Veterinarians are involved with performing physical examinations, TB tests, and serology on new arrivals and animals to be shipped out.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
• Growth of calves from birth to weaning is critical for winter survival as well as for achieving desirable market weights.
• Calves normally experience little to no weight gain in the winter and are typically unable to eat enough forage to maintain their weight. Supplementation with concentrates or pelleted diets is often indicated.
• During the spring, summer, and fall, young stock have great potential for growth, and feeding programs should be adjusted to take advantage of this natural phenomenon.

ZOONOTIC POTENTIAL
Brucellosis, tuberculosis, lyme disease, leptospirosis, rocky mountain spotted fever, Q fever, cryptosporidiosis, salmonella, yersiniosis, and anthrax.

PREGNANCY
• Hinds have their greatest energy demands during the summer when they are lactating. If pasture quality is poor, lactating hinds should be supplemented with grain, pelleted ration or high-quality legume hay to ensure adequate milk production.
• The goals for the fall breeding period are to help hinds regain conditioning lost during lactation and build up their fat reserves for winter. Grain supplementation in the fall conditions the hinds and introduces the soon-to-be-weaned calves to feed.

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
• Proper record keeping is essential for good management and compliance with governmental regulations.
• Identification of animals is required to maintain accurate records. To participate in the USDA-APHIS national CWD herd certification program (HCP) all animals must be identified with two forms of permanent identification. The official animal identification must be linked to that animal and herd in the National CWD Database or a state database that is approved by APHIS. The farm must also have a unique national premise identification number assigned by the state, tribal authority or federal authority that is linked to the physical location of the farm.
• The APHIS traceability website provides information on official forms of identification: http://www.aphis.usda.gov/traceability/downloads/ADT_eartags_criteria.pdf
• It is essential to have accurate breeding records including sire and dam and their pedigrees, breeding date(s), previous reproductive history, and related medical problems. Weights should be obtained and recorded any time an animal is handled to maintain growth and body condition information.
• Medical records: Medical procedures, worming dates, vaccination dates, parasitology data, prescription information, anesthesia records, clinical pathology information, necropsy and histopathology data and may also include nutrition and diet-related information.

CERVIDAE: CAPTURE MYOPATHY

BASICS

OVERVIEW

• Capture myopathy (CM) is also known as post-capture myopathy, overstraining disease, transport myopathy, exertional rhabdomyolysis, and exertional myopathy.
• Wild and farmed deer are susceptible to CM. It is reported in animals that have been captured or handled by a variety of methods: short or long distance chases, chemical immobilization, drop netting, net gunning, boma capture, handling, and restraint in chutes.
• CM can be divided into four phases: Capture shock syndrome, ataxic myoglobinuric syndrome, ruptured muscle syndrome, and delayed-peracute syndrome.
• CM is generally undetected at the time of the animal's release, resulting in mortality hours to weeks post-capture.
• If capture-related mortality among deer within farmed settings is >2% of all deaths, new strategies must be implemented for handling and capture.

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

• Musculoskeletal
• Urinary

PATHOPHYSIOLOGY

• Exerted muscle changes its metabolism from aerobic to anaerobic, leading to lactic acid buildup in the bloodstream.
• Systemic acidosis follows and affects the heart output. Reduced oxygen to the affected muscle causes necrosis and release of myoglobin, which can damage the renal tubules and stress the body further. It also causes the muscle to be prone to rupture.
• The disease process is characterized by metabolic acidosis, muscle necrosis, and myoglobinuria.

HISTORICAL FINDINGS

Recent capture or immobilization

SIGNALMENT

• All cervids are susceptible.
• Capture myopathy can be a significant cause of mortality for white-tailed deer (*Odocoileus virginianus*). In one study, 10% of white-tailed deer caught from net guns died from CM.
• The semimembranosus and semitendinosus muscles are often ruptured in elk suffering from ruptured muscle syndrome.
• Net gun capture causes ataxic myoglobinuric syndrome and death in roe deer.

PHYSICAL EXAMINATION FINDINGS

• Cervids often are hyperthermic, tachycardic, and can develop a stiff or weak gait. Muscle tremors may develop involving few muscles or entire muscle groups, and the animal may just collapse and die.
• Capture shock syndrome: Observed in recently trapped animals or during immobilization. Animals usually die within 1–6 hours post-capture. Clinical signs include depression, tachypnea/dyspnea, tachycardia, hyperthermia, weak pulse, and death.
• Ataxic myoglobinuric syndrome: This is thought to be the most common in cervids. It can be seen several hours to several days post-capture. Clinical signs include ataxia, torticollis, and myoglobinuria, ranging from mild to severe in nature.
• Ruptured muscle syndrome: Animals appear normal at capture but show clinical signs 24–48 hours later, including a marked drop in the hindquarters and hyperflexion of the hock. This is often caused by unilateral or bilateral gastrocnemius, semimembranosus or semitendinosus muscle rupture. This has been seen in wild captured elk.
• Delayed peracute syndrome: Usually seen in animals that have been in a stressful captive situation for >24 hours. The animals appear normal when undisturbed, but if disturbed, handled, or captured, the animals try to escape and stop abruptly, often standing or lying still for several minutes. This is a rare form of CM, and these animals often die from ventricular fibrillation.

GENETICS

N/A

CAUSES/RISK FACTORS

• Several factors can either act alone or, more commonly, in combination, to lead to the development of CM.
• Factors include restraint methodology, overexertion, hyperthermia, isometric exercise, drug effects, alterations in the muscle pump activity, species predisposition, individual variation, seasonal effects, environmental factors, fear/habituation and familiarity with events, environment, and personnel.

DIAGNOSIS

History and clinical signs are important.

DIFFERENTIAL DIAGNOSES

• Enzootic ataxia or acute central nervous system disease
• Selenium deficiency, white muscle disease
• Fractures, other traumatic injuries, and wasting diseases

CBC/BIOCHEMSTRY/URINALYSIS

• Capture shock syndrome: Elevated AST, CPK, and LDH. Increased serum potassium and lactic acid levels may occur during the acute phase.
• Ataxic myoglobinuric syndrome: Elevated AST, CPK, LDH, BUN, and creatinine (due to renal tubular damage).
• Ruptured muscle syndrome: AST, CPK, and LDH levels are extremely elevated. BUN levels are usually normal.
• Delayed peracute syndrome: AST, CPK, and LDH, may be elevated but sometimes death occurs before elevations are observed.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Gross Postmortem Findings

• Capture shock syndrome: Congestion and edema of the lungs, severe congestion of small intestine and liver, sometimes frank blood within small intestine.
• Ataxic myoglobinuric syndrome: Renal and skeletal muscle lesions, swollen and dark kidneys, empty urinary bladder occasionally containing brown urine, multifocal pale, soft, dry areas with small white foci found in cervical and lumbar muscles and in flexors and extensors of the limbs. The lesions are often bilateral but not symmetrical, and subtle in animals that die 1–2 days post-capture but more pronounced in animals that survive longer.
• Ruptured muscle syndrome: Massive subcutaneous hemorrhage of the rear limbs and multifocal, small to large, pale, soft lesions in the limbs, diaphragm, cervical and lumbar musculature. Muscular lesions are similar to those described for the ataxic myoglobinuric phase, but are more severe and widespread. Small to large ruptures can be found within necrotic muscles. Commonly ruptured muscles include the gastrocnemius, subscapularis, middle and deep gluteal, semitendinosus, and semimembranosus muscles.
• Delayed peracute syndrome: There are often no visible lesions seen, though there could be a few small pale foci within the skeletal muscles.

Histopathologic Findings

• Capture shock syndrome: Small areas of necrosis occasionally found in skeletal muscle and brain, liver, heart, adrenal glands, lymph nodes, spleen, pancreas, and renal tubules – most prominent when an animal was hyperthermic.
• Ataxic myoglobinuric syndrome: Primarily lesions within the renal cortex and skeletal muscle. Renal lesions are characterized by dilation of tubules, moderate to severe tubular necrosis, and myoglobin casts. Muscular lesions are characterized by acute rhabdomyolysis with swollen myocytes.
• Ruptured muscle syndrome: Most lesions within the skeletal muscles and characterized

CERVIDAE: CAPTURE MYOPATHY (CONTINUED)

by massive necrosis. Similar to lesions found in white muscle disease, but there is less mineralization in CM-affected muscles.
• Delayed peracute syndrome: Lesions within muscle are characterized by mild to moderate rhabdomyolysis throughout the skeletal muscle, especially in the hindlimbs.

TREATMENT

THERAPEUTIC APPROACH
• Treatment of capture myopathy in cervids is often unsuccessful.
• In the hyperthermic stage, animals are sedated with anesthetics that provide central muscle relaxation (benzodiazepines and alpha-2 agonists).
• The most important treatment is intravenous fluids to allow for improved blood flow to kidneys to reduce tubular damage by myoglobin, dilute lactic acid within the bloodstream, expand blood volume, address mechanisms of shock, correct acid-base and electrolyte abnormalities, and reverse hyperthermia.
• Administration of vitamins, analgesics, and anti-inflammatory drugs have been tried, with little success.
• Successful treatment depends on the type of CM and the ability to treat without exacerbating existing conditions.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
Prophylactic use of sedative and tranquilizing drugs have been employed to prevent the development of capture myopathy syndromes in cervids not used to human contact, handling, and captivity. A combination of long-acting neuroleptics (LANs) have been shown to greatly reduce morbidity and enhance capture and translocation of numerous cervid species.

CONTRAINDICATIONS
• Animals released under the influence of LANs into new herd situations are at high risk of being harassed or attacked by other animals.
• Releasing cervids onto hunting ranches with LANs on board can reduce their perceptiveness and increase their risk of predation and self-trauma.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Extremely poor prognosis in all forms. Even animals who survive a mild CM event may be debilitated, leading to loss of productivity or failure to breed.

POSSIBLE COMPLICATIONS
Animals that recover have long-term muscle damage (especially cardiac muscle) and can succumb later in times of stress.

CLIENT EDUCATION
• Importance of proper restraint methods and for training of handlers.
• Be aware and be able to identify specific symptoms and behaviors that indicate stress in individuals.

PATIENT CARE
N/A

PREVENTION/AVOIDANCE
• Choice of the most suitable method of restraint and handling for each herd situation is vital, and depends on the needs of each producer, ranch, or farm.
• Ensure that the animals are habituated to human presence, handling, chute and hallway systems, and various enclosure types.
• Cervids should never be rushed through handling situations. It is best to habituate them to the hallway and chute systems by positive reinforcement, such as highly palatable feeds, to decrease apprehensive stress when the processing day arrives.
• Handling, processing, and capture of cervids should be avoided in harsh environmental conditions. Increased ambient temperatures combined with handling can precipitate hyperthermia in most cervids.
• Noise and movement should be kept at a minimum: blindfolds can help decrease stimuli on individuals that are immobilized or restrained in a chute system and help reduce stress.
• Immobilized animals or those restrained for extended periods of time should be monitored for hyperthermia by rectal temperature.
• Transporting cervids should be done in well-suited crates or trailers. Some species are best suited to be transported alone, while others do better in small groups. Ensure crate- or trailer-mates are compatible; do not place mature males together with females or neonates.
• Food and water should be provided to meet the specific needs of the animals during transport, especially during long trips.
• If chemical immobilization is used, ensure appropriate dosages, drugs, and delivery systems for each species.
• When releasing animals into new pens or new herd situations, ensure the individuals already in the enclosure or pen do not harass the new arrivals.

MISCELLANEOUS

ASSOCIATED CONDITIONS
White muscle disease has a very similar symptomatic process with a different etiology.

AGE-RELATED FACTORS
All ages may be affected, but studies in white tailed deer (*Odocoileus virginianus*) show that the very young and very old are more susceptible.

CERVIDAE: CHRONIC WASTING DISEASE

BASICS

OVERVIEW

• Chronic wasting disease (CWD) is a transmissible spongiform encephalopathy (TSE) that affects free-ranging and captive cervids including mule deer, black-tailed deer, white-tailed deer, Rocky Mountain elk, and moose. Exotic cervids may also be susceptible. • CWD was first recognized in captive mule deer in Colorado in the 1960s and later identified as a TSE in 1978. • TSEs are a group of diseases characterized by the accumulation of a misfolded normal host prion protein in the brain. • Additional TSEs in other species include bovine spongiform encephalopathy (BSE) in cattle, scrapie in sheep and goats, transmissible mink encephalopathy(TME) in mink, kuru, Creutzfeldt-Jakob disease (CJD), and vCJD in humans, and feline spongiform encephalopathy. • Horizontal spread of the disease by oral exposure to infected carcasses, excretions, secretions, contaminated soil, or other tissue source has been proven by epidemiologic studies. The agent is shed in feces, urine, saliva, blood, and antler velvet. • Clinical signs of CWD include changes in behavior, weight loss, loss of muscle mass, and salivation. The average age of affected animals is in the range 3–5 years.

INCIDENCE/PREVALENCE

• Epidemiologic modeling suggested that chronic wasting disease might have been present among free-ranging animals in some portions of the disease-endemic area several decades before it was initially recognized. • Incidence varies with the geographic region and species. • It also differs between wild populations and captive herds. This disease can be highly transmissible within captive deer and elk populations. In newly infected herds of farmed cervids, the prevalence may be <1%. However, once the disease has become established, 50% of the herd or more often becomes infected, and in some cases, the incidence may be as high as 100%. Generally, only one animal shows signs of disease at a time. Long-term environmental contamination has been suggested by both biochemical and epidemiologic studies. • CWD is less common in wild than farmed cervids. The prevalence is usually <1% in elk; however, it can be as high as 30% in concentrated populations of wild deer. Between 1996 and 1999, 4.7% of mule deer, 2% of white-tailed deer, and 0.5% of elk killed in northeastern Colorado and southeastern Wyoming were infected with the CWD prion overall, although there were "hot spots" where greater numbers of deer were infected. In Wisconsin, up to 13% of the male deer are infected in some areas. In contrast, the estimated prevalence in South Dakota in 2003 was 0.001% in white-tailed deer and no cases were reported in elk or mule deer. More than 97% of cases found during the surveillance of wild deer and elk are subclinical. • The low prevalence and lack of large-scale surveys has hampered identifying genetic profiles of susceptible populations and the use of genotyping to identify susceptible populations.

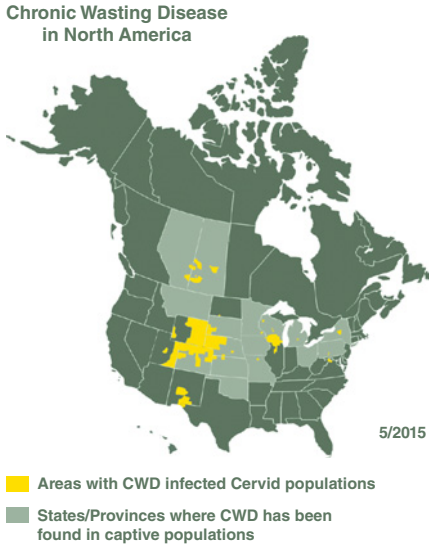

Figure 1.

The geographic distribution of CWD in free-ranging deer in the United States and Canada (courtesy Chronic Wasting Disease Alliance; www.cwd-info.org).

GEOGRAPHIC DISTRIBUTION

• North America, potentially worldwide (see Figure 1). • CWD has been detected in wild populations in at least 17 US states and 2 Canadian provinces, and has been diagnosed in captive populations in numerous other states.

SYSTEMS AFFECTED

• Nervous • Hemolymphatic
• Musculoskeletal

PATHOPHYSIOLOGY

• Transmission of CWD within wild populations appears to be via oral exposure to infected carcasses, secretions, and excretions. • Dead and decaying carcasses, placenta, and placental fluids are suspected to be common sources of infection, and may contribute to long-term infectivity in soils. • Analysis by immunohistochemical studies of the tissue distribution of prions in CWD-infected cervids identified the agent in the brain, spinal cord, eyes, peripheral nerves, tongue, and lymphoreticular tissues. • Involvement of the mucosal lymphoid tissues and peripheral nerves early in the course of experimental and natural prion infection indicates involvement of the lymphoreticular and peripheral nervous systems in the pathogenesis and transmission of the disease. • A unifying feature of all the prionoses is their neuropathology. CWD affects the gray matter of the central nervous system (CNS), producing neuronal loss, gliosis, and characteristic spongiform change. In addition, plaques with the typical staining properties of amyloid (e.g., apple-green birefringence after Congo red staining when viewed under polarized light) are observed.

SIGNALMENT

• Both free-ranging and captive white-tailed deer (*O. virginianus*), Rocky Mountain elk (*Cervus elaphus nelsoni*), mule deer (*Odocoileus hemionus*), black-tailed deer (*Odocoileus hemionus columbianus*), and moose (*Alces alces shirasi*) have all been diagnosed with CWD. • Most affected cervids are >2 years of age and many are 3–5 years old. • In captive cervids, most cases occur in animals 2–7 years of age; however, the disease has been reported in cervids as young as 17 months and as old as >15 years of age.

PHYSICAL EXAMINATION FINDINGS

• Many cervids diagnosed with CWD are asymptomatic. The more chronically affected animals have progressive fat and muscle loss over a period of weeks or months. • Additional clinical signs include changes in behavior, which can include loss of fear to humans, increased salivation, and atrophy of muscles around the head leading to droopy ears. • Clinical manifestations of CWD include weight loss over weeks or months, behavioral changes, excessive salivation, difficulty swallowing, polydipsia, and polyuria. In some animals, ataxia and head tremors may occur.

GENETICS

• The PRNP (prion) gene may relate to susceptibility to some TSEs. • The PRNP gene is highly conserved among diverse cervid species, with limited polymorphisms. • While no genotype has been absolutely correlated to resistance or susceptibility, genetic data has indicated certain genotypes in white-tail deer, elk, and moose may demonstrate enhanced susceptibility to disease.

CAUSES AND RISK FACTORS

• CWD and other TSEs are believed to be caused by a pathogenic effect on neurons of an abnormal isoform of a host-encoded glycoprotein, the prion protein. • The pathogenic form of this protein appears to be devoid of nucleic acids and supports its own amplification in the host through conversion of the secondary structure of host prion protein to the pathogenic protein structure. TSEs in animals primarily occur by transmitting the etiologic agent within a species, either naturally or through domestic husbandry practices. A notable exception among the TSEs is the apparent ability of BSE to effectively cross species barriers, affecting most mammalian species. • Although CWD does not appear to occur naturally outside the cervid family, it has been

CERVIDAE: CHRONIC WASTING DISEASE (CONTINUED)

transmitted experimentally by intracerebral injection to a number of animals, including laboratory mice, ferrets, mink, squirrel monkeys, cattle, and goats. Oral transmission has not been demonstrated to cause diseases in any species but cervids. • The mode of transmission among deer and elk is not fully understood; however, evidence supports lateral transmission through direct animal-to-animal contact or as a result of indirect exposure to the causative agent in the environment, including contaminated feed, soil, and water sources.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Bluetongue • Epizootic hemorrhagic disease • Locoweed • Meningeal worm (*Parelaphostrongylus tenuis*) infection

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER DIAGNOSTIC PROCEDURES

• Immunohistochemical (IHC) staining of the retropharyngeal lymph nodes and obex with a monoclonal antibody is considered the gold standard for postmortem diagnosis of CWD. ELISA-based diagnostic test on fresh retropharyngeal lymph node tissue has been used to test large numbers of wild cervids in a short time frame. • There is currently no approved antemortem test for CWD. • Prion strain diversity is believed to be encoded in the three-dimensional conformation of the protein, which determines the cleavage site and molecular size of proteinase-K–treated prion fragment, indicating that the difference in molecular size may correlate with strain differences. However, one-dimensional immunoblot analysis may not identify more subtle differences that may influence the conformation of different prion strains. • Analysis of the glycoform ratios of prion fragments and application of a two-dimensional immunoblot may help further identify these subtle differences.

PATHOLOGIC FINDINGS

• There are no gross pathognomonic changes in cervids with CWD. Gross examination of the brain is unremarkable in cervids with CWD. Additional postmortem changes in chronically affected animals are nonspecific, but can include emaciation, serous atrophy of fat, abomasal ulcers, and aspiration pneumonia. • Histopathologic lesions of chronic wasting disease include spongiform change of the gray matter; neuronal intracytoplasmic vacuolation, degeneration, and loss; and astrocytosis in the absence of a host inflammatory response.

TREATMENT

THERAPEUTIC APPROACH

N/A

MEDICATIONS

DRUGS OF CHOICE

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Most animals with the disease die within several months of onset of symptoms, sometimes from aspiration pneumonia. In rare cases, illness may last for ≥1 year.

PREVENTION

In establishing new enclosures for farmed cervids, a "new" uncontaminated area needs to be found. CWD, like other prion proteins, can survive in contaminated environments for many years.

MISCELLANEOUS

AGE-RELATED FACTORS

In captive cervids, most cases occur in animals 2–7 years of age; however, the disease has been reported in cervids as young as 17 months and as old as >15 years of age.

ZOONOTIC POTENTIAL

• There is no plausible link between CWD and BSE in cattle and scrapie in sheep. No known human has been infected with CWD. • CWD appears host specific and will not readily transmit to humans, sheep, swine, cattle, or other wildlife. • Increasing spread of CWD has raised concerns about the potential for increasing human exposure to the CWD agent. The foodborne transmission of bovine spongiform encephalopathy to humans indicates that the species barrier may not completely protect humans from animal prion diseases.

BIOSECURITY

• State and national programs have been implemented to reduce the spread of CWD. • Many states have mandatory identification and postmortem testing of all captive cervids. In addition to testing, some states have restricted movement of deer and elk across state boundaries. • Captive herds with a CWD-positive animal are typically eliminated. • CWD, like other prion proteins, can survive in contaminated environments for many years.

PRODUCTION MANAGEMENT

• Mandatory identification and postmortem testing of all captive cervids. • Captive herds with a CWD-positive animal are typically eliminated. • CWD, like other prion proteins, can survive in contaminated environments for many years.

CERVIDAE: GAME PARK MANAGEMENT, FACILITIES

BASICS

OVERVIEW

• All aspects of animal care and husbandry in a captive environment.
• Scale and type of issues faced can vary markedly depending on type of facility, i.e., indoor versus outdoor, zoological garden versus commercial deer farm versus hunting preserve, and type of cervid species.
• There are over 40 species of Cervidae ranging from pudu (*Pudu pudu*) that weigh approximately 7 kg to moose (*Alces alces*) that weigh up to 800 kg.
• Antlers are present in the males of all species except from the genus *Hydropotes*. Females of the genus *Rangifer* also have antlers.

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

• Cervids are naturally distributed throughout most of North and South America, Eurasia, and northern Africa.
• Deer have been introduced into wild habitats in Australia, New Zealand, Cuba, New Guinea, and elsewhere.
• Deer are farmed for meat and velvet production in numerous countries.

PRODUCTION MANAGEMENT

Handling Facilities

• Facility design is important to facilitate animal handling for medical and management procedures.
• Properly designed pens with communicating alleyways allow for loading animals into trailers for transport or into chutes or mechanical restraint devices to allow for physical examinations, hoof trimming, or minor medical procedures.
• Farms need a yard system that will lead animals up to corrals where they can be sorted and moved through a chute. It is best to make a gradual transition from open fencing to solid walls in areas of crowding. Wooden walls are better than metal as they are quieter and do not absorb heat as readily. It is important that animals cannot see escape routes and that facilities and hardware such as hinges stand up to the animals pushing against gates and walls.
• Moving animals through alleyways as part of a normal routine facilitates moving them when necessary for other procedures.
• It is important to have adequate ventilation and shade in handling areas to reduce the likelihood of animals overheating. Nonslip, level substrate that does not retain moisture is important for areas in which animals will be gathered for handling.
• The system design should be based upon the size and number of animals present on the farm.
• In general, deer do best when they are herded around blind bends because this gives them the sense that they are escaping from danger. Therefore, raceways should incorporate turns and curves rather than long straight runs. Raceways should be wide enough to allow passage of tractors or other necessary machinery.
• In handling areas, fences should be solid and a minimum of 8 feet high and probably 9 feet for elk and red deer. Physical restraint may be accomplished with a drop floor chute, or mechanical or hydraulic crush restraints. Covering the animal's eyes with a towel or other cover will help keep it calm while being restrained.
• Areas in which animals are brought in or loaded out should be within a perimeter fence to prevent escape off the farm should an animal break free.
• The loading area should allow for a trailer to pull up without gaps between the trailer and the walls of the loading chute. If there are gaps, wood planks or plywood can be used to fill the void. Having an adjustable floor to allow it to be level with the trailer floor will facilitate loading. It is essential to avoid gaps in the floor between trailer and loading chute where an animal might get a foot or leg caught.
• Operant conditioning of animals for blood collection and voluntary injections of anesthetic agents, vaccines, and medications facilitates care of cervids in captivity. An appropriate barrier system should be in place to protect persons doing these procedures.
• Smaller cervid species such as muntjac or pudu can be run into opaque restraint bags made of canvas or nylon mounted on a metal frame. The dark bag has a calming effect, and having the animal in a bag decreases the risk of injury to the animal and the person(s) restraining the animal.

Housing

• Requirements will depend on species and geographic location of the animal collection.
• In temperate regions, tropical species may require indoor housing during cold seasons.
• Outdoor facilities require adequate shade as well as protection from wind and rain. Animals must have access to a clean reliable source of water in any areas in which they are housed.
• State, provincial, and federal regulations typically dictate minimal fencing requirements for outdoor exhibits. USDA CWD program standards require fencing to be a minimum of 2.4 meters (96 inches) high, complying with any other state regulations or requirements, and that the fence is constructed and maintained in a way that prevents ingress of wild cervids onto the premises and egress of captive cervids to the wild.
• In areas of high snowfall, additional fence height or snow removal may be required to maintain effective fencing.
• A large percentage of animal escapes from deer farms are due to gates not being properly closed. Having well-designed gates with good locking mechanisms and considering double gates in areas of high traffic may be beneficial to reduce this problem.
• Solid fencing and high tensile page wire are commonly used for red deer and elk facilities. Electric fencing is sometime incorporated along with primary fencing, but may be removed by antlered animals as mature antlers are devoid of sensory innervation. Electric fencing inside or outside of the primary fence has been shown to reduce the chance of nose-to-nose contact between the captive animals and wild cervids outside the enclosure.
• Entanglement of antlers or limbs is of concern with chain link or other forms of permeable fencing and it is not recommended to house stags in adjacent pens during rut because they may attempt to fight through the fence.
• It is generally not recommended to house multiple stags in a single enclosure during rut because it will cause fighting and may lead to severe injuries or mortalities. During periods when antlers are shed or are in velvet, stags are not likely to fight. Antlers can be removed to reduce the potential for serious injuries between animals.
• With adequate space, a single stag and multiple hinds (harem) and juveniles are typically housed together, but it is important to have the ability to isolate the stag to manage reproduction.
• Natural dirt substrate typically works well. In outdoor exhibits shelter and windbreaks should be provided in sufficient numbers for all animals.
• Visual barriers/hiding places are important to allow animals to feel secure at certain times such as during calving or for newly introduced animals.
• Cervids will destroy exhibit plants that are not protected, but stags require rubbing posts or trees to clean off velvet.
• It is important to provide multiple food and water sources to allow lower-ranking animals access.
• An isolation/hospital pen should be available for sick or injured animals. Depending on the facility this may also suffice for a quarantine area for new animals or there may be a need for a separate quarantine area. Ideally a quarantine area will be physically separated from the rest of the collection and should have separate staff and equipment to care for these animals (see chapter, Biosecurity: Cervidae).

CERVIDAE: GAME PARK MANAGEMENT, FACILITIES (CONTINUED)

• If animals are managed on pasture, it is ideal to be able to rotate animals between pastures to maintain quality of pasture forage and to minimize parasite build-up on pastures.

Social Requirements

Most cervid species are social animals and live in herds at least during part of the year.

Laws and Regulations

• Federal regulations under the Animal Welfare Act and Animal Welfare Regulations apply to cervids, and licensure through the USDA is generally required for zoos (except federal facilities), promotional exhibits (use of animals for promotion or advertisement of goods or services, use of animals as prizes, use of animals to promote photography, use of animals in public venues), public exhibitions, and performing animals.
• Licensure is not required for operations raising animals for food and fiber, game preserves, or hunting preserves unless animals from these ventures are sold to other ventures requiring licensure. License fees depend on a number of factors, including the type of license required. In certain situations an exhibitor may be registered rather than licensed and as such no fees apply.
• The Animal Welfare Act and Animal Welfare Regulations are available online: http://awic.nal.usda.gov/government-and-professional-resources/federal-laws/animal-welfare-act
• Both state and federal laws and regulations apply to maintaining a captive cervid population, although federal laws may not apply unless there is interstate movement of the animals. Local zoning ordinances may also apply. Federal regulations apply to any interstate movement of cervids, but state regulations may be more restrictive in relation to allowing cervids to enter a state, if not just passing directly through. In addition to specific testing and various requirements for herd certification, an official certificate of veterinary inspection (CVI) signed by an accredited veterinarian is required for interstate movement of captive cervids.
• Contacts for appropriate state agencies can be found online: http://www.aphis.usda.gov/import_export/animals/animal_import/animal_imports_states.shtml
• Questions regarding international importation and exportation of live cervids can be emailed to: VS.Live.Animal.Import.Export@aphis.usda.gov or can be answered by calling: (301)851-3300.

CAPTIVE CERVID HERD CWD CERTIFICATION PROGRAM

• USDA-APHIS has established a voluntary captive cervid herd CWD certification program (HCP) to reduce the risk of introduction, transmission and spread of chronic wasting disease in captive cervid herds in the United States. The federal CWD program only covers cervids of the genus *Cervus* (e.g. elk, red deer) *Odocoileous* (e.g. white-tailed deer, mule deer) and *Alces* (moose). A state may oversee its own certification program with the approval of USDA-APHIS. A state's program must at least meet the requirements of the federal HCP, but may be more restrictive and may include all species of cervid.
• All participating cervid farms must have a unique premises identification number (PIN). Captive cervids that are not from a CWD "certified herd" cannot be transported between states. There are special exemptions for animals used for research, wild animals being moved for reintroduction efforts, or animals being taken directly to slaughter facilities.
• Deaths of program animals that are 12 months or older must be reported to state or federal representatives and the animals must be tested for CWD. Exceptions to testing may be permitted by approved state agencies due to extenuating circumstances beyond the herd owner's control.
• In states which allow cervid ownership, but do not have an approved CWD herd certification program, interested parties can enroll directly by applying to APHIS. Herd animals require two forms of positive animal identification. One form of ID must be an officially approved device with a nationally unique animal identification number that is linked to that animal in the CWD national database or in an approved state database.
• An animal must be identified with appropriate methods by the time it is 12 months old or if it leaves the farm. Information about official identification can be obtained at the at the USDA website: http://www.aphis.usda.gov/traceability/downloads/ADT_eartags_criteria.pdf
• A herd reaches "certified" status 5 years after it has been continuously enrolled in the program and has maintained requirements for progressing from first- through fifth-year status.
• Should a CWD-positive animal be detected in a herd, regulatory agents work with the owner to develop a herd plan to eradicate CWD from the infected herd and prevent the introduction of CWD into uninfected herds. The implemented plan is a management program written by a state or federal representative with input from the herd owner, the herd veterinarian, and other affected parties.
• Herd plans take steps to stop the introduction of CWD into uninfected herds, eradicate CWD from infected herds, and control the risk of CWD in suspect herds. A plan could require depopulation of a herd and could prevent cervids from occupying the affected site for a specified period of time if a herd was found to be CWD-positive. Perimeter fencing around the herd must be adequate to prevent ingress or egress of cervids.
• A herd may be classified as: **CWD positive**—a herd which contains CWD-infected animals; **CWD exposed**—one in which a CWD-positive animal has resided within 5 years prior to that animal's diagnosis as CWD positive as determined by an APHIS employee or state representative; **CWD suspect**—one that has laboratory evidence or clinical signs suggestive of CWD, but has not yet had a conclusive, confirmed diagnosis.
• USDA CWD Program Standards can be found at: https://www.aphis.usda.gov/animal_health/animal_diseases/cwd/downloads/cwd_program_standards_2014.pdf
• Voluntary herd tuberculosis accreditation and brucellosis certification programs are available for cervids and are administered by regulatory agencies in each state. States also regulate importation requirements for cervids and the State Board of Animal Health or similar state or provincial regulatory agency should be contacted prior to making arrangements for interstate movements.

CAUSES AND RISK FACTORS
Noninfectious Causes
Trauma and Handling-Related Deaths
• Mortality as a result of trauma was a leading cause of death in adult captive WTD and elk populations surveyed.
• Traumatic injuries related to handling are usually a result of poorly designed handling facilities or improper handling techniques, especially with inexperienced farmers.
• Yearling males tend to have the highest percentage of handling-related injuries.
• Capture myopathy in WTD seems to be a leading cause of handling-related deaths in adult females.
• Traumatic injuries from fighting among animals, especially adult males in rut, can result in perforations (i.e., thoracic, abdominal) if antlers are not removed or head/neck injuries (vertebral/skull fractures, brain abscesses, meningitis) if antlers are removed.
• Darting injuries can result in skeletal fractures, body cavity perforations, and deep tissue damage with subsequent disease.
• Accidental anesthetic overdose can directly cause death.
• Conversely, underdosing with anesthetics can lead to traumatic injuries due to ataxia, prolonged induction, and capture myopathy.

Nutrition
• Starvation in neonates can result from dam agalactia or abandonment.
• Starvation in yearlings and adults occur with improper feed supplementation throughout the winter months or when age groups are mixed such that older, dominant animals monopolize the feed sources.
• Ruminal acidosis ("grain overload") has been reported to affect as many as 25% of adult deer, with more dominant animals being predisposed due to overindulging on supplementary feed.
• Congenital white muscle disease, caused by inadequate vitamin E and selenium intake by pregnant dams, can lead to stillborn or weak neonates that die shortly after birth.
• Chronic vitamin E deficiency in juvenile or adult deer can cause fatal cardiomyopathy.
• Copper deficiency usually manifests as clinical disease (enzootic ataxia and osteochondrosis) and can lead to poor performance, bullying from herdmates, and death.

Infectious Causes
Bacterial Diseases
Necrobacillosis
• Primary etiologic agent is *Fusobacterium necrophorum*; second most common cause is *Trueperella pyogenes*; occasionally *Fusobacterium varium* is isolated in WTD.
• The leading cause of overall death in WTD fawns and most common cause of bacterial death in both fallow and WTD.
• Results in significant morbidity due to the development of foot rot, wooden tongue, and lumpy jaw with secondary multi-organ abscessation and erosion or ulceration of the intestinal wall (esp. rumeno-reticulum).
• Stressors such as heat, cold, overcrowding, mud, and malnutrition predispose deer to infection.
• Good management practices can minimize incidence of clinical disease and include stress prevention, good hygiene, decreasing food coarseness, ensuring adequate nutrition, and choosing substrates that do not retain water.
• Vaccines against *F. necropohorum* have been developed for cattle and may be used in deer, but its efficacy has not been evaluated. Autogenous vaccines may be used in some herds.
Tuberculosis (*Mycobacterium bovis*)
• Has been reported in at least 14 Cervidae species including red deer, fallow deer, elk, and WTD.
• Transmission usually occurs through the mouth or nasal cavity, resulting in subacute to chronic disease.
• Lesions are usually found in retropharyngeal lymph nodes, followed by lung and associated lymph nodes.
• Clinical signs are often nonspecific and include weight loss, emaciation, and rough hair coat, with death usually occurring after the onset of clinical signs.
• Lymphadenopathy occurs commonly, and all abscess-like lesions should be cultured for mycobacteria.
• Testing can be performed antemortem using a tuberculin skin test or a serologic test and is generally required for interstate movement of captive cervids (elk, red deer, WTD, fallow deer, reindeer) in the US.
Johne's Disease (*Mycobacterium avium* subsp. *paratuberculosis*)
• Deer show clinical signs earlier than other ruminants, but only a small proportion exposed become clinically ill.
• Adult deer show chronic loss of condition and weight over a few months (similar to sheep and cattle), and young deer tend to exhibit a much more acute, rapid loss of weight and muscle mass over a few weeks.
• Affected deer also experience diarrhea and death due to poor condition.
Respiratory Diseases
• Pneumonia is the most common respiratory disease associated with mortality.
• Primary etiology commonly unknown, but *T. pyogenes* has been reported most frequently with *Mannheimia haemolytica*, *Escherichia coli*, *Pasteurella* spp., *Streptococcus* spp., *Fusobacterium necrophorum*, and *Mycobacterium* spp. also having been reported.
• If untreated, can progress to septicemia, acute hemorrhagic disease, and death.
Gastrointestinal Diseases
• Common bacterial pathogens associated with acute enteritis and mortality include *E. coli*, *Clostridium perfringens*, *Salmonella* spp., and *Yersinia pseudotuberculosis*.
• Colibacillosis (*E. coli*)
  ◦ Clinical signs include endotoxic shock and sudden death, acute diarrhea (± hemorrhage), and/or neurologic deficits due to meningitis.
  ◦ Neonates most severely affected with slightly older fawns/calves experiencing mild scours and colic.
  ◦ Vaccine (autogenous/extra-label) may be available for pregnant dams; best prevention strategy is practicing good hygiene and ensuring adequate colostrum intake.
• Clostridial Disease
  ◦ In adults, usually a result of sudden change in feed composition.
  ◦ *C. perfingens* type D has been reported as a cause of acute enteritis and death in young cervids.
  ◦ Vaccination of dams 30–60 days before calving and of calves at weaning and 30 days later is used in preventive programs. However, the efficacy is unproven.
• Salmonellosis
  ◦ Many different *Salmonella* spp. have reportedly caused isolated cases of peracute septicemia, acute enteritis, and sudden death in neonates.
  ◦ The only preventive methods available are practicing good hygiene, reducing stress, and ensuring adequate colostrum intake.

- Yersiniosis (*Yersinia pseudotuberculosis*)
  - Sudden death is most common initial finding when outbreak occurs.
  - Formation of microabscesses of various sizes enveloping large bacterial colonies in the intestinal lamina propria is typical histologic lesion; can be easily isolated from intestine and mesenteric lymph nodes.
  - Affected deer tend to be weanlings during inclement weather within their first fall, but other stressors (malnourishment, transport, concurrent diseases) can also predispose them.
  - An effective licensed vaccine is available in New Zealand.

Anthrax (*Bacillus anthracis*)
- Severe outbreaks have been reported in red deer, wapiti, moose, and fallow deer.
- Transmission generally through ingestion of contaminated soil or water.
- Septicemia and sudden death may occur <2 days after exposure in acute form.
- Other animals may show nonspecific signs of abdominal pain or have bloody discharge from nostrils and anus.
- Any suspected cases must be reported.
- Vaccine may be available in endemic areas.

Leptospirosis
- Caused by serovars of bacterium *Leptospira interrogans*.
- Young cervids most susceptible, experiencing clinical signs ranging from sudden death in peracute cases to fever, anorexia, and hemoglobinurea in others.

Viral Diseases

Malignant Catarrhal Fever
- The most important viral disease of farmed deer, worldwide.
- Cervid outbreaks are commonly sheep-associated (OvHV-2), but a currently unnamed gammaherpesvirus has been reported in WTD.
- Elk and red deer often develop the chronic "head and eye" form, characterized by excessive salivation, lachrymation, and nasal discharge.
- WTD, axis deer, Père David's deer, and rusa deer are all highly susceptible and may die acutely or peracutely.
- Widespread hemorrhages ± mucosal erosions are most commonly observed.
- Lymphocytic vasculitis with lymphoid hyperplasia is a characteristic histologic finding that can be confirmed using ELISA or PCR.

Hemorrhagic Diseases
- Two closely related Orbiviruses, bluetongue (BT) and epizootic hemorrhagic disease (EHD) of deer, have been reported to cause major epizootic deaths in WTD, with less severe effects in mule deer.
- An adenovirus has also been implemented as a cause of acute hemorrhagic disease and death in several cervid species with similar lesions to those seen in BT and EHD.
- Transmission of BT and EHD are through biting gnats or sandflies of the genus *Culicoides*, whereas adenovirus is transmitted through direct contact.
- Widespread hemorrhages of mucus membranes, pulmonary edema, and enteropathy are often observed, and EHD is usually more acutely fatal.
- Autogenous vaccines have been used with some success for control of EHD and BT.

Rotavirus and Coronavirus
- Frequently associated with enteric disease in young cervids.
- Watery diarrhea is most consistent clinical sign with secondary dehydration and depression.
- Can be managed with appropriate supportive care (oral or IV fluids; ± antibiotics for secondary bacterial infection; tube feeding) as death may occur if no intervention occurs; however, careful monitoring is crucial as hypernatremia has been reported in wapiti calves treated with oral fluids designed for cattle.
- Cattle vaccines are available and have been used with variable success; appropriate management of the dam and environmental conditions are of utmost importance for prevention.

Parasitic Diseases

Lungworms (*Dictyocaulus* spp.)
- Cause a chronic disease in young cervids (3–5 months most susceptible).
- Nonspecific clinical signs such as decreased appetite, weight loss, impaired growth, roughened coat, and sudden death.
- Asphyxia from massed dead adult worms in the airways has been reported after anthelmintic administration.

Gastrointestinal Worms
- Important intestinal parasites of the family Trichostrongylidae include *Ostertagia, Haemonchus,* and *Spiculopteragia*.
- Type II ostertagiasis has been reported in WTD, red deer, and wapiti, causing poor performance and death.
- Hemonchosis has been associated with anemia, emaciation, and death in WTD.
- Infestations can occur concurrently with lungworm.

Liver Fluke (*Fascioloides magna*)
- Also known as the giant liver fluke, has an indirect life cycle involving aquatic snail intermediate hosts.
- Heavily infected wapiti and WTD may die with extensive liver damage.
- Calves and fawns may develop peritonitis and die acutely.

Meningeal worm (*Parelaphostrongylus tenuis*)
- Has an indirect life cycle involving gastropod intermediate hosts.
- Severity of clinical signs varies based on species and seems to be dose-dependent, with WTD being relatively resistant.
- Moose and elk appear to be most susceptible, exhibiting clinical signs that include ataxia, blindness, collapse, and death.

Cryptosporidiosis
- Similar syndrome to that in other livestock.
- Usually only occurs in 2- to 4-week-old animals, especially when hand reared.
- Severe diarrhea can lead to dehydration and death.
- Has occurred in outbreak form.
- Marked zoonotic potential—good hygiene is essential for personnel.

Prion Disease

Chronic Wasting Disease
- Within the group of transmissible spongiform encephalopathies, characterized by abnormal proteinaceous material accumulation in the CNS.
- Has been reported in mule deer, WTD, moose, and elk in the US and Canada, with mule deer being most susceptible.
- Mode of transmission is generally thought to be oral and incubation periods are prolonged.
- Clinical signs include chronic weight loss, polydipsia, polyuria, drooling, and ataxia followed by death.
- Secondary aspiration pneumonia is commonly seen on necropsy.
- Surveillance programs are in place to minimize spread and transmission throughout captive cervid populations and include submission of obex and medial retropharyngeal lymph nodes from dead animals for testing.

AGE-RELATED FACTORS
• Most mortality in young stock occurs in summer or just after weaning.
• The highest mortality rate in yearlings and adults occurs in winter.

ZOONOTIC POTENTIAL
Brucellosis, tuberculosis, leptospirosis, and cryptosporidiosis are all zoonotic in nature.

PREGNANCY
N/A

BIOSECURITY
Many infectious diseases can be prevented by practicing good biosecurity, which includes quarantining new animals and implementing vaccination and treatment protocols.

PRODUCTION MANAGEMENT
• Trauma is a major cause of mortality in all farmed deer, and is usually associated with poorly designed handling systems or improper handling techniques.
• Capture myopathy is a potential sequela, but its incidence can be minimized by vitamin E supplementation, proper handling, and acclimation of animals.
• Nutritional causes are less common causes of death in captive deer populations and can be minimized with proper management.

BASICS

OVERVIEW

• There are ~40 species in the family Cervidae, many of which vary greatly from one another in their reproductive strategies.
• Most cervid species are of northern temperate origin and are seasonally polyestrous, breeding in the autumn when day length is decreasing.
• The breeding season lasts between 4 and 6 months and is tightly synchronized with gestation length so that birth occurs late spring to mid-summer.
• Tropical species, such as chital deer, have less well-defined seasonal constraints and are able to reproduce year-round.
• Onset of puberty and reproductive success are largely influenced by nutritional availability and BCS.
• Nomenclature depends on species and geographic locale:
  ◦ Adult male: stag, bull, buck
  ◦ Adult female: hind, cow, doe
  ◦ Juvenile: calf, fawn

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide, depending on species

PATHOPHYSIOLOGY

N/A

SYSTEM AFFECTED

Reproductive

HISTORICAL FINDINGS

N/A

SIGNALMENT

Commonly studied species include those within the genera *Cervus* (red deer, wapiti), *Dama* (fallow deer), *Axis* (chital deer), *Rangifer* (reindeer), *Odocoileus* (white-tailed deer, black-tailed deer, mule deer), *Alces* (moose), *Capreolus* (roe deer), *Ozotoceros* (Pampas deer), *Elaphurus* (Père David's deer), *Rucervus* (swamp deer, Barasingha).

PHYSICAL EXAMINATION FINDINGS

Puberty and the Reproductive Cycle in the Female

• Onset of puberty: red deer, wapiti, fallow deer: between 9–18 months of age; white-tailed deer, reindeer: as early as 6 months of age; chital deer: ~14 months of age; Pampas deer: ~12 months of age; age at onset can vary based on environmental stressors.
• Species of northern temperate origin are seasonally polyestrous, with cycles beginning in Sept/Oct and continuing, if unmated, for 4–6 months.
• Tropical species (e.g., *Axis*) are aseasonal and exhibit estrous cycles year-round.
• The estrous cycle length varies by species but is generally between 18–24 d in length with *Cervus* species being shorter (18–20 d) and *Odocoileus* species being longer (21–27 d).
• Short cycles of 8–10 d with no overt signs of estrus (i.e., "silent ovulation") at the beginning of the season have been reported in most species and help to synchronize the first estrus of the season within a herd.
• One exception is the roe deer, which exhibits estrus as early as July, is monoovulatory, and, subsequently, experiences delayed implantation to allow for birthing to occur in the summer.
• Behavioral estrus tends to be subtle, with females exhibiting increased activity and displaying proceptive behaviors towards the male.
• In some species, overt estrus is terminated following successful copulation and may be as brief as a few minutes. If unmated, duration of standing heat can range from a few hours to >24 h. Ovulation generally occurs ~24 h after onset of estrus.

Pregnancy

• Gestation length varies with species and tends to increase with increasing body mass (e.g., *Odocoileus* 200 d; *Rangifer* 216 d; *Dama* 234 d; *Cervus* 240 d; *Elaphurus* 284 d).
• Variation in gestation lengths are compensated for by adjustments of up to 8 weeks in the onset of mating season between species to allow for parturition to occur mid-summer.
• "R-selected" populations are those species that normally produce twins or triplets, achieve early sexual maturation (<1 year), and experience a short breeding life (<10 years); this includes species within *Odocoileus* and *Capreolus*. The fecundity of these species can be influenced by habitat and nutritional availability.
• "K-selected" populations are those species that normally produce a single offspring, achieve later sexual maturation (>1 year), and experience a long breeding life (10+ years); includes species within *Cervus, Dama, Axis, Elaphurus,* and *Rangifer*.
• Similar to other ruminants, cervids undergo synepitheliochorial placentation. However, cervids have fewer placentomes (6–12) and are considered oligocotyledonary.
• The presence of a functional corpus luteum (CL) is required for pregnancy maintenance in both red deer and white-tailed deer. Conversely, reindeer appear to have some contribution of progesterone from the fetoplacental unit for pregnancy maintenance.

Parturition

• As in domestic ruminants, the mammary development begins about a week before parturition, with the udder becoming noticeably turgid.
• Females become restless and will isolate themselves from the herd in the days preceding parturition.
• The 1st stage of labor is marked by increased pacing of the fence line with a high stepping gait and extended neck, vocalization, and vulvar licking.
• The 2nd stage of labor is initiated with visible abdominal contractions, followed by appearance and subsequent rupturing of the amniotic sac, and is terminated with the expulsion of the fetus. The fetus can be expelled either standing or lying down.
• The progression of parturition can vary in duration among species, but producers should monitor captive females in labor to ensure that some progress is made every 30 min after entering the 2nd stage of labor.
• The placenta is usually expelled within the first hours postpartum (15 min to 4 h).

Puberty and Sexual Activity in the Male

• Puberty onset occurs when testosterone (T) production from the testis begins and development of secondary sex characteristics and accessory sex glands occurs. Onset depends mostly on body weight, but also somewhat on photoperiod.
• In *Cervus* and *Dama* species, males usually reach puberty in the 2nd autumn of life, at ~15 months of age, though they may not be able to breed in the presence of older males.
• Similar to females, white-tailed deer and reindeer males can attain puberty and successfully breed as early as 6 months of age if nutrition is adequate.
• Antler growth ("velvet") from the pedicle occurs during the spring and summer months while T levels are low. In temperate species, testicular atrophy occurs and spermatozoa are not produced during this time.
• As day length decreases, LH and T output increase, modulated through the pineal gland's effect on the hypothalamic-pituitary-gonadal axis (similar to sheep and goats), and the antlers mineralize and shed the velvet (i.e., "hard antler").
• In rut, males are at their most fertile with maximal testicular size, spermatogenesis, and androgenic activity. Adult males undergo rapid mobilization of fat and catabolization of muscle, causing a decrease in live weight of up to 30% that is not regained until the following spring.
• During the rutting season males have an increased neck girth and some species develop a characteristic long shaggy mane. *Cervus* species display urine spraying over the ventral abdomen, thorax, and forelegs, giving the male a strong pungent odor. Other behaviors include increased aggressiveness and special vocalization.

GENETICS

N/A

CAUSES AND RISK FACTORS

Poor reproductive performance may be due to poor management (nutrition, male selection, and pregnancy loss).
Dystocia is rare in cervids.

CERVIDAE: REPRODUCTION (CONTINUED)

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Pre-mating BCS of the female is associated with conception rate, conception date, and weight of weaned offspring.
• Brucellosis and leptospirosis has been reported to cause abortions or infertility in many cervid species.
• Dystocia is rare and usually occurs as a result of an overconditioned female.
• Causes of infertility in the male include epididymitis, orchitis, and cryptorchidism. Ulcerative posthitis (pizzle rot) and prolapsed prepuce are observed frequently in wapiti.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Pregnancy specific protein B (PSPB) detection in the serum can also be used efficiently for pregnancy diagnosis past 30 days in all species.
• Serology and bacteriology in cases of abortion.

IMAGING
Pregnancy diagnosis using transabdominal ultrasound is easy and accurate after 35 days' gestation. Number of fetuses can be determined using this method if performed in first two trimesters of pregnancy (mid-Jan to early March).

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Infertility
• Abortion

AGE-RELATED FACTORS
• Females >10 years of age may produce offspring with low birthweight.
• Primiparous females tend to begin cycling later in the season than multiparous females, giving birth later in the summer.

ZOONOTIC POTENTIAL
Many reproductive diseases are zoonotic (*Leptospira* spp., *Brucella* spp., etc.). Care should be maintained when diseases are suspected.

BIOSECURITY
Brucellosis testing for susceptible species

PRODUCTION MANAGEMENT
• Hormonal control of the estrous cycle of cervids is similar to that of domestic ruminants and can be manipulated using similar protocols to those used in sheep and goats for artificial insemination.
• Neonatal losses are in the range 5–20% in farmed cervid and are usually due to dystocia, accidental injuries, and starvation (rejection or agalactia).
• Offspring are preferably weaned before the start of the rutting season to allow dry-off and weight gain. However, lactation does not seem to interfere with ovarian activity and ovulation unless the BCS deteriorates.

CESAREAN SECTION: BOVINE

BASICS

OVERVIEW
• Indications for C-section in the bovine include dystocia caused by uterine torsion, feto-maternal disproportion, fetal abnormalities, emphysematous fetus, and fetal maldispositions not resolved by obstetric manipulations.
• C-section may be performed electively in high-risk pregnancies.
• Selection of a surgical approach is based on several factors.

INCIDENCE/PREVALENCE
C-section is the second most common abdominal surgery performed in the bovine.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEM AFFECTED
• Reproductive
• Multisystemic depending on complications

PATHOPHYSIOLOGY
C-section is indicated when other obstetric manipulations to resolve a dystocia are not possible.

HISTORICAL FINDINGS
• Signs of parturition without progression
• Unsuccessful obstetric manipulations

SIGNALMENT
Pregnant females at term

PHYSICAL EXAMINATON FINDINGS
• Depend on duration of the dystocia and manipulation attempts. Elevated heart and respiratory rates are common. Abdominal contraction and tenesmus are common. Dehydration is present in protracted cases.
• Dilated and edematous vulva if parturition has progressed to the second stage.
• Presence of discharge or fetal parts at the vulva.
• Vaginal speculum and manual vaginal palpation is performed to determine cervical dilation status and fetal disposition.

GENETICS
• Double muscled breeds (Belgian blue, some Charolais lines are at risk)
• Breeding to bulls with poor calving ease

CAUSES AND RISK FACTORS
• Dystocia
• Severe fetal abnormalities
• Uterine torsion
• Small heifers

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Refer to chapter, Dystocia: Bovine

CBC/BIOCHEMISTRY/URINALYSIS
Performed in severely compromised/valuable females. Electrolyte imbalances, hypocalcemia, hypophosphatemia, and elevated liver enzymes are common with pregnancy toxaemia.

OTHER LABORATORY TEST
N/A

IMAGING
N/A

DIAGNOSIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
Vary depending on the cause of dystocia. Large offspring syndrome is encountered in pregnancies from somatic cell nuclear transfer cloned embryos.

TREATMENT

THERAPEUTIC APPROACH
• C-section may be performed on the farm without need of hospitalization is the patient is stable and the surgery is uncomplicated.
• Complicated cases should be handled in a hospital setting with capability of support (fluid therapy, pain management).

SURGICAL CONSIDERATIONS AND TECHNIQUES

Surgical Considerations
• Choice of approach depends on facilities, animal temperament, the medical condition of the animal, environment, and availability of assistance.
• Surgical approaches include standing paralumbar laparotomy, ventral midline celiotomy, paramedian celiotomy, left oblique celiotomy, and ventrolateral celiotomy.
• The two most common procedures are the standing paralumbar laparotomy and the ventrolateral celiotomy.
• Local anesthesia via an aseptic epidural injection of 2% lidocaine is almost always indicated to prevent straining,
• If the calf is dead and fetotomy is not an option, standing paralumbar laparotomy is performed if the cow is in good health and the fetus is not emphysematous. A ventrolateral celiotomy should be used if the calf is emphysematous, to improve exteriorization of the uterus and reduce risk of contaminating the abdomen.
• The use of preoperative antibiotics and anti-inflammatories should be considered on a case-by-case basis.

Standing Paralumbar Laparotomy
• The left side approach is the most common. The rumen serves as a visceral retainer and the small intestine is less likely to prolapse out of the incision.
• In dairy cattle, a right-sided incision allows to secure the abomasum during the procedure.
• The hair is clipped in the paralumbar fossa and the area cleansed from debris, hair, and gross contamination.
• Local anesthesia is achieved by lidocaine line block, inverted-L block, distal paravertebral (Cakala) block, and proximal paravertebral (Farquharson) block.
• The surgical site is aseptically prepared and a surgical drape placed over the side of the cow. The drape can be secured by towel clamps placed directly on the topline, then at the corners of the drape where local anesthesia is not present or with backtag glue or eyepatch glue at the periphery of the surgical area.
• A vertical incision, 30–50 cm depending, is made in the paralumbar fossa.
• The incision is extended through the skin and external abdominal oblique muscle.
• The internal abdominal oblique muscle and transverse abdominus muscle can then each be separated bluntly parallel to their fiber orientation in a "grid" technique to reduce hemorrhage and provide better apposition during closure.
• The peritoneum can then be bluntly entered or tented with an instrument and incised to gain access to the abdominal cavity.
• The uterus is identified by palpation in the caudal abdomen. Wearing a sterile obstetric sleeve makes manipulation easier and decreases risk for adhesions.
• The fetal horn is identified and grasped around the hock or carpus of the fetus then gently brought to the incision line.
• Exteriorization of the uterine horn is the most difficult step, particularly if the uterus is very contracted or fetus is large.
• A small incision is made between the calf toes, a sterile obstetric chain is placed and handed to an assistant, then incision is extended to allow exteriorization of the other foot, then the entire fetus.
• The incision should be long enough to allow extraction of the calf without tearing the uterus.
• The uterus should be maintained exteriorized during the procedure.
• The uterus is checked for presence of any abnormalities or twins prior to closing.
• Extraneous detached placenta is removed, but the placenta should be left in place if not detached.
• The uterine incision is closed in an inverting pattern (Cushings or Utrecht) using #2 absorbable suture. If the uterus is compromised, two layers are recommended, the first layer being a simple continuous pattern oversewn with an inverting pattern.
• Whenever possible the knots should be buried to prevent adhesion formation.
• The uterus is examined again for tears. The serosal surface is cleaned gently with warm

CESAREAN SECTION: BOVINE (CONTINUED)

sterile saline the replaced into the abdomen. Aggressive use of gauze sponges on the uterine surface in this process should be avoided as this precipitates adhesion formation.
• The body is closed in three layers (the transverse abdominus and internal oblique layers in one layer followed by the external abdominal oblique) using size 2 or 3 absorbable suture material.
• The skin is closed with nonabsorbable suture in a simple continuous or Ford interlocking pattern. The ventralmost aspect of the incision is closed with 2 or 3 simple interrupted sutures to allow drainage if a postoperative incisional abscess or seroma is formed.

Ventrolateral Celiotomy

• The patient is placed in lateral or oblique-lateral recumbency after casting or placing on tilt table.
• All legs and the head of the cow should be restrained with ropes to maintain recumbency throughout the procedure.
• The uppermost back leg should be secured up and away from the abdomen. Right lateral recumbency is preferred to minimize the risk of small intestinal prolapse during surgery.
• Hair is clipped from the ventral abdomen and the area is cleaned from gross contamination.
• The incision is parallel to and lateral to the milk vein beginning approximately a hand's width caudal to the level of the umbilicus and coursing caudally.
• In dairy cattle the course of the milk vein is traced with a permanent marker as the vein will collapse the longer the animal is in lateral recumbency, and incising this vein should be avoided at all costs.
• Local anesthesia is performed using a generous lidocaine line block. The surgical site is aseptically prepared and draped.
• A linear incision is made through the skin extending through the aponeuroses of the muscle layers. The incision may need to be oriented obliquely to avoid mammary tissue caudally.
• The uterus should then be easily identified in the caudal abdomen.
• The gravid uterine horn should be exteriorized from the incision as much as possible to avoid contamination of the abdomen with uterine fluid. The uterine incision, fetal extraction, and closure are performed as described under "Standing Paralumbar Laparotomy."
• The body wall is closed in at least 3 layers using size 3 synthetic absorbable suture material (Vicryl), due to the increased tension this incision experiences postoperatively.
• The skin can be closed in a simple continuous or Ford interlocking pattern.

MEDICATIONS

DRUGS OF CHOICE

• Anti-inflammatory: Meloxicam (1 mg/kg orally) or flunixin meglumine IV.
• Patients undergoing ventrolateral celiotomy should also be placed on broad-spectrum antibiotics for 5–7 days perioperatively.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Dam survival rate is >80% when fetus is alive, 79% when fetus is dead and 33% when fetus is emphysematous.
• Ventrolateral celiotomies carry a less favorable prognosis because of the condition of the uterus and/or increased risk of gross contamination of the abdomen during surgery.
• Uncomplicated C-sections carry a very good prognosis for future fertility. Females may be bred after 60 days.

POSSIBLE COMPLICATIONS

• The most common complication of paralumbar laparotomy is incisional swelling with possible resultant abscess formation.
• Peritonitis is a common complication of patients undergoing ventrolateral celiotomy.
• Retained placenta is common after C-section.

CLIENT EDUCATION

• Management techniques to prevent dystocia
• Male selection for calving ease

PATIENT CARE

• Dam care
  ◦ Animals should be monitored for signs of septicemia and peritonitis.
  ◦ Daily monitoring includes rectal temperature, appetite, defecation, urination, vaginal discharge, maternal behaviour, mammary development, and milk production.
• Neonatal care
  ◦ Resuscitation may be necessary after delivery
  ◦ Colostrum administration
  ◦ Normal care

CESAREAN SECTION: CAMELID

BASICS

OVERVIEW
A surgical procedure involving laparotomy and hysterotomy for the removal of a fetus when obstetric manipulation is unsuccessful or impossible.

INCIDENCE/PREVALENCE
Dystocia in camelids is rare (1–5% of parturitions) but life-threatening for the dam and fetus.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEM AFFECTED
- Reproductive
- Other systems depending on complications

PATHOPHYSIOLOGY
- Camelids present several unique obstetric characteristics compared to ruminants. The epitheliochorial microcotyledonary placentation and short and explosive second stage labor make dystocia a life-threating condition for both the dam and fetus.
- Fetal hypoxia occurs rapidly following placental detachment and may result in death or birth of a severely compromised neonate.
- Immediate C-section in indicated in term pregnancies when a live fetus demonstrates persistent tachycardia (>130 beats/min) or bradycardia (<50 beats/min).
- The narrow pelvis and strong expulsive effort make obstetric manipulation difficult. Lengthy manipulations result in cervical laceration, necrotic vaginitis, and vaginal adhesions.
- C-section is often considered in cases of uterine torsion, uterine inertia, failure of cervical dilation, severe fetal malposition, fetal malformations, twins, and rarely oversized fetuses.

HISTORICAL FINDINGS
- Protracted first stage of labor.
- Rupture of the chorioallantois without expulsion of the fetus, or presence of fetal extremities without progression.
- Excessive abdominal contractions, straining, and rolling.
- Unsuccessful attempted assisted vaginal delivery.

SIGNALMENT
- Term pregnant female. It important to remember that gestation length is extremely variable in camelids.
- Both multiparous and maiden females are equally represented.

PHYSICAL EXAMINATON FINDINGS
- Physical examination of the dam must be performed quickly and efficiently.
- Females may present with tachycardia, tachypnea, and sometimes diarrhea due to stress (camels).
- The degree of dehydration is variable but should be assessed.
- Bloody vaginal discharge may be present, particularly in cases of bilateral hip flexion.
- The mammary gland is well developed and colostrum is present.
- Diarrhea, rectal or vaginal prolapse are not uncommon in protracted cases.

GENETICS
N/A

CAUSES AND RISK FACTORS
- In one study cesarean section was performed due to dystocia (95.8% of cases) or concurrent maternal disease (4.2% of cases).
- The most common dystocia of maternal origin resulting in C-section is uterine torsion and the most common dystocia of fetal origin resulting in C-section is fetal malposition (most commonly bilateral hip flexion).
- Failure of cervical dilation may result from administration of exogenous progesterone.
- Metabolic disorders and obesity (hepatic lipidosis, hypocalcemia, etc.) predispose to uterine inertia.
- Obstetric manipulations are not possible in animals with small stature, small pelvic size, or abnormal pelvis.

DIAGNOSIS

- Fetal viability and uterine integrity should be assessed by transabdominal ultrasonography.
- A protocol of obstetric evaluation should be followed in order to determine the type of dystocia and whether C-section is indicated.
- Suspected uterine torsion must be diagnosed/confirmed by transrectal palpation.

DIFFERENTIAL DIAGNOSES
Abortion and other causes of colic if no evidence of parturition

CBC/BIOCHEMISTRY/URINALYSIS
The most common abnormalities in camelids undergoing C-section are leukophilia due to neutrophilia, elevated creatinine kinase, hypocalcemia, hyperglycemia, and elevated liver enzymes.

OTHER LABORATORY TESTS
N/A

IMAGING
Transabdominal ultrasonography for evaluation of fetal viability and uterine/placental integrity.

OTHER DIAGNOSIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
Variable depending on the cause and duration of the dystocia and systemic condition of the dam at presentation.

TREATMENT

THERAPEUTIC APPROACH
- Cesarean sections can be performed on the farm if the patient is stable and the surgery is uncomplicated.
- Complicated cases should be handled in a hospital with capability of additional supportive care (i.e., fluid therapy, general anesthesia).
- Pre-surgical care includes anti-inflammatory and antibiotic therapy.
- A neonatal resuscitation kit should be available.

SURGICAL CONSIDERATIONS AND TECHNIQUES
- In SAC, both ventral midline and left paralumbar fossa approaches may be used. The left paralumbar or low flank approaches are used in camels.

Ventral Midline Approach
- Indicated in cases of uterine torsion or when the uterus is compromised.
- General anesthesia is required: Induction with propofol (0.6–2 mg/kg IV slowly to effect) and maintenance on isoflurane in oxygen.
- The animal is placed in dorsal recumbency and the ventral abdomen prepared for surgery.
- A 30 cm skin incision is made on midline starting just cranial to the mammary gland.
- The linea alba is incised and the abdominal cavity is penetrated exposing the uterus.
- The left uterine horn is exteriorized and an incision is made over the greater curvature. The fetus is exteriorized.
- The placenta is removed if already detached, otherwise it should be peeled off 2 cm from the edge of the uterine incision to avoid trapping it in the uterine closure. A continuous "whipstitch" with absorbable suture material may be used to stop bleeding before closing the uterus with a 1 or 2 layer inverting pattern (i.e., Utrecht, Cushing, Lembert) using an absorbable suture.
- The abdominal wall and skin are closed.

Left Paralumbar Flank Approach
- The female is restrained in cush position under sedation or injectable anesthesia.
  ◦ SAC: butorphanol tartrate 0.05–0.1 mg/kg IM and/or diazepam 0.1–0.2 mg/kg IV, IM; or butorphanol 0.03 mg/kg, xylazine 0.3 mg/kg, ketamine 3 mg/kg, IM ◦ Camels: xylazine 0.25 mg/kg IV
- Local analgesia is provided by line or inverted L block, using 2% lidocaine.
- Caudal epidural placement is helpful.
- An oblique skin incision is made parallel to the thigh making sure not to extend too low into the aponeurosis. The abdominal muscles are incised as for the bovine. Care should be taken not to penetrate the abdominal cavity with the scalpel and nick the spleen.

CESAREAN SECTION: CAMELID (CONTINUED)

• The uterus is exteriorized by firmly grasping it around a fetal limb. The fetus is exteriorized as described for "Ventral Midline Incision."
• Abdominal closure is similar to C-section in other large animal domestic species.

MEDICATIONS

DRUGS OF CHOICE
• Sedation: Benzodiazepines (e.g., diazepam) and/or opioids (e.g., butorphanol). Avoid α_2-adrenergic agonists where possible due to their potential marked sedation/cardiovascular depression in the neonate.
• Anesthesia: Induction with propofol where possible due to more rapid metabolism and reduced depression in the neonate.
• NSAIDs prior to the surgery and postoperatively as needed.
• Broad-spectrum antibiotics for 3–5 days. The most common bacteria isolated from uterine culture include *Escherichia coli*, *Streptococcus equi zooepidemicus*, β-hemolytic streptococci, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, and *Arcanobacterium pyogenes*. Therefore, antimicrobial selection should include both Gram-positive and Gram-negative spectrum.
• Oxytocin q4h, IM (5–7.5 IU in alpacas; 10 IU in llamas, 20 IU in camels) to prevent/manage retained placenta.
• Pain management.
• Additional supportive care: IV fluid therapy, correction of electrolyte/trace mineral imbalances, and transfaunation, may need to be considered on a case-by-case basis.

CONTRAINDICATIONS
Appropriate milk and meat withdrawal times must be followed.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Dam survival is high (>90%).
• Neonate survival is highly dependent on duration of dystocia and time from rupture of the allantochorion.
• Uncomplicated C-sections carry a good prognosis for future fertility.

POSSIBLE COMPLICATIONS
• Retained placenta (most common)
• Peritonitis
• Incisional infection/surgical dehiscence
• Abdominal herniation
• Toxic metritis

CLIENT EDUCATION
Recognize signs of normal parturition and early identification of signs of dystocia.

PATIENT CARE
• Dam:
  ◦ Dam should be confined to a small paddock and monitored daily through physical examination, appetite, demeanor, assessment of vaginal discharge, mothering ability, and appropriate lactation.
  ◦ Suture removal and reproductive evaluation 14 days after surgery.
  ◦ Females can be rebred after 60 days of sexual rest if no complications.
• Neonate:
  ◦ Resuscitation kit available at time of cesarean section.
  ◦ Colostrum administration.
  ◦ Physical examination to evaluate for potential congenital abnormalities.
  ◦ Daily monitoring should include through physical examination, appetite, demeanor, appropriate weight gain, ability to ambulate, nursing appropriately.

CESAREAN SECTION: SMALL RUMINANT

BASICS

OVERVIEW
Cesarean section (C-section) is a surgical procedure to remove the fetus from the uterus following laparotomy and uterotomy.

INCIDENCE/PREVALENCE
• C-section is the most common abdominal surgery performed in small ruminants.
• About 7% of dystocia in goats are resolved by C-section.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEM AFFECTED
• Reproductive
• Multisystemic depending on complications

PATHOPHYSIOLOGY
• C-section is indicated when other obstetric manipulations to resolve a dystocia are not possible.
• The most common indications are:
  ◦ Failure of cervical dilation (ringwomb)
  ◦ Irreducible vaginal prolapse
  ◦ Fetopelvic disproportion
  ◦ Fetal maldisposition, emphysema, or other abnormalities
  ◦ Uterine torsion
  ◦ Vulvovestibular stricture
  ◦ Metabolic compromise (i.e., pregnancy toxemia, hypocalcemia) and uterine inertia

HISTORICAL FINDINGS
• If breeding date is not available, term pregnancy may be estimated form history (mating period), and presence of colostrum
• Signs of parturition without progression
• Excessive abdominal contraction/straining
• Unsuccessful obstetric manipulations

SIGNALMENT
Pregnant females at term

PHYSICAL EXAMINATON FINDINGS
• Depend on duration of the dystocia and manipulation attempts. Vocalization, elevated heart and respiratory rates are common. Abdominal contraction and tenesmus are common. Dehydration is present in protracted cases.
• Mammary gland development and presence of colostrum.
• Dilated and edematous vulva if parturition has progressed to the second stage.
• Presence of discharge or fetal parts at the vulva.
• Vaginal speculum and manual vaginal palpation is performed to determine cervical dilation status and fetal disposition.

GENETICS
• Small breeds (Pigmy goats) and prolific breeds (Romanov and Finnsheep) are more predisposed
• Meat breeds (selective breeding of heavily muscled animals)

CAUSES AND RISK FACTORS
• C-section is the best approach for resolving dystocia if obstetric manipulation is not possible, particularly if the fetus(es) are alive.
• Ventral wall defect (hernia, prepubic tendon rupture).

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Abortion should be ruled out from history and physical examination.

CBC/BIOCHEMISTRY/URINALYSIS
• Performed in severely compromised/valuable females. Electrolyte imbalances, hypocalcemia, hypophosphatemia, and elevated liver enzymes are common with pregnancy toxaemia.
• At a minimum, a PCV and TP should be obtained prior to surgery in animals that appear dehydrated.

OTHER LABORATORY TESTS
N/A

IMAGING
Percutaneous transabdominal ultrasonography should be performed in order to evaluate fetal viability and uterine integrity if the cervix is closed.

DIAGNOSIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
Vary depending on the cause of dystocia. Large offspring syndrome is encountered in pregnancies from somatic cell nuclear transfer cloned embryos.

TREATMENT

THERAPEUTIC APPROACH
• C-section may be performed on the farm without need of hospitalization if the patient is stable and the surgery is uncomplicated.
• Complicated cases should be handled in a hospital setting with capability of support (fluid therapy, pain management).

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Small ruminant cesarean section may be done in a hospital setting or on the farm. Clear communication with the clients should include outcome for the dam and fetuses on a case by case basis.
• If surgery is performed on the farm, adequate clean area and help are needed.
• A neonatal resuscitation kit should be available.
• Instrumentation:
  ◦ Iodine-based surgical scrub
  ◦ 4 sterile towels
  ◦ Complete small surgical tray for abdominal surgery
  ◦ 4 obstetric straps
  ◦ Suture material
  ◦ Bucket with antiseptic for the obstetric straps.
• General anesthesia, local anesthesia with light sedation or a combination of general and local anesthesia can be used in sheep and goats.
• Usually a light sedation with xylazine (0.07 mg/kg BW, IM) in addition to a local block with 1% lidocaine (line, inverted "L" or paravertebral blocks) and physical restraint is enough to keep the animal recumbent during the surgery. Anesthesia can be also achieved successfully by lumbosacral or sacrococcygeal epidural in association with a local block.
• Two approaches can be considered: ventral midline or left paralumbar flank technique.

Left Paralumbar Flank Approach
• The left flank is clipped and scrubbed and an inverted L-block is performed with 1% lidocaine.
• The area is draped. A 15–20 cm incision is made through the skin. The external and internal abdominal oblique and transversus abdominis are dissected and gridded or incised with Metzenbaum scissors. The peritoneum is identified and incised using Metzenbaum scissors.
• The abdominal cavity is explored and the uterus identified. The uterine horn is grasped around the fetus and brought to the incision. A stab incision is made between the fetal claws and the uterus is opened with Metzenbaum scissors along the greater curvature. The fetus is removed. Fetus in the other horn is removed through the same incision.
• The placenta is only removed if it is not firmly attached to the uterus.
• The uterine incision is closed with absorbable suture in an inverting pattern (e.g., Utrecht, Cushing, and Lambert).
• The peritoneum and transversus abdominis are closed in a simple continuous pattern with absorbable suture.
• The internal abdominal oblique and the external abdominal oblique are each closed with a simple continous pattern with absorbable suture.
• The skin is closed with a nonabsorbable suture using a Ford interlocking pattern.

Ventral Midline Approach
• This approach offers a better exposure of the uterus but requires general anesthesia or deeper analgesia with better restraint. It should be considered in cases of uterine torsion, uterine rupture or fetal emphysema.
• The patient is placed in dorsal recumbency and prepared for surgery. A skin incision is made just cranial to the mammary gland and extending 20–30 cm towards the umbilical scar.
• The linea alba is incised and the uterus is exposed. Other steps are similar to the flank

CESAREAN SECTION: SMALL RUMINANT (CONTINUED)

approach. The linea alba is closed with absorbable suture and the skin is closed according to surgeon's preference.

MEDICATIONS

DRUGS OF CHOICE
• Xylazine (0.05–0.2 mg/kg, IM) and butorphanol (0.2–0.5 mg/kg, IM) provide an excellent option for a deeper sedation.
• General anesthesia may be obtained with xylazine (0.1 mg/kg BW, IM) followed by ketamine (4–8 mg/kg BW, IM).
• Lidocaine 1% is used for local desensitization of the incision site.
• NSAID may be administered as necessary.
• Multiple broad-spectrum antibiotics to prevent peritonitis and other septic conditions (penicillin 22,000 IU/kg SQ or IM q12h for 7 days).
• Energy and mineral supplementation (calcium, magnesium, phosphorus) may be indicated in some cases.
• Oxytocin administration (5–10 IU) a few hours post-surgery is suggested to promote uterine involution and placental delivery.

CONTRAINDICATIONS
• Small ruminants are very sensitive to xylazine, with unpredictable effects, but antipamezole is effective in reversing the effects of xylazine.
• Goats are more sensitive to lidocaine and xylazine than are sheep.
• Appropriate milk and meat withdrawal times must be followed.

PRECAUTIONS
Lidocaine dose should be closely monitored to avoid toxicity (sheep: 10 mg/kg; goats: 5 mg/kg).

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Dam survival rate is higher than 90% when foetuses are fresh but drops to 50% when fetus(es) are autolyzed
• Uncomplicated c-sections carry a very good prognosis for future fertility. Females may be bred after 60 days
• Females with failure of cervical dilation, or severely compromised uterus should be culled after they wean their offsprings

POSSIBLE COMPLICATIONS
• Peritonitis
• Incision site infection and dehiscence
• Retained placenta
• Toxic metritis

CLIENT EDUCATION
• Management techniques to prevent dystocia
  ◦ Breeding age and weight
  ◦ Pregnancy diagnosis and fetal numbering
  ◦ Feeding strategy
  ◦ Male selection
• Early identification of signs of dystocia and need for veterinary assistance

PATIENT CARE
• Dam care
  ◦ On the farm, the patient should be confined for a few days to a warm, clean area and monitored.
  ◦ Animals should be monitored for signs of septicemia and peritonitis.
  ◦ Daily monitoring includes rectal temperature, appetite, defecation, urination, vaginal discharge, maternal behaviour, mammary development and milk production.
  ◦ Transfaunation is indicated in animals that are anorexic.
• Neonatal care
  ◦ Resuscitation may be necessary after delivery
  ◦ Colostrum administration
  ◦ Normal care

PREVENTION
• Culling strategies and genetic selection
• Proper BCS and appropriate diet during pregnancy based on fetal numbers

MISCELLANEOUS

CHLAMYDIOSIS

BASICS

OVERVIEW

Chlamydophila abortus is an important cause of abortion in small ruminants around the world. *Chlamydophila pecorum* is a sporadic cause of polyarthritis and conjunctivitis in ruminants. These agents may rarely be associated with pneumonia, enteritis, or encephalomyelitis in individual animals.

INCIDENCE/PREVALENCE

Chlamydophila abortus is a leading cause of third-trimester abortion in small ruminants.
• High rates of abortion (abortion storms) are common when the pathogen is introduced to naïve flocks or herds.
• *C. abortus* causes sporadic third-term abortion in cattle, or abortion outbreaks after 90 days' gestation in sheep and goats.
• In flocks or herds where disease is endemic, a lower rate of abortion occurs, primarily affecting young animals and new introductions.

GEOGRAPHIC DISTRIBUTION

Disease has been reported in most parts of the world

SYSTEMS AFFECTED

• Reproductive
• Ophthalmic
• Musculoskeletal

PATHOPHYSIOLOGY

Death of the fetus occurs primarily due to placentitis, although in utero infection of the fetus can also occur, contributing to fetal death or the birth of infected and clinically ill neonates.

SIGNALMENT AND CLINICAL SIGNS

• All naïve animals are susceptible, but reliable immunity that develops after abortion generally prevents future abortions.
• In a newly infected sheep flock, between 30% and 60% of the pregnant animals may abort. Storms of 60–90% abortions in goats have been reported.
• In an endemic herd or flock, the animals in their first gestation or naïve new introductions are at highest risk to abort.
• Polyarthritis, pneumonia, enteritis, or encephalomyelitis are generally limited to young stock. Conjunctivitis can occur in animals of all ages.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Causes of third-term or late gestation abortion associated with placentitis include toxoplasmosis, Q fever, *Campylobacter jejuni* or *C. fetus fetus*, brucellosis, listeriosis, salmonellosis, aspergillosis, and leptospirosis.

OTHER DIAGNOSTIC PROCEDURES

• Paired serology can indicate a rising titer after recent infection; serologic tests used include complement fixation (CF) and ELISA.
• Ruminants can exhibit titers without clinical disease.
• In most laboratories, CF titers of 1:16 to 1:32 are considered positive. Most animals that have aborted from chlamydiosis will have a titer of 1:80 or higher that peaks 2–3 weeks after abortion.
• Serology is generally not useful for individual animal diagnosis, or identification of latently infected animals.
• Serologic cross reaction between *C. abortus* and *C. pecorum* may complicate diagnosis.
• The agent is difficult to isolate so culture is not routinely used for diagnosis.
• Cytology using impression smears of affected placentas may reveal elementary bodies; these are most easily seen by staining with modified Ziehl-Neelsen or Gimenez stains.

PATHOLOGIC FINDINGS

• Placenta: dark red or gray-brown cotyledons, leathery or opaque intercotyledonary areas.
• Fetus: usually fresh but may be autolyzed. Often excess fluid is seen in the abdominal cavity, as are small necrotic foci in the liver.
• Histopathologic evaluation of placentas with special staining to identify organisms may also be diagnostic.

TREATMENT

THERAPEUTIC APPROACH

After the initial outbreak, good management techniques combined with judicious use of antibiotics should reduce the rate of abortion to negligible levels.

MEDICATIONS

DRUGS OF CHOICE

• Abortions—various protocols suggested
  ◦ Long-acting oxytetracycline (OTC) (20 mg/kg) at 10–14-day intervals from midgestation until parturition.
  ◦ 400–500 mg OTC/head/day orally.
• General chlamydiosis
  ◦ Single dose of long-acting OTC (20 mg/kg).
  ◦ Three treatments at 3-day intervals has also been suggested.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• After the initial outbreak, good management techniques combined with judicial use of antibiotics and/or vaccines should reduce the rate of abortion to negligible levels.
• Animals that have aborted are generally immune from further abortions.

POSSIBLE COMPLICATIONS

• Following abortion some ewes or does may have retained placenta.
• Perinatally infected neonates may be weak with pneumonia or infection in other organ systems.

PREVENTION

• Vaccines given prior to breeding will significantly reduce abortion but do not eliminate the carrier state or excretion.
• In various parts of the world, different vaccines are available which may be used to limit disease.
• In the midst of an abortion storm, treatment with tetracycline in feed or by injection may help to decrease fetal loss.
• All aborting animals should be segregated from the flock to prevent transmission to other stock. In some herds, individuals which have experienced abortion have been culled.
• Aborted fetuses, placental membranes, bedding, and other contaminated materials should be removed and destroyed.
• As animals that aborted may continue to excrete the organism for several weeks, breeding rams that have been with them should not have access to other clean stock.
• Abortion can be prevented by feeding tetracycline or periodic treatment with long-acting tetracycline by injection in the last 4–6 weeks of gestation.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Rarely, other diseases including conjunctivitis, polyarthritis, pneumonia, enteritis, or encephalomyelitis can be associated with infection by *Chlamydophila abortus* or *Chlamydophila pecorum.*

ZOONOTIC POTENTIAL

• *C. abortus* may cause abortion in pregnant women who should, therefore, not work in a flock with this disease.
• The avirulent live vaccine used in some parts of the world may be zoonotic.

PREGNANCY

High rates of abortion (abortion storms) are common when the pathogen is introduced to naïve flocks or herds.

BIOSECURITY

• All aborting animals should be segregated from the flock to prevent transmission to other stock. In some herds, individuals which have experienced abortion have been culled.
• Aborted fetuses, placental membranes, bedding, and other contaminated materials should be removed and destroyed.

CHLAMYDIOSIS (CONTINUED)

• As animals that aborted may continue to excrete the organism for several weeks, breeding rams that have been with them should not have access to other clean stock.

PRODUCTION MANAGEMENT

Vaccines given prior to breeding will significantly reduce abortion but do not eliminate the carrier state or excretion.

SYNONYMS

• Enzootic abortion of ewes (EAE)
• Ovine enzootic abortion

ABBREVIATION

OTC = oxytetracycline

CLOSTRIDIAL DISEASE: GASTROINTESTINAL

BASICS

OVERVIEW
Clostridium perfringens is an important cause of enteric diseases in ruminants. Its virulence is based largely upon toxinogenesis.

INCIDENCE/PREVALENCE
Clostridial enterotoxemia is sporadic, but outbreaks have been reported.

GEOGRAPHIC DISTRIBUTION
• Types A, C, and D are considered a problem in North America.
• Type B is frequently reported in Europe, Africa, and Asia.
• Type E has rarely reported in North America.

SYSTEMS AFFECTED
• Digestive
• Cardiovascular
• Nervous

PATHOPHYSIOLOGY
• Clostridia form part of the gastrointestinal tract of many normal ruminants and can also be found in many soils.
• Factors favoring intestinal clostridial bacteria overgrowth, such as high-carbohydrate diets, result in rapid toxin production with subsequent clinical signs and death.
• Clinical signs depend on the predominate type of toxin produced although there is considerable crossover.
• Clinical isolates are assigned to one of the types (A, B, C, D, E) on the basis of production of the major toxins (*alpha, beta, epsilon and iota*).
• Strains of *C. perfringens* can also produce other recognized soluble antigens of pathogenic importance such as enterotoxin (CPE) and beta-2-toxin.
• *Alpha-toxin (type A)* is a phospholipase that causes lysis of the red blood cells, platelets and leukocytes, vascular permeability through endothelial damage. In the intestines, the toxin causes necrosis and hypersecretion of fluid into the lumen.
• *Beta-toxin (types B and C)*, a trypsin-sensitive toxin, is a potent cytotoxin causing necrosis and hemorrhage of affected tissues, especially the intestine.
• *Epsilon-toxin (types B and D)* alters intestinal mucosal permeability that facilitates absorption into the bloodstream. The toxin subsequently causes widespread vascular damage and increased vascular permeability. Vascular damage in the brain results in characteristic perivascular edema and focal symmetrical encephalomalacia.

SIGNALMENT
• All ruminant species
• Young animals more susceptible

PHYSICAL EXAMINATION FINDINGS
• *C. perfringens* type A is associated with hemorrhagic bowel disease (HBS; jejunal hemorrhagic syndrome) in high-producing dairy cattle. Clinical signs—decreased milk production, scant feces, and colic. Feces can contain partially digested or clotted blood. Rectal examination—distended loops of small intestine.
• In sheep, type A is associated acute enterotoxemia in lambs (yellow lamb disease). Clinical signs—depression, anemia, icterus and hemoglobinuria. Animals usually die within 6–12 h of the onset. In calves, limited reports have associated type A with abomasitis.
• In camelids, type A can cause neonatal enterotoxemia. Clinical signs—severe depression, colic, and sudden death. Diarrhea can be seen if the cria survive >12 h.
• In small ruminants, type B has been associated with lamb dysentery and hemorrhagic enteritis in young animals, whereas type C has been associated with struck in adult sheep. Types B and C produce similar clinical signs including sudden death or acute neurologic signs with or without hemorrhagic diarrhea. In calves, type C has been associated with acute fatal hemorrhagic enteritis in young calves.
• Type D is associated with enterotoxemia (overeating disease) affecting young ruminants. Clinical signs—profuse and bloody diarrhea, ataxia, trembling, stiff limbs, opisthotonus, convulsion, coma and death.
• Regardless of the type, many cases are simply found dead. If affected animals are found alive, most cases present with colic and/or neurologic signs such as convulsions and opisthotonus before death.

CAUSES AND RISK FACTORS
• *Clostridium perfringens* types A, B, C, and D.
• Sudden change of diet—usually from milk/forage to grain, high-grain diet, or offspring of dams that produce abundant milk.
• Ingestion of protein-rich diet in a protease-deficient intestinal tract allows rapid growth of *C. perfringens* organisms.
• Inconsistent feeding practices—feed changes, temperature, mixing, frequency, volume.
• The healthy, rapidly growing young ruminant is most at risk.
• Copper deficiency.
• Heavy tapeworm infestation in sheep.
• Cold weather.
• Stress.
• Concomitant infestation with coccidia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Causes of acute death—anthrax, various poisonings
• Abomasal diseases
• Salmonellosis
• Leptospirosis
• Polioencephalomalacia

CBC/BIOCHEMISTRY/URINALYSIS
• Leukopenia and neutropenia—enterotoxemia.
• Hemoconcentration, metabolic acidosis, hyperglycemia, and glucosuria—lambs with type D enterotoxemia.
• Hyperglycemia, hyponatremia, hypochloremia, and hypokalemia—cattle with HBS.

OTHER LABORATORY TESTS
• Culture and impression smears
• Toxin identification essential for diagnosis

IMAGING
Cattle suffering from HBS—transabdominal ultrasound can reveal distension of small intestine and homogeneous echogenic intraluminal material compatible with intraluminal hemorrhage and clot formation.

OTHER DIAGNOSTIC PROCEDURES
• History, physical examination, gross postmortem examination.
• *C. perfringens* proliferates after death and can invade tissues beyond the gut. Thus, isolation of the bacteria in a postmortem sample is not sufficient basis for a diagnosis.
• Detection of the toxin in intestinal content and histopathologic lesion compatible with the disease are essential for the diagnosis.
• ELISA and counter-immunoelectrophoresis tests for toxins are comparable to the traditional mouse lethality tests.
• Intestinal fluid for toxin evaluation should be frozen until testing.

PATHOLOGIC FINDINGS
• Type A—watery blood, icterus, hemoglobinuria, excessive fluid in abdominal and thoracic cavities, and evidence of hemorrhages on thoracic and abdominal viscera.
• Type B—inflammation, ulceration, and necrosis of the intestinal tract, liver, and adjacent lymphatic.
• Type C—acute hemorrhagic enteritis, bloody diarrhea can be present at death. Swollen and hemorrhagic mesenteric lymph nodes.
• Type D—paintbrush hemorrhages of the subendocardium of the left ventricle are most typical and hydropericardium.

CLOSTRIDIAL DISEASE: GASTROINTESTINAL (CONTINUED)

TREATMENT

THERAPEUTIC APPROACH

- Response to treatment is usually poor.
- Animals with right-sided bloat will benefit from relieving the distention in the abomasum.
- Anecdotal evidence suggests that oral antibiotics such as penicillin or tetracycline can be beneficial.
- Type C and D antitoxin can be beneficial (see below).
- Activated charcoal and mineral oil—anecdotal evidence.
- Fluid therapy. (See chapters, Diarrheal Diseases: Bovine, Diarrheal Diseases: Camelid, Diarrheal Diseases: Small Ruminant for details.)
- If at all possible, eliminate oral nutrition during the first hours of treatment.

MEDICATIONS

DRUGS OF CHOICE

- Procaine penicillin G at doses of 20,000–30,000 IU/kg, IM or SC q12h.
- Type C and D antitoxin can be beneficial at doses ranging from 3 mL in lambs to 30 mL in adult cattle. IV or SC administration. Dosages can be repeated q3–4h.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed.

PRECAUTIONS

Type C and D antitoxin—anaphylactoid reactions can occur.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- The prognosis is fair at best for ambulatory patients. If the patient is recumbent, the prognosis is guarded to grave.
- The prognosis for affected cows with JHS is grave, even with aggressive medical and surgical therapy.
- Mortality approaches 100% regardless of type.

PREVENTION

- Passive transfer of immunity protects against *C. perfringens* types C and D.
- Vaccination strategies should take into consideration the necessity for a booster vaccination approximately 4 weeks after the first vaccination.
- Vaccination of the dams in late gestation using the type C and D toxoid.
- The type C and D toxoid could protect against type B due to overlap of toxins.
- Neonates can be vaccinated as early as 10 days of age and 2 weeks later.
- Outbreaks—antitoxin can be administered to neonates at birth if necessary.
- Preventive measures for type A diseases include proper animal husbandry, sanitation, and feeding (avoid excessive milk intake).
- *C. perfringens* type A autogenous bacterins are being used in many herds with HBS but it is unlikely that a bacterin without toxoid will prevent the disease.
- Vaccines for type B appear to be useful in countries in which the disease occurs.

MISCELLANEOUS

AGE-RELATED FACTORS

Young ruminants, although adults can be affected.

BIOSECURITY

- Environmental hygiene. Cleaning and disinfection of environmental sites.
- Hand and outerwear hygiene. Wash hands and disinfect boots, maintain coveralls free of fecal material.
- Segregating sick animals will reduce the pathogen exposure.
- Clostridial diseases are not spread from animal to animal.
- Carcasses should be disposed of properly by burial or incineration.

PRODUCTION MANAGEMENT

- Consistent feeding practices—adaptation before change.
- Appropriate fiber length, storage, and fermentation of total mixed ration.
- Prevent the occurrence of rumen acidosis.

SYNONYMS

- *C. perfringens* type A in cows; hemorrhagic bowel disease (HBS; jejunal hemorrhagic syndrome JHS)
- *C. perfringens* type A associated acute enterotoxemia in lambs; yellow lamb disease
- *C. perfringens* type B in young animals; lamb dysentery and hemorrhagic enteritis
- *C. perfringens* type C in adult sheep; struck
- *C. perfringens* types C in young calves; acute fatal hemorrhagic enteritis
- *C. perfringens* type D in young ruminants; enterotoxemia, overeating disease

ABBREVIATIONS

- ELISA = enzyme-linked immunosorbent assay
- HBS = hemorrhagic bowel syndrome
- IM = intramuscular
- IV = intravenous
- JHS = jejunal hemorrhagic syndrome
- SC = subcutaneous

CLOSTRIDIAL DISEASE: MUSCULAR

BASICS

OVERVIEW
Clostridial myositis is a term used to describe two diseases (blackleg and gas gangrene) characterized by a rapid course of myonecrosis and sometimes cellulitis, and high mortality.

INCIDENCE/PREVALENCE
• The incidence is usually low (generally <10%), but lethality (death of affected animals) is always close to 100%. Infrequently, outbreaks of gas gangrene associated with the use of contaminated medical instruments can present with a very high incidence.
• Some herds may go for many years without clostridial myositis cases.
• Most cases of blackleg are seen in the late summer to early winter.
• Cases of gas gangrene may occur any time during the year.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Musculoskeletal
• Integument

PATHOPHYSIOLOGY
• Endogenous pathogenesis (blackleg): Spores are ingested, absorbed into the bloodstream and phagocytized by macrophages of skeletal and/or cardiac muscles. The spores can survive for several months in the cytoplasm of the macrophages, but when an area of muscle becomes anaerobic, usually associated with blunt trauma, the spores germinate and the bacteria proliferate and produce exotoxins that produce local necrosis and toxemia.
• Exogenous pathogenesis (gas gangrene; formerly known as malignant edema): Spores enter the organism via skin or mucosal wounds and proliferate in the anaerobic environment produced by those same injuries. Bacterial proliferation and toxin production ensues as described for blackleg.

SIGNALMENT
• Blackleg is typically a disease of young cattle (6 months to 2 years of age), although cases can sporadically occur in animals outside this age range. Rare cases have been reported in sheep.
• Gas gangrene can occur in several animal species (cattle, sheep, goats, pigs, horses, dogs) of any age.

PHYSICAL EXAMINATION FINDINGS
• Blackleg: Most cases are characterized by sudden death. When clinical signs are observed, they include depression, lethargy, anorexia, and reluctance to move, which is quickly followed by death. When superficial muscles are affected, swelling and crepitation of the affected area is evident associated with lameness, most commonly in rear legs. Signs of congestive heart failure may be seen when the heart is affected.
• Gas gangrene: Most cases are acute; subacute and chronic cases can occasionally occur. Clinical signs are similar to those of blackleg, except that skin or mucosal wounds are usually present.

CAUSES AND RISK FACTORS
• Blackleg: *Clostridium chauvoei*
• Gas gangrene: *Clostridium septicum*, *Clostridium chauvoei*, *Clostridium sordellii*, *Clostridium perfringens* type A, *Clostridium novyi* type A, acting alone or in combination of two or more of these microorganisms.
• The organisms survive as spores in the environment. The spores can gain access to the organism by ingestion as in the case of blackleg (endogenous pathogenesis) or via skin or mucosal wounds in cases of gas gangrene (exogenous pathogenesis).
• Animals on high planes of nutrition and in excellent body condition are most likely to develop blackleg.
• No relationship with nutritional level has been found for cases of gas gangrene.
• Unvaccinated herds are most at risk for both diseases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Conditions that result in sudden death in ruminants should be considered as differentials. These include, but are not limited to, gunshot, anthrax, snake bite, toxic plants (oleander, Japanese yew, others), various toxicants (lead, arsenic), nitrate and cyanide poisoning.

CBC/BIOCHEMISTRY/URINALYSIS
Of little benefit

OTHER DIAGNOSTIC PROCEDURES
• Presumptive field diagnosis may be based on characteristic signs and gross lesions. Impression smears of affected tissues or fluids showing large Gram-positive, sporulated rods is helpful, particularly in fresh carcasses.
• Confirmation of the diagnosis must be based on demonstration in affected tissues of the clostridial species involved. This can be achieved by anaerobic culture, PCR, fluorescent antibody testing or immunohistochemistry.

PATHOLOGIC FINDINGS
• Necropsy reveals areas of dark muscle necrosis and subcutaneous edema. In blackleg, the muscular lesions are more significant than those in the subcutaneous tissue and they frequently affect both skeletal and cardiac muscle.
• Gas gangrene is characterized by subcutaneous lesions with less prominent and inconsistent skeletal muscle lesions. In blackleg the affected muscle may have an odor of rancid butter.

TREATMENT

THERAPEUTIC APPROACH
• Because most cases of blackleg and gas gangrene in ruminants are acute, there is frequently not enough time to start treatment.
• Course permitting, procaine penicillin G (PPG) is very effective against the clostridial species involved in these diseases.
• Anti-inflammatory drugs, fluid therapy, and incisions of the skin over the affected muscles to drain exudates and gas, and washing these wounds with hydrogen peroxide and iodine solution is also recommended in valuable animals.

SURGICAL CONSIDERATIONS AND TECHNIQUES
Serial fasciotomy of affected areas to allow aeration and drainage.

MEDICATIONS

DRUGS OF CHOICE
• Procaine penicillin G (PPG) at high doses (24,000 IU/kg), IM.
• Many other antimicrobials may be effective but penicillin is the drug of choice.
• Anti-inflammatory drugs may be administered for pain, shock, and inflammation.

CONTRAINDICATIONS
• Because of the poor prognosis, humane euthanasia should be considered. Slaughter is usually not an option.
• Drug withdrawal time must be determined and maintained for the treated animal.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Prognosis is guarded to grave at best. Even if the animal survives, it may be permanently disabled.

CLIENT EDUCATION
The most important client education is to convey the need to vaccinate the whole herd preventively.

PREVENTION
• Vaccinate all young stock (<2 years of age) at least twice a year against blackleg and for the life of the animal against gas gangrene. The first vaccination in the life of an animal should be followed by a booster 4–6 weeks later. Protective immunity usually occurs by 2 weeks post-vaccination.

CLOSTRIDIAL DISEASE: MUSCULAR (CONTINUED)

• Vaccinate cows in late gestation to boost colostral immunity for neonates that will not be vaccinated until the next cattle working period.
• When faced with an outbreak, vaccinate all susceptible stock and administer PPG at the same time in an attempt to prevent further cases while waiting for protective titers to develop.
• Vaccines are economical and efficacious.
• Carcasses should be burnt or buried deeply and covered with lime as they represent concentrated areas of clostridial spores.

MISCELLANEOUS

AGE-RELATED FACTORS

Blackleg appears to be most common among young ruminants between 6 months and 2 years of age. Gas gangrene can occur at any time in the life of an animal.

ZOONOTIC POTENTIAL

Several of the clostridial species involved in gas gangrene may infect humans, particularly if they are immunocompromised.

PRODUCTION MANAGEMENT

Vaccination should help prevent clinical disease.

SYNONYMS

• Black leg: black quarter, clostridial myositis
• Gas gangrene: malignant edema (this term should be abandoned)

ABBREVIATIONS

• IM = intramuscularly
• PCR = polymerase chain reaction
• PPG = procaine penicillin G

SEE ALSO

• Anthrax

CLOSTRIDIAL DISEASE: NERVOUS SYSTEM

BASICS

OVERVIEW

The most significant clostridial nervous diseases are tetanus, botulism, and *Clostridium perfringens* type D enterotoxemia. Occasionally other clostridial diseases may manifest nervous clinical signs. Because each of these diseases are dealt with in different chapters (Clostridial Disease: Gastrointestinal, Clostridial Disease: Muscular) we present here only the most significant features of the clostridial diseases that manifest themselves as neurologic disease.

INCIDENCE/PREVALENCE

The incidence of *C. perfringens* type D enterotoxemia is usually low (generally <5%). Tetanus can present as individual cases, but large outbreaks following procedures with contaminated medical instruments have been reported. Botulism is frequently seen as large outbreaks in mammals, birds, and fish. In some areas of the world (Australia, South Africa, and South America) botulism intoxication is a fairly common occurrence and is considered an endemic problem.

GEOGRAPHIC DISTRIBUTION

- Worldwide for tetanus and *C. perfringens*.
- Various botulinum toxins (BoTx) tend to have a unique geographic distribution.
  - Type B BoTx-producing organisms prefer moist neutral pH soils and commonly found in Europe and the Eastern United States.
  - Type C BoTx-producing organisms prefer slightly acidic soils and commonly found in the Western United States.
  - Type D BoTx-producing organisms prefer alkaline soils and commonly found in South Africa, South America, and Australia.

SYSTEMS AFFECTED

- Nervous

PATHOPHYSIOLOGY

- Tetanus occurs after wound contamination with *C. tetani* spores acquired from the environment. Deep wounds with a little exposure to air and the presence of necrotic tissue favor spore germination. This microorganism produces tetanus toxin (TeTx) and tetanolysin. TeTx is formed in wounds colonized by *C. tetani*. TeTx diffuses in the extracellular fluid and can target all types of nervous endings (sensory, adrenergic neurons and motor neurons), but it is mainly transported retrogradely through the motor neurons.
- Botulism can be caused by one of eight different neuroparalytic toxin subtypes (A to H). These botulinum neurotoxins (BoTxs) are produced by anaerobic Gram-positive clostridia, mainly *Clostridium botulinum*. Two main routes of exposure to BoTxs have been identified: (1) ingestion of preformed toxins in food, water, or carrion, and (2) in vivo production of BoTxs, so-called toxicoinfection, and is encountered during wound botulism. After diffusion into the extracellular fluid and bloodstream, BoTXs target motor neuron endings. The toxin attaches to the nerve and incorporates into the nerve's cytoplasm where it acts as a metalloprotease that inactivates proteins needed to release the neurotransmitter acetylcholine. Each BoTx affects different areas of the docking proteins needed for the release of acetylcholine. Prevention of neurotransmitter (acetylcholine) release at the neuromuscular junction results in muscle weakness and paralysis.
- *Clostridium perfringens* type D enterotoxemia: This microorganism produces epsilon prototoxin which is proteolytically activated in the intestine. After facilitating its own absorption into the bloodstream, epsilon toxin reaches several internal organs including the brain, where there is vascular damage and also direct action on brain cells, including neurons, astrocytes, and oligodendrocytes.

SIGNALMENT

- Tetanus occurs in multiple species of mammal of any age.
- Botulism occurs in cattle, goats, sheep and in several other mammalian, avian and fish species. Most cases involve adult or young growing animals. Cattle are very sensitive to the toxins (13 times more than mice to BoTx C).
- *C. perfringens* type D enterotoxemia affects mostly sheep and goats and, occasionally, cattle. Most cases occur in animals >2 weeks of age.

PHYSICAL EXAMINATION FINDINGS

Tetanus

- Stiffness and reluctance to move are often the initial signs.
- Twitching and tremors of the muscles.
- Lockjaw.
- Prominent protruding third eyelid.
- Unsteady gait with stiff, held-out tail.
- Affected cattle are usually anxious and easily excited by sudden movements or handling.
- Bloat is common because the rumen stops working.
- Later signs include collapse, lying on side with legs held stiffly out, spastic paralysis and death.

Botulism

- Clinical signs develop usually 48–72 hours after ingestion, but may appear as early as 24 hours and as late as 10–14 days, dependent on the amount of BoTx ingested.
- Animals often first present with a hunched-up appearance and strain to defecate. Owners may say that animals are colicky.
- Affected animals may be weak, stagger about, or go down. Progressive muscle weakness (paresis) is the hallmark of the disease.
- Over the next 24–48 hours, the animals become weaker with staggering and muscle fasciculation of large muscle groups; they lean against fences or walls for support. When lying down, animals remain in sternal recumbency. Eventually, the animal becomes prostrate.
- Cattle characteristically display flaccid paralysis and occasionally protrusion of the tongue. Tongue is easily removed from the mouth. Once the tongue is released, the animals have difficulty in replacing the tongue back into the mouth. Jaw muscle tone is also reduced.
- Animals will usually lose tail tone as the disease progresses, with the tail easily handled and elevated.
- Signs in sheep and goats are similar to cattle but protrusion of the tongue may not be as obvious. They may bob their head when walking due to muscle weakness.
- Serous nasal discharge and excessive salivation common are due to loss of tongue tone and coordination. In most cases the disease is fatal although some animals may recover.
- When a large amount of toxin has been ingested, the animal may be found dead without having been seen any signs of disease

C. perfringens Type D Enterotoxemia

- Enterotoxemia progresses very rapidly, with death occurring within minutes or a few hours after onset of clinical signs.
- Sudden death may also occur.
- Some lambs will show symptoms of muscle tremors, circling, opisthotonus or convulsions.
- Other nervous system signs are frothing of the mouth, grinding of the teeth, blindness, and oscillations of the eyes. Diarrhea may also be present, although infrequently.
- In goats, the course of disease ranges from peracute to chronic, with signs that vary from watery diarrhea with or without blood to sudden death. The chronic form in goats can result in diarrhea and nervous signs over several weeks, ending in death.
- Affected calves not found dead show convulsions, blindness, and death within a few hours. Subacutely affected calves are stuporous for a few days and may recover.

CAUSES AND RISK FACTORS

- Tetanus: *Clostridium tetani* is the etiologic agent. Risk factors include deep wounds and failure to use tetanus vaccines.
- Botulism: *Clostridium botulinum* is the etiologic agent. There are eight antigenically distinct BoTx (A, B, C_1, D, E, F, G, and H). Each toxin is found in different environments and affects different species of animals. Rare cases of botulism in humans have been associated with some strains of *Clostridium baratii* and *Clostridium butyricum*. Risk factors include exposure to decomposed

CLOSTRIDIAL DISEASE: NERVOUS SYSTEM (CONTINUED)

carcasses, contaminated feed, feeding poultry litter, phosphorus-deficient diets with associated bone chewing (pica), and lack of botulism vaccination in high risk areas.
• *C. perfringens* type D enterotoxemia: *Clostridium perfringens* type D is the etiologic agent. Risk factors include sudden access to large amounts of highly fermentable carbohydrates and failure to vaccinate animals for *Clostridium perfringens* type D.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Conditions that result in sudden death in ruminants should be considered as differentials. These include but are not limited to gunshot, anthrax, snakebite, toxic plants (oleander, Japanese yew, others), various toxicants (gossypol, lead, arsenic, strychnine, nitrate, monensinn, and cyanide) poisoning.
• Neurologic differentials include listeriosis, rabies, bacterial and viral encephalitides, plant toxicities that cause tremor or ataxia, pesticides including organophosphates, carbamates, and ionophores.

CBC/BIOCHEMISTRY/URINALYSIS
Glycosuria may be observed in a few cases of C. perfringens type D enterotoxemia

OTHER DIAGNOSTIC PROCEDURES
• Tetanus: Clinical signs. Mouse bioassay may also be performed, but it is rarely available.
• Botulism: Clinical signs, toxin detection in feed and/or gastrointestinal content and/or liver. Feed samples from the previous 2–5 days should be evaluated for BoTx contamination. The sample should be closely examined for evidence of animal tissues present in the feed source. Animal samples to submit for BoTx testing are serum, liver, rumen content, and cecal content. Mouse bioassay is still the gold standard. Agar immunodiffusion testing and ELISA testing for the toxin can also be performed. The diagnostic value of isolation of *C. botulism* is questionable as this microorganism can be found, albeit not frequently, in the gastrointestinal content of healthy animals.
• *C. perfringens* type D enterotoxemia: Histopathology of brain (perivascular edema is diagnostic); detection of epsilon toxin in intestinal content by ELISA; PCR for detection of epsilon toxin gene is available for identification of the isolates as type D, although this does not confirm the diagnosis as this microorganism may be present in the intestine of a normal animal.

PATHOLOGIC FINDINGS
• Tetanus: usually no lesions; except for presence of deep wounds
• Botulism: usually no lesions, dilated rectum with dry content sometimes observed
• *C. perfringens* type D enterotoxemia: None or hydropericardium, a few hyperemic areas on the intestine and pulmonary edema in acute cases. Cerebellar vermis herniation and/or focal symmetrical encephalomalacia can be seen in subacute and or chronic cases. Rapid postmortem autolysis of the kidneys has led to the popular name of pulpy kidney disease; however, the diagnostic significance of this finding is questionable. Hemorrhagic or necrotic enterocolitis may be seen in goats.

TREATMENT

THERAPEUTIC APPROACH
• Tetanus: Treatment of valuable animals consists of tranquilization of the animal and tetanus antitoxin in large doses; however, treatment is often unrewarding in animals exhibiting clinical signs. Supportive treatment to prevent dehydration and starvation may need to be given for 1–4 weeks.
• Botulism: Antitoxin in valuable animals.
• *C. perfringens* type D enterotoxemia: Usually none as anti-epsilon toxin is not usually commercially available.

MEDICATIONS

DRUGS OF CHOICE
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
For all three diseases the prognosis is poor and most animals will succumb; and euthanasia should be considered for the welfare of the animal.

PREVENTION
• Tetanus: Vaccination; avoid contamination of surgical wounds.
• Botulism: Vaccination in endemic areas; phosphorus supplementation in areas with phosphorus-deficient soils; removing carcasses from pastures; not feeding poultry litter; insure ensiled feed (rye, oat, and barley silage and hay) has been fermented correctly. No animal parts to be present in the feed.
• *C. perfringens* type D enterotoxemia: Vaccination; avoid sudden changes to diets rich in highly fermentable carbohydrates.

MISCELLANEOUS

ZOONOTIC POTENTIAL
Botulism: Since this is an intracellular toxin bound to the nerves, minimal risk to individuals working with affected animals. Affected animals should be disposed of by burial or rendering. Animals should not be sent to slaughter for human consumption. Evidence of milk contamination with the toxin from intoxicated cows has been inconclusive.

PRODUCTION MANAGEMENT
See "Prevention"

SYNONYMS
• Tetanus—lockjaw
• Botulism—loin disease, bulbar paralysis, lamsiekte
• *C. perfringens* type D enterotoxemia—pulpy kidney disease, overeating disease

COCCIDIOIDOMYCOSIS

BASICS

OVERVIEW
• Coccidioidomycosis is a fungal infection caused by the dimorphic soil ascomycete fungi, *Coccidioides immitis* and *C. posadasii*.
• The disease also known as valley fever, California fever, and San Joaquin valley fever, affects many mammalian and some reptile species. Transmission of the fungus is by inhalation of airborne spores (arthroconidia) leading to asymptomatic or symptomatic infection.

INCIDENCE/PREVALENCE
• Clinical cases are rarely seen in cattle or sheep, but asymptomatic infections may be common.
• Lesions have been reported in 5–15% of cattle slaughtered in some parts of Arizona, and in 2.5% of cattle slaughtered in Mexico.
• In some endemic regions of Mexico, 13% of the cattle were seropositive, and approximately 7% of cattle tested positive with the coccidioidin skin test.
• Up to 20% of cattle can be affected in enzootic areas.

GEOGRAPHIC DISTRIBUTION
Southwestern United States and parts of Mexico and Central and South America; the fungus was recently found in south central Washington state.

SYSTEMS AFFECTED
• Respiratory
• Integument
• Multisystemic in cases of dissemination

PATHOPHYSIOLOGY
• *Coccidioides* spp. propagate by two asexual reproductive structures—arthroconidia (arthospores) and endospores.
• Soil mycelial forms release arthroconidia which are dispersed by wind. These can germinate to form new mycelia in appropriate conditions, but can also be infectious to humans and animals.
• Arthroconidia are mainly inhaled and reach alveoli where they form endospore-producing nonbudding spherules.
• Spherules enlarge and rupture to release endospores that can develop into new spherules.
• Dissemination of endospores to other parts of the body is through blood and lymphatics causing disseminated disease. If they reach the environment, endospores can form new mycelial forms.
• Ascending infections via the vagina have been associated with abortions in mares. Though uncommon, arthroconidia can be inoculated directly into skin, bone or other tissues by penetrating objects.

SIGNALMENT
• All domesticated, captive exotic and wild ruminants especially camelids
• No age, sex or breed predilection

PHYSICAL EXAMINATION FINDINGS
• Primarily a respiratory disease, rarely with dissemination to other organs.
• Primary pulmonary infections usually become symptomatic 1–4 weeks after exposure, while disseminated disease can occur months to years later.
• Commonly causes subclinical infections or may manifest as a self-limiting respiratory infection.
• Animals may exhibit persistent cough, anorexia, depression, peripheral lymphadenopathy, chronic weight loss, fever, skin lesions.

CAUSES AND RISK FACTORS
• Coccidioidomycosis is caused by dimorphic soil fungi *C. immitis* and *C. posadasii*. Fungi grow in semiarid regions with sandy alkaline soils, and can grow in environmental extremes including alkaline conditions, extreme temperatures, and high salinity.
• Risk factors include airborne dust containing arthroconidia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Actinomycosis/bacillosis
• Blastomycosis
• Caseous lymphadenitis (sheep and goats)
• Histoplasmosis
• Nocardiosis
• Tuberculosis

CBC/BIOCHEMISTRY/URINALYSIS
Mild nonregenerative anemia, monocytosis, leukocytosis

IMAGING
Radiographs: The most common lung abnormality is consolidation as solitary or multiple areas of lung, simulating bacterial pneumonia. Osteolytic lesions develop if bone is involved.

OTHER DIAGNOSTIC PROCEDURES
• Cytology: Presence of spherules in affected tissues, exudates, transtracheal or bronchoalveolar lavage fluids, lymph nodes and pleural fluid. Spherules are round, thick-walled, 20–80 µm in diameter, and can be as large as 200 µm, and contain 2–5 µm endospores. Occasionally there may be hyphae in tissues.
• Serology: ELISA, immunodiffusion and CFT.
• Culture of affected body fluids, exudates or tissue specimens.
• Molecular testing (PCR).

PATHOLOGIC FINDINGS
• Raised, miliary to nodular, firm, caseous or liquefactive lesions in lung or disseminated to mediastinum, thoracic lymph nodes, and viscera.
• Abortion, in llamas, with placental and fetal lesions.
• On histology, granulomas and pyogranulomas with fibrosis. Presence of double-contoured spherules 20–200 µm in diameter with or without 2–5 µm diameter endospores in affected tissues.

TREATMENT

THERAPEUTIC APPROACH
• Antifungal drugs including amphotericin B and azole drugs such as ketoconazole, itraconazole and fluconazole for 6–12 months, up to several years in disseminated disease.
• Disease is often self-limiting but relapses can occur.

MEDICATIONS

DRUGS OF CHOICE
Antifungal drugs including amphotericin B and azole drugs such as ketoconazole, itraconazole, and fluconazole.

CONTRAINDICATIONS
Appropriate withdrawal times for meat and milk in all food-producing animals following antifungal administration.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Primary pulmonary infections may be symptomatic in 1–4 weeks after exposure; disseminated disease occurs months to years later.
• Decreasing titers are associated with clinical improvement.
• Death in severe pulmonary or disseminated disease.

PATIENT CARE
Serology to test for IgM and IgG

PREVENTION
• Limit animal exposure to large concentrations of arthroconidia, such as in desert soils, areas of soil disturbance, and dusty conditions. Dust storms after a rainy season may contain especially high concentrations of aerosolized spores.
• No vaccine is available.

(CONTINUED) COCCIDIOIDOMYCOSIS

MISCELLANEOUS

ZOONOTIC POTENTIAL

• Not contagious but disease can occur following cutaneous inoculation or inhalation of arthroconidia.
• Often limited to mild or asymptomatic respiratory tract infection, but may disseminate to other tissues (skin, brain, lymph node, musculoskeletal system) in some instances such as immunosuppression.
• Signs include flu-like illness, coughing, and chest pain.
• Cutaneous lesions and regional lymphadenopathy.

PREGNANCY

• Abortion associated with ascending infections in mares.
• Fetuses can become infected in birth canal during parturition.

BIOSECURITY

The mycelial phase in laboratory culture plates is highly infectious; biosafety level 2 (BSL2) or higher needed for isolation.

SYNONYMS

• California fever
• Desert rheumatism
• San Joaquin valley fever
• Valley fever

ABBREVIATIONS

• CFT = complement fixation test
• ELISA = enzyme-labeled immunosorbent assay
• IgG = immunoglobulin G
• IgM = immunoglobulin M
• PCR = polymerase chain reaction

SEE ALSO

• Actinomycosis: Lumpy Jaw
• Caseous Lymphadenitis (CLA)
• Tuberculosis: Bovine

COCCIDIOSIS

BASICS

OVERVIEW

• Most ruminants are exposed and infected with coccidia. Infection is usually asymptomatic and self-limiting with the development of species-specific immunity.
• Clinical signs develop when large numbers of oocytes are ingested or the host's immune system is suppressed.
• *Eimeria* species infect ruminants. Coccidia are species specific. The most common coccidia in cattle are *E. bovis* and *E. zuernii*, in sheep *E. ovinoidalis*, and in goats *E. arloingi*.

INCIDENCE/PREVALENCE

• Incidence of nervous coccidiosis is highest in the winter.
• Incidence of diarrhea is related to the buildup of infective oocysts within the animals' environment and associated stresses, such as weaning.

SYSTEMS AFFECTED

• Digestive
• Nervous

PATHOPHYSIOLOGY

• Oocysts are shed in the feces of infected animals, either from those with clinical signs or from older carrier animals. The oocysts are not infective until sporulation has occurred. Sporulation occurs within a week. Sporulation time is related to the moisture content and temperature of the environment; warm moist environments promote sporulation.
• Sporulated oocytes are ingested and during the asexual reproductive stage intestinal epithelia are damaged. Oocysts are produced during the sexual phase. The number of infective oocysts ingested is related to the severity of clinical signs.
• Healthy non-immune animals ingesting few oocysts may not show any clinical signs as intestinal damage is not significant and is quickly repaired. If a healthy non-immune animal is exposed to many oocysts, widespread intestinal damage occurs with disruption of the intestinal mucosa.
• Mucosal damage produces diarrhea as a result of alterations in gut function, loss of blood, fluid, protein, and electrolytes into the intestinal lumen. Fecal material may contain pieces of sloughed mucosa and blood. Mucosal damage allows for bacterial invasion into and through the gut wall.
• Animals experiencing stress are more likely to exhibit clinical signs.
• Animals acquire active immunity solely to the species to which they are exposed.
• The pathophysiology of nervous coccidiosis is not fully elucidated but a neurotoxin is suspected to be involved.

HISTORICAL FINDINGS

• Animals were recently weaned, moved from individual to group housing, housed in a crowded area that has a buildup of fecal material, or the housing environment has become wet or muddy.
• Owners may report poor feed intakes and weight gains.
• In cases of nervous coccidiosis, the animal has recently exhibited signs of diarrhea, tenesmus, or hematochezia along with cold environmental temperatures.

SIGNALMENT

• Bovine, caprine, and ovine.
• There is no specific age range for infection. Most clinical signs are observed in animals <1 year of age. Clinical signs may be observed as early as 16 days of age.
• Clinical signs are often associated with the stress of weaning and movement into a feed yard.

PHYSICAL EXAMINATION FINDINGS

• The disease is primarily of young animals managed as groups in unsanitary conditions. Most animals in a group become infected but only a minority may exhibit signs.
• Clinically, animals may have suppressed appetites and poor weight gains for several weeks after enteric signs resolve.
• Impairment of growth is observed in animals with subclinical infection.
• Rough hair coat, poor body condition, and fecal-stained perineum are commonly observed in young animals. Animals have varying degrees of dehydration, anorexia, and weakness.
• Depending on the severity of the infection, feces may contain mucus, strands of mucosa, and blood. Feces may be dark in small ruminants but hematochezia is rarely observed.
• Tenesmus is common with slight rectal prolapse.
• Nervous coccidiosis, initial signs of depression and incoordination are noted, progressing to muscle tremors, hyperesthesia, clonic-tonic convulsions, nystagmus, and blindness.

CAUSES AND RISK FACTORS

• *Eimeria* species infect ruminants. Coccidia are species specific. The most common coccidia in cattle are *E. bovis* and *E. zuernii*, in sheep *E. ovinoidalis*, and in goats *E. arloingi*.
• Changes in feed, weaning, and transport increase the development of clinical signs of disease.
• Housing which encourages buildup of fecal material such as crowded conditions and group housing.
• Exposure to moist environments such as areas around leaking waterers and poorly drained feeding stations.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Enteric Coccidiosis

Salmonellosis, BVDV infection, abomasal or intestinal nematode parasitism, cryptosporidiosis

Nervous Coccidiosis

Polioencephalomalacia, lead intoxication, thromboembolic meningitis, rabies.

CBC/BIOCHEMISTRY/URINALYSIS

• Hemoconcentration, although a slight anemia may exist but is masked by dehydration.
• Inflammatory leukogram if mucosal damage is severe.
• Plasma proteins are increased initially due to dehydration; however, plasma protein levels decrease due to leakage into the gut and depressed feed consumption.

OTHER LABORATORY TESTS

• Fecal flotation.
• Diarrhea may be present for 3 or 4 days prior to the presence of oocysts in the feces.
• Checking multiple individuals increases the chances of finding oocysts, as stages of oocyst development will vary among individual animals.
• Presence or absence of oocysts in a single fecal examination is neither diagnostic nor confirmatory for coccidiosis. An animal can shed large numbers of oocysts; yet show no clinical disease because of immune status.

PATHOLOGIC FINDINGS

• Mucosa of the ileum, cecum, colon and rectum may be congested, hemorrhagic and thickened.
• The mucosa may be sloughing and ulcerated in severe cases resulting in blood and pieces of mucosa present within the lumen of the gut.
• The mucosa may also contain small white nodules.

TREATMENT

THERAPEUTIC APPROACH

• Treatment with anticoccidial drugs (see "Drugs of Choice").
• Fluid therapy, consisting of commercial oral or intravenous polyionic fluids, may be needed to correct dehydration and restore electrolytes.

MEDICATIONS

DRUGS OF CHOICE

• Sulfamethazine 110 mg/kg for 5 days, for cattle, may help control bacterial invasion and

pneumonia. Resistance to sulfamethazine has been observed.
• Amprolium 10 mg/kg for 5 days, for cattle.
• Amprolium 50 mg/kg for sheep, 100 mg/kg for goats for 5 days; use in goats and sheep is extra-label.

CONTRAINDICATIONS
• Use of amprolium may increase the risk of polioencephalomalacia.
• With the use of medications the meat and milk withdrawal times must be maintained appropriately.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Course of diarrhea is dependent on severity of infection. Feces begin to firm after several days of treatment with antimicrobials or amprolium.
• Prognosis is based on how debilitated the animal is at the time of presentation.
• Animals that are severely affected may have long-term reduction in weight gains, especially kids, as a result of damage to the intestinal lining.

POSSIBLE COMPLICATIONS
• Pneumonia has been associated with outbreaks of coccidiosis.
• Bacterial invasion through damaged gut wall may lead to septicemia.

PATIENT CARE
• Monitor attitude, appetite, fecal color and consistency, and hydration status.
• Fluid therapy, consisting of commercial oral or intravenous polyionic fluids, may be needed to correct dehydration and restore electrolytes.
• Because animals tend to be thin, feeding an appropriate amount of grain and high-quality forage is indicated.

PREVENTION
• Cleanliness is the basis of prevention. Clean and disinfect animal holding facilities between groups of animals. Drying and exposure to sunlight increases die-off of oocysts.
• Do not overcrowd animals. Reduce manure buildup. Eliminate muddy areas in the animal's environment. Feed up off the ground.
• Do not allow animals to defecate in water or feed.
• Feeding of coccidiostats in feed or in salt mixes.
  ◦ Amprolium 5 mg/kg for 30 days for cattle.
  ◦ Amprolium 15 mg/kg for 30 days for sheep and goats.
  ◦ Decoquinate 0.5 mg/kg for 30 days, for cattle, sheep, and goats.
  ◦ Lasalocid 20–30 g/ton of feed, for cattle and sheep, or 1 mg/kg per head per day.
  ◦ Monensin 20 g/ton of feed, for cattle and goats, or 1 mg/kg per head per day.
• Clients should be made aware of the potential shedding of oocysts in feces and contamination of the environment, especially in and around waterers and feed troughs.

MISCELLANEOUS

AGE-RELATED FACTORS
• Clinical signs of disease can occur any time after 16 days of age.
• All ages are susceptible until immunity is developed.

ZOONOTIC POTENTIAL
None

PRODUCTION MANAGEMENT
• Do not overcrowd animals.
• Reduce manure buildup.
• Eliminate muddy areas in the animal's environment.
• Feed up off the ground.

ABBREVIATION
BVDV = bovine viral diarrhea virus

SEE ALSO
• Bovine Viral Diarrhea Virus
• Cryptosporidiosis
• Lead Toxicosis
• Rabies
• Salmonellosis

COENUROSIS

BASICS

OVERVIEW

• Coenurosis is a condition caused by invasion of the central nervous system (CNS) by the cystic larval stage (*Coenurus cerebralis*) of the tapeworm *Taenia multiceps* (bladder worm). This parasite normally inhabits the intestinal tract of carnivores after they have ingested infected raw sheep brain or cyst-contaminated offal. Coenurosis is most frequently encountered in sheep, but goats, deer, horses, cattle, and humans can also be affected.
• A similar condition results from infection with *Coenurus serialis*, the larval form of *Taenia serialis*. It usually affects lagomorphs, with coenuri most often developing in muscle or subcutaneous tissues.

INCIDENCE/PREVALENCE

In the 1980s, UK slaughterhouse surveys showed regional prevalence ranging from 0.5% to 5.8%. Nowadays the disease is less common.

GEOGRAPHIC DISTRIBUTION

Taenia multiceps is present worldwide in scattered foci, including Africa, Asia, parts of Europe, and the Americas. It is more common in temperate regions.

SYSTEMS AFFECTED

Nervous

PATHOPHYSIOLOGY

The intermediate hosts (sheep, goats, deer, etc.) become infected when they eat forage contaminated with the eggs of *Taenia multiceps*. Eggs hatch in the intestines and the released oncospheres enter the bloodstream and form coenuri primarily in the CNS. Lesions of the CNS may result from:
• The large numbers of immature/migrating worms entering and causing encephalitis
• Interference with cerebrospinal fluid drainage
• Large cerebral cysts compressing surrounding nervous tissue
Most signs are caused by the mature *Coenurus cerebralis*, which may be up to 5 cm in diameter after 6–7 months of development.

SIGNALMENT

• Most common in sheep (can also affect cattle, goats, and wild ruminants).
• Whereas acute coenurosis is most commonly seen in young (6–8 weeks of age) lambs, chronic disease is usually reported in sheep aged 6–18 months, and is rarely seen in sheep >3 years of age.

PHYSICAL EXAMINATION FINDINGS

Acute disease may develop due to larval migration approximately 10 days after ingestion of the eggs of *Taenia multiceps*. It is usually seen after a flock of sheep is introduced in a pasture heavily contaminated with dog feces infested with tapeworm eggs. Signs may include:
• Blindness
• Pyrexia
• Listlessness
• Ataxia
• Muscle tremors
• Nystagmus
Chronically infected animals with mature *Coenurus cerebralis* that have grown over 2–6 months may show signs of:
• Solitude
• Partial or complete unilateral blindness
• Depression
• Head pressing and incoordination
• Gradual development of paresis/paralysis and recumbency if the spinal cord is involved.

CAUSES AND RISK FACTORS

Ingestion of forage contaminated with *Taenia* eggs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Coenurosis should be differentiated from other space-occupying lesions in the CNS, including abscesses, hemorrhage, and neoplasia and from other infectious agents causing neurologic disease such as listeriosis or louping ill.
• Presumptive diagnosis can be based on clinical signs and knowledge of the presence of *Taenia multiceps* in the area.
• Definitive diagnosis requires locating the metacestode in the brain or spinal cord. In 80–90% of cases, the cyst is located in one cerebral hemisphere.

CBC/BIOCHEMISTRY/URINALYSIS

Concentrations of serum creatine kinase brain iso-enzyme (CK-BB) may be increased with brain injury. Normally there is no serum CK-BB, just serum CK-MM (muscle).

OTHER LABORATORY TESTS

Results of cerebrospinal fluid evaluation may be consistent with increased eosinophil concentrations.

IMAGING

Skull radiographs/CT/MRI may be helpful in identifying the cyst.

PATHOLOGIC FINDINGS

Acute disease:
• Gross lesions include pale yellow tracts that are visible on the surface of the brain and in cut sections of the brainstem and cerebellum.
• Histologically eosinophils and giant cells predominate in the inflammatory reaction surrounding these tracts.
Chronic disease:
• Thin-walled cysts are most commonly found on the external surfaces of the cerebral hemispheres on gross examination.
• Local pressure atrophy of neural tissue is usually apparent.
• Spinal cord lesions usually occur in the lumbar region.

TREATMENT

THERAPEUTIC APPROACH

• Surgical removal is the only therapy with any demonstrated success.
• Anthelmintics may have application in the future (see "Drugs of Choice").

SURGICAL CONSIDERATIONS AND TECHNIQUES

• Surgical drainage of the cyst may prolong life.
• Surgical removal of the cyst may lead to complete recovery.

MEDICATIONS

DRUGS OF CHOICE

No drugs are labeled for treatment. Coenuri are susceptible to praziquantel, and there are reports of human patients treated with the combination of surgical excision and praziquantel. In an experimental study, 100% of lambs afflicted with coenurosis recovered after treatment with albendazole (25 mg/kg) or with the combination of fenbendazole and praziquantel (100 mg/kg) for 6 days.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Prognosis is poor without surgery. After accurate localization of the lesion, 85% success rate for surgical removal of the coenuros cyst has been reported.

PREVENTION

• The spread of infection with *Taenia multiceps* is best prevented by controlling the mature worms in dogs through effective periodic deworming.
• Carnivores should not be given access to carcasses of animals infested with the intermediate stage of *Taenia multiceps.*
• Carnivores should be prevented from defecating in areas where ruminants graze, to minimize exposure to *Taenia* eggs.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Human infection is rare but can occur after ingestion of eggs of *Taenia multiceps* or *Taenia serialis*. Coenuri of *Taenia multiceps* are usually found in the eyes and/or brain, whereas those of *Taenia serialis* are usually present in the subcutaneous tissue. Proper hygiene (washing

hands and wearing gloves) when handling dog feces helps prevent infection.

BIOSECURITY

Not allowing dogs to defecate on forage to be consumed by ruminants helps decrease exposure to *Taenia* eggs.

COLIC: BOVINE

BASICS

OVERVIEW
Acute colic is defined as abdominal pain of ≤48 hours duration.

INCIDENCE/PREVALENCE
Colic is common in all domestic ruminant species, and the incidence and prevalence varies dependent on the etiology.

GEOGRAPHIC DISTRIBUTION
Depends on individual diagnoses

SYSTEMS AFFECTED
- Digestive
- Urinary
- Reproductive
- Cardiovascular

PATHOPHYSIOLOGY
- The GI tract is the most common source of acute abdominal pain; and any abdominal organ can be involved.
- Pain results from distension, displacement, torsion/volvulus, obstruction, smooth muscle spasm, or mesenteric tension, and may involve hypermotility, hypomotility, ischemia, and inflammation.
- GI lesions can be strangulating or non-strangulating.
- Strangulating lesions are associated with reduced blood supply that results in necrosis.
- Non-strangulating lesions result in less circulatory disturbance and are not usually associated with necrosis unless they become chronic.
- Any interference with gastrointestinal function can result in endotoxemia.
- Pain may also arise from the urinary tract, reproductive tract, peritoneum or other abdominal organs.

HISTORICAL FINDINGS
- Historical assessment often identifies information relevant to the clinical complaint, including recent parturition, dietary or other management factors, fecal and urinary output, and attempted treatment.

SIGNALMENT
- Any age or gender.
- Certain etiologies may be more common in specific production groups.

PHYSICAL EXAMINATION FINDINGS
- Abdominal pain may range from mild to severe, reflected by slight depression, restlessness and anorexia, to stretching, treading, bruxism, kicking at the abdomen, straining to urinate or defecate, getting up and down repeatedly, and lying in unusual positions.
- Tachycardia often reflects systemic compromise.
- Abdominal distension.
- Reduced gastrointestinal sounds or hypermotility.
- Tympany in the abdomen (pings audible on percussion) indicate a gas-fluid interface under pressure.
- Lack of urine or feces.
- Palpably distended or displaced viscus on rectal examination.
- Grainy or constricted rectal palpation (peritonitis).
- Vomiting (rare).

GENETICS
N/A

CAUSES AND RISK FACTORS
- Risk factors can include dietary change(s), water restriction, recent parturition, and intestinal parasitism.
- Colic related to the forestomachs can reflect ruminal acidosis, vagal indigestion, traumatic reticuloperitonitis, omasal impaction, ruminal fermentation, and gas or frothy bloat.
- Colic related to the abomasum can reflect ulcers, impaction, right abomasal volvulus, abomasal rupture, vagal indigestion, or abomasal stricture.
- Colic related to the small intestine can reflect enteritis, ileus, impaction, stricture, entrapment, torsion, jejunal flange torsion, jejunal hemorrhage syndrome, intussusception, adhesions, fat necrosis, neoplasia, or herniation (inguinal, umbilical, diaphragmatic).
- Colic related to the large intestine can reflect colitis, impaction, cecal tympany, displacement, torsion, volvulus, adhesions, fat necrosis, neoplasia, intussusception, or atresia coli.
- Peritonitis and hepatic disease can cause colic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Many diseases have signs resembling colic, including choke, rabies, tetanus, myositis, hypocalcemia, septicemia, urolithiasis, and dystocia.

CBC/CHEMISTRY/URINALYSIS
- Increased WBC count with peritonitis or other inflammation
- Increased PCV and TP with dehydration
- Decreased Cl, K, Na with most intestinal obstructive lesions in adult cattle
- Increased fibrinogen in inflammatory conditions
- Metabolic alkalosis in most obstructive lesions in adult cattle
- Acidosis with grain overload or severe, long-standing obstructions
- Azotemia and lactatemia with severe dehydration or urinary obstruction

OTHER LABORATORY TESTS
- Abdominocentesis
  - Increased WBC, TP, turbidity
  - Serosanguineous color indicative of strangulating obstruction
  - Foul smell or plant material indicative of GI rupture or enterocentesis
  - Volume increased with inflammation
- Rumen fluid analysis
  - Decreased protozoal activity with poor rumen function or obstruction
  - Decreased pH with acidosis and abomasal reflux
  - Increased Cl with abomasal reflux
  - Abnormal color or smell with acidosis, ruminal fermentation, rumenitis

IMAGING
- Ultrasound may identify intestinal distention, excessive fluid, masses, urinary tract disorders, and other abnormalities in the abdomen.
- Radiographs and contrast radiology are not usually useful in adult cattle but can be used to evaluate some urinary or gastrointestinal disorders in small ruminants.
- Computed tomography with oral and IV contrast administration can be useful in calves and small ruminants with a variety of abdominal disorders.

OTHER DIAGNOSTIC PROCEDURES
- Liptak test
  - Transabdominal paracentesis of a viscus on the left side of the adult cow to differentiate displaced abomasum from rumen. Low pH = abomasum, high pH = rumen.
- Laparotomy
  - Often used diagnostically in cows. The problem can be identified and repaired in many cases by flank laparotomy.
- Laparoscopy
  - Can be used as diagnostic procedure, but most abdominal problems require laparotomy to repair.

PATHOLOGIC FINDINGS
Depend on individual diagnoses, but necropsy is commonly diagnostic.

TREATMENT

THERAPEUTIC APPROACH
Colic should be considered an emergency. Primary or supporting medical therapy is critical; however, surgical treatment is indicated for severe abdominal pain or distension, tachycardia (HR >80 bpm), abnormal abdominocentesis, or based on some abnormal imaging findings.

SURGICAL CONSIDERATIONS AND TECHNIQUES
- Consider positioning before surgically exploring the abdomen. If the animal is

incapable of standing for the entire procedure, the complications can be dramatic.
• Surgical approach in adult bovines is typically via standing right flank laparotomy. However, in many cases general anesthesia will be required and the animal should be positioned in left lateral recumbency with a hole in the padding into which the rumen can sink. If the desired lesion is located on the left side, a left flank approach can be made, but only limited exploration of the right side of the cow is available.
• In small ruminants, the right flank, paramedian, or midline approaches can be used.

MEDICATIONS

DRUGS OF CHOICE
• Analgesics
  ◦ Flunixin meglumine 1.1–2.2 mg/kg IV q24h or divided q12h.
  ◦ Butorphanol 0.02–0.04 mg/kg IV.
• Laxatives
  ◦ Mineral oil 10 mL/kg via ororuminal tube. Use with caution in surgical candidates, especially if an enterotomy may be needed.
  ◦ Magnesium oxide 0.5–1.0 kg per adult cow by ororuminal tube.
  ◦ Dioctyl sodium succinate 10–30 mg/kg of 10% solution by ororuminal tube.
• Anti-bloat agents
  ◦ Mineral oil.
  ◦ Poloxalene 30–60 mL per animal (can be repeated) by ororuminal tube.
  ◦ Detergent soap can be used in emergency.
• Prokinetics
  ◦ Metoclopramide 0.1 mg/kg SQ q6–12h (abomasal stimulation).
  ◦ Erythromycin 10 mg/kg IM (increase abomasal emptying).
  ◦ Bethanechol 0.07 mg/kg SQ q8h (cecal stimulation).
• Antibiotics
  ◦ For infectious conditions or perioperatively.
• Transfaunation
  ◦ 4–8 L of fresh rumen juice for repopulation of rumen.
  ◦ Probiotic gels and yeast can be used.
• Endotoxemia
  ◦ Flunixin meglumine 0.25–1.1 mg/kg IV, q6–12h.

CONTRAINDICATIONS
Prokinetic drugs should not be used if obstruction is present.

PRECAUTIONS
• Prolonged use of NSAIDs can cause ulceration of the abomasum and renal damage.
• Use of butorphanol or xylazine for pain control may cause ileus.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Varies depending on the initial condition

POSSIBLE COMPLICATIONS
Peritonitis, adhesions, shock, endotoxemia, gastrointestinal rupture

CLIENT EDUCATION
Clients should be educated that animals with a distended abdomen that are not passing feces have a potentially life-threatening disorder.

PATIENT CARE
• Once stable, refeeding should begin slowly with the animal monitored for passage of manure, recurrence of colic or distension, or deteriorating cardiovascular status.
• Animals with severe rumen bloat require immediate ororuminal intubation to relieve pressure.
• IV fluids are often necessary. Alkalosis is most common so a neutral or acidifying fluid is recommended. In grain overload or other situations of confirmed acidosis, an alkalinizing fluid and/or bicarbonate is needed. IV fluids should be supplemented to correct any electrolyte abnormalities.
• Large volume oral fluids may be administered for impaction and may be combined with hypertonic saline (1 mL/kg/min) to restore vascular volume.

PREVENTION
• Avoid sudden feed changes.
• Ensure access to water in all weather and temperatures.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
• Young animals are more likely to have intussusception or strangulating hernias.
• Old animals are more likely to have neoplasia or fat necrosis.
• Pregnant animals have indigestion of pregnancy/pseudo-obstruction.
• Peripartum animals are predisposed to displacements or torsions of the abomasum, and abomasal ulcers.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
Late gestation cows most likely to have indigestion of pregnancy/pseudo-obstruction, uterine torsion

COLIC: SMALL RUMINANT

BASICS

OVERVIEW
• Acute colic represents abdominal pain of <48 hours' duration; chronic pain persists beyond 48 hours' duration or occurs in recurrent bouts.
• A wide variety of disorders cause colic in small ruminants; some require surgical intervention for resolution.
• Signs of acute abdominal pain usually represent gastrointestinal (GI) disease but can also reflect disease of other organs including the urinary and reproductive tracts.

INCIDENCE/PREVALENCE
Colic is usually a sporadic disorder unless associated with a problem that can affect multiple individuals (e.g., grain overload, toxic agents).

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Digestive
• Urinary
• Reproductive
• Cardiovascular

PATHOPHYSIOLOGY
• Gastrointestinal pain can result from distension, displacement, torsion/volvulus, obstruction, smooth muscle spasm, and mesenteric tension, and may involve hyper- or hypomotility, ischemia, and inflammation. Endotoxemia is a common accompaniment due to the large volume of natural gastrointestinal flora.
• Urinary tract pain can result from obstruction, inflammation, or infection.
• Reproductive tract pain can result from parturition, abortion, dystocia, uterine torsion, inflammation, infection, or neoplasia.

HISTORICAL FINDINGS
Determining the signs of concern, how long clinical signs have been present, events of potential significance (accidental access to grain, procedures), and any treatments administered prior to examination are important historical factors.

SIGNALMENT
• All small ruminant species, breeds, ages, and sexes can be affected.
• Castrated males are more likely to have urolithiasis.
• Young animals are more likely to develop intussusception and bezoars.
• Pre-weaned animals are more likely to have rumen putrefaction, abomasitis, abomasal tympany, and necrotizing enteritis.

PHYSICAL EXAMINATION FINDINGS
• Abdominal pain ranges from mild to severe; early signs may be subtle and easily missed.
• Ruminants are stoic animals that tend to display subtle signs of pain.
• Mild colic is reflected by slight depression, reduced appetite, and restlessness.
• Moderate colic can be reflected by reduced appetite and manure output, restlessness, stretching out (sawhorse stance), teeth grinding, posturing to urinate or defecate without production, and tail flagging.
• Severe colic can provoke kicking at the abdomen, recumbency, obtundation, vocalization, straining to urinate or defecate, profound restlessness (getting up and down repeatedly), and even rolling (unusual).
• Other findings can include increased respiratory rate, changes in temperature, abdominal distension and/or asymmetry, and changes in rumen motility or fill.
• The veterinarian should be familiar with the location of the gastrointestinal components in ruminants, and with associated areas of tympany (pings), which indicate gas distension of a viscus.
• Tachycardia is often present and can indicate endotoxemia, shock, hypovolemia, or pain.
• Vomiting is unusual, and most often associated with grayanotoxicity.
• Fecal production may be absent or feces may have abnormal appearance (loose, hemorrhagic, raspberry jam). The contents of the rectum can be assessed by digital palpation.
• Inguinal, scrotal, umbilical, or abdominal hernias may present as a mass, which may be warm, painful and non-reducible.
• Anuria, stranguria, pollakiuria, hematuria, or pyuria or the presence of blood or sediment on preputial hair can suggest urinary tract disease.
• Vulvar discharge may be evident with reproductive disease.
• Tenesmus may occur, and young neonates should be checked for a patent anal opening.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Disease of the forestomachs can arise due to acidosis (grain overload), grayanotoxicity, gas or frothy bloat, penetrating foreign body, impaction (feed, sand), or blockage of the reticulo-omasal groove by a foreign body.
• Disorders of the abomasum include ulcers, abomasitis, abomasal tympany, impaction (sand, feed), phytobezoars/trichobezoars, abomasal emptying defect, and very rarely, displacement.
• Small intestinal disorders include enteritis (parasites, *Salmonella*), intraluminal obstruction (tricho- or phytobezoar; especially pylorus and duodenum), segmental volvulus, mesenteric root volvulus, intussusception, adhesions, fat necrosis, neoplasia, and entrapment (inguinal, umbilical, diaphragmatic hernia).
• Large intestinal disorders include colitis, impaction, intussusception, cecal tympany, cecal volvulus, spiral colon volvulus, adhesions, fat necrosis, neoplasia, rectal prolapse, rectal tear, and atresia coli/ani.
• Reproductive disorders causing colic include dystocia, uterine torsion, parturition, abortion, tumor, periuterine abscess, testicular torsion, testicular trauma, seminal vesiculitis, and inguinal/scrotal hernia.
• Urinary tract disorders include urolithiasis, cystitis, nephrolithiasis, pyelonephritis, and ruptured bladder.
• Other causes of colic include peritonitis, umbilical abscess (internal remnant), hepatic disease (lipidosis, cholelithiasis, flukes), and potentially aortic, iliac, or femoral thrombosis.
• Some risk factors include dietary change(s), sand ingestion, water restriction, previous abdominal surgery, pregnancy, NSAIDs, and recent breeding or parturition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Many diseases can cause signs resembling abdominal pain, including rabies, tetanus, and severe musculoskeletal problems/injuries.
• Differential diagnoses will vary depending on the animal's signalment, clinical signs, and the body system involved. In ruminants, when colic is attributed to the GI tract, additional diagnostic procedures should primarily aim at differentiating between problems that are oral versus aboral to the abomasum.

CBC/CHEMISTRY/URINALYSIS
• CBC changes that might be observed include an increased white cell count and fibrinogen with peritonitis or other inflammatory disorders, and hemoconcentration (increased PCV and protein).
• Hyperlactatemia is common in grain overload, strangulating gastrointestinal disease, severe long-standing obstructions, and any disorder causing severe systemic compromise.
• Hypochloremic metabolic alkalosis is observed in most GI lesions affecting outflow of the abomasum (obstruction, severe ileus).
• With forestomach lesions, chloride and total CO_2 concentrations are typically normal.
• Azotemia can indicate urinary obstruction or severe dehydration.
• Urinalysis may identify increased white cells, red cells, bacteria, or crystals with urinary tract disease.

OTHER LABORATORY TESTS
• Cytologic analysis of peritoneal fluid may identify increased total nucleated cell count (>5,000 cells/μL) and total protein concentrations (>5 g/dL) in inflammatory disease. A serosanguineous character suggests strangulation, and foul smell and plant

material can indicate GI rupture (or enterocentesis). A uriniferous smell can indicate uroabdomen.
• Rumen fluid analysis can be performed on samples obtained by ororuminal tube. Decreased protozoal activity may be observed with poor rumen function or obstruction, rumen pH may be decreased with acidosis and abomasal reflux, rumen chloride may be increased (>30 mEq/L) with abomasal reflux, and an abnormal color or smell can occur with acidosis, indigestion, and ruminitis.

IMAGING
• Ultrasonography is useful for examination of the digestive, urinary, and reproductive tracts. Attention should be paid to the amount and character of peritoneal fluid. Small intestinal or spiral colon distention, abnormal motility, and increased wall thickness can be observed in some disorders. Small intestinal intussusception is rare but may have a characteristic "bullseye" appearance.
• Radiographs can help with detection of radiodense uroliths, or sand impaction or metallic foreign bodies of the GI tract. Contrast radiographs are helpful in the diagnosis of intestinal atresia.
• Computed tomography is useful for evaluating all organ systems that might cause signs of abdominal pain, and can be performed several hours after ororuminal administration of contrast agent to help facilitate identification of GI obstruction.

OTHER DIAGNOSTIC PROCEDURES
Exploratory laparotomy can be used in the diagnosis and repair of some lesions. Surgical approach (right, left, midline, paramedian) must be carefully determined based on signalment, history, clinical signs, and the results of diagnostic tests to determine the most likely differentials to be investigated.

PATHOLOGIC FINDINGS
Vary with respective causes, see relevant chapters.

TREATMENT

THERAPEUTIC APPROACH
• Animals with severe rumen bloat require immediate ororuminal intubation to prevent respiratory compromise and collapse.
• IV fluids are often indicated. GI disease typically provokes alkalosis in adult ruminants and a neutral or acidifying fluid (such as 0.9% NaCl) is recommended. If grain overload or systemic acidosis is confirmed, a neutral or alkalinizing fluid is recommended. Electrolytes should be supplemented according to laboratory anomalies.
• Oral fluids may be administered where finances or disease (impaction) indicate.
• Oral fluids can be combined with hypertonic saline (2–4 mL/kg) to quickly restore vascular volume in appropriate patients.
• Feed should be withheld until resolution of signs, then re-introduced slowly to avoid recurrence or complications.
• Transfaunation can be beneficial in animals with persistently poor appetite, by providing 2–4 L of fresh rumen juice via ororuminal tube for repopulation of rumen microbes.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Colic should be considered an emergency; diagnosis and treatment initiated immediately and feed withheld until the cause is determined and addressed.
• Indications for immediate surgical treatment include severe abdominal pain, severe abdominal distension, HR >90 bpm, presence of pings, abnormal abdominocentesis, urinary obstruction, uterine torsion nonresponsive to rolling or manipulation, fetal oversize causing dystocia, and confirmed gastrointestinal torsion, displacement, or obstruction.
• Surgical exploration of the abdomen of small ruminants is typically performed with the animal in lateral or dorsal recumbency, and usually under general anesthesia.
• If the desired lesion is located on the left side (i.e., rumen or uterus), a left flank approach can be made, knowing that exploration of the right side of the animal will be limited. The right flank is otherwise almost always selected for entry.
• A paramedian approach is typically chosen for small ruminants with suspected urolithiasis.

MEDICATIONS

DRUGS OF CHOICE
Analgesics
• Flunixin meglumine: 1.1–2.2 mg/kg IV q24h or divided q12h; also useful for endotoxemia at 0.25–1.1 mg/kg IV q6–12h (off label use in food animals).
• Ketoprofen: 2 mg/kg IM q24h (not labeled for use in food animals in the USA).
• Butorphanol: 0.05–0.1 mg/kg IV, IM or SQ, q6–8h.
• Xylazine: 0.05–0.3 mg/kg IM (may cause recumbency when used at higher dose or IV).
• Lidocaine: 1.3 mg/kg IV slowly over 10–15 minutes, then 0.05 mg/kg/min in saline or LRS over 24 hours (based on equine literature).

Laxatives
• Mineral oil: 5–10 mL/kg by ororuminal tube.
• Magnesium hydroxide: 50 g (for adult goat/sheep) by ororuminal tube.
• Dioctyl sodium succinate: 15–30 mL (for adult goat/sheep) of 10% solution given by ororuminal tube.

Antibloat Agents (Frothy Bloat)
• Mineral oil: 5–10 mL/kg given by ororuminal tube.
• Poloxalene: 30 mL/45 kg (can be repeated) by ororuminal tube.
• Detergent soap can be used in emergency.

Prokinetics
• None are truly effective for promoting forestomach motility.
• Metoclopramide: 0.1 mg/kg SQ q6–12h may provide some abomasal stimulation.
• Bethanechol: 0.07 mg/kg SQ q8h may provide some cecal stimulation.
• Erythromycin: 1 mg/kg in 1 L of saline over 60 minutes may provide stimulation throughout the GI tract.

Antibiotics
Antibiotics are indicated for infection and potentially perioperatively.

CONTRAINDICATIONS
• Prokinetic drugs should not be used if GI obstruction is present.
• Prolonged use of NSAIDs can cause ulceration of the abomasum and renal damage.

PRECAUTIONS
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
• Butorphanol or xylazine reduce GI motility.
• Xylazine may cause recumbency when used at the higher dose; small ruminants are extremely sensitive to xylazine, hence it should be used with caution and sound monitoring.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Varies with the causative condition, generally disorders that are acute, nonsurgical, and diagnosed and treated promptly have a good prognosis.

POSSIBLE COMPLICATIONS
• Peritonitis
• Adhesions
• Shock
• Endotoxemia
• Gastrointestinal or bladder rupture
• Fetal loss

CLIENT EDUCATION
Promote good management protocols in regard to dietary management and parasite control.

PATIENT CARE
• Once stable, refeeding should begin slowly and fecal passage monitored.

COLIC: SMALL RUMINANT (CONTINUED)

• If the urinary tract was involved, urination must be monitored.
• Monitor for recurrence of colic or distension, or deteriorating cardiovascular status.

PREVENTION
• Avoid sudden feed changes.
• Ensure access to water in all weather and temperatures.
• Investigate signs of abdominal pain or distension early.
• Investigate dams that are pregnant beyond their due date.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
• Young animals are more likely to develop intussusception and bezoars.
• Pre-weaned animals are more likely to have rumen putrefaction, abomasitis, abomasal tympany, and necrotizing enteritis.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
Late gestation dams may have indigestion of advanced pregnancy/pseudo-obstruction and uterine torsion.

CONGENITAL DEFECTS: BOVINE

BASICS

OVERVIEW

• Numerous congenital defects have been reported in cattle.
• Congenital defects may be of genetic, toxic, nutritional, or infectious origin and commonly result in abortion, stillbirths, dystocia, or neonatal loss.
• This chapter discusses only defects associated with a known cause and that can be prevented by proper selection and management.

INCIDENCE/PREVALENCE

Some defects are breed specific.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Multisystemic

PATHOPHYSIOLOGY

• Hereditary congenital defects
  ◦ Several genetic disorders have been recently reported to cause congenital defects in cattle.
  ◦ Arthrogryposis multiplex in Angus cattle, due to a lethal autosomal recessive gene, commonly referred to as "curly calf syndrome." It results in severe malformations of the spine and limbs due to lack of communication between nerves and muscle tissue (in utero paralysis).
  ◦ Complex vertebral malformation is an inherited lethal disorder in Holstein cattle, responsible for increased early embryonic death, abortion, and perinatal death. Affected calves show various skeletal abnormalities.
  ◦ Congenital contractural arachnodactyly, due to a nonlethal recessive gene in Angus cattle. Affected calves are born with elongated limbs, congenital proximal limb contracture, and distal limb hyperextension.
  ◦ Bovine arachnomelia syndrome, due to an autosomal recessive trait with complete penetrance in brown Swiss and Fleckvieh/Simmental cattle, resulting in skeletal abnormalities and a spidery appearance of the limbs.
  ◦ Bovine citrullinemia, due to an autosomal recessive gene in Holstein cattle, causes an impairment of urea cycle resulting in elevated citrulline and ammonia in plasma and a neurologic syndrome.
  ◦ Dwarfism or chondrodysplasia has been described in several breeds of cattle and is characterized by shortness and deformities of limbs, head and vertebrae. Some forms have been linked to a recessive (Aberdeen Angus) or incomplete dominant (Dexter) autosomal gene.
  ◦ Brachyspina syndrome is a lethal malformation in Holstein cattle.
  ◦ Crooked tail syndrome occurs in Belgian Blue cattle and is due to a deletion in the myostatin gene. Affected animals show growth retardation, abnormal skull, and extreme muscle hypertrophy.
  ◦ Developmental duplication, due to an autosomal recessive gene in Angus cattle, results in birth of calves with supernumerary limb.
  ◦ Neuropathic hydrocephalus, due to a lethal autosomal recessive gene of Angus cattle.
  ◦ Syndactyly or "mule foot" (Holstein, Angus), fusion of digits due to an autosomal recessive gene.
  ◦ Tibial hemimelia (dairy Shorthorn, Maine-Anjou), lethal genetic disease characterized by malformed or absent tibia, long shaggy haircoat, cryptorchidism, and meningocele.
  ◦ Pulmonary hypoplasia with anasarca (Brown Swiss), due a recessive often lethal gene.
  ◦ Goiter (Holstein).
  ◦ Chediak-Higashi syndrome (Hereford, Brangus, Waygu), causes albinism and increased susceptibility to infection.
  ◦ Ehlers-Danlos syndrome. Joint laxity and loss of skin tensile due to disorder of collagen type 1 and 2 formation.
  ◦ Glycogen storage disease. Muscle weakness and inability to rise properly.
  ◦ Epitheliogenesis imperfecta. Autosomal recessive, animal shows discontinuities in the skin or mucus membranes.
• Virus-induced congenital malformations
  ◦ BVDV
    ▪ Teratogenic effects occur between 79 and 150 days of pregnancy and affect the CNS which is in the process of growth and differentiation. The virus causes destruction or failure of migration of the neuronal and neuroglial cells, resulting in failure of development and cavitary lesions formation. Inflammation causes vascular lesions and destruction of cerebellar folia resulting in cerebellar hypoplasia. Accumulation of fluids in the cavities results in development of hydranencephaly or hydrocephalus.
    ▪ Other lesions: Ocular lesions (bilateral microphthalmia, cataracts) due to retinal dysplasia and optic neuritis. Alterations of thymus (hypoplasia), bone (brachygnathia inferior, growth retardation), hair coat (hypotrichosis, alopecia, curly hair), lungs (hypoplasia), and kidneys (dysplasia).
  ◦ Bluetongue virus
    ▪ Infection between 70 and 130 days of pregnancy results in brain malformations due to effects on neuronal and glial precursor cells and vascular injuries. Later in gestation, the virus may cause encephalitis.
  ◦ Akabane and Aino viruses
    ▪ Infection between 79 and 104 days' gestation results in hydranencephaly whereas in infection between 103 and 174 days gestation results in arthrogryposis.
  ◦ Schmallenberg virus
    ▪ CNS lesions (brain and spinal cord) depend on the stage of pregnancy (fetal immunocompetency) and virulence of the virus. In early pregnancy severe dyspalastic lesions and in late gestation encephalomyelitis. Arthrogryposis is suspected to be the result of CNS lesions.
• Congenital defects caused by teratogenic plants
  ◦ Lupine toxicosis is well documented in North America. Ingestion of the plant between 40 and 70 days or pregnancy results in the "crooked calf syndrome" characterized by various degrees of arthrogryposis, scoliosis, torticollis, lordosis, and cleft palate due to alkaloid-induced fetal movement inhibition resulting from desensitization of skeletal muscle type nicotinic acetylcholine receptors.
  ◦ Various other plants (locoweed, poison hemlock, tobacco, *Veratrum californicum*, mimosa) cause a variety of skeletal malformations when ingested by cattle between 30 and 60 days of pregnancy.
• Other causes: Cloning by somatic cell nuclear transfer has been associated with severe abnormalities of the umbilical cord, organomegaly commonly referred to as "abnormal offspring syndrome" and believed to be due to epigenetic errors of development
• Other congenital defects
  ◦ Amelia: Absence of a limb or limbs
  ◦ Atresia ani or atresia coli
  ◦ Brachygnathia
  ◦ Cryptorchidism
  ◦ Hernias: Umbilical, inguinal, diaphragmatic hernia
  ◦ Cardiac abnormalities: Ventral septal defect, ectopic heart, ventricular hypoplasia
  ◦ Freemartinism

HISTORICAL FINDINGS

• Presence of an epidemiologic factor such as introduction of new animals (viral infections), change in pasture management (toxic plants), use of the same bull for breeding
• Abortion or stillbirth
• Abnormal pregnancy (hydrops allantois) obtained from cloned embryos
• Dystocia
• Neurologic syndrome, head press, convulsion, ataxia (bovine citrullinemia)
• Visible conformation abnormalities (inability to stand, severe angular deformities)

SIGNALMENT

• Abortus or neonate
• Nonlethal congenital defects, particularly of the reproduction system, are usually discovered upon breeding soundness examination.

CONGENITAL DEFECTS: BOVINE (CONTINUED)

PHYSICAL EXAMINATION FINDINGS
• Congenital abnormalities are identified upon routine neonatal examination or because of complaints of severe distress of a neonate.
• Several conformational and musculoskeletal congenital abnormalities are evident upon inspection of the animal.
• Behavioral abnormalities, neurologic signs, dummy calf, inability to stand may be seen in animal with genetic disorders.

GENETICS
Some congenital defects have been confirmed to be hereditary.

CAUSES AND RISK FACTORS
Genetics; viral infections during pregnancy; exposure to teratogens; see "Pathophysiology"

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Congenital defects often present in similar forms. Differential diagnosis of the cause relies primarily on epidemiologic data, herd history, thorough postmortem examination, and genetic evaluation.
• All malformed aborted fetuses and stillborn calves should be submitted to a diagnostic laboratory and processed as for an abortion investigation.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Genetic testing if a hereditary cause is suspected.
• Toxicology and viral investigation on abortus or neonates with severe congenital defects.

IMAGING
• Abdominal ultrasonography for suspected gastrointestinal abnormalities
• Thoracic/cardiac ultrasonography for diaphragmatic hernia, pulmonary and cardiac abnormalities.

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• BVDV: Hydranencephaly, porencephaly, cerebellar hypoplasia, hydrocephalus, microencephaly, microphthalmia, cataracts
• Bluetongue: Hydranencephaly, cerebellar defects, porencephaly, hydrocephalus
• Akabane and Aino viruses: Hydranencephaly or arthrogryposis
• Schmallenberg virus: Hydranencephaly, arthrogryposis
• Arthrogryposis multiplex: Arthrogryposis, scoliosis, torticollis, hydroamnion
• Toxic plants: Various degrees of arthrogryposis, cleft palate

TREATMENT

THERAPEUTIC APPROACH
Severe congenital defects warrant humane euthanasia as early as the diagnosis is made.

SURGICAL CONSIDERATIONS AND TECHNIQUES
Surgical correction should be considered for some abnormalities (i.e., congenital hernias, abnormal umbilical stump, atresia ani, atresia vulvi, angular limb deformities) in order to improve the animal's welfare, provided the animal is not used for breeding.

MEDICATIONS

DRUGS OF CHOICE

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Animals with severe congenital abnormalities should be humanely euthanized.
• Dam and sire should be tested if hereditary/genetic condition is suspected.

POSSIBLE COMPLICATIONS
N/A

CLIENT EDUCATION
• Examination should be performed on all neonates for early detection of common congenital defects.
• Animal with congenital defects suspected to be hereditary should be eliminated from reproduction.

PATIENT CARE
Depends on the condition

PREVENTION
• Eliminate animals with known hereditary defects from breeding.
• Keep good records on genetics.
• Avoid exposure to toxic plants during critical periods of pregnancy.
• Preventive program for viral causes of abortion and congenital abnormalities.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Abortion
• Sudden death in neonate
• Ill-thrift

AGE-RELATED FACTORS
Congenital defects are usually detected on abortus, stillborn calves, or neonates.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
N/A

BIOSECURITY
• Prevent introduction of animals from infected areas.
• Test animals for viral diseases before introduction.
• Properly dispose of carcasses from fetuses and dead neonates.
• Isolate and test aborting cows.

PRODUCTION MANAGEMENT
Pasture management to avoid exposure of pregnant cows to teratogenic plants

SYNONYMS
N/A

CONGENITAL DEFECTS: CAMELID

BASICS

OVERVIEW

• Congenital defects are abnormalities of development or system function that the animal is born with. They can be recognized before birth (i.e., abortion), at birth, or years after birth (necropsy).
• Congenital defects may be of genetic, toxic, nutritional, or infectious origin. They may be lethal or nonlethal.
• Presence of congenital defects raises ethical questions at breeding.

INCIDENCE/PREVALENCE

Incidence of congenital defects is high in SAC compared to traditional domestic animal species.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Multisystemic

PATHOPHYSIOLOGY

• Common hereditary congenital defects: Several congenital defects are suspected to be hereditary although the mode of inheritance is often not known. The majority of the known hereditary defects are due to recessive genes or to complex multigenetic origins. The most common defects are:
  ◦ Maxillofacial abnormalities: Choanal atresia, wry face, craniofacial shortening, cleft palate, prognathism, cyclopia
  ◦ Reproductive abnormalities: Cryptorchidism, testicular hypoplasia, ovarian dysgenesis or hypoplasia, segmental aplasia of the tubular genitalia, atresia vulvi, polythelia, or supernumerary teats
  ◦ Gastrointestinal: Atresia ani, atresia coli, megaesophagus
  ◦ Cardiac: Ventricular septal defects
  ◦ Renal: Renal agenesis
  ◦ Musculoskeletal: Tail agenesis, kinked tail or sacro-coccygeal defect, syndactyly, polydactyly, dwarfism, patellar luxation
  ◦ Sensory organs: Blindness, blue eye (auditory nerve degeneration, deafness), nasolacrimal duct aplasia, gopher ears
  ◦ Hernias: Diaphragmatic, umbilical
  ◦ Immune system: Juvenile immunodeficiency syndrome (JIDS)
• Congenital defects suspected to be caused by teratogens
  ◦ Viral infections are suspected to cause congenital defects similar to those described in other species. These include BVDV (microphthalmia, hydrocephalus, impaired immune system), bluetongue virus (arthrogryposis, cerebellar hypoplasia).
  ◦ Arthrogryposis, cleft palate and ankyloses have been suspected to occur following ingestion of locoweed, poison hemlock, lupine, and tobacco. These effects are suspected to be due to a sedative effect of alkaloids on the fetus. Craniofacial malformation seen with *Veratrum californicum* may be due to steroidal alkaloids and inhibition of glucose metabolism by the cephalic primordia.
  ◦ Congenital goiter is common in camels and is suspected to be due to iodine deficiency or a toxic form of congenital hypothyroidism.

HISTORICAL FINDINGS

• Abortion, stillbirth, or sudden death of neonates.
• Visible abnormalities (inability to stand, inability to defecate or urinate, joint laxity or overextension, severe angular deformities), respiratory, circulatory, or metabolic complications.
• History of infertility.
• Poor doer or recurrent infections.

SIGNALMENT

• Abortus or neonate in most severe congenital defects.
• Compromise immunity generally discovered around 2–3 months of age.
• Most nonlethal defects are discovered upon pre-purchase or pre-breeding examination.

PHYSICAL EXAMINATION FINDINGS

• Congenital abnormalities are identified during routine neonatal examination or because of complaints of severe distress of a neonate. Several conformational and musculoskeletal congenital abnormalities are evident on inspection of the animal. Palpation of the tail head reveals various degrees of deviation or kinking of the tail in animals with sacro-coccygeal defects.
• Neonates with respiratory distress (dyspnea, open mouth breathing) should be examined for total or partial choanal atresia or diaphragmatic hernia. Air flow may be verified by fogging of a dry glass slide or a mirror placed under the nostril. Obstruction at the level of the medial canthus may be detected by a Foley catheter placed in each nostril.
• Neonates with cleft palate or maxillofacial abnormalities may present for lack of suckling ability or milk discharge from the nose.
• Animals with gastrointestinal abnormalities may present for bloat, lack of defecation, or straining (atresia ani, atresia coli).
• Animals with cardiovascular abnormalities may present for various signs of lethargy or collapse and respiratory distress. Cardiac auscultation reveals abnormal sounds (murmurs of variable degrees).
• Animals with urogenital abnormalities (ectopic ureters, intersex) may show evidence of dysuria or urine scalding.

GENETICS

Congenital defects confirmed to be hereditary in nature include maxillofacial abnormalities, tail abnormalities, polydactyly, and syndactyly.

CAUSES AND RISK FACTORS

• Genetics
• Viral infections during pregnancy
• Exposure to teratogens

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Differential diagnosis between hereditary and nonhereditary congenital defects is important for the management of breeding animals.
• Respiratory distress may be caused by respiratory tract abnormalities, cardiovascular abnormalities, or diaphragmatic hernias. Differential diagnosis requires imaging.
• Lethal congenital disorders require a thorough necropsy evaluation.
• Disorders resulting in infertility may be identified in the external genitalia or after ultrasonographic evaluation.

CBC/BIOCHEMISTRY/URINALYSIS

• Indicated to evaluate the effect of a severe defect and make a decision on euthanasia.
• CBC is helpful in identifying animals with JIDS.

OTHER LABORATORY TESTS

• Genetic testing for animals with suspected intersex or freemartinism.
• Toxicology and viral investigation on abortus or neonates with congenital defects.

IMAGING

• Transabdominal ultrasonography for suspected atresia coli, congenital abnormalities of the kidneys.
• Transrectal ultrasonography to identify all congenital abnormalities of the genitalia in the female.
• Echocardiogram for suspected cardiac defects.
• Radiology to confirm choanal atresia, diaphragmatic hernia, and evaluate the severity of angular limb deformities.

OTHER DIAGNOSTIC PROCEDURES

• Laparoscopic exploration is helpful in the diagnosis of some genital abnormalities (uterus unicornis, ovarian dysgenesis, hypoplasia).
• Brainstem auditory evoked response (BAER) measurement for deafness evaluation in blue-eyed alpacas.

PATHOLOGIC FINDINGS

• Choanal atresia: Lack of or reduced communication between the nasal and pharyngeal cavity.
• Diaphragmatic hernias and various atresia of the gastrointestinal system are evident on postmortem examination.
• Cardiac abnormalities include ventral septal defect, atrial septal defects, tetralogy of Fallot, transposition of the great vessels, persistent right aortic arch, and patent ductus arteriosus.

CONGENITAL DEFECTS: CAMELID (CONTINUED)

• Defects of the urogenital system can be lethal (bilateral renal agenesis, bladder agenesis, and complete atresia vulvi).
• Reproductive system disorders: Monorchism is often associated with unilateral renal agenesis. Testicular and ovarian hypoplasia are confirmed by absence or lack of germinal epithelium activity.

TREATMENT

THERAPEUTIC APPROACH
• Most severe congenital defects warrant humane euthanasia as early as the diagnosis is made.
• Less severe congenital defects that do not jeopardize the animal's wellbeing may be managed conservatively (slight angular deformities, slight facial deviations, congenital abnormalities resulting in infertility).

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Surgical correction of some abnormalities should be considered in order to improve the animal's welfare providing the animal is not used for breeding.
• Castration and ovariectomy should be considered for animals with suspected hereditary congenital defects or defects that may jeopardize the welfare of the animal during mating or pregnancy.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Animals with severe congenital abnormalities should be humanely euthanized.
• Animals with sensory abnormalities can have a good life but their management and behavior can be difficult around people and other animals.
• Animals with slight angular limb deformities have a very good prognosis for normal behavior and life.

POSSIBLE COMPLICATIONS
• Angular limb deformities may result in chronic lameness and osteoarticular disorders.
• Animals with cardiac abnormalities may show lethargy and poor growth. Females may have other systemic complications during pregnancy if mated.
• Non-diagnosed congenital defects of the reproductive system may result in overbreeding, reproductive tract infection, or injury, and jeopardize the animal's welfare.

CLIENT EDUCATION
• All neonates should be examined for common congenital defects.
• Animals with congenital defects suspected to be hereditary should be eliminated from reproduction.

PATIENT CARE
Depends on the condition

PREVENTION
• Eliminate animals with known hereditary defects from breeding.
• Keep good records on genetics to make rational mating decisions.
• Avoid exposure of pregnant animals to toxic plants and viruses known to cause congenital abnormalities in other species.

CONGENITAL DEFECTS: SMALL RUMINANT

BASICS

DEFINITION
Lethal or sublethal defects present at birth due to genetic or environmental influence on embryonic or fetal development.

INCIDENCE/PREVALENCE
• Defects occur generally sporadically, with <1% newborns affected.
• Prevalence of genetic conditions is higher in inbred herds or flocks.
• Entropion is the most common congenital defect in sheep, with 1–10% of lambs affected, and up to 80% of lambs and 50% of kids in highly inbred herds.
• Prevalence of arthrogryposis is 0.3%, but 58% of lambs were affected with genetic arthrogryposis.
• Intersexes are seen in 2–11% of kids born.
• Testicular hypoplasia was seen in 33% of sterile bucks.

GEOGRAPHIC DISTRIBUTION
Varies with distribution of viruses or their vectors, and toxic plants.

SYSTEMS AFFECTED
Depends on etiology

PATHOPHYSIOLOGY
• Chromosomal abnormalities occur during gametogenesis or fertilization.
• Gene mutations, deletions, or translocations lead to heritable defects.
• Plant toxins cause fetal defects if they cross the placenta at a high dose and at a time of gestation when the fetus is susceptible to their effect.
• Viruses cause congenital defects if the fetus is infected during susceptible stages of gestation.
• Defects may be due to excessive or arrested division, failure of normal fusion, failure or excess of tissue growth or development, failure to assume final form or position, failure of normal persistence, or disappearance of structures.

GENETICS
• Most genetic defects are single autosomal recessive traits.
• Entropion may be caused by several recessive genes with additive effects.
• Cryptorchidism and testicular hypoplasia may have the same genetic basis in sheep.
• Some intersex conditions are associated with the polled trait in goats.

HISTORICAL FINDINGS
• Similar congenital problems in progeny of related animals, affected animals descend from a common ancestor, increased frequency of the defect with inbreeding with genetic defects.
• Sudden increase in the percentage of animals born affected, introduction of new animals to the herd with infectious origin.
• Known presence of toxic plants or mineral/vitamin deficiencies in the area.

SIGNALMENT
• Genetic conditions are more prevalent in certain breeds.
• Fetuses and newborn lambs and kids.

PHYSICAL EXAMINATION FINDINGS
• Bunyavirus: Abortion, maternal fever, neonatal deaths, arthrogryposis, torticollis, scoliosis, lordosis, hydrocephalus, cerebellar abnormalities, muscular hypoplasia, anasarca.
• Bluetongue: Neurologic signs in newborns, arthrogryposis.
• Border disease virus: Abortions, mummified or macerated fetuses, stillbirths, weak lambs with hairy fleece and tremors, ataxia, facial and ocular abnormalities, poor growth, depressed immune system, cerebellar hypoplasia, hydranencephaly, porencephaly, arthrogryposis.
• Schmallenberg virus: Maternal diarrhea, dullness, decreased milk production, fever, infertility, weak lambs with poor vision and neurologic signs, arthrogryposis, torticollis, scoliosis, kyphosis, flattened skull, brachygnathia inferior, porencephaly, hydranencephaly, dysplasia of the cerebellum, brainstem and spinal cord.
• Locoweeds, tree tobacco, and poison hemlock: Abortion, infertility, congenital arthrogryposis, crooked legs, scoliosis, torticollis, hydrops, weak neonates.
• Skunk cabbage: With acute poisoning, maternal salivation, vomiting, fast irregular heart rate, muscle tremors, incoordination, coma. With ingestion at 15 days'f gestation, congenital cyclopia, protruding and twisted mandible, shortened upper jaw and prosboscis ("monkey face"). With ingestion at 30–35 days' gestation, congenital cleft palate, hairlip, shortened legs, tracheal stenosis.
• Cerebellar atrophy: Wide stance, opisthotonos, tremors, ataxia.
• Ceroid lipofuscinosis: Blind lambs, nodding head, twitching of eyelids, lips and muzzle, locomotor disturbance.
• Muscle dystrophy: Poor growth, locomotor problems, inability to forage, in Merinos.
• Spider lamb syndrome or chondrodysplasia: Abnormal limb length, bent legs, flattened rib cages, arthrogryposis, spinal and facial deformities.
• Achondroplasia or dwarfism: Short bowed legs, deformed heads.
• Hypotrichosis congenita: No fleece or only patches of hair. Bilateral hypotrichosis is seen with congenital hypothyroidism.
• Epitheliogenesis imperfecta: Defects in the epithelium, oral cavity, and tongue. In redfoot form, hooves are shed soon after birth.
• Epidermolysis bullosa: Subepidermal bullae, erythematous patches, alopecia, hypopigmentation, erosions, ulcers, crusty or scaly areas over bony prominences, lips, nasolabial plane, mouth, tongue, gums, or palate.
• Collagen dysplasias: Abnormally fragile skin that lacerates easily, oral lesions due to trauma of suckling that infect and cause fatal septicemia, skin laxity.
• Copper deficiency: Poor appetite, weakness, twisted joints, hear tremors, ataxia, paresis and paralysis in goats.
• Entropion: Inverted lower eyelids, blepharospasm, epiphora, protophobia, eye rubbing, keratoconjunctivitis, secondary corneal ulcers.
• Intersex: Nearly normal female or male at birth. After puberty, genitalia are ambiguous with small teats, a short penis or an enlarged clitoris, hypospadias, increased anogenital distance, cryptorchidism, and varying degrees of masculinization. Type of gonadal tissue and tubular genitalia varies with the condition.

CAUSES AND RISK FACTORS

Genetic
Arthrogryposis (Merino, Suffolk), cerebellar atrophy (Border Leicester, Corriedale), dwarfism or achondroplasia (Norwegian, Merino, Southdown, Dorset, Blackface, Cheviot), prognathia, brachygnathia, atresia ani, patent foramen ovale, patent ductus arteriosus, spider lamb syndrome or chondrodysplasia (black-faced breeds), ceroid lipofucsinosis (South Hampshire), muscle dystrophy, muscle hyperplasia, hypotrichosis congenita, congenital hypothyroidism, epitheliogenesis imperfecta, epidermolysis bullosa (Suffolk, North Dorset), collagen dysplasias (Dala, Border-Leicester crosses), hydronephrosis, polycystic kidneys, unilateral agenesis, renal fibrosis (Southdown), mesangiocapillary glomerulonephritis (Finnish Landrace), cryptorchidism, entropion (Boer, Charolais, Texel).

Viral
Bunyavirus (Cache Valley virus, Akabane virus, Rift Valley fever virus, Nairobi sheep disease virus), Border disease virus, Schmallenberg virus, bluetongue virus.

Toxic Plants
Locoweeds (*Astragalus* spp., *Oxytropis* spp.), skunk cabbage (*Veratrum californicum*), tree tobacco (*Nicotiana glauca*), poison hemlock (*Conium maculatum*).

Nutritional
Copper deficiency, selenium/vitamin E deficiency

Risk Factors
• Nutritional, social or environmental stress (viral)
• Seasonal presence of vectors and geographic location (viral)
• Presence of toxic plants (toxic)
• Use of genetic carrier dams or sires in breeding programs (genetic)
• Inappropriate nutrition or soil and plant deficiencies (nutritional)

CONGENITAL DEFECTS: SMALL RUMINANT (CONTINUED)

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Facial deformities: Bluetongue virus, Bunyavirus, Border disease virus, locoweeds, skunk cabbage, spider lamb syndrome, dwarfism.
• Neurologic signs: Border disease virus, Bunyavirus, Schmallenberg virus, bluetongue virus, skunk cabbage, ceroid lipofucsinosis, genetic cerebellar atrophy, copper deficiency.
• Muscular disorders: Selenium/vitamin E deficiency, muscle dystrophy, muscle hyperplasia.
• Spinal defects: Bunyavirus, bluetongue virus, Schmallenberg virus, skunk cabbage, poison hemlock, tree tobacco, spider lamb syndrome.
• Bowed legs: Chondrodysplasia, dwarfism, locoweeds, parbendazole administration at 12–24 days' gestation, copper deficiency.
• Arthrogryposis: Bunyavirus, bluetongue virus, Border disease virus, Schmallenberg virus, tree tobacco, locoweeds, poison hemlock, spider lamb syndrome, recessive gene in Merinos and Suffolks.
• Skin or hair abnormalities: Hypotrichosis congenita, congenital hypothyroidism, Border disease, epitheliogenesis imperfecta, epidermolysis bullosa, collagen dysplasias.
• Ambiguous sex phenotype or intersex: Male pseudohermaphrodite, true hermaphrodite, freemartinism, persistent Mullerian duct syndrome, polled intersex (XX sex reversal), testicular hypoplasia.

OTHER LABORATORY TESTS
Serology, microbiology

IMAGING
• Hydrops and enlarged fetal heart on transabdominal ultrasound with locoweed toxicity.
• Multiple irregular islands of ossification in the elbow, shoulder, and sternum on radiographs with spider lamb syndrome.

OTHER DIAGNOSTIC PROCEDURES
• Necropsy and gross examination
• Histopathology
• Antibody detection in fetal fluids, maternal serum, or precolostral lamb serum (viral)
• Viral isolation from fetal blood, antigen capture ELISA (Border disease virus)
• PCR on fetal brainstem (Schmallenberg virus)
• Identification of toxic plants
• Detection of swansonine in blood within 2 days of ingestion (locoweeds)
• Karyotype (intersexes)

PATHOLOGIC FINDINGS
• Varies with the condition.
• See "Physical Examination Findings" for gross abnormalities in lambs and kids.

TREATMENT

THERAPEUTIC APPROACH
N/A

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Cesarean section may be indicated due to impossibility to deliver severely malformed fetuses vaginally.
• Entropion may be surgically corrected. Lambs and kids should not be used for reproduction.

MEDICATIONS

DRUGS OF CHOICE
N/A

CONTRAINDICATIONS
Avoid using modified-live virus or attenuated vaccines against BVDV in small ruminants (Border disease virus).

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Prognosis is poor for life and normal development with severe malformations.
• Cull affected animals. For genetic conditions, cull dams and sires.

POSSIBLE COMPLICATIONS
Dystocia due to fetal malformations, possibly followed by retained fetal membranes and metritis.

CLIENT EDUCATION
• If >1% of lambs or kids are born with similar congenital defects, call a veterinarian to investigate the cause.
• If a genetic component is identified, the dam and sire of the affected lambs and kids should be culled. Even if normal in appearance, these animals may be carriers of the gene.

PATIENT CARE
N/A

PREVENTION
• Optimize the herd's health status.
• Reduce exposure to vectors (Bunyavirus).
• If available, vaccinate susceptible animals (Bunyavirus).
• Test and cull affected animals.
• Test and quarantine new additions to the herd.
• Separate sheep from cattle (Border disease).
• Keep pregnant animals off pastures with toxic plants.
• Cull dam and sire from animals affected by genetic conditions.
• Nutritional supplementation of pregnant animals.

CONGENITAL OCULAR DISORDERS

BASICS

OVERVIEW
• Congenital disorders are abnormalities that exist at birth, regardless of cause.
• These may be inherited, due to incidental errors of development, or result from intrauterine infection, deficiency, or teratogen exposure.

INCIDENCE/PREVALENCE
Typically sporadic and rare; however, disorders with a hereditary component can achieve a high prevalence in poorly managed flocks or herds.

GEOGRAPHIC DISTRIBUTION
Worldwide, although disorders with toxic or infectious influences may be regional.

SYSTEMS AFFECTED
• Ophthalmic
• Nervous
• Musculoskeletal

PATHOPHYSIOLOGY
• Vitamin A: Vitamin A allows regeneration of rhodopsin in the retina and normal function of osteoclasts/osteoblasts, epithelial tissues, and the choroid plexus. Deficiency occurs in cattle consuming poor-quality diets and drought-stressed forages, with restriction of green feed. Vitamin A deficiency during pregnancy causes abnormal cranial development in calves, with narrowing of the optic canals and constriction of the optic nerves. Microphthalmia and limb anomalies can also occur. Thickening of the arachnoid and dura results in impaired CSF absorption, increased CSF pressure, and hydrocephalus.
• Cyclopia, the presence of a single central eye, occurs in sheep ingesting *Veratrum californicum* (California false hellebore) on day 14 of gestation. The plant grows mainly in mountainous areas with moist/swampy conditions above 5,000 ft. The prosencephalon of affected lambs does not cleave; there is one midbrain/optic nerve and optic canal. Systems affected by *V. californicum* depend on the day of gestation that exposure occurs. Spontaneous cyclopia is occasionally reported in crias.
• Entropion describes inversion of the eyelid (typically the lower). This can be congenital, hereditary, or acquired (dehydration). Cornea-lid contact can result in ulceration, blepharospasm, and lacrimation.
• Ectropion describes eversion of the eyelid (typically the lower), and can be congenital, hereditary, or acquired.
• Congenital cataracts describe the presence of lens opacities at birth. The disorder is hereditary in some bovine breeds, with prevalence up to 34%. Accompanying abnormalities include retinal detachment, microphakia, and hydrocephalus. Other causes include in utero BVDV exposure, and exposure to electromagnetic fields.
• Microphthalmia and anophthalmia occur when one or both eyes are small or absent. Depending on severity, there may not be visual deficits. It is congenital or hereditary, and has been observed with concurrent intraocular anomalies in lambs grazing seleniferous pasture.

HISTORICAL FINDINGS
May reflect exposure to causes and risk factors for congenital ophthalmic disease.

SIGNALMENT
Most congenital ocular disorders are observed at birth or shortly after. Entropion and cyclopia are more frequent in lambs, and congenital cataracts, microphthalmia, and blindness associated with vitamin A deficiency more frequent in calves.

PHYSICAL EXAMINATION FINDINGS
• Calves with vitamin A deficiency show weakness, anorexia, intermittent fever, ill-thrift, blindness, diarrhea, and pneumonia. Dilated, unresponsive pupils and a domed forehead are evident. Papilledema develops and the optic disc becomes pale with indistinct borders.
• Cyclopia is marked by a single central eye, and microphthalmia and cleft palate can occur.
• Entropion induces blepharospasm, epiphora, corneal ulceration, conjunctivitis, and corneal edema with an inverted eyelid; ectropion appears similarly but with an everted eyelid.
• Congenital cataracts create uni- or bilateral white intraocular opacities, typically visible to the naked eye; other congenital disorders may be evident.
• Microphthalmia reflects unusually small palpebral fissures and eyes, typically bilaterally, with entropion and corneal damage.

GENETICS
• A hereditary component for congenital cataracts has been described for Holstein-Friesians, Herefords, Jersey, and Brown Swiss cattle, as well as New Zealand Romney sheep.
• Entropion likely has a heritable component in some breeds, including Boer goats, Simmental cattle, and Hampshire sheep.
• Microphthalmia with a hereditary component is described in Japanese Black cattle, Texel sheep, Hereford cattle, Jersey calves, and White shorthorn cattle.

CAUSES AND RISK FACTORS
• Vitamin A deficiency arises with lack of green feed, poor-quality forages, cereal grains, beet pulp, and cottonseed hulls. Disease conditions and growth increase requirement. Prolonged feeding of mineral oil can decrease vitamin A absorption.
• Exposure to *V. californicum* on day 14 of gestation (cyclopia) or seleniferous pastures (microphthalmia).
• Prematurity, dehydration, sepsis, or eyelid malformation (entropion).
• Intrauterine BVDV exposure between days 79 and 150 of gestation, and exposure to electromagenetic fields influence congenital cataracts in cattle.
• Heritable predispositions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Vitamin A deficiency can be differentiated from polioencephalomalacia or salt poisoning by assessing pupillary light responses; absent in vitamin A deficiency due to retinal degeneration, and intact in the other disorders.
• Disorders that cause corneal damage or infection (entropion, ectropion) must be differentiated from traumatic ocular injury, corneal infection with *Chlamydia* or *Mycoplasma*, foreign body irritation, and ectopic cilia.
• Schmallenberg virus, bluetongue virus and Akabane virus can cause similar clinical signs in calves to BVDV infection; however, the presence of congenital cataracts is suggestive of fetal BVDV exposure.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Assay vitamin A/carotene in plasma and feed or liver samples.
• Culture/sensitivity and cytology of corneal lesions.
• BVD testing (cataracts, microphthalmia).

IMAGING
Ultrasonography and/or computed tomography can assist evaluation of ocular and cranial structures in complicated disorders.

OTHER DIAGNOSTIC PROCEDURES
Complete ophthalmic examination with fluorescein staining and assessment of the fundus where indicated, combined with assessments of cranial nerve function.

PATHOLOGIC FINDINGS
• Gross abnormalities are readily evident in microphthalmia, entropion, ectropion, and cyclopia.
• Calves with vitamin A deficiency have narrowing of bony foramina of the skull, closure of the optic foramen, possibly with transection of optic nerve. Retinal hemorrhage, enlargement of the carpi, and cerebellar/cerebral compression may be evident. Microscopically, the optic nerves display necrosis, demyelination, and fibrosis. Retinal atrophy and gliosis of the ganglion cell layer and the nerve fiber layer may occur.

CONGENITAL OCULAR DISORDERS (CONTINUED)

• Congenital cataracts related to BVDV infection may be accompanied by cerebellar hypoplasia, bilateral microphthalmia, retinal degeneration, and optic neuritis with combinations of brachygnathism, hypotrichosis, hydrocephalus, or microencephaly.

TREATMENT

THERAPEUTIC APPROACH
Euthanasia is indicated for severe congenital anomalies that result in blindness or which are associated with other significant disorders.

SURGICAL CONSIDERATIONS AND TECHNIQUES
Rarely indicated with the exception of entropion and ectropion, which may require surgical intervention when severe. Entropion can be corrected with temporary tacking sutures/horizontal mattress sutures, or a modified Hotz-Celsus resection. Ectropion often requires surgical correction, with a V-to-Y blepharoplasty.

MEDICATIONS

DRUGS OF CHOICE
• Adult cattle with vitamin A deficiency may respond to 440 IU/kg of vitamin A parenterally followed by 6,000 IU/kg every 2 months; diet should be enriched.
• Any underlying cause for entropion should be addressed (dehydration). Corneal ulceration in ectropion or entropion can be treated with topical ophthalmic antibiotics and atropine if necessary for miosis. The lid can be everted by injecting 0.5–1 mL of procaine penicillin G subcutaneously immediately below the eyelid margin.

CONTRAINDICATIONS
• Surgical correction is contraindicated for entropion secondary to temporary causes such as dehydration.
• Topical corticosteroids are contraindicated when corneal ulceration is present.
• Surgical correction of any disorder with a possible heritable component is discouraged unless necessary for function or pain relief, and breeding of that animal is contraindicated.

PRECAUTIONS
• Aggressive surgical correction of entropion can create ectropion.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Prognosis is poor for severe and complicated congenital ocular disorders.
• Animals with potentially heritable disorders, even if mild (entropion), should ideally be culled or excluded from breeding.

POSSIBLE COMPLICATIONS
Disorders that expose or traumatize the cornea (entropion, ectropion, microphthalmia) can create severe discomfort, corneal ulceration, corneal rupture, and permanent blindness if not addressed promptly.

CLIENT EDUCATION
Focus on breeding management for potentially heritable disorders.

PATIENT CARE
Repeat monitoring of the cornea using intermittent fluorescein stain and evaluation of the lids is indicated for disorders where corneal compromise is likely.

PREVENTION
• Maintain appropriate concentrations of vitamin A in adult and calf rations.
• Avoid exposure to toxic plants and infectious diseases during gestation.
• Monitor neonates and young stock for signs of ocular discomfort and discharge.
• Remove any animals that might have a heritable disorder from the breeding pool.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Several ocular congenital disorders including cyclopia, vitamin A deficiency, and microphthalmia are accompanied by structural and functional anomalies of the skull, limbs, and CNS. Animals with congenital ocular disorders should be carefully assessed for anomalies of other body systems.

AGE-RELATED FACTORS
Most disorders are evident at birth or in the first week of life.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
A controlled ration with no vitamin deficiencies, and avoiding exposure to toxic plants and infectious diseases is critical during pregnancy.

BIOSECURITY
• Avoid mixing pregnant animals, especially early in gestation.
• Vaccinate appropriately pre-breeding (especially for BVDV), quarantine new arrivals, and purchase from a known source.

PRODUCTION MANAGEMENT
• Prophylactic dietary supplementation with vitamin A should be provided to all cattle lacking green feed access. Recommended concentrations of vitamin A in feed (IU/kg dry matter) are 2,200 IU for feedlot cattle, 2,800 IU for pregnant cows, 3,900 IU for lactating cows, and 11,000 IU in pre-ruminant calf milk replacer.
• Avoid grazing fields with *V. californicum* during the first trimester of pregnancy.
• Breeding combinations that consistently produce offspring with entropion or other anomalies should be avoided.

SYNONYMS
N/A

ABBREVIATION
BVDV = bovine viral diarrhea virus

SEE ALSO
• Bovine Viral Diarrhea Virus

CONTAGIOUS BOVINE PLEUROPNEUMONIA

BASICS

OVERVIEW

• Contagious bovine pleuropneumonia (CBPP) is a highly contagious bacterial disease of cattle and related ruminants resulting in severe, acute fibrinous pneumonia and occasionally polyarthritis.
• The causative agent is *Mycoplasma mycoides mycoides* (Mmm), formerly designated as small colony (SC) type.
• In Africa, causes greater economic losses in cattle than any other disease.
• OIE List A disease; reportable.

INCIDENCE/PREVALENCE

• Incidence of CBPP varies by country.
• Two major strain clusters exist; African strains may exhibit 30–90% morbidity and 10–90% mortality, while European strains exhibit 10–50% morbidity and 5–30% mortality.

GEOGRAPHIC DISTRIBUTION

• Endemic in much of subSaharan Africa.
• Also present sporadically in Asia, particularly the Middle East, Malaysia, and Mongolia.
• Europe has been free since 2004.
• North America and the western hemisphere are free of CBPP.
• Reported in 26 countries in 2014.

SYSTEMS AFFECTED

• Respiratory
• Musculoskeletal
• Urinary
• Reproductive

PATHOPHYSIOLOGY

• Transmission is via aerosol droplet from clinically affected or carrier animals.
• Carrier animals can shed the organism intermittently in respiratory secretions for months to years following recovery from clinical disease.
• Mycoplasmas transit the lung and mycoplasmemia distributes organism to multiple organs including kidney, joints, udder, and uterus.
• Mycoplasmas can be shed in respiratory secretions, urine, milk, seminal fluid, and birth fluids.
• Transplacental transmission can occur.
• The incubation period is 3–12 weeks post-exposure.
• Up to 50% of cases are subclinical.

SIGNALMENT

• Bovine: *Bos indicus* and *Bos taurus*
• Other susceptible species: yak, bison, antelope, reindeer, water buffalo
• Rarely, sheep and goats
• Camels are resistant

PHYSICAL EXAMINATION FINDINGS

• Acute disease:
  ◦ Fever, depression, anorexia, decreased lactation.
  ◦ Cough, exercise intolerance.
  ◦ Tachypnea, dyspnea, standing with elbows abducted.
  ◦ Pleurisy.
  ◦ Friction rubs, dullness or crackles on thoracic auscultation.
  ◦ Open-mouth breathing.
  ◦ Lameness and joint effusion in calves.
  ◦ Death may occur in 1–3 weeks.
• Subacute disease:
  ◦ Mild fever, inappetence, mild tachypnea, ± cough.
  ◦ Subacute cases usually recover.
• Chronic disease:
  ◦ Poor doers, emaciation, chronic cough.
• Subclinical cases also occur.
• Up to one-third of recovered animals may become chronic carriers and shed organism intermittently for years from pulmonary sequestrae.

CAUSES AND RISK FACTORS

• Caused by *Mycoplasma mycoides mycoides* (Mmm), a fastidious mycoplasma maintained in carrier cattle.
• Mmm is never considered a commensal.
• Mmm is not likely to be isolated from routine aerobic culture; index of suspicion must be present and specific testing requested.
• Risk factors include:
  ◦ Exposure to carrier or clinically ill animals.
  ◦ Crowded conditions.
• Herd movement into an endemic area, common in pastoral and migratory cultures.
• Herd manager knowledge of CBPP is vital for effective control.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Pasteurellosis
• *Mannheimia haemolytica*
• *Mycoplasma bovis*
• *Histophilus somni*
• BVDV
• BRSV
• IBR
• PI3
• Hardware disease/traumatic reticulopericarditis
• East coast fever
• Bovine ephemeral fever
• Bovine farcy
• Hydatid cyst
• Actinobacillosis
• *Mycobacterium bovis*

CBC/BIOCHEMISTRY/URINALYSIS

Inflammatory leukograms are often present in acutely affected animals.

OTHER LABORATORY TESTS

• Mycoplasmas lack cell walls and are too small to see with light microscopy, so conventional staining techniques are unhelpful.
• Mmm is fastidious and slow-growing; fresh clinical samples should be submitted in transport media to a diagnostic laboratory for culture.
• Specific mycoplasma culture must be requested, as Mmm requires specific media and growth conditions not present in routine aerobic culture.
• Culture of the organism from clinical samples is the standard of diagnosis.
• Antemortem samples may include pleural fluid, tracheal wash, bronchoalveolar lavage, urine, milk, synovial fluid, or placental tissue.
• Nasal swabs are not ideal, as many subclinical or chronic cases have negative nasal swabs.
• Postmortem samples may include fresh lung, pleural fluid or tissue, synovium, or kidney.
• Serologic tests are primarily useful on a herd basis.
  ◦ Complement fixation test (CFT).
  ◦ Dot blot or Western blot may be more sensitive than CFT in some situations.
  ◦ Latex agglutination may be more sensitive in early disease.
  ◦ An ELISA field test is available.
  ◦ No single serologic test reliably detects animals in all stages of disease.
  ◦ Acute and convalescent sera should be evaluated.
• Polymerase chain reaction on lung, pleural fluid, urine, and cultured colonies.
• Histopathology.
• Immunohistochemistry.

IMAGING

• Imaging techniques are not commonly used.
• Radiographs could reveal evidence of pleural effusion and pulmonary consolidation.
• Ultrasound could demonstrate pleural fluid and guide transthoracic sampling.

PATHOLOGIC FINDINGS

• Pulmonary lesions are frequently unilateral.
• Acute disease:
  ◦ Pleuritis and pneumonia with copious fibrin-rich yellow pleural fluid.
  ◦ Lung tissue is marbled in appearance due to distended interlobular septae.
  ◦ Mediastinal lymph nodes are enlarged and petechiated.
  ◦ Alveolar spaces are infiltrated by edema fluid and accumulations of leukocytes. Fibrin thrombi are evident with intense inflammatory infiltrate and necrosis of alveolar septae.
  ◦ Renal infarcts may be seen.
  ◦ In polyarthritis, copious fibrinous fluid is found within large joints.
• Chronic lesions:
  ◦ Sequestrae in pulmonary tissue are encapsulated with fibrosis.
  ◦ Lymphocytic infiltration with thickening along interlobular septae, fibrosis of interlobular septae, and coagulative necrosis of lobules.
  ◦ Calves may have endocarditis.

CONTAGIOUS BOVINE PLEUROPNEUMONIA (CONTINUED)

• Acute through chronic stages are common in the same animal.

TREATMENT

THERAPEUTIC APPROACH

• Countries with control programs in place may prohibit the treatment of CBPP; slaughter may be mandated.
• While antibiotic treatment may not cure infected animals, it dramatically reduces transmission to susceptible animals and may have a role in outbreak control.

MEDICATIONS

DRUGS OF CHOICE

• No controlled field studies have been done comparing efficacy of antibiotics in naturally infected herds.
• *Mycoplasma mycoides mycoides* is susceptible in vitro to a variety of antimicrobials, including quinolones, tilmicosin, tetracyclines, tylosin, florfenicol, tulathromycin, and streptomycin.
• Mycoplasmas are universally resistant to beta-lactams because they lack a cell wall.
• Danofloxacin (2.5 mg/kg for three consecutive days) has been demonstrated to reduce shedding and decrease infection rates in in-contact naïve cattle.

CONTRAINDICATIONS

• Treatment of CBPP may be prohibited; many countries mandate slaughter of infected animals.
• Antimicrobial therapy may favor the formation of sequestrae and create a carrier state.

PRECAUTIONS

Always follow local laws regarding use and withdrawal of antimicrobials in food animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Chronically affected animals may be poor doers and become progressively emaciated.

POSSIBLE COMPLICATIONS

Up to one third of recovered animals may become long-term carriers.

PATIENT CARE

Monitor for signs of hypoxia and severe dyspnea; if advanced treatment is not available, euthanasia may be appropriate for distressed animals.

PREVENTION

• Two live attenuated vaccines are available, T1/44 and T1/SR.
• In Africa, vaccination against CBPP remains the primary control option.
• Vaccine performance is suboptimal. Low efficacy (33–67%) and a short duration of immunity (6–12 months) are continuing problems.
• Vaccination often generates an extensive tissue reaction, especially primary vaccination or revaccination after a lapse in coverage. Because of this the vaccine is often given in the tail tip, which may become necrotic and slough. Fatal vaccine reactions have occurred.
• Quarantine of farms with testing and slaughtering of animals can provide effective control in the event of an outbreak.
• In endemic areas, uncontrolled or illegal movement of cattle facilitates the spread of disease.
• Vaccination of at-risk or exposed animals may help control an outbreak.
• Serologic testing and quarantine of animals for importation is recommended.

MISCELLANEOUS

ZOONOTIC POTENTIAL

• CBPP is not zoonotic.
• *M. mycoides mycoides* does not constitute a food safety threat.

PREGNANCY

Transplacental transmission can occur.

BIOSECURITY

• CBPP is reportable in many countries.
• Isolating infected herds and restricting movement of animals is imperative to control the spread of disease.
• Separation between animals of 6 meters is considered sufficient to stop droplet transmission.
• Two negative serologic tests two months apart are recommended to verify negative status; however, carriers may be seronegative.
• Animals recovered from clinical disease may be long-term intermittent shedders of the organism.
• *M. mycoides mycoides* survives well in vivo, but is quickly inactivated by external environmental conditions; fomite transmission is unlikely.
• Mmm is susceptible to all common disinfectants.

CONTAGIOUS CAPRINE PLEUROPNEUMONIA

BASICS

DEFINITION
Contagious caprine pleuropneumonia (CCPP) is an extremely contagious bacterial disease of goats resulting in severe, acute pneumonia with high mortality. CCPP is one of the most devastating diseases of goats worldwide.

INCIDENCE/PREVALENCE
• Incidence for CCPP varies worldwide.
• Morbidity often reaches 100% and mortality may be 70–100% in naïve herds.

GEOGRAPHIC DISTRIBUTION
CCPP is considered endemic in east Africa, Asia, and the Middle East. Isolation of the causative agent is difficult and clinical signs can resemble other pneumonias so the actual distribution in these regions is unknown.

SYSTEMS AFFECTED
Respiratory

PATHOPHYSIOLOGY
The bacterial agent *Mycoplasma capricolum capripneumoniae* (*Mccp*, formerly mycoplasma biotype F-38) is extremely contagious and is spread through respiratory secretions from infected goats, resulting in severe respiratory disease and mortality in a naïve herd. Disease caused by *Mycoplasma capricolum capripneumoniae* is limited to the respiratory system. Infection with *Mycoplasma mycoides capri* or other related organisms can occur but demonstrate additional extrarespiratory signs. Secondary infections with other viral pneumonias complicate disease presentation and diagnosis.

HISTORICAL FINDINGS
A severe respiratory disease in goats with high morbidity (100%) and mortality (may approach 100%) within 7–10 days after clinical disease onset. CCPP may present as peracute (animals die within a few days), acute, subacute, and chronic.

SIGNALMENT
• Caprine.
• Sheep may be affected in mixed herds.
• Wild ruminants have been diagnosed.

PHYSICAL EXAMINATION FINDINGS
• CCPP is limited to the respiratory tract. Animals acutely infected with *Mycoplasma capricolum capripneumoniae* present with high fever (106°F), cough, labored breathing, weakness, and anorexia, leading to exercise intolerance and respiratory distress. Goats will stand with legs spread, neck extended downward, and tongue protruded.
• Frothy nasal discharge and continuous stringy salivation appear shortly before death.
• Infection with *Mycoplasma mycoides capri* results in a more generalized infection with respiratory signs as well as lesions beyond the respiratory system.

CAUSES AND RISK FACTORS
• *Mycoplasma capricolum capripneumoniae* causes CCPP.
• Other related organisms, such as *Mycoplasma mycoides capri*, cause a similar condition, sometimes considered a less common form of CCPP, in goats. However, lesions are not limited to the respiratory tract.
• Disease is spread through direct contact and inhalation of infective aerosols.
• A subclinical carrier state in some survivors is suspected but has not been demonstrated.
• Introduction of infected animals into previously uninfected herds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
Peste des petits ruminants, pasteurellosis, other *Mycoplasma* spp. such as *Mycoplasma mycoides capri* pneumonias, and *Salmonella* spp.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Serologic tests such as complement fixation, latex agglutination, indirect hemagglutination, and ELISA can be used, particularly on a herd basis. In an outbreak, animals often die before measurable titers are obtained.
• PCR is the technique of choice for CCPP diagnosis and can be applied to postmortem lung tissues and pleural fluid.
• Confirmatory diagnosis is made by culturing the agent from lung, pleuritic fluid, swabs of major bronchi, and tracheobronchial or mediastinal lymph nodes.

PATHOLOGIC FINDINGS
• With *M. capricolum capripneumoniae* infection, one or both lungs may be affected and may be adhered to the thoracic wall due to thickened pleura, with straw-colored fluid in the thoracic cavity. The lungs will have a fibrinous pneumonia and may have pea-sized, yellow-colored nodules with congestion surrounding the nodules. An entire lobe may become solidified or develop massive hepatization. Thickening of the interlobular septa, as seen in bovine pleuropneumonia, is not usually observed in goats.
• Histopathology reveals serofibrinous to fibrinonecrotic pleuropneumonia with infiltrates in the alveoli, bronchioles, interstitial septae, and subpleural connective tissue.
• Peribronchial lymphoid hyperplasia with mononuclear cell infiltration may also be seen.

TREATMENT

THERAPEUTIC APPROACH
• Veterinarians who suspect this disease should follow the regulatory guidelines for their country/locality. In many countries CCPP is a disease reportable to veterinary authorities.
• Due to the contagious nature of this disease, affected animals should be isolated and the entire herd placed under quarantine.

MEDICATIONS

DRUGS OF CHOICE
• Macrolides, tetracyclines, and quinolones are reportedly active against *M. capricolum* subsp. *capripneumoniae*. However, in many countries, including in North America, CCPP is a reportable disease and treatment may not be an option. It is not known whether treated animals could still spread the disease or develop a subclinical carrier status.

CONTRAINDICATIONS
Observation of drug withdrawal periods for meat and milk are important when using antibiotic agents.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Acute disease has a morbidity of 70–100% with mortality reaching 100% in some goat herds.

POSSIBLE COMPLICATIONS
It is suspected, but not confirmed, that recovered goats could potentially maintain a subclinical carrier status, leading to exposure of susceptible animals.

CLIENT EDUCATION
Clients should be made aware of the seriousness of CCPP and the contagious aspects and that the disease may have regulatory consequences. Clients can be encouraged to practice good biosecurity practices, such as isolation of new animals, to help prevent introduction of any contagious diseases onto their premises.

PATIENT CARE
• Monitor animals for signs of labored breathing and nasal discharge to ensure a patent airway.
• Affected animals should be isolated and activity restricted because of the exercise intolerance due to the severe respiratory disease.
• Maintain a good plane of nutrition with fresh food and water daily.

CONTAGIOUS CAPRINE PLEUROPNEUMONIA (CONTINUED)

PREVENTION

• A lyophilized saponin-inactivated *Mccp* vaccine is commercially available. Vaccination is reported to have good to excellent success in preventing disease.
• Testing, slaughter of infected animals, vaccination, cleaning and disinfection of infected premises, animal movement control, and quarantine are some of the strategies used to control the disease in endemic countries.

MISCELLANEOUS

ZOONOTIC POTENTIAL

CCPP is not known to be a zoonotic disease.

BIOSECURITY

Isolating infected animals is imperative for the control of this disease. Testing, slaughter of infected animals, vaccination, cleaning and disinfection of infected premises, animal movement control, and quarantine are some of the strategies used to control the disease in endemic countries.

COPPER DEFICIENCY AND TOXICITY

BASICS

OVERVIEW

• Copper (Cu) is an essential trace element involved in multiple enzyme systems throughout the body. Failure of these enzyme systems interferes with growth and cellular functions, and can result in significant clinical disease.
• Cu plays a necessary role in iron (Fe) metabolism, elastin and collagen formation, bone formation, melanin production, hemoglobin synthesis, myelination of the spinal cord, and antioxidant functions. It is also necessary for normal reproductive and immune function.
• The liver is considered the key organ in Cu metabolism, storage, and excretion.
• Ruminants store Cu in the liver during periods of excess intake and deplete Cu from the liver when intake is low.
• Cu can be toxic if consumed in excessive or unbalanced amounts in feed, via inadvertent ingestion of other copper sources, or with iatrogenic administration of excessive Cu.
• Several other elements have a negative impact on Cu absorption and metabolism including molybdenum (Mo), sulfur (S), iron (Fe), and zinc (Zn). The negative interactions between Cu and these elements significantly affect Cu availability and animal requirements, and can influence the development of Cu deficiency or toxicity.

INCIDENCE/PREVALENCE

• Cu deficiency is uncommon, but is generally associated with specific geographic regions with suboptimal soil conditions (such as in marshy, peaty, or coastal land).
• Cu toxicity is also uncommon; however, a high prevalence can occur in flocks or herds exposed to excessive dietary Cu or other sources of Cu.

GEOGRAPHIC DISTRIBUTION

• Worldwide, influenced by species distribution, soil factors and management systems.
• Cu deficiency is heavily influenced by soil type and is common under natural grazing conditions in Australia, New Zealand, the Netherlands, and the UK, in areas with sandy and limestone soils, and washed-out soils that have low Cu concentrations, resulting in low plant Cu concentration. Reclaimed swamps or peat bogs are often high in Mo.
• Many areas in the United States and Canada are also Cu deficient; however, there can be tremendous variation in Cu soil content within a small region, and even on a given property.

SYSTEMS AFFECTED

Deficiency:
• Integument
• Nervous
• Digestive
• Musculoskeletal
• Cardiovascular
• Hemolymphatic
• Reproductive

Toxicity:
• Digestive
• Cardiovascular
• Hemolymphatic

PATHOPHYSIOLOGY

• Cu is involved in a variety of critical enzyme systems including superoxide dismutase, cytochrome oxidase, lysyl oxidase, ascorbic acid oxidase, and ceruloplasmin. Adequate Cu is also required for iron metabolism and the prevention of cellular oxidative damage. Decreased function of these systems can propagate a wide variety of clinical syndromes that can vary depending on the species and age of the affected animals.
• Primary Cu deficiency arises due to insufficient copper in the diet of the pregnant ewe/doe (congenital deficiency) and/or the diet of the growing lamb/kid (delayed deficiency). Plant copper concentrations <5 mg/kg DM are dangerous and <3 mg/kg DM are likely to result in primary Cu deficiency. Cu-deficient soils are generally sandy and of poor quality.
• Secondary Cu deficiency occurs when dietary concentrations of molybdenum (most commonly), sulfur (occasionally), or iron or zinc (rarely) are high. These minerals compete with Cu uptake and increase excretion of Cu from the body. Secondary deficiency is more likely to occur in grazing adult animals. Forage concentrations of Mo >10 mg/kg are associated with secondary Cu deficiency. Peaty soils are more often associated with excess Mo. S-containing fertilizers may exacerbate Cu deficiency.
• Acute Cu toxicosis is rare and results from ingestion or administration of a large amount of Cu (usually as a soluble copper salt) in a short period of time. This is most common in cattle and occasionally goats.
• Chronic Cu toxicosis is more common and results from chronic ingestion of excess dietary Cu, or rations with a high Cu : Mo ratio (>10:1 for sheep) resulting in slow accumulation of Cu in the liver. Once a threshold is reached, or alternatively a hepatotoxic incident occurs, large quantities of Cu are suddenly liberated from the liver. High serum Cu concentrations then provoke a hemolytic crisis which results in hemoglobinemia, hemoglobinuria, methemoglobinemia, and anemia, with severe systemic disease and a high likelihood of mortality. This is most likely to occur in sheep.

HISTORICAL FINDINGS

Identifies factors related to soil or plant management that could provoke Cu deficiency, or alternatively, identifies potential sources of exposure to excessive Cu.

SIGNALMENT

• Potentially all ruminant species can suffer from deficiency or toxicity.
• Sheep are most susceptible to Cu toxicity.
• Adult cattle are more resistant to Cu toxicity than younger cattle.
• Young cattle are most susceptible to Cu deficiency.
• Young lambs and kids are susceptible to neurologic disease with Cu deficiency.

PHYSICAL EXAMINATION FINDINGS

Copper Deficiency

• Signs of deficiency are variable and affect a large number of body systems.
• Signs of anemia can arise because decreased ceruloplasmin impairs iron oxidation and decreased delta-aminolevulinic acid dehydratase impairs heme synthesis. This causes alterations of the protein skeleton of the erythrocyte resulting in delayed maturation and decreased lifespan of erythrocytes. Anemia can result in decreased production parameters, lethargy and ill thrift.
• Poor hair/fiber quality occurs because of impaired keratinization of the hair or wool, causing a long rough hair coat, or the formation of poorly crimped, "steely" wool. Hair changes indicate late stage Cu deficiency.
• Hypochromotrichia arises from decreased tyrosinase activity causing morphologic and functional changes in melanocytes with lightening of the hair coat color. It is typically most evident in black cattle with the formation of lighter-colored hair on the face around the eyes, or a reddish-orange tinge may be seen behind the shoulder and on the lower hair coat.
• Ataxia in neonatal or juvenile kids and lambs arises because decreased cytochrome oxidase and superoxide dismutase activity in utero causes oligodendrocyte dysfunction and hypomyelination of nerves.
• Reproductive failure represented by decreased fertility, delayed or depressed estrus, fetal death and resorption, and decreased semen quality can occur.
• Pathologic fractures and lameness can arise from decreased lysyl oxidase activity creating increased bone fragility, irregular thickness of the physis, and joint deformation.
• Increased susceptibility to infectious diseases occurs because a decline in superoxide dismutase and cytochrome oxidase provoke decreased number and function of both neutrophils and lymphocytes.
• Diarrhea occurs because decreased cytochrome oxidase activity leads to mitochondrial changes in the intestine resulting in crypt elongation, goblet cell hyperplasia, and villous and mucosal atrophy.
• Poor growth and/or loss of body weight is observed.

Copper Toxicosis

• Acute Cu toxicosis can present with salivation, colic, diarrhea, convulsions,

COPPER DEFICIENCY AND TOXICITY (CONTINUED)

paralysis and collapse, related to severe irritation to the GI tract. Hemolysis can follow in animals that survive the acute consequences.
• Chronic Cu toxicosis can result in anorexia and weakness, and signs relating to intravascular hemolysis and anemia including hemoglobinuria, weakness, tachycardia, and pallor progressing to jaundice. Death occurs, and is often acute. Signs of renal failure (anuria, oliguria, or polyuria; polydipsia and edema) may occur in animals that survive the initial crisis. Goats with chronic toxicity may display neurologic signs without hemolysis.

GENETICS
• There is a strong breed component to the susceptibility of sheep to Cu deficiency. Scottish Blackface and Finnish Landrace sheep are poor utilizers of Cu and very susceptible to deficiency. Conversely, they are more resistant to Cu toxicity.
• Merino sheep are also more resistant to Cu toxicosis; however, Texel sheep require little Cu and are resistant to Cu deficiency but very susceptible to Cu toxicity.
• Simmental and Charolais cattle appear to have higher Cu requirements than Angus cattle.

CAUSES AND RISK FACTORS
Copper Deficiency
• Cu deficiency is considered a severe limitation to grazing ruminants throughout the world, and is more frequent on pastures than in feedlots.
• Cu deficiency in ruminants can result from low Cu concentration in feeds (i.e., <3 mg/kg DM) but most commonly occurs when Cu concentrations in forages are normal (i.e., 6–16 mg/kg DM) but Cu is less available due to concurrently high concentrations of Mo or S.
• Cu deficiency can occur when forage Mo concentration exceeds 3 mg/kg DM and Cu concentration is <5 mg/kg DM.
• Cu deficiency can occur under dietary conditions of low Cu (i.e., <5 mg/kg DM), low Cu and high Mo (i.e., ratio 2:1), higher Mo (i.e., >20 mg/kg DM), and normal Cu and low Mo but with high levels of soluble proteins from lush pastures.
• Overgrazing and excessive dietary calcium or zinc also decrease Cu absorption.

Copper Toxicity
• An extended period of time (i.e., weeks or months) is usually needed for development of chronic Cu toxicity.
• Sheep are considered the most sensitive domestic animal species in regard to Cu toxicity. Marked elevation of hepatic Cu was demonstrated in sheep fed diets containing Cu at 26–38 mg/kg DM whereas rats tolerated diets containing Cu concentrations as high as 500 mg/kg DM.
• Significant differences have also been shown between sheep and cattle in dietary Cu tolerance (i.e., 25 vs. 100 mg/kg DM). Adequate dietary Cu for sheep is around 5–8 mg/kg DM, and >8 mg/ kg DM can promote toxicity.
• Chronic Cu toxicity has been reported in dairy cows fed diets containing Cu at 37.5 mg/kg DM during lactation and 22.6 mg/kg DM dry cows. The minimum recommended dietary Cu concentration for cattle is 4–10 mg/kg.
• Inappropriate feeding of sheep with commercial products designed for other species (horses, cows) can result in Cu toxicity, particularly in susceptible breeds. Camelids have developed toxicosis after consuming cattle feed.
• Grazing on plants treated with fungicides, pastures fertilized with manure from Cu-fed swine or poultry, or pastures contaminated by copper smelting can create toxicity.
• Other sources of Cu that can be associated with toxicity include copper sulfate foot bath solution which might be inappropriately ingested if not properly disposed of after use. Calf milk replacer excessively supplemented with Cu can induce toxicity in calves.
• Diets with a high Cu : Mo ratio (>10:1) allow enhanced storage of Cu in the liver, due to reduced formation of Cu : Mo complexes which aid Cu excretion.
• Ingestion of hepatotoxic plants can create hepatocellular damage and increase hepatocyte affinity for Cu, which may result in toxicity even when dietary Cu intake is within acceptable limits.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Differential diagnoses for Cu deficiency can include iodine deficiency, vitamin D deficiency (rickets), sulfur deficiency, and vitamin E/selenium deficiency. Additionally, parasitism (internal and external), poor nutrition, Johne's disease, and other causes of anemia should be considered.
• Acute Cu toxicity must be differentiated from intestinal accidents, enteritis, arsenic and nitrate poisoning, and urethral obstruction.
• Differential diagnoses for chronic copper toxicity include ingestion of hemolyzing toxins or plants, and causes of chronic hepatic failure.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC might reveal microcytic, hypochromic anemia in deficiency, and hemoglobinemia, methemoglobinemia, Heinz bodies and anemia are often evident in toxicity.
• Serum chemistry in animals with Cu toxicity might show hyperbilirubinemia, increased liver enzymes, and azotemia (prerenal and/or renal origin). Both AST and GGT can be elevated in advance of a hemolytic crisis, and can be used to identify affected animals within a group for chelation therapy prior to development of more severe clinical signs.
• Urinalysis is most likely to be abnormal with hemolytic crisis of Cu toxicity, in which case, darkly discolored urine is evident due to hemoglobinuria, and urine specific gravity may be isosthenuric despite azotemia. Red cells, protein and casts in the urine reflect acute nephrosis from hemoglobin damage to the renal tubules.

OTHER LABORATORY TESTS
• Diagnosis of Cu disorders can be difficult. The liver stores Cu and will release it to maintain blood Cu concentrations and essential host functions. Consequently, measurement of blood Cu concentration overestimates body Cu stores in deficient states and underestimates body Cu stores in Cu toxicity states.
• Deficiency diagnosis—sheep
  ◦ Serum or plasma Cu (plasma Cu is ~5% higher)
    ▪ Deficient: <0.4 ppm
    ▪ Marginal: 0.4–0.7 ppm
  ◦ Erythrocyte superoxide dismutase activity
    ▪ Short-duration deficiency: youngstock <0.5, adult <0.3 mg/g hemoglobin
    ▪ Prolonged deficiency: youngstock <0.3, adult <0.2 mg/g hemoglobin
  ◦ Tissue Cu
    ▪ Liver: deficient <4.0 ppm DW
    ▪ Liver: marginal 5.0–20 ppm DW
    ▪ Fetal liver: deficient <10 ppm DW
    ▪ Wool: deficient 0.5–2.5 ppm DW
• Deficiency diagnosis—goat
  ◦ Serum Cu
    ▪ Deficient: <0.5 ppm
    ▪ Marginal: 0.5–0.8 ppm
  ◦ Tissue Cu
    ▪ Liver: deficient <10 ppm DW
    ▪ Liver: marginal 15–25 ppm DW
    ▪ Fetal liver: deficient <20 ppm DW
    ▪ Hair: deficient <3 ppm DW
• Toxicity Diagnosis
  ◦ Increased whole blood Cu concentration: 50–200 µg/dL normal, and 10–20 fold increase occurs in toxicity.
  ◦ Increased liver copper concentrations >250 ppm DM.
  ◦ Increased kidney Cu concentration >100 ppm DM.

IMAGING
Radiographs can be relevant to investigation of bony pathology associated with Cu deficiency.

OTHER DIAGNOSTIC PROCEDURES
Forage or soil concentrations of Cu, S, and Mo may be helpful adjuncts in the recognition of copper deficiency.
• Normal soils have Cu concentrations of 18–22 ppm and deficient soils generally have copper concentrations <2 ppm.
• Soil Mo concentrations >10 ppm will often precipitate secondary Cu deficiency.

(CONTINUED) # COPPER DEFICIENCY AND TOXICITY

PATHOLOGIC FINDINGS

• Chronic Cu toxicity results in a pale, friable liver, "gunmetal" kidneys, and splenomegaly. Histopathologically, there is centrilobular hepatic necrosis, hepatic fibrosis, and biliary hyperplasia. Kupffer cells contain pigment, and granules in the liver stain positive for copper on rhodanine stain. Cu concentration should be measured in both liver and kidney, since liver concentrations will decrease once a hemolytic crisis has occurred.
• Acute toxicity is marked by severe gastrointestinal inflammation. Cu concentrations in the liver and kidney may be normal in these animals, but elevated in rumen content and feces.

TREATMENT

THERAPEUTIC APPROACH

• Treating or preventing Cu deficiency can be achieved in juvenile and adult animals through a variety of means. Cu deficiency is corrected by supplementation of Cu in the diet, via inclusion in the concentrate mixture of feedlot diets, or supplementing grazing ruminants with Cu compounds through injections or oral treatments. Chelated forms (organic complexes) of Cu have higher bioavailability than inorganic sources.
• Treatment of Cu toxicity is often unrewarding. A variety of protocols exist with varying intensity of treatment and cost. Most protocols focus on methods to chelate Cu.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

• For deficiency, oral treatment with 1.5 g of Cu sulfate for ewes and 35 mg for lambs can be given as a single dose; cattle can be injected with Cu glycinate (400 mg SC to adult; 100–200 mg SC to calves) or with copper disodium edetate.
• Treating toxicity can be achieved through a variety of methods to compete with or chelate Cu. These include:
  ◦ Administration of Mo and S
    ▪ Ammonium molybdate (100 mg) and sodium sulfate (1 g) in 20 mL of water or in feed daily for 5–6 weeks (lambs)
    ▪ Sodium thiosulfate 6–20 mg/kg PO once daily for 3 weeks
    ▪ Ammonium molybdate 5–10 mg/kg or 50–500 mg PO daily for 3 weeks
    ▪ Ammonium tetrathiomolybdate 2–7 mg/kg IV or SC every 2–3 days for 3–6 treatments.
  ◦ Sodium EDTA 70 mg/kg IV daily for 2 days
  ◦ D-penicillamine 50 mg/kg PO q24h or divided q12h for 6 days (expensive)
  ◦ Vitamin E 2,000–5,000 IU PO q24h for 3 weeks (antioxidant)
  ◦ Zinc 100–200 mg/kg DM of feed decreases liver Cu accumulation
  ◦ Fluid therapy, oral or IV, should be instituted to help prevent or limit the detrimental effects of hemoglobin on renal tubules.

CONTRAINDICATIONS

• If a diagnosis of deficiency is incorrect (i.e., not supported by analysis of Cu levels in the animal), Cu supplementation may result in toxicity.
• Injectable copper can be very toxic in sheep and goats.

PRECAUTIONS

• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
• Injectable forms of Cu can cause tissue reactions and even mortality.
• Different forms of Cu have varying availability which must be taken into account when formulating mineral mixes. For example, feed grade Cu sulfate offers 25% Cu on an as-fed basis (40% DM basis) whereas feed grade Cu oxide offers 50% Cu as fed (80% DM). Salt mixtures for sheep should usually only contain 0.0625–0.13% Cu.

POSSIBLE INTERACTIONS

Cu interacts significantly with Mo, Zn, and S; hence the balance of these elements must be assessed during thorough nutritional analysis of ruminant rations.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• The prognosis for Cu deficiency is dependent on the type and severity of clinical signs. Animals with subclinical deficiency or mild clinical signs will often respond well to direct treatment of the presenting syndrome and Cu supplementation. Severely affected animals with more complicated issues, such as pathologic fractures, may require euthanasia.
• The prognosis for Cu toxicity is guarded. It is very poor in severely affected animals in hemolytic crisis, in spite of aggressive intervention. Affected cohorts with minimal or mild signs can respond to chelation and fluid therapy.

POSSIBLE COMPLICATIONS

• Renal failure is common with hemolytic crisis.
• Injections with Cu glycinate and Cu EDTA solutions can cause tissue reactions or acute death.

CLIENT EDUCATION

Provide accurate information regarding Cu requirements for the species and ages within the production system, and measures to control or prevent deficiency and toxicity (depending on which is the more relevant concern).

PATIENT CARE

N/A

PREVENTION

Deficiency

• Cu is distributed in feeds at various concentrations that can range from 1 to 50 mg/kg of dry matter (DM). The Cu content of feeds depends on geographic location of origin, soil pH, climate, crop management, and plant species, maturity, and yield. Cu concentrations are highest in legumes and clover (i.e., 15 mg/kg DM), lowest for grasses (i.e., 5 mg/kg DM), and intermediate for grains (i.e., 4–8 mg/kg DM).
• Copper oxide wire particles or rods contained within a gelatin capsule can be given orally to ruminants at risk of deficiency. Rods are liberated into the rumen and abomasum to release Cu over 4–12 months. Dosing protocols are as follows:
  ◦ Sheep: 1.25 g Cu to weaned lambs, 2.5 g Cu to adults
  ◦ Goats: 2 g Cu to kids 5 weeks of age, 4 g to does in early pregnancy
  ◦ Cattle: 12.5 g Cu to calves, 25 g for animals ≥500 lb
• Copper heptonate can be administered IM (25 mg Cu to weaned lambs and 37.5 mg Cu to adults) once every 3–9 months, respectively. Cu glycinate and Cu EDTA can also be given by injection at 3- to 6-month intervals to prevent deficiency.
• Copper sulfate can be spread on pasture at 1.5–3.0 kg/ha.
• Dosing ewes 8 and 4 weeks prior to lambing with 200 mg Cu sulfate can prevent congenital Cu deficiency in lambs; does can be given Cu glycinate (150 mg SC) mid gestation for the same effect.
• Cu methionate injection (5 mg) can be given to lambs at 3–10 days of age to prevent delayed deficiency; or Cu glycinate (60 mg SC) can be given at birth.
• Cu also can be offered in a free choice mineral mix containing 0.2–0.6% Cu. Under severe deficiency, Cu sulfate could be increased in the mineral mix to 0.5%.

Toxicity

• Feed appropriate feed and mineral supplements, particularly to sheep.
• Avoid contact with compounds that have high Cu concentrations such as fungicides and foot bath compounds.
• Evaluate dietary elements: Mo at 2–5 mg/kg of the ration, S at 0.4%, and zinc at 200 mg/kg will limit copper absorption in ruminants.

COPPER DEFICIENCY AND TOXICITY (CONTINUED)

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Cu deficiency can provoke anemia, severe diarrhea, neonatal ataxia, reproductive failure, hypochromotrichia, depressed immune function, poor growth, reduced appetite, keratinization failure in hair and wool, and weak, fragile long bones that break easily.
• Toxic plant ingestion can exacerbate Cu toxicity.

AGE-RELATED FACTORS

In general, young and growing ruminants have higher Cu requirements than older animals and are more susceptible to deficiency.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Abortion secondary to Cu deficiency has been reported.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

Nutritional requirements:
• It is difficult to provide exact dietary Cu requirements or to predict potential toxic levels of Cu for ruminants under different feeding programs. This is because Cu concentrations and availability vary significantly among feeds and even within the same feed (e.g., a forage species grown in different environmental conditions). Absorption rates of Cu are also affected by homeostatic controls and many other dietary factors.
• Dietary Mo concentrations have the greatest impact on Cu requirements. High dietary Mo under certain grazing conditions significantly increases Cu requirements.
• High intakes of Zn, Fe, and Ca decrease Cu absorption.
• Dietary Cu concentrations of 8, 10, and 7–11 mg/kg DM were recommended to meet the requirements of beef cattle, dairy cattle, and sheep, respectively.
• Because Cu availability in lush pastures is low and its level decreases with forage maturity, Cu supplementation should be increased at early and late maturity stages of forages to prevent deficiency.

SYNONYMS

• "Teart" or "peat scours" refer to ill thrift and diarrhea in cattle with secondary Cu deficiency.
• "Pine" refers to stiffness, epiphyseal enlargement, and ill thrift in young ruminants with Cu deficiency.
• Enzootic ataxia or "swayback" refers to neurologic signs in neonatal and juvenile goats and lambs with Cu deficiency.

ABBREVIATIONS

• Ca = calcium
• CNS = central nervous system
• Cu = copper
• DM = dry matter
• DW = dry weight
• Fe = iron
• Mo = molybdenum
• S = sulfur
• Zn = zinc

CORKSCREW CLAW

BASICS

OVERVIEW

• Corkscrew claw is a deformity of the claw where overgrowth of the abaxial wall displaces the sole axially and dorsally.
• The result is a claw that has a spiral or corkscrew shape. In an animal with a corkscrew claw, the weight-bearing surface of the affected claw is the abaxial wall instead of the sole.
• The lateral claw of the hindlimb is most often affected and the condition is typically bilateral. The deformity is considered heritable.

INCIDENCE/PREVALENCE

The reported incidence rates vary and range from <1% to 11%, with 3% being most typical.

GEOGRAPHIC DISTRIBUTION

Reports are from North America and Europe; however, the condition is likely worldwide.

SYSTEMS AFFECTED

Musculoskeletal

PATHOPHYSIOLOGY

• Animals with corkscrew claw typically have malalignment of the second and third phalanxes with an 11° rotation of the distal interphalangeal joint in the plantar plane.
• Bone exostosis is commonly found on the lateral aspect of the distal interphalangeal joint. In addition, the third phalanx is abnormally long and narrow and curved on its abaxial margin, resulting in an angled ventral surface of the pedal bone.
• The abnormal conformation is thought to cause abnormal mechanical stresses within the claw, with excessive force being applied to the region of the abaxial white line.
• The growth rate of the abaxial wall is significantly faster than in a normal claw, which causes the abaxial wall to curve and displace the sole axially. The result is the abaxial wall becomes the weight-bearing surface and the sole is partially covered by wall and the remaining, exposed sole faces axially. The result is a claw that appears to have twisted along its long axis, thus giving it a corkscrew appearance.

HISTORICAL FINDINGS

Gait is always abnormal in animals with corkscrew claw but the severity of lameness is variable.

SIGNALMENT

Beef and dairy breeds are both affected. Male and female are both affected. Age is typically 3 years and older but may occur in animals as young as 2 years of age.

PHYSICAL EXAMINATION FINDINGS

Typical findings in corkscrew claw are:
• The abaxial wall is not perpendicular to the ground.
• The abaxial wall is displaced axially and curls under the sole.
• The sole is displaced axially and dorsally.
• The toe is elevated in a clockwise rotation.
• The heel is overgrown and higher than the opposite claw.
• Sole hemorrhages, white line hemorrhages, and white line separation commonly accompany corkscrew claw.

GENETICS

The condition is considered heritable with estimates of heritability ranging from 0.11 to 0.23.

CAUSES AND RISK FACTORS

The condition is heritable and underlying conformation of the animal is the most important risk factor for corkscrew claw. Diet and environment may be contributing factors that affect rate of onset and severity of the deformity.

DIAGNOSIS

Diagnosis is based on the physical appearance of the claw.

DIFFERENTIAL DIAGNOSES

• Chronic laminitis. Abnormal hoof growth is common in chronic laminitis. There may be a long, upturned toe commonly referred to as "slipper toe" but there is not overgrowth of the abaxial wall and deviation of the sole.
• Scissor claw. In some cases, overgrowth of the claws, typically of the front limbs, will result in a curvature of the toe towards the axial plane. This is commonly referred to a "scissor claw." In this case, there is not significant overgrowth of the abaxial wall and deviation of the sole.

CBC/BIOCHEMISTRY/URINALYSIS

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Postmortem examination is not performed for clinical cases. See "Pathophysiology" for explanation of changes that are present.

TREATMENT

THERAPEUTIC APPROACH

Corrective Hoof Trimming

• Straighten the dorsal wall and remove the curve in the toe as best as possible but stop if bleeding occurs. A small breech in the dorsal wall will not cause any problems. Straightening the dorsal wall is best done with a sanding disc or chipper wheel.
• Gradually shorten the toe length to approximately 7.5 cm but stop if bleeding occurs. This is best done with hoof nippers.
• Remove the excess wall and sole from the weight-bearing surface of the claw until it is similar in height to the opposite claw. Quarter-round hoof nippers work well to remove the bulk of the material. The remainder of the work is best accomplished with a sanding disc or chipper wheel. The sole is often abnormally thin at the abaxial edge. Proceed with caution and check sole thickness frequently by pressing firmly on the sole to see if it flexes. It may not be possible to achieve a normal balance with the other claw.
• Remove excess horn from the axial aspect of the affected claw and slope the sole on the axial half of the claw.
• Trim the normal claw to achieve as close to normal conformation as possible while maintaining some sense of balance with the affected claw.

MEDICATIONS

DRUGS OF CHOICE

No medications are required.

CONTRAINDICATIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Gait is typically improved immediately after trimming. The condition is chronic and incurable so the abnormal conformation will recur. The time until significant regrowth occurs is variable but most animals require trimming at least twice per year.

POSSIBLE COMPLICATIONS

It is not uncommon to breech the wall or sole during corrective trimming. Complications as a result of this are unusual.

CORKSCREW CLAW (CONTINUED)

CLIENT EDUCATION
Educate regarding the genetic component of this condition.

PATIENT CARE
Monitor for recurrence, which will usually be evident in 6 months.

PREVENTION
• Affected animals should be removed from the herd when economically feasible. Bulls with corkscrew claw should not be used for breeding.
• Regular hoof trimming every 4–6 months will help maintain relatively normal conformation and help prevent secondary complications that could cause significant lameness.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Sole hemorrhages, sole ulcers, white line hemorrhages, and white line separation can be present in the affected claw.

AGE-RELATED FACTORS
Typically seen in animals 3 years of age and older but can occur as early as 2 years of age.

PRODUCTION MANAGEMENT
At the typical incidence rates, the condition is not an economically significant concern for most producers. Because the condition is heritable, affected cows should be removed from the herd when economically feasible and affected bulls should not be used for breeding.

CORNEAL DISORDERS

BASICS

OVERVIEW

• The cornea is transparent and avascular. The cornea is also the most refractive surface of the eye. The cornea is composed of four layers: the epithelium, stroma, Descemet's membrane, and the endothelium.
• Corneal disorders in ruminants include blunt compressive trauma, ulcerative keratitis, corneal lacerations, foreign body penetrations, and congenital dermoids. Occasionally neoplastic lesions (SCC) affect the cornea.
• In food-producing species, infectious disease of the cornea (keratoconjunctivitis) is much more frequently a cause of corneal damage than trauma.
• Treatment of corneal ulceration or infection should ideally be guided by results of ocular examination, cytologic examination, bacterial culture and sensitivity assessments, and topical fluorescein stain.

INCIDENCE/PREVALENCE

• Corneal disorders are common in sheep, goats, and cattle.
• Specific infectious pathogens can cause sporadic herd or flock outbreaks of infectious keratoconjunctivitis that occasionally affect most of the group.
• Infectious bovine keratoconjunctivitis (IBK) is the most common ocular disease of cattle, estimated to affect 5% of beef cattle in the United States and up to 50% of herds.
• Congenital ectropion can reach high prevalence in poorly managed sheep flocks, resulting in a high prevalence of secondary corneal disease.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Ophthalmic

PATHOPHYSIOLOGY

• Tear film proteases normally provide surveillance and repair functions to detect and remove damaged cells or collagen caused by regular wear and tear on the cornea. These enzymes exist in balance with inhibitory factors to prevent excessive degradation of normal tissue.
• Congenital (entropion) or acquired (trauma, foreign bodies) damage to the cornea can cause significant disruption to the epithelium of the cornea, exposing the underlying stroma and permitting secondary infection.
• Bacterial or fungal pathogens that invade the cornea induce upregulation of cytokines in the tear film and matrix metalloproteinases, and elicit a powerful inflammatory and degradative process.
• In conditions such as ulcerative keratitis, excessive proteases can lead to rapid degeneration of collagen, potentially inducing corneal "melting."
• Significant loss of corneal stroma can lead to exposure of Descemet's membrane and even corneal rupture.
• Common causes of infectious keratoconjunctivitis include *Moraxella bovis* in cattle, and *Mycoplasma conjunctivae* and *Chlamydophila pecorum* in sheep and goats.
• Systemic viral infections such as malignant catarrhal fever and bovine herpesvirus 1 can also induce corneal edema and inflammation in cattle.

HISTORICAL FINDINGS

• Dependent on the condition in question, but acute onset of blepharospasm and ocular discharge is often reported.
• With infectious keratoconjunctivitis disorders, a number of individuals in the group may be reported affected.

SIGNALMENT

• Any species and age of ruminant can develop a corneal disorder.
• IBK tends to be more common in calves and yearling cattle.
• Neoplastic disease (SCC) is most common in mature Hereford cattle.
• Entropion is most common in neonatal sheep, and British breeds such as the Suffolk have a greater predisposition.

PHYSICAL EXAMINATION FINDINGS

• Corneal edema
• Corneal irregularities/infiltrates/defects
• Blepharospasm
• Ocular discharge
• Photophobia
• Eye rubbing
• Lid anomalies (ectropion, laceration, entropion)

GENETICS

• Some sheep breeds have a greater predisposition to congenital entropion.
• Herefords may be more prone to IBK, thought to relate to lack of pigmentation at ocular margins.

CAUSES AND RISK FACTORS

• Exposure to viruses or bacteria associated with corneal disease.
• Crowding and transport can increase potential for traumatic corneal injuries.
• Breed predispositions exist for entropion, IBK, and neoplasia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Corneal trauma (blunt trauma, penetrations, lacerations, entropion)
• Corneal foreign body
• Uveitis or glaucoma (causing corneal edema)
• Bacterial, fungal, or viral keratoconjunctivitis
• Dermoids (appear as a piece of skin attached to the cornea, may be mistaken for neoplastic lesions)
• Corneal neoplasia

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER DIAGNOSTIC TESTS

• The cornea should be examined as part of a complete ophthalmic examination, using at least a direct ophthalmoscope. A bluish hue is indicative of corneal edema, and white opacities may indicate scarring, calcification, or stretching of Descemet's membrane (Haab's striae). A yellow-white color is usually indicative of white blood cell infiltration of the corneal stroma, which may be epithelialized over the surface (stromal abscess); red linear regions indicate neovascularization.
• Foreign bodies and dermoids can usually be readily appreciated with a light source, preferably a trans-illuminator head attachment.
• The slit beam of a direct ophthalmoscope can be used to assess the depth of corneal defects and the quality of the anterior chamber. Accompanying uveitis will create decreased clarity of the aqueous that can be viewed via the slit beam.
• Any pathologic condition of the cornea warrants fluorescein staining to determine the integrity of the cornea. After topically applying the stain, the cornea is evaluated using a cobalt light to determine the size, depth, and severity of a laceration or ulcer. Very deep lesions are represented by a ring of positive fluorescence around a nonstaining dark central region, indicating exposure of Descemet's membrane (desmetocele) with risk of imminent corneal rupture and iris prolapse.
• A perforated cornea may present with aqueous humor draining from the defect, or fibrin or part of the iris may occlude the perforation. Animals with deep corneal defects need to be handled carefully during diagnostic procedures to prevent globe collapse prior to surgical intervention if it is an option.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

• Bacterial and fungal cultures can be collected using a cotton swab and should be obtained prior to placing topical anesthetic products on the cornea since these might inhibit pathogen isolation.
• Corneal scrapings allow collection of samples for direct microscopic examination which can facilitate the diagnosis of neoplasia, and fungal or bacterial keratitis. Scraping can be performed using the blunt end of a scalpel blade after topical anesthetic (often 0.5% proparacaine hydrochloride) has been applied

CORNEAL DISORDERS (CONTINUED)

to the cornea; the material obtained is placed onto slides that are air dried and stained prior to analysis.

PATHOLOGIC FINDINGS
N/A

TREATMENT

THERAPEUTIC APPROACH
• Therapy is dictated by the type and severity of the corneal injury, the complications encountered, the intended use and economic value of the animal, and other welfare and production considerations.
• Dermoids may be asymptomatic if the abnormal region is small and devoid of hair, and in such cases do not require treatment. Clinical signs can arise as dermoids increase in size or develop hair, which may require surgical intervention.
• Plant material embedded in the epithelium or superficial stroma is the most frequently encountered foreign body in the ruminant eye. Foreign bodies are usually easily removed with a moistened cotton tip applicator or ophthalmic forceps. Topical anesthetic, sedation, and motor or sensory blocks may facilitate removal in animals with significant pain, concerned owners, or intractable nature.
• Confirmed corneal ulceration or incomplete corneal laceration can be managed with medical therapy including topical antibiotic administration q4–8h times daily if feasible (plus topical atropine as needed to control painful ciliary body spasm that can accompany severe corneal disease). Affected eyes must be evaluated q24h until resolved in case of sudden deterioration or lack of improvement. Affected eyes may be protected from rubbing by employing a cup or cover over the eye.
• Antibiotic selection should be based on cytologic assessment and/or bacterial culture and sensitivity results unless the presenting clinical and historical characteristics are strongly suggestive of a specific pathogen.
• Subpalpebral lavage systems can be placed in animals that are reluctant to have direct ocular treatments, that are intractable, or if the severity of the injury warrants frequent and prolonged treatment.
• Topical ointments versus solutions are preferred for direct application due to increased contact time. Ophthalmic solutions are best used in subpalpebral lavage systems.
• Nonsurgical management of severe corneal ulceration may include use of ophthalmic adhesives and soft contact lens application.
• Corticosteroid agents are contraindicated in the treatment of corneal ulceration or laceration, and corneal infection, as they can delay healing and further compromise the diseased cornea.
• Infectious keratoconjunctivitis can be a self-limiting disorder in many animals, with self-cure in 2–3 weeks, which should be considered when determining the need for antibiotic therapy.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Surgical intervention should be considered for deep corneal ulcerations, especially if the Descemet's membrane is exposed, and particularly in high value, breeding or show animals. Procedures of value include conjunctival pedicle flap and keratoplastic procedures.
• Severe corneal lacerations may warrant surgical repair depending on severity and individual animal value.
• Superficial dermoids can be removed via superficial keratectomy using sharp excision. Surgical anesthesia is recommended to perform a controlled and precise corneal incision without eye movement, particularly for deep or extensive dermoids.
• Enucleation is a sound treatment option if the prognosis is poor, or because of the economic value and expected productivity of the animal. It can be readily performed in standing cattle with manual restraint and appropriate local anesthesia techniques.

MEDICATIONS

DRUGS OF CHOICE
• Most bacterial pathogens of sheep and goats are susceptible to tetracycline. Long-acting tetracycline products can be administered (e.g., oxytetracycline 200 mg/mL given at 20 mg/kg IM or SQ, q72h) and can be combined with an ophthalmic preparation of tetracycline applied q6–8h.
• *M. bovis* is also susceptible to oxytetracycline (20 mg/kg once or twice); penicillin administered subconjunctivally (600,000 IU in 2 mL); florfenicol (20 mg/kg IM, given twice 48 hours apart, or 40 mg/kg SQ once); ceftiofur crystalline-free acid (6.6 mg ceftiofur equivalents/kg given once, SQ, in the posterior aspect of the pinna); and tulathromycin (2.5 mg/kg).
• Atropine can be administered topically to animals displaying significant pain, miosis or with characteristics of uveitis. Ophthalmic ointment preparations or solution (1%) are recommended, or injectable preparations can be diluted to ≤1%.
• Flunixin meglumine can be used at label doses to control pain and inflammation.
• 5% topical hypertonic saline ointment can be applied q6–12h if significant corneal edema is present.
• Identification of fungal hyphae on cytologic examination requires administration of topical antifungal agents (and potentially atropine and systemic NSAIDs). Natamycin, miconazole, itraconazole, ketoconazole, or fluconazole may be appropriate.

CONTRAINDICATIONS
• Corticosteroids are contraindicated when the integrity of the cornea is compromised by ulceration or laceration.
• Topical NSAID preparations are also typically contraindicated when corneal integrity is compromised.

PRECAUTIONS
• Ophthalmic therapy is often associated with extra-label drug use and should be approached with caution.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Dependent on etiology and treatment

POSSIBLE COMPLICATIONS
• Permanent corneal scarring
• Blindness
• Corneal rupture
• Decreased weight gain and production

CLIENT EDUCATION
Focus on preventive measures for contagious disorders (IBK) when relevant

PATIENT CARE
• All patients with active corneal disease should have the affected eye or eyes evaluated at least q24h since rapid deterioration can occur, in some cases resulting in blindness and potentially loss of the eye.

PREVENTION
• Infectious keratoconjunctivitis conditions can be controlled by quarantining new arrivals, practicing control of possible vectors (face flies), isolating affected animals, or using a patch over affected eyes.
• Mass medication has been practiced during outbreaks of infectious keratoconjunctivitis with parenteral or oral antibiotic administration to all members of the group.
• Commercial and autogenous vaccines for *M. bovis* exist; variable efficacy reported.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Blindness

AGE RELATED FACTORS
Younger animals are more prone to specific conditions including entropion (sheep) and IBK (cattle).

(CONTINUED) CORNEAL DISORDERS

ZOONOTIC POTENTIAL
None

BIOSECURITY
Infectious keratoconjunctivitis conditions benefit from management strategies to reduce spread among a group.

PRODUCTION MANAGEMENT
IBK has a significant economic impact on the cattle industry related to significantly lighter weaning weights in affected calves and treatment-related expense.

SYNONYMS
Pink eye (bacterial keratoconjunctivitis)

ABBREVIATIONS
- IBK = infectious bovine keratoconjunctivitis
- SCC = squamous cell carcinoma

Consulting Editor Erica C. McKenzie

CORONAVIRUS

BASICS

OVERVIEW

• Disease of neonatal ruminants.
• The causative agent is a coronavirus. All coronaviruses are of the same serotype.
• Pathogenicity is related to load of exposure, level of immunity to the virus, concurrent infection with other neonatal pathogens, and stress. Most infections are concurrent with other neonatal pathogens.
• Virus is ubiquitous with seroprevalence in the adult herd of 80–90%.
• Morbidity of coronavirus is estimated to be 15–25%. Mortality rate in uncomplicated cases is 5–10% but may reach 50% with concurrent bacterial or parasitic infections.

INCIDENCE/PREVALENCE

• Prevalence of coronavirus infections is in the range 15–25% with a great variation in mortality, 5–50% depending on concurrent bacterial and parasitic infections.
• Seroprevalence in the adult herd may be close to 100%.

GEOGRAPHICAL DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

• Digestive
• Respiratory

PATHOPHYSIOLOGY

• The virus is acquired either through the ingestion of fecal contaminated material or inhalation. Initially villous epithelial cells are infected in the proximal small intestine with infection progressing caudally into the colon.
• The infection extends into the colon resulting in infection of the epithelial cells of the ridges as well as the crypts.
• The virus is cytocidal, resulting in sloughing of epithelial cells. Coronavirus may also infect undifferentiated epithelial cells, fibroblasts, and endothelial cells of the lamina propria, resulting in significant damage to the colon. Infected cells contain large numbers of virus and are desquamated into the lumen. Immature crypt cells replace the absorptive epithelium of the small intestine but denuded areas within the colon may take several days to heal.
• The loss of epithelial cells results in a maldigestive as well as a malabsorptive type diarrhea. Maldigestion and malabsorption result in change in bacterial populations which may contribute to the diarrhea.
• Undigested carbohydrates undergo bacterial fermentation resulting in an increase in osmotic pressure and water being drawn into the intestinal lumen.
• Diarrhea results due to increased osmotic pressure and decreased absorption. The physical loss of the epithelial cells results in increased susceptibility to other pathogens because of loss of the villous integrity and decreased secretion of lactoferrin and lysozymes as well as the release of inflammatory mediators.
• Damage predisposes the attachment of ETEC and attaching and effacing *E. coli* to the intestinal villi.
• The loss of electrolytes, bicarbonate, and water leads to dehydration and metabolic acidosis.
• The virus can also infect the respiratory epithelium resulting in a mild respiratory or subclinical respiratory infection.

HISTORICAL FINDINGS

• Sudden onset of diarrhea that spreads rapidly through the neonatal population.
• A few cases may have been noticed initially but the frequency of cases increases as the calving season progresses due to build-up of pathogen load.
• Increased number of cases are observed following periods of stress such as a snowstorm or cold wet weather.

SIGNALMENT

• Bovine, ovine, caprine; potentially all ruminant species.
• Most infections occur <3 weeks of age.
• Calves as old as 3 months of age may be affected.

PHYSICAL EXAMINATION FINDINGS

• Mild to severe watery diarrhea with pieces of milk curd and flecks of blood; color, consistency, and composition will vary with coexisting infections.
• Dehydration and depression with degrees of inappetence or reluctance to nurse. Some animals may be weak to the point of recumbency.
• Bruxism and nasal discharge.
• Clinical signs are more severe than rotavirus-induced diarrhea.
• Acute onset of diarrhea varying from mild to severe, depression, and reluctance to nurse.
• Clinical signs last 3–5 days during which calves become progressively depressed, weak, and experience weight loss.
• Some calves may exhibit signs of abdominal pain. In uncomplicated cases, diarrhea may exist for 2–3 days. In cases of secondary bacterial infection, diarrhea may last 4–6 days.

CAUSES AND RISK FACTORS

• Coronavirus. All cattle coronaviruses are of the same serotype.
• Inadequate colostral transfer of immunoglobulins resulting in agammaglobulinemia or hypogammaglobulinemia. Lack of local colostral immunity in calves 5 days postpartum or in calves raised on milk replacers.
• Birthing areas contaminated with fecal material containing coronavirus.
• Neonatal housing in which build-up of pathogen load occurs.
• Neonates housed or maintained in a cold wet environment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• *E. coli*
• Rotavirus
• Cryptosporidium
• *Salmonella* spp.
• *Clostridium perfringens* type C
• Nutritional causes: History contains a dietary change or identification of nutritional deficiencies or excesses.

CBC/BIOCHEMISTRY/URINALYSIS

• CBC: Hemoconcentration, increased plasma proteins.
• Serum chemistry: Metabolic acidosis with low plasma bicarbonate. Glucose and electrolyte values will be low depending on severity of diarrhea, prerenal azotemia.
• Urinalysis: Depending on state of dehydration, urine will be concentrated resulting in an increased specific gravity.

OTHER LABORATORY TESTS

• Feces should be collected as soon as diarrhea is noted because exfoliation of virus-laden enterocytes is short-lived and occurs early in the disease process.
• Feces can be submitted for electron microscopy and identification of virus. A few drops of formalin can be added to 10 mL of feces for preservation, or feces can be frozen.
• Serology can detect sero-conversion or a 4-fold increase in serum immunoglobulin levels.
• Fresh sections of the small intestine, preferably mid ileum, and colon tied at the cut ends to contain intestinal contents can be submitted on ice for immunofluorescent microscopy.

PATHOLOGIC FINDINGS

• No specific gross lesions, distended bowel containing undigested milk and fluid. The mucosa may be congested with petechial hemorrhages throughout the intestinal tract.
• Histologically, the villi will be shortened and covered with squamous to cuboidal epithelial cells.

(CONTINUED) CORONAVIRUS

TREATMENT

THERAPEUTIC APPROACH

• Fluid therapy is needed to correct dehydration, circulatory impairment, and electrolyte and metabolic imbalances.
• Fluid deficit should be calculated as well as maintenance requirement, 80–100 mL/kg, and fluid loss in the diarrhea to determine volume of fluids needed during a 24-hour period.
• Fluids may be administered orally or intravenously. Commercial oral electrolyte solutions containing glucose and a non-bicarbonate alkalinizing agent are recommended if the neonate is still nursing. Although oral electrolytes are less likely to be absorbed due to enterocyte pathology, not all enterocytes are affected so some absorption does occur.
• Neonates without a suckle response need IV fluids: isotonic 1.3% sodium bicarbonate solution initially (2 L) followed by Lactated Ringer's Solution.
• Dextrose solution (2.5–5%) is indicated in cases of hypoglycemia. With hypoglycemia and after correcting acid-base status, a 2.5% dextrose and 0.45% saline solution has been recommended.
• Plasma transfusion, although not specific for coronavirus infections, may be warranted in cases of failure of passive transfer and depending on value of the animal.

MEDICATIONS

DRUGS OF CHOICE

• Broad-spectrum antibiotics may be considered because of the potential for mixed infections as well as the loss of mucosal integrity.
• Oral amoxicillin trihydrate 10 mg/kg PO q12h for non-ruminating calves (extra-label in small ruminants), 20-day slaughter withdrawal. Amoxicillin trihydrate-clavulanate potassium 12.5 mg combined drug/kg PO q12h for 3 days (extra-label usage).
• Parenteral ceftiofur 2.2 mg/kg IM q24h for 3 days (extra-label usage).
• Drug withdrawal times must be determined and maintained in the treated animal.

CONTRAINDICATIONS

• Do not use kaolin and pectin as use may increase electrolyte loss.
• Meat and milk withdrawal time periods must be maintained.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• In uncomplicated infections, diarrhea is present for 2 to 3 days. Prognosis is good, as this infection tends to be self-limiting and generally requires minor supportive care.
• Duration of diarrhea may be 4–6 days with secondary bacterial infections. Prognosis is dependent on the degree of pathology produced by the secondary bacteria.
• Prognosis is good to fair with supportive care. It may take a couple of weeks for animals to fully recover.

POSSIBLE COMPLICATIONS

Hypovolemic shock and death

CLIENT EDUCATION

• Clients need to insure that calves acquire an adequate amount of colostrum. Neonates should be kept dry and in a draft-free environment.
• Animals should be moved and fed in such a way as to reduce the build-up of mud and fecal material in the neonate's environment. Diarrheic animals should be isolated from healthy neonates as they are sources for large numbers of pathogens.
• Owners should work with healthy calves before working with sick calves and should clean equipment, bottles, and nipples adequately between calf usage.
• Owners should be advised as to how to reduce pathogen transfer between calves in regard to equipment, clothing, and shoes/boots.

PATIENT CARE

• Neonates with a suckle response should be left with the dam and allowed to nurse.
• Monitor attitude, suckling response and appetite, fecal color and consistency, and hydration status.
• Monitor age cohorts for signs of diarrhea.
• Animals being reared artificially should remain on their diet or switched to whole milk or colostrum. If the diarrhea becomes worse or the calf becomes depressed, removal from the dam or milk is warranted. In the case of hand-fed neonates that are depressed and not interested in sucking, or neonates not nursing the dam, neonates should receive a high-energy electrolyte solution at a rate of 10% of body weight divided into a minimum of four feedings.
• Calves should also receive 5% of their body weight in electrolyte solutions, spacing 2 hours before or after milk feedings. Milk should not be withheld longer than 24 hours and can be given via an esophageal feeder. No more than 1 liter should be tube-fed at a time.
• Milk and electrolyte solutions can be altered as described previously with a minimum of 10% body weight of fluid per day.
• Oral electrolytes containing bicarbonate should not be fed when calves are receiving milk, as milk digestion maybe disrupted.

PREVENTION

• Reduce exposure, clean maternity areas, move to a clean area after birth. Those handling sick neonates should practice biosecurity measures to reduce exposure to healthy neonates, wash hands and disinfect boots, maintain clothes free of fecal material.
• Vaccination of dams prepartum according to manufacturers' recommendations with a coronavirus vaccine will increase colostral antibody.
• In dairy calves, colostrum management of newborn calves includes the feeding of 2–4 liters of colostrum in the first 24 hours following birth. In beef calves, insure that newborn calves suckle within 1–2 hours after birth.
• Oral vaccination of neonates with a modified-live oral vaccine will produce IgA and IgM. This vaccine is cumbersome for management as it is to be given prior to colostrum consumption, and colostrum must be withheld for several hours after vaccination. This may increase the opportunity for bacterial infections and failure of passive transfer.
• In the case of dairy animals, feed neonates colostrum for 30 days if coronavirus is an endemic problem.
• Eliminate areas of fecal build-up.
• Keep environment dry and draft-free.

MISCELLANEOUS

ASSOCIATED CONDITIONS

A mild respiratory infection may occur simultaneously.

AGE-RELATED FACTORS

• Most cases occur at 7–21 days of age.
• Range is 1 day to 3 months.

ZOONOTIC POTENTIAL

None

BIOSECURITY

• See "Client Education."
• Diarrheic animals should be isolated from healthy neonates as they are sources for large numbers of pathogens.
• Feed youngest animals first and oldest animals last.
• Those handling sick neonates should practice biosecurity measures to reduce

CORONAVIRUS (CONTINUED)

exposure to healthy neonates, wash hands and disinfect boots, maintain clothes free of fecal material.
• Disinfect with bleach, a phenolic, or peroxymonosulfate. Surface must be free of organic material and surface contact is a minimum of 10 minutes.

PRODUCTION MANAGEMENT

See "Prevention"

COWPOX

BASICS

OVERVIEW
• Cowpox is caused by an orthopoxvirus closely related to but distinguishable from the human orthopoxviruses vaccinia and variola.
• Cattle develop poxlike lesions commonly on the teat and udder in adult animals and on the lips and oral cavity of suckling calves.

INCIDENCE/PREVALENCE
Cowpox affects a broad host range that includes cattle, wild and domestic *Felidae*, dogs, numerous rodents, and some zoo animals.

GEOGRAPHIC DISTRIBUTION
Europe

SYSTEMS AFFECTED
Integument

PATHOPHYSIOLOGY
• While this viral disease carries the name "Cowpox," it is a disease of rodents that occasionally infects domestic cats, which usually pass the disease onto humans and cattle through direct contact.
• Further spread from cattle to other cattle is believed to be by exposure to the infected hands of herdsmen during the milking process or by inoculation with contaminated fomites such as teat dipping cups and milking equipment.
• While most animals develop localized skin lesions, cottontop tamarins (*Saguinus oedipus*) develop generalized disease and die.

SIGNALMENT
• Infections in cattle are uncommon because the virus is not endemic in cattle.
• Virus tends to spread rapidly through a naïve herd, particularly during times of the year when the teats and udders are likely to have abrasions on the surface.
• Heifers, as they are introduced to the milking string, are more likely to become involved in endemic herds.

PHYSICAL EXAMINATION FINDINGS
• Incubation: 3–10 days.
• Typical pox lesions are noted only on the teats and udder. In severe cases, the pox lesions can be identified on the thin skin of the inguinal region and occasionally on the perineum.
• Bulls can develop lesions on the scrotum.
• Nursing calves can develop oral lesions similar to bovine papular stomatitis.
• Lesions progress from circular raised reddened areas of erythema and edema to firm 1–2 cm nodules that form a central vesicle. The vesicle ruptures, forming a central crater that undergoes further necrosis and scab formation if the animal is not being milked.
• Milked animals develop a raised circumscribed lesion with a central umbilicated ulcer that is slow to heal.

CAUSES AND RISK FACTORS
• Disease is endemic in rodents of Europe and Asia with the virus occasionally infecting cattle.
• Voles, mice, and gerbils serve as the natural reservoir for this disease.
• Domestic cats are commonly infected in endemic areas by hunting and eating infected rodents. Infected cats usually develop solitary lesions on the face, neck, or paws. It is believed that these infected cats act as a means of spreading the disease to humans and cattle by direct contact.
• Further spread from cattle to other cattle is believed to be by exposure to the infected hands of herdsmen during the milking process or by inoculation with contaminated fomites such as teat dipping cups and milking equipment.
• Insects are also suspected of transferring the virus from cow to cow.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Bovine papular stomatitis: Virus is a parapoxvirus often associated with proliferative calf lesions on the lip, tongue, and palate. But may observe proliferative targetoid/umbilicated lesions on the teats.
• Bovine fibropapilloma virus: Multiple verrucous proliferative growths on teats and udder; lesions are often scabbed over due to trauma.
• Brazilian vaccinia viruses: Vaccinia-like virus that is an endemic disease in Brazilian cattle with papules that develop into painful ulcers on the teats and udder of the mammary gland.
• Buffalopox virus (India/Pakistan regions): A vaccinia-like virus with lesions similar to cowpox on the teats and udder. Disease is observed in domesticated water buffalo and occasionally cattle. Affected udders and teats are painful, leading to a decrease in milk production.
• Caustic substances that are placed on the teat.
• Foot and mouth disease: Vesicles and ulcers can be observed on the teat and/or udder. Affected animals also have lesions in the mouth and on the feet.
• Herpes mammillitis (bovine herpesvirus-2, Allerton virus): Small, slow-healing ulcers develop on teats and udders. Viral cultures will assist in differentiating poxviruses from herpesviruses.
• Pseudocowpox (milker's nodules): Pseudocowpox is a parapoxvirus with lesions similar to cowpox. Virus is similar to bovine popular stomatitis.
• *Staphylococcus aureus* and *Streptococcus* spp. infections on the teats can cause vesicles which may spread to the udder, resulting in furunculitis and boils.
• Vesicular stomatitis virus: Affected animals develop vesicles/ulcers on the teats and udder. Significant lesions (vesicles and ulcers) are often associated with and most prevalent in the mouth and feet.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
PCR testing to determine specific type of poxvirus

OTHER DIAGNOSTIC PROCEDURES
• Biopsies of the lesions will identify typical poxvirus intracytoplasmic inclusions in the epithelium.
• Electron microscopy of the infected epithelium identifies characteristic poxvirus present in infected keratinocytes.

PATHOLOGIC FINDINGS
• On gross examination, lesions are circumscribed raised firm blanched nodules with a circular basilar area of hyperemia. Nodules form a central vesicle/pustule.
• Lesions undergoes necrosis/collapse causing a central cavitary depression. Scab will form over the necrotic tissue which, once removed, identifies a slow-healing ulcerated surface.
• Lesions are seen primarily on the teats and udder but can also be located in the perineal region and the scrotum of bulls.
• Suckling calves can have lesions in the oral cavity.
• Histologically, the pox lesions consist of edema, congestion, and lymphocytic infiltration of the superficial dermis. The associated epithelium becomes hyperplasic with ballooning degeneration and necrosis of the affected epithelium in the stratum spinosum.
• Eosinophilic intracytoplasmic inclusion bodies are seen in the swollen keratinocytes.
• Epithelial cells of the stratum spinosum separate, forming small vesicles that fill with neutrophils, forming a pustule. Later, the associate epithelium beneath the pustules becomes necrotic, forming an ulcerated epidermis with serocellular debris overlying the lesion.
• Variable numbers of neutrophils are present in the affected dermal connective tissues.

TREATMENT

THERAPEUTIC APPROACH
• No treatment for the pox-associated lesions.
• Keep lesions clean and free of secondary bacterial infections.
• Debris/scabs from wounds should be picked up and disposed of to insure that contaminated materials does not contact other animals.
• Antibacterial ointments may assist in healing.

COWPOX (CONTINUED)

MEDICATIONS

DRUGS OF CHOICE
N/A

CONTRAINDICATIONS
If antibiotics are used for secondary bacterial infections, appropriate milk and meat withdrawal times must be followed for all compounds used.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Cowpox is considered a mild disease and should cause little discomfort to affected cattle. Most cases resolve without complications.

POSSIBLE COMPLICATIONS
Secondary bacterial infections of the lesions can cause mastitis in affected quarters or a severe dermatitis involving the skin of the affected udder.

PATIENT CARE
- Lesions are usually self-limiting.
- Keep the lesions clean and free of contamination to prevent secondary bacterial infections.

PREVENTION
- Herdsmen with lesions should limit involvement in milking since this is a major method of spreading the disease.
- Cleaning cloths, teat dipping cups, and milking machines should be thoroughly disinfected before use on noninfected animals.
- Quaternary ammonia compounds and teat dipping compounds with viricidal activity should be adequate for preventing the spread of the disease.
- Monitor cats for lesions; remove animals from vicinity of cattle or workers while cat is infected.
- Currently no vaccine is available for use in outbreaks.

MISCELLANEOUS

AGE-RELATED FACTORS
- Young animals, particularly naive heifers coming into an endemic herd, are most susceptible.

ZOONOTIC POTENTIAL
- Handling infected material can lead to lesions on the hands and face. Lesions are usually mild and self-limiting.
- Exposure to infected cats (usually handling these cats) is believed to be the most common source of infection in people.
- Exposure to Buffalopox and Brazilian vaccina viruses from cattle can cause lesions in humans.

BIOSECURITY
Keep infected cats or handlers with lesions away from animals.

ABBREVIATION
PCR = polymerase chain reaction

CRYPTOCOCCOSIS

BASICS

OVERVIEW

• Cryptococcosis is a noncontagious fungal infection caused by the dimorphic basidiomycete yeasts, *Cryptococcus neoformans* and *C. gattii.*
• Humans and a range of domestic species can be infected, including occasionally sheep, goats, and camelids.
• Distributed in temperate and subtropical climates; in both rural and urban environments.
• Sporadic ruminant cases involve the respiratory tract, CNS, mammary glands and wounds or incisions.
• The major risk arises from inhalation of fungus-contaminated soil/dust, bird (pigeon) excreta, or organic debris from Eucalyptus trees.

INCIDENCE/PREVALENCE

Ruminant infections are rare and sporadic; most cases are subclinical.

GEOGRAPHIC DISTRIBUTION

Worldwide distribution with most infections observed in subtropical and temperate climates. *C. gattii* infection is observed particularly in British Columbia, the Pacific Northwestern US, Australia and Papua New Guinea, and in parts of Africa, Asia, Europe, Mexico, and South America.

SYSTEMS AFFECTED

• Respiratory
• Hemolymphatic
• Nervous
• Integument

PATHOPHYSIOLOGY

• Disease typically arises from inhalation of dust containing basidiospores or desiccated yeast forms.
• Most infections are subclinical, and may persist for months without dissemination.
• Organisms inhaled into the lungs are destroyed by the host, remain dormant with no clinical disease, or precipitate active infection.
• Macrophages phagocytize yeast organisms and transport them to other regions of the body where infections can develop.
• *Cryptococcus* demonstrates significant thermotolerance allowing the yeast to grow in the host.
• The thick polysaccharide capsule of *C. neoformans* inhibits phagocytosis, migration of inflammatory cells to the infected site (poorly immunogenic), complement activation, and release of multiple virulent factors (lactase, phospholipase B-1, and urease) that slow, stop, or degrade inflammatory cells recruited to the infected area.
• Organism thrives in the acidic environment that develops during the inflammatory response involving the release of phagosomal enzymes that macrophages use for organism destruction.
• May cause variably sized respiratory tract granulomas or gelatinous diffuse pulmonary infiltrates. Solitary pulmonary nodules may be confused with carcinoma, and lymph node lesions may mimic fungal or bacterial granulomas.
• Occasional hematogenous spread occurs; the most frequent secondary site of colonization is the meninges.
• Yeast have the potential to disseminate to the skin, bone, liver, kidneys, and other organs.
• Retrograde movement up the teat canal or contaminated udder infusions can cause *Cryptococcus* mastitis; infections of wounds or incisions have also been documented in ruminants.

HISTORICAL FINDINGS

Dependent on system infected; onset of signs can be acute or chronic.

SIGNALMENT

• *C. neoformans* tends to affect debilitated or immunocompromised individuals; *C. gattii* frequently afflicts healthy individuals.
• Cattle, sheep, goats, llamas, alpacas, and other ruminants can be affected, in addition to cats, humans, and other species.

PHYSICAL EXAMINATION FINDINGS

• Vary depending on system involved.
• Signs of upper or lower respiratory tract disease may occur with variable respiratory distress.
• Persistent low-grade fever and weight loss are common in advanced disease.
• CNS infection can induce stiffness, hyperesthesia, blindness, and incoordination.
• Nonhealing skin lesions can occur in ruminants.
• Lymphadenitis.
• Swelling, heat, and pain in the udder can occur with mastitis, and caseous debris in viscid secretions.

GENETICS

N/A

CAUSES AND RISK FACTORS

• *C. neoformans* and *C. gattii* have free-living yeast forms that are present in the soil; contaminated soil is a reservoir for these organisms and inhalation presents the main risk.
• *C. neoformans* is identified in bird (pigeon) guano, decaying wood and other debris; organism growth is enhanced by creatinine, which is often present in bird feces. Bird guano protected from direct sunlight (in lofts and roosts) is most commonly associated with disease.
• *C. gattii* is identified in decaying leaves, debris, and flowers of Eucalyptus trees, but has been observed in debris from over 50 tree species.
• Debilitated/immunocompromised animals are at a higher risk for disseminated disease (more relevant to *C. neoformans* infection).
• Habitation of high-risk areas (British Columbia, Pacific Northwestern US) is relevant to *C. gattii* infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Cryptococcosis is a rare diagnosis in ruminants but should be considered as a possible differential for ruminants with acute CNS signs, acute or chronic lower respiratory tract disease, nasal or tracheal masses, nonhealing wounds or incisions that respond poorly to standard treatments, and mastitis or lymphadenitis.

CBC/BIOCHEMISTRY/URINALYSIS

Neutrophilia may be observed if CBC is performed in clinically diseased animals.

OTHER LABORATORY TESTS

N/A

IMAGING

Ultrasonography, radiography, computed tomography, and other forms of imaging have utility in valuable animals for characterizing the location and extent of infections, and potentially in monitoring response to treatment.

OTHER DIAGNOSTIC PROCEDURES

• Latex agglutination testing can define *C. neoformans* antigens in serum, CSF, or urine. False-negative results occasionally observed in animals with localized disease.
• Fungal culture of tissues/fluids with speciation based on differential media, appearance, biochemical testing, DNA sequencing.
• Cytologic examination of smears, swabs or aspirates of exudates, tissues, CSF or respiratory fluids demonstrate yeast forms (4–8 μm) with a thick capsule on India ink wet mounts and a variety of other stains.
• Immunofluorescence or immunohistochemistry techniques are available.

PATHOLOGIC FINDINGS

• Large numbers of poorly staining yeast (4–8 μm) with a thick capsule and narrow-based budding bodies off yeast cells are observed. Yeast are surrounded by few macrophages and multinucleated giant cells.
• Granulomas and other evidence of inflammation may be noted at sites of infection.

TREATMENT

THERAPEUTIC APPROACH

• Infections are frequently self-limiting.
• Treatment of disseminated or severe local disease is often futile due to poor prognosis and limited means of effective therapy.

CRYPTOCOCCOSIS (CONTINUED)

SURGICAL CONSIDERATIONS AND TECHNIQUES
Individual granulomatous lesions may be amenable to resection or removal in valuable animals.

MEDICATIONS

DRUGS OF CHOICE
• There are rare reports of treatment in ruminants; use of oral fluconazole has been reported in a goat. However, information regarding absorption by this route in ruminants is lacking.
• Antifungal drugs used in other species have included amphotericin B, flucytosine, ketoconazole, and itraconazole.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Clinical disease tends to be chronic and/or progressive, particularly without treatment.
• The prospect of complete recovery is often very poor.

POSSIBLE COMPLICATIONS
Hypoxemia, recumbency, death

CLIENT EDUCATION
Educate clients regarding sources of exposure to these pathogens.

PATIENT CARE
N/A

PREVENTION
• Avoid exposure to soils contaminated with bird (pigeon) excreta or decaying cellular debris from trees.
• Insure proper udder/teat cleanliness prior to infusions with mammary products.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Immunocompromising conditions might be present in individuals with *C. neoformans* infection.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
Cryptococcosis is not considered zoonotic; however, infection potential exists linked with accidental inoculation (such as when handling infected tissues); human-to-human transmission has been reported very rarely (such as with solid organ transplantation and mechanical ventilation near another infected patient).

PREGNANCY
N/A

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
• Contaminated udder infusions/improper teat management has been associated with outbreaks of *Cryptococcus* mastitis in cattle.
• Monitor bedding material and be cautious of using Eucalyptus bark as bedding material.

SYNONYMS
• Pigeon fancier's disease
• Torulosis
• European blastomycosis
• Busse-Buschke disease

ABBREVIATIONS
• CNS = central nervous system
• CSF = cerebrospinal fluid

CRYPTOSPORIDIOSIS

BASICS

OVERVIEW

• Cryptosporidiosis in ruminants and camelids is caused by a nonhost-specific and widely distributed coccidian parasite, *Cryptosporidium.*
• Several species of *Cryptosporidium* have been identified in ruminants, varying with geographic location and host species.
• *C. parvum* is typically associated with diarrhea in neonatal ruminants and camelids, inducing disease that is clinically similar to many other causes of neonatal scours.
• Infection with *Cryptosporidium* is also often subclinical, and this pathogen is contagious and zoonotic.

INCIDENCE/PREVALENCE

• *C. parvum* was found in 22.4% of calves in a survey of dairy farms in the United States.
• *C. parvum* has caused outbreaks of diarrhea in neonatal crias within individual alpaca herds in the US.
• Shedding of *Cryptosporidium* has been reported in up to 85% of pre-weaned lambs in some systems.
• Morbidity can reach 80–100% and mortality >50% in affected groups of goat kids.

GEOGRAPHIC DISTRIBUTION

• Worldwide
• The predominant *Cryptosporidium* species isolated varies between geographic regions, particularly in small ruminants

SYSTEMS AFFECTED

Digestive

PATHOPHYSIOLOGY

• There are >20 known species of *Cryptosporidium* within the phylum Apicomplexa.
• *C. parvum* is the most significant species affecting neonatal calves, small ruminants, and camelids.
• *C. andersonii*, *C. bovis*, and *C. ryanae* have been isolated in cattle but are not considered to be clinically significant.
• *C. xiaoi* has been isolated from diarrheic goat kids, and *C. ubiquitum* from lambs.
• Infected hosts, which can be neonatal or adult animals, shed oocysts into the feces which are sporulated and immediately infective.
• The primary route of transmission is direct and fecal-oral; however, indirect transmission via environmental contamination is common, and *Cryptosporidium* is environmentally resistant.
• The pathogen can complete its life cycle within a single host, including the asexual (merogony) and sexual (sporogony) reproductive cycles; therefore autoinfection of the host can occur.
• Ingested oocysts are activated in the stomach and upper small intestine to release four infective motile sporozoites which are taken into intestinal epithelial cells where they undergo the sexual and asexual multiplication stages that result in the production of oocysts.
• A vacuole is formed between the cytoplasm and cell membrane that causes villous atrophy, villous fusion, and, later, inflammatory changes of the mucosa.
• Clinical diarrhea develops usually 4 days after infection, and arises from a combination of malabsorption and maldigestion. Secretory mechanisms and increased intestinal permeability are also thought to play a role.
• Gastric cryptosporidiosis has been described in cattle. *C. andersonii* (formerly categorized as *C. muris*) can cause gastric cryptosporidiosis by infecting the glands of the abomasum in a small percentage of adult cattle. Animals appear clinically normal but inhibition of acid production in the abomasum can lead to decreased milk production in chronically affected cattle.

HISTORICAL FINDINGS

The onset of diarrhea after 4 days of life and within the first 2–3 weeks of life is the typical complaint.

SIGNALMENT

• Cryptosporidiosis causes diarrhea in a wide range of mammals including humans, cattle, small ruminants, and camelids.
• The highest frequency of infection is seen in neonatal ruminants between 5 days and 3 weeks of age, many of which will be asymptomatically infected.

PHYSICAL EXAMINATION FINDINGS

Diarrhea, dehydration, anorexia, and tenesmus are common findings in affected neonates.

GENETICS

N/A

CAUSES AND RISK FACTORS

• Infection with *Cryptosporidium* spp., most commonly *C. parvum* in domestic neonatal ruminants and camelids.
• Poor hygiene in intensively managed systems can increase pathogen exposure from the environment and between neonates.
• Immunocompromised neonates are at greater risk for severe or multiple infections.
• Multi-pathogen infections are common; the significance of other infectious pathogens in permitting or enhancing *Cryptosporidium* infection is not clear.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Rotavirus
• Coronavirus
• Bovine viral diarrhea (BVD)
• *Clostridium perfringens*
• *Escherichia coli*
• Nutritional diarrhea
• Salmonellosis
• Giardiasis

CBC/BIOCHEMISTRY/URINALYSIS

• Serum chemistry analysis may reflect dehydration (azotemia, hyperalbuminemia), acidosis (low total CO_2), hyperkalemia, and hypoglycemia.
• Mixed infections with bacteria or viruses should be considered in animals that are severely or chronically diseased and that have significant acid-base abnormalities, electrolyte disturbances, hypothermia, and weight loss.

OTHER LABORATORY TESTS

High-power magnification with acid-fast staining can be used on feces or mucosal scrapings to identify the organism.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

• Sheather's flotation sedimentation staining
• Fluorescent antibody assays
• ELISA assays
• PCR
• Rapid immunochromatographic assay

PATHOLOGIC FINDINGS

• Gross necropsy identifies hyperemic intestinal mucosa with yellow degraded intestinal contents.
• Histologic evaluation of the tissues reveals atrophy, fusion, and inflammation of the intestinal villi with circular, intramembranous, extracytoplasmic organisms contained within the brush border.

TREATMENT

THERAPEUTIC APPROACH

• There are currently no recommended specific medications for cryptosporidiosis; however, diarrhea is usually self-limiting, with a 7-day or shorter course expected in uncomplicated cases.
• Treatment consists of supportive care through provision of appropriate nutrition, fluid and electrolyte replacement, and correction of acidosis and hypothermia.
• Antimicrobial therapy may be indicated in cases with secondary bacterial infection.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

• Paromomycin sulfate administered at 100 mg/kg/day, PO (for 11 days from day 2

CRYPTOSPORIDIOSIS (CONTINUED)

of life) reportedly prevented natural disease in goat kids.
• Antimicrobial therapy can be considered if there is evidence of secondary bacterial infection or significant immunocompromise.
• Nonsteroidal anti-inflammatory drugs may be used to reduce pain and discomfort in some cases, with caution indicated in dehydrated animals.
• The addition of lactase products to milk may help subsequent digestion in compromised intestines.
• Compounds that improve fecal consistency (bismuth subsalicylate) may be of value.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Diarrhea usually resolves within one week in uncomplicated cryptosporidiosis affecting immunocompetent individuals.
• Asymptomatic infection is a common phenomenon.

POSSIBLE COMPLICATIONS
• Severe dehydration, electrolyte disturbances, and acidosis can lead to weakness, recumbency, and death.
• Acute renal failure can result from severe dehydration in conjunction with administration of nephrotoxic drugs such as NSAIDs and specific antibiotics (including oxytetracycline).

CLIENT EDUCATION
• *Cryptosporidium* is a zoonotic pathogen so it is critical to educate clients regarding appropriate hygiene precautions when handling infected individuals.
• Exposure of children and immunocompromised individuals to neonatal ruminants should be performed with strict attention to hygiene.

PATIENT CARE
• Electrolyte and rehydration therapy must be balanced with appropriate nutritional support through the provision of milk or milk replacer.
• Electrolyte/fluid products can inhibit milk clot formation in the abomasum so they should be administered 1–2 hours after milk feedings.
• Decreasing the volume but increasing the number of feedings may help reduce the osmotic effects of provided fluids in the gut.

PREVENTION
• *Cryptosporidium* is very resistant to destruction. Ammonia products (5%), hydrogen peroxide (3–6%), 10% formol saline, chlorine dioxide, desiccation, and extremes of temperature (freezing or >65°C) can destroy oocyst infectivity and help disinfect the environment.
• Individual housing and sanitation of feeding equipment for neonates helps control exposure.
• Adherence to hygienic practices in maternity areas and cleaning manure from neonatal areas can also decrease exposure.
• Isolate diarrheic neonates as soon as clinical disease is noticed and for at least one week after resolution of signs.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Acute renal failure

AGE-RELATED FACTORS
• Clinical disease most typically occurs in neonatal ruminants and camelids <3 weeks of age.
• Oocyst shedding in asymptomatically infected ruminants is also strongly age related, and highest in neonates.

ZOONOTIC POTENTIAL
• *C. parvum* is highly contagious and one of the most common causes of clinical cryptosporidiosis in humans.

PREGNANCY
N/A

BIOSECURITY
See "Prevention." Since cryptosporidiosis is a highly contagious disorder with limited targeted treatments, biosecurity is critical for the control of disease within production systems.

PRODUCTION MANAGEMENT
Cryptosporidium is a major agent of neonatal diarrhea and can cause severe production losses through neonatal morbidity and mortality.

SYNONYMS

CYANIDE TOXICOSIS

BASICS

OVERVIEW

• Cyanide poisoning is characterized by the abrupt onset of severe neurologic signs.
• Many *Prunus* spp. are cyanogenic, but only a few present a serious risk to livestock: Choke cherry (*P. virginiana*), black cherry (*P serotina*), and cherry laurel (*P. laurocerasus*).
• Other cyanide-containing plants associated with livestock toxicosis are Sudan grass, Johnson grass, milo and sorghum (*Sorghum* spp.), arrow grass (*Triglocin* spp.), bird's-foot trefoil (*Lotus* spp.), vetch (*Vicia* spp.), elderberry (*Sambucus* spp.), cassava and tapioca plant (*Manihot* spp.), corn (*Zea mays*), clover (*Trifolium* spp.), California holly (*Heteromeles arbutifolia*), flax (*Linum spp.*), June berry (*Amelanchior* spp.), fava bean (*Vicia* spp.), and eucalyptus (*Eucalyptus* spp.). Although many grasses contain cyanogenic compounds they are rarely at high enough levels to cause intoxication.

INCIDENCE/PREVALENCE

• Depending on the type of exposure (type of plant, environmental conditions), morbidity and mortality are variable.

GEOGRAPHIC DISTRIBUTION

• Worldwide
• Local occurrence depends on the type of exposure

SYSTEMS AFFECTED

Nervous

PATHOPHYSIOLOGY

• Ruminants are more susceptible to the toxic effects than monogastric animals because rumen microorganisms produce enzymes that facilitate rapid hydrolysis of cyanogenic glycosides.
• Hydrogen cyanide is readily absorbed from the gastrointestinal tract and acts by inhibiting cytochrome oxidase.
• Cyanogenic glycosides commonly present are amygdalin, prunasin, dhurrin, linamarin, and triglocinin.

SIGNALMENT

• All ruminant species are very susceptible. Most reported cases involve goats and cattle.
• Losses in sheep and deer have also been reported.

PHYSICAL EXAMINATION FINDINGS

• Abrupt onset of apprehension and distress occurs within 10–15 minutes of ingestion.
• This is quickly followed by weakness, ataxia, hyperventilation, and hypotension. In severe cases, the animals become recumbent and develop cardiac arrhythmias and tetanic-type seizures.
• Death may occur within 15–60 minutes of exposure.
• Mucus membranes are initially bright cherry red due to the well-oxygenated venous blood.
• Cyanosis may be observed at a later stage of poisoning.

CAUSES AND RISK FACTORS

• Young and rapidly growing plants have the highest concentration of cyanide.
• Plant trimmings remain toxic as long as the leaves are green and have not completely dried.
• All parts of the plants have cyanogenic potential. The highest concentrations of cyanogenic glycosides are found in the leaves, but concentrations are subject to many influences and may vary considerably.
• Insect-, frost-, and drought-damaged cyanogenic plants have been associated with a greater risk for cyanide poisoning.
• Concentrations of greater than 200 µg/g of cyanide in plant material are considered potentially toxic.
• Cyanide in mill tailing ponds at gold mines can present a risk to wild ruminants.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Nitrate/nitrite toxicosis—chocolate-colored blood
• Nonprotein nitrogen toxicosis—exposure to NPN supplements, toxic levels of ammonia in rumen content and blood
• Organophosphorus or carbamate insecticide exposure—gastrointestinal irritation and neurologic signs, evaluation of cholinesterase activity, detection of pesticides
• Lead poisoning—determination of blood lead concentration
• Neurotoxic plants (poison hemlock, water hemlock, tree tobacco, lupine)—analysis for plant toxins in gastrointestinal contents, history of exposure
• Cardiotoxic plants (oleander, milkweeds, and azaleas)—analysis for plant toxins in gastrointestinal contents, history of exposure
• Neurotoxic blue-green algae—identification of algae material in rumen contents
• ABPE—onset of clinical signs usually 1–4 days after an abrupt change to lush pasture, pathologic evaluation of lung

CBC/BIOCHEMISTRY/URINALYSIS

No specific changes

OTHER LABORATORY TESTS

• Detection of cyanide in blood, rumen content, liver, and skeletal muscle
• Samples must be collected promptly and stored frozen in airtight containers until analysis.
• Concentrations in tissues from lethal exposures may be reduced to one third of the initial values within 1 hour of death.
• If liver is not collected within 4 hours of death, skeletal muscle is the preferred sample for analysis.
• Because of the volatility of hydrogen cyanide in biological samples, "toxic" thresholds are not established.

PATHOLOGIC FINDINGS

• There are no clearly distinctive changes.
• Cherry red blood may be evident immediately after death, but the color of blood darkens as postmortem time increases.
• Hemorrhages may occur in the subendocardium, subepicardium, and abomasums.
• There may be mild congestion and edema of the lungs.

TREATMENT

THERAPEUTIC APPROACH

• Immediate removal of the cyanogenic plant material
• Avoid stress
• General supportive care in nonsevere cases
• Administration of antidotes as soon as possible in severe cases

MEDICATIONS

DRUGS OF CHOICE

• The primary antidote for ruminants is thiosulfate. Thiosulfate (20%–40% solution) administered IV at a dose of 25–50 mg/100 kg body weight.
• Sodium nitrite can be given concurrently, but may not be of additional benefit in ruminants. If given, the recommended dose is 10–20 mg/kg body weight IV.
• Cobalt compounds, such as cobalt chloride or hydroxycobalamin, have been used successfully in the treatment of cyanide poisoning in Europe, but have not been approved for use in animals in the United States. Recommended doses for cattle, sheep, and goats are 10–15 mg/kg slowly IV, 15 g in 250 mL dextrose 5%.

CONTRAINDICATIONS

• Do not administer methylene blue, as it is ineffective as a producer of methemoglobinemia.
• If there is suspicion that cyanide poisoning is combined with nitrate poisoning, administration of sodium nitrite is contraindicated.
• Meat and milk withdrawal periods for drugs given must be determined.

CYANIDE TOXICOSIS (CONTINUED)

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Animals poisoned with cyanide are often found dead.
- Cyanide poisoning progresses so rapidly that treatment is often too late. In most cases, the affected animals have a poor-to-grave prognosis.
- If treatment is initiated promptly, the prognosis is fair.
- Animals that live beyond 1 hour following intake are likely to survive.

PREVENTION

- Delaying grazing until cyanogenic forage has matured.
- Slow and thorough drying of forage reduces the cyanide concentration.
- Avoid exposure of animals to frost- or insect-damaged cyanogenic plants. After a killing frost, wait for at least 4–6 days before grazing.
- Do not allow hungry cattle to graze cyanogenic plants.
- Feeding material as silage will reduce the risk of poisoning, as correct ensilage for 3 weeks reduces levels of toxin by approximately 50%.
- Suspect forage should be analyzed for cyanide concentrations.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Sorghum spp. often contain toxic nitrate concentrations.

PRODUCTION MANAGEMENT

- Delay grazing until cyanogenic forage has matured.
- Slow and thorough drying of forage reduces the cyanide concentration.
- Avoid exposure of animals to frost- or insect-damaged cyanogenic plants. After a killing frost, wait for at least 4–6 days before grazing.
- Do not allow hungry cattle to graze cyanogenic plants.
- Ruminants are more susceptible to the toxic effects than monogastric animals because rumen microorganisms produce enzymes that facilitate rapid hydrolysis of cyanogenic glycosides.

DEATH CAMAS

BASICS

OVERVIEW

• Approximately 14 species of *Zygadenus* are present in North America including:
  ◦ Black death camas, black snakeroot, crow poison (*Z. densus*)
  ◦ Mountain death camas, white camas, elegant death camas (*Z. elegans*)
  ◦ Chaparral death camas, star lily (*Z. fremontii*)
  ◦ Death camas, sand-bog death camas (*Z. leimanthoides*)
  ◦ Poison camas, Nuttall's death camas (*Z. nuttallii*)
  ◦ Foothill death camas, panicled death camas, sand corn (*Z. paniculatus*)
  ◦ Alcove death camas (*Z. vaginatus*)
  ◦ Meadow death camas, grassy death camas (*Z. venenosus*)
• Of these *Z. nuttallii, Z. venenosis,* and *Z. paniculatus* are the most toxic.
• *Zygadenus* spp. are an herbaceous perennial plant.
• Leaves are hairless, grass-like, linear, V-shaped, and parallel-veined. They are not hollow. The leaves are the most frequently ingested part of the plant.
• This species arises from an onion-like bulb that has a black membranous outer layer. The bulb is located 6–8 inches below the soil surface. These become present in early spring. The bulb is the most toxic part of the plant.
• The bulb and leaves can be mistaken for wild onion; however, they lack the onion smell.
• Flowers are small, perfect, greenish white to yellow, that inflorescence with a terminal raceme or panicle blooming typically around June.
• Seeds are fusiform to oblong, smooth, angular and light brown.

INCIDENCE/PREVALENCE

• Poisoning is most likely to occur in early spring when few other plants are available.
• Mortality of 10% occurred in a flock of about 2,400 sheep.

GEOGRAPHIC DISTRIBUTION

Found mainly in mountain valleys, sandy hills, and grass plains of the United States.

SYSTEMS AFFECTED

Cardiovascular

PATHOPHYSIOLOGY

• Toxic compounds are steroidal alkaloids, most notable being zygadine and zygacine. The alkaloids are similar to those found in *Veratrum* spp.
• Alkaloids produce hypotensive effects.
• Toxic compounds are found in variable concentrations depending on growth stage with vegetative and pod stages containing the highest concentration and the flowering stages appearing to be the lowest.
• Seeds and leaves in the early stages of growth are most toxic.
• Toxic dose is estimated at 0.2–1% of body weight.

HISTORICAL FINDING

Presence of plant or cuttings of the plant within the pasture

SIGNALMENT

• Sheep are most commonly affected.
• Also cattle, goats, and camelids.

PHYSICAL EXAMINATION FINDINGS

• Salivation
• Depression and weakness
• Low head carriage, arched back
• Incoordination
• Coma, labored breathing, and death

CAUSES AND RISK FACTORS

• Presumed steroidal alkaloid resulting in hypotension.
• Range fire can result in increased nitrogen levels during regrowth. It is unknown if the increased nitrogen has an effect on the toxic compounds but it may increase the palatability of the plant.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Other cardiovascular toxicities (i.e., cyanide toxicosis, cardiotoxic plants)
• Monensin poisoning

CBC/BIOCHEMISTRY/URINALYSIS

No unremarkable changes

OTHER DIAGNOSTIC PROCEDURES

• History of exposure to the plant
• Finding of plant material within gastric contents on gross pathology

PATHOLOGIC FINDINGS

• No characteristic lesions.
• Pulmonary congestion and edema with scattered small hemorrhages are most likely to be present, although there may also be reddening of the mucosa of the stomach and small intestine.

TREATMENT

THERAPEUTIC APPROACH

• Remove from the source.
• Early treatment with atropine 2 mg and 8 mg picrotoxin in 5 mL of water administered subcutaneously per 50 kg bwt.
• Recovery can occur if removed from source and or treated at the beginning of clinical sign presentation.

MEDICATIONS

DRUGS OF CHOICE

Treatment with atropine 2 mg and 8 mg picrotoxin in 5 mL of water administered subcutaneously per 50 kg bwt.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Recovery possible
• Death once recumbent

PREVENTION

Avoid grazing pastures that have *Zygadenus* spp. in the spring.

MISCELLANEOUS

PRODUCTION MANAGEMENT

Identify pasture areas that contain *Zygadenus spp.* that are risk areas.

DERMATOPHILOSIS

BASICS

OVERVIEW
A common pustular/crusting, nonpruritic disease of ruminants caused by *Dermatophilus congolensis.*

INCIDENCE/PREVALENCE
• Highest in regions with wet weather.
• Morbidity can reach 100%.
• Subclinical infections can be present in endemic areas.

GEOGRAPHIC DISTRIBUTION
Worldwide distribution with significant prevalence in Africa, the Middle East, Mediterranean Europe, and the Americas.

SYSTEMS AFFECTED
Integument

PATHOPHYSIOLOGY
• *D. congolensis* is an aerobic to facultatively anaerobic, non-acid-fast, Gram-positive actinomycete.
• Two morphologic forms exist: filamentous hyphae and motile zoospores.
  ◦ Hyphae: branching filaments, divide transversely/longitudinally, mature into flagellated ovoid zoospores.
  ◦ Zoospores: infective form, released when scabs are exposed to moisture.
• Disruption of the protective barrier of skin allows bacterial entry, related to ectoparasites, self-trauma, foreign body penetration, or shearing abrasions/burns.
• Serous exudation/crusting due to neutrophilic infiltrate leads to matting of wool/hair after an incubation as short as 2 weeks.

HISTORICAL FINDINGS
Recent wet weather and other predisposing incidents might be reported.

SIGNALMENT
All ruminants of all ages can be affected, but juveniles are predisposed and lambs <5 weeks of age are most susceptible.

PHYSICAL EXAMINATION FINDINGS
• Clinical signs correspond to predisposing factors: Moisture and microtrauma of the skin. Areas of body most often affected are those exposed to trauma.
• Lesions begin with matting of hair/wool and coalesce, forming crusts/scabs. Undersides of scabs have a paintbrush appearance. Accumulations of cutaneous keratinized material form wart-like lesions.
• Cattle: Thick crusts palpable under hair coat, scabs, and/or wart-like lesions on head, chest, dorsum, and upper lateral surface of neck. Lesions may be seen on legs of cattle standing in water, mud or lush pasture; or may be localized to the udder/scrotum.
• Sheep: Serous exudate at base of wool, fleece becomes matted (lumpy wool disease). Chronic lesions persist as crusts on face, nose, or ears.
• Strawberry footrot in sheep: Proliferative dermatitis affecting skin from the coronet to the carpus/hock. Lesions heal by granulation, observed when crusts are removed (strawberry appearance). Clinical cases are most severe in young stock (<1 year old).
• Lambs may rapidly develop generalized infection on the dorsum. Severe serous exudate can make movement difficult. Secondary bacterial infections or flystrike may lead to death if severe.
• Goats: Wartlike scabs on inner pinnae. Nose, muzzle, feet, scrotum, and tail may be affected.
• Buffaloes/cattle may develop erosive/granulomatous lesions on palate, lips, and tongue.
• Subcutaneous and lymph node abscesses may occur in cattle, sheep, and goats.
• Camelids: Focal subcutaneous swelling in addition to the superficial dermatitis is described in Australia. Loosely fleeced areas (face, neck, distal extremities, inguinal region) are most affected. Syndrome is characterized by the development of local abscesses, granulomas, and regional lymphadenopathy. Plant material found within lesions suggests that penetrating or migrating plant material causes the deep infection.
• New world camelids: Lesions on ears, neck, rump, dorsum and feet; wool rot.

GENETICS
• Breed variability with respect to susceptibility
• Zebu cattle considered more resistant than *Bos taurus*
• West African N'dama, and Muturu breeds highly resistant
• Fine wool sheep breeds more susceptible
• More prevalent in Old World camelids than in New World camelids

CAUSES AND RISK FACTORS
• The most important predisposing factors are chronic wetting, maceration, or microtrauma to the skin. Intact healthy skin is not believed to be susceptible.
• Infected animals, healthy carrier animals and apparently recovered animals may transmit the disease.
• Outbreaks most common after periods of heavy rain/high humidity.
• Long hair may predispose to infection.
• Ectoparasites are an important cause of microtrauma.
• Mechanical transmission can occur via ectoparasites, animal-to-animal contact, and during dipping practices.
• Environment/equipment can be contaminated.
• Dried scabs from infected animals are important sources of infection for susceptible animals and for recurrence of infection.
• Sheep may carry the infection subclinically, acting as carriers of the disease.
• Unpigmented skin may be more susceptible.
• Malnutrition/concurrent disease may predispose animals.
• Zoospores can remain viable in crusts at temperatures of 28–31°C for up to 42 months.
• Zoospores in crusts can remain viable when dried and after being heated to temperatures of 100°C.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Contagious ecthyma
• Crusted mange lesions
• Dermatophytosis
• Malignant catarrhal fever
• Mucosal disease
• Pemphigus foliaceus
• Peste des petits ruminants
• Staphylococcal infections
• Ulcerative dermatosis
• Zinc-responsive dermatosis

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• Cutaneous impression smears of underside of moist scabs: Staining with Gram, Giemsa, Wright or Diff Quik stains demonstrate coccoid/branching filamentous organisms when viewed with oil immersion magnification.
• Cytologic examination of deep layer of crusts adjacent to granulation tissue: coccoid bacteria branching into "railroad track" formation.
• Crust preparation: Mince crusts in sterile water on glass microscope slide; allow to dry; stain and examine with oil immersion. This may prove helpful when only older crusts are available.
• Skin biopsy: see "Pathologic Findings."
• Bacterial culture: Grow organism from crusts/skin biopsy on blood agar in increased carbon dioxide atmosphere.
• Indirect fluorescent antibody and ELISA tests are available for herd investigations.

PATHOLOGIC FINDINGS
Skin biopsy: Folliculitis, intraepidermal pustular dermatitis and intracellular edema. Surface crusting is characterized by alternating layers of ortho- and/or parakeratotic hyperkeratosis and neutrophilic exudates. Organism is seen within keratinous debris.

(CONTINUED) DERMATOPHILOSIS

TREATMENT

THERAPEUTIC APPROACH
• Separate clinically affected animals from normal animals.
• Provide shelter from rain.
• Improve nutrition (protein, energy, mineral) and ectoparasite control.
• Tick control is essential in the control of the disease.
• Protect animals from flystrike.
• Disease is self-limiting over several weeks if affected animals are kept dry.
• Remove infected crusts/tufts of crusted hair or clip matted hair to reduce the number of organisms present.
• Bathe with antibacterial shampoo such as chlorhexidine, or use topical agents such as dilute povidone iodine (1:4) to aid healing.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Parenteral antibiotics for minimum 4–6 days (longer in refractory cases).
• Procaine penicillin G (20,000–70,000 units/kg body weight, IM) q12–24h.
• Ceftiofur at standard doses.
• Oxytetracycline (200 mg/ml) 20 mg/kg body weight, SQ or IM, q72h.
• Polymixin B, bacitracin, and sulfonamides may be effective.
• Copper sulfate 0.2%, lime sulfur 0.2–0.5%, potassium aluminum sulfate 1%, or zinc sulfate 0.5% as topical dips or sprays.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Disease generally resolves in 2–4 weeks if animals are removed from wet, moist conditions.

POSSIBLE COMPLICATIONS
Secondary infection of the skin might occur

CLIENT EDUCATION
Educate clients with regard to risk factors and methods of prevention

PATIENT CARE
N/A

PREVENTION
• Provide shelter from excessive moisture and minimize ectoparasite infestations.
• Isolate affected animals, cull chronically infected animals, and disinfect environment.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Lameness in sheep
• Mastitis in dairy cows, sheep, and goats

AGE-RELATED FACTORS
Young animals are more susceptible

ZOONOTIC POTENTIAL
• Potential zoonotic disease.
• Wear gloves when handling infected animals, hair, wool or crusts.
• Wash hands with disinfectant soap after handling infected animals.
• Properly dispose of infected hair, wool, and crusts.
• Disinfect all items in contact with affected areas (grooming equipment, clippers, etc.).

PREGNANCY
N/A

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
• Decreased milk production in dairy cows and goats
• Decreased fertility
• Cachexia and death
• Impaired heat resistance in camels
• Hides/skin unsuitable for leather
• Fleece with scabs downgraded in quality
• May predispose animals to flystrike

SYNONYMS
• Cakey wool

DERMATOPHYTOSIS

BASICS

OVERVIEW
• Fungal infection of the keratinized tissues of the skin; affects the stratum corneum layer of epidermis, hair, hoof, and horns.
• Primary causative agents: *Trichophyton* spp. and *Microsporum* spp.

INCIDENCE/PREVALENCE
Dermatophytosis is one of the most common infectious/contagious skin diseases of large animals.

GEOGRAPHIC DISTRIBUTION
• Worldwide
• Common in areas with high humidity—warm subtropical/tropical geographic regions
• Occurs in winter climates where animals are housed indoors

SYSTEMS AFFECTED
Integument

PATHOPHYSIOLOGY
• Naturally infective state is an arthrospore.
• Exposure to infective spores occurs via direct contact with infected animals and/or exposure to contaminated environments.
• Rodents may be reservoirs of infection for *Trichophyton* spp.
• Exposure does not guarantee infection. Organism must evade natural host defenses. Infective spores are brushed off or fall off.
• Moisture/microtrauma to skin allows organism to gain entry and germinate. The organism invades actively growing hairs, making them fragile. Nutrition source is keratin.
• Incubation 1–3 weeks.
• Recovery occurs when host develops a cell-mediated immune response.
• Disease is generally self-limiting.
• Increased immunity in animals previously exposed. Duration of immunity unknown.

HISTORICAL FINDINGS
N/A

SIGNALMENT
• Sheep and cattle most often affected
• Most common in young, old, or debilitated animals

PHYSICAL EXAMINATION FINDINGS
• Clinical signs highly variable; may be affected by treatments administered by client.
• Pruritus can be absent to severe.
• Variably sized annular rings of alopecia, erythema, scaling, crusting, or thick adherent crusts.
• Cattle: Well-demarcated, tightly adherent, grayish crusts; may develop into severe areas of alopecia, crusting, exudation, and ulceration.
• Calves: Most common around eyes and on head/neck. Cows/heifers: Most common on the udder. Bulls: Dewlap and in intermaxillary spaces.
• Sheep/goats: Most common on face, neck, thorax, and back; appear as circular areas of alopecia and thick, gray crusts.
• Lesions at coronary band may lead to lameness.
• Kerion reactions are inflammatory reactions, particularly to *M. gypseum,* and may look like an abscess.

GENETICS
N/A

CAUSES AND RISK FACTORS
• *Trichophyton* spp.: *T. verrucosum*, *T. mentagrophytes*, *T. equinum*, *T. quinckenum*, *T. sarkisovii*, *T. schoeleinii*, *T. dankaliense*, *T. tonurans*.
• *Microsporum* spp.: *M. canis*, *M. nanum*, *M. gypseum*.
• Not species-specific.
• Age extremes, pre-existing illness, debilitated or immunocompromised animals.
• Poor nutrition.
• Overcrowding.
• Lack of exposure to sunlight.
• Excessive moisture/warmth leading to maceration/skin damage.
• Adult animals are infected/reinfected when new animals are introduced to herd.
• Parasite infestation may predispose animals to infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Demodicosis
• Dermatophilosis
• Dermatomycosis
• External parasites
• Immune-mediated diseases including Pemphigus foliaceus
• Pemphigus foliaceus
• Staphylococcal dermatitis
• Zinc-responsive dermatosis

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• Wood's lamp: Fluorescence is not definitive for diagnosis. Causes of false-positives include scaling, sebum, and medications. Most pathogenic dermatophytes do not fluoresce.
• Potassium hydroxide treated hair/scale may reveal ectothrix spores. This is not cost effective and many artifacts can occur; invasion of hair shafts is most easily seen with *M. canis.*
• Take scrapings/hairs from periphery of lesions (active growth). Organism is aerobic. Exudate from inflamed epithelial layers, epithelial debris, and fungal hyphae produce crusts, resulting in a more anaerobic environment. Organisms die out in center of lesions under crusts.
• Culture: Wipe lesions with alcohol and allow to dry. Remove crusts or pluck infected hairs/scale and embed in fungal culture media—Sabouraud dextrose agar and DTM dual plate.
  ◦ Color change (red) on DTM not pathognomonic for presence of the pathogen, only that rapidly growing colonies are suspect
  ◦ *Microsporum* spp. colonies usually grow within 7–10 days. *Trichophyton* spp. may take up to 21 days.
  ◦ Pathogens are not grossly or microscopically pigmented.
  ◦ Use lactophenol cotton blue stain and clear cellophane tape to identify colonies.
• Skin biopsy is the most cost-effective diagnostic tool. Do not scrub/prep lesion prior to biopsy. Include crusts and sample periphery.
• Diagnosis often based upon history and clinical signs; it may not be cost effective to make a definitive diagnosis in all cases.

PATHOLOGIC FINDINGS
• Primarily focal areas of alopecia. Disease is characterized by folliculitis, furunculosis, hyperkeratosis, intraepidermal pustules, and nodular to diffuse pyogranulomatous infiltrates.
• Definitive diagnosis: Presence of fungal hyphae in nodular reactions, in hair shafts/hair follicles. Fungal elements may be seen with H & E stain, but special stains may allow for easier identification.
• Skin biopsy recommended if lesions are atypical and/or if animal does not respond to therapy.

TREATMENT

THERAPEUTIC APPROACH
• Isolate infected animals.
• Eliminate spread by herd animals, farm personnel, or fomites.
• All exposed animals, environment, and fomites should be treated.
• Many treatments are of unknown efficacy and often represent extra-label use; withdrawal times are unknown with respect to meat and milk.
• Improve nutrition/housing; allow animals to go outside, decrease crowding.
• Clean and disinfect environment repeatedly since infective spores are extremely difficult to eradicate. Reduce contamination of the environment by properly disposing of debris containing infective spores. Must be done

repeatedly since spores are difficult to eradicate and remain viable for years.
• Treatment of environment: Sprays such as lime sulfur 5%, sodium hypochlorite 5%, formalin 5%, Captan 3% and Cresol 3% have been used. Enilconazole (Clinafarm®) has also been used as a spray or fogger.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Topical treatments can be applied after patient preparation. Remove crusts/scales and clip infected hairs in a wide margin including lesions. Dispose of material properly. Bathe animal, rinse, and towel dry before treatment. Treat lesion, extending out past periphery.
  ◦ Natamycin—animals improve, but cure not achieved.
  ◦ Listerine® mouthwash for spot treatment, scrubbed into wound once daily for 7 days.
  ◦ Chlorhexidine 0.5% solution reported for show lamb fungus, is inactivated by soap.
  ◦ Iodine 7% mixed with emollient Bag Balm® applied once daily for 7 days.
  ◦ Topical sprays include Captan 3%, lime sulfur 2–5% topically for 5 days, then weekly for 3–4 weeks. Treat entire animal by thoroughly soaking the hair coat/wool using a vat dip or sprayer. Do not rinse.
  ◦ Antifungal spray/dip: Enilconazole 0.2% (Imaverol emulsion) not licensed in the United States. Enilconazole (Clinafarm® in US **only**) 55.6 mL/gal; off-label.
• Systemic antifungal drugs—efficacy unknown. Cost prohibitive.
  ◦ Griseofulvin (at published dosages) orally once daily until cured. Expensive. No specified withdrawal time.
  ◦ Itraconazole 5–10 mg/kg orally once daily until cured, or use as pulse therapy (week on-week off).
  ◦ Sodium iodide 10–20% at 1 g/14 kg IV once a week reported effective.

CONTRAINDICATIONS
Some systemic antifungal drugs are contraindicated in pregnant animals.

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Disease generally resolves within 70–100 days.
• Consider immunosuppressive conditions or predisposing environmental factors if animals not recovered after 4 months.

POSSIBLE COMPLICATIONS
• Lime sulfur discolors white hair coats.
• Systemic antifungals (especially griseofulvin) are teratogenic and should not be used in pregnant animals.

CLIENT EDUCATION
See "Prevention"

PATIENT CARE
Treat animals until cure achieved—clinical cure occurs before mycologic cure. Minimum period is 4–6 weeks.

PREVENTION
• Provide good nutrition, good housing, and adequate exposure to dry, well-ventilated housing.
• Antifungal vaccines: Clinical signs decreased in cattle and camels in eastern Europe, Scandinavia, Kazakhstan, and United Arab Emirates. However, use is controversial; no evidence to show protection against challenge exposure. Not available in the US.
• Isolate new animals before adding to the herd. Prophylactic dipping with lime sulfur may be useful in preventing introduction of organism in "clean" herd.
• Treat all animals to prevent reinfection and/or spread of the disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Young animals more susceptible

ZOONOTIC POTENTIAL
This is a zoonotic disease and animal handlers should take appropriate precautions.

PREGNANCY
N/A

BIOSECURITY

DIARRHEAL DISEASES: BOVINE

BASICS

OVERVIEW
Diarrhea can be defined as abnormally increased water content in the feces, usually associated with increased frequency of defecation.

INCIDENCE/PREVALENCE
The USDA dairy report (2007) included 2,194 herds—diarrhea was reported (by owners) in 2.5% of the mature cows and 24% of the unweaned heifers.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
- Digestive
- Cardiovascular
- Urinary
- Hemolymphatic

PATHOPHYSIOLOGY
- Diarrhea results from different mechanisms including hypersecretion, abnormal permeability, increased intraluminal osmolality, and abnormal motility; most diarrheic states are caused by more than one mechanism.
- Hypersecretory diarrhea arises from an increase in the amount of fluid being drawn into the lumen of the bowel, overwhelming the absorptive capacity of the intestines. Typically caused by infectious agents.
- Abnormal permeability: Mucosal inflammatory ulceration or necrosis can result in abnormal tight junction functions of the intestinal epithelium, leading to fluid loss (mild cases), and loss of albumin, red blood cells, and globulins (severe cases).
- Osmotic: Presence of poorly absorbed, osmotically active substance causes movement of water from the extracellular fluid into the gut lumen (i.e., loss of lactase activity secondary to damage of the intestinal epithelium).
- Abnormal motility: Hypermotility can result from inflammation of the gastrointestinal tract leading to faster transport of intestinal contents and diarrhea.
- Loss of large volumes of electrolyte-rich fluid can result in electrolyte, fluid, and acid-base disorders.
- Damage to the enteric barrier can result in albumin loss, toxemia, bacteremia, systemic inflammation and multi-organ dysfunction associated with hypovolemic and septic shock.
- Bacteremia/septicemia can result in septic arthritis, pneumonia, and abortion.

HISTORICAL FINDINGS
Epidemiologic information, including age and number of animals affected, management characteristics, season, and clinical course can help distinguish appropriate differentials.

SIGNALMENT
Any age, breed or gender

PHYSICAL EXAMINATION FINDINGS
- Mild cases—loose feces and appear otherwise clinically normal.
- Severe cases—fever, diarrhea, dehydration, weakness, and potentially frank blood in the feces (coccidiosis, coronavirus, salmonellosis, torovirus). Diarrhea and oral erosions (30–50% of the cases) can be seen in acute cases of bovine viral diarrhea virus (BVDV).
- Chronic diarrhea—associated with progressive wasting and loss of body condition.

GENETICS
N/A

CAUSES AND RISK FACTORS

Neonatal Calf Diarrhea
Infectious
- Viral—rotavirus, coronavirus, BVDV, torovirus, norovirus, and nebovirus.
- Bacterial—enterotoxigenic *E. coli*, enteropathogenic *E. coli*, *Salmonella* spp., *C. perfringens* (rarely, type A and type C associated with enteritis and abomasitis).
- Protozoal—*Cryptosporidium parvum*, *Giardia*, *Eimeria bovis, Eimeria zuernii,* and *Eimeria alabamensis*.

Noninfectious
- Nutritional diarrhea. Anecdotal evidence suggests that ingestion of large volumes of milk can result in diarrhea. Lactose intolerance secondary to infectious diarrhea.
- Diarrhea and emaciation caused by milk replacer feeding. Inappropriate quality (low protein or fat content) and quantity (usually not enough) of milk replacer.
- Poor clotting ability of the milk is associated with low calcium content.

Adult Cattle
Infectious
- Viral—BVDV, coronavirus (winter dysentery), torovirus (winter-like dysentery), acute malignant catarrhal fever (MCF) can cause severe diarrhea as a prominent sign.
- Bacterial—*Salmonella* spp., *Mycobacterium avium* subsp. *paratuberculosis* (MAP, Johne's disease), *C. perfringens* (type C associated with diarrhea).

Noninfectious
- Arsenic toxicosis
- Oak (acorn) toxicosis
- Copper or cobalt deficiency
- Administration of cathartics

Risk Factors
- Failure of passive transfer of immunity.
- Inappropriate volume, fat, protein, or calcium content of milk or milk replacer.
- High stocking density and poor hygiene.
- Presence of other animals with diarrhea, salmonellosis, or advanced MAP in the herd.
- Pastures or diets deficient in cobalt or copper, or with abundant acorn crops.
- Arsenic—wood preservatives, burn piles, discontinued insecticides and molluscicides.
- Copper—diets low in copper or high in sulfates, zinc, or molybdenum.
- Cobalt—diets deficient in cobalt, heavy fertilization with limestone.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
- Septicemia
- Peritonitis
- Gastrointestinal parasitism
- Neoplasia

CBC/BIOCHEMISTRY/URINALYSIS
- Normal in mildly affected and clinically stable animals.
- Anemia can reflect dysentery, cobalt or copper deficiency, parasitism, or MAP.
- Hemoconcentration—dehydration.
- Leukopenia with neutropenia, left shift, and toxic changes—severe gastroenteritis and toxemia.
- Hypoproteinemia—loss of albumin, the magnitude of hypoalbuminemia can be attenuated by dehydration.
- More severe acute or chronic disease creates changes reflecting dehydration (hemoconcentration, azotemia), inflammation (leukocytosis or leukopenia with neutropenia, left shift, and toxic changes), protein loss (hypoalbuminemia), and metabolic acidosis (reduced TCO_2, increased lactate).
- Electrolyte abnormalities often include low sodium, potassium and chloride.
- Hyperglycemia and glucosuria occur with type D enterotoxemia.

OTHER LABORATORY TESTS
- Culture of feces—*E. coli*, *Salmonella* spp., MAP
- PCR—*E. coli*, *Salmonella* spp., rotavirus, coronavirus, MCF
- Immunoassays—*C. perfringens* toxins, coronavirus, MCF
- Immunofluorescence assays—*Cryptosporidium* and *Giardia*
- Electron microscopy—rotavirus, coronavirus
- Hepatic concentration of copper (normal 90–200 µg/g)
- Serum vitamin B_{12} (cobalt deficiency)—normal 1–3 ng/mL

IMAGING
Transabdominal ultrasonography and abdominocentesis might be useful for distinguishing differentials.

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
N/A

(CONTINUED) DIARRHEAL DISEASES: BOVINE

TREATMENT

THERAPEUTIC APPROACH

• Success relies on early identification of the problem, immediate correction of dehydration, metabolic acidosis, and electrolyte abnormalities.
• Determine fluid requirements in terms of replacement, maintenance, and ongoing losses.
• Animals estimated to be >8% dehydrated should be rehydrated IV initially, and then can be maintained on IV or oral fluid therapy. Large volumes of water and rehydration solutions can be administered orally to cattle (20–40 L at a time several times per day to adults).
• The volume (L) of fluids to replace the deficit can be calculated as: *Volume (L) = body weight (kg) × % dehydration.* Balanced crystalloids can be given at 20 mL/kg/h (highest rate reached through a 14 gauge catheter) for fluid replacement.
• Maintenance fluids can be continued at a rate of 2–4 mL/kg/h.
• Cows with mild acidemia (base deficits <10 mmol/L) will usually respond to basic fluid therapy.
• Cows with more severe acidemia (base deficits >10 mmol/L) can benefit from isotonic sodium bicarbonate (156 mEq $NaHCO_3$/L; or 1.3% solution).
• The total bicarbonate deficit can be calculated from base deficit on blood gas analysis or by estimating from the decrease in TCO_2 on serum chemistry (*Bicarbonate deficit (mEq) = body weight (kg) × base deficit (mEq/L) × 0.6*).
• Hypertonic saline (5% or 7.2%) can be administered to dehydrated cows at dose of 4–5 mL/kg, IV, over 5 minutes. The cow must be allowed to drink water, and cows not observed to drink within 5 minutes should receive 20 L of water via orogastric tube.
• Ruminal transfaunation can be beneficial in cases of prolonged anorexia.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

• Animals with prolonged dysentery can need whole blood transfusion (4–8 L).
• Antimicrobials are recommended when septicemia/bacteremia are suspected—beta-lactam drugs (ceftiofur, amoxicillin, or ampicillin), tetracyclines, or potentiated sulfonamides (where permitted).
• Nonsteroidal anti-inflammatory drugs—beneficial in cattle with toxemia (flunixin meglumine or meloxicam).
• Arsenic toxicity—sodium thiosulfate (40 mg/kg IV q8h and 80 mg/kg PO q24h)
• Copper deficiency—copper glycinate 400 mg SC (calves 100 mg). Cattle can be supplemented with copper in salt mineral mixes at 50 g/cow/day.
• Cobalt deficiency—vitamin B12, 2,000–3,000 μg weekly until improvement.

CONTRAINDICATIONS

Nephrotoxic drugs are contraindicated in severe dehydration and azotemia.

PRECAUTIONS

Dehydrated ruminants can generate profound azotemia which is prerenal in origin, and should not be mistaken for renal failure. Prerenal azotemia is expected to respond rapidly to appropriate fluid therapy.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Prognosis is good to fair for animals with infectious or nutritional diarrhea receiving supportive care.
• Prognosis is grave for cases of arsenic or oak toxicosis or with severe secondary complications.

POSSIBLE COMPLICATIONS

• Shock and death.
• Intussusception, associated with changes in GI motility.
• Renal failure.

CLIENT EDUCATION

Focus on encouraging protocols for optimizing passive transfer to crias, managing stocking density, and controlling parasitic infestations.

PATIENT CARE

Monitor attitude, fecal consistency, and hydration status.

PREVENTION

• Ensure good-quality colostrum intake to neonates.
• Environmental hygiene.
• Vaccination protocols.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Septicemia
• Meningitis
• Septic arthritis
• Abortion

AGE-RELATED FACTORS

More common in calves <1 month of age.

ZOONOTIC POTENTIAL

• Ruminants can be considered as a reservoir for pathogenic *E. coli, Salmonella* spp., and *Cryptosporidium* spp.

PREGNANCY

N/A

BIOSECURITY

• Environmental and personnel hygiene are critical: gloves, outerwear, hand washing, disinfection.
• Segregate sick animals.

DIARRHEAL DISEASES: CAMELID

BASICS

OVERVIEW
Diarrhea reflects abnormally increased water content in the feces, usually with increased frequency of defecation.

INCIDENCE/PREVALENCE
• Varies with etiology; often sporadic.
• Specific infectious agents can occur with high prevalence in vulnerable groups.

GEOGRAPHIC DISTRIBUTION
Worldwide, with specific distributions of some infectious agents.

SYSTEMS AFFECTED
• Digestive
• Cardiovascular
• Urinary

PATHOPHYSIOLOGY
• Diarrhea results from mechanisms including abnormal permeability, hypersecretion, abnormal motility, and increased intraluminal osmolality.
• Most diarrheic states are caused by more than one mechanism.
• The colon of camelids has large absorptive capacity; therefore, gastric and small intestinal diseases do not consistently cause diarrhea, except when damage is severe, a systemic complication exists (e.g., hypoproteinemia), or the colon is concurrently diseased.
• Loss of large volumes of electrolyte-rich fluid can result in electrolyte imbalances, dehydration, and acid-base disorders.
• Damage to the enteric barrier can result in albumin loss, toxemia, bacterial translocation, and multi-organ dysfunction associated with hypovolemic and septic shock.

HISTORICAL FINDINGS
Depend on the primary disorder. Epidemiologic information, including age and number of animals affected, management characteristics, season, and clinical course can help distinguish appropriate differentials.

SIGNALMENT
• All breeds and ages are susceptible.
• Some infectious disorders are more common in neonates (*E. coli*, *Cryptosporidium*).

PHYSICAL EXAMINATION FINDINGS
• Initially, signs of systemic illness—lethargy, anorexia, and possibly fever, but without diarrhea.
• Mild, acute cases—clumped stool or low volume, liquid feces.
• Severe, acute cases—fever, liquid feces, dehydration, weakness, hematochezia (blood in the feces), tenesmus, abdominal distension, and colic.
• Chronic diarrhea—progressive wasting, which may not be noted promptly in large herds, or because of fleece cover, avoidance to handling and stoicism of affected camelids.
• Lymphoma—peripheral lymphadenopathy (occasionally).

GENETICS
N/A

CAUSES AND RISK FACTORS
Neonatal and Juvenile Camelids
• Viral—rotavirus or coronavirus in crias >7 days. Potentially bovine viral diarrhea virus (BVDV) and parvovirus.
• Bacterial—*E. coli* and other pathogens that can cause concurrent septicemia in very young crias; *Salmonella* spp. (rare); *Clostridium perfringens* (type A, C, or D).
• Parasites—*Cryptosporidium* spp. or *Giardia* in crias ≥7 days. Internal parasitism—important cause of diarrhea in crias >4–6 weeks old (heavy infestations of small coccidia, *Eimeria macusaniensis* (E. mac), and also *Trichuris* and *Nematodirus battus* among other nematodes).
• Noninfectious—nutritional diarrhea due to inappropriate quality and quantity of milk or milk replacer, related to mixing errors or the use of alternative milk sources (sheep, cow, goat) with different protein and fat content to camelid milk. In older crias, lush pastures or sudden dietary changes.

Adult Camelids
• Viral—coronavirus.
• Bacterial—*Salmonella* spp. (rare), *C. perfringens.*
• Parasites—*Trichuris*, *N. battus,* and heavy infestations with other nematode species or small *Eimeria* spp; E. mac.
• Noninfectious—forestomach acidosis, peritonitis.

Chronic Diarrhea and Weight Loss
• Bacterial—*Mycobacterium avium* subsp. *paratuberculosis* (Johne's disease) and *M. avium* subsp. *avium*; *Yersinia enterocolitica*, and *Y. pseudotuberculosa*.
• Parasites—*Trichuris*, liver flukes, E. mac.
• Noninfectious—inflammatory bowel disease (eosinophilic or lymphocytic-plasmacytic infiltration), neoplasia (lymphoma, squamous cell carcinoma, adenocarcinoma).

Risk Factors
• Failure of passive transfer in crias.
• Inappropriate volume, or fat, protein or calcium content of milk or milk replacer.
• High population density and poor hygiene.
• Presence of other animals with diarrhea.
• *Salmonella*, *Cryptosporidium,* Johne's disease or E. mac within a herd.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Septicemia
• Peritonitis

CBC/BIOCHEMISTRY/URINALYSIS
• Typically normal in mildly affected, clinically stable animals.
• Anemia—GI hemorrhage, chronic disease, or heavy parasitism.
• More severe acute or chronic disease—dehydration (hemoconcentration, azotemia), inflammation (leukocytosis or leukopenia with neutropenia, left shift and toxic changes), protein loss (hypoalbuminemia) and metabolic acidosis (reduced TCO_2, increased lactate).
• Electrolyte abnormalities—hypernatremia more common than hyponatremia, and can be accompanied by hyperchloremia. Hypokalemia, hypochloremia, and hypocalcemia also possible.
• Hyperosmolar syndrome can arise from diarrhea or be induced during treatment (iatrogenic), usually in crias, with profound elevations in serum glucose, urea nitrogen, and sodium.
• Hypoglycemia—septic crias; hyperglycemia is a more common response of camelids to physiologic stress.

OTHER LABORATORY TESTS
• Fecal culture—*E. coli*, *Salmonella* spp., *Myocbacterium*.
• PCR—*E. coli*, *Salmonella* spp., coronavirus, E. mac.
• Immunoassays—*C. perfringens* toxins, coronavirus.
• Fecal egg count (quantitative McMaster technique, sugar centrifugation)—internal parasitism.
• Light microscopy of direct smears—*Giardia*, *Eimeria*, *Cryptosporidium*.
• Immunofluorescence assays—*Cryptosporidium* and *Giardia*.
• Sucrose flotation—E. mac.

IMAGING
• Ultrasonography can identify thickening of the small intestine and/or colon due to E. mac, neoplasia, and inflammatory bowel disease.
• Thickening of the gastric compartments (particularly C2, C3) can occur with lymphoma.
• Free peritoneal fluid can indicate neoplasia, peritonitis, or ascites.

OTHER DIAGNOSTIC PROCEDURES
• Abdominocentesis—peritonitis, lymphoma.
• Biopsy—can require exploratory procedures to accomplish safely.

PATHOLOGIC FINDINGS
Depend on the etiology of the disease.

TREATMENT

THERAPEUTIC APPROACH
• Success relies on early identification, diagnosis, and correction of dehydration,

acid-base and electrolyte abnormalities.
• Fluid therapy can be provided by oral, IV, or SC routes depending on severity of dehydration. Intraosseous or intra-peritoneal routes have also been utilized in crias.
• Determine fluid requirements by estimating replacement (*Volume (L) = body weight (kg) × % dehydration)*, maintenance (50 mL/kg/day adults, 70–80 mL/kg/day crias), and ongoing losses (variable).
• Replacement volume can be given over approximately 4 h; maintenance and ongoing losses can be attended over time.
• If hypoproteinemia is present, administer half the replacement volume over 4–6 h and the remainder can be incorporated into the ongoing administration.
• Balanced polyionic fluid—recommended for IV administration, and can be supplemented as needed with electrolytes and glucose.
• Bicarbonate—only when significant metabolic acidosis is confirmed and is poorly responsive to fluid supplementation. Half the deficit (calculated as *body weight (kg) × (0.3–0.6) × base deficit*) can be added to non-calcium containing fluids. The value 0.3 is often used in adults, and 0.6 in neonates.
• Oral electrolytes designed for calves can be used for maintenance or rehydration of mildly dehydrated neonates at 2- or 3-fold the recommended dilution for calves, or oral human pediatric solutions can be used.
• Hypoglycemia—add dextrose to IV fluids to a final concentration of 2.5–5%. Severe hypoglycemia (glucose <30 mg/dL)—administer 1 mL/5 kg body weight of 50% dextrose.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Antibiotics to treat or prevent bacteremia/sepsis—ceftiofur; penicillin + aminoglycoside (gentamicin or amikacin).
• Nonsteroidal anti-inflammatory drugs can address colic, inflammation, toxemia—flunixin meglumine or meloxicam. Hypoproteinemia—plasma 5–10 mL/kg IV once to twice; llama plasma can be given to alpacas.
• Coccidiosis—amprolium (10 mg/kg, PO, q24h for 5 d); ponazuril or toltrazuril (20 mg/kg, PO, q24h, for 3 d). Sulfadimethoxine (110 mg/kg, PO, q24h for up to 50 d).
• *Giardia*—fenbendazole (10–50 mg/kg, PO, q24h for 1–3 d).
• Nematodes—fenbendazole; ivermectin (0.3–0.6 mg/kg, PO or SC once).

CONTRAINDICATIONS
• Metronidazole is illegal in food-producing animals.
• Nephrotoxic drugs are contraindicated in severe dehydration and azotemia.

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Prognosis is good to fair for animals with infectious and nutritional diarrhea receiving supportive care.
• Prognosis is guarded for animals with chronic diarrhea.

POSSIBLE COMPLICATIONS
• Hyperosmolar syndrome can accompany diarrhea or occur during treatment. Monitoring blood glucose, blood sodium, and urea nitrogen is recommended.
• Shock and death.
• Renal failure.

CLIENT EDUCATION
Focus on encouraging protocols for optimizing passive transfer to crias, managing stocking density, and controlling parasitic infestations.

PATIENT CARE
Monitor attitude, fecal consistency, and hydration status.

PREVENTION
• Ensure adequate intake of good-quality colostrum in crias.
• Practice good environmental hygiene.
• Cattle vaccines against enteric pathogens can provide protection; however, antigenic variability is a limitation.
• Periodic herd monitoring of body condition—identify chronic diseases early.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Septicemia
• Gastrointestinal parasitism

AGE-RELATED FACTORS
Diarrhea can be a life-threatening disorder in young crias.

ZOONOTIC POTENTIAL
Camelids can serve as a reservoir for human infection with *Salmonella* spp., *Cryptosporidium*, and *Giardia*.

PREGNANCY
N/A

BIOSECURITY
• Environmental, hand, and outerwear hygiene.
• Segregate and diagnose sick animals.
• Quarantine new animals, visiting animals, or stock that have left the herd temporarily.

PRODUCTION MANAGEMENT
See "Biosecurity"

DIARRHEAL DISEASES: SMALL RUMINANT

BASICS

OVERVIEW
Diarrhea reflects increased water content in the feces, usually associated with increased frequency of defecation.

INCIDENCE/PREVALENCE
• Diarrhea is the most common and costly disease of neonatal small ruminants, and can contribute to over 40% of mortality.
• Gastrointestinal parasitism is an important cause of diarrhea in any ruminant >6 days old.

GEOGRAPHIC DISTRIBUTION
N/A

SYSTEMS AFFECTED
• Digestive
• Cardiovascular
• Urinary
• Hemolymphatic

PATHOPHYSIOLOGY
• Diarrhea results from different mechanisms—hypersecretion, abnormal permeability, increased intraluminal osmolality, and abnormal motility; most diarrheic states are caused by more than one mechanism.
• Loss of large volumes of electrolyte-rich fluid can result in electrolyte, fluid, and acid-base disorders.
• Damage to the intestinal mucosa can result in hypoproteinemia (albumin loss), toxemia (absorption of toxins), bacteremia (translocation of bacteria), hypovolemia, and septic shock.
• Bacteremia can result in secondary complications including septic arthritis, pneumonia, and abortion.

HISTORICAL FINDINGS
Epidemiologic information, including age and number of animals affected, management characteristics, season, and clinical course can help distinguish appropriate differentials.

SIGNALMENT
Small ruminants of any age, breed, or gender

PHYSICAL EXAMINATION FINDINGS
• Mildly affected cases—clumped or loose feces, appearing otherwise normal.
• Severely affected neonates—dehydration, obtundation, weak or absent suckling reflex, excessive salivation, and liquid diarrhea. Dysentery can reflect specific pathogens (*Salmonella*, enteropathogenic *E. coli*, *Clostridium*).
• Older animals—fever, diarrhea, dehydration, weakness, and frank blood in feces (*Coccidia*, *Salmonella*).
• Internal parasitism in juvenile or adult small ruminants—often asymptomatic. Severely infested animals—diarrhea, anemia, poor growth, submandibular edema, and decreased weight gain and milk production.
• Chronic diarrhea—progressive wasting with reduced body condition score.

GENETICS
N/A

CAUSES AND RISK FACTORS

Neonates
• Viral—rotavirus, coronavirus.
• Bacterial—enterotoxigenic *E. coli* (ETEC), *Salmonella* spp; rarely, enteropathogenic *E. coli*.
• Protozoal—*Giardia* and *Cryptosporidium* spp.
• Noninfectious—nutritional diarrhea due to inappropriate quality and quantity of milk or milk replacer, related to mixing errors or the use of alternative milk sources with different protein and fat content.

Older Lambs and Kids
• Bacterial—*Salmonella* spp., *C. perfringens* (rarely, type A, B, C, D). Type D is associated with enterotoxemia in sheep.
• Internal parasitism—most important cause of diarrhea in sheep <18 months of age. This can relate to infection with G*iardia* or *Eimeria* spp, or a variety of nematode parasites.
• Noninfectious—lush pastures.

Adult Sheep and Goats
• Bacterial—*Salmonella* spp., *Yersinia* spp., *Mycobacterium avium* subsp. *paratuberculosis* (MAP, Johne's disease). Chronic diarrhea only occurs in 20% of cases of Johne's disease; weight loss is more prominent.
• Internal parasitism—*Eimeria* spp. and nematodes, though older animals are often more resistant.
• Noninfectious—ruminal acidosis, arsenic toxicosis, cobalt or copper deficiency.

Risk Factors
• Failure of passive transfer of immunity.
• Inappropriate volume, or fat, protein or calcium content of milk or milk replacer.
• High population density and poor hygiene.
• Presence of other animals with diarrhea or with *Salmonella*, *Cryptosporidium* or MAP within a herd.
• Internal parasitism can be exacerbated by high density stocking, overgrazing, inadequate protein intake, and inappropriate deworming protocols.
• *C. perfringens* type D—associated with high calorie (grain) diets.
• Arsenic—wood preservatives, burn piles, discontinued insecticides and molluscicides.
• Cobalt—diets deficient in cobalt, heavy fertilization with limestone.
• Copper—diets deficient in copper, or excess intake of molybdenum, iron, zinc or calcium.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Septicemia
• Peritonitis
• Neoplasia

CBC/BIOCHEMISTRY/URINALYSIS
• Generally normal in mildly affected and clinically stable animals.
• Anemia can occur with parasitism, dysentery, cobalt or copper deficiency and MAP.
• More severe acute or chronic disease creates changes reflecting dehydration (hemoconcentration, azotemia), inflammation (leukocytosis or leukopenia with neutropenia, left shift and toxic changes), protein loss (hypoalbuminemia), and metabolic acidosis (reduced TCO_2, increased lactate).
• Electrolyte abnormalities often include low sodium, potassium, and chloride.
• Hyperglycemia and glucosuria occur in lambs *Clostridium* with type D enterotoxemia.

OTHER LABORATORY TESTS
• Culture of feces—*E. coli*, *Salmonella* spp., MAP.
• Fecal egg count (quantitative McMaster technique)—internal parasitism.
• PCR—*E. coli*, *Salmonella* spp., rotavirus, coronavirus.
• Immunoassays—*C. perfringens* toxins, coronavirus.
• Immunofluorescence assays—*Cryptosporidium* and *Giardia.*
• Iodine-stained wet mounts of feces—*Giardia*.
• Electron microscopy—rotavirus, coronavirus.
• Liver cobalt or copper content.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
Consistent with gastrointestinal inflammation or disease, evidence of parasitism or other disorders.

TREATMENT

THERAPEUTIC APPROACH
• Success relies on early identification, diagnosis, and correction of dehydration, acid-base and electrolyte abnormalities.
• Fluid therapy can be provided by oral, IV or SC routes depending on severity of dehydration

• In animals with dehydration judged to be >8%, provide IV fluids initially, followed by IV or oral fluids for maintenance.
• Fluid deficits can be calculated as: *Volume (L) = body weight (kg) × % dehydration*, and can be replaced over 4–6 hours using balanced polyionic solutions.
• Maintenance requirements (50 mL/kg/day adults; 80–100 mL/kg/day neonates) should then be provided continuously IV or by intermittent IV or oral bolus; additional volume (0.5–2 L) is required for estimated ongoing losses per day depending on animal size and severity of diarrhea.
• Severe dehydration and metabolic acidemia can be addressed by administering isotonic sodium bicarbonate (156 mEq $NaHCO_3$/L; or 1.3% solution) at a third to a half of the calculated deficit volume, followed by a balanced crystalloid for remaining deficit, maintenance, and ongoing losses.
• Oral electrolytes designed for calves can be used for maintenance or rehydration of mildly dehydrated kids and lambs at 250–500 mL q6–8h.
• Hypoglycemia can be treated by adding dextrose to IV fluids (final concentration of 2.5–5%).
• Milk and milk replacer should not be withheld for more than 4–6 h.
• Animals with prolonged dysentery or severe anemia (internal parasitism) may need whole blood transfusion (approximately 1–2 L to adults).

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Antibiotics to address bacteremia/toxemia can include beta-lactam drugs (ceftiofur, amoxicillin, or ampicillin) and potentiated sulfonamides (where permitted).
• Nonsteroidal anti-inflammatory drugs can address colic, inflammation, toxemia—flunixin meglumine or ketoprofen.
• *C. perfringens* Type D antitoxin (15–20 mL SC) can be administered during outbreaks of enterotoxemia, especially if animals are not vaccinated.
• Cobalt deficiency can be addressed with oral cobalt (1 mg/head/day); methods for addressing copper deficiency are provided elsewhere in this text (see *Copper Deficiency and Toxicity*).

Parasite infestations should be addressed by judicious use of appropriate anthelmintic agents in combination with relevant management methods. See *Parasite Control Programs: Small Ruminant* for anthelmintic drug doses.

CONTRAINDICATIONS
Nephrotoxic drugs are contraindicated in severe dehydration and azotemia.

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Prognosis is grave for severely diseased animals, or those with protracted diarrhea nonresponsive to treatment.
• Prognosis good to fair for mildly to moderately affected animals receiving appropriate care.

POSSIBLE COMPLICATIONS
• Edema
• Septicemia
• Shock and death
• Renal failure

CLIENT EDUCATION
Focus on encouraging protocols for optimizing passive transfer to lambs and kids, managing stocking density, and controlling parasitic infestations.

PATIENT CARE
Monitor attitude, fecal consistency, and hydration status.

PREVENTION
• Ensure adequate good-quality colostrum intake via good nutrition and vaccination of dams with bovine ETEC and rotavirus vaccines, and *C. perfringens* type C and D toxoid to provide colostral antibodies; lambs and kids can be vaccinated for *C. perfringens* during the first week of life when needed.
• Anecdotal evidence suggests that decoquinate provides some control of cryptosporidiosis, decreasing morbidity and mortality rates.
• Newly introduced individuals should be isolated for 1 month. Fecal culture for *Salmonella* and MAP should be considered but is only useful if positive results are obtained.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Septicemia
• Abortion

AGE RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
Ruminants can be considered as a reservoir for human pathogenic *E. coli, Salmonella* spp., *Cryptosporidium* spp., and *Giardia*.

PREGNANCY
N/A

BIOSECURITY
• Environmental hygiene. Cleaning and disinfection of environmental sites.
• Hand and outerwear hygiene. Wash hands, disinfect boots, and maintain coveralls free of fecal material.
• Segregating sick animals will reduce pathogen exposure.

PRODUCTION MANAGEMENT
N/A

SYNONYM
Scours

DISPLACED ABOMASUM

BASICS

OVERVIEW

• Displacement of the abomasum (DA) is a very common digestive condition affecting lactating dairy cattle, but has also been reported in sheep, goats, beef cattle, and calves.
• The abomasum lies in a ventral position in the right cranial quadrant of the abdomen between the 7th and 11th ribs.
• Displacement mostly occurs after parturition when more space is available in the abdominal cavity due to fetal expulsion and a rumen with less content. This generates enough space for the abomasum to slide down under the rumen. In addition, the muscular tone of the abomasum is reduced due to hypocalcemia. This creates excess gas buildup and allows for dorsal displacement along the left side (~90% of the time) or right side (~10% of displacements).
• In some right-sided displacements, a life-threatening volvulus may develop.

INCIDENCE/PREVALENCE

Lactational incidence of LDA may range between 0.2% and 15%. The prevalence of DA among dairy herds is variable depending on geographic location, management practices, climate, and other factors.

GEOGRAPHIC DISTRIBUTION

Worldwide in dairy cattle

SYSTEMS AFFECTED

Digestive

PATHOPHYSIOLOGY

See "Causes and Risk Factors"

HISTORICAL FINDINGS

• Decreased DMI and milk production
• Depression
• High ketones detected in blood, urine, or milk
• RDA: Colic and toxemia possible
• Herd level: Elevated NEFA prepartum can be used as metabolic predictor of LDA incidence in lactating dairy cows.

SIGNALMENT

Bovine, predominantly dairy breeds, predominantly female

PHYSICAL EXAMINATION FINDINGS

• High-pitched ping during simultaneous percussion and auscultation over the ipsilateral paracostal area.
• Mild to moderate tachycardia, sometimes bradycardia.
• Ketonuria/ketonemia.
• Scant, pasty manure, but sometimes diarrhea.
• Dehydration may be present but is usually mild unless the displacement is to the right side. Cows with RDA and volvulus may demonstrate tachycardia, rapid dehydration, and metabolic alkalosis with paradoxical aciduria.
• Different degrees of abdominal distension, especially in the paralumbar fossa corresponding to the side of displacement.

GENETICS

Most commonly affected breed is Holstein; however, DA has been diagnosed in all dairy and some beef breeds. For Holsteins, heritability estimates for DA are between 0.03 and 0.53. Genome-wide significant genomic regions associated with LDA have been determined on bovine chromosomes 1, 3, 11, 20, and 23.

CAUSES AND RISK FACTORS

• DA is a multifactorial syndrome.
• The highest risk period for DA is the early postpartum until 30 DIM. However, DAs do occur throughout lactation and occasionally during the dry period.
• DMI is reduced during the transition period, causing decreased rumen fill.
• After parturition, the smaller rumen moves slightly backwards generating enough space for the distended abomasum to slide under the rumen and move upward between the lateral wall of the ventral and dorsal sac of the rumen and left costal wall. Reduced abomasum motility decreases its emptying rate. Consequently, a diet rich in nonstructural carbohydrates will continue fermenting, producing extra gas that worsens abomasum distension.
• Hypocalcemia is also common right after calving. Subclinical hypocalcemia (<8.0 mg Ca per dL of blood) may even last for 10 days in lactation, especially in multiparous cows. Low calcium levels decrease abomasal outflow rate, causing further abomasal distention.

Risk Factors

• *Cow level*: Hypocalcemia, high BCS at calving, winter season, plasma NEFA concentration >0.3 mEq/L at 35–3 d prepartum, low DMI, high levels of ketone bodies postpartum (>1.2 mmol/L of BHB), other concurrent disease such as metritis that induce fever and affect eating behavior, high predicted transmitting ability (PTA) for milk production, body size and depth.
• *Herd level*: High average BCS of the herd; winter and summer seasons; precalving rations containing energy densities >1.65 Mcal of NE_L/kg of DM; rations high in concentrate and corn silage with not enough effective fiber during the postpartum period causing reduction of chewing activity, ruminal fill, motility, fiber mat formation, and increased ruminal VFA concentration; improper feed bunk management due to reduced bunk space, feed availability and freshness of the feed; excessive pen changes, mixing of primiparous and multiparous cows, overcrowded housing and feeding systems; prolonged confinement in individual maternity pens, excessive heat, mud, or extreme cold; silages that contain abnormal levels of butyric or acetic acid, mycotoxins, and moldy feed; general deficiencies in cow comfort.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Many differential diagnoses exist for animals with acute decrease in milk production and anorexia. The differentials when a ping is auscultated include: gas in the cecum, spiral colon or duodenum, rumen gas cap with decreased fiber mat (i.e., secondary to ruminal acidosis or anorexia), collapsed rumen, pneumoperitoneum, physometra (i.e., anaerobic bacterial metritis), and other causes less commonly found.

CBC/BIOCHEMISTRY/URINALYSIS

• Hypochloremia, hypokalemia, hypocalcemia, metabolic alkalosis, ketonemia, ketonuria, sometimes paradoxical aciduria, hypoglycemia, and elevated levels of beta-hydroxybutyrate (>1.2 mmol/L) and nonesterified fatty acids (>0.7 mEq/L).
• Normal CBC

OTHER LABORATORY TESTS

N/A

IMAGING

Ultrasound can be used to differentiate the abomasal wall from other viscera; however, this is not commonly performed.

OTHER DIAGNOSTIC PROCEDURES

• Liptak test: performed by aspirating fluid from the viscus present beneath the area where percussion yields the loudest ping. Fluid pH differentiates between abomasum (<3.0) and rumen (>6.0).

TREATMENT

THERAPEUTIC APPROACH

• Supportive therapies are recommended to correct metabolic disturbances, including oral or parenteral calcium and IV dextrose, IV fluids to correct acid-base status, oral fluids containing electrolytes and glucose precursors (calcium propionate, propylene glycol, glycerol), anti-inflammatories such as flunixin meglumine for pain management and fever, and systemic antibiotics for 3–5 days, considering withdrawal periods.
• Each case should be evaluated independently and the decision based on the probability of success and return to lactation, cost of the procedure, and potential compensation based on current lactation numbers, previous/predicted production level, feed cost, and milk price. In some cases, culling instead of surgery is the best decision.

(CONTINUED) DISPLACED ABOMASUM

• Although surgical repair is the preferred treatment, medical treatment may be attempted in the case of LDA with varying long-term success rates. Medical treatment generally includes casting the animal into right lateral recumbency and rolling into left lateral recumbency to replace abomasum. This is followed by administration of oral fluids, vitamin B, and offering a high-quality forage diet along with the above treatments indicated for ketosis and any underlying disease.

SURGICAL CONSIDERATIONS AND TECHNIQUES

• The most common treatment for LDA is the surgical approach (blind or open). Blind technique is based on the toggle suture. Open techniques may be accomplished by laparoscopic approach or standing left flank abomasopexy, standing right flank omentopexy, and dorsal recumbency right paramedian abomasopexy. The toggle suture technique has a higher complication rate in most circumstances.
• All techniques have good results in the short term; however, cows with DAs have a higher risk for culling during the current and following lactation.

MEDICATIONS

DRUGS OF CHOICE

Dependent on underlying disease.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Dependent on underlying cause of DA, chronicity, and concurrent disease.

POSSIBLE COMPLICATIONS

Incisional infections, pyloric strictures (pyloropexy), abomasal fistulas (toggle-pin procedure), omental bursitis (omentopexy), vagal nerve damage (chronic DA), abomasal rupture ± enterotoxemia (abomasal volvulus).

CLIENT EDUCATION

See "Prevention"

PATIENT CARE

• Early treatment of a displaced abomasum will limit severity of secondary complications such as ketosis and rumen stasis.
• The focus during and after initial medical or surgical intervention is to reestablish adequate dry matter intakes and minimize negative energy balance. Patients should be offered good-quality, high fiber feed and water ad libitum along with adequate feed space to decrease competition.
• Supportive care for ruminal health and gastrointestinal motility is imperative and may include calcium supplementation, vitamin B complex, and probiotics.
• Patients should be monitored for possible complications (see "Possible Complications").

PREVENTION

• Prevention of abomasal displacement must be based on controlling the identified risk factors for this condition.
• Proper cow comfort and management is crucial. Avoidance of excessive body condition score during the entire production cycle by using the proper nutritional program during late lactation and the dry period is recommended.
• Balanced rations and uniform mixing of the diet during the prepartum and postpartum period is fundamental. Appropriate fiber in the form of effective NDF (no less than 20% of total dry matter) must be followed as a rule of thumb. Avoid excessive corn silage and provide adequate particle size to decrease the sorting behavior.
• Genetic factors are more difficult to control; therefore manage the cow for her milk production potential but preventing the presence of other diseases.
• Establish a postpartum health monitoring program checking rectal temperature, evaluating uterine size and involution, testing blood, urine or milk ketones, and using daily milk production records if the milking equipment will allow it (drop in milk yield and fat : protein ratio).

MISCELLANEOUS

ASSOCIATED CONDITIONS

Drop in feed intake and milk production and failure of cows to succeed during the postpartum period.

AGE-RELATED FACTORS

Younger animals that are genetically superior in milk production are more likely to have the best opportunity for economic payback from surgical intervention; with older animals having a shorter expected future productive life, or lower producing animals that have a lower predicted return, culling may be considered.

PREGNANCY

Cows with DA are less likely to become pregnant than unaffected cows.

PRODUCTION MANAGEMENT

This disorder causes tremendous economic losses to the dairy industry, mostly due to marked reduction in milk yield among affected cows, substantial treatment costs, and increased culling risks. Estimated cost of LDA has been reported to be $340 per cow. LDA has been linked with increased risk for early lactation culling.
Avoid excessive body condition and stressful conditions such as overcrowding, heat, cold, or mud. Proper nutrition management and cow comfort are the key factors to prevent DAs and other related diseases.

ABBREVIATIONS

• BCS = body condition score
• BHB = beta-hydroxybutyrate
• DA = displaced abomasum
• DIM = days in milk
• DM = dry matter
• DMI = dry matter intake
• GI = gastrointestinal
• IV = intravenous
• LDA = left displaced abomasum
• NDF = neutral detergent fiber
• NEFA = nonesterified fatty acids
• NE_L = net energy for lactation
• PTA = predicted transmitting ability

DISSEMINATED INTRAVASCULAR COAGULOPATHY

BASICS

OVERVIEW
Disseminated intravascular coagulopathy (DIC) is a pathologic process characterized by inappropriate activation of the clotting cascade, resulting in consumption of coagulation and fibrinolytic factors leading to disseminated microthrombosis and hemorrhagic diathesis.

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
- Cardiovascular
- Urinary
- Digestive
- Respiratory
- Nervous

PATHOPHYSIOLOGY
- DIC is not a primary disorder, but occurs secondary to severe systemic diseases including neoplasia, inflammatory or ischemic GI disorders, or overwhelming Gram-negative infection.
- Any disease that activates coagulation or causes blood vessel endothelial injury can result in acquired coagulopathy.
- Severity can range and change over time, producing minimal clinical signs through to diffuse thrombosis, ischemic organ failure, and severe hemorrhagic diathesis.
- Initiation of the coagulation cascade leads to formation of blood clots and fibrin deposition within small vessels (microvascular thrombosis). This promotes ischemia of vital tissues followed by organ dysfunction.
- Coagulation occurs simultaneously with fibrinolysis. As the thrombotic stimulus continues, there is depletion of both coagulation factors and natural anticoagulant factors such as anti-thrombin III.
- Petechial or ecchymotic hemorrhages can occur on mucosae/sclerae along with a tendency to bleed from minor trauma.
- Coagulopathy most commonly occurs in a compensated form in cattle and rarely presents as overt hemorrhage, but rather as microvascular thrombosis.
- Microvascular thrombosis can cause ischemic cortical necrosis and acute tubular necrosis of the kidney, with oliguria, depression, and ileus. GI microthrombosis and ischemia may cause colic secondary to submucosal necrosis, and GI hemorrhage may cause melena. Rarely, microvascular thrombosis of pulmonary arteries causes tachypnea and hypoxia.
- Altered consciousness may occur due to cerebral microvascular thrombosis, but is rare. Affected animals may display delirium, convulsions, and coma.

HISTORICAL FINDINGS
Consistent with a primary disorder capable of eliciting DIC.

SIGNALMENT
Any ruminant species of any age or gender is susceptible.

PHYSICAL EXAMINATION FINDINGS
- Often dominated by signs of the primary disease, and in regard to DIC, depend on extent and location of microvascular thrombosis.
- Colic, melena, ileus, oliguria, tachypnea, tachycardia, and altered consciousness can occur.
- Venous thrombosis or prolonged bleeding may occur following routine venipuncture or IV catheter placement, and petechial or ecchymotic hemorrhages may be evident on the pinnae, sclerae, and mucosal surfaces.
- Compensated DIC is chronic DIC that results from a weak/intermittent activating stimulus. Destruction and production of coagulation factors and platelets are approximately equal. The main sign of compensated DIC might be sudden, inappropriate thrombosis.

GENETICS
N/A

CAUSES AND RISK FACTORS
- DIC occurs secondary to inflammatory or ischemic conditions, particularly where GI mucosal compromise occurs, resulting in endotoxemia.
- Vasculitis, heatstroke, snake envenomation, systemic or localized sepsis (mastitis, pleuritis, peritonitis), neoplasia, renal disease, hemolytic anemia, intestinal strangulation, and other severe GI disorders, thromboembolic infarction, and acute hepatic failure can all evoke DIC.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
- Warfarin toxicosis.
- Moldy sweet clover toxicosis (dicoumarol).
- Inherited coagulation abnormalities: congenital afibrinogenemia (Saanen goats); hemophilia A (factor VIII deficiency) in Japanese Brown cattle and Swiss White Alpine sheep; factor XI deficiency (Holstein cattle); Chediak-Higashi syndrome (Hereford, Japanese Black, and Brangus cattle); hereditary thrombopathy (Simmental cattle); a Simmental calf has been diagnosed with von Willebrand disease.
- Hepatic failure.
- Immune mediated thrombocytopenia.
- Acute bovine viral diarrhea virus infection.
- Bracken fern toxicosis.
- Familial myelophthisis (pygmy goats).
- Endotoxemia.
- Acquired platelet function defects secondary to aspirin, phenylbutazone, sulfonamides, estrogens, or phenothiazines.

CBC/BIOCHEMISTRY/URINALYSIS
- Systemic diseases predisposing to DIC often result in leukopenia, neutropenia, lymphopenia, and thrombocytopenia.
- Hypofibrinogenemia may occur in DIC but is uncommon in large animals. The primary disease usually provokes hyperfibrinogenemia.
- Renal and hepatobiliary involvement may be reflected on serum chemistry.
- Platelet counts below 10,000–20,000/µL are correlated with spontaneous hemorrhage. Hematoma formation following minor trauma can occur when platelet counts fall below 40,000/µL.

OTHER LABORATORY TESTS
- Serial testing may be necessary when clinical suspicion of DIC is present. Diagnosis is supported by evidence of platelet consumption (often the earliest indicator of DIC), in addition to evidence of coagulation factor consumption (prolongation of one or more clotting tests), and evidence of increased fibrinolysis.
- Clotting tests include measurement of prothrombin time (PT), activated partial thromboplastin time (APTT), and TT (thrombin time). Prolonged clotting times are insensitive indicators of early disease. If the only laboratory abnormality is persistently prolonged PTT, a hereditary factor deficiency should be suspected.
- Evidence for increased fibrinolysis includes elevated fibrin degradation products (FDPs). Serum FDP concentrations >40 µg/mL or plasma FDP >20 µg/mL are consistent with DIC. Elevated D-dimers (an FDP that is more specific for fibrinolysis) and decreased antithrombin III also support DIC.

IMAGING
Ultrasonography can be used to assess peripheral large vessel thrombosis.

OTHER DIAGNOSTIC PROCEDURES
As indicated for the primary disorder

PATHOLOGIC FINDINGS
- Reflect the primary disease process.
- Thrombosis/fibrin deposition may be evident in large vessels.
- Petechiae, ecchymoses, and hematomas may be grossly visible.
- Microthrombi may be microscopically visible in the vascular beds of kidneys, lung, spleen, adrenal glands, heart, brain, and liver.

TREATMENT

THERAPEUTIC APPROACH
- Treat the underlying cause.
- Control intravascular coagulation.
- Maintain organ perfusion.
- Replace coagulation factors and proteins.

DISSEMINATED INTRAVASCULAR COAGULOPATHY (CONTINUED)

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Intravenous fluid therapy to prevent organ dysfunction due to microthrombosis, and to correct acid-base/electrolyte abnormalities.
• Septic conditions require antimicrobial therapy.
• Flunixin meglumine reduces effects of endotoxemia.
• Fresh plasma (15–30 mL/kg) may be indicated when petechiation or hemorrhage is present, to restore coagulation factors and anticoagulant proteins.
• Heparin therapy is controversial and might be contraindicated if bleeding tendencies are present, but is given to prevent microvascular thrombosis and further consumption of coagulation factors. Heparin is a cofactor of AT III, therefore adequate AT III must be present for heparin to be effective, which can be provided by plasma transfusion.

CONTRAINDICATIONS
• Corticosteroids are contraindicated due to a reduction in phagocytic activity and worsening of vasoconstrictive effects of catecholamines.
• Avoid drugs that cause hypotension (phenothiazines and α_2 agonists).
• Avoid drugs that negatively affect organ systems compromised by DIC, i.e., nephrotoxic or hepatotoxic drugs.
• Hetastarch might be contraindicated in patients with known coagulation deficiencies as it can prolong coagulation times if given at high doses.

PRECAUTIONS
• Correct sample handling is vital for accurate coagulation testing. Samples should be submitted in citrate anticoagulant (blue-top vacutainer) following atraumatic blood collection.
• Consider simultaneous submission of blood from a normal cohort for quality control.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Prognosis for acute, fulminant DIC is guarded to grave. Prognosis for compensated DIC is better. Prognosis depends on ability to identify and neutralize the underlying cause.

POSSIBLE COMPLICATIONS
Multiple organ failure, large vessel thrombosis, hematoma formation, hemorrhage, shock, and death.

CLIENT EDUCATION
N/A

PATIENT CARE
• Frequent physical examinations during acute disease to monitor heart rate and rhythm, pulse quality, respiratory rate, temperature, urine production, and mucus membrane character. Monitor for development of organ system dysfunction via physical examination and laboratory testing.
• Serial monitoring of CBC and coagulation variables (PT, APTT, FDPs, AT III); interpret in light of patient condition. Serial platelet counts can be particularly useful.

PREVENTION
Detecting and treating underlying disease is imperative to prevention of DIC, particularly inflammatory or ischemic conditions of the GI tract.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Renal failure
• Multi-organ failure
• Primary disorders

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
If *Salmonella* or other infectious pathogens are involved in the primary disorder, zoonotic risks may be present.

PREGNANCY
Abortion may occur due to severe systemic compromise.

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
N/A

SYNONYM
Disseminated intravascular coagulation

DOWN BOVINE

BASICS

OVERVIEW

• Cattle with the inability to rise unassisted. Affected cattle may be found in sternal or lateral recumbency for prolonged periods of time.
• Down cattle are often grouped into two categories depending on the patient's mental state:
  ◦ Alert downers
  ◦ Depressed downers

SYSTEMS AFFECTED

• Musculoskeletal
• Nervous

PATHOPHYSIOLOGY

• Many etiologies may result in downer cows (see Table 1).
• Alert downers
  ◦ Nerve pathology may result in decreased muscular control. Obturator and/or sciatic nerve involvement may be secondary to dystocia (parturient paresis). Radial nerve damage is also common from prolonged recumbency due to surgical procedures where prolonged pressure is placed on the shoulder area. Spinal cord involvement may be due to instability of the bony spinal column resulting from fracture or luxation or cord compression from tumors.
  ◦ Direct musculoskeletal issues such as long bone fractures, luxations, avulsions, or other orthopedic issues can also result in a cow's inability to rise.
• Depressed downers
  ◦ Electrolyte imbalances may result in decreased muscle function.
  ◦ Toxic mastitis, toxic metritis, or other causes of endotoxemia can result in generalized obtundation and weakness, causing an animal to be recumbent.
• Down cows will have some muscle damage from prolonged pressure on the dependent muscle. Pressure necrosis and compartment syndrome can result and contribute to the weakness and inability to stand. The cow may continue to be down even after correction of the primary problem.
• Muscle damage results in increased circulating CK and myoglobin which can cause renal damage, further compromising the patient.
• Down cows are also susceptible to pneumonia due to poor ventilation, and mastitis because their udder and teats are in constant contact with the ground.
• Secondary orthopedic problems such as gastrocnemius rupture can result from trying to rise. Cattle commonly will develop abrasions over bony prominences. Lacerations can lead to localized infections, or infections of synovial structures.
• Secondary coxofemoral luxation is another potential sequela in downer cattle.

HISTORICAL FINDINGS

Obtaining a good history will aid in diagnosis: age, parity, production level, calving history, length of recumbency, etc.

SIGNALMENT

• Dairy or beef cattle.
• Older, periparturient, high producing, and heavier cattle are most commonly affected.
• Cattle in intensive housing/management operations more common.

PHYSICAL EXAMINATION FINDINGS

• May be alert or depressed depending on the cause of recumbency.
• Alert downers typically have a fair to good appetite.
• Superficial abrasions common.
• Dry manure may progress to diarrhea.
• Urine may be dark due to myoglobinuria.
• If assisted to stand, cattle may make weak attempts or may be able to support themselves for short periods of time but generally appear weak and uncoordinated. Cattle may knuckle on fetlocks and exhibit signs of specific nerve paralysis/paresis (peroneal and radial common).

CAUSES AND RISK FACTORS

• Hypocalcemia, hypokalemia, hypophosphatemia, hypomagnesemia
• Intrapelvic trauma and inflammation (secondary to dystocia)
• Toxic mastitis/metritis
• Trauma induced by falls secondary to being ridden while coming into heat or wet, slippery flooring
• Long bone fractures
• Joint luxations (coxofemoral and scapulohumeral)
• Spinal cord lymphoma

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Being "down" is a clinical sign rather than a diagnosis.
• Finding a specific cause for an animal to go down (Table 1) can be challenging.

OTHER LABORATORY TESTS

• CBC and chemistry panel may reveal signs of underlying disease.
• Serum creatinine kinase (CK), a marker for muscle damage, is elevated significantly in the early stages but has a short half-life and is not reliable for prognosis in clinical cases.
• Serum calcium and potassium levels may point to metabolic problems.
• Urine should be examined for color and, if dark or brown, myoglobin levels may be evaluated.

Table 1

Possible causes for the animal being down
Alert downer
• Nerve damage
◦ Sciatic/obturator (calving paresis/paralysis)
◦ Radial
◦ Peroneal
◦ Spinal cord (vertebral body abscess/ fracture/lymphoma)
• Muscle damage
◦ Trauma
◦ Pressure necrosis (from being down)
• Joint luxation
◦ Coxofemoral
◦ Scapulohumeral
◦ Others
• Fracture
◦ Long bone
◦ Avulsion fracture
Depressed downer
• Metabolic
◦ Hypocalcemia
◦ Hypokalemia
◦ Hypophosphatemia
◦ Hypomagnesemia
• Endotoxemia/infectious
◦ Mastitis
◦ Metritis
◦ Septicemia

IMAGING

• Radiographs can be useful to confirm musculoskeletal injury such as fracture or coxofemoral luxation. Due to the size of adult patients, this may be impractical.
• Diagnostic ultrasound may be useful to diagnose tendon and ligament injuries and certain fractures.

OTHER DIAGNOSTIC PROCEDURES

• TPR, examination of the udder and uterus for signs of mastitis and metritis.
• Cutaneous testing of hindlimbs for evidence of sensory reflexes.
• Palpation of limbs for luxation or fractures.
• Rectal palpation for pelvic fractures or hip luxation, evidence of crepitus.
• Lifting with hip clamps is useful for musculoskeletal and neurologic examination but should be very brief, to avoid pressure damage of muscles in the tuber coxae region. The clamps should be well padded to minimize tissue damage.
• Some cows may be able to stand unassisted once lifted. Standing these animals will help with assessment of weakness.
• Response to treatment in a floatation tank is useful but labor intensive.

DOWN BOVINE (CONTINUED)

TREATMENT

THERAPEUTIC APPROACH

• The primary objective is to prevent further muscle and nerve damage due to recumbency.
• Soft, clean, and dry bedding is essential. Sand is easier to keep clean than straw bedding. Hard, slippery concrete should be avoided. A dirt lot or a manure pack may provide the patient with good footing.
• Frequent repositioning will reduce pressure damage.
• Hydrofloatation therapy reduces pressure damage and enhances vascular supply to compressed tissues. Warm water (body temperature) is essential for hydrofloatation to be beneficial. Hydrofloatation predisposes to development of cutaneous wounds as it softens the skin. Mastitis in lactating cows, incisional infections in postoperative cattle, and catheter site infections may be a result of hydrofloatation in dirty water.
• Hobbles on the hindlimbs prevent limb abduction which may lead to coxofemoral luxation.
• Hindlimb knuckling can be managed with a cast on the affected lower limb.
• An effort should be made to correct the underlying cause if possible.

SURGICAL CONSIDERATIONS AND TECHNIQUES

Teat amputation provides drainage for a quarter with toxic mastitis.

MEDICATIONS

DRUGS OF CHOICE

• Antibiotic and anti-endotoxin treatment is indicated in the case of metritis, mastitis, or generalized sepsis.
• Pain medication will make the patient more willing to attempt to move and improve appetite.
• Topical ointments for dermatitis and pressure sores.

PRECAUTIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Dependent on etiology and proper management of the down cow. Prognosis is often poorer than one may consider due to secondary problems like muscle damage.

POSSIBLE COMPLICATIONS

• Muscle tearing or avulsion due to struggling to stand
• Hip luxation
• Muscle damage due to excessive use of hip clamps
• Drowning (complication of hydrofloatation)
• Renal compromise due to myoglobinemia

CLIENT EDUCATION

• Owners should be educated that a down cow is an emergency because irreversible pressure damage can occur in as short as 6 hours of recumbency.
• All animal care personnel should be educated in appropriate methods for moving down animals, and farms should develop uniform protocols for down cow management and end-point determinants.

PATIENT CARE

• Successful treatment of down cows is labor intensive and requires frequent monitoring of the patient.
• Keeping the bedding clean and dry is important.
• Providing a constant supply of fresh drinking water is important but difficult when animals move continually. A large rubber tub that is not easily turned over works best. The water should be close enough to the patient so that they can access the water easily; however, care should be taken not to allow the patient to drown.
• Frequent skin cleansing is important to prevent urine scalding.
• Frequent repositioning is helpful to minimize pressure damage.
• Floatation therapy requires frequent monitoring to prevent drowning.

PREVENTION

• Prevention is more efficacious than therapy.
• Dry cow feeding should be aimed at prevention of parturient paresis.
• Provision of clean, well-bedded calving stalls is essential to prevent slipping.
• Periparturient cows should be monitored frequently so that problems can be treated before they get worse.

MISCELLANEOUS

AGE-RELATED FACTORS

• Older animals are more susceptible to periparturient problems.
• Older animals are heavier and more likely to succumb to secondary problems.
• Lymphoma may be more common in aged animals.

ABBREVIATIONS

• CK = serum creatinine kinase
• TPR = temperature/pulse/respirations

DOWN CAMELID

BASICS

OVERVIEW

• Camelids often present with the complaint of being "down," i.e., recumbent.
• Recumbency can be classified as intermittent (animal voluntarily rises and moves but is recumbent more than normal), preferred (animal can be coaxed to rise for short periods), or constant (animal cannot physically rise).
• Thorough history collection and detailed physical examination are critical steps in determining the likely system affected and possible differential diagnoses.

INCIDENCE/PREVALENCE

• Typically recumbency is a sporadic complaint unless related to a disorder that can affect multiple animals in a group.

GEOGRAPHIC DISTRIBUTION

Worldwide; some specific conditions including *Parelaphostrongylus tenuis* (meningeal worm) infestation and *Cryptococcus gattii* meningitis have strongly regional distributions.

SYSTEMS AFFECTED

• Nervous
• Musculoskeletal
• Hemolymphatic
• Cardiovascular
• Respiratory
• Digestive

PATHOPHYSIOLOGY

• A wide range of disorders affecting virtually any body system can result in recumbency by inducing pain, weakness, systemic illness, nervous dysfunction, musculoskeletal damage, or other consequences; pathophysiology is strongly dependent on individual etiology.
• Orthopedic problems including fractures and luxations can result in recumbency from pain and/or loss of function.
• Neurologic conditions are a common cause of recumbency, and in regions in which *P. tenuis* infection is prevalent, aberrant migration of larval parasites through the spinal cord and brain is considered a very common cause of acute recumbency related to inflammation and trauma to the delicate nervous tissues. Other disorders include *Cryptococcus gattii* infection of the central nervous system; bacterial meningitis (most often in crias, and associated with *Listeria*, *E. coli*, *Streptococcus*, *Histophilus* and other organisms); polioencephalomalacia related to anomalies of thiamine metabolism and availability; and vitamin D deficiency which most commonly affects dark-coated crias born in autumn in geographic regions with lower UV exposure, resulting in bone fragility and limb and spinal fractures (rickets). Camelids can also develop viral meningitis from infection with West Nile virus, Eastern equine encephalitis, equine herpesvirus 1, and rabies.
• Diseases that cause profound anemia often create recumbency due to hypoxia, and include infection with the epierythrocytic parasite *Candidatus Mycoplasma haemolamae* and high burdens of *Haemonchus contortus*.
• Debilitation causing recumbency can result from megaesophagus, round cell neoplasia, chronic peritonitis, malnutrition, abdominal abscesses (*S. zooepidemicus, C. pseudotuberculosis*), chronic renal disease, Johne's disease, and oral pathology.
• Gastrointestinal diseases can result in recumbency from pain, systemic illness and debilitation, including parasitism with gastrointestinal nematodes or *Eimeria macusaniensis*, and a variety of disorders causing abdominal pain related to gastrointestinal torsion, ulceration, perforation, or obstruction.
• Cardiorespiratory disease can result in recumbency due to hypoxemia and/or impaired circulation, and can relate to pneumonia, pleuritis (from *S. zooepidemicus*, or esophageal or thoracic injury), diaphragmatic paralysis, congenital cardiac defects, and thrombotic endocarditis.
• Heat stress typically occurs during hot weather and affects animals in full fiber.
• Toxicities such as tick paralysis and ryegrass staggers cause recumbency from injected or ingested neurotoxins.
• Urogenital disorders can cause recumbency related to pain and systemic illness, including uterine torsion in late gestation females and urinary tract obstruction in male or castrated male camelids.

HISTORICAL FINDINGS

Historical findings of significance will vary with the cause of recumbency but enquiries should include the age and gender of the affected animal(s), how long the animal has been recumbent; any interventions or handling that have occurred, and the anthelmintic, vitamin D and other medication and treatment history of the operation.

SIGNALMENT

Age and gender influence the likelihood of specific disorders causing recumbency including rickets, uterine torsion, urinary obstruction, and congenital cardiac defects.

PHYSICAL EXAMINATION FINDINGS

• Reluctance or inability to stand.
• Obtundation suggests central nervous system disease or significant systemic illness.
• Thorough palpation of the spine, limbs, and thorax may identify causative luxations or fractures, or evidence of rickets (enlarged costochondral junctions, rib fractures).
• Pale mucus membranes and tachycardia suggest profound anemia.
• Cardiac murmurs are typically abnormal in camelids and suggest congenital or acquired cardiac disease, or can result from significant anemia.
• Peripheral edema (brisket, ventrum) ± jugular venous distension suggests cardiac disease.
• Increased respiratory effort may indicate pleural effusion or other cardiorespiratory disorders; paradoxic respiratory pattern (thoracic movement contradictory to abdominal movement) is common in camelids with diaphragmatic paralysis.
• Abnormal positioning of limbs (stretched out in front or behind, or placed to the side) can suggest abdominal pain or occasionally respiratory difficulty.
• Neurologic examination (proprioception, sensation, spinal reflexes) and ophthalmic assessment form part of a complete examination of a recumbent camelid patient, but can be challenging to perform in some circumstances.

GENETICS

N/A

CAUSES AND RISK FACTORS

• *P. tenuis* (in proximity to its definitive and intermediate hosts)
• Severe anemia (usually parasitism)
• Central nervous system trauma or infection (fungal, bacterial, viral)
• Musculoskeletal trauma
• High environmental temperatures and animals in full fiber
• Poor management procedures (parasitism, rickets, malnutrition, infectious diseases)
• Dental disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Recumbency is a clinical sign rather than a diagnosis. Every attempt should be made via thorough anamnesis and physical examination to determine the likely body systems involved; this subsequently defines the differential list and directs diagnostic procedures.
• Anemia
• Cardiac disease
• Rickets
• Polioencephalomalacia
• Tetanus
• Meningitis (bacterial, viral, fungal)
• *S. zooepidemicus* infection
• Colic
• Trauma
• Tick paralysis
• Uterine torsion
• Debilitation
• Heat stress

CBC/BIOCHEMISTRY/URINALYSIS

The presence and severity of changes are dependent on the underlying disorder but laboratory results should be assessed for anemia, significant acid-base and electrolyte

DOWN CAMELID (CONTINUED)

disturbances, and evidence of causative or accompanying major organ disease (abnormalities of liver, renal or muscle variables).

OTHER LABORATORY TESTS

• Blood gas analysis is useful for evaluating cardiorespiratory disorders and to clarify the severity and characteristics of acid-base disturbances.
• Collection of CSF can be readily achieved at the lumbosacral space, or at the atlanto-occipital space (under anesthesia) for cytologic evaluation ± bacterial culture and other tests to identify conditions including bacterial, viral, and fungal meningitis, and infestation with *P. tenuis*.
• PCR on EDTA blood can detect infection with *Candidatus Mycoplasma haemolamae.*

IMAGING

• Radiographs are useful to evaluate orthopedic and thoracic disorders, and can identify urinary obstruction in areas where calcium carbonate urolithiasis occurs.
• Ultrasonography is useful for evaluating cardiorespiratory disorders and abdominal pain, and for assessing fetal viability.
• CT is a useful diagnostic modality for imaging the skull, spine, and other bony structures. Addition of intravenous contrast greatly enhances imaging of most soft tissues, and provision of orogastric contrast several hours prior to imaging is helpful in evaluation of gastrointestinal disorders.

OTHER DIAGNOSTIC PROCEDURES

• Oral examination (may require sedation and speculum).
• Abdominocentesis and/or thoracocentesis to evaluate cavitary effusions for evidence of infection or neoplasia.

PATHOLOGIC FINDINGS

See individual disorders in this text

TREATMENT

THERAPEUTIC APPROACH

• Management should include strategies to prevent bone, muscle, eye, and nerve damage due to recumbency and handling.
• Soft, deep, clean, and dry bedding is essential. Animals should only be encouraged to stand or move with adequate support.
• Frequent repositioning will reduce pressure damage and will help respiratory function; animals should be maintained in sternal, not lateral, recumbency.
• Floating animals in a water tank reduces pressure damage to musculature and enhances vascular supply to compressed tissues, and can be performed q12–24h. Camelids in full fiber must be adequately dried after removal from the tank to prevent flystrike and dermatitis.
• Slings can be utilized in animals that will tolerate it and which are capable of supporting at least 30–50% of their own weight.
• Hobbles on the hind pasterns can help prevent traumatic limb abduction in weak camelids that splay on slippery surfaces or in deeply bedded stalls.
• The underlying cause of recumbency must be determined and treated if possible, which may require fluid, electrolyte and colloid support, antibiotics, anti-inflammatory drugs, anthelmintics, cavity drainage, fracture repair, or reduction of joint luxations.

SURGICAL CONSIDERATIONS AND TECHNIQUES

• Dependent on the underlying cause of recumbency. Generally recumbent patients are poor surgical candidates unless recumbency relates to a surgically reversible issue (such as pain arising from surgically amenable colic).
• Surgical intervention (cesarean section) is typically avoided in uterine torsion of camelids unless the torsion cannot be corrected by repeated attempts at external manual repositioning (rolling).

MEDICATIONS

DRUGS OF CHOICE

• Dependent on the underlying cause.
• *P. tenuis* infestation is often treated with fenbendazole (50 mg/kg PO q24h for 5 days) and/or ivermectin (0.2–0.3 mg/kg PO or SQ, once or repeated).
• Anti-inflammatory drugs can include flunixin meglumine (1.1 mg/kg IV q12–24h) or meloxicam (1–2 mg/kg PO, followed by 1 mg/kg PO q24h). Corticosteroids are occasionally recommended as adjunct therapy for neurologic disorders and may be of value in individual cases (prednisolone sodium succinate 0.5–1.0 mg/kg IV, IM, or SQ).
• Oxytetracycline can be used to suppress (but will not eradicate) *Candidatus Mycoplasma haemolamae* infection (20 mg/kg SQ or IV, q24h for 3–5 days).
• Vitamin D supplementation is recommended for crias at risk of rickets (1,000–2,000 IU/kg SQ).
• Thiamine supplementation is useful in camelids with prolonged anorexia or suspected polioencephalomalacia (10 mg/kg SQ, q4–24h depending on indication).
• Severe pain may require additional analgesia with opioids: butorphanol (0.05–0.2 mg/kg IV or IM); buprenorphine (2–3 µg/kg IM, q4–6h); or morphine (0.5–1.0 mg/kg IM, q6h). In animals requiring intensive management, topical fentanyl patches or constant intravenous infusions (lidocaine, butorphanol, or ketamine) are useful.
• Animals requiring colloid support can receive llama plasma or hydroxyethylstarch products. Whole blood (llama or alpaca) can be given to either species if blood transfusion is indicated.
• Seizures can be treated with IV diazepam or midazolam.

CONTRAINDICATIONS

Corticosteroids (even topical) should not be used in any pregnant camelid female due to high risk of abortion or stillbirth.

PRECAUTIONS

Nephrotoxic drugs including oxytetracycline, vitamin D, aminoglycosides, and NSAIDs should be avoided or used very cautiously in azotemic or significantly dehydrated patients.

POSSIBLE INTERACTIONS

Bicarbonate will react with calcium-containing IV fluids.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Prognosis and course depend upon the reason underlying recumbency; however, the prognosis is typically reduced with chronic diseases, significant neurologic impairment, or secondary complications.

POSSIBLE COMPLICATIONS

• Muscle trauma from compression and struggling
• Aspiration
• Renal compromise
• Corneal ulceration or trauma
• Decubitus ulceration
• Hepatic lipidosis
• Seizures

CLIENT EDUCATION

Focus on herd management and targeted health-related procedures (vitamin D or selenium supplementation, vaccination, parasite management protocols) that are individualized to operations to avoid preventable diseases.

PATIENT CARE

• Monitor for progression during treatment to allow adjustments.
• Slings may be required in animals capable of supporting some of their own weight; the duration of time animals are kept in a sling should be adjusted based on individual tolerance and ability to monitor safely.
• Animals placed into float tanks should be attended at all times to prevent drowning; water should be kept close to body temperature to prevent cold stress. Animals with IV catheters should not be floated, to avoid infection.
• Crias with rickets should be handled with extreme caution due to the risk of inducing major skeletal trauma during routine procedures.
• Intravenous (dextrose, amino acids) or orogastric (transfaunation) nutritional

support is indicated in camelids with poor to absent appetite for prolonged durations.

PREVENTION
- Dependent on underlying cause.
- Routinely supplement crias with vitamin D in areas where rickets occurs.
- Periodic preventive anthelmintic treatment is performed in regions with a high prevalence of *P. tenuis*, though it should be acknowledged that this contributes to resistance issues in a range of parasites.
- Teach owners how to appropriately body condition score individual animals so that they can identify condition loss before it becomes extreme.
- Encourage management practices including vaccination for relevant diseases, supplementation to avoid vitamin and mineral deficiencies, and parasite control programs.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Rhabdomyolysis from prolonged recumbency

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY
Recumbent late gestation females should be evaluated carefully for evidence of uterine torsion; this can include limited (wrist deep) per rectum examination.

BIOSECURITY

DOWN SMALL RUMINANT

BASICS

OVERVIEW
Inability to stand and/or remain standing without assistance

INCIDENCE/PREVALENCE
Worldwide

GEOGRAPHIC DISTRIBUTION
- Depends on cause.
- Meningeal worm occurs wherever white-tailed deer are in contact with small ruminants.

SYSTEMS AFFECTED
- Musculoskeletal
- Nervous
- Multisystemic

PATHOPHYSIOLOGY
See specific disease chapters

HISTORICAL FINDINGS
History is very important to obtain when assessing a down small ruminant. The signalment, stage of pregnancy and lactation, diet changes, recent treatments, and history of trauma will be very helpful in reaching a diagnosis.

SIGNALMENT
All ovine, caprine

PHYSICAL EXAMINATION FINDINGS
- Sternal or lateral recumbency
- A thorough neurologic examination is important
- See specific disease chapters for specifics

CAUSES AND RISK FACTORS
See "Differential Diagnosis." Many diseases can be minimized through good husbandry, preventive health care, and nutrition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Neurologic Disease
- Polioencephalomalacia
- Listeriosis
- *Parelaphostrongylus tenuis*
- Bacterial meningitis
- Tick paralysis
- Botulism
- Rabies
- Scrapie
- Trauma
- Tetanus
- Neoplasia of CNS or spinal cord
- Abscess of CNS or spinal cord

Alimentary Disease
- Debilitation due to severe gastrointestinal parasitism
- Debilitation due to social starvation

Musculoskeletal Disease
- Peripheral nerve damage
- Trauma
- Infectious arthritis (lambs/kids)
- Laminitis

Metabolic Disease
- Pregnancy toxemia
- Hepatic lipidosis
- Hypocalcemia

Intoxications
Urea (ammonia)

Polioencephalomalacia
Necrosis of cortical gray matter associated with thiamine deficiency, often occurs in conjunction with a sudden feed change. Can occur due to a high sulfur diet or overdose of amprolium.

Clinical Signs

Central blindness (absence of menace with intact PLRs), depression and incoordination progressing to recumbency, and seizures.

Diagnosis

Based on history, clinical signs, and rapid response to therapy, though laboratory tests are available.

Treatment

Thiamine (10 mg/kg) intravenously, followed by IM or SC q6h for the first day, with additional doses q6–12h for the next 2–3 days. Thiamine hydrochloride can cause anaphylaxis if given intravenously, therefore it is recommended that the thiamine dose be diluted and administered slowly.

Listeriosis
Acute meningoencephalitis caused by Gram-positive bacterium *Listeria monocytogenes.*

Clinical Signs

Listeriosis most frequently causes focal encephalitis, usually affecting the cranial nerves but animals frequently present in later stages when they may be recumbent. Trigeminal, facial, and vestibular nerve lesions are most frequent, resulting in inability to eat, weakness of facial muscles, and head tilt. Animals may become dehydrated and acidotic due to loss of salivary secretions.

Diagnosis

- Based on clinical signs (particularly multifocal brainstem lesions) and elimination of other differential diagnoses.
- CSF analysis may demonstrate elevated protein (>40 mg/dL) and >5 mononuclear cells/μL.

Treatment

High doses of penicillin (40,000 U/kg q6–8h or 60,000 U/kg q12h), oxytetracycline (5–10 mg/kg IV q12h), or florfenicol (20 mg/kg IM q48h) in addition to supportive care such as anti-inflammatories, correction of hydration status and electrolyte abnormalities, and supplemental feeding as needed.

Parelaphostrongylus tenuis (Meningeal Worm)
- Nematode found in white-tailed deer and carried by snails and slugs.
- Small ruminant ingests snail or slug carrying larvae.
- Larvae are released in stomach and migrate to spinal cord and mature in gray matter; migrate to brain through the spinal subdural space.

Clinical Signs

- The parasite does not cause clinical signs in white-tailed deer.
- Infection in small ruminants can cause signs of neurologic disease including ataxia, paresis, circling, and recumbency. Lesions are more likely to occur in the spinal cord such that the animal retains normal mentation, but larvae can also migrate to the brain and cause depression and central nervous system signs such as blindness.

Diagnosis

- There is no reliable antemortem diagnostic test; the only definitive diagnostic test is identification of larvae in the spinal cord on histologic examination.
- CSF eosinophilia is supportive of infestation and affected animals may also have a peripheral eosinophilia.
- Other causes of ataxia and recumbency should be ruled out.

Treatment

- Ivermectin (0.2–0.4 mg/kg SQ) for 3 days to kill larvae outside the CNS.
- Fenbendazole at a dose rate of 50 mg/kg PO for 3–5 days to kill larvae inside the CNS.
- Supportive care if needed including intravenous fluids, in addition to anti-inflammatory medication such as flunixin meglumine or corticosteroids (in nonpregnant animals).
- Floatation therapy and/or physical therapy may be beneficial.

Prevention

Limit access to snail habitat, control snail/slug populations with domestic poultry, minimize contact with white-tailed deer. Monthly anthelmintic treatment as a preventive measure against meningeal worm is likely to promote anthelmintic resistance and is not recommended in most cases.

Rabies
Invariably fatal neurologic disease caused by rabies virus

Clinical Signs

- Neurologic signs are variable and include depression, ataxia, and anorexia, and can progress to recumbency, salivation, coma, and convulsions among many other signs.
- Should be considered in any case of nonresponsive central nervous system disease.

Diagnosis

- No clinical diagnostic test is available.
- Postmortem diagnosis is confirmed by histopathology of brain tissue and indirect fluorescent antibody testing of brain sections.

(CONTINUED) DOWN SMALL RUMINANT

Trauma

• Musculoskeletal or peripheral nerve injury or head trauma may result in inability to stand.
• Vertebral fractures can occur in growing animals with dietary imbalances (e.g., calcium or vitamin D deficiency).
• A complete neuromuscular examination should be performed.

Neoplasia or Abscess of CNS or Spinal Cord

• A neurologic examination should be performed to attempt to localize the lesion. Causes of CNS abscesses in small ruminants include *Corynebacterium pseudotuberculosis*, *Trueperella pyogenes*, and *Staphylococcus*. Lymphosarcoma is the most common spinal cord tumor in small ruminants.
• Diagnosis can be achieved in some cases with head or spinal radiographs, magnetic resonance imaging, or computed tomography.

Haemonchus contortus

A blood-sucking gastrointestinal strongyle parasite. Severe cases may progress to debilitation and recumbency as a result of anemia and hypoproteinemia. This is the main rule-out in a recumbent animal with pale/white mucus membranes.

Clinical Signs

• Pale mucus membranes
• Tachycardia
• Poor body condition
• Ventral edema, bottle jaw

Diagnosis

• Diagnosis is based on clinical signs and presence of large numbers of strongyle eggs on fecal float.
• *Haemonchus* cannot be readily identified by float alone but a diagnostic test using fluorescently-labeled peanut agglutinin that specifically binds *Haemonchus* eggs is available at diagnostic laboratories.

Treatment

• Elimination of *Haemonchus contortus* burdens can be difficult due to widespread resistance to commonly used dewormers.
• See chapter, Parasite Control Programs: Small Ruminant, and chapter, Haemonchosis.

Pregnancy Toxemia

Ewes and does carrying multiple fetuses may develop pregnancy toxemia if their increased nutritional needs are not met. A negative energy balance results in mobilization of fat and can cause excessive production of ketones.

Clinical Signs

• Depression and recumbency in ewes and does in the final trimester of pregnancy
• May progress to tremors, ataxia, opisthotonus
• Elevated blood and urine ketones
• Hypoglycemia

Treatment

• Cesarean section is required in critical cases
• Dextrose and propylene glycol are mainstays of treatment
• See chapter, Pregnancy Toxemia: Small Ruminant, for further information

Hypocalcemia

Usually affects ewes and does in the last 2 weeks of pregnancy.

Clinical Signs

• Ataxia progressing to recumbency
• Bloat (decreased eructation)
• Sluggish pupillary light responses

Treatment

1 g calcium per 45 kg body weight, may be split IV and SQ

TREATMENT

See "Differential Diagnoses"

MEDICATIONS

DRUGS OF CHOICE

See "Differential Diagnoses"

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Dependent on primary cause of disease

POSSIBLE COMPLICATIONS

Neuromuscular damage due to prolonged recumbency, especially on surfaces with inadequate bedding.

PATIENT CARE

Animals should be assisted to stand 3 or 4 times per day to allow for muscle perfusion and ease of urination. Clean, dry, deep bedding is important to prevent neuromuscular damage.

PREVENTION

Specific recommendations for prevention of disease will depend on the underlying cause. See specific disease chapters for more information.

MISCELLANEOUS

AGE-RELATED FACTORS

Neonates are at higher risk of systemic infectious causes of recumbency such as bacterial meningitis (including ascending infection as a result of tail docking) and infectious polyarthritis.

ZOONOTIC POTENTIAL

Rabies is a zoonotic disease.

PREGNANCY

Pregnant small ruminants are at risk of pregnancy toxemia and hypocalcemia.

ABBREVIATIONS

• CNS = central nervous system
• CSF = cerebral spinal fluid
• IV = intravenous
• PLR = pupillary light response
• PO = per os, by mouth
• SQ = subcutaneous

SEE ALSO

Consulting Editor Kaitlyn A. Lutz

Drug Hypersensitivities

BASICS

OVERVIEW
• Hypersensitivity reactions can occur following exposure to any drug.
• These reactions encompass the classic Gell and Coombs I–IV classification system.
• Identifying the type of reaction involved in a case can be challenging, but most reactions represent either type I or type III reactions. Cattle (especially Holsteins) can develop an endotoxin reaction from Gram-negative vaccines as well.
• Due to the rapid onset of type I reactions (often occurring within minutes), recognizing the signs of the reaction and properly responding with appropriate therapeutic agents is critical to help ensure the survival of the animal.

INCIDENCE/PREVALENCE
• Overall incidence is not well documented, but has been estimated at 1 per 10,000.
• Incidence and prevalence is dependent on spontaneous reporting by the animal owner or veterinarian. www.fda.gov/AnimalVeterinary/SafetyHealth/ReportaProblem/ucm055305.htm is an internet portal to the US FDA to report adverse drug reactions.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Cardiovascular
• Respiratory
• Integument
• Digestive

PATHOPHYSIOLOGY
• Hypersensitivity reactions typically are a result of either type I (IgE mediated/allergic) or type III (immune complex) reactions and require a pre-sensitized host.
• Type I reactions ("anaphylaxis") result from the antigen binding to various cells including basophils and mast cells, which trigger the release of vasoactive substances (e.g., histamine, leukotrienes, chemotactic factors) resulting in multi-organ effects including systemic shock, which are usually rapid and can be fatal in some cases.
• Type III reactions ("immune complex") result from the continued presence of soluble immune complex molecules becoming lodged in vessels and tissues, initiating the complement cascade and resulting in vasculitis, and can be slower in onset.

HISTORICAL FINDINGS
• Generally, hypersensitivity reactions are sporadic and involve individual animals within a group.
• Determine why a drug was given, dose, how the drug was obtained and handled, if more than one individual might be at risk, and the clinical signs suspected to relate to the drug versus the primary disorder being treated.

SIGNALMENT
All ruminant species and breeds of any age and gender potentially affected, though pre-sensitization is more likely to have developed in mature animals.

PHYSICAL EXAMINATION FINDINGS
• Type I ("allergic") reactions
  ◦ Diffuse swelling/edema of skin (especially the face and head) and udder
  ◦ Salivation and lacrimation
  ◦ Behavioral changes including anxiety, trembling, restlessness, or excitement
  ◦ Open mouth respirations and tongue protrusion due to difficulty breathing
  ◦ Wheezing and/or labored respirations, rhinitis
  ◦ Tachycardia
  ◦ Tachypnea
  ◦ Decreased rumen motility
• Type III ("immune complex") reactions
  ◦ Erythema and swollen joints with lameness or ataxia
  ◦ Changes in behavior
  ◦ Fever, polyuria, polydipsia

GENETICS
N/A

CAUSES AND RISK FACTORS
• Previous exposure to offending agent resulting in sensitization.
• Multiple Gram-negative vaccines administered on the same day may increase risk of endotoxin reaction in Holsteins.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Type I hypersensitivity may be generated as a response to some infections and infestations in cattle or sheep (e.g., *Ostertagia ostertagi or Bovicola* [*Damalinia*] *ovis*).
• Hypersensitivity reactions (suspected from drugs) should be differentiated from other agents the animal may have been exposed to (e.g., natural toxins).
• Type I hypersensitivity may need to be differentiated from accidental vascular injection of drugs or other types of adverse drug reactions.
• Type III reactions are often a diagnosis of exclusion; common etiologies for the signs of type III reactions could include chronic infections or malignancies.
• Due to the complexity of exposures that animals may have, identifying the offending agent (which may include feed or other exposures) can be challenging.

CBC/BIOCHEMISTRY/URINALYSIS
• Agranulocytosis, thrombocytopenia, or anemia may be noted on CBC depending on the type of reaction.
• Evidence of nephritis, proteinuria, and markers for inflammation may be evident on standard blood chemistry and urinalysis.

OTHER LABORATORY TESTS
Coombs' test or antinuclear antibody testing may help identify the cause.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
Cytologic examination and bacterial culture of joint fluid might be relevant to rule out septic arthritis in cases of type III reaction.

PATHOLOGIC FINDINGS
• Postmortem findings following true type I (IgE) reactions may show evidence of inflammation and edema (especially of the lungs). In adult cattle and sheep, bronchial constriction and retained air in alveoli may be present. In juvenile cattle, pulmonary edema and vascular engorgement is more common.
• Pathologic evidence of renal injury including interstitial nephritis may be present.

TREATMENT

THERAPEUTIC APPROACH
• Immediately discontinue or remove the suspected agent involved.
• Aggressive symptomatic management focusing on cardiovascular support and administration of anti-inflammatory agents is indicated for type I reactions.
• Antibiotics (as needed) for suspected or confirmed infections and anti-inflammatory agents and supportive fluid therapy as needed if renal impairment is noted for type III reactions.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Drainage of infected tissues or abscesses occurring from type III reactions may be necessary.

MEDICATIONS

DRUGS OF CHOICE
• Epinephrine 1:1,000—0.5–1.0 mL/50 kg or /100 lbs SQ or IM (extra-label use)
• Dexamethasone 20 mg IM or IV (extra-label)
• Isoflupredone 10–20 mg (total dose) IM based on size of animal and severity of signs
• Methylprednisolone 100–500 mg IM
• Flunixin meglumine 1.1–2.2 mg/kg slow IV
• Diphenhydramine hydrochloride 0.5–2.0 mg/kg slow IV or IM

CONTRAINDICATIONS
Corticosteroids should be avoided in pregnant animals and used judiciously in animals with an underlying infectious disease.

PRECAUTIONS
• Ensure proper dilution of epinephrine solution prior to administration (ideally to 1:10,000).
• Antihistamine drugs can occasionally cause paradoxic excitement.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
• Many potential drug and disease-state interactions.
• Refer to the specific drug package insert for details regarding interactions.
• Milk and meat withdrawal times may be impacted based on therapeutic agent(s) administered.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Good prognosis if recognized early during development of the reaction and treated appropriately with supportive care including cardiovascular support if needed.

POSSIBLE COMPLICATIONS
• Abortion
• Renal failure

CLIENT EDUCATION
Educate owners on risk for recurrence of hypersensitivity reactions following administration of the same drug or drugs from the same class.

PATIENT CARE
• Monitor heart rate and respiratory status.
• Monitor activity, behavior, demeanor, and appetite to gauge response to therapy.

PREVENTION
Avoid administering suspected offending agent or related agents in the future.

DRUG INTERACTIONS

BASICS

OVERVIEW

• The impact on the overall activity [including the dissolution, pharmacokinetics (PK) and pharmacodynamics (PD)] that one drug has upon another drug can be termed, generally, as a "drug interaction."
• Drug interactions can result in a wide variety of consequences which can be harmful (even fatal), beneficial, or inconsequential depending upon a variety of factors.
• Drug interactions may lead to therapeutic failures due to specific PK or PD effects between co-administered agents (e.g., competitive binding, enhanced drug elimination).
• Interactions between drugs can occur as a result of a physical incompatibility (e.g., mixing drugs in the same syringe or IV bag) or due to the PK or PD properties of the agents.
• Animal-specific factors, including age or end-organ function, can directly impact the likelihood and severity of some interactions.
• Access to up-to-date clinical or electronic references to identify potential interactions is essential for every practitioner to limit the likelihood of harmful interactions.

INCIDENCE/PREVALENCE

• The overall incidence and prevalence of interactions is not well described.
• Many drug interactions do not produce outward signs.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Multisystemic

PATHOPHYSIOLOGY

In Vitro Interactions

• Physical or physicochemical incompatibility of agents may occur prior to administration and involve interactions between active ingredients, excipients (e.g., fillers, diluents or bulking agents), IV fluids or administration equipment (e.g., IV bag or syringe).
• Cloudiness, color changes, or visible precipitation may be evident.
• Changes in pH of the agent or inactivation of one or more of the drugs may occur.
• The risk of in vitro interactions can be reduced through utilization of IV drug stability and incompatibility references.

Pharmacokinetic (PK) Interactions

• Pharmacokinetic interactions between drugs impact the absorption, distribution, metabolism, and/or excretion of one or more of the drugs.
• Overall, the impact that PK interactions have may result in higher or lower than expected plasma drug concentrations, potentially resulting in drug toxicity or therapeutic failure, respectively.
• Absorption of tetracycline-class antibiotics can be inhibited by the presence of co-administered drugs high in certain metal ions (e.g., calcium, magnesium) due to formation of chelating complexes.
• Drugs that impact the acid secretion or digestive tract motility may increase or decrease absorption (e.g., H_1/H_2 inhibitors, such as ranitidine or cimetidine; anticholinergic agents such as atropine; opioids).
• Distribution of drugs can be impacted by the presence of co-administered agents due to effects on protein binding (e.g., sulfonamides competing with phenylbutazone for protein binding sites).
• Metabolism of some drugs may be enhanced or inhibited due to the impact that other drugs exert on cytochrome P450 enzyme systems involved with the metabolism of the therapeutic agent.
• Elimination of some agents in the urine can be impacted by changes in the pH of the urine (alkalization or acidification), or through competition for protein carrier sites resulting in either inhibition or prolongation of excretion.

Pharmacodynamic (PD) Interactions

• Pharmacodynamic interactions occur at the level of the receptor site and involve the impact one drug may have on binding, with subsequent inhibition or enhancement of clinical effects.
• Drugs may act as a full or partial antagonist at receptor sites, limiting (or blocking) the effect other agents have at that site (e.g., extra-label use of yohimbine blocking the action of xylazine at α_2 receptor sites).
• Drugs may also act as physiologic antagonists to each other, binding to separate and functionally opposing receptor sites (e.g., extra-label use of doxapram in cattle to reverse respiratory depression from inhaled anesthetics).
• Agents with unique receptor site targets, when administered together, may produce either additive effects (e.g., $1 + 2 = 3$) or synergistic effects (e.g., $1 + 1 = 5$) depending on the agents used.

HISTORICAL FINDINGS

N/A

SIGNALMENT

All ruminant species of any age or gender can be affected by drug interaction.

PHYSICAL EXAMINATION FINDINGS

• Signs of a drug interaction vary widely depending on the specific interaction and the impact on various organ system(s).
• Toxic effects may range from mild depression or inappetence to collapse of the animal.
• Outward signs may indicate enhancement of one of the administered agents or lack of efficacy (therapeutic failure).

GENETICS

• Variations in the expression of the cytochrome P450 system exist between ruminant species, leading to marked differences in metabolism (and toxicity) of some agents between species (e.g., susceptibility to pyrrolizidine alkaloid toxicity of sheep vs. cattle). Even among breeds within a species (conventional farm pig vs. Göttinger minipig) large variations in susceptibility may exist.
• The full impact of this varied expression has not been fully described; caution should be exercised when administering therapeutic agents in an extra-label manner.

CAUSES AND RISK FACTORS

• The risk for interactions to occur increases with the number of drugs administered.
• Animal-specific factors including age or pre-existing end-organ dysfunction can directly impact the likelihood and severity of some interactions.
• Older animals predictably experience changes to drug absorption, distribution, and excretion due to age-related physiologic changes which may result in previously unexpected drug interactions.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• The physiologic impact of drug interactions may mimic any number of disease conditions.
• A review of all current therapeutic agents (including dosing schedule in relation to other drugs) should be made.
• Involvement of a drug interaction should be considered when apparent signs of drug toxicity occur or in the event an animal's condition does not improve following the initiation of new drug therapy.

CBC/BIOCHEMISTRY/URINALYSIS

• Variable impact based on specific interaction.
• Toxic effects on the kidneys or liver as a result of a drug-drug interaction may mimic underlying diseases.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

• Variable depending on specific interactions.
• Most commonly the liver and kidneys are affected if interaction is significant enough to result in end-organ damage.

TREATMENT

THERAPEUTIC APPROACH
• Immediate discontinuation of suspected offending agent(s).
• Gastrointestinal decontamination with intraruminal administration of activated charcoal, cathartics, or rumenotomy should be considered when orally administered drugs may result in a serious or life-threatening toxic event.
• Symptomatic and supportive treatment based on specific expected or resultant injury; fluid therapy and electrolyte support to correct perfusion, cardiovascular function, and metabolic disturbances.

FOLLOW-UP

POSSIBLE COMPLICATIONS
Variable complications including end-organ injury (liver, kidney).

EXPECTED COURSE AND PROGNOSIS
• Based on a variety of factors including the specific interaction and any resulting injury, age, and underlying end-organ health.
• Early recognition and appropriate action may improve the expected course and prognosis.

CLIENT EDUCATION
Close observation of animals following the initiation or change in drug therapy to recognize the effects of drug interactions.

PATIENT CARE
Close observation of animals following the initiation or change in drug therapy to recognize the effects of drug interactions.

PREVENTION
• Avoid administering agents with known or high likelihood of interactions.
• Limit overall drug administration (rational drug therapy).
• Stagger drug dosing to limit concomitant exposure to multiple agents.
• Adjust dosing of agents based on individual therapeutic response.
• Micromedix (www.micromedex.com) is a Commercial Drug Interaction Database that can be utilized.

DRUG TOXICITIES

BASICS

OVERVIEW
• The term "drug toxicity" represents a broad spectrum of potential adverse drug reactions (ADRs) associated with drug therapy.
• A "toxic effect" of a drug describes events not typically associated with the normal dosing of a medication. Other reported effects, termed "adverse effects," include all other unwanted effects regardless of mechanism.
• Terminology introduced in the 1970s to describe ADRs has included: type A ("augmented") events which occur based solely on the dose administered; and type B ("bizarre") events which are not connected to the dose administered (e.g., idiosyncratic or immune reactions).
• Other events may be categorized based on the chronic nature or overall duration of therapy or events that encompass a genetic predisposition; all events are considered ADRs.
• Some events may not be identified until substantial post-marketing surveillance has been completed.
• In addition to stand alone drugs, supplemented feed may be involved in some drug toxicities.

INCIDENCE/PREVALENCE
Accurate rates of ADRs are difficult to identify; they are dependent on reporting to the pharmaceutical company or to the US FDA.

GEOGRAPHIC DISTRIBUTION
Worldwide; regional distribution might be influenced by quality control procedures and marketing practices.

SYSTEMS AFFECTED
• Digestive
• Integument
• Musculoskeletal
• Cardiovascular
• Nervous
• Respiratory
• Urinary

PATHOPHYSIOLOGY
• Varies based on the drug involved and the organ system(s) affected.
• Type A reactions are more predictable and are a reflection or extension of the pharmacologic effects of the drug (e.g., the effects of an overdose of xylazine). Often such effects have been identified in pre-market studies.
• Type B reactions involve more unexpected or unpredictable mechanisms of toxicity, often appear to be either immune-related or otherwise idiopathic in nature, and can have a highly variable onset.
• Either the parent compound or a reactive metabolite can be involved in type B events.
• Frequently in type B events, the liver is involved, presumably because of its role in drug metabolism. The skin or bone marrow may also be adversely affected.

HISTORICAL FINDINGS
• Determine why a drug was given, the dose, how the drug was obtained and handled, if more than one individual might be at risk, and the clinical signs suspected to relate to the drug versus the primary disorder being treated.
• Route of drug administration is important when an unexpected reaction is observed; signs might relate to accidental arterial injection, or inadvertent penetration of a vessel during IM administration, rather than a true drug reaction.

SIGNALMENT
All species of any age/gender

PHYSICAL EXAMINATION FINDINGS
• Signs vary based on the underlying mechanism of the reaction (e.g., immunologic, pharmacologic).
• Nonspecific signs such as skin reactions (including photosensitivity), inappetence, apparent lameness, behavior changes, tremors, salivation, or diarrhea may be evident depending on the drug or the organ system involved.
• Outward signs may mimic a variety of injuries or organic diseases. Some may have a characteristic "toxidrome"—a group of signs that constitute the basis for a diagnosis of poisoning (e.g., cholinesterase inhibitors).

GENETICS
N/A

CAUSES AND RISK FACTORS
• Administration of any drug creates risk; administering agents above label doses may increase risk of a type A reaction.
• Feed may be implicated in some cases such as in ionophore toxicity, or if feed is supplemented with selenium or copper.
• Topical application of some agents, such as insecticides, can also provoke adverse reactions.
• Pre-existing disease may induce a higher risk of a toxicity event, for example, drug-associated nephrotoxicity is more likely in hypovolemic animals.
• Due to the infrequent and unpredictable nature of some events, a full list of causes and risk factors is not known.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Depending on clinical signs and clinicopathologic findings, the differential diagnosis list may include a variety of organic diseases including infections or physical injury.
• Pharmaceutical agents as an etiologic cause should be considered as part of the routine evaluation of a diseased animal.
• Common exposures (e.g., feed, natural toxins, plants) should be considered if multiple animals are clinically affected with similar findings.

CBC/BIOCHEMISTRY/URINALYSIS
• Routine laboratory assessments are often indicated and can include a CBC with differential, a blood chemistry profile encompassing renal, hepatic, and muscular indices; and urinalysis.
• Laboratory findings vary based on the degree and duration of the adverse event and any accompanying disorder for which the drug might have been administered. Changes in some end-organ variables (e.g., liver enzymes, creatinine) may evolve over time depending on acute versus chronic injury.

OTHER LABORATORY TESTS
• Bone marrow aspiration can help identify hematopoietic diseases.
• Analysis of stomach/rumen contents for ionophore concentrations.

IMAGING
Ultrasonography can be used to evaluate the liver or kidney in some cases of suspected drug toxicity.

OTHER DIAGNOSTIC PROCEDURES
Percutaneous biopsy of liver or kidney if indicated.

PATHOLOGIC FINDINGS
• Variable based on organ injury.
• Lesions in skeletal and cardiac muscle occur from ionophore toxicity.
• Stomach/rumen contents should be collected for analysis where relevant.

TREATMENT

THERAPEUTIC APPROACH
• Discontinue treatment or exposure to the suspected agent.
• Consult with an animal poison center if a "drug overdose" or poisoning is suspected, to review decontamination and necessary care.
• Appropriate treatment including the use of specific antidotes varies based on the toxic agent.
• Fluid therapy, nutritional support, and corticosteroids can be administered if indicated.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

(CONTINUED) DRUG TOXICITIES

MEDICATIONS

DRUGS OF CHOICE

• Incomplete list; consultation with a poison center is recommended in the event of a drug overdose or suspected poisoning.
• Anti-inflammatory:
  ◦ Dexamethasone (IV) 0.05–0.1 mg/kg body weight
• Digestive tract decontamination:
  ◦ Activated charcoal (extra-label): 1–5 g/kg as a slurry by mouth or ororuminal tube
  ◦ Sodium or magnesium sulfate: 250–500 mg/kg added to the charcoal slurry
• Atropine sulfate (for cholinesterase inhibitor toxicity)—dose varies based on degree of toxicity
• Epinephrine (extra-label, for anaphylaxis): 0.5–1 ml per 100 lbs (45 kg) of bodyweight of 1:1,000 SQ or IM; dilute to 1:10,000 if using IV; repeat every 15 minutes as needed.

CONTRAINDICATIONS

Refer to the package insert of the individual drugs for details.

PRECAUTIONS

• Corticosteroids should be avoided in pregnant animals and used judiciously in animals with underlying infectious disease.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

• Refer to the package insert of the individual drugs for details.
• Milk and meat withdrawal times may be impacted based on therapeutic agent(s) administered.
• Using combinations of drugs from the same class (e.g., use of more than one NSAID agent at once) may enhance the possibility of toxic effects.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Variable course and prognosis depending on timing of recognition, and management, age and underlying health status of the affected animal.
• Animals with ionophore toxicity may have a guarded prognosis due to the possibility of developing chronic cardiac disease.
• Animals suffering severe impact to other systems (bone marrow, kidneys) also have a guarded prognosis depending on response to treatment and progression over time.

POSSIBLE COMPLICATIONS

Chronic end-organ dysfunction from initial insult

CLIENT EDUCATION

Animal owners should be alert for changes in animals following drug administration.

PATIENT CARE

Periodic reevaluation of blood chemistries, urine characteristics, and behavior as needed.

PREVENTION

• Avoid drugs from the same class following previous immune-related events.
• Avoid nephrotoxic drugs in dehydrated patients or those with suspected renal disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Renal failure
• Hepatic failure
• Diarrhea

AGE-RELATED FACTORS

Changes in drug metabolism may occur as the animal ages. Metabolic pathways in young animals may not have fully matured.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Adverse drug reactions in pregnant animals may invoke abortion or stillbirth.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

• Refer to drug label or appropriate references for meat and milk withdrawal times for all agents administered.
• www.fda.gov/AnimalVeterinary/SafetyHealth/ReportaProblem/ucm055305.htm is an internet portal to the US FDA to report adverse drug reactions.

DYSTOCIA: BOVINE

BASICS

OVERVIEW
• Dystocia, or difficulty calving, occurs when the first or second stage in the parturition process is interrupted or prolonged.
• Varying degrees of intervention may be required to correct the cause of dystocia, provide assistance for delivery of the fetus, and preserve the health and fertility of the cow.

INCIDENCE/PREVALENCE
• Incidence varies depending on herd management, age and size at breeding, size and breed of dam, parity, gender of the fetus, and breed of sire of the fetus.
• In US Holstein-Friesian cattle, the reported incidence is 13.7% (22.6% in primiparous animals).
• In beef cattle, the reported incidence is 17.7% for primiparous and 2.7% for multiparous cows.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Reproductive
• Musculoskeletal
• Multisystemic

PATHOPHYSIOLOGY
• Causes of dystocia can be fetal or maternal in origin and may be related to lack of expulsive forces or obstruction of the birth canal.
• The most common cause of dystocia in cattle is feto-maternal size disproportions.
• Fetal causes of dystocia:
  ◦ Fetal abnormalities due to congenital or genetic defects frequently result in dystocia.
  ◦ Abnormal position, presentation or posture.
    ■ *Presentation* is defined as the orientation of the spinal axis of the fetus to that of the dam (cranial, caudal, or transverse).
    ■ *Position* is the orientation of the dorsum of the fetus in relation to the quadrants of the maternal pelvis (dorsosacral, dorsoilial, dorsopubic).
    ■ *Posture* is the relationship of the fetal extremities with respect to its torso (e.g., left carpal flexion, lateral neck flexion).
• Maternal causes include uterine torsion, uterine inertia, incomplete cervical or vulvar dilation, small pelvic size, obesity, fear, or genetic predisposition.
  ◦ Failure of expulsive forces may be due to primary or secondary uterine inertia.
  ◦ Primary uterine inertia is failure of the myometrium to contract due to over-stretching (hydrops) or metabolic disease (hypocalcemia).
  ◦ Secondary uterine inertia is the result of exhaustion of the myometrium due to prolonged second stage of labor.

HISTORICAL FINDINGS
• Lack of progress after initiation of parturition
• Continuous violent abdominal contractions without visualization of fetal parts
• Unsuccessful attempts by either an owner or herdsman to deliver the calf

SIGNALMENT
• Dystocia may occur in cows of any parity; however, incidence is higher in primiparous than multiparous animals.
• Incidence varies by species and breed.
• Belgian Blue cattle have a higher rate of dystocia with over 90% of calvings reported to result in cesarean section.

PHYSICAL EXAMINATION FINDINGS
• Prior to assisting a dystocia, the minimal requirements are an ample supply of clean warm water, disinfectant, buckets, lubricant (petroleum jelly or methylcellulose-derived products), and two obstetrical chains with handles.
• Transrectal palpation to rule out uterine torsion should be performed if no fetal parts are present at the vulva.
• Vaginal examination should be performed if there has been little progress for 2 hours after the amniotic sac is presented at the vulva.
  ◦ The presentation, position, and posture of the fetus are determined and fetal viability and birth canal integrity are assessed.
  ◦ The fetus can live up to 10 hours within the birth canal after the amniotic sac is ruptured.
  ◦ If the head is accessible in cranial presentation, the swallowing reflex may be elicited by inserting a finger into the mouth; if the fetus is alive, swallowing will occur.
  ◦ The pedal reflex may be assessed by applying pressure between the hooves; a responsive fetus will retract its leg.
  ◦ A blink reflex may also be elicited by applying pressure over the globe.
• The fetus must be in dorsosacral position with a normal posture prior to extraction.
• The final step is to determine whether or not there is sufficient space and lubrication to achieve vaginal delivery of the fetus.
• Fetal traction requires correct placement of chains above the fetlock and below the dewclaws of the fetus.

Anterior/Cranial Presentation
• The front limbs are identified by the flexion of the fetlock and carpus joints in the same direction.
• The head of the fetus should be extended and rest on both knees of the extended front limbs with the legs fully presented in the birth canal.
• Vaginal delivery is possible if one person can pull the first leg presented until the pastern is 6 inches (12 cm) outside the vulva and, while holding the first leg in this position, the second leg can be extended equally far outside the vulva.
• At these distances, both shoulders of the fetus will have passed the bony entrance to the maternal pelvis.
• Pulling alternately on the forelimbs during delivery will decrease the width of the shoulders as the fetus moves through the maternal pelvis.

Posterior/Caudal Presentation
• About 5% of parturitions occur with a fetus is in posterior presentation.
• Both hind legs should be extended. The hindlimbs are identified by the opposite direction of the fetlock and hock flexion.
• Vaginal delivery is possible if both hocks can be exteriorized.
• Passage of the fetal pelvis through the maternal pelvis may be facilitated by rotating the fetus approximately 90 degrees.

GENETICS
The rate of dystocia increases with inbreeding in Holstein cattle.

CAUSES AND RISK FACTORS
• Obesity
• Twins
• Hypocalcemia
• Small frame size
• Oversized fetus

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

DIAGNOSTIC PROCEDURES
See "Physical Examination Findings"

PATHOLOGIC FINDINGS
N/A

TREATMENT

THERAPEUTIC APPROACH
• Caudal epidural analgesia helps with obstetric manipulations.
• Epinephrine can be administered to help relax the uterus during manipulation of the fetus.
• Rules of obstetric manipulations should always be followed (i.e., ample lubrication, correct diagnosis, retropulsion, mutation, and traction).
• Uterine torsion may be corrected by rolling, use of detorsion rod if the fetus is accessible, or cesarean section.

• In anterior presentation, the abnormal limb flexion is corrected and the head is extended with the help of a snare before applying traction.
• Unilateral or bilateral (breech) hip flexions are corrected by pushing the rump forward and grasping a rear foot and flexing it at the fetlock and hock to reorient the legs to coxo-femoral extension. The procedure is repeated on the other limb, then the fetus is extracted.
• Abnormal position due to failure of rotation of the fetus requires the use of the detorsion rod.
• Manipulation time should be kept to a minimum. Fetotomy may be performed if the fetus is dead, the cervix is completely dilated, and there is enough room.

SURGICAL CONSIDERATION
• Cesarean section may be indicated if a live calf cannot be delivered vaginally.
• Dead emphysematous calves or fetal monsters may require a fetotomy.

MEDICATIONS

DRUGS OF CHOICE
• Activation of β2 receptors in the myometrium via administration of epinephrine (1 mL 1:1000 epinephrine IV or 10 mL IM) will result in uterine relaxation.
• Systemic antibiotics.
• Oxytocin (10–20 IU, IM or IV) administered within 48–72 hours may enhance myometrial contractions and aid in evacuation of uterine contents following dystocia.
• Uterine lavage is recommended if the fetus is dead.

CONTRAINDICATIONS
• Sedatives may cause recumbency and may reach fetal circulation.
• Appropriate milk and meat withdrawal times must be followed.

PRECAUTIONS
Obstetric manipulation should be performed in a safe area for the dam and examiner.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Prognosis depends on severity of dystocia, degree of trauma suffered by the dam's reproductive tract during forced fetal extraction, and occurrence of other postpartum diseases.

POSSIBLE COMPLICATIONS
• Retained fetal membranes
• Trauma and lacerations to the genital tract
• Downer cow syndrome (due to damage to sciatic or obturator nerves)
• Metritis
• Necrotic vaginitis

CLIENT EDUCATION
• Management practices to prevent risk factors for dystocia.
• Calving management and techniques for prompt and correct handling of dystocia.

PATIENT CARE
• Cows should be monitored for appetite, demeanor and fever.
• Character, odor, and amount of vaginal discharge should be noted.
• Administration of antibiotics, NSAIDs, and calcium supplements may be indicated.
• Walking or movement should be limited in those animals that are weak after parturition.

PREVENTION
• Proper nutrition to prevent obesity, negative energy balance, and hypocalcemia.
• Sire selection for calving ease.
• Heifer selection (pelvimetry).

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
• Obese primiparous animals.

DYSTOCIA: CAMELID

BASICS

OVERVIEW
• Dystocia is an abnormal prolongation of the first or second stage of parturition requiring assistance for delivery of the fetus.
• Urgent attention should be given to any complaint of dystocia in camelids as the prognosis for survival of the fetus and the female decrease rapidly.
• Obstetric approaches for fetal extraction vary depending on the cause and include assisted vaginal delivery, controlled vaginal delivery, cesarean, or fetotomy.

INCIDENCE/PREVALENCE
Dystocia is rare in camelids. Less than 5% of parturition requires advanced obstetric manipulations by the veterinarian.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Reproductive
• Other systems depending on complications

PATHOPHYSIOLOGY
• Normal parturition in camelids is faster than that of ruminants. Premonitory signs include mammary gland enlargement and pelvic ligament relaxation 2–3 weeks prior to parturition. Vulvar edema and bulging of the perineal area appear a few days prior to parturition. The first stage of labor lasts 3–48 hours and is characterized by frequent urination and defection, discomfort, and signs of colic. The expulsion of the fetus takes 5–90 minutes (average 20 minutes) from rupture of the chorioallantoic sac.
• Dystocia is suspected if there is no progression of labor with increased signs of colic, depression, abnormal perineal or vaginal discharge.
• The cause of dystocia may be maternal or fetal in origin.
• The most common maternal causes are: uterine torsion, uterine inertia, uterine rupture, failure of cervical or vestibular dilation. Primary uterine inertia is frequent in dairy camels and may be due to hypocalcemia.
• Fetal causes include maldispositions or malpostures which are common due to the length of the neck and legs in camelids. Fetal abnormalities (contracted tendons, hydrocephalus, neck and limb ankyloses, schistosomus reflexus) have been reported in cases of dystocia.
• Fetomaternal disproportion and twinning are possible but rare.
• Prognosis for fetal survival decreases rapidly after rupture of the chorioallantois because of rapid detachment of the epitheliochorial, microcotyledonary diffuse placenta resulting in fetal asphyxia.

HISTORICAL FINDINGS
• Normal pregnancy length (320–375 days in SAC, 315–440 days in camels).
• Clinical signs of preparation for delivery 2–3 weeks prior (relaxation of the pelvic ligaments, udder development, vulvar elongation).
• Increasingly violent abdominal contractions without visible fetal parts at the vulva or progression.
• Initiation of stage 2 of parturition with no progression and excessive rolling, kicking at the belly, and vocalization.
• Owner reporting abnormalities (bloody vaginal discharge, fetal or birth canal abnormalities) or lack of success after attempting to assist.

SIGNALMENT
Pregnant female at term or later abortion

PHYSICAL EXAMINATION FINDINGS
• General demeanor and health of the female is usually normal. The only sign present may be abdominal contractions. Protracted cases may show severe vulvar edema, dehydration, and injected sclera. Diarrhea is not uncommon in distressed camels.
• Transrectal palpation is indicated if no fetal parts are visible at the vulva. Sedation and epidural analgesia are required for this evaluation.
• Examination per vaginam is performed as aseptically as possible using ample lubrication to determine presentation, position, and posture of the fetus and assess integrity of the birth canal.
• Clinical assessment of fetal viability in camelids is very difficult. The fetus should only be considered dead if there is evidence of autolysis or lack of cardiac activity.
• Uterine torsion is a common cause of dystocia and can be ruled in or out by transrectal palpation.
• Cranial presentation is the most common (98%). The front limbs should be fully extended with one slightly more advanced than the other and the head resting at the level of the carpi. The most common fetal maldispositions in this presentation are carpal or shoulder flexion and lateral or ventral head deviations. In maiden females, failure of progression may be due to lack of dilation of the vestibular area.
• Caudal presentation is less common (2%). The hind legs should be completely extended. The most common fetal malpostures are unilateral or bilateral hock or hip flexions.
• Transverse presentation is rare.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Obesity
• Progesterone supplementation to maintain pregnancy
• Injuries to the birth canal

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Other causes of colic. Verify accuracy of breeding date to ascertain that the female is at term.

CBC/BIOCHEMISTRY/URINALYSIS
Indicated if a decision is made to perform a cesarean section on a compromised female.

OTHER LABORATORY TESTS
N/A

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
Postmortem examination of dead fetus may confirm abnormalities that caused the dystocia.

TREATMENT

THERAPEUTIC APPROACH
• Caudal epidural analgesia is sufficient for simple obstetric manipulations (correction of carpal or hock flexion, vestibular dilation).
• Sedation with butorphanol in addition to caudal epidural is helpful for the correction of uterine torsion by rolling and for assisted vaginal delivery in cases of shoulder flexion or slight lateral head deviations.
• Heavy sedation or general anesthesia is required for controlled vaginal delivery. Large llamas and camels should be hobbled in sternal position with the hindquarter elevated to allow manipulation.
• Manipulation time should be <30 minutes in order to minimize complications (necrotic vaginitis).
• Obstetric manipulations require fetal repulsion, mutation, then extraction. These are facilitated by administration of a tocolytic.
• Partial fetotomy may be considered in large llamas and camels but should be avoided in alpacas as the risks for vaginal adhesions are very high.
• Uterine lavage should only be performed if indicated (dead autolyzed fetus or lengthy manipulation).
• Pain management and antimicrobial therapy should be considered on a per case basis.
• Vulvar swelling can be reduced by application of cold compresses (ice) for a few minutes every couple of hours.
• Prevention of adhesions from necrotic vaginitis may be prevented by placement of vaginal tampons covered with protective ointment (lanolin and oxytetracycline).
• Neonatal resuscitation and care should be immediately provided.

SURGICAL CONSIDERATIONS AND TECHNIQUES
Cesarean section should be considered if manipulation is not possible.

MEDICATIONS

DRUGS OF CHOICE
• Epidural: Lidocaine 2% (1 mL/100 kg)
• Sedation: Xylazine (0.1 mg/kg), butorphanol (0.05 mg/kg)
• Anesthesia: In the field use combination of xylazine, ketamine, and butorphanol
• Tocolytic: Clenbuterol IM (300 µg in camels, 100 µg in SAC), epinephrine IV (1:1000 IU per mL, 5 mL in SAC, 10 mL in camels), N-butylscopolammonium bromide (4 mg/10 kg, camels)
• Uterotonic: Oxytocin IM (5–10 IU in SAC, 20–30 IU in camels)
• Antimicrobials: Ceftiofur (2.2. mg/kg IM), procaine penicillin G IM (22,000 IU/kg)
• NSAID: Flunixin meglumine (1.1 mg/kg IV or SQ)

CONTRAINDICATIONS
Appropriate meat and milk withdrawal times must be followed.

PRECAUTIONS
Do not handle camel dystocia with the camel in a standing position.

POSSIBLE INTERACTIONS
Ketamine has a severe depressing effect on the fetus and should be avoided if the fetus is alive.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Recovery and prognosis for fertility depends on length of manipulation. Normal fertility is expected in females with no postpartum complications.
• Delayed involution and decreased fertility is expected following prolonged manipulations, retained placenta or uterine infections.
• Prognosis for dam survival is poor if the uterus or broad ligaments are compromised.
• Prognosis for fetal survival is poor if not extracted within 90 minutes of rupture of the chorioallantois.

POSSIBLE COMPLICATIONS
• Retained placenta
• Necrotic vaginitis
• Uterine, cervical, or vagina tears
• Toxic metritis and peritonitis

CLIENT EDUCATION
• Keep good breeding record.
• Learn the normal signs of parturition and how to recognize obstetric situations.
• Avoid excessive manipulations and call for veterinary help as soon as possible.

PATIENT CARE
• Provide good-quality hay and water and an area of exercise.
• Monitor appetite and any signs of depression.
• Monitor mothering behavior and lactation.
• Perform a postpartum evaluation 10–15 days after delivery.

PREVENTION
• Proper feeding and exercise during pregnancy.
• Observe rules for age, weight, and height at mating for maiden females.

MISCELLANEOUS

ASSOCIATED CONDITIONS
n/A

AGE-RELATED FACTORS
• Older primiparous females are at high risk (failure of vestibular dilation)
• Age at first mating

ZOONOTIC POTENTIAL
Wear protective gear for manipulation if brucellosis, chlamydiosis, and Q fever are endemic.

PREGNANCY
N/A

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
• Close monitoring of females at term.
• Increase frequency of observation near term (parturition barn with webcam).
• Use electronic alerting devices (i.e., vulvar devices) in extremely valuable camels.

SYNONYMS
N/A

ABBREVIATIONS
• IM = intramuscular
• IV = intravenous
• NSAIDs = nonsteroidal anti-inflammatory drugs
• SAC = South American camelids

DYSTOCIA: SMALL RUMINANT

BASICS

OVERVIEW
• Difficult parturition characterized by prolongation of stage 1 or stage 2 of labor.
• Early recognition of dystocia and appropriate assistance make the difference in the life of the fetus and of the dam.

INCIDENCE/PPREVALENCE
• Incidence is highly variable (3–34%).
• Difference between sheep and goat is controversial.
• Certain breeds (pygmy goats, Dorset sheep, and crossbred Texel sheep) are overrepresented in some studies.
• There is a reported higher incidence of dystocia with twins (11%) and triplets (14%) versus that seen in singleton births (10%).
• Incomplete cervical dilation is the most common cause of dystocia (up to 43.5%).
• Incidence of fetal maldispositions are the most common fetal causes of dystocia in ewes (25%) and does (19.1%).

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Reproductive
• Musculoskeletal

PATHOPHYSIOLOGY
• Dystocia can be due to fetomaternal disproportion, fetal maldisposition (abnormal presentation, position, or posture), uterine inertia, or failure/incomplete cervical dilation.
• Uterine torsion, hydrops conditions, conditions secondary to vaginal prolapse (especially in sheep), and perineal herniation can result in dystocia in a low percentage of cases.
• Management, genetics, nutrition, and/or metabolic state of the animal can predispose to dystocia.
• Stage 1 of labor and cervical dilation lasts 6–12 hours for doelings and ewe lambs and 4–8 hours in adults.
• Stage 2 of labor begins with rupture of the allantochorion and ends with expulsion of a fetus. It lasts 1–4 hours in doelings and ewe lambs and 30 minutes to 1 hour in adults.

HISTORICAL FINDINGS
No apparent progress within an hour of first seeing the fetal membranes, or 70 min in doelings and ewe lambs.

SIGNALMENT
Periparturient females

PHYSICAL EXAMINATION FINDINGS
Fetal membranes, fluid and or bloody to serosanguinous discharges from the vagina, abdominal contractions with straining, anorexia, and colicky behavior.

GENETICS
• Small or prolific breeds
• Bucks and rams size, especially when mating to doelings and ewe lambs.
• Bucks and rams that are known to produce excessively large offspring (fetal oversize).

CAUSES AND RISK FACTORS
• Breed predisposition: Pygmy goats, Dorset sheep and crossbred Texel sheep
• Poor BCS
• Pregnancy toxemia or other metabolic disorders
• Oversized singleton fetuses
• Clover pasture may predispose to failure of cervical dilation

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Abortion, uterine torsion, bloat, cystitis, hydrops conditions as well as displacement and/or torsion of the abomasum, cecum, or mesentery may all present with similar clinical signs of colicky behavior and straining.
• Abortion and cystitis may also have a similar looking serosanguinous discharge from the vagina.

CBC/BIOCHEMISTRY/URINALYSIS
• Hypocalcemia, and pregnancy toxemia (ketosis with an elevated anion gap).
• Elevated creatinine kinase, and lactic acidosis (uterine torsion, and exhaustion).
• Anemia (uterine rupture). Loss of blood and parasites can cause a ewe or doe to be very anemic and weak and hence predispose to dystocia as well.
• Neutrophilia and increased fibrinogen (inflammatory/infectious process).
• Urinalysis: Ketonuria (pregnancy toxemia), presence of bacteria and neutrophils (cystitis), increased protein (amyloidosis).

OTHER LABORATORY TESTS
N/A

IMAGING
• Imaging may help determine proper management of dystocia.
• Radiographs for determination of fetal number.
• Ultrasonography to determine fetal viability and uterine integrity.

OTHER DIAGNSTIC PROCEDURES
• Accurate history and physical examination are imperative in appropriate management of dystocia.
• Vaginoscopy is helpful if no fetal parts are visible at the vulva (incomplete cervical dilation) and in very small patients.
• Vaginal examination with sterile obstetric lube and gloved hand to assess cervical dilation and fetal abnormalities and abnormalities of presentation, position, and posture.

PATHOLOGIC FINDINGS
Incomplete cervical dilation, abnormalities of presentation, position and posture, fetal oversize, fetal anasarca, congenital abnormalities, ruptured uterus, metritis, vaginal lacerations, peritonitis are all pathologic findings of dystocia.

TREATMENT

THERAPEUTIC APPROACH
• Medical management of dystocia includes standard therapies such as analgesia, fluids, oxytocin, and antibiotics.
• Hypertonic saline, steroids, dextrose, and blood transfusions may be warranted if shock, pregnancy toxemia, and anemia are present.
• Tetanus prophylaxis if no recent history of tetanus vaccination.
• Correction of fetal malpresentation, position, and posture may be possible if complete cervical dilation has been achieved.
• Caudal epidural analgesia helps with obstetric manipulations.
• Epinephrine can be administered to help relax the uterus during manipulation of the fetus.
• Adequate lubrication should be provided during manipulation.
• There are a multitude of fetal maldispositions but similar principles apply and rules of obstetric manipulations should always be followed (i.e., ample lubrication, correct diagnosis, retropulsion, mutation, and traction).
• It is important to ascertain that fetal parts belong to the same fetus and there are both anterior or posterior before traction is initiated.
• Elevation of the patient's hind legs may provide more room for manipulation.
• Traction should be moderate in a downward fashion and synchronized with the dam's contractions. Slight rotation of the fetus during traction is helpful.
• In anterior presentation, once the forelimbs are extended, the head will often flex back. Extension of the head may be aided by grasping the bony orbits or placing a head snare.
• In cranial longitudinal presentation, dorso-sacral position with forelimbs extended posture and downward flexion of the head, elevation of the hindlimbs before repulsion helps to provide space for correction. A head snare or grasping of the orbits may be necessary to prevent the head from flexing again.
• A caudal/posterior longitudinal presentation, dorso-sacral position with coxofemoral extension is not considered abnormal but risk for premature umbilical rupture and incomplete cervical dilation are increased.

(CONTINUED) DYSTOCIA: SMALL RUMINANT

• Bilateral hip flexion (breech) must be corrected by pushing the rump forward and grasping a rear foot and flexing it at the fetlock and hock to reorient the legs to coxo-femoral extension. The procedure is repeated on the other limb, then the fetus is extracted.
• Cranial longitudinal presentation, dorso-pubic position with flexion of the forelimb is best corrected by mutation into a caudal longitudinal presentation and dorso-sacral position by reaching for the hind feet over the head.
• Manipulation time should be kept to a minimum. Fetotomy may be performed if the fetuses are dead, the cervix is completely dilated, and there is enough room.

SURGICAL CONSIDERATIONS AND TECHNIQUES

Cesarean section should be considered if the fetuses are alive.

MEDICATIONS

DRUGS OF CHOICE

• Antiobitic: Pencillins, cephalosporins, tetracyclines, florfenicol.
• Supportive therapy: Flunixin meglumine, intravenous fluids (dextrose, hypertonic saline, calcium, phosphorus, magnesium).

CONTRAINDICATIONS

• Aminoglycosides and enrofloxacin should not be used in cases of dystocia.
• Meat and milk withdrawal times should be followed.

PRECAUTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Prognosis for life and fertility is good with early intervention, especially when there are no metabolic disorders.
• About half of obstetric situation will require surgery (57.3% in ewes and 47.7% in does).

POSSIBLE COMPLICATIONS

• Metritis, vaginitis, peritonitis, cystitis, nerve injury, anemia, and shock in the dam
• Neonatal loss from sepsis or respiratory compromise

CLIENT EDUCATION

• Recognition of signs of labor and dystocia
• Welfare aspects of obstetric manipulations

PATIENT CARE

• Monitor dam for signs of anemia, septicemia, shock, and infection.
• Monitoring neonates for adequate consumption of colostrum and milk.

PREVENTION

• Adequate nutrition and assessment of BCS
• Appropriate breeding management including correct pairings to avoid fetal oversize
• Close monitoring of preparturient females (use of gestation charts and observation).

MISCELLANEOUS

ASSOCIATED CONDITIONS

Pregnancy toxemia, anemia due to parasites, metritis, vaginitis, peritonitis, and shock

AGE-RELATED FACTORS

• Primiparous females at high risk.
• Older dairy does and ewes need to be watched closely for metabolic problems.

ZOONOTIC POTENTIAL

Several bacterial diseases that cause abortion are zoonotic and risk is increased during dystocia management.

PREGNANCY

N/A

BIOSECURITY

Testing and quarantine of new animals to prevent abortion

PRODUCTION MANAGEMENT

• Timely pregnancy diagnosis, monitoring of BCS, and adequate nutrition to prevent pregnancy toxemia.
• Proper facilities for management of lambing/kidding.
• Close monitoring of parturient females.
• Improper nutrition during gestation negatively influences survival rate, postpartum interval, milk production, and weaning weights.

SYNONYMS

N/A

ABBREVIATION

BCS = body condition score

ECHINOCOCCOSIS

BASICS

OVERVIEW
Echinococcosis is a zoonotic disease condition caused by infection with larvae of *Echinococcus* spp. tapeworms.

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
Worldwide with the exception of Iceland and Greenland. Each species has a distinct geographic range.

SYSTEMS AFFECTED
- Nervous
- Cardiovascular
- Musculoskeletal
- Digestive
- Urinary
- Respiratory

PATHOPHYSIOLOGY
- *Echinococcus* spp. have an indirect life cycle. In many cases, the parasite cycles through specific predators or scavengers, and their prey.
- The definite hosts of *Echinococcus* are canines and intermediate hosts are herbivores and small rodents.
- The final hosts are canines which become infected by ingesting the muscles and organs containing cysts of the intermediate hosts. The protoscolex evaginates and attaches to the intestinal wall and develops into adult stages in 32–80 days. Later, gravid proglottids release eggs which are passed into feces. Under favourable conditions, these eggs remain viable for several weeks or months in pastures or on fomites. If exposed to sunlight, they are viable for a short period of time.
- The intermediate hosts are domesticated and wild herbivores.
- The intermediate hosts ingest eggs while grazing or scavenging depending on their feeding habits. The oncospheres of eggs hatch and penetrate into the intestinal wall. Later, they migrate to various organs including the liver, lungs, heart, brain, bones, kidney, skeletal muscles, and spleen through the circulatory system and develop into a hydatid cyst. The cyst contains protoscolices and daughter cysts which fill the cyst interior.

HISTORICAL FINDINGS
- History will vary depending on location of cysts.
- A small liver cyst may not produce any symptoms for 10–20 years until it gets large enough to be felt by physical examination.

SIGNALMENT
- The intermediate hosts of *E. granulosus* are sheep, goat, swine, cattle, horses, and camels where the final hosts are canids, felids, and hyaenids. Sheep and goats are the most commonly affected ruminant species.
- The intermediate hosts of *E. multilocularis* are small rodents and the final hosts are canids, felids, coyotes, and wolves. Dogs may also act as an intermediate host by ingesting eggs shed in feces or through autoinfection and mechanical vector by carrying feces on their fur. The larvae proliferate indefinitely, resulting in excessive invasion of surrounding tissues.
- The larval stage of *E. vogeli* develops in both external and internal parts of organs, resulting in multiple vesicles. The intermediate hosts associated are rodents and the final hosts are bush dogs. *E. vogeli* may undergo exogenous and endogenous proliferation, resulting in multi-chambered cysts in accidental hosts such as primates. But the natural hosts seem to develop exogenous proliferation.
- The intermediate hosts for *E. oligarthrus* are rodents and the final hosts are wild felids.

PHYSICAL EXAMINATION FINDINGS
Pain in upper right part of the abdomen, chest pain, bloody sputum, cough, fever, severe skin itching, diarrhea.

GENETICS
Traditionally, the *Echinococcus* spp. have been divided into different strains, named G1 to G10.

CAUSES AND RISK FACTORS
- *Echinococcus* spp.
- Cattle, deer, pigs, sheep
- Feces of dogs, wolves, or coyotes

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Gastrointestinal parasitism, multifocal tumors, CNS diseases

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
ELISA, PCR (copro-DNA assay), indirect immunofluorescence, indirect hemagglutination, immunoblotting, latex agglutination, and rarely complement fixation.

IMAGING
Imaging techniques such as MRI or CT scan followed by serologic tests.

OTHER DIAGNOSTIC PROCEDURES
Direct examination of intestine during postmortem

PATHOLOGIC FINDINGS
- When liver cyst ruptures, marked and transient elevation of cholestatic enzyme levels occurs. It is often associated with hyperamylasemia and eosinophilia.
- Brain cyst or eye cyst and calcified cysts often induce no or low antibody titers.

TREATMENT

THERAPEUTIC APPROACH
Treatment is not commonly pursued in food-producing animals due to a low rate of diagnosis and prolonged treatment course. The following are based off of the human literature.
- Therapeutic treatment with anthelmintics is effective.
- Percutaneous treatment of the hydatid cysts with the PAIR (puncture, aspiration, injection, re-aspiration) technique.

SURGICAL CONSIDERATIONS AND TECHNIQUES
Surgical removal of cysts may also be practiced but this is complicated.

MEDICATIONS

DRUGS OF CHOICE
The following anthelmintics and dose rates are based off of the human literature. Literature involving treatment of echinococcosis in ruminants is scarce at the time of publication.
- Albendazole at 10–15 mg/kg body weight q12h for 1–6 months. For patients weighing <60 kg, total dose should not exceed 800 mg/day.
- Mebendazole can also be used at 40–50 mg/kg body weight for several months.
- Postoperative chemotherapy with praziquantel and albendazole or mebendazole long term (around 2 years), may be practiced.

CONTRAINDICATIONS
N/A

PRECAUTIONS
Appropriate withdrawal times must be observed after compounds are administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Cystic echinococcosis caused by *E. granulosus* is the most common form of disease in comparison to alveolar echinococcosis caused by *E. multilocularis* though the latter is more pathogenic and difficult to treat.

POSSIBLE COMPLICATIONS
When the cyst ruptures there is a high chance of spreading infection to multiple organs.

(CONTINUED) ECHINOCOCCOSIS

Cyst rupture may cause allergic reactions, fever, low blood pressure, and shock.

CLIENT EDUCATION
• Anthelminthic calendar and training should be provided.
• Avoid contact with infected dogs and provide regular deworming for dogs.

PATIENT CARE
N/A

PREVENTION
• Regular examination of dogs, sheep, and goats, and treatment with anthelmintic drugs.
• The on-farm slaughter of small ruminants should be abandoned.
• Humans should avoid consuming raw meat.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Inflammatory nodules or tumors
• Other intestinal parasites

ZOONOTIC POTENTIAL
Humans are infected by hand-to-mouth transfer of *Echinococcus* eggs. Humans are the dead end host. Transmission from humans to humans does not occur. However, human echinococcosis occurs in four forms: mainly cystic echinococcosis caused by *E. granulosus*; alveolar echinococcosis caused by *E. multilocularis*; polycystic echinococcosis caused by *E. vogeli*; and unicystic echinococcosis caused by *E. oligarthrus.* The most important forms of disease in humans are cystic echinococcosis and alveolar echinococcosis. Cystic echinococcosis is also referred to as alveolar hydatidosis.

SYNONYM
Hydatid disease

ABBREVIATIONS
• CNS = central nervous system
• CT = computed tomography
• ELISA = enzyme-linked immunosorbent assay
• MRI = magnetic resonance imaging
• PCR = polymerase chain reaction

EMBRYO TRANSFER: BOVINE

BASICS

OVERVIEW
• Embryo transfer (ET) is an advanced reproductive technology in which embryos from a superstimulated female are collected and transferred to recipient females.
• Embryos can be produced in vivo or in vitro and may be transferred fresh or after cryopreservation.
• Embryo transfer is used to improve genetics, improve reproductive efficiency of females, and reduce disease transmission.

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Reproductive

PATHOPHYSIOLOGY
• ET is a multifactorial process that depends on a series of carefully orchestrated sequential steps.
• Poor performance in any of the steps could directly affect the success rate and final outcome of any program.

SIGNALMENT
• Females of breeding age
• Some techniques (oocyte collection and IVF) may use prepubertal calves

HISTORICAL FINDINGS
• Genetically superior females
• Infertility or inability to maintain pregnancy
• Animals with oviductal problems may be used as oocyte donors

PHYSICAL EXAMINATION FINDINGS
Donor Selection
• Criteria: genetic merit and reproductive soundness
  ◦ Insure genetic progress for selected traits
  ◦ Avoid genetic diseases
  ◦ Cycling regularly with no abnormalities of the reproductive tract, normal conception rates (ideal)
• Other considerations: good body condition, free of contagious/systemic disease, minimum of 50–60 days postpartum, current on vaccinations

Recipient Selection
• Criteria to consider:
  ◦ Reproductive performance/ability to calve
  ◦ Disposition/mothering ability
  ◦ Udder conformation/milking ability
• Other considerations: body condition score, adequate nutrition, free of contagious/systemic disease, minimum 50–70 days postpartum (first calf heifers >70 days postpartum), virgin heifers cycling and minimum 13–14 months of age, current on vaccinations

GENETICS
• Genetic selection/improvement is the primary goal of ET and associated biotechnologies.
• There is a significant variation in response to superovulation between *Bos taurus* and *Bos indicus* cattle.
• The embryos of some breeds (Jersey) do not tolerate cryopreservation because of high fat content.

CAUSES AND RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
N/A

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Serum AMH concentrations may be used to indicate the ovarian follicular reserve and help predict a donor's response to a superstimulation protocol.
• Pregnancy diagnosis using PSPB 25 days following transfer.

IMAGING
Transrectal ultrasonography for pregnancy diagnosis 20–25 days following transfer.

DIAGNOSTIC PROCEDURES
• See "Treatment/Donor Management/Embryo collection, evaluation, and handling."
• Embryo cryopreservation: Conventional slow freezing (requires specialized equipment) or vitrification.

PATHOLOGIC FINDINGS
N/A

TREATMENT

Donor Management
• Single embryos or multiple embryos may be collected from naturally ovulating or superstimulated (superovulated) donors. Ideally 2–4 donors are prepared in order to share cost of recipient management if fresh ET is considered.
• Superstimulation
  ◦ Superstimulation is achieved using FSH.
  ◦ Superstimulation protocols are most successful if initiated during the mid-luteal phase (day 8–12) of the donor's estrous cycle.
  ◦ An alternative is to start superstimulation after CIDR treatment. A simple protocol consists of (Day 0 = Start FSH, 36 hours after GnRH):
    ▪ Day -8: $PGF2_{\alpha}$ and insert CIDR
    ▪ Day –1: GnRH injection
    ▪ Day 0: FSH pm
    ▪ Day 1: FSH am/pm
    ▪ Day 2: FSH am/pm
    ▪ Day 3: FSH am/pm, $PGF2_{\alpha}$ am
    ▪ Day 4: FSH + remove CIDR + $PGF2_{\alpha}$ am
    ▪ Day 5: GnRH am and AI pm
    ▪ Day 6: AI am
    ▪ Day 12: embryo collection am
  ◦ Response is variable and depends on age, breed, lactational status, nutritional status, and stage of the cycle at which treatment is initiated.
• Artificial insemination
  ◦ AI should be performed twice with a 10–12 hour interval to cover the range of time over which ovulations may occur.
  ◦ AI performed 4–6 hours after the onset of estrus and repeated once 10–12 hours later.
  ◦ Timed AI at 48 hours after progesterone removal and repeated once 60 hours after progesterone removal.
  ◦ Double insemination dose may be used at each insemination.
• Embryo collection, evaluation, and handling
  ◦ Embryo collection is performed nonsurgically 6–8 days after insemination.
  ◦ The uterine horns can be flushed individually or both at the same time.
  ◦ Caudal epidural analgesia is placed and a Foley catheter is introduced using the rectovaginal technique. The balloon is placed at the base of one horn and inflated.
  ◦ Flushing medium used is Dulbecco's PBS with added fetal calf serum or a commercially prepared variant.
  ◦ Flushing medium should be warmed to body temperature and protected from ultraviolet light and contaminants.
  ◦ The flushing medium is recovered into embryo filters and the embryos quality graded based on stage of development and morphology according to IETS guidelines.
  ◦ Embryos should be kept in a holding medium, washed according to IETS recommendation then loaded in straws (0.25 mL French straws) for fresh ET or submitted to cryopreservation if Grade I or II.

Recipient Management
• Fresh ET requires preparation of 8–10 recipients per donor.
• Pregnancy rates following ET are best when the recipient is in estrus from 36 hours before to 12 hours after the donor.
• With fresh embryos, pregnancy rates were similar if the donor and recipient estrus were –1.0 to +1.0 days.
• For transfer of frozen embryos, the recipient must be synchronous with the stage of development of the embryo.
• Recipients can be selected from a large pool based on heat detection or synchronized in order to match the stage of development of the embryo.
• Embryo transfer procedure

- Nonsurgical transfer (may consider placement of caudal epidural).
- Transrectal palpation (or ultrasonography) should be performed to confirm the presence and side of CL at the time of transfer.
- Embryo is deposited approximately one third of the way up the uterine horn ipsilateral to the CL.
- A negative correlation has been demonstrated between the time spent manipulating the cervix/uterine horn and pregnancy rates.

SURGICAL CONSIDERATIONS
N/A

MEDICATIONS

DRUGS OF CHOICE
- pFSH for superstimulation: in decreasing dose, total dose (400 mg NIH-FSH-P1 or 700 IU)
- $PGF2_{\alpha}$ (dinoprost tromethamine 25 mg, IM) or cloprostenol (500 µg, IM)
- CIDR (1.3 mg of progesterone)
- GnRH (100 µg, IM)

CONTRAINDICATIONS
Appropriate milk and meat withdrawal times must be followed.

PRECAUTIONS
N/A

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- Pregnancy rates are in the range 55–80% with fresh embryos. A reduction of 10–20% is observed with frozen-thawed embryos.
- Success of an ET program can be measured by the following:
  - Number of CL from superstimulation (measures response)
  - Number of embryos obtained per CL (measures donor selection and flushing technique)
  - Number of fertilized embryos (measures donor selection, semen quality, semen handling, and AI technique)
  - Number of recipients that become pregnant (measures embryo quality, recipient selection, management, and transfer technique)
  - Number of embryos transferred that produce calves (measures embryo quality, recipient selection/management, and transfer technique)

POSSIBLE COMPLICATIONS
- Perforation of the vagina or uterus may occur if the practitioner is unskilled or inexperienced.
- Uterine infection is possible if the technique is not performed cleanly.

CLIENT EDUCATION
Clients should be aware of the expected pregnancy rates and factors affecting success in an ET program.

PATIENT CARE
- Donors:
  - $PGF2_{\alpha}$ or analogs are administered following embryo collection in order to prevent pregnancy.
  - Donors can be superstimulated at 2-month intervals for 3 treatments without any appreciable decrease in embryo recovery rate.
- Recipients:
  - Pregnancy diagnosis should be performed and confirmed at a later date.
  - Pregnant recipients are managed similar to any pregnant cow.

PREVENTION
N/A

MISCELLANEOUS

ASSOCIATED CONDITIONS
Increased early embryonic loss and abnormal pregnancies (hydrallantois, abnormal offspring syndrome) are associated with transfer of SCNT embryos.

AGE-RELATED FACTORS
N/A

ZOONOTIC POTENTIAL
N/A

PREGNANCY
Check for early embryo loss.

BIOSECURITY
- Donors and recipients should have health screening and infectious disease testing prior to use in an ET program.
- Bull studs are subjected to strict health requirements and disease control.

PRODUCTION MANAGEMENT
- ET enables acceleration of the proliferation of genetic material from the dam as well as the sire.
- ET is beneficial for preservation of genetics, transport of genetics internationally, and disease control/biosecurity.

SYNONYMS
N/A

EMBRYO TRANSFER: CAMELID

BASICS

OVERVIEW
• Embryo transfer (ET) is an important reproductive biotechnology to propagate genetically superior females and significantly reduce generation interval.
• ET offers other advantages such as reproduction of females that can no longer carry pregnancy to term because of acquired reproductive pathologies or systemic and musculoskeletal disorders that may be exacerbated by pregnancy.
• ET is an even more powerful tool for genetic improvement when combined with other biotechnologies such as in vitro production of embryos by in vitro fertilization, intracytoplasmic sperm injection, or somatic cell nuclear transfer.
• Interspecies transfer within camels (Bactrian camel embryos in dromedary) or SAC (i.e., alpaca embryos in llamas) is possible and can be used for the preservation of endangered species such as the Bactrian camel, vicuna, or guanaco.
• Use of frozen-thawed embryos in ET programs is still limited by the poor pregnancy rate.

INCIDENCE/PREVALENCE
ET is commercially used in racing camels and in llamas and alpaca.

GEOGRAPHIC DISTRIBUTION
Worldwide, depending on breed association regulations

SYSTEMS AFFECTED
Reproductive

PATHOPHYSIOLOGY
• Following ovulation and fertilization, the camelid embryo develops until the morula stage in the uterine tube. The embryo passes through the uterotubal junction and descends into the uterine cavity around 7 days after fertilization at the hatched blastocyst stage.
• Recovery of blastocysts from the uterine cavity is best performed between 8 and 9 days after mating as the embryo grows quickly and collapses after this time.
• The corpus luteum (CL) is mandatory for maintenance of pregnancy. Therefore recipients should be synchronous with the stage of embryo development and maintain their CL after transfer.
• Synchronization between donors and recipients is often difficult to achieve unless a large pool of females is available.
• Blastocysts are collected nonsurgically by uterine flushing using a Foley catheter (12–16 Fr in SAC, 18–22 Fr in camels) inserted through the cervix and manipulated trransrectally to place the balloon just cranial to the cervix. Uterine horns can be flushed separately or at the same time using commercial embryo collection medium (DPBS or its variants).
• Flushing medium is filtered and the embryos are identified, washed using a holding medium, loaded in 0.25 or 0.5 mL straws, and transferred nonsurgically into the uteri of synchronous recipients.
• Factors affecting pregnancy rate following transfer include embryo quality, health of the recipient, and CL maintenance.
• CL maintenance (i.e., prevention of $PGF2_{\alpha}$ release and luteolysis) is highly dependent on technical ability of the operator.

HISTORICAL FINDINGS
• Donors are selected based on their genetic potential or performance abilities.
• Recipient should be parous and in good general and reproductive health.
• Old and maiden females are not good recipient candidates.

SIGNALMENT
N/A

PHYSICAL EXAMINATION FINDINGS
• Donors should undergo a complete physical examination and reproductive evaluation to determine their ability to ovulate and achieve fertilization and early embryo development.
• Recipient should have the following characteristics:
  ◦ Good body condition
  ◦ Good general health
  ◦ Normal reproductive function
  ◦ Normal mammary gland development and evidence of at least one normal pregnancy and lactation

GENETICS
Only genetically superior females should be used as embryo donors.

CAUSES AND RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
N/A

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Serum progesterone level determination is useful for screening potential recipients in large-scale ET programs.
• Serology for the most common infectious diseases is warranted for recipients.

IMAGING
Transrectal ultrasonography is required for monitoring of superovulation, mating, and induction of ovulation in donors and for selection of recipient for induction of ovulation and synchronization with donors and determination of CL quality at the time of transfer.

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
• Turbidity of the recovered flushing fluid is an indicator of possible uterine infection.
• Cytologic evaluation is recommended if return fluid contains mucus or purulent material.

TREATMENT

THERAPEUTIC APPROACH
• Embryo collection may be performed with or without prior ovarian superstimulation.
• Superstimulation of follicular development is obtained by the use of FSH, eCG, or their combination. The best results are obtained when treatment is commenced at the beginning of follicular recruitment.
• Control of follicular wave development is obtained by daily progesterone treatment for 7–14 days or by initiation of treatment 2 days after induction of ovulation.
• Ovulation is induced in donors after mating when follicles reach mature size (8–10 mm in SAC, 15–18 mm in camels) using hCG or GnRH. Ovulation is induced in the same manner in recipients.

SURGICAL CONSIDERATIONS AND TECHNIQUES
Surgical collection and transfer of embryos is possible but not common.

MEDICATIONS

DRUGS OF CHOICE
• Control of follicular wave development:
  ◦ Camels: Daily progesterone injection (150 mg IM) for 10–14 days.
  ◦ Llamas and alpacas: Progesterone injection (50 mg IM) or vaginal inserts for 7–14 days.
• Superstimulation:
  ◦ FSH: Porcine FSH is administered q12h for 3–5 days in decreasing doses (total dose 150–300 mg in SAC, 300–450 mg in camels).
  ◦ eCG: A single IM injection (1500–6000 IU in camels, 500–2000 IU in llamas, 500–1000 IU in alpacas).
  ◦ Some protocols use one injection of eCG followed by FSH.
• Induction of ovulation:
  ◦ hCG: IV injection (camels 1,500 IU, llamas and alpacas 750–1000 IU).
  ◦ GnRH: IM injection (camels 100 μg, alpacas and llamas 50 μg) or buserelin (4–8 μg).
• Induction of luteolysis:
  ◦ Donors should be given a dose of $PGF2_{\alpha}$ or its analogs after embryo collection (dinoprost tromethamine 25 mg in camels,

cloprostenol 500 µg in camels, 250 µg in SAC).
• Epidural analgesia: Lidocaine 2% in caudal epidural to reduce straining particularly in llamas, alpacas, and young maiden camels.
• Sedation: Xylazine (0.1 mg/kg IM) and butorphanol (0.05 mg/kg) is often necessary for sedation of alpacas.

CONTRAINDICATIONS
Appropriate meat and milk withdrawal times must be followed.

PRECAUTIONS
• Females may become refractory to superstimulation treatments
• Overstimulation of the ovaries is common problem in donors resulting is poor embryo recovery
• Some donors may fail to ovulate and develop large anovulatory follicles following superstimulation

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Embryo recovery rate in absence of superstimulation varies from 60% to 80% and depends on donor fertility.
• Embryo recovery rate following superstimulation is highly variable (0–70%). The average number of transferable embryos obtained following superstimulation is 3 in SAC and 5 in camels.
• Embryo collection may be performed every 2–3 weeks in absence of superstimulation.
• Superstimulation may be repeated every 2 months.
• Pregnancy rate per transferred embryo varies between 20% and 60%.
• Pregnancy rate is optimized by using good-quality embryos transferred to recipients that ovulated on the same day or one day after the donor.
• External factors affecting pregnancy rate in recipients include general health, body condition score, and lactation status.
• The effect of side of transfer of the embryo in relationship to the CL is still controversial.

POSSIBLE COMPLICATIONS
• Uterine perforation
• Rectal perforation
• Cervical damage
• Uterine infection

CLIENT EDUCATION
• Clients should be informed about the high variability of the results of superovulation, the importance of donor fertility, male fertility, recipients' quality (health and fertility), and recipient management.
• It is important to stress that this manipulation require veterinary care and supervision and that the welfare of the animal may be compromised if not done properly.

PATIENT CARE
• Donors should be provided exercise and a nutritional plan to avoid obesity. They should be observed following flushing for any signs of discomfort or abnormal vaginal discharge.
• Recipients should be handled without stress before and after embryo transfer.

PREVENTION
• Herd health program to prevent abortive diseases
• Laboratory procedures to prevent embryo contamination

MISCELLANEOUS

ASSOCIATED CONDITIONS
Infertility, IVF

AGE-RELATED FACTORS
Embryo quality is affected by age of the donor.

ZOONOTIC POTENTIAL
Brucellosis, Q-fever

PREGNANCY
N/A

BIOSECURITY
• Male used in ET should be regularly tested for brucellosis and other potentially venereal diseases particularly if they are used in natural mating of other females.
• Some infectious disease may potentially be transmitted by the embryos.
• Quarantine should be applied to all potential embryo recipients and donors before entering an ET program.
• Embryo handling (evaluation, washing) should be performed in a clean room preferably under a hood. Embryos should be loaded and transferred aseptically.

PRODUCTION MANAGEMENT

EMBRYO TRANSFER: SMALL RUMINANT

BASICS

OVERVIEW
• Embryo transfer (ET) is an important reproductive biotechnology to propagate genetically superior females, import new genetics, and reduce biosecurity risks.
• Cryopreservation of embryos allows easy transport around the world.
• Although other biotechnologies such as in vitro production of embryos by in vitro fertilization, intracytoplasmic sperm injection, or somatic cell nuclear transfer are available, most of ET in sheep and goats still uses embryos produced in vivo.

INCIDENCE/PREVALENCE
ET is primarily used in high-end purebred sheep and goat operations.

GEOGRAPHIC DISTRIBUTION
Countries where sheep and goat production are well developed

SYSTEMS AFFECTED
Reproductive

PATHOPHYSIOLOGY
• ET in sheep and goats relies on hormonal manipulation of the cycle for the synchronization of estrus and superovulation.
• Superstimulated donors are mated naturally or inseminated artificially at specific times after progesterone withdrawal.
• Factors affecting response to superovulation include health, individual animal, age, breed, nutritional status, and season.
• Embryo recovery from the uterine cavity is performed surgically (laparotomy or laparoscopy-assisted) 5–7 days after ovulation when the embryos are at the late morula or early blastocyst stage. Nonsurgical (transcervical) collection of embryos is possible in some large breeds of goat but is not routinely used.
• Early luteolysis is a common problem after superovulation in goats. Donors should receive another CIDR 2 days after ovulation to maintain high levels of progesterone and avoid embryo loss.
• Embryos are washed and transferred surgically to synchronous recipients. Each recipient receives two embryos in the horn ipsilateral to the CL.
• Factors affecting success of ET program include: embryo quality, health of the recipient, nutritional management, and CL maintenance.
• Surgical embryo collection may be repeated during the same season but it is preferable to allow the donor to carry a pregnancy in between 2 or 3 flushes.

HISTORICAL FINDINGS
• Donors are selected based on their genetic potential or performance.
• Recipient should be parous and have good general and reproductive health history.

SIGNALMENT
N/A

PHYSICAL EXAMINATION FINDINGS
• Donors should undergo a complete physical examination and reproductive evaluation to determine their ability to ovulate and achieve fertilization and early embryo development.
• Females should be in good health in order to undergo general anesthesia.
• Recipient should have the following characteristics:
  ◦ Body condition score: 3–3.5
  ◦ Good general health and current on vaccination and deworming program
  ◦ Normal reproductive function
  ◦ Normal mammary gland development and evidence of at least one normal pregnancy and lactation

GENETICS
Only genetically superior females should be used as embryo donors.

CAUSES AND RISK FACTORS
N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
N/A

CBC/BIOCHEMISTRY/URINALYSIS
Total protein and packed cell volume should be determined before anesthesia.

OTHER LABORATORY TESTS
Serology for common infectious diseases is recommended for selection of recipients.

IMAGING
• Transrectal ultrasonography is helpful in identifying number and side of ovulation in donors and recipient prior to surgery.
• Transabdominal ultrasonography for pregnancy diagnosis at 45 days.

OTHER DIAGNOSTIC PROCEDURES
N/A

PATHOLOGIC FINDINGS
Periuterine adhesions may develop after multiple surgeries.

TREATMENT

THERAPEUTIC APPROACH
• Ovarian follicular superstimulation is obtained using FSH or eCG at the end of a progesterone (CIDR) treatment.
• Several protocols have been described. A classical protocol for sheep is to start FSH on day 12 of the CIDR treatment and continue FSH q12h for 3–4 days.
• An example of a short superovulation protocol is:
  ◦ Day 0, place CIDR
  ◦ Day 4, FSH (36 mg pm)
  ◦ Day 5, FSH (36 mg am, 24 mg pm)
  ◦ Day 6, FSH (24 mg am, 24mg pm) then $PGF2_{\alpha}$ or analog and removal of the CIDR
  ◦ Day 7, FSH (24 mg am, 16 mg pm), estrus detection and mating
  ◦ Day 8, FSH (16 mg am), GnRH and estrus detection and mating
  ◦ Day 14: Embryo collection
• Superstimulated females are joined to males 24–36 hours after removal of the CIDR and mating recorder. Alternatively, females can be inseminated 12–24 hours after onset of estrus (fresh semen) or 45–50 hours after CIDR removal if frozen semen is used laparoscopically. Donors are given GnRH 30–36 hours after CIDR removal.
• Recipients are synchronized in the same manner as donors and given either eCG (200 IU in season, 400–500 IU out of season) or PG 600. Estrus detection is performed after CIDR removal.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Laparoscopy-assisted technique for embryo collection and transfer is the best approach in order to minimize risks for surgical complications.
• Ewes and does should be fasted for 24 hours and water withheld for 12 hours.
• Anesthesia is obtained by administration of xylazine and ketamine. A local block with lidocaine at the portal site is recommended.
• The donor is placed in dorsal recumbency in a Trendelenburg position. An endoscope portal is placed about 5 cm lateral to midline and 10–15 cm from the base of the mammary gland. A second portal for grasping forceps is placed on midline about 4 cm from the base of the mammary gland.
• The abdominal cavity is penetrated with a trocar after insufflation with CO_2. The ovaries and uterus are visualized and CLs are counted. The grasping forceps is used through the second portal to hold and elevate the tip of one horn to the body wall. The midline incision is extended to allow exteriorization of both uterine horns.
• A Foley catheter (size 8–10 Fr) is placed at the base of the horn through a small stab incision in the serosa and blunt penetration through the muscularis and endometrium. The balloon is inflated (2–3 mL depending on size) and the uterine horn is flushed by injecting embryo collection medium (30–50 mL) from the tip of the horn towards the base.
• The procedure is repeated on the other side and the uterus is replaced and incision sites closed as per routine.
• For transfer the recipients are handled in the same manner for surgery. Only a small

proximal loop of the uterine horn ipsilateral to the CL is exteriorized and the embryos are injected in the lumen through a small tomcat catheter.

MEDICATIONS

DRUGS OF CHOICE

- Synchronization: CIDR-G (0.3 mg progesterone, vaginal)
- Superstimulation
  - FSH: porcine FSH, q12h for 3–4 days in decreasing doses (total dose 150–250 mg depending on breed and size)
- Induction of ovulation
  - GnRH: IM injection (100 µg, IM)
- Induction of luteolysis
  - Donors should be given a dose of $PGF2_{\alpha}$ (10 mg IM) or cloprostenol (250 µg, IM) after embryo collection
- Anesthesia: Xylazine (0.2 mg/kg, IM) followed 5–10 minutes later with ketamine (5–10 mg/kg, IM). Inhalation anesthesia is another option if available. Xylazine may be reversed with talazoline (2–4 mg/kg slow IV or IM) or yohimbine (0.125 mg/kg, slow IV or IM)
- Antibiotics: Procaine penicillin (20,000 IU, IM daily for 3 days)
- Anti-inflammatory: Flunixin meglumine (1.1–2.2 mg/kg IV or IM)

CONTRAINDICATIONS

Appropriate meat and milk withdrawal times must be followed.

PRECAUTIONS

Females may become refractory to superstimulation treatments.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Embryo recovery rate following superstimulation is highly variable. The average number of transferable embryos obtained following superstimulation is 5–6.
- Pregnancy rate per transferred embryo varies between 50% and 60% in well-managed programs.

POSSIBLE COMPLICATIONS

- Periuterine adhesions, broard ligament tears
- Gastrointestinal perforation
- Peritonitis

CLIENT EDUCATION

- Clients should be informed about the high variability of the results of superovulation, the importance of donor fertility, male fertility, recipients' quality (health and fertility), and recipient management.
- It is important to stress that this manipulation requires veterinary care and supervision and that the welfare of the animal may be compromised if not done properly.

PATIENT CARE

Donors and recipients should be monitored for 2–3 days for any signs of pain, loss of appetite, colic, or evidence of surgical site infection.

PREVENTION

- Herd health program to prevent abortive diseases
- Laboratory procedures to prevent embryo contamination

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Superovulation response and embryo quality is affected by age of the donor.

ZOONOTIC POTENTIAL

Brucellosis, Q fever, chlamydiosis

PREGNANCY

Pregnancy diagnosis, and fetal number determination should be performed at 45 days.

BIOSECURITY

- Males used in ET should be regularly tested for potentially venereal diseases, particularly if they are used in natural mating of other females.
- The risk for disease transmission via embryos is very limited.
- Quarantine should be applied to all potential embryo recipients and donors before entering an ET program.
- Embryo handling (evaluation, washing) should be performed in a clean room preferably under a hood. Embryos should be loaded and transferred aseptically.

PRODUCTION MANAGEMENT

- The success of ET programs is extremely dependent on excellent management of the donor and recipient animals.
- All animals should have adequate BCS and an increased nutritional plan.
- Preventive treatment should be administered at least 6 weeks prior to breeding.

SYNONYMS

N/A

EMESIS

BASICS

OVERVIEW
• Emesis, or vomiting, is a centrally mediated event originating in the medulla.
• Emesis is a reflex action that results in expulsion of gastric and proximal small intestinal content through the mouth.
• Emesis is an unusual occurrence in ruminant species, and tends to be most commonly observed in goats.

INCIDENCE/PREVALENCE:
N/A

GEOGRAPHIC DISTRIBUTION
N/A

SYSTEMS AFFECTED
• Digestive
• Nervous

PATHOPHYSIOLOGY
• The medullary vomiting center receives humoral, neural, and chemical input from visceral afferent stimuli derived in the gastrointestinal tract, urogenital tract, heart, liver, and peritoneum; from the chemoreceptor trigger zone in the area postrema of the medulla; from the vestibular system; and from the cerebral cortex and limbic system.
• In ruminant species, activation of the chemoreceptor trigger zone most often results from stimulation via toxins.

HISTORICAL FINDINGS
Dependent upon the cause of disease; history should query exposure to plant and chemical toxins, dietary changes or other signs of GI disturbance. Questioning regarding potential exposure to various toxins or poisonous plants is especially pertinent when multiple animals are showing signs.

SIGNALMENT
There is no breed, gender, or age predilection, although goats are likely most often affected as a result of toxic plant ingestion (e.g., rhododendron).

PHYSICAL EXAMINATION FINDINGS
• Anorexia, hypersalivation, and retching typically precede the powerful abdominal contractions characteristic of emesis.
• Emesis involves coordinated contractions of the abdominal and diaphragmatic muscles with concurrent relaxation of the cardia, and forceful expulsion against a closed glottis to increase intra-abdominal pressure.
• The active nature of gastric content expulsion differentiates emesis from the passive process of regurgitation.
• Additional clinical signs that may accompany emesis associated with intoxication can include bloat, depression, colic, diarrhea, ptyalism, fever, recumbency, seizures, tachycardia, fasciculations, and seizures, depending on the inciting toxin.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Toxins that can cause emesis include methanol, ethanol, copper, phosphorus, arsenic, nitrates, snake venom, and petroleum products.
• Numerous poisonous plants can cause emesis with exposure dependent on plant availability. A partial list of plants includes *Solanum* spp., *Melia* (chinaberry), *Delphinium* (larkspur), cyanogenic plants (arrow grass, Johnson grass, Sudan grass, chokecherry, elderberry, etc.), nitrate accumulators (pigweed, lamb's quarter, Jimson weed, fireweed, dock, Johnson grass, oats, millet, rye, corn, sorghum, etc.), *Zigandenus* spp. (death camas), castor bean, oleander, cocklebur, *Veratrum* (hellebore), and laurel.
• Azalea/rhododendron ingestion (grayanotoxin) is a common cause of vomiting in small ruminants, particularly goats.
• Deoxynivalenol (vomitoxin) is a mycotoxin produced by toxigenic *Fusarium* species infesting corn, wheat, and barley.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Most cases of feed returning to the mouth of ruminants is due to regurgitation (i.e., reflux of esophageal or rumen contents into the mouth or nose).
• Excessive regurgitation typically results from physical blockage of the esophagus, cardia, or rumenoreticular outflow.
• Common conditions resulting in regurgitation include foreign bodies, tumors, papillomas, granulomas, abscesses, diaphragmatic hernia, or esophageal irritation.
• Pharyngeal lesions (e.g., balling gun injury) may also cause gagging or retching, but not true emesis.
• Soft palate lacerations or deformities may present with nasal regurgitation of water and feed material and tracheal aspiration of this material.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
N/A

IMAGING
No modalities are directly applicable to emesis; however, ultrasound, radiology (plain or contrast), endoscopy, or CT may be useful to investigate pharyngeal or esophageal disease.

OTHER DIAGNOSTIC PROCEDURES
Passage of a stomach tube may aid in determining if the normal passage of ingesta from mouth to the cardia is impeded.

PATHOLOGIC FINDINGS
• Toxins or toxic plants present in forestomachs
• CNS lesions involving medulla
• Additional lesions such as GI hemorrhage or erosions depending on inciting toxin

TREATMENT

THERAPEUTIC APPROACH
• Remove exposure to offending toxin or toxic plants.
• Specific antidotes or treatments for various toxins may be indicated.
• The use of laxatives, charcoal or ruminotorics to decrease toxin absorption, increase forestomach motility and passage of ingesta is unlikely to be of practical benefit in an animal that is actively vomiting.
• Transfer of fresh rumen fluid from a healthy donor is likely to restore rumen flora and function once vomiting has ceased.

SURGICAL CONSIDERATIONS AND TECHNIQUES
Rumenotomy may be indicated to remove toxicants after recent ingestion.

MEDICATIONS

DRUGS OF CHOICE
• The use of antiemetic agents in ruminant species is not well documented.
• Theoretically antiemetic drugs that can be administered IV, IM, or SC may potentially be effective in ruminants, which could include phenothiazine tranquilizers, diphenhydramine, maropitant, and metoclopramide.

CONTRAINDICATIONS
• It may be contraindicated to chemically block the elimination of toxicants from the forestomach of an animal that is actively vomiting.
• Drugs with prokinetic tendencies (metoclopramide, erythromycin) are likely contraindicated in animals that are actively vomiting.

PRECAUTIONS
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

(CONTINUED) EMESIS

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Depending on the type, dose, and duration of a toxic insult, prognosis is guarded to good if animals are immediately removed from the source of the toxin.
• Complications including metabolic derangements, renal failure, neurologic damage, and aspiration pneumonia worsen the prognosis.

POSSIBLE COMPLICATIONS

• Complications associated with emesis (or regurgitation) include aspiration pneumonia, dehydration, electrolyte derangements, and acid-base abnormalities.
• The term "internal vomiting" has been used to describe a form of vagal indigestion whereby abomasal outflow is blocked and the abomasal contents are refluxed into the reticulorumen. Hypochloremic metabolic alkalosis often results from internal vomiting and could conceivably occur with prolonged emesis.

CLIENT EDUCATION

Identification of toxicants to which ruminants may be exposed is crucial to prevention.

PATIENT CARE

• Activity should be reduced to allow animals to recover.
• Provision of highly palatable good-quality forage can help restore normal rumen function.
• Monitor patient for continued signs of emesis and possible complications.

PREVENTION

Avoid exposure to poisonous plants or toxic compounds by maintaining a safe and clean environment and providing adequate feed to reduce the likelihood of ingestion of inappropriate plants.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

• In young animals congenital anomalies such as persistent aortic arch or esophageal diverticula/dilation may result in suspected emesis (regurgitation).
• Young animals are also more prone to diseases such as meningitis and potentially trauma to the central nervous system.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

• Pharyngeal lesions (e.g., balling gun injury) may also cause gagging or retching, but not true emesis.
• Restricting access to toxic plants and chemicals, and providing adequate good-quality feed prevents common intoxications.

SYNONYMS

Vomiting

ABBREVIATIONS

• CNS = central nervous system
• GI = gastrointestinal

ENDOCRINE DISORDERS

BASICS

OVERVIEW

• The endocrine system consists of several glands that produce substances (hormones) that are released into the circulatory system having effect in different organs.
• Endocrine glands include the hypothalamus, pituitary, gonads, adrenal, uterus, placenta, pineal, thyroid, parathyroid, and pancreas. Other organs such as the liver and kidney can produce substances with hormonal action.
• Hormones are chemically polypeptides, steroid, tyrosine derivatives (catecholamine and iodothyronine) or fatty acids.
• The endocrine system coordinates multiple mechanisms responsible for maintenance of homeostasis, mechanism of defense (immune system), metabolism, and reproduction during external and internal changes.
• Hormones and neurotransmitters in the hypothalamus and hormones synthesized in the pituitary gland control reproductive, metabolic, urinary, and digestive function.
• Endocrine disorders can be originated by primary or secondary hyperfunction of a gland, hypersecretion of hormones or hormone-like substances by non-endocrine tumors, iatrogenic syndromes, or consumption of toxic plants.

INCIDENCE/PREVALENCE

Reproductive endocrine disorders are common in dairy cows.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

• Multisystemic
• Digestive
• Reproductive
• Urinary

PATHOPHYSIOLOGY

• Alterations in calcium metabolism in bulls
• Milk fever or hypocalcemia causing postpartum paresia, uterine prolapse, delayed uterine involution, and predisposing to abomasum displacement.
• Deficiency in thyroglobulin (congenital dyshormonogenetic goiter in sheep, goats, and cattle) causing subnormal growth, sparse hair coat, myxedema, weakness, and sluggish behavior (most die shortly after birth).
• The thyroid hormones influence thermoregulation and energy/protein metabolism but low T_3 may be also involved in ovarian function and postpartum diseases such as ketosis, mastitis, and endometritis in dairy cows.
• Hyperestrogenia by consumption of estrogenic plants is suspected to cause infertility and failure of cervical dilation.
• Ovarian cysts in cattle are due to lack of or poor release of LH.
• In high producing dairy cattle, increased liver metabolism is responsible for sub-physiologic levels of estradiol and progesterone, resulting in alteration of the cycle, poor estrus expression, and increased early pregnancy loss.
• Pituitary abscesses may cause neurologic signs due to secondary meningitis/encephalitis.
• Adenoma of lactotroph cells with excess of prolactin are reported in nonpregnant lactating goats.
• Prolonged gestation in cattle (up to 11 months) due to genetic failure of adenohypophysis to develop with the consequent lack of development of the adrenal cortex of the fetus.
• Prolonged gestation in sheep by consumption of toxic plants that affect development of central nervous system and hypothalamus of the lamb.
• Hypoluteoidism has been reported anecdotally as a cause of recurrent pregnancy loss in camelids. The pathophysiology of this phenomenon is not known.
• Spontaneous ovulation or luteinization of anovulatory follicle with elevated progesterone levels is suspected to be the cause of nonreceptivity in nonmated camelids.

HISTORICAL FINDINGS

• Poor health—ill thrift
• Abnormal behavior
• Poor reproductive performance
• Prolonged gestation

SIGNALMENT

• Age of onset and reproductive stage depends on disorder.
• In goats, abnormal development of the mammary gland and undesirable lactation is common in older, companion animals.

PHYSICAL EXAMINATION FINDINGS

• Most animals with reproductive endocrine disorders will not show any outward clinical signs.
• Ovarian disorders may be accompanied by abnormalities of estrous cycle and behavior.
• Animal with abnormalities of thyroid function may show poor body condition or obesity, goiter, abnormal growth, or abnormal hair coat.

GENETICS

• Autosomal recessive disorder in some breeds of sheep, goats, and cattle for congenital dyshormonogenetic goiter.
• Aplasia of the adenohypophysis is a genetic defect in Guernsey and Jersey cattle; results in hypoplasia of adrenal cortex, cessation of fetal development after 7 months, and prolonged gestation.

CAUSES AND RISK FACTORS

• Thyroid C-cell adenoma or carcinoma inducing hypercalcitoninism and osteosclerosis in bulls (excess of calcium and vitamin D in the diet).
• Pituitary abscesses are sporadic in ruminants.
• Low T_3 syndrome in cattle.
• Reduced response of parathyroids due to high calcium diets prepartum, together with high milk production and reduced dry matter intake end up in milk fever postpartum.
• Consumption of estrogenic plants (e.g., clover, alfalfa).
• High milk production, low progesterone levels, and stress predispose to ovarian cysts in dairy cattle.
• Ingestion of the toxic plant *Veratrum californicum* by ewes in early pregnancy causes craniofacial deformity and aplasia/hypoplasia of the fetal pituitary; results in hypoplasia of the adrenal cortex, fetus continues to grow but prolonged gestation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Diseases or conditions affecting hormonal levels
• Postpartum diseases in dairy cattle
• Metabolic disorders

CBC/CHEMISTRY/URINALYSIS

Calcium and vitamin D levels

OTHER LABORATORY TESTS

Hormone assays:
• Hormonal assays are rarely performed in production animals except in research setting or for very valuable animals.
• Progesterone assays can confirm the presence of luteal tissue. Serum progesterone levels in animals with recurrent pregnancy loss may be indicative of poor luteal function.
• Inhibin and anti-Mullerian hormone determination are both helpful in the confirmation of diagnosis of granulosa-theca cell tumors (GTCT).
• Thyroid hormones determination may be helpful in the diagnosis of hypothyroidism. However, the interpretation of these hormones is difficult.

IMAGING

Ultrasonography of genital tract for ovarian cysts or tumors

OTHER DIAGNOSTIC PROCEDURES

• Biopsy
• Histopathology and immunohistochemistry

PATHOLOGIC FINDINGS

• The thyroid C-cell adenoma in bulls is characterized by tumor masses in the thyroid gland including polyhedral to spindle shaped with scanty cytoplasm, lightly eosinophilic and indistinctly outlined. Oval or elongate nuclei with one or more nucleoli and evenly distributed chromatin.
• Hypoplasia of pituitary gland and ACTH-dependent part of the adrenal cortex (prolonged gestation in cattle).

• Ovarian cysts are characterized by persisting multiple follicles, lack of corpus luteum, and uterine tonicity.
• Ovarian tumors.

TREATMENT

THERAPEUTIC APPROACH
• Prostaglandin $F2_{\alpha}$ and dexamethasone for prolonged gestation.
• GnRH/hCG or synchronization of ovulation for ovarian cysts.
• Progesterone supplementation may be considered for animals with recurrent pregnancy loss due to hypoluteoidism.
• Calcium metabolism disturbances may be addressed by oral or IV calcium supplementation in cases of hypocalcemia.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Ovariectomy for persistent ovarian cysts or GTCT.
• Mastetectomy should be considered in companion goats with severely enlarged mammary gland.

MEDICATIONS

DRUGS OF CHOICE
• $PGF2_{\alpha}$ IM (25 mg in cattle and camels, 5–10 mg in small ruminants)
• Cloprostenol IM (500 µg in cattle and camels, 125 mg in small ruminants and SAC)
• Dexamethasone IM (20 mg/kg in cattle and sheep)
• Gonadorelin acetate IM (100 µg in cattle, 50 µg in goats and camelids)

CONTRAINDICATIONS
Appropriate milk and meat withdrawal times must be followed.

ENDOMETRITIS

BASICS

OVERVIEW

• Endometritis is an inflammation of the lining of the uterus (endometrium) without signs of systemic illness. It is associated with chronic bacterial infection of the uterus beyond 3 weeks postpartum.
• Clinical endometritis is characterized by the presence of a purulent vaginal discharge (PVD).
• In subclinical endometritis, visible purulent exudate is absent and case confirmation is by finding an abnormal increase in the proportion of neutrophils in uterine cytology samples collected 21 or more days postpartum.
• PVD, while frequently associated with endometritis, is more a sign rather than a specific disease process and refers to the presence of a purulent or mucopurulent discharge in the cranial vagina that also occurs with vaginitis or cervicitis.
• Endometritis is a significant disease to the extent that it causes impaired fertility. Both clinical and subclinical endometritis reduce reproductive efficiency by lowering conception rate and increasing the incidence of embryonic loss.
• Most information is generated from and applicable to dairy cattle populations. Camelids are also commonly affected while the condition is rarely diagnosed or treated in sheep or goats.

INCIDENCE/PREVALENCE

• The reported incidence of postpartum endometritis in dairy cattle varies widely, depending on the case definition, diagnostic methodology, and the interval postpartum at examination.
• Using validated diagnostic criteria, between 3 and 5 weeks postpartum, the incidence in dairy cattle was 17%, varying from 5% to 26%.
• Endometritis, as defined here, is primarily a postpartum disease, therefore the prevalence in any given population will vary with the relative distribution of reproductive cycle stage.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Reproductive

PATHOPHYSIOLOGY

• This chapter deals with inflammation resulting from nonspecific infectious agents that are opportunistic contaminants of the tubular genital tract, primarily during the postpartum period but also affecting immune-compromised or anatomically incompetent animals at other stages of the reproductive cycle.
• Infection and inflammation of the reproductive tract is also a feature of the acute phase of many specific genital diseases (e.g., see brucellosis, toxoplasmosis, and IBR). These are, however, contagious diseases that can infect animals at any stage of the reproductive cycle and are not covered here.
• All animals experience a transient bacterial contamination of the genital tract during and after parturition. The key elements in the pathophysiology of endometritis are an impairment of the immune response of the uterus and of the physical involution and repair of the tubular genital tract required to clear bacterial infection.
• The primary mechanisms of bacterial clearance are local immunity, phagocytosis, and physical clearance as the uterus involutes. By 3–4 weeks postpartum, the number of bacteria and the variety of species have diminished substantially in healthy animals.
• Intact and functional physical barriers (i.e., vulva, vestibulovaginal sphincter, and cervix) and normal estrous cyclicity are necessary to prevent recurrent contamination of the genital tract. Estrus and estrogens appear to promote bacterial clearance while progesterone delays it.
• In dairy cattle, the negative energy balance in early lactation results in metabolic disruptions (e.g., elevated NEFA) that contribute to the inflammatory cascade and suppressed immunologic efficacy.
• Historically, in cows with endometritis the most common bacteria cultured in association with impaired reproductive function were *Truperella pyogenes, E. coli, Prevotella* spp., and *Fusobacterium necrophorum.* More recent studies using FTIR spectroscopy, RAPD and 16S ribosomal DNA PCR strongly suggest that the bacterial flora of healthy and infected postpartum cattle is both more diverse and more dynamic than previously believed. Specific bacterial involvement may also vary with farm, species, and geography. Organisms isolated from camelidae are similar to those found in cows and mares, with *E. coli* and *Strep. equi* ssp. *zooepidemicus* found most commonly.
• Toxins and enzymes from these bacteria cause inflammation of the endometrium, which may impair ovarian function, delay resumption of normal ovulatory cycles, and inhibit establishment of pregnancy.
• In camelids, the long duration of mating and the site of semen deposition (deep in utero) predisposes to severe inflammatory reaction and establishment of infection if breeding is not managed correctly.

HISTORICAL FINDINGS

• Postpartum females, generally with a history of dystocia, retained placenta, or metabolic disorders.
• Abnormal mucupurulent discharge
• In camelids, often a history of infertility and repeat breeding.

SIGNALMENT

• Postpartum females; predominantly dairy cattle 3–8 weeks after calving
• All species of camelidae
• Less commonly sheep and goats

PHYSICAL EXAMINATION FINDINGS

• Clinical signs often lacking
• Mucopurulent or purulent discharge from the vulva (PVD)
• Repeat breeder syndrome

GENETICS

N/A

CAUSES AND RISK FACTORS

• Delayed clearance of opportunistic organisms allows them to establish an infection in the uterine lumen.
• RP, dystocia, twins, metritis, anestrus, OCD, and clinical ketosis are risk factors for endometritis.
• Traumatic injury to the birth canal during breeding or parturition, as well as poor perineal and pelvic conformation, are likely contributors to chronic contamination and inflammation of the genital tract.
• Repeated (excessive) mating is reportedly the most common cause of uterine disease in camelidae.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Metritis
• Pyometra
• Vaginitis
• Cervicitis
• Pelvic abscess
• Uro-/pneumovagina

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

• Uterine bacteriologic culture (collected transcervically using a guarded swab or brush) and uterine biopsy are the definitive antemortem diagnostic tests but are not timely enough and are far too costly for routine use in production animals. Their use is generally restricted to camelidae.
• Subclinical endometritis is diagnosed by uterine cytology obtained by transcervical scraping (cytobrush) or uterine lavage. A sample taken more than 3 weeks postpartum with >5% PMNs is considered positive.

IMAGING

Transrectal ultrasonography can be used to detect uterine enlargement or small amounts of abnormal luminal fluid present in some cases of endometritis. It is also useful for assessing ovarian structures to determine cyclic status of individual animals.

OTHER DIAGNOSTIC PROCEDURES

• For reproductive examinations before the breeding period to have value, they must identify animals at increased risk of failure to become pregnant in a timely way so that they may benefit from treatment.
• Cows with endometritis will frequently have been affected with one or more risk factors early in the current lactation.
• Transrectal palpation of the uterus has traditionally been the means of diagnosis of endometritis, but this method is subjective and has poor sensitivity and specificity for identifying cows with impaired fertility.
• Vaginoscopy can improve the sensitivity and specificity of the diagnosis but may be impractical for use in cattle.

PATHOLOGIC FINDINGS

Histologically, disruption of the endometrial epithelium, infiltration of inflammatory cells, and accumulations of lymphocytes with vascular congestion, and stromal edema.

TREATMENT

THERAPEUTIC APPROACH

• Spontaneous resolution commonly occurs as dairy cows return to a positive energy balance and resume estrous cycles. Concurrently address any nutritional issues that may be promoting inflammation, delaying involution, or suppressing immune function.
• Intrauterine infusion of cephapirin has been shown to improve the reproductive performance of cows with PVD.
• Camelids are frequently treated with uterine lavage during estrus followed by repeated daily infusion of an antibiotic dictated by culture and sensitivity testing. Systemic antibiotic therapy may replace local infusion or be used as an adjunct.
• It is well established that estrus occurrence has a restorative effect on the postpartum uterus. Treatments that increase the number of estrus periods prior to mating should in theory be beneficial to animals with endometritis. Repeated use of $PGF2_{\alpha}$ products to cause luteolysis and return to estrus are indicated for cycling females. Anovular females should be treated with GnRH with or without progesterone to hasten the onset of ovulatory cycles.

SURGICAL CONSIDERATIONS AND TECHNQUES

Perineal and vaginal trauma at delivery, often associated with pneumovagina and occasionally with urovagina, may contribute to chronic contamination of the uterus. For valuable cows and camelidae, appropriate surgical repair is indicated.

MEDICATIONS

• The general principle of therapy for endometritis is to reverse inflammatory changes that impair fertility by reducing the load of pathogenic bacteria and enhancing the processes of uterine defense and repair.
• There are limited reports of well-designed studies that confirm an advantage for medical treatment of endometritis in cattle. Treatment in camelids is primarily based on clinical impression.

DRUGS OF CHOICE

• Intrauterine (IU) antibiotic
  ◦ The principle is to reduce the load of pathogens. There are two valid studies showing that one treatment of 0.5 g cephapirin benzathine IU at approximately 30 days in milk reduced time to pregnancy relative to untreated cases.
  ◦ In camelids, antibiotic choice is based on culture and sensitivity. Aminoglycosides should be buffered for IU use.
• $PGF2_{\alpha}$—the principle is to induce luteolysis and, in turn, estrus. Reducing or removing the influence of progesterone on the uterus increases uterine tone and promotes physical clearance, potentially resolving cases of endometritis. There is little evidence suggesting that $PGF2_{\alpha}$ causes myometrial contraction or provides any other benefits for treatment of endometritis in the absence of a CL. Although clearcut data are lacking, IM injection of $PGF2_{\alpha}$ (0.5 mg cloprostenol or 25 mg dinoprost) after approximately 30 DIM is likely beneficial as treatment for endometritis. A second administration of $PGF2_{\alpha}$ 14 days later may provide additional benefit, although clinical trial data are lacking.

CONTRAINDICATIONS

• Appropriate milk and meat withdrawal times must be followed.
• Use of PGF before approximately 26 DIM is controversial. Some studies suggest beneficial effects, many suggest no benefit, and a few report a deleterious effect on subsequent reproductive performance of cows with endometritis.
• Cephapirin benzathine is approved for use in lactating cows in Canada and the European Union, but not in the United States.
• There are reports of treatment of endometritis by IU infusion of oxytetracycline, crystalline penicillin G, and numerous other antibiotics, as well as Lugol's iodine, povidone iodine, and other disinfectants, and systemically administered estradiol, tetracycline, penicillin, and ceftiofur. There is little evidence that any of these improve reproductive performance, and several of the IU substances may cause damage to the endometrium or to uterine defenses.

PRECAUTIONS

Catheterization of the cervix is difficult in camelids.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Affected cows take longer to conceive, and are at increased risk of failure to become pregnant.
• Clinical signs will be resolved by 60 DIM in >95% of cases after one (or in a minority of cases, two) treatment with cephapirin IU or PGF.
• It is unknown how many of these are truly cured as opposed to cases of ongoing subclinical endometritis.
• In camelids, females treated for endometritis are at a higher risk for developing a new episode if breeding is not managed correctly.

POSSIBLE COMPLICATIONS

• Given the case definition of a localized uterine condition, there is no mortality attributable to endometritis, and no direct loss of milk production. Reports have shown an increase in the mean calving to pregnancy interval from 7 to 48 days for cows with endometritis compared to unaffected herd mates, despite various treatments administered to affected animals.
• A meta-analysis of 23 studies found that endometritis increased mean days open by 15, decreased the relative risk of pregnancy by 150 DIM by 31%, and reduced the rate at which cows became pregnant by 16%.
• Cows with mucopurulent or purulent cervical discharge or cervical diameter >7.5 cm at approximately 4 weeks postpartum had an increase of 32 days in median time to pregnancy over unaffected cows.
• In camelids, the main complication is iatrogenic damage to the cervix or uterus during treatment if not performed correctly.

CLIENT EDUCATION

• In cattle, record keeping of all reproduction disease and production parameters.
• Development of a herd health program with the veterinarian.
• In camelids, follow sound practices in management of breeding.

PATIENT CARE

• Follow-up examination and repeated treatment 2 weeks after initial diagnosis and treatment (i.e., at approximately 45 DIM) might be useful to identify refractory cases.
• However, in almost 80% of cases, clinical signs will be resolved by this time, even if untreated.

ENDOMETRITIS (CONTINUED)

PREVENTION

• The key element in preventing establishment of chronic uterine infection appears to be the effectiveness of uterine defense mechanisms in clearing the inevitable postpartum or post-breeding infection. However, there is little information on preventive measures specific to endometritis.
• Management and nutritional practices that prevent dystocia, RP, metritis, and ketosis will enhance peripartum immune function (i.e., appropriate diet and adequate bunk space) and potentially reduce the incidence of endometritis in dairy cows.
• Effective breeding management will reduce or eliminate overbreeding in camelidae.

ENZOOTIC ATAXIA

BASICS

OVERVIEW
Copper deficiency in the dam may lead to neuronal degeneration and demyelination in the fetus/neonate, resulting in symmetrical ascending posterior paresis in newborn or young lambs or goat kids.

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
- Musculoskeletal
- Nervous
- Integument

PATHOPHYSIOLOGY
- Hypomyelinogenesis occurs in utero or shortly after birth in affected kids and lambs resulting in a progressive ataxia, muscle atrophy, paresis, and paralysis.
- Affected animals often have stiffness of the back and legs and are reluctant to rise. When individuals do stand, there may be a characteristic swaying of the hindquarters.
- Other neurologic signs can include blindness, obtundation, and head tremor.
- Abnormal bone growth and increased fragility of bones predisposing to fractures of long bones is apparently due to defects in development of connective tissue and growth plates.
- There may be persistent diarrhea, unthriftiness, and poor fleece in lambs.
- The pathogenesis is not known.

HISTORICAL FINDINGS
Copper-deficient diet with lack of supplementation

SIGNALMENT
- Sheep, goats, Bactrian camels, beef calves, piglets, blesbok (*Damaliscus dorcas phillipsi*), black wildebeest (*Connochaetes gnou*), sika deer (*Cervus nippon Temminck*), and red deer (*Cervus elaphus*) may be affected.
- In the neonatal form, clinical signs are present at birth; in the delayed form, clinical signs often appear at 14–30 days of age.

PHYSICAL EXAMINATION FINDINGS
- Progressive symmetrical ataxia and ascending posterior paresis or paralysis with associated muscle atrophy, ultimately resulting in permanent recumbency if left untreated.
- Most cases occur in lambs or kids that are 1–2 months of age.
- Severity of clinical signs decreases with increasing age at onset.
- Majority of affected lambs/kids are normothermic, bright, alert, and maintain the ability to suckle and vocalize.
- Hypermetric gait may be seen in animals with cerebellar involvement.
- Adult animals with copper deficiency are often asymptomatic, but signs may include ill thrift, diarrhea, anemia, and depigmentation of hair/wool.
- Ewes of affected lambs may have a loss of crimp resulting in a straight and "steely" appearance to the wool.
- Depigmentation of the wool is more noticeable in ewes with black wool.
- Osteoporosis, which can result in long bone fractures, may also occur with copper deficiency.

GENETICS
There is a possible familial predisposition. Dwarf goats have been reported to be overrepresented. Breed or family line may play a role in ewes, possibly through altered intestinal absorption and copper storage efficiency.

CAUSES AND RISK FACTORS
- Copper deficiency in the maternal diet is responsible for the clinical signs; however, the pathogenesis is not known. It is speculated that copper deficiency results in altered phospholipid metabolism and reduced synthesis of myelin.
- Animals raised on pasture with copper-deficient soil are at greater risk of disease.
- There is a possible familial predisposition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
Neonatal Form
- Hydrocephalus
- Congenital vertebral or spinal anomalies
- Trauma resulting in vertebral luxation/subluxation or fracture
- Protozoal encephalitis or myelitis, including *Sarcocystis*, *Neospora*, or *Toxoplasma* spp.

Delayed Form
- Trauma resulting in vertebral luxation/subluxation or fracture
- Vertebral abscess or osteomyelitis, ± associated pathologic fracture
- Protozoal myelitis, including *Sarcocystis*, *Neospora*, or *Toxoplasma* spp.
- Neurologic form of caprine arthritis and encephalitis (CAE) virus infection in kids
- Nutritional muscular dystrophy (white muscle disease)
- Listeriosis
- Rabies

CBC/BIOCHEMISTRY/URINALYSIS
Ewes may have a microcytic anemia.

OTHER LABORATORY TESTS
Liver biopsy or collection at necropsy is the most reliable method to determine true copper status. Serum or plasma copper levels may also be low. Analysis of feed, water, and possibly soil may facilitate diagnosis on a flock or herd level.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
Generally diagnosed based on clinical signs with possible decreased blood or liver copper levels. Definitive diagnosis is based on low liver copper levels and necropsy and histopathologic lesions. Analysis of CSF and/or spinal radiographs may rule out other differential diagnoses.

PATHOLOGIC FINDINGS
Gross
- Possible symmetric cavitations in the subcortical white matter can lead to marked internal hydrocephalus.
- In severe cases, little is left of the hemispheres except the cortical shell of gray matter.
- Severe osteoporosis and long bone fractures may be present.

Histopathologic
- Neuronal degeneration in the form of chromatolysis, neuronal necrosis, or both may be found in the central portions of the cerebral hemispheres, brainstem, cerebellum, and/or spinal cord.
- Demyelination occurs in the brainstem and spinal cord. Myelinated tracts may have a spongy appearance with some collections of gitter cells.
- Chromatolysis of neurons in the red nucleus may occur.

TREATMENT

THERAPEUTIC APPROACH
Evaluate copper status of the herd and soils where animals are pastured. Copper supplementation should be provided as needed to dams. Administration of parenteral copper glycinate has reportedly been an effective treatment in affected goat kids; however, treatment is generally unrewarding.

MEDICATIONS

DRUGS OF CHOICE
- Oral
  - Copper sulfate
  - Copper oxide wire particles (as a bolus)
- Parenteral
  - Copper glycinate (must be compounded, consider AMDUCA prior to administering)

CONTRAINDICATIONS
Oversupplementation or supplementation of copper in animals with normal liver copper levels could lead to copper toxicity, particularly in sheep.

ENZOOTIC ATAXIA (CONTINUED)

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- Prompt supplementation with copper may improve signs, but complete recovery is uncommon.
- Severely affected animals usually have permanent neurologic deficits.
- Prognosis is guarded to poor.

POSSIBLE COMPLICATIONS
N/A

PATIENT CARE
N/A

PREVENTION
Provide appropriate copper/mineral supplements. Supplements can be administered in various forms such as a top dressing to pasture or feed, or a weekly drench given to individual animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Copper supplementation can be toxic to treated animals.

AGE-RELATED FACTORS
Onset of clinical signs usually occurs between birth and 6 months of age. Average age of onset in goat kids with the delayed form is reported to be 13 weeks.

ZOONOTIC POTENTIAL
None

PREGNANCY
Maternal copper deficiency is the cause of clinical signs in lambs and kids.

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
- Etiology is copper deficiency in the ewe/doe.
- Making a definitive diagnosis of copper deficiency in a single animal indicates the need for judicious copper supplementation in animals managed similarly.
- More than one form of copper supplementation may be required in herds/flocks with severe copper deficiency.

SYNONYM
Swayback (often applied to the neonatal form of this condition)

ABBREVIATIONS
- AMDUCA = Animal Medicinal Use Clarification Act of 1994
- CAE = caprine arthritis encephalitis
- CSF = cerebrospinal fluid

SEE ALSO
Caprine Arthritis Encephalitis Virus

ENZOOTIC PNEUMONIA OF CALVES

BASICS

OVERVIEW
Respiratory disease of young calves <6 months of age caused by multiple etiologic agents, a decreased host defense system, and environmental risk factors such as poor ventilation and overcrowding.

INCIDENCE/PREVALENCE
• Based on producer diagnosis, 7.4–11% of dairy calves
• Based on veterinary diagnosis, 25.6–29% of dairy calves

SYSTEMS AFFECTED
Respiratory

PATHOPHYSIOLOGY
• Enzootic pneumonia of calves is part of the bovine respiratory disease complex that also includes shipping fever of feedlot cattle and pneumonia of adult cows.
• The bacterial pathogens involved with this disease are normal inhabitants of the nasal and pharyngeal mucosa.
• Host and environmental factors combine to weaken the normal pulmonary defense mechanisms.
• Viral infections cause damage to the mucosal lining of the upper respiratory tract and may reduce the mucociliary clearance and production of secretory defenses.
• Viral infections may also have an effect on alveolar macrophages or neutrophils, which can enhance bacterial adherence.
• Factors such as failure of passive transfer and nutritional deficiency, stressors such as overcrowding and mixing, poor ventilation, and high relative humidity also allow the proliferation of these opportunistic bacteria.

HISTORICAL FINDINGS
• Multiple animals depressed and febrile
• Partial anorexia
• Increased respiratory rates
• Coughing
• Nasal discharge
• Lacrimation
• Decreased weight gains
• Rough hair coats
• High morbidity
• Low mortality

SIGNALMENT
• Most common in housed dairy calves and veal calves
• Beef calves in crowded conditions
• Calves <6 months of age
• Peak incidence at 5–6 weeks of age

PHYSICAL EXAMINATION FINDINGS
• Not pathognomonic, but used for decades in the treatment management.
• DART: Depression; Appetite loss; Respiratory distress; Temperature elevation.
• Fever (39.5–40.5°C)
• Polypnea
• Mild to severe dyspnea
• Abnormal cranioventral lung sounds such as loud harsh breath sounds, crackles, and wheezes
• Harsh, dry, cough response on tracheal compression
• Intensity of heart sounds is increased dorsal to heart base

CAUSES AND RISK FACTORS
Multifactorial disease that involves animal stress frequently with co-infections with bacteria and/or viruses.

Bacterial Agents
• *Mannheimia haemolytica*
• *Pasteurella multocida*
• *Histophilus somni*
• *Biberstenia trehalosi*
• *Mycoplasma bovis*

Viral Agents
• Bovine respiratory syncytial virus
• Parainfluenza-3 virus
• Bovine herpesvirus-1
• Bovine coronavirus

Secondary Bacterial Agents
Trueperella (formerly *Arcanobacterium*) *pyogenes* (considered as an opportunistic agent)

Stressors
• Bovine viral diarrhea virus infection
• Low colostral immunity
• Abrupt weaning
• Mixing of social/ age groups
• Adverse climatic conditions (precipitations and rapid change of environmental temperature)
• Poor air quality in calf barns
• High relative humidity
• Housing calves together in large groups
• Overcrowding
• Poor nutrition: Vitamin E, selenium, zinc and/or copper deficiency

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Aspiration pneumonia
• Congenital cardiac defects
• Septicemia (*E coli*, *Salmonella* spp.)

CBC/BIOCHEMISTRY/URINALYSIS
The measurement of serum haptoglobin can serve as an indicator of inflammatory disease and a measure of disease severity.

OTHER LABORATORY TESTS
Isolation and identification of organisms
• Nasopharyngeal swabs
• Transtracheal washes
• Lung lavage samples
• Serologic tests for confirmation of BRSV infections
• Immunohistochemistry, PCR, virus isolation or antigen capture ELISA for identification of persistently infected BVDV calves
• Necropsy findings, histopathology, aerobic bacterial culture, fluorescent antibodies (BRSV, IBR) and/or PCR

IMAGING
Ultrasonography of the thorax is being proposed as an accurate and sensitive method for the detection and diagnosis of bronchopneumonia in calves, compared to thoracic auscultation.

OTHER DIAGNOSTIC PROCEDURES
New methods for diagnosis are being proposed, such as a computer-aided lung auscultation system (Whisper Veterinary Stethoscope System®) which, when used properly, increase the proportion of cattle accurately diagnosed with bovine respiratory disease.

PATHOLOGIC FINDINGS
• Extensive cranioventral lung consolidation.
• Suppurative bronchopneumonia, with or without fibrinous pleuritis, pus in airways, areas of necrosis (lytic and/or coagulative), with sequestrae and abscess formation.
• Interstitial pneumonia and inflammation of nasal mucosa associated with viral infections.

TREATMENT

THERAPEUTIC APPROACH
• Medical management: Identification of the pathogen followed by use and selection of appropriate antibiotics.
• Appropriate selection and treatment of cases.
• Sick calves should be isolated from healthy calves.

MEDICATIONS

DRUGS OF CHOICE
• Ideally bacterial cultures and antibacterial sensitivity test will be performed on symptomatic, nontreated calves. These may include, among others:
  ◦ Short-acting or long-acting oxytetracyclines
  ◦ Tilmicosin
  ◦ Trimethoprim-potentiated sulfonamides
  ◦ Ceftiofur
  ◦ Florfenicol
  ◦ Enrofloxacin (beef calves only)
• Efficacy of NSAIDs in these cases is questionable.

PRECAUTIONS
• Failure to respond to treatment may indicate predominantly viral infections, *Mycoplasma* infections, or late selection and treatment of cases.

ENZOOTIC PNEUMONIA OF CALVES (CONTINUED)

• Drug withdrawal times must be determined and maintained for treated animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Response to antimicrobial therapy should be evident within 48 hours if the primary pathogen is bacterial.
• *Mycoplasma* and viral infections may not respond to antimicrobial therapy.
• Calves that are selected early in the course of the disease for treatment will generally have a very low case fatality rate.
• Case fatality rates have been reported at 2.25%.

CLIENT EDUCATION

• Discuss probable causes and risk factors.
• Warn that viral or *Mycoplasma* pneumonias may not respond to antimicrobial therapy.

PATIENT CARE

• Fluid therapy such as oral electrolyte solutions or intravenous fluids may be indicated in dehydrated animals.
• Well-ventilated, draft-free environment provided.
• DART may be utilized as a measure of response to therapy. Calves that are still febrile after 3 days of therapy could be categorized as a relapse and considered for an alternative antimicrobial.

PREVENTION

• Improving air quality is an important criterion for control.
• Dairy calves should not share the same air space as adult animals.
• Rearing dairy calves in calf hutches is an excellent method for reducing the potential risk factors associated with enzootic calf pneumonia.
• Alternatively, use group housing in cold well-ventilated facilities.
• Humidity levels between 55% and 75% are optimal.
• Avoid mixing of various age groups of calves.
• Utilize all-in–all-out approach in group housing, if possible.
• Avoid overcrowding.
• Ensure that calves have high levels of passive immunity by ensuring adequate colostrum ingestion shortly after birth.
• This is a multifactorial disease. Recent studies regarding vaccination provide encouraging results, especially with BRSV vaccines. Further investigation is needed to support the use of vaccines in young calves and their benefit in preventing enzootic pneumonia.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Neonatal diarrhea may be associated with enzootic pneumonia, as many of the same risk factors are shared.

ZOONOTIC POTENTIAL

N/A

BIOSECURITY

• Keeping age groups of calves separate is a significant preventive measure.
• Avoid mixing of calves from various sources.
• Purchased calves may be persistently infected with BVDV, which may predispose infected animals to enzootic pneumonia.

PRODUCTION MANAGEMENT

• Heifers that do not experience enzootic pneumonia are twice as likely to calve and will calve 6 months earlier than heifers that did have enzootic pneumonia.
• Enzootic pneumonia cases are at an increased risk of culling.

SYNONYM

Bovine respiratory disease complex

ABBREVIATIONS

• BRSV = bovine respiratory syncytial virus
• BVDV = bovine viral diarrhea virus
• ELISA = enzyme-linked immunosorbent assay
• IBR = infectious bovine rhinotracheitis
• NSAIDs = nonsteroidal anti-inflammatory drugs
• PCR = polymerase chain reaction

SEE ALSO

• Aspiration Pneumonia
• Congenital Defects: Bovine
• *Histophilus somni* Complex
• Respiratory Disease: Bovine

EPIZOOTIC HEMORRHAGIC DISEASE VIRUS

BASICS

OVERVIEW

• Epizootic hemorrhagic disease (EHD) is an important noncontagious arthropod-borne, viral infection of white-tailed deer (WTD) that often results in epidemic outbreaks of hemorrhagic fever in North America during periods of high vector activity at the end of the summer and early fall.
• An abnormally large number of EHD cases were reported in WTD and cattle in the United States in the summer and Fall of 2012.
• Severe outbreaks of EHD clinical disease have been reported in cattle in Japan, Réunion Island, Israel, Morocco, Algeria, Jordan, and Turkey. In the United States, the majority of EHD infections in cattle are subclinical, but vesicular lesions and pregnancy loss have been reported.
• Since the report of outbreaks of EHD in cattle in four Mediterranean countries, EHD is considered an emerging disease in cattle and has been added to the OIE list of reportable diseases.
• EHDV shows immunologic cross-reactivity with the bluetongue virus (BTV).
• Ibaraki disease (ID) is a noncontagious viral disease of cattle caused by EHD in Japan and other countries, characterized by fever, anorexia, lacrimation, salivation, nasal discharge, conjunctival hyperemia, and dysphagia. Original reports indicated that ID was caused by EHD-2 but recent phylogenetic analysis of an isolate from an outbreak in Japan indicates that ID virus is less related to EHDV serotype 2 and should be classified as EHDV serotype 7.

INCIDENCE/PREVALENCE

• In endemic areas, outbreaks tend to occur every 2–3 years and in epidemic areas every 8–10 years. Most outbreaks of the disease in WTD are seasonal, occurring from mid-summer to late autumn.
• In the US, the disease has been reported sporadically in cattle, with morbidity as high as 7%.
• Serum EHDV antibodies have been found in black-tailed deer, red deer, wapiti, fallow deer, and roe deer.

GEOGRAPHIC DISTRIBUTION

• The distribution of EHDV coincides with areas where the vector is active, usually in tropical and subtropical areas approximately between latitudes 35°S and 49°N.
• Outbreaks of the disease have been reported in North America, Africa, Asia, Australia, and more recently in countries surrounding the Mediterranean basin including Morocco, Algeria, Tunisia, Israel, Jordan, and Turkey.
• Seropositive animals have been found in South America.
• In North America, EHD clinical disease is generally more severe in more northern latitudes, where EHD occurs sporadically and where the EDHV naïve population is high. In contrast, in the southwestern US, where the infection is endemic, clinical disease is less common.

SYSTEMS AFFECTED

• Cardiovascular
• Hemolymphatic
• Digestive
• Musculoskeletal

PATHOPHYSIOLOGY

• EHD is caused by epizootic hemorrhagic disease virus (EHDV), an *Orvivirus* in the Reoviridae family. EHD is closely related to BTV, African horse sickness virus, and equine encephalosis virus. Currently, seven EHDV serotypes are recognized worldwide.
• EHD is a double-stranded RNA virus with a 10-segmented genome.
• EHD serotype is determined by the interaction of virus proteins 2 and 5 (VP2 and VP5) with neutralizing antibodies.
• Currently EHDV has 7 serotypes (EHDV-1 to -7) as determined by sequencing of the VP2 region of the genome.
• In the US, EHDV serotypes 1, 2, and 6 have been identified.
• The virus is transmitted by insects of the genus *Culicoides* and can infect the majority of domestic and wild ruminants. Clinical disease is observed in WTD and to a lesser extent in mule deer and pronghorn antelope.
• In North America, *Culicoides sonorensis* is the primary vector of EHDV.
• Intrauterine transmission and abortion can occur in cattle with EHDV-2 (Ibaraki).
• Viremia can be detected as early as 2 days post-infection and usually lasts for 3 weeks; in some animals, EHDV can be isolated from the blood for over 50 days post-infection.

HISTORICAL FINDINGS

N/A

SIGNALMENT

• All ages of deer are susceptible. Passive immunity may be protective in fawns, but this has not been sufficiently evaluated.
• Morbidity may reach 90% and mortality 60% or higher.
• There is no sex predilection.
• Goats and sheep do not appear to be susceptible to natural infection.

PHYSICAL EXAMINATION FINDINGS

• Infection with EHDV in WTD can be subclinical or can result in high morbidity and mortality.
• Clinical disease can be hyperacute, acute, and chronic.
• In the hyperacute form, sudden death is often reported. In deer where clinical signs are observed, there is swelling of the head, neck, tongue, and eyelids. Death may occur 1–3 days after the initial clinical signs.
• Fever, depression, weakness, respiratory distress, salivation, ulceration of the oral mucosa, anorexia, subcutaneous edema of the head and neck, swelling of the tongue or eyelids, and lameness are observed in the acute form. Death may occur 7–9 days after infection.
• In the chronic form, affected deer may show signs for several weeks but generally recover. Affected deer lose weight; develop coronitis, cracks in the hooves, and exhibit lameness. The hoof sloughs off in some animals resulting in prostration or knee-walking.
• In North American cattle, EHDV infection is generally subclinical or characterized by a mild-to-moderate transient febrile disease. In some animals, there is fever, respiratory distress, anorexia, salivation, decreased milk production, conjunctivitis, nasal and ocular discharge, oral and nasal erosions, and lameness. Affected cattle usually recover. Death may occur in a few cases as a result of secondary bacterial infections.
• EHD infection of cattle can result in fetal loss or fetal hydranencephaly when pregnant cows are infected between 70 and 120 days of gestation.
• Severe clinical disease has been reported in cattle in Japan, Israel, Morocco, Algeria, Jordan, Tunisia, and Turkey.

GENETICS

N/A

CAUSES AND RISK FACTORS

WTD, mule deer, pronghorn antelope, and cattle living in areas where the vector, *Culicoides,* and EHDV coexist are at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• EHD in WTD needs to be differentiated from BTV, malignant catarrhal fever (MCF) and adenovirus infection.
• In cattle EHD can be confused with other vesiculo-ulcerative diseases such as foot and mouth disease (FMD), vesicular stomatitis (VS), and MCF.

CBC/BIOCHEMISTRY/URINALYSIS

• Thrombocytopenia and lymphopenia
• Increased creatine kinase, lactate dehydrogenase, and aspartate aminotransferase

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

• Diagnostic samples include serum, heparinized blood, or chilled unfixed spleen or other blood-rich tissues.

EPIZOOTIC HEMORRHAGIC DISEASE VIRUS (CONTINUED)

• Serum is used for the detection of EHDV antibodies by the AGID test, virus neutralization, or ELISA.
• EHDV can be isolated in cell culture from heparinized blood and from the spleen and other blood-rich tissues.
• Numerous real-time RT-PCR formats for the detection and serotyping of EHDV are used in diagnostic laboratories.

PATHOLOGIC FINDINGS

• Gross findings in the hyperacute and acute forms include severe subcutaneous edema in the head, neck and limbs, and hyperemia of the sclera, conjunctiva and oral mucosa.
• The tongue may be swollen and dark red with hemorrhages or mucosal ulceration.
• Widespread petechiae and ecchymoses are common in mucus membranes, subcutis, and internal organs including the heart and gastrointestinal tract.
• There is severe pulmonary congestion and edema, and straw-colored pericardial fluid.
• Erosions and ulcerations of the rumen and omasum are common.
• Paintbrush hemorrhages occur in the epicardium and papillary muscles.
• The main microscopic lesion consists of disseminated vasculitis and thrombosis, multifocal areas of hemorrhage, and ischemic necrosis in various organs.

TREATMENT

THERAPEUTIC APPROACH

There are no specific treatments for EHD.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

Broad-spectrum antimicrobials are used to treat secondary bacterial infections.

CONTRAINDICATIONS

N/A

PRECAUTIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• The majority of infections are subclinical.
• Mortality is high in clinically affected deer.

POSSIBLE COMPLICATIONS

Secondary infections or recumbency due to limb lesions

CLIENT EDUCATION

N/A

PATIENT CARE

N/A

PREVENTION

• In the US, there are no commercially available vaccines to prevent EHD.
• The use of autogenous EHDV inactivated vaccines is permitted in the US. Two or in some cases one dose of inactivated vaccine can provide considerable immunity against EHDV.

ERYTHROCYTOSIS (POLYCYTHEMIA)

BASICS

OVERVIEW

• Erythrocytosis is defined as an increase in the red blood cell (RBC) count, hemoglobin (Hb) concentration, and/or packed cell volume (PCV).
• Polycythemia and erythrocytosis are commonly considered synonyms.
• Polycythemia indicates erythrocytosis with concurrent leukocytosis and thrombocytosis.
• Therefore, the term erythrocytosis should be used when referring specifically to the RBC population.

INCIDENCE/PREVALENCE

• Relative erythrocytosis is the most common form of erythrocytosis.
• Absolute erythrocytosis is less common and is usually due to chronic diseases causing systemic tissue hypoxia.

GEOGRAPHIC DISTRIBUTION

• Cattle and sheep can develop erythrocytosis at 6,000 ft (1,800 m) above sea level.

SYSTEMS AFFECTED

• Cardiovascular
• Nervous
• Multisystemic

PATHOPHYSIOLOGY

• Relative erythrocytosis is defined as a relative increase in total RBC mass caused by hemoconcentration or splenic contraction.
• Hemoconcentration is due to a decrease in plasma volume usually caused by dehydration or endotoxemia.
• Dehydration is usually caused by reduced water intake and/or excessive loss or sequestration of body fluids.
• Endotoxemia is due to the endogenous release of mediators in response to Gram-negative bacterial cell wall components (endotoxins).
• Splenic contraction is due to an increase in blood catecholamine concentration caused by transportation, handling or exercise.
• Absolute erythrocytosis is defined as an absolute increase in total RBC mass caused by increased proliferation of erythroid precursors (erythropoiesis).
• Absolute erythrocytosis may be classified as either primary or secondary.
• Primary absolute erythrocytosis is caused by increased erythropoiesis in the absence of increased erythropoietin (EPO) production.
• Secondary absolute erythrocytosis is caused by increased erythropoiesis due to increased EPO production.
• Increased EPO production may be appropriate (due to systemic tissue hypoxia) or inappropriate (due to EPO-secreting neoplasms or renal tissue hypoxia).
• Erythropoiesis can also be stimulated by hormones other than EPO including cortisol, androgen, thyroxin, and growth hormone.
• Absolute erythrocytosis is characterized by an increase in blood volume and viscosity.
• Hypervolemia interferes antidiuretic hormone release, leading to polyuria and polydipsia.
• Hyperviscosity interferes with tissue oxygen delivery and distends capillaries, leading to an increased risk of thrombosis and rupture of these vessels.

HISTORICAL FINDINGS

Relative Erythrocytosis

• Excitement, exercise, handling, or transportation

Absolute Erythrocytosis

• Weakness, lethargy, anorexia, weight loss, or exercise intolerance

SIGNALMENT

• Cattle and sheep appear more susceptible to high altitude hypoxia.
• Camelids have small ellipsoid RBCs, resulting in fewer problems of sludging.
• Camelids and small ruminants have higher RBC counts than cattle but similar PCV.
• Camelids have higher blood Hb concentration than cattle and small ruminants.

GENETICS

• Familial absolute erythrocytosis has been described in Jersey cattle.

PHYSICAL EXAMINATION FINDINGS

• Relative erythrocytosis is usually mild to moderate and of no clinical significance.
• Most clinical signs associated with absolute erythrocytosis result from blood hyperviscosity.

Relative Erythrocytosis

• Signs of dehydration: Sunken eyes, reduced skin turgor, and dry mucus membranes.
• Signs of endotoxemia: Fever, tachycardia, tachypnea, scleral injection, pale or congested mucus membranes, and cold extremities.

Absolute Erythrocytosis

• Lethargy, ataxia, seizures, central blindness, or behavioral changes.
• Congested brick-red mucus membranes and dilated retinal blood vessels.
• Dyspnea, tachypnea, or harsh bronchovesicular sounds (due to pulmonary congestion).
• Retinal hemorrhage, epistaxis, hematemesis, hematochezia, melena, or hematuria.
• Polyuria and polydipsia (due to hypervolemia).

CAUSES AND RISK FACTORS

Relative Erythrocytosis (Most Common)

• Common causes of splenic contraction include exercise, transportation, and handling.
• Common causes of dehydration include decreased water intake, diarrhea, polyuria, and upper gastrointestinal stasis.
• Common causes of endotoxemia include coliform mastitis, puerperal metritis, and salmonellosis.

Secondary Absolute Erythrocytosis Caused by Appropriate EPO Production (Common)

• Residence at high altitude.
• Congenital heart defects leading to right-to-left shunting including tetralogy of Fallot and double outlet right ventricle.
• Severe chronic pulmonary disease.

Secondary Absolute Erythrocytosis Caused by Inappropriate EPO Production (Rare)

• EPO-secreting neoplasms including renal and hepatic carcinomas.
• Causes of chronic renal disease include pyelonephritis, urolithiasis, amyloidosis, and glomerulonephritis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• The first step is to identify causes of relative erythrocytosis including splenic contraction, dehydration, or endotoxemia.
• Another blood sample should be collected under less stressful conditions in excitable animals.
• Another blood sample should be collected after administration of intravenous fluids in animals with dehydration or hypovolemia.
• In the absence of response to fluid therapy, absolute erythrocytosis should be suspected.
• The second step is to differentiate primary and secondary absolute erythrocytosis.
• Systemic tissue hypoxia should be investigated using arterial blood gas analysis.
• Thoracic auscultation, radiography, and ultrasonography may help identify congenital heart defect or severe chronic pulmonary disease.
• In the absence of hypoxemia and cause of appropriate secondary erythrocytosis, the next step is to investigate causes of inappropriate EPO production.
• Abdominal radiography and ultrasonography may help identify EPO-secreting neoplasm or chronic renal disease.

CBC/BIOCHEMISTRY/URINALYSIS

Sample Collection and Handling

• Blood collected in a tube containing EDTA is the sample of choice for a CBC.
• Blood tubes should be filled to completion to ensure the proper blood-to-EDTA ratio and gently inverted several times immediately after filling.

ERYTHROCYTOSIS (POLYCYTHEMIA) (CONTINUED)

• Blood should be analyzed within 30–60 minutes of collection or stored at refrigerator temperature (4°C) and analyzed within 24 hours.

CBC Interpretation Principles (see Table 1)

• Primary absolute erythrocytosis can ultimately cause sludging of blood and leading to systemic tissue hypoxia and increased EPO production.
• Secondary absolute erythrocytosis is not always associated with increased EPO production if the erythrocytosis has resolved tissue hypoxia.

OTHER LABORATORY TESTS

• PaO_2 <80 mmHg indicates hypoxemia.
• Bone marrow examination should reveal erythroid hyperplasia in animals with absolute erythrocytosis.
• Determination of serum EPO activity has been traditionally recommended to distinguish the two types of absolute erythrocytosis.
• Increased serum EPO activity is expected with secondary absolute erythrocytosis.
• Thorough evaluation is still needed given the overlap in serum EPO activity between animals with primary and secondary erythrocytosis and the absence of validated assays in ruminants.

IMAGING

• Thoracic radiography and ultrasonography may help identify a cause of appropriate absolute erythrocytosis including congenital heart defect or severe chronic pulmonary disease.
• Abdominal radiography and ultrasonography may help identify a cause of inappropriate absolute erythrocytosis including EPO-secreting neoplasm or chronic renal disease.

PATHOLOGIC FINDINGS

N/A

TREATMENT

THERAPEUTIC APPROACH

Relative Erythrocytosis

• Fluid therapy is indicated in animals with dehydration or endotoxemia and the underlying cause(s) should be addressed.

Absolute Erythrocytosis

• Oxygen therapy is indicated in animals with severe chronic pulmonary disease.
• PCV should be maintained <60% to minimize effects of hyperviscosity.
• Phlebotomy (5–10 mL/kg) might be used to control blood hyperviscosity.
• Simultaneous administration of intravenous fluids is indicated to prevent severe hypotension and cardiovascular collapse.
• Excessive phlebotomy (PCV<50%) may worsen systemic tissue hypoxia in animals with secondary appropriate erythrocytosis.
• Surgery may be indicated in animals with EPO-secreting neoplasms.

MEDICATIONS

DRUGS OF CHOICE

• Radioactive phosphorus and chemotherapy drugs including hydroxyurea, doxorubicin, and busulfan have been used in small animals with absolute erythrocytosis with some benefit.

CONTRAINDICATIONS

• Phlebotomy may be contraindicated in patients with secondary appropriate erythrocytosis.

PRECAUTIONS

• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

COURSE AND PROGNOSIS

• Long-term prognosis of ruminants with absolute erythrocytosis depends on underlying cause.
• Primary erythrocytosis may be managed by repeated phlebotomy, but evidence on long-term prognosis is lacking.
• Secondary erythrocytosis caused by congenital heart defect or chronic pulmonary or renal disease usually has a poor prognosis.
• EPO-secreting neoplasms may have a better prognosis if surgical removal is successful.

POSSIBLE COMPLICATIONS

• Blood hyperviscosity is associated with increased risk of thrombosis and hemorrhage.
• Iron deficiency anemia may develop after repeated phlebotomy and warrant a decrease in the frequency of phlebotomy and iron supplementation.
• Chemotherapy drugs may cause leukopenia, thrombocytopenia, and/or anemia.

PATIENT CARE

• Heart rate, respiratory rate, mucus membrane color, blood lactate, and arterial blood gas analysis can be used to monitor systemic tissue oxygen delivery.

Table 1

CBC Interpretation Principles

	Relative erythrocytosis	*Primary absolute erythrocytosis*	*Appropriate secondary erythrocytosis*	*Inappropriate secondary erythrocytosis*
Mechanism	Splenic contraction, dehydration, or endotoxemia	Neoplastic or non-neoplastic proliferation of erythroid precursors	Systemic tissue hypoxia and increased EPO production	EPO-secreting neoplasms or chronic renal disease
PCV	↑ - ↑↑	↑↑ - ↑↑↑	↑↑ - ↑↑↑	↑↑ - ↑↑↑
Plasma protein	N - ↑	N	N	N
EPO	N	N - ↑	↑↑	↑↑ - ↑↑↑
PaO_2	N	N	↓	N
WBC count	N - ↓	N - ↑	N	N
Platelet count	N - ↑	N - ↑	N - ↑	N

N = normal, ↑ = slightly increased, ↑↑ = moderately increased, ↑↑↑ = markedly increased, ↓ = slightly decreased

• PCV and total solids should be monitored daily in animals with dehydration or hypoproteinemia.
• PCV and total solids should be monitored after repeated phlebotomy to allow for frequency adjustment.
• CBC should be performed weekly in animals receiving chemotherapy drugs.

ESCHERICHIA COLI

BASICS

OVERVIEW
Escherichia coli (*E. coli*) is the most common cause of diarrhea and septicemia in newborn ruminants.

INCIDENCE/PREVALENCE
• *E. coli* can be isolated in >50% of bacteremic calves.
• Enterotoxigenic *E. coli* (ETEC) is the most common cause of diarrhea in calves <3 days old.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Cardiovascular
• Urinary
• Hemolymphatic
• Digestive
• Cardiovascular

PATHOPHYSIOLOGY
• Commensal *E. coli* organisms can be found in soil and the GI tract of most mammals.
• A small number of *E. coli* are distinguished into pathovars (bacterial strains with the same or similar characteristics differentiated at infrasubspecific level).
• Pathotyping is based on the presence of two virulence factors: K99 fimbriae (F) and heat stable toxin (thermolabile [LT] and thermostable [STa and STb]).
• Enterotoxigenic *E. coli* (ETEC) causes neonatal calf diarrhea. ETEC possesses K99 fimbriae that mediate attachment to the intestinal epithelium, while LT, STa, and STb induce a secretory response resulting in diarrhea.
• The capacity of ETEC to bind to the intestinal epithelium is age dependent. Calves >3–5 days are resistant.
• Enteropathogenic *E. coli* (EPEC) include attaching and effacing *E. coli* (AEEC) and Shiga-like toxin-producing *E. coli* (SLTEC) which have been associated with diarrhea and dysentery in calves due to cytotoxic damage to intestinal epithelium.

HISTORICAL FINDINGS
Acute onset of systemic illness and/or diarrhea in young ruminants

SIGNALMENT
• All ruminant species can be affected.
• Septicemic disease occurs in ruminants <2 weeks of age.
• ETEC affects neonates 1–5 days old.
• AEEC and SLTEC affect calves 2–30 days old, but calves up to 4 months old can be affected.

PHYSICAL EXAMINATION FINDINGS
• Septicemic neonates display tachycardia, tachypnea, dehydration, obtundation, weakness, and reduced suckle. Pyrexia is uncommon but hypothermia due to dehydration and SIRS can occur. Swollen joints, diarrhea, pneumonia, meningitis, cloudy eyes, and/or a large, tender navel can develop.
• Diarrhea related to ETEC ranges from mild to severe. Mild signs include loose feces or mild diarrhea and weak suckle. Severe cases have diarrhea and dehydration that progresses rapidly to circulatory shock and death (and can resemble *E. coli* septicemia).
• Bradycardia and cardiac arrhythmias can develop in compromised animals with hyperkalemia, hypoglycemia, and hypothermia.
• Depression, dehydration, weakness, diarrhea, and frank blood in the feces are observed with AEEC and SLTEC.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Sepsis can occur due to a multitude of strains of *E. coli*.
• Diarrhea relates to infection with enterotoxigenic *E. coli* (ETEC), or enteropathogenic *E. coli* (EPEC) including AEEC and SLTEC.
• The main risk factor for *E. coli* septicemia and diarrhea is failure of passive transfer of immunity which can arise from a range of factors including being born to a compromised, dirty, or maiden dam, dystocia, being born into extreme weather, or incidental separation from the dam.
• High animal density and poor hygiene in feeding, housing, and maternity areas.
• Inappropriate volume, fat or protein content of milk or milk replacer.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Septicemia can occur due to a variety of pathogens in neonatal ruminants, which are often hard to differentiate without appropriate diagnostics.
• Diarrhea in neonatal ruminants can relate to rotavirus, coronavirus, cryptosporidiosis, giardiasis, salmonellosis, and clostridiosis.

CBC/BIOCHEMISTRY/URINALYSIS
• CBC findings reflect hemoconcentration (dehydration), inflammation (leukopenia, neutropenia, left shift, and toxic changes) and hypoproteinemia (protein loss or suboptimal passive transfer of immunity).
• Serum chemistry can reveal metabolic acidosis (low TCO_2), hypoglycemia (sepsis and reduced milk intake), and electrolyte disturbances (hypokalemia, hyponatremia, and hypochloremia). Hyperkalemia can be observed in severely dehydrated and acidemic calves.

OTHER LABORATORY TESTS
• Blood culture is essential for confirming bacteremia or sepsis; ideally three samples are obtained over 24 hours to improve the chance of success. Bacteremia occurs in approximately 30% of diarrheic calves and *E. coli* is most commonly isolated (>50% of calves).
• Sepsis score is useful to predict bacteremia/sepsis in a clinical setting.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• ETEC—feces and/or ileum content, or ileum tissue can be submitted for histopathology, immune-chromatography assay, atomic emission spectroscopy, latex agglutination, PCR, or slide agglutination.
• EPEC—ileum and colon tissue can be submitted for histopathology and culture, PCR typing of intimin (eae) genes, or toxin detection.
• Mixed infections are common, therefore feces or intestinal content should be analyzed for other possible pathogens.

PATHOLOGIC FINDINGS
• ETEC—distension of the colon with watery, yellow fluid.
• EPEC—colonic mucosa can be normal or have reddening, roughening, and petechial hemorrhages. Frank hemorrhage and fibrin can also be evident.
• Histopathologic findings consistent with sepsis and disseminated intravascular coagulation can occur in septicemic neonates.

TREATMENT

THERAPEUTIC APPROACH
• Fluid therapy (oral, IV or SC) is a cornerstone of therapy.
• Oral electrolytes can be administered to diarrheic neonates that are standing and appear strong, and can be fed as an extra meal.
• In neonates with dehydration judged to be >8%, provide IV fluids initially, followed by IV or oral fluids for maintenance.
• Fluid deficits can be calculated as: *Volume (L) = body weight (kg) × % dehydration*, and can be replaced over 4–6 h.
• Maintenance requirements (50–100 mL/kg/day) should be provided continuously IV or by intermittent IV or oral bolus; additional volume (1–4 L) is required for estimated ongoing losses per day and is dependent on species and severity of diarrhea.
• Fluid resuscitation is typically adequate to reverse mild to moderate acidemia, particularly if a lactate- or acetate-containing solution is used.
• Severe metabolic acidosis in calves can be addressed by administering isotonic sodium bicarbonate (156 mEq $NaHCO_3$/L; or 1.3%

solution), at 1–4 L over 4–6 h, or until deficits are mostly resolved.
• The total bicarbonate deficit can be calculated from base deficit on blood gas analysis or by estimating from the decrease in TCO_2 on serum chemistry (*Bicarbonate deficit (mEq) = body weight (kg) × base deficit (mEq/L) × 0.6*). Alternatively it can be estimated from depression score charts available online. Typically, half of the deficit is administered if bicarbonate supplementation of fluids is performed, and can be repeated if necessary.
• Dextrose can be added to IV fluids to a final concentration of 2.5–5% for hypoglycemia.
• Milk and milk replacer should not be withheld for more than 8–12 h. Milk should be reintroduced in small amounts starting with 1 L q6–12h.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Antibiotics to treat or prevent bacteremia or sepsis can include beta-lactam drugs (ceftiofur, amoxicillin, or ampicillin) and potentiated sulfonamides (where permitted).
• Combining a beta-lactam with an aminoglycoside (gentamicin or amikacin) can be used in neonatal camelids.
• Nonsteroidal anti-inflammatory drugs (flunixin meglumine or meloxicam) may be beneficial, suggested by results in experimental calves orally challenged with heat-stable *E. coli* enterotoxin.

CONTRAINDICATIONS
Nephrotoxic drugs are contraindicated in severe dehydration and azotemia.

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• The prognosis is grave for septic, obtunded, and hypothermic neonates.
• Prognosis is good to fair for diarrheic cases receiving supportive care.

POSSIBLE COMPLICATIONS
• Septicemia
• Meningitis
• Septic arthritis
• Pneumonia
• Renal failure

CLIENT EDUCATION
Focus on hygiene and passive transfer protocols to reduce prevalence.

PATIENT CARE
Monitor attitude, suckling response, fecal consistency, and hydration status.

PREVENTION
• Ensure good-quality colostrum intake (3–4 L for calves) during the first 2–4 h after birth.
• Calves receiving colostrum from cows vaccinated 6 and 3 weeks before calving have high levels of antibodies and are effectively protected from ETEC diarrhea.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Septicemia
• Meningitis
• Septic arthritis

AGE-RELATED FACTORS
GI disease with *E. coli* is a neonatal phenomenon.

ZOONOTIC POTENTIAL
• Ruminants are a reservoir for human pathogenic *E. coli*, including EPEC and enterohemorrhagic *E. coli* (EHEC).
• EHEC O157:H7 is commonly associated with hemorrhagic enteritis and hemolytic uremic syndrome in humans.

PREGNANCY
N/A

BIOSECURITY
• Environmental and personnel hygiene are critical; gloves, outerwear, hand washing, disinfection.
• Segregate sick animals.

PRODUCTION MANAGEMENT
Vaccination protocols can be efficacious in preventing neonatal calf scours including *E. coli*-related diseases.

SYNONYM
Scours

ABBREVIATIONS
• AEEC = attaching and effacing *E. coli*
• EPEC = enteropathogenic *E. coli*
• ETEC = enterotoxigenic *E. coli*

ESOPHAGEAL DISORDERS

BASICS

OVERVIEW

• Esophageal disorders are any conditions that disrupt the normal function of the esophagus.
• Esophageal disorders in ruminants and camelids are relatively uncommon.
• The esophagus may be affected by obstruction (choke), inflammation, trauma, stricture, viral/parasitic infections, and megaesophagus.
• Choke is the most common esophageal condition and is defined as the partial or complete obstruction of the esophageal lumen resulting in the inability to effectively move a bolus from the pharynx to the rumen (or C1). The obstruction may be caused by an intraluminal obstruction such as feed material or foreign body, or by an extraluminal obstruction, such as abscess or neoplasia.
• The esophageal muscles in camelids differ from ruminants due to a circular muscle layer surrounding an internal longitudinal muscle layer. This muscle pattern allows active regurgitation of ingesta.

INCIDENCE/PREVALENCE

• Esophageal obstruction is most common in cattle due to their indiscriminant eating habits, and least common in camelids due to their ability to actively regurgitate.
• Megaesophagus is rare in ruminants and camelids.

PATHOPHYSIOLOGY

N/A

SYSTEMS AFFECTED

Digestive

SIGNALMENT

There does not appear to be any age, breed, or sex disposition.

PHYSICAL EXAMINATION FINDINGS

The presence of clinical signs varies with the duration (acute to chronic) and severity of the lesion(s), and may include:
• Ptyalism
• Extension of the head and neck
• Anxiety and restlessness
• Dysphagia
• Regurgitation
• Coughing
• Feed staining on muzzle or mandible
• Nasal discharge
• Repeated attempts to swallow
• Continuous chewing
• Bruxism
• Bloat
• Tachycardia/tachypnea
• Respiratory distress
• Dehydration
• Poor body condition score
• Loss of body condition
• Decreased interest in feed

GENETICS

A genetic inheritance of megaesophagus in camelids has been proposed but not proven.

CAUSES AND RISK FACTORS

Esophageal Obstruction

• Usually caused by impaction of feed material in the esophagus or ingestion of foreign bodies.
• Ingestion of large items such as corncobs, apples, and potatoes can be the sole cause of the obstruction.
• Foreign material (e.g., glass or metallic objects).
• Consuming dry or pelleted feeds if the bolus is not moist enough to allow passage through the esophagus. This is most common in sheep.
• Extraluminal space-occupying mass (abscess, granuloma, or neoplasia). Peri-esophageal hematomas obstructing the esophageal lumen have been reported in camelids.
• Secondary to other disorders of the esophagus such as pre-existing strictures (including vascular ring anomalies, VRA) or diverticula, intraluminal neoplasia, such as squamous cell carcinoma or papillomas, or by underlying neurologic dysfunction.

Esophagitis

• Ingestion of irritants including toxic plant material (rhododendron or oleander).
• Secondary to ingestion of sharp feedstuffs or foreign objects, or iatrogenically with use of esophageal/gastric tubes or during administration of oral boluses.
• Erosive or ulcerative esophagitis may occur in cases of BVDV, bovine malignant catarrhal fever, vesicular stomatitis, papular stomatis, FMD, and after parasite death in infections with *Hypoderma lineatum*.
• Esophageal parakeratosis has been described in camelids after prolonged treatment with sodium EDTA and in individuals with zinc deficiency.

Megaesophagus

• Most cases are idiopathic. Congenital and acquired causes have also been reported in ruminants and camelids.
• VRA have been reported in camelids, cattle, and bison. Most cases present with esophageal dilation proximal and sometimes distal to the VRA stricture point.
• Primary nerve or muscle dysfunction in the neck (including vagal nerve) or secondary to chronic partial obstruction of the esophagus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Botulism, tetanus, listeriosis, and rabies can all cause bloat, dysphagia, and ptyalism. Toxic plants, such as milkweed, larkspur, sneezeweed, *Rhizoctonia leguminicola,* and infected red clover, also cause ptyalism.
• Traumatic damage to the pharynx can also cause ptyalism and localized cellulitis.
• Bloat can be caused by vagal indigestion or trauma and inflammation associated with the vagal nerve.

CBC/BIOCHEMISTRY/URINALYSIS

• Packed cell volume and serum protein level may be elevated due to dehydration.
• Metabolic acidosis, hyponatremia, hypophosphatemia, and hypokalemia may be present due to the loss of saliva.
• The leukogram and fibrinogen concentration may be altered due to inflammatory changes associated with the primary disease process or secondary aspiration pneumonia.

IMAGING

Radiography

• Both survey and contrast radiography may be helpful to determine the etiology and severity of esophageal lesions. Contrast material should not be administered until an obstruction is relieved due to risks associated with aspiration of the material.
• The cervical and thoracic esophagus can be easily visualized by radiography in calves, small ruminants, and camelids. In most cases, adult cattle require specialized radiology systems to obtain diagnostic images of the thoracic esophagus.
• Fluoroscopy may be helpful to diagnose motility disorders.
• Computed tomography has been used to investigate causes of extraluminal esophageal obstructions including identifications of VRA.

Ultrasonography

• May be useful to identify intra- or peri-esophageal masses in the cervical region and can occasionally identify intraluminal obstructions.
• May aid in diagnosis of aspiration pneumonia.

OTHER DIAGNOSTIC PROCEDURES

• In small ruminants and camelids, the object may be palpated in the cervical esophagus. This is often not possible in the bovine patient due to overlying musculature.
• Passage of an orogastric tube can establish the location of the obstruction. The tube should be passed through an oral speculum and should be advanced gently to avoid damage to affected mucosa.

Endoscopy

• Esophagoscopy will aid in localizing and characterizing lesions, as well as determining the severity of esophageal damage.
• A 2–3-m endoscope may be necessary to visualize the extent of the bovine esophagus, however, a 1-m or pediatric endoscope is adequate for the small ruminant and many camelids. Use of an oral speculum is necessary to prevent damage to the endoscope. Insufflation with air will help advance the endoscope and allow visualization of the

esophagus, especially in cases where a large amount of saliva is present.

PATHOLOGIC FINDINGS
N/A

TREATMENT

THERAPEUTIC APPROACH

Esophageal Obstruction
• Some cases of esophageal obstruction will resolve spontaneously. Acute cases can be monitored for resolution of the choke in an area free of any feed, bedding or water. If not resolved in a few hours, the animal should be treated.
• Sedation may be given to reduce anxiety and promote relaxation of esophageal spasms; however, this increases risk of aspiration and thus low head carriage should be encouraged.
• If obstruction is palpable within the cervical esophagus, it may be manually extracted by applying gentle and steady pressure in the jugular groove aboral to the obstruction, pushing it orally. Once in the proximal esophagus, it may be propelled into the pharynx or grasped and removed. Sedation, a speculum, and manipulation of the tongue are helpful.
• Thoracic obstructions may be corrected by pushing the object into the rumen and foreign bodies can then be retrieved via rumenotomy. This should not be performed if the object has sharp edges as identified by endoscopy.
• Objects in the cervical esophagus should not be pushed aborally due to the narrowing of the esophagus at the thoracic inlet.
• For persistent obstructions, the animal should be sedated to allow low head carriage. An orogastric tube can be passed to the level of the obstruction, and obstructions that are feed material based may be broken down with a gentle lavage of warm water.
• Aspiration of lavage material can be prevented by placement of a large-bore ET tube into the esophagus, cuff inflated, and the smaller oroesophageal tube inserted through the ET tube. This allows lavage material and fluid to pass through the ET tube and reduce risk of aspiration. Several attempts may need to be made to break down the obstruction, and it may take a significant amount of time. Breaks should be taken to allow the animal to rest.
• If the obstruction cannot be relieved with the animal standing, general anesthesia may be required. The patient is placed in lateral recumbency with the head lowered and the same lavage techniques are used. If this does not allow relief of the obstruction, esophagotomy may be required.
• Rumen or C1 decompression through trocarization or surgical decompression may be required in cases of complete esophageal obstruction leading to free-gas bloat.

Megaesophagus
• There are no specific treatments for megaesophagus. If an underlying disease process is identified, neuromuscular function of the esophagus may improve after resolution of the inciting cause.
• Elevation of feed and inclined footing to raise the animal's fore-end may help with movement of the feed bolus through gravity.

General Management of Esophageal Disorders
• In cases of dehydration, the patient may require intravenous fluid therapy.
• Diet recommendations are dependent on type and severity of the disease present.
• Ruminants with minimal esophageal mucosal damage and no decrease in motility can be fed frequent small amounts for the first 24–72 hours.
• More severe esophageal damage, decreased motility, or surgical correction will require alternative alimentation.
  ◦ Temporary rumenostomy cannula.
  ◦ Placement of an esophagostomy tube distal to the esophageal lesion is best reserved for pre-ruminant calves, as the regurgitated feed material and saliva will leak around the tube. Daily passage of an orogastric tube can be used for feeding if done cautiously to avoid further mucosal damage.

SURGICAL CONSIDERATIONS AND TECHNIQUES
• Esophageal surgery carries a high complication rate.
• If there is evidence of esophageal rupture, surgical management may be necessary. In acute cases, survival with surgery is possible.
• If the rupture is long-standing, involves contamination of the thorax, or involves extensive soft tissue contamination, the prognosis is extremely guarded.

MEDICATIONS

DRUGS OF CHOICE
• Xylazine (sedation and esophageal relaxation)
  ◦ Cattle, small ruminants: 0.01–0.02 mg/kg, IV
  ◦ Camelids: 0.1–0.15 mg/kg, IV or 0.2–0.3 mg/kg, IM or SQ
• Acepromazine (anxiolytic, antispasmotic)
• Butorphanol may be used in camelids for restraint during procedures with limited sedative effects
  ◦ Camelids: 0.1 mg/kg, IV or IM
• Flunixin meglumine (inflammation and pain)
  ◦ Cattle, small ruminants: 1.1 mg/kg, IV
  ◦ Camelids: 1 mg/kg, IV
• Broad-spectrum antimicrobials should be given in cases of esophageal necrosis, aspiration pneumonia, or esophageal surgery.
• Sucralfate (camelids and pre-ruminants) or bismuth subsalicylate may be used to improve animal comfort while esophageal ulcerations heal.
• Oxytocin is not effective for treatment of esophageal obstruction in ruminants (unlike its possible use in Equidae) due to the presence of striated muscle for the length of the esophagus.

CONTRAINDICATIONS
The use of lubricants, such as mineral oil or surfactants (DSS) to relieve an esophageal obstruction, is contraindicated due to the risk of aspiration.

PRECAUTIONS
• Drug choices should be made with regard to meat and milk withdrawal times.
• NSAIDs should be given judiciously to the dehydrated patient due to the risk of nephrotoxicity.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Prognosis is dependent on duration and severity of the lesion and occurrence of complications.
• Prognosis is good for esophageal obstructions if resolution of the obstruction occurs spontaneously or with minimal manipulation and mucosal damage. Prognosis is guarded with more aggressive manipulation or if surgical correction is required, and grave to poor with prolonged obstruction and rupture of the esophagus.
• Prognosis for esophagitis is dependent on underlying cause of the esophageal lesions.
• Megaesophagus can be managed in some animals through diet change and feeding conditions. Some camelids have been reported to live years after diagnosis though most animals are euthanized or culled after diagnosis.

POSSIBLE COMPLICATIONS
• Rumenal or 1st compartment (C1) bloat
• Esophageal perforation
• Esophageal stricture
• Esophageal diverticulum
• Recurrent obstructions
• Aspiration pneumonia
• Altered esophageal motility

PATIENT CARE
See "Treatment"

PREVENTION
Dependent on underlying cause. The diet should be thoroughly evaluated for risk factors (see "Causes and Risk Factors").

ESTRUS SYNCHRONIZATION: BOVINE

BASICS

OVERVIEW
• Estrus synchronization is a management technique involving scheduled hormonal treatment which allows synchronized follicle growth, controlled CL regression, predictable estrus expression, and ovulation within a narrow window of time.
• Synchronization of estrus and ovulation allows artificial insemination at a predetermined time.
• Synchronization of estrus improves efficiency of insemination by reducing or eliminating the need for heat detection.

INCIDENCE/PREVALENCE
Common

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Reproductive

PATHOPHYSIOLOGY
• Synchronization protocols rely on simulation of a luteal phase using progestogens or interruption of the natural luteal phase using $PGF2_{\alpha}$ or its analogs. Progestogens and $PGF2_{\alpha}$ may also be used in combination.
• Follicular wave dynamics can be controlled by estrogens or GnRH.
• Ovulation is induced with administration of GnRH which induces an LH surge.
• Combined treatment with estrogens and progesterone causes:
  ◦ A transitory decrease in plasma FSH, decreases LH pulse frequency, and reduces growth and estradiol activity in the largest follicle.
  ◦ Atresia of the follicular wave present at the time of treatment and emergence of a new follicular wave 3–6 days later.
  ◦ Estrogens are luteolytic when administered during the early part of the estrus cycle.
• Effects of GnRH
  ◦ Induces an LH and FSH surge of variable magnitude depending on days postpartum, progesterone concentration, and stage of the follicular wave.
  ◦ GnRH injection causes either ovulation or luteinization of a dominant follicle (≥10 mm in diameter with sufficient LH receptors) with emergence of a new follicular wave 2 days later.
  ◦ Injection of GnRH before dominance does not affect the follicular wave.
• Effects of $PGF2_{\alpha}$ or analogs:
  ◦ Luteolysis is induced in presence of a mature CL (day 5 to day 17 of the cycle).
  ◦ Progesterone decreases to basal levels within 24 hours after injection. LH pulse frequency increases, causing a significant increase in estradiol from the dominant follicle and induction of estrus and ovulation.
  ◦ The interval from $PGF2_{\alpha}$ until estrus depends on the stage of the follicular wave and size of the dominant follicle at the time of injection. Cows treated in presence of dominant follicle will display estrus 2–3 days later, whereas cows treated at the beginning of a follicular wave and those whose dominant follicle has become atretic, will require more time (4–6 days) for a dominant follicle to emerge and ovulate.

HISTORICAL FINDINGS
• Dairy cattle: Poor heat detection, increased interval from calving to first ovulation, poor pregnancy rates.
• Beef cattle: Implementation of an artificial insemination program.

SIGNALMENT
Breeding age heifers or mature cows

PHYSICAL EXAMINATION FINDINGS
• Heifers **s**hould meet requirement for breeding age and maturity (height and weight) and be cycling. Reproductive tract scoring may be used to select mature heifers.
• Mature cows should be cyclic and at least 50 days (beef cattle) or 30 days postpartum (dairy).

OTHER LABORATORY TESTS
• Serum progesterone determination may help determine cyclicity status and monitor response.
• PSPB or PAG1 may be used as pregnancy diagnosis test.

IMAGING
Transrectal ultrasonography helps determine cyclicity status and response.

OTHER DIAGNOSTIC PROCEDURES
Heat detection aids may be used to determine response.

PATHOLOGIC FINDINGS
N/A

TREATMENT

THERAPEUTIC APPROACH
• Estrus synchronization with progestogens:
  ◦ MGA, an orally active steroid with progestin activity, fed at a rate of 0.5 mg/day/cow for 14–18 days is used to synchronize estrus.
  ◦ Estrus is exhibited 3–7 days after progestin withdrawal. However, conception rates following long-term MGA treatment are low. Subsequent heats show normal fertility. Injection of $PGF2_{\alpha}$ 16–17 days after MGA treatment will induce a fertile estrus.
  ◦ Decreased fertility at the first estrus after MGA treatment may be due to ovulation of an aged oocyte from a persistent follicle, the prolonged period of chronically elevated concentrations of estradiol, reduced weight of corpora lutea, changes in cervical mucus quantity and quality, interference of gamete transport and function, abnormal timing of ovulation, or alteration of the histology and function of the endometrium.
  ◦ Short-term MGA (5–7 days) followed by injection of $PGF2_{\alpha}$ did not improve synchrony and conception rate.
• Estrus synchronization with $PGF2_{\alpha}$ or analogs:
  ◦ These protocols are only effective in cyclic animals.
  ◦ Two injections 11 or 12 days apart increase the percentage of cows exhibiting estrus within 2–4 days.
  ◦ Heifers tend to show estrus and ovulate earlier than cows.
  ◦ In multiparous cows, 2 injections of $PGF2_{\alpha}$ administered 12 hours apart may be necessary to induce complete luteolysis. Cows with incomplete luteolysis are unlikely to show estrus and have lower conception rates to TAI.
  ◦ AI is performed 12 hours after standing estrus.
• Estrus synchronization combining progestogen and $PGF2_{\alpha}$:
  ◦ These protocols decrease the length of required progestogen treatment. They are easy to implement and offer substantial savings in time and labor in large herds.
  ◦ Progesterone is delivered as a CIDR or PRID™ Delta® implant.
  ◦ CIDR is a T-shaped silicone intravaginal insert impregnated with 1.38 g of progesterone.
  ◦ CIDR protocols of 5 and 7 days' duration have been described with similar conception rates.
  ◦ A high proportion of cows (>80%) display estrus within 36–60 hours after progesterone removal.
  ◦ Administration of $PGF2_{\alpha}$ or analogs 24 hours before removal of progestogen induces luteolysis and improves estrus synchrony.
  ◦ Cows are observed for estrus 2–6 days following CIDR removal and inseminated 12 hours after onset of standing estrus.
  ◦ FTAI may be performed 56–72 hours following removal of the progestin insert with concurrent administration of GnRH.

ESTRUS SYNCHRONIZATION: BOVINE (CONTINUED)

- ◦ CIDR inserts have also been used in combination with GnRH-based protocols to improve synchrony by preventing early ovulation.
- ◦ PRID™ Delta® is a triangular shaped device made from a polyethylene spine and ethyl vinyl acetate impregnated with 1.55 g of progesterone.
- ◦ PRIDs™ are left in the vagina for 7 days. $PGF2_\alpha$ is administered 24 hours prior to removal in all cattle. Noncycling cattle receive an injection of eCG on the day of PRID™ removal.
- ◦ All animals are inseminated at 48 hours and 72 hours or at 56 hours after PRID™ removal.

• Ovulation synchronization (Ovsynch®):
- ◦ Ovulation synchronization eliminates need for heat detection and increases AI submission rate of cows eligible for AI.
- ◦ The standard protocol consists of an injection of GnRH followed 7 days later by an injection of $PGF2_\alpha$ or analog to induce luteolysis. A second injection of GnRH is administered 48–56 hours after $PGF2_\alpha$ to induce ovulation of the newly emerged dominant follicle. Cows are inseminated 16 hours after the second GnRH injection.
- ◦ A Co-synch protocol, used to decrease labor and animal handling, consists of a FTAI concurrently with the second GnRH injection. There is a tendency for lower conception rates compared to Ovsynch®.
- ◦ The Ovsynch® protocol is less successful in heifers because of differences in their follicular wave patterns compared to adult cows. There are several variations of this scheme to further improve synchrony and pregnancy rates.
- ◦ The success rate (overall pregnancy rate) of the Ovsynch® program depends on:
  - ▪ *Cyclicity of cows treated.* Progesterone supplementation for 7 days between the first GnRH and $PGF2_\alpha$ injections of Ovsynch® may improve fertility in anovular cows.
  - ▪ *Complete regression of CL after $PGF2_\alpha$ injection.* Incomplete luteolysis has been reported in 10–25% of cows during Ovsynch® protocols. Two injections of $PGF2_\alpha$ given 12 hours apart will enhance CL regression, especially in multiparous cows, and improve fertility.
  - ▪ *The stage of the estrous cycle of treated cows*. Cows enrolled in Ovsynch® between days 12 to 21 of the cycle may experience early CL regression prior to $PGF2_\alpha$ injection and ovulate prior to the second GnRH injection, resulting in lower conception rates. Cows receiving their first injection of GnRH between days 1 and 4 of the estrous cycle will not ovulate in response to the GnRH injection and will not be synchronized to ovulate at the appropriate time for FTAI.
  - ▪ *Rate of ovulation to the first GnRH injection.* Only cows that ovulate in response to the first GnRH of Ovsynch® will be at the correct stage of the estrous cycle to respond to subsequent injections. Cows at day 6 of the cycle have the highest rate of ovulation (85–94%) to the first injection of GnRH.

• Presynchronization protocols:
- ◦ These protocols are aimed at ensuring cows are at a phase of the estrous cycle associated with optimal response to Ovsynch®.
- ◦ Presynch-Ovsynch: Cows receive two $PGF2_\alpha$ injections 14 days apart followed by an Ovsynch® protocol 11–12 days after the second $PGF2_\alpha$. This approach improves pregnancy rates by 12–18% in cycling lactating dairy cows.
- ◦ G6G: Cows receive an injection of $PGF2_\alpha$ then GnRH 2 days later and Ovsynch® is initiated 6 days following GnRH injection.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• $PGF2_\alpha$ (dinoprost tromethamine, 25 mg IM) or cloprostenol sodium (500 µg, IM)
• GnRH (100 µg, IM)

CONTRAINDICATIONS
• Appropriate milk and meat withdrawal times must be followed.
• Estrogens are not approved in some countries.
• PRID™ implants are not approved in the United States.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Results depend on cyclicity, health, and compliance.

POSSIBLE COMPLICATIONS
N/A

CLIENT EDUCATION
• Compliance is critical for success of estrus synchronization programs and schedules for hormone treatments should be followed closely.
• CIDR or PRID™ implants may cause mild vaginitis in some cows. Insertion of implants should be done in a clean manner.
• Insemination in the absence of estrus is more difficult due to the absence of cervical mucus.
• Reproductive hormones must be handled with caution. Handling of $PGF2_\alpha$ by asthmatics and women of child-bearing age should be avoided.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Infertility

AGE-RELATED FACTORS

ESTRUS SYNCHRONIZATION: SMALL RUMINANT

BASICS

OVERVIEW

• Estrus synchronization protocols are treatments that allow manipulation of the estrous cycle and concentration of females in heat over a specific period of time to allow
  ◦ Artificial insemination
  ◦ Concentration of the lambing period
  ◦ Preparation for recipients for embryo transfer
• Synchronization of estrus may be achieved by hormonal treatment, modification of the photoperiod, or the male effect
• Synchronization protocols are also helpful for out-of-season breeding
• Important components of synchronization programs are:
• A good preventive health program (vaccination/deworming)
• Appropriate nutrition
• Ideal BCS (3 out of 5)
• Estrus detection if artificial insemination is used

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Reproductive

PATHOPHYSIOLOGY

• Male pheromones may induce an LH surge if the animals are in the transition to the breeding season. However, cycles induced are shorter than normal (poor luteal activity).
• Direct manipulation of response to light using artificial photoperiod or by hormonal treatment (melatonin) can induce cyclicity but this is not widely used.
• The hormonal protocol simulates a luteal phase using progesterone delivery devices or interrupts the normal luteal phase with $PGF2_{\alpha}$ if the animal is cycling. The combined use of progestogens and $PGF2_{\alpha}$ allows shortening of the treatment period.
• Response to hormonal treatment depends on normal reproductive function, health, and nutrition status.

HISTORICAL FINDINGS

Desire by owner to implement artificial insemination, concentrate lambing, or breed out of season.

SIGNALMENT

• Sheep and goats of breeding age.
• Animals must be reproductively sound and in adequate health and body condition.
• Maiden females should be at least 65% of mature body weight and size.

PHYSICAL EXAMINATION FINDINS

N/A

GENETICS

• There is great variation in seasonality among breeds.
• Dose of eCG should be adjusted to the breed and season.

CAUSES AND RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

N/A

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

Transrectal ultrasonography to assess the reproductive status; however, this is not used routinely.

OTHER DIAGNOSTIC PROCEDURES

• Male breeding soundness examination if natural mating
• Semen evaluation if artificial insemination

TREATMENT

THERAPEUTIC APPROACH

Male (Ram or Buck) Effect

• Females that are separated (smell, sight, and contact) from males for at least 3–4 weeks will show estrus between 2 and 6 days after the sudden introduction of a male. Ovulation occurs in response to an LH surge in a large proportion of females.
• Males used for induction of estrus and ovulation are usually vasectomized or fitted with an apron.
• Induced estrus may result in short cycles.
• The best results using this technique are achieved during the transition season.
• The male effect provides good synchronization of sheep and goats for natural breeding.
• Synchronization is not tight enough to use artificial insemination.

$PGF2_{\alpha}$ or Analogs

• $PGF2_{\alpha}$ causes luteolysis and return to estrus during the breeding season.
• Treated females should be cyclic and at least 5 days after ovulation.
• A single injection induces estrus 3–6 days after treatment in about 60% of the females.
• A two-injections protocol allows more females (>85%) to be synchronized about 48 hours after the second injection. The interval between injection is different for sheep and goats because of the difference in cycle length.
• In sheep, the injections are given 9–11 days apart.
• In goats, the injections are given 11–12 days apart.
• This system is efficient for AI if combined with heat detection.

Progestogens

• Progestogens are delivered using vaginal insert (sponges or silicone) devices (progesterone, subcutaneous implants (Norgestomet) or oral administration (MGA)
• The most commonly used treatment for synchronization of estrus in sheep in the United States is progesterone CIDR
• During the breeding season, length of treatment without use of $PGF2_{\alpha}$ is 14 days for sheep and 17 days for goats.
• Outside of the breeding season, length of treatment is shortened.
• Shorter treatments may be used during the breeding season but require administration of a luteolytic dose of $PGF2_{\alpha}$ at progestogen withdrawal.
• Administration of an FSH-like hormone (eCG or PG 600) the day before or on the day of progesterone withdrawal improves estrus synchrony and promotes follicular development, especially in the non-breeding season.
• Estrus can be expected approximately 54 and 48 hours after progestogen withdrawal in ewes and does, respectively.
• Administration of $PGF2_{\alpha}$ 24 hours before progestogen withdrawal and introduction of a teaser male 24 hours later further tightens estrus synchrony.

Other Methods

• Photoperiod manipulation can be used for out-of-season breeding but does not provide a good synchronization and is seldom used because of the facilities requirements.
• Melatonin treatment (18 mg SQ for 35 days) in combination with photoperiod manipulation, CIDRs or ram effect has been effective in advancing the breeding season and synchronizing estrus.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

$PGF2_{\alpha}$ and Analogs

• $PGF2_{\alpha}$ (dinoprost tromethamine) IM: Sheep: 15 mg/animal, Goats: 10 mg/animal
• Synthetic analog (cloprostenol): Sheep: 125–150 µg/animal Goats: 50–150 µg/animal

Progestogens

• Vaginal implants
  ◦ CIDR: Progesterone 330 mg
  ◦ FGA: 30–40 mg
  ◦ MAP: 60 mg
• Subcutaneous implants: Norgestomet 3 mg

ESTRUS SYNCHRONIZATION: SMALL RUMINANT (CONTINUED)

Gonadotropins
• eCG: 400 IU out of the breeding season and 200 IU during the breeding season.
• PG 600: 400 IU eCG and 200 IU hCG

Melatonin
Melatonin subcutaneous implant has been used to increase ovulation rate and anticipate the breeding season (not available in US).

CONTRAINDICATIONS
• Some synchronization treatments are not approved in some countries.
• Progestogens are not approved for dairy animals in some countries.
• Appropriate milk and meat withdrawal times must be followed.

PRECAUTIONS
Hormones should not be handled by pregnant women. Protective wear is advised during administration.

POSSIBLE INTERACTION
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Response rate in terms of estrus induction is excellent (>90%) with progestogen protocols.
• Fertility after natural breeding depends on the male : female ratio.
• Fertility after fixed-time insemination ranges from 50% to 80%.
• Prolificacy depends on the season and dose of eCG.

POSSIBLE COMPLICATIONS
• Vaginitis may be observed at progestogen withdrawal but subsides within a couple of days.
• Loss of the vaginal insert will result in poor response.

CLIENT EDUCATION
• Instruction on appropriate methods of injections and placement/removal of CIDR.
• Compliance in treatment schedule and dosing.
• Ram/buck breeding soundness examination and male power prior to synchronization.

PATIENT CARE
• Monitoring for signs of heat
• Monitoring for CIDR loss

FAILURE OF PASSIVE TRANSFER

BASICS

OVERVIEW

• Newborn ruminants are born hypogammaglobulinemic due to the nature of their placentation.
• Although immunocompetent at birth, neonatal ruminants are immunonaïve and dependent on maternally derived immunoglobulin and other factors absorbed from colostrum.
• Neonates that fail to acquire adequate passive immunity are said to suffer failure of passive transfer.
• Failure of passive transfer is not a disease, but a condition that predisposes animals to contracting infectious diseases.

INCIDENCE/PREVALENCE

• May vary by species, farm, and production system employed on the farm.
• An association exists between higher IgG levels and lower disease incidence.
• This association appears to have a greater influence in herds with high disease incidence compared to herds with low disease incidence.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

• Multisystemic
• Digestive
• Musculoskeletal
• Respiratory

PATHOPHYSIOLOGY

• Composition and formation of colostrum
  ◦ Colostrum is a complex fluid that contains immunoglobulins, immune cells, immunoactive substances such as cytokines, and nutritional elements.
  ◦ While all of these components are important, we often focus on immunoglobulins because they are a large constituent of colostrum and they are the most thoroughly studied component.
  ◦ Immunoglobulin G1 (IgG1) is the primary immunoglobulin in bovine colostrum.
  ◦ Colostral IgG1 originates from maternal serum and is transferred by active, IgG1-specific, Fc receptors into colostrum during the last 4–6 weeks of gestation.
• Colostral cellular makeup
  ◦ Colostrum contains $>1 \times 10^6$ cells per milliliter.
  ◦ Lymphocytes make up approximately 20–30% of colostral cells in sheep and cattle and differ from those in maternal circulation. They function by modulating the neonatal immune system and the secretion of various cytokines, as well as the secretion of immunoglobulin A.
  ◦ Macrophages and neutrophils make up the remainder of colostral cells.
  ◦ Macrophages are thought to serve as cytokine-producing and antigen-presenting cells.
  ◦ The neutrophils are likely involved in the protection of the mammary gland rather than the neonate.
  ◦ While interleukin-2 (IL-2) and tumor necrosis factor (TNF) have been found in colostrum, their role as yet is unknown.
  ◦ Colostrum is rich in insulin-like growth factor-1 (IGF-1), which helps regulate newborn growth and may enhance the early neonatal immune response.
  ◦ Transforming growth factor is present in high concentrations in bovine colostrum but decreases by 30 days postpartum.
• Absorption of colostrum
  ◦ Absorption and transfer across the neonatal intestinal epithelial cells occur via nonselective pinocytosis initiated by the presence of macromolecules.
  ◦ The efficiency of immunoglobulin absorption declines to zero over the first approximately 24 hours of life.
  ◦ The term "closure" is used to define the point at which absorption of immunoglobulins by the gut ceases.
  ◦ The absorptive process across the gut epithelium appears to be saturable. That is, a finite capacity exists for the absorption of all macromolecules.
  ◦ The presence of high levels of non-immunoglobulin molecules fed during the first 24 hours of life may adversely compete with the absorption of colostral immunoglobulins.

SIGNALMENT

Neonates of any ruminant species

PHYSICAL EXAMINATION FINDINGS

• Failure of passive transfer is not a disease, but a condition that predisposes to the development of infectious diseases.
• Affected animals are at increased risk for the development of diseases such as septicemia, enteritis, diarrhea, omphalitis, arthritis, and respiratory disease.
• Animals with FPT may be clinically normal in a low infection pressure environment.

CAUSES AND RISK FACTORS

• An association exists between higher IgG (or protein) levels and lower disease incidence.
• This association appears to have a greater influence in herds with high disease incidence compared to herds with low disease incidence.
• The rate of disease occurrence is obviously a balance between a calf's ability to resist disease and the severity of disease challenging the calf.
• Serum immunoglobulin concentration is only one factor that contributes to disease resistance. Other factors that influence disease resistance might include the less-studied non-immunoglobulin components of colostrum (cells, cytokines, etc.).
• Additional factors to consider in assessing disease risk include general hygiene, pathogen virulence, pathogen concentration, physical environment (e.g., temperature, humidity, wind chill), nutritional status, and miscellaneous stresses (e.g., transportation, handling, surgery).

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

N/A

CBC/BIOCHEMISTRY/URINALYSIS

• Results of these tests may be indicative of clinical disease as a result of FPT.
• Serum protein >5.5 g/dL is indicative of adequate passive transfer.

OTHER LABORATORY TESTS

• Many methods are available to measure immunoglobulin concentrations in calf serum after absorption from colostrum.
• Serum IgG1 concentration of 10 mg/mL at 48 hours of age is the objective value for defining the threshold between adequate passive transfer and failure of passive transfer.
• The various tests for immunoglobulin concentration vary in their speed, accuracy, and equipment required for operation.
• Single radial immunodiffusion (SRID) and the enzyme-linked immunosorbent assay (ELISA) are the only tests that directly measure serum IgG concentration. Other tests including zinc sulfate turbidity, sodium sulfite precipitation, whole blood glutaraldehyde coagulation, total serum solids by refractometry, and gamma-glutamyl transferase activity indirectly estimate serum IgG concentration based on colostral total proteins.
• The techniques for performing these tests and the values used for their interpretation can be found in numerous manuscripts and texts (see "Suggested Reading").
  ◦ Test endpoints for many assays can be manipulated depending on the goals of the individual producer.
• Results of the various testing methods on any particular operation must be kept in perspective and their use not over-interpreted.
• Test accuracy
  ◦ Accurate measurement of serum immunoglobulin in a particular calf does not necessarily guarantee protection from disease, for the following reasons:
    ▪ The tests only quantify a calf's serum immunoglobulin concentration. They do not determine specific protective capabilities of the absorbed immunoglobulins.
    ▪ The tests cannot determine if the absorbed immunoglobulins will reach the appropriate site of challenge in a calf in sufficient concentrations to neutralize a particular pathogen.
  ◦ These two points are not meant to conclude that there is no benefit in

F

FAILURE OF PASSIVE TRANSFER (CONTINUED)

measuring serum immunoglobulin levels as an indicator of passive transfer of immunity. They illustrate the potential limitations of measuring immunoglobulin levels.

PATHOLOGIC FINDINGS
N/A

TREATMENT

In cases of failure of passive transfer and depending on the value of the animal, plasma transfusion may be warranted.

MEDICATIONS

DRUGS OF CHOICE
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
- Approximately 70% of animals with FPT will survive, but may have long-term production losses when compared to their peers.
- In animals that become sick, clinical course and prognosis vary and are associated with the underlying disease process. Without aggressive therapy in sick animals, failure of passive transfer warrants a guarded to poor prognosis.

PREVENTION
- Proper colostral management
  - Dairy calves should get a minimum of 3 L of good-quality colostrum within 6 hours after birth.
  - Beef calves, kids, lambs, and cria typically will achieve adequate passive transfer if the dam has colostrum and the neonate stands and nurses within the first 2–4 hours.
- Only first milking colostrum should be fed to the newborn during the first 12 hours of life.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Septicemia, enteritis, diarrhea, omphalitis, arthritis, and respiratory disease

AGE-RELATED FACTORS
First 24–48 hours of life

BIOSECURITY
- Do not pool colostrum. Feed colostrum from an individual preselected dam to individual young stock.
- Minimize disease transfer via colostrum (e.g., Johne's disease, CAE, BLV) by preselecting negative dams.

PRODUCTION MANAGEMENT
- Young stock whose dam produces inadequate colostrum should be fed colostrum from a preselected donor.
- Frozen colostrum should be stored from individual donors, identified, and marked prior to freezing.
- Maintain a bank of frozen, high-quality colostrum for use in emergency situations.
- Feed young stock within 2 hours of birth and again within 12 hours of birth.

ABBREVIATIONS
- CAE = caprine arthritis encephalitis
- ELISA = enzyme-linked immunosorbent assay
- Fc = IgG1-specific Fc receptors
- IGF-1 = insulin-like growth factor-1
- IgG1 = immunoglobulin G1
- IL-2 = interleukin-2
- SRID = single radial immunodiffusion
- TNF = tumor necrosis factor

FATTY LIVER

BASICS

OVERVIEW

• Fatty liver is a pathologic fat accumulation resulting from high concentrations of blood NEFA, especially in cows with a high BCS or excessive abdominal fat at calving. Obesity occurs when dry cows are overfed during the prepartum period, or are dried off in an overconditioned state.
• Fatty liver is related to other diseases occurring during the postpartum period such as ketosis, RFM, metritis, hypocalcemia, and displaced abomasum.
• Fatty liver may be a slow, insidious process or may develop abruptly within 48 hours after parturition. Consequently, clinical signs may range from mild decreased milk production to sudden death in a few days post parturition.

INCIDENCE/PREVALENCE

In the United States, incidences ranging from 10% to 20% have been reported.

GEOGRAPHIC DISTRIBUTION

Worldwide

SYSTEMS AFFECTED

Multisystemic

PATHOPHYSIOLOGY

• At calving and beyond, catecholamines and glucagon are increased and insulin is reduced. As a result, hormone-sensitive lipase is activated. Particularly in cows with excessive body fat stores, a large amount of NEFA are released from the TG. This process continues during the postpartum period driven by the process of milk production and the low dry matter intake characterizing the early postpartum cow.
• The cow progresses to a negative energy balance during the postpartum period, which is a normal process. However, obese animals or cows experiencing other postpartum disease may experience a more severe fat mobilization.
• TGs are broken down and released as NEFA and glycerol, which are directed to the liver via the bloodstream.
• The liver of the cow takes up NEFA from the blood. Inside the hepatocyte, they are either oxidized to acetate or re-esterified to TG. If NEFA are in excess, re-esterification is the leading process. Because the bovine liver has a reduced capacity to synthesize and export back to the blood the excess of TG in the form of VLDL, the net result is the accumulation of TG in the cytosol of the cells. If this accumulation is profound, severe liver damage occurs.

HISTORICAL FINDINGS

• Obesity at calving ± history of overfeeding during the dry period.
• Concurrent postparturient disorders such as metritis, retained fetal membranes, milk fever, ketosis, and/or displaced abomasum.

SIGNALMENT

• Primarily high-producing dairy cows, particularly with high BCS at parturition.
• Heifers fed high-energy diets, thus calving while extremely obese, may experience severe fatty liver.
• May be individual animal case or a herd problem.
• Fatty liver has been commonly diagnosed in Holstein cattle; however, it has also been reported in Jersey, Guernsey, and Ayrshire breeds.

PHYSICAL EXAMINATION FINDINGS

Clinical signs are related to the degree of liver damage:
• Overcondition
• Anorexia
• Depression and weakness
• Decreased milk production
• Occasionally sudden death
• These signs can persist even after the levels of hepatic TG decrease back to baseline.

GENETICS

There are no heritability estimates for fatty liver. However, for the related diseases of ketosis and displaced abomasum, heritability estimates are low to moderate.

CAUSES AND RISK FACTORS

Risk factors for fatty liver are obesity at calving (>3.75/5), severe feed restriction during the prepartum close to calving, feeding excess energy during the entire dry period, and long calving intervals. During lactation, risk factors include periparturient disease, anorexia, ketogenic diets, sudden feed changes, dystocia, stress, and poor cow comfort.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Concurrent postpartum diseases
• Secondary differentials include other types of hepatitis such as toxic, infectious (salmonellosis and clostridiosis), parasitic (fluke), and miscellaneous (cholestasis, hepatic encephalopathy, and abscesses).

CBC/BIOCHEMISTRY/URINALYSIS

CBC

Changes may be nonspecific but frequently include leukopenia, neutropenia, lymphopenia, and a degenerative left shift. Fibrinogen, haptoglobin, and serum amyloid A may be increased.

Biochemistry

The common biochemical profiles are variable depending on the degree of liver damage.
• Marked increase: Glutamate dehydrogenase, γ-glutamyl transferase, aspartate aminotransferase, malondialdehyde, cholic acid, bile acids and bilirubin, albumin.
• Mild to moderate increase: Lactate dehydrogenase, sorbitol dehydrogenase, alkaline phosphatase, and ornithine carbamoyl transferase.
• Decrease: Albumin, α-tocopherol, VLDL, HDL, and LDL.

OTHER LABORATORY TESTS

• Increased NEFA, BHB, and acetoacetate
• Decreased glucagon, insulin, glucocorticoids, IGF-I, and thyroid hormones

IMAGING

Ultrasonography of the liver will show increased echogenicity and possibly enlargement depending on severity.

OTHER DIAGNOSTIC PROCEDURES

Liver biopsy is the definitive diagnostic test for fatty liver. The sample can be evaluated either chemically or histologically.

PATHOLOGIC FINDINGS

• On necropsy, the liver is enlarged with rounded edges, greasy to the touch, extremely friable, and has different degrees of yellow color depending on the amount of TG accumulated. In addition, excessive subcutaneous, abdominal, and omental fat can be observed. Other findings may be toxemia, metritis, RFM, mastitis, and displacement of abomasum.
• Histologic evaluation of liver biopsy shows fatty cysts in parenchyma, increased volume of hepatocytes, mitochondrial damage, and decreased volume of nuclei and other organelles.

TREATMENT

Treatment of fatty liver depends on the degree of fat infiltration, signs and origin of the problem.

THERAPEUTIC APPROACH

• Mild to moderate fatty liver can be challenging to diagnose. Consequently, treatments may be similar to those for preventing hepatic lipidosis.
• Stimulation of feed intake should be done by offering fresh, high-quality diets several times a day. Transfaunation of rumen fluid from healthy cows is complementary.
• Supportive therapy must aim to correct the negative energy balance, reduce fat mobilization, and promote carbohydrate metabolism. The use of feed additives such as ionophores (sodium monensin 300 mg per cow daily), gluconeogenic precursors such as glycerol (200 g/d), propylene glycol (300 g/d), calcium propionate (500 g/d), and vitamins such as protected choline (60 g/d) and niacin (12 g/d), protected methionine and chromium as Cr-methionine, both prepartum and postpartum are recommended.

FATTY LIVER (CONTINUED)

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Most treatments are aimed at controlling ketosis.
• Dextrose IV at 50%, 250–500 mL. Repeat for 3 days.
• Glucocorticoids (10–30 mg dexamethasone; 2–5 mg flumethasone, or 100–200 mg prednisolone). Be aware glucocorticoids also depress immunity.
• Glucagon SQ at 15 mg/day for 14 days.

CONTRAINDICATIONS
Appropriate milk and meat withdrawal times must be followed for all compounds. Corticoids in pregnant animals are contraindicated.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
The prognosis is very poor in severe and complicated cases of fatty liver. Early diagnosis and treatment of fatty liver and underlying health conditions will markedly improve the outcome.

CLIENT EDUCATION
See "Production Management"

PREVENTION
• The most effective tool for preventing fatty liver is to avoid an overconditioned dam at calving and to improve overall cow comfort and management. During lactation, the goal is to minimize the negative energy balance.
• Overall proper nutritional and feeding management during the entire transition period is a must.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Clinical signs and the fate of fatty liver are related to the degree of liver damage and to other calving-related disorders that may be simultaneously present.

AGE-RELATED FACTORS
Generally, animals in their second through fourth lactation; however, overconditioned heifers can be a real problem in certain herds.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
Prepartum fatty liver is likely and consequently it may affect the pregnancy status. In addition, fatty liver and ketosis may compromise further fertility of the current lactation.

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
Good transition cow management, in all areas, is imperative to preventing fatty liver. This includes nutrition, health, and facilities management. See chapter, Transition Cow Management (www.fiveminutevet.com/ruminant) for more information.

SYNONYM
Hepatic lipidosis

ABBREVIATIONS
• BCS = body condition score
• HDL = high density lipoprotein
• LDL = low density lipoprotein
• NEFA = non-esterified fatty acid
• RFM = retained fetal membranes
• TG = triglyceride
• VLDL = very low density lipoprotein

FESCUE TOXICITY

BASICS

OVERVIEW

• Tall fescue (*Festuca arundinacea*) is a cool season perennial grass grown worldwide.
• The grass itself is not the cause of toxicity, but rather an endophytic fungus that infects it, *Neotyphodium coenophialum* (endophyte-infected).
• *N. coenophialum* produces several ergot-type alkaloids, which cause the clinical signs associated with fescue toxicity.
• Three syndromes are seen in ruminants: fescue foot, summer slump, and fat necrosis.
• Another syndrome causing severe reproductive abnormalities in pregnant mares is seen less commonly in ruminants.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

• Tall fescue is a cool season perennial grass grown worldwide.
• Over 40 million acres of tall fescue are used for livestock grazing in the United States. Tall fescue is the predominant pasture grass east of the Mississippi River. Cases of fescue toxicity have been reported throughout the country.

SYSTEMS AFFECTED

• Cardiovascular
• Musculoskeletal
• Reproductive
• Hemolymphatic

PATHOPHYSIOLOGY

• *N. coenophialum* produces several ergot-type alkaloids, namely ergovaline, which are responsible for the clinical signs of fescue toxicity.
• Ergovaline acts as a D2 dopaminergic receptor agonist resulting in inhibition of prolactin secretion and imbalances of progesterone and estrogen.
• Decreased prolactin secretion causes reduced lactation or agalactia and also inhibits function of the hypothalamic thermoregulatory center.
• The toxin also causes peripheral vasoconstriction, resulting in inadequate blood flow to the extremities in cold weather and inhibited thermoregulatory capacity in hot weather.

SIGNALMENT

• This toxicosis affects cattle, sheep, and goats, as well as horses.
• All ruminant species are potentially affected.
• Any animal that is grazing or consuming fescue hay can be affected.
• Cases of exotic ruminants in zoos and wildlife parks have been reported.

PHYSICAL EXAMINATION FINDINGS

• Fescue foot:
  ◦ Signs usually develop within 10–14 days after being introduced to contaminated pasture in cool weather.
  ◦ Progressive lameness, particularly in rear limbs.
  ◦ Redness and swelling around coronary band.
  ◦ Cold extremities.
  ◦ Gangrenous necrosis of the distal limbs below the level of the pastern or fetlock.
  ◦ Tips of ears and switch of tail may also necrose.
  ◦ Affected animals are often underweight but remain alert.
• Summer slump:
  ◦ Period of poor production (decreased feed intake, growth, milk production) due to heat intolerance when the ambient temperature exceeds 75–80°F.
  ◦ Hirsutism, retention of winter coat.
  ◦ Elevated temperature and respiratory rate.
  ◦ Animals seek shade or wet spots and spend increased amounts of time lying down.
  ◦ Hypersalivation.
  ◦ Lowered reproductive performance: Delayed puberty; decreased conception and pregnancy rates.
• Fat necrosis:
  ◦ Most often an incidental finding at rectal palpation or on necropsy.
  ◦ When present, signs are related to obstruction of abdominal organs (e.g., bloat, colic).

CAUSES AND RISK FACTORS

• Consumption of tall fescue that is infected with *N. coenophialum.*
• The fungus has a symbiotic relationship with the fescue, providing insect resistance, drought tolerance, and increased nitrogen utilization to the plant.
• Noninfected varieties of tall fescue are available but they do not withstand extreme environmental conditions so well as the endophyte-infected varieties.
• *Neotyphodium coenophialum* is present within the seed and throughout the plant.
• Summer slump is seen in warm to hot ambient temperatures.
• Fescue foot is more commonly seen in cold ambient temperatures.
• Fescue foot follows introduction to contaminated pasture; cattle permanently pastured on the field are rarely affected.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Fescue foot:
  ◦ Ergot toxicosis/*Claviceps purpurea* toxicity
  ◦ Foot rot
  ◦ Frostbite
  ◦ Trauma
  ◦ Selenium toxicity
• Summer slump:
  ◦ Ergot toxicosis/*Claviceps purpurea* toxicity
  ◦ Heat stress
  ◦ Nutritional deficiencies
  ◦ Water deprivation
  ◦ Gastrointestinal parasitism
• Fat necrosis:
  ◦ Lymphosarcoma
  ◦ Intestinal obstruction

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER DIAGNOSTIC PROCEDURES

• High index of suspicion is provided by observation of classic clinical signs.
• History of consuming fescue (pasture or in hay).
• Clinical signs (with the exception of fat necrosis) may be indistinguishable from those of *Claviceps purpurea* toxicity. As the associated ergotoxins may also be present in tall fescue, a definitive diagnosis may not be achieved.
• Exclusion of other differentials for poor production (e.g., poor nutrition, parasitism) is recommended when summer slump is suspected.
• Microscopic examination of fescue for fungus; the fungus is found throughout the plant, including the seeds, stems, and leaf sheaths.

PATHOLOGIC FINDINGS

• All syndromes
  ◦ Poor body condition
  ◦ Rough hair coat
• Fescue foot: Gangrenous tissue on extremities, particularly rear limbs, with a line of demarcation from normal tissue.
• Fat necrosis: Presence of calcified fat in abdomen.
• Histologic lesions seen with fescue foot include vascular thrombosis, tissue necrosis in lower limbs.

TREATMENT

THERAPEUTIC APPROACH

• Removal from affected pasture or removal of contaminated hay.
• Early treatment of fescue foot with antibiotics and nursing care may be beneficial. Treatment is generally unrewarding after the onset of tissue necrosis.

MEDICATIONS

DRUGS OF CHOICE

Fescue foot: Broad-spectrum antibiotic therapy may be warranted for secondary bacterial infections.

FESCUE TOXICITY (CONTINUED)

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Gangrenous lesions associated with fescue foot are irreversible and are associated with a poor prognosis for return to production.

PREVENTION
• Avoid grazing fescue pastures when ambient temperature rises.
• Avoid grazing animals in heavy lactation or within 60 days of parturition in affected pastures when possible.
• Gradually introduce animals to fescue pastures by limiting time spent on pastures or by providing hay or alternate forage sources to limit intakes.

MISCELLANEOUS

ASSOCIATED CONDITIONS
• Reproductive effects of fescue toxicity are seen primarily in mares grazing affected pastures. Clinical signs of toxicity include agalactia, prolonged gestation, dystocia, and thickened or retained placenta.
• Classic ergotism, caused by *Claviceps purpurea* toxicity, can produce clinical signs identical to fescue foot and summer slump.

PREGNANCY
Toxicity less commonly results in complication of pregnancy in ruminants than in mares.

PRODUCTION MANAGEMENT
• Pasture dilution with clovers or other grasses can be used to control or limit fescue toxicity.
• Avoid overfertilization of tall fescue with nitrogen as this often precipitates endophyte growth and intoxication.
• Ammoniation of hay removes the toxicity.
• Nontoxic varieties of endophyte-infected fescue have been developed and appear to be hardier than noninfected fescue but with a much lower potential to cause the untoward effects seen with toxic endophyte-infected varieties.
• Recent research suggests that treatment of fescue or direct feeding of seaweed extract (*Ascophyllum nodosum*) may decrease the toxic effects of endophyte-infected fescue.

SYNONYMS
• Fescue foot
• Summer slump

FLOPPY KID SYNDROME

BASICS

OVERVIEW

• Floppy kid syndrome (FKS) is a type of acute-onset metabolic acidosis observed in 3- to 10-day-old goat kids and characterized by severe weakness and flaccid paresis.
• The syndrome was first documented in Canada in 1981, and was subsequently recognized in the United States and Europe.
• A major outbreak of FKS occurred in the mid-1990s in west Texas after introduction of the Boer goat and changes in husbandry related to this breed of goat.
• Although confirmation of FKS can be achieved by demonstrating metabolic acidosis on venous blood gas analysis, in the majority of cases, the diagnosis is established on the basis of clinical history, response to treatment, and necropsy findings in nonsurvivors.

INCIDENCE/PREVALENCE

• The incidence of FKS in a given herd varies from year to year.
• Morbidity can reach 10 to >50%.
• If untreated, mortality can be as high as 30–50% of affected kids.

GEOGRAPHIC DISTRIBUTION

The disease has been recognized in Canada, the United States and Europe.

SYSTEMS AFFECTED

Musculoskeletal

PATHOPHYSIOLOGY

• The exact cause of FKS is not well understood.
• Some infectious agents including *Clostridium botulinum*, *Escherichia coli*, *Cryptosporidium* and caprine herpes virus have been suspected as contributing to the syndrome but this has not been definitively confirmed.
• Clinical disease results from metabolic acidosis without dehydration.

HISTORICAL FINDINGS

• In affected herds, recent management changes are often reported which might include improving nutrition of the does prior to or during pregnancy, and greater confinement of doe-kid pairs.
• Affected kids usually have a history of normal birth and no signs of disease for the first few days of life.

SIGNALMENT

• Clinical signs of FKS appear in kids between 3 and 10 days after birth.
• There is no sex or breed predilection.

PHYSICAL EXAMINATION FINDINGS

• At 3–10 days of age, affected goat kids display severe depression, weakness, decreased muscle tone, somnolence, and flaccid tetraparesis without accompanying diarrhea, dehydration, or fever.
• Affected kids are generally presented in sternal or lateral recumbency with carpal flexion and inability to rise.
• Once clinical signs appear, affected kids are unable to suck but they can swallow.
• Abdominal distension is a commonly reported clinical sign in affected kids.
• The signs of depression and paralysis in affected kids can fluctuate in severity over minutes to hours, and affected kids can give the appearance of being dead. Spontaneous transient recovery can occur, often followed by a return to severe depression and coma.
• Affected animals that are not treated may die within a few days.
• Signs of aspiration pneumonia can accompany the condition in kids that are force-fed, due to aspiration of milk during inadequate suckling.

GENETICS

N/A

CAUSES AND RISK FACTORS

• Goat kids raised in pens, with continuous access to milk, are at high risk of FKS.
• Goat kids that are bottle-fed with excessive amounts of pasteurized or unpasteurized milk are also at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Diseases that cause weakness, recumbency, and/or abdominal distension should be considered including nutritional myopathy (vitamin E/selenium deficiency), abomasal bloat, neonatal septicemia, colibacillosis, enterotoxemia (pulpy kidney disease), and enzootic ataxia (copper deficiency).

CBC/BIOCHEMISTRY/URINALYSIS

• All affected animals have metabolic acidosis.
• Floppy kids have a significantly larger anion gap than healthy kids (31.2 ± 3.7 versus 21.5 ± 8.5 mM); decreased serum bicarbonate, normal to increased chloride, and occasional hypokalemia.
• The concentration of L-lactate is lower in floppy kids than in healthy kids (0.67 ± 0.49 versus 1.60 ± 1.02 mM), but the concentration of D-lactate is higher in floppy kids (7.43 ± 2.71 versus 0.26 ± 0.24 mM in healthy kids).
• The serum concentration of urea is increased in goat kids with FKS.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

• The most characteristic gross lesion found in affected kids is a severely distended abomasum that is full of coagulated milk with a very strong acid smell.
• Some affected kids have evidence of secondary bacterial or aspiration pneumonia.
• There are no characteristic microscopic findings in goat kids affected with FKS.

TREATMENT

THERAPEUTIC APPROACH

• Recognition of the disease during the early stages with adjustment of base deficits and provision of good supportive care are critical.
• Under ideal conditions affected kids should be treated with isotonic sodium bicarbonate solution intravenously, sufficient to replace the calculated base deficit determined as body weight (kg) × 0.5 × base deficit, and delivered over 1–3 hours.
• Administration of intravenous fluids can result in dramatic clinical improvement.
• Alternatively, affected kids can be denied milk for 24–36 hours, and administered a solution of sodium bicarbonate using one teaspoon of baking soda dissolved in one cup of water and delivering 10–20 mL of this solution orally at 2- to 3-hour intervals.
• When treatment is initiated early, most kids will show clear improvement within 6–10 hours. Treated kids first become more active and will initially pass very solid feces that subsequently turn into diarrhea.
• Diarrhea is usually self-limiting and considered a positive indication of returning GI peristalsis.

SURGICAL CONSIDERATIONS AND TECHNIQUES

N/A

MEDICATIONS

DRUGS OF CHOICE

• The condition does not seem to respond to antibiotics; however, administration of broad-spectrum antibiotics can be used to prevent secondary bacterial infections, particularly pneumonia.
• Vitamin E and selenium should be supplemented if inadequate.

CONTRAINDICATIONS

N/A

PRECAUTIONS

• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
• Because the clinical appearance is that of very weak animals "lacking energy," most producers try to solve the problem by force feeding affected kids. This exacerbates disease since it seems to result from overconsumption

FLOPPY KID SYNDROME (CONTINUED)

of milk, and increases the potential for GI distension, bloat, and aspiration.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Affected kids treated early during the course of the disease generally recover.

POSSIBLE COMPLICATIONS
Secondary bacterial infections and/or pneumonia, the latter resulting from aspiration of milk when kids are bottle fed, are common.

CLIENT EDUCATION
Early recognition and treatment of this condition are critical to optimize successful recovery.

PATIENT CARE
After 36 hours of treatment and monitoring, affected kids can be placed back with their dams. Kids that are rejected after treatment will need to be raised on a milk substitute.

PREVENTION
- Can be attempted by managing factors that promote the overconsumption of milk.
- In dairy goat herds, does should be milked before putting them back with the kids. In meat or Angora goats this is difficult to accomplish.
- Hand-raised kids should be provided appropriate amounts of cool milk or milk substitutes more frequently, to avoid gorging.
- When environmental conditions allow, it is better to allow does to kid on pasture. The constant movement of does under pasture conditions prevents kids from ingesting large quantities of milk in a short time. Kids that are kept constantly penned with their dams often suck frequently, leading to overconsumption of milk.
- FKS has been prevented by separating kids from does and raising them on bovine colostrum/milk.

MISCELLANEOUS

ASSOCIATED CONDITIONS
N/A

AGE-RELATED FACTORS
Most affected goat kids are 3–10 days old at the time of clinical onset.

ZOONOTIC POTENTIAL

FLUID THERAPY: INTRAVENOUS

BASICS

OVERVIEW

• Intravenous fluid therapy is indicated when patients are severely dehydrated or unable or unwilling to ingest oral fluids.
• General goals are to replace fluid and electrolyte deficits and meet ongoing needs and losses.

SYSTEMS AFFECTED

Hemolymphatic

SIGNALMENT

All ruminant species

PHYSICAL EXAMINATION FINDINGS

• The degree of patient dehydration is typically determined by physical examination.
• Skin turgor and elasticity, position of the eye within the orbit, tenacity of mucus within the oral cavity, capillary refill time, and patient demeanor are all indicators of patient hydration status.
• As a general rule of thumb, fluid deficits <6% of body weight cannot be detected on clinical examination and deficits >12% of body weight are fatal. Table 1 summarizes expected clinical signs of dehydration in cattle.
• Clinical demeanor also has been associated with acid-base status in neonatal calves with diarrhea.
• Table 2 summarizes expected base deficits in calves of varying ages. It should be emphasized that this information is relevant only in neonatal calves with primary uncomplicated gastrointestinal disease.
• Calves with septicemia will have highly variable acid-base status. Furthermore, these rules of thumb are not appropriate in adult ruminants.
• Under ideal circumstances, fluid and electrolyte disorders are confirmed by inexpensive, minimally invasive laboratory procedures (see "CBC/Biochemistry/Urinalysis").

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS

• Hematocrit and serum protein concentration are readily determined in most veterinary practices.
• These procedures are useful adjuncts to physical examination in confirming the presence of dehydration.
• Serum chemistry analyzers suitable for clinic and ambulatory practice are becoming more common.
• Although panel composition varies with instrument and test kit, patient-side confirmation of azotemia, acid-base status, and serum calcium and potassium is now possible. It should be noted that many of these instruments have not been validated for use in ruminants; however, most practitioners find them useful adjuncts in the development of fluid therapy protocols.

TREATMENT

THERAPEUTIC APPROACH

General Rules

1. Oral fluids are generally preferred unless medically contraindicated. Oral fluids are inexpensive and safe and can be administered rapidly in field conditions.
2. Hypoglycemia is rare in adult ruminants, but occurs occasionally in neonates. Diseases of adult ruminants, which result in hypoglycemia, include fatty liver, ketosis, and pregnancy toxemia.
3. Mild hypocalcemia is common in anorectic adult cattle.
4. Mild metabolic alkalosis is common and expected in anorectic adult cattle.
5. Metabolic alkalosis and increased serum concentrations of albumin may decrease serum-ionized calcium. Metabolic acidosis and hypoalbuminemia may increase serum-ionized calcium. Many laboratories measure total calcium; however, animals recognize and regulate serum-ionized calcium. Correction factors developed for companion animals are inaccurate in ruminants.
6. Sodium bicarbonate administration is appropriate only for correction of metabolic acidosis. Metabolic acidosis is common in neonates with diarrhea, grain engorgement, and salivary loss, but rare in most other conditions of ruminants.
7. Maximum short-term IV fluid administration rates should not exceed 80–90 mL/kg/h (20 mL/kg/h in llamas).
8. Maximum long-term IV fluid administration rates for cattle should not exceed 20 mL/kg/h.
9. Hypokalemia is common in anorectic adult cattle.
10. Neonates with diarrhea often have hyperkalemia (increased serum potassium concentrations); however, body stores of potassium (intracellular potassium) are often very low.

Table 1

Assessing Hydration Status in Ruminants

% Dehydration	*Demeanor*	*Sunken Eye*	*Skin Tenting*
<6%	Normal	–	–
6–8%	Depressed	+	+/–
8–10%	Depressed	++	2–5 sec
10–12%	Comatose	+++	5–10 sec
>12%	Dead	++++	>10 sec

Table 2

Estimating Base Deficit (mmol/L) in Calves of Various Ages with Diarrhea

Calf Demeanor	*≤8 days*	*≥8 days*
Bright, alert, ambulatory	0	5
Depressed, stands only with assistance	5	10
Unable to stand, suckling reflex intact	10	15
Comatose, suckling reflex absent	10	20

FLUID THERAPY: INTRAVENOUS (CONTINUED)

11. Potassium administration rates should not exceed 0.5 mmol/kg/h unless the patient is severely hypokalemic, or glucose and/or bicarbonate are administered concurrently. Glucose and bicarbonate administration will cause extracellular potassium to shift to the intracellular space.
12. Near isotonic (300 mOsm/L) fluids should be used under most conditions.
13. Fluid deficit is generally calculated as follows: Body weight (kg) × (% dehydration/100) = deficit (L).
14. Estimates of daily maintenance requirements vary from 60 to 120 mL/kg/day, depending on severity of ongoing losses (diarrhea, renal losses). The values above include ongoing losses. Maintenance requirements are calculated as follows: Body weight (kg) × [(60–120 mL/kg/day)/1,000 mL/kg] = requirement (L).
15. Total daily fluid needs are calculated by adding deficits and daily maintenance requirements.
16. Base deficit is typically calculated as follows: Body weight (kg) × [measured deficit (mmol/L)] × [bicarbonate space]. Bicarbonate space is typically estimated as 0.5–0.6 in cattle. Bicarbonate replacement is used to replace 50–100% of base deficit. Higher percentages of deficit replacement, approaching 100%, are appropriate in neonates with diarrhea.
17. The core electrolyte abnormalities in calves with diarrhea include dehydration, acidosis, low systemic potassium with serum hyperkalemia due to acidosis, and hypoglycemia.
18. Isotonic = 300 mOsm/L. Isotonic sodium bicarbonate = 1.3% = 1.3 g/100mL = 13 g/L. Isotonic sodium chloride = 0.9% = 0.9 g/100 mL = 9 g/L.
19. Do not withhold milk from calves with diarrhea. Do not feed beef calves more than 1 L/feeding. Beef calves are acclimated to small, frequent meals.
20. Oral fluids are probably adequate in mildly dehydrated calves (≤8%). Severely dehydrated calves probably require at least short-term intravenous fluids.

Clinical Approach

In general, fluid therapy can be reduced to the following set of questions:
1. What is the fluid deficit?
2. What is the daily maintenance requirement for fluids?
3. What will the total fluid needs be over the next 24 hours?
4. What is the base deficit?
5. What volume of isotonic sodium bicarbonate will replace this deficit?
6. How would you prepare this volume of isotonic sodium bicarbonate solution?
7. What is the maximum rate of fluid administration in the first hour?
8. How much 50% dextrose will we add to the first hour's fluids to create a 1% solution?
9. What is the theoretical maximum concentration of potassium for fluids administered in the first hour of therapy?
10. Based on the above answers, design a fluid therapy protocol for the patient.

Example

You are examining a 50-kg Holstein heifer calf with profuse diarrhea. The calf is 15 days old. On physical examination, the calf is severely dehydrated (estimate 10%) and is comatose.

1. **What is the calf's fluid deficit?**
Body weight (kg) × (% dehydration)/100 = 50 kg × 10/100 = 5 L
2. **What is the calf's daily maintenance requirement for fluids?**
Body weight (kg) × 100 mL/kg = 50 kg × 100 mL/kg = 5,000 mL = 5 L
3. **What will the calf's total fluid needs be over the next 24 hours?**
Deficit + Maintenance = 5 L + 5 L = 10 L
4. **What is the calf's base deficit?**
Body weight (kg) × (estimated base deficit) × bicarbonate space = base deficit. Estimated deficit based on the calf's demeanor (comatose) and age (>8 days) is 20 mmol/L, so 50 kg × 20 mmol/L × 0.6 = 600 mmol HCO_3^-.
Alternatively, base deficit can be calculated from measured blood bicarbonate. For purposes of this calculation, we will assume the calf has a pure metabolic acidosis and serum bicarbonate of 5 mmol/L, and that normal is 25 mmol/L.
Body weight (kg) × (normal bicarbonate minus measured bicarbonate) × 0.6 = 50 kg × (25 – 5) × 0.6 = 600 mmol/L HCO_3^-
5. **What volume of isotonic sodium bicarbonate (1.3%) will replace this deficit?**
Each liter of an isotonic solution has 300 mOsm/L. In the case of isotonic sodium bicarbonate, half the particles in solution are Na^+ and half are HCO_3^-. Therefore, each liter of isotonic sodium bicarbonate contains 150 mmol/L of HCO_3^-. [Calculated deficit (mmol)]/150 mmol/L = [600]/150 = 4 L 1.3% sodium bicarbonate ($NaHCO_3$)
6. **How would you prepare this volume of isotonic sodium bicarbonate solution?**
1.3% = 1.3 g/100 mL = 13 g/L. Volumes required × 13 g/L = 4 L × 13 g/L = 52 g $NaHCO_3$ in 4 L sterile water It is important that base deficit be corrected using isotonic solutions.
7. **What is the maximum rate of fluid administration in this calf for the first hour?**
Calves may be administered as much as 40–80 mL/kg during the first hour of therapy without creating an inordinate risk of pulmonary edema. Thereafter, administration rates should be reduced to maintenance fluid rates, which in calves is approximately 4 mL/kg/h. If ongoing losses are great, fluid rates may remain higher but should not exceed 20 mL/kg/h. Body weight (kg) × 80 mL/kg/h = 50 kg × 80 mL/kg/h = 4,000 mL = 4 L
8. **How much 50% dextrose will we add to the first hour's fluids to create a 1% solution?**
We desire a 1% dextrose solution. Standard solutions, which we carry in our truck, are 50% solutions. Consequently, we will need to make a 1:50 dilution to create a 1% solution. 1 L = 1,000 mL, 1,000 mL/50 = 20 mL. Therefore, we add 20 mL of 50% dextrose to each of the 4 L we administer in the first hour. Remember, not all calves with diarrhea are hypoglycemic and excessive glucose supplementation will cause serum glucose to exceed the renal threshold, causing an osmotic diuresis, an undesirable effect in a dehydrated patient.
9. **What is the theoretical maximum concentration of potassium for fluids administered in the first hour of therapy?**
Generally, we limit potassium administration to a maximum of 0.5 mmol/kg/h. (Body weight (kg) × 0.5 mmol/kg)/volume administered, so (50 × 0.5)/4 = 6.25 mEq/L. Having performed this calculation, we recognize that the concurrent administration of bicarbonate and glucose will cause potassium to move intracellularly, resulting in a precipitous decline in serum potassium. Consequently, we will typically administer 8 to 12 mmol/L potassium in bicarbonate-containing fluids.
10. **Based on the above answers, we design a fluid therapy protocol for a calf.**
Obviously, these are not exact calculations. Here is a rough plan.
a. Hour 1: 4 L isotonic sodium bicarbonate, each liter supplemented with 10 mmol K/L. Each of the first 2 L is supplemented with 20 mL 50% dextrose.
b. Hour 2: 2 L of a commercially available oral electrolyte solution (total volume 6 liters).
c. Hour 8: 2 L whole milk (total volume 8 liters).
d. Hour 14: 2 L of a commercially available oral electrolyte solution (total volume 10 liters).
If the calf is readily nursing, alternate oral electrolytes and milk at 6-hour intervals. If hydration appears normal, one or both daily electrolyte feedings may be discontinued. Do not use stool characteristics as criteria for administration of milk.

FOLLOW-UP

In animals receiving extensive fluid therapy, the need to reassess hydration and acid-base status at frequent intervals should be considered.

(CONTINUED) FLUID THERAPY: INTRAVENOUS

MISCELLANEOUS

• Many practitioners use hypertonic fluids. These solutions can be rapidly administered in an ambulatory setting.
• As general rule, 7–8% sodium chloride solution is administered at a rate of 5 mL/kg IV.
• When using such protocols, oral fluids should be provided or administered.

ABBREVIATIONS

• IV = intravenous
• $NaHCO_3$ = sodium bicarbonate

FLUID THERAPY: ORAL

BASICS

OVERVIEW
• Oral fluid therapy is a practical and economical approach in ruminants with mild to moderate dehydration or electrolyte and acid-base imbalances.
• Intravenous (IV) fluid therapy is indicated in ruminants with hypovolemia or severe electrolyte or acid-base imbalances.
• Oral fluid therapy can often be used in conjunction with IV fluid therapy.
• Fluid therapy can be beneficial and life-saving and should be considered as important as other medications in the management of ill ruminants.

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
N/A

SYSTEMS AFFECTED
• Multisystemic

PATHOPHYSIOLOGY
• Daily maintenance water requirement is about 6% of body weight (BW) in adults and 8% of BW in neonates, and varies with activity level, ambient and body temperatures, and physiologic status (lactation, pregnancy).
• Dehydration is defined as a decrease in total body water and usually leads to a decrease in extracellular fluid volume.
• Extracellular fluid is distributed between interstitial and intravascular fluid compartments.
• Hypovolemia is defined as a decrease in intravascular fluid volume and leads to decreased cardiac output and tissue perfusion.
• The rumen acts as a water reservoir in adults, but can also be a site of fluid sequestration in GI disorders such as grain overload or vagal indigestion.

HISTORICAL FINDINGS
• Lack of access to palatable water
• Evidence of body fluid losses including diarrhea, polyuria, sweating, and prolonged tachypnea.

SIGNALMENT
N/A

PHYSICAL EXAMINATION FINDINGS
• Dehydration can be estimated by assessing skin elasticity, mucus membranes, capillary refill time (CRT), and eyeball recession (degree of enophthalmos) (see Table 1).
• Enophthalmos can also be caused by emaciation and decreased skin elasticity can be normal in geriatric ruminants.

Table 1

Assessing Hydration in Ruminants

Dehydration (% of BW)	*Skin tent (seconds)*	*Mucus membranes*	*CRT (seconds)*	*Enophthalmos (mm)*
Mild (5–7)	2–5	moist	<2	2–3
Moderate (8–10)	6–7	tacky	2–4	4–6
Severe (>10)	>7	dry	≥5	7–8

• Signs of hypovolemia include tachycardia, pale mucus membranes, prolonged CRT, cold extremities, weak peripheral pulses, obtundation, and reduced jugular fill.
• Bradycardia can be caused by hypothermia, hypoglycemia, or hyperkalemia.
• Cardiac arrhythmias are usually caused by severe hyperkalemia in neonates and upper GI obstruction in adults.
• Sucking reflex and body position can aid in assessing metabolic acidosis in calves with diarrhea (see Tables 2 and 3).

GENETICS
N/A

CAUSES AND RISK FACTORS
• Dehydration is usually caused by reduced water intake and/or excessive loss or sequestration of body fluids.
• Common causes of excessive loss or sequestration of body fluids include diarrhea, polyuria, heat stress, upper GI obstruction or stasis, and grain overload.
• Common causes of upper GI obstruction include abomasal displacement or volvulus, vagal indigestion, and intestinal volvulus or intussusception.
• Common causes of reduced water intake include lack of access to palatable water, esophageal obstruction, and dysphagia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
N/A

CBC/BIOCHEMISTRY/URINALYSIS
• Serum biochemistry and blood gas analyses are indicated in critically ill ruminants to evaluate and monitor electrolyte and acid-base imbalances.
• Diarrhea is often associated with hypoglycemia, hyponatremia, hypochloremia, hyperkalemia, and metabolic acidosis in neonates.
• Upper GI obstruction is often associated with hypokalemia, hypochloremia, hyponatremia, hypocalcemia, and metabolic alkalosis in adults.
• Grain overload is often associated with azotemia, hyperphosphatemia, hypocalcemia, and metabolic acidosis.

TREATMENT

THERAPEUTIC APPROACH
• Total volume of fluids to administer should account for dehydration, maintenance daily water requirement, and losses through GI, urinary, or respiratory tracts.
• Volume of fluids required to correct dehydration can be calculated as follows:
  ◦ Volume (L) = BW (kg) × dehydration (%).
• Daily maintenance requirement is about 6% of BW in adults and 8% of BW in neonates
  ◦ Volume (L) = BW (kg) × maintenance requirement (%).
• Ongoing losses are usually estimated (1–4 L per day in calves with diarrhea).
• For example, a 40-kg calf with severe dehydration (10%) and diarrhea (1L per day) should receive over 24 hours:
  ◦ Volume (L) = 40 × 0.1 + 40 × 0.08 + 1 = 8.2
• Volume should not exceed 5% of BW per oral administration:
  ◦ Volume (L) = BW (kg) × 0.05.
• For example, a 40-kg calf can be given safely 2L of oral fluids at one time.
• Neonates with a strong sucking reflex can be offered oral fluids via nipple bottle.
• Drenching syringes can be used in small ruminants and camelids to administer small volumes of oral fluids.
• Care must be taken in recumbent or weak animals due to increased risk of aspiration.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE

Oral Fluid Therapy in Neonatal Ruminants
• Alkalinizing fluids are indicated in calves with metabolic acidosis
  ◦ 13 g $NaHCO_3$ + 1L water
  ◦ 150 mL 8.4% $NaHCO_3$ + 1L water
• Amount of bicarbonate required to correct metabolic acidosis in neonates can be calculated as follows:
  ◦ HCO_3^- (mEq) = BW (kg) x base deficit (mmol/L) × 0.6
• Base deficit can be estimated from clinical signs or calculated using blood gas results as follows:
  ◦ Base deficit (mmol/L) = 30 – (T_{CO2})
• Amount of sodium bicarbonate to administer can be calculated knowing that 1mL 8.4% $NaHCO_3$ contains 1mEq HCO_3^- and 1g $NaHCO_3$ contains 12mEq HCO_3^-
• Commercial electrolyte solutions containing 50–80 mmol/L of acetate, propionate, or citrate can also be used to treat calves with metabolic acidosis.
• Bicarbonate has a direct alkalinizing effect compared to acetate, proprionate, and citrate, and may have a more rapid and profound effect.
• As opposed to bicarbonate, acetate and propionate can be administered with milk and facilitate sodium and water intestinal absorption.
• Commercial electrolyte solutions should contain 90–130 mmol/L of sodium and 40–80 mmol/L of chloride.
• Electrolyte feedings should not replace milk feedings but be given in addition to them to provide adequate fluid and energy intake.
• Diarrheic calves should ideally be offered small feedings of milk 3–4 times a day.
• Calves that are not interested in nursing can be given an electrolyte solution rich in glucose instead of milk.

Oral Fluid Therapy in Adults
• Acidifying fluids are indicated in adults with metabolic alkalosis
  ◦ 180g NaCl + 20L water
  ◦ 140g NaCl + 50g KCl + 10g $CaCl_2$ + 20L water
  ◦ 2.5L 7.2% NaCl + 20L water
• Alkalinizing fluids are indicated in adults with metabolic acidosis
  ◦ 250 g $NaHCO_3$ + 20L water
• Amount of bicarbonate required to correct metabolic acidosis in adults can be calculated as follows:
  ◦ HCO_3^- (mEq) = BW (kg) × base deficit (mmol/L) × 0.3
• Addition of calcium to the fluids is indicated in ruminants with hypocalcemia (<2 mmol/L)
  ◦ 500mL of calcium 23% solution per 20L of oral fluids
• Oral administration of KCl is indicated in ruminants with severe hypokalemia (<2.5 mmol/L)
  ◦ 10-20 g KCl per 100 kg of BW q8-12h
• Oral administration of phosphate salts is indicated in ruminants with severe hypophosphatemia (<0.5 mmol/L)
  ◦ 150–200 g NaH_2PO_4 for an adult cow

CONTRAINDICATIONS
• Commercial solutions containing more than 40 mmol/L of bicarbonate or citrate are likely to interfere with milk clotting
• Commercial electrolyte solutions intended to be mixed with hundreds of liters of water are not suitable for diarrheic calves as they are too dilute.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Rapid reversal of hypovolemia is expected after administration of IV fluids in ruminants with severe dehydration.
• Maintenance fluid requirements and ongoing losses can be addressed with oral fluids once hypovolemia has been corrected.
• Correction of dehydration and restoration of the renal function may address mild electrolyte or acid-base imbalances.
• Diarrheic calves with concurrent infections usually have a poor prognosis.

POSSIBLE COMPLICATIONS
• Careful thoracic auscultation is essential to identify ruminants at risk for fluid overload.
• Oral fluids with high osmolality (>650 mOsm/L) can cause reduced abomasal emptying and abomasal bloat in calves.
• Commercial electrolyte solutions do not always have an energy source, and therefore neonates should not be held off milk for more than 24 hours.

CLIENT EDUCATION
• Clients administering oral fluids via esophageal feeder or orogastric tube should be trained to prevent complications

PATIENT CARE
• Mentation, heart rate, CRT, mucus membranes, extremity temperature, peripheral pulses, and jugular fill should be monitored.
• Urine output and urine specific gravity can be used to monitor hydration and renal function.
• PCV and total solids can be used to monitor hydration and prevent fluid overload, especially in calves, small ruminants, and camelids.
• Blood lactate and blood gas analysis can be used to monitor tissue perfusion and electrolyte and acid-base imbalances.
• Blood glucose monitoring is often indicated in neonates, camelids, and ruminants with pregnancy toxemia.

PREVENTION
• Colostrum management is essential to reduce the incidence of neonatal diarrhea in ruminants.
• Incidence of GI disorders in adult ruminants can be decreased by improving

FLUID THERAPY: ORAL (CONTINUED)

overall herd management, specifically feeding management, and biosecurity measures to decrease enteric pathogens.

MISCELLANEOUS

ASSOCIATED CONDITIONS

• Neonates with diarrhea should be examined carefully for signs of concurrent infections including omphalitis, otitis, arthritis, and pneumonia.

ABBREVIATIONS

• BW = body weight
• $CaCl_2$ = calcium chloride
• CRT = capillary refill time
• GI = gastrointestinal
• HCO_3^- = bicarbonate
• IV = intravenous
• KCl = potassium chloride
• mEq = milliequivalent
• NaCl = sodium chloride
• $NaHCO_3$ = sodium bicarbonate
• NaH_2PO_4 = monosodium phosphate
• PCV = packed cell volume
• T_{CO2} = total carbon dioxide

FLUORIDE TOXICITY

BASICS

OVERVIEW
• Fluoride (F^-) is absorbed by the gastrointestinal tract and lungs depending on the form.
• Clinical signs associated with chronic F^- exposure are manifest primarily in skeletal and dental abnormalities and may take months to years to become apparent depending on the solubility of the fluoride compound, amount of F^- absorbed, and duration of exposure.

INCIDENCE/PREVALENCE
Usually chronic and can affect large percentage of the herd. Occurs in areas with fluoride emissions or contamination.

GEOGRAPHIC DISTRIBUTION
Occurs in areas with high levels of fluorides in the soil, water or air.

SYSTEMS AFFECTED
• Cardiovascular
• Digestive
• Mammary
• Musculoskeletal
• Nervous

PATHOPHYSIOLOGY
• Exposure to fluorides delays and alters mineralization by replacing hydroxyapatite in the crystalline structure of bone and mostly affects the matrices supporting formation of enamel, dentine, cementum, and bone. Teeth are affected during development due to damage from the failure to accept minerals normally. Skeletal fluorosis interferes with formation of adequate matrix and mineralization by osteoblasts, resulting in a dysfunction of normal sequences of osteogenesis, acceleration of bone remodeling, production of abnormal bone (exostosis, sclerosis).
• Effects of fluorosis may include brittle bones, calcification of ligaments, and joint pain.
• Fluorosis in cattle has been associated with lameness and spontaneous fractures.
• Chronic fluorosis is commonly due to ingestion of mineral supplements with high F^- content or consumption of contaminated forage and water by industrial emissions containing F^-.
• Acute toxicity is rare but may result from inhalation of gases containing fluoride or ingestion of highly toxic rodenticides containing fluoride. In acute cases, clinical signs are referable to the nervous system and death results from respiratory or cardiac failure. These acute symptoms are the result of a direct effect on serum calcium.

SIGNALMENT
All ruminant species are susceptible. Dairy cattle are considered more at risk of chronic toxicity due to their longer lifetime in production. There is no breed, sex predilection, or genetic basis for fluorosis.

PHYSICAL EXAMINATION FINDINGS
• Dental abnormalities occur only if animals are exposed during permanent tooth development prior to eruption and include dullness, mottling, pitting, and discoloration of tooth enamel, and abnormal tooth wear and loss, particularly in pairs of teeth that erupt at the same time.
• Dental problems may result in decreased feed and water intake, difficulty with mastication, weight loss, and general unthriftiness.
• Other clinical signs include decreased milk production and skeletal abnormalities; lameness, arthritis, fractures of the pedal bones; bilateral enlargement and roughening of metatarsals, metacarpals, ribs, and mandible; and abnormal hoof wear resulting from altered gait with elongated toe, especially on hind feet.

CAUSES AND RISK FACTORS
• >40–100 mg F^-/kg feed cattle, >60 mg F^-/kg feed ewes, >150 mg F^-/kg feed lambs.
• Rock phosphate deposits, nondefluorinated or inadequately defluorinated mineral supplements, monoammonium, diammonium, and gypsum phosphate fertilizers or other sources of phosphorus containing <100:1 parts phosphorus to fluoride, contaminated forage and water from industrial aerial emissions, deep well and thermal spring water, fluorinated municipal water, sewage effluent from municipalities using fluorinated water, forage and water contamination by volcanic gas and ash pose a risk.
• Forage usually has a low level of fluoride but levels are variable and should be considered.
• A calcium-deficient diet may increase F^- accumulation. Animals in poor body condition may be more susceptible.
• Rodenticides containing sodium monofluoroacetate (1080) or fluoroacetamide are highly toxic and may account for acute toxicity. Due to the highly lethal nature of these compounds, their use is restricted in the United States.
• Fluoride absorption is related to solubility; sodium fluoride > rock phosphate > dicalcium phosphate > defluorinated phosphate.

DIAGNOSIS

Clinical signs, history of exposure/mineral supplementation, radiography, and feed/bone/urine F^- levels.

DIFFERENTIAL DIAGNOSES
Arthritis; osteoporosis; deficiencies in calcium, phosporus, or vitamin D; traumatic injury

CBC/BIOCHEMISTRY/URINALYSIS
Eosinophilia, anemia, hypoglycemia, increased ALP. F^- can be detected in urine.

OTHER LABORATORY TESTS
• F^-, Ca^{2+}, P concentrations in forage, mineral supplements, soil, and water
• F^- content in bone (normal content will vary with bone selected), antler, kidney, serum
• >10 ppm F^- in urine
• T4, T3 hypothyroidism

IMAGING
Radiography: periosteal hyperostosis, exostosis, sclerosis in metacarpals, metatarsal, mandible, and ribs

PATHOLOGIC FINDINGS
• Gross—teeth: pitting, discoloration, chalkiness of enamel, irregular wear, and tooth loss
• Skeletal—exostoses, sclerosis, arthritis, stunted growth
• Histopathologic—abnormal remodeling of bone, atrophy of osteoblasts and bone marrow cells, retardation of cartilage cell differentiation

TREATMENT

THERAPEUTIC APPROACH
Remove from source. Treatment is symptomatic and supportive. Provide feeds that are easily masticated, symptomatic treatment for osteoarthritis/lameness.

MEDICATIONS

DRUGS OF CHOICE
None

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
In mild cases, improvement may be seen over weeks to months as fluoride body stores are depleted. In severe cases of lameness or inability to consume adequate forage, euthanasia may be required as some bony lesions are irreversible.

PREVENTION
• Aluminun sulfate, aluminum chloride, calcium aluminate, and calcium carbonate reduce absorption of fluorides.
• Use only feed-grade sources of phosphorus supplements.

FLUORIDE TOXICITY (CONTINUED)

MISCELLANEOUS

AGE-RELATED FACTORS
Young animals with growing bones are most severely affected. Exposure of adult animals will result in normal dentition with skeletal lesions.

PREGNANCY
Congenital fluorosis has been reported in calves born to fluoride-intoxicated cows.

ABBREVIATIONS
- ALP = alkaline phosphatase
- Ca^{2+} = calcium
- F = fluoride
- P = phosphorus
- ppm = parts per million

SEE ALSO

FOOT AND MOUTH DISEASE

BASICS

OVERVIEW
Foot-and-mouth disease (FMD) is a highly contagious viral disease of cloven-footed domestic and wild animals. The disease is characterized by fever and vesicular lesions in the mouth, tongue, nostrils, feet, and teats. Sheep and goats are maintenance hosts showing very mild signs while pigs are amplifying hosts as they produce extremely high concentrations of virus particle in aerosols. Cattle are indicators of this disease as they generally are the first species to show signs of infection; the lesions are more severe and progress more rapidly than in other animals.

INCIDENCE/PREVALENCE
Morbidity reaches to almost 100% in susceptible populations. Mortality usually ranges from 1% to 5%, although may be higher in young animals.

GEOGRAPHIC DISTRIBUTION
FMD is a transboundary animal disease distributed worldwide. Various types of FMDV have been identified in Asia, Africa, and South America. Chile, North Central America, Australia, and New Zealand have been free of FMD for many years.

SYSTEMS AFFECTED
- Integument
- Respiratory
- Reproductive
- Cardiovascular
- Urinary

PATHOPHYSIOLOGY
- FMD virus usually enters the host via the respiratory and oral route.
- Infected animals secrete virus in all the secretions, so contact and consumption of animal products such as meat, milk, bones, glands, and cheese can spread the disease.
- Incubation time of the virus is in the range 2–14 days depending on the susceptibility of the host and infecting dose. Clinical signs generally develop in 3–5 days.
- Diseased animals usually recover in 1–3 weeks. Skin lesions usually heal in 7 days after recovery but secondary bacterial infection may complicate the healing process.

SIGNALMENT
- Predominant in cattle, pigs, sheep, goats, water buffalo, deer, elk, bison, antelopes, and wildebeest.
- Other susceptible animals include elephants, nutrias, armadillos, reindeer, mouse, antelopes, chamois, gazelles, impala, giraffe, and hedgehogs and may serve as sources of transmission to ruminants.
- South American camelids are less susceptible to FMDV, whereas camels are resistant to natural infection.

GENETICS
Genetic variation as a predisposing factor of FMD within the same species has not been well documented but, in experimental infection, susceptibility differed within the species. High-yielding European breeds are also found to be more susceptible than low-yielding Asian breeds.

PHYSICAL EXAMINATION FINDINGS
- Best-known signs of FMD are fever together with vesicles (blisters) in the mouth, nares, muzzle, hooves, and teats which progress to erosions and sloughing, leading to lameness and anorexia.
- Sticky, foamy, and stringy drooling saliva from the mouth, serous nasal discharge, and decreased milk production.
- Young animals may die without clinical signs and abortion occurs in pregnant animals.

CAUSES AND RISK FACTORS
- FMD is caused by *Aphthovirus* belonging to the Picornaviridae family. Various strains have been identified under seven immunologically and serologically distinct types: O, A, C, Southern African Territories (SAT)-1, SAT-2, SAT-3, and Asia-1. Immunity to one type or subtype does not confer immunity against other types and subtypes.
- Risk factors include naïve population exposed to exotic serotypes, unvaccinated population in endemic areas, poor biosecurity, and feeding contaminated feed to susceptible animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
The disease is confused with other diseases which show lesions in the mouth. These diseases include vesicular stomatitis, papular stomatitis, bovine viral diarrhea-mucosal disease, malignant catarrhal fever, foot rot, herpes mammillitis, pseudocowpox, rinderpest, bluetongue, contagious ecthyma (orf) in sheep, infectious bovine rhinotracheitis, and chemical and thermal burns.

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
- Samples to collect for diagnosis: Vesicular fluid, epithelium that covers vesicles, whole blood, serum, and esophago-pharyngeal fluid from convalescent animals in cell culture fluid.
- Samples must be kept in PBS of pH 7.4 in order to maintain the pH to protect the virus.
- Antigen detection: Virus isolation (gold standard), complement fixation, ELISA.
- Nucleic acid detection: PCR.
- Antibody detection: Virus neutralization, ELISA.

PATHOLOGIC FINDINGS
- Vesicles in foot and mouth ranges from 2 mm to 10 cm in size, sometimes joining with adjacent lesions. The vesicles rupture leaving a red, eroded area, which is then covered with a gray fibrinous coating. This coating becomes yellow, brown, or green, replaced by new epithelium.
- Denuded rumen papillae and a gray or yellow streaking in the myocardium ("tiger heart") can be seen in young animals that die acutely, caused by degeneration and necrosis.

TREATMENT

THERAPEUTIC APPROACH
Supportive treatment of infected individuals is warranted. Milking time hygiene is of utmost importance. In areas where FMD is exotic, health care is usually swift and terminal.

MEDICATIONS

DRUGS OF CHOICE
Drugs are not available to treat FMD. But broad-spectrum antibiotics are intended to control bacterial secondary infection so that the lesions in the mouth and hoofs heal fast.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
FMD is self-limiting disease with fair prognosis for recovery in 2–3 weeks. Prognosis for young animals is sometime grave depending on the strains of the virus associated with the disease. Animals vaccinated with the epidemic strains have good prognosis.

POSSIBLE COMPLICATIONS
Long-term infection leads to severe loss of production. Sloughing of the hoofs causes secondary bacterial infection and takes a long time to heal. Possibility of tetanus infection through the sloughed hoofs in case of delayed healing.

PATIENT CARE
Diseased animals should be carefully monitored for fever and vesicular lesions. Continuous fever and anorexia for a long time leads to the collapse of the animal, so fluid therapy and dexamethasone are indicated in severe cases.

PREVENTION
- Strict biosecurity procedures, good animal husbandry practices (e.g., restriction of high-risk visitors, quarantine of high-risk animals and animal products, etc.) aids in the exclusion of FMDV.

FOOT AND MOUTH DISEASE (CONTINUED)

• Vaccines against FMD are available but cross-protection between different serotypes is limited. Therefore, it is important that the vaccine contain the same subtype of virus as is in the area. This necessitates frequent checking of the serotype and subtype during an outbreak as FMD virus frequently changes during its natural passage through various species. At the time of outbreak, ring vaccination with the same strains can protect against a possible epidemic.

MISCELLANEOUS

AGE-RELATED FACTORS

All ages of animal are susceptible to infection with FMD. Neonates and the young are more susceptible to fatal cardiac disease related to FMD infection.

ZOONOTIC POTENTIAL

FMD has been isolated from only about 40 human cases, despite widespread occurrence of the disease in animals. Vesicular lesions can be seen, but signs are mild. Because of this, FMD is not considered an important public health concern.

PREGNANCY

Some pregnant animals may abort.

BIOSECURITY

• Stringent quarantine rules and regulations prevent the transmission of FMDV over a wide geographic area.

• Sodium hydroxide (2%), sodium carbonate (4%), and citric acid (0.2%) are effective disinfectants. FMDV is resistant to iodophors, quaternary ammonium compounds, hypochlorite, and phenol, especially in the presence of organic matter.

ABBREVIATIONS

• ELISA = enzyme-linked immunosorbent assay
• FMD = foot and mouth disease
• FMDV = foot-and-mouth disease virus
• OIE = Office International des Epizooties
• PBS = phosphate buffered saline
• PCR = polymerase chain reaction
• SAT = South African Territories

FOOT ROT: BOVINE

BASICS

OVERVIEW
Interdigital phlegmon (foot rot) is an opportunistic, acute to subacute, necrotizing infection of the soft tissues of the digit in cattle. Bacteria enter through damaged skin of the interdigital space and the infection extends into the underlying tissues resulting in diffuse digital swelling and moderate to severe lameness. Prompt treatment with antibiotics has a high cure rate.

INCIDENCE/PREVALENCE
• Beef cattle: 1–3%; dairy cattle: 2–4% (range of 0–36% reported).
• Occurrence is usually sporadic but can be epidemic under some conditions.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Integument
• Musculoskeletal

PATHOPHYSIOLOGY
• Foot rot is caused by an opportunistic mixed bacterial infection of the soft tissue of the foot. The bacteria typically involved are *Fusobacterium necrophorum*, *Porphyromonas levii*, and *Prevotella intermedia*. *F. necrophorum* is thought to be the dominant pathogen with other bacteria playing synergistic roles.
• The bacteria involved are normal inhabitants of the rumen and thus are common in the environment of cattle.
• Compromise of the integrity of the interdigital skin through chronic wetting or trauma allows colonization of the tissues of the interdigital space. After gaining entry, the bacteria liberate proteases and leukotoxins which cause extensive local tissue damage. The damage to local tissue can be severe and will cause acute lameness.
• There are variations in the virulence of *F. necrophorum* which appear to be predominantly related to the quantity of leukotoxin produced. In addition, some strains are resistant to some antibiotics.
• Lameness can occur <24 hours after infection. Progression of symptoms can be rapid. Most infections are confined to the soft tissue of the digit; however, some cases can progress to involve tendons, joints, and bones of the digit.

HISTORICAL FINDINGS
• Significant decrease in milk production.
• Reduced feed intake or reluctance to come to the bunk.
• Weight loss is not usually evident at the onset of the condition.

SIGNALMENT
All production types are affected. The incidence may be higher in *Bos taurus* than in *Bos indicus*.

PHYSICAL EXAMINATION FINDINGS
• Acute lameness, usually unilateral.
• Symmetrical swelling in the pastern region (may extend to the fetlock if treatment is delayed). There is often separation of the claws due to the swelling in the interdigital region.
• Necrotic defect in the skin of the interdigital space with malodorous material.

GENETICS
Heritability for susceptibility to foot rot is low (estimated to be 0.14). Incidence may be higher in *Bos taurus* than in *Bos indicus*.

CAUSES AND RISK FACTORS
Presence of causative bacteria in the environment along with loss of integrity of interdigital skin due to mechanical trauma or hydropic maceration due to constant moisture.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Septic arthritis, osteomyelitis, deep digital sepsis of the heel region, and white line disease: usually asymmetrical swelling over affected claw.
• Fracture, luxation, and other trauma: Usually lack significant cellulitis as seen with foot rot.
• Foreign body: Likely to have an associated wound track but may be difficult to definitely rule out on physical examination alone.

IMAGING
Radiographs may be indicated for cases with extensive swelling or that have not responded to treatment.

OTHER DIAGNOSTIC PROCEDURES
Physical examination is usually sufficient to make the diagnosis. Microbiologic culture is seldom used due to the time and expense involved in culturing anaerobic organisms.

PATHOLOGIC FINDINGS
There is cellulitis and necrosis of the interdigital skin and subcutaneous tissue of the digit. Postmortem examination or tissue biopsy is rarely done.

TREATMENT

THERAPEUTIC APPROACH
• Prompt treatment with antibiotics is essential. A wide variety of antibiotics are labeled for treatment of foot rot in cattle. Most cases respond well to treatment so criteria such as cost, convenience, and withholding time should be considered in the selection.
• Amputation of a claw may be necessary if septic arthritis or osteomyelitis occurs secondary to interdigital phlegmon.
• Animals should be housed in an area with easy access to feed and water, a comfortable resting surface, and flooring with good traction.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• Antibiotics approved for treatment of foot rot that also have clinical evidence to support their use include ceftiofur, florfenicol, tulathromycin, and oxytetracycline. Tylosin and sulfadimethoxine are also labeled for treatment of foot rot. There is evidence indicating ampicillin is efficacious but it is not labeled for treatment of foot rot. Readers should refer to drug labels for doses and withholding times.
• Topical antibiotics are not of use and the foot should not be bandaged.
• Nonsteroidal anti-inflammatory drugs are commonly used as an adjunct to therapy with antimicrobial drugs. While flunixin meglumine is commonly used, meloxicam (0.5 mg/kg PO) is a reasonable alternative for ongoing treatment because animals will often voluntarily consume the tablets when mixed with grain. Injectable meloxicam (0.5 mg/kg), ketoprofen (3 mg/kg), and carprofen (1.4 mg/kg) are effective alternatives in countries where they are labeled for use in food-producing animals. There is no published data to support improved outcome with the use of NSAIDs; however, the use of pain-relieving drugs in cases with significant lameness is justifiable for animal welfare.

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Recovery is usually uneventful if the disease is diagnosed and treated promptly. Treatment within 24 hours of the onset of symptoms typically results in recovery in 2–4 days. Delaying treatment can prolong the recovery period by 10 days or more. Some strains of *F. necrophorum* are multi-drug resistant and may not be responsive to treatment with antibiotics.

POSSIBLE COMPLICATIONS
Septic arthritis, septic tenosynovitis, rupture of the flexor tendon, abscessation of the interdigital space, and osteomyelitis.

FOOT ROT: BOVINE (CONTINUED)

CLIENT EDUCATION
See "Prevention"

PATIENT CARE
Monitor affected cattle during treatment for indications that pain and swelling are abating. Improvement should be seen within 72 hours of initiating treatment with antibiotics. If improvement is not seen, an alternative class of antibiotic may be used. Radiographs may be justified in these cases.

PREVENTION
• Management of the environment is key to controlling foot rot. For confined cattle, a dry, comfortable resting surface must be provided and the facility stocked such that cattle are able and willing to lie down for at least 10 hours per day. Feeding and traffic areas need to have manure removed regularly to avoid constant wetting of the feet. For pastured cattle, animals should have access to dry ground during wet seasons. Watering and feeding areas should be well drained and be cleaned of manure regularly. Handling facilities should have alleyways that are free of debris (stones, sticks, etc.) that would likely damage the feet of the cattle.
• Footbaths with antiseptic solutions are commonly used on dairies to prevent new cases of infectious foot diseases including interdigital phlegmon. Commonly used footbath compounds are copper sulfate or zinc sulfate (5–10%) or formalin (3%–5%). It is commonly recommended that the footbath be drained, cleaned, and refilled after every 100–300 animals pass through.
• A commercial vaccine (Fusogard®) is available and has a label claim to aid in the reduction of clinical signs of foot rot in cattle 6 months of age and older. There is little data to support the use of the vaccine. There is one published study that showed a reduction in the incidence of foot rot in cattle on a forage diet but not in cattle on a grain diet.
• Feed additives: Chlortetracycline is labeled to aid in the prevention of foot rot in cattle and may be useful in situations where the incidence of foot rot is expected to be high or when several cases are identified in a short period of time. The feeding rate is far below the therapeutic rate and thus should not be used to treat animals clinically affected with foot rot. The product cannot be fed at a rate higher than on the label.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Other infectious causes of lameness exacerbated by poor foot hygiene or wet or muddy conditions, such as interdigital dermatitis, digital dermatitis, and heel horn erosion.

AGE-RELATED FACTORS
Found in all ages

ZOONOTIC POTENTIAL
None

BIOSECURITY
Introduction of new cattle onto a facility may introduce new, highly virulent strains of the bacteria and cause outbreaks of interdigital phlegmon.

PRODUCTION MANAGEMENT
• For dairy cattle, estimates of milk production loss are up to 3,500 lbs per lactation. The risk of culling is up to 5 times greater that of non-lame herdmates. An additional 15 days open is expected if onset occurs at <70 days in milk. Economic losses are estimated to be up to $240 per case, depending on milk production and pregnancy status.
• An estimate of the economic losses associated with foot rot in beef cattle is not available.

ABBREVIATION
NSAID = nonsteroidal anti-inflammatory drug

FOOT ROT: SMALL RUMINANT

BASICS

OVERVIEW
• Widespread, economically important, disease of sheep.
• Caused primarily by *Dichelobacter nodosus*.
• Characterized by interdigital swelling, progressive lameness, and separation of the horny portions of the hoof from underlying tissues.
• Footrot is classified as benign or virulent based on pathogen characteristics and severity of clinical signs.
• Treatment includes removal of underrun horn and administration of topical or parenteral bactericidal agents.
• Carrier sheep serve as reservoirs of *D. nodosus*; transmission is enhanced in wet conditions.

INCIDENCE/PREVALENCE
Common problem wherever sheep are exposed to wet conditions.

GEOGRAPHIC DISTRIBUTION
Worldwide in major sheep-producing countries with the exception of arid and semi-arid areas where sheep do not have access to wet areas.

SYSTEMS AFFECTED
Musculoskeletal

PATHOPHYSIOLOGY
• Invasion of the foot by *D. nodosus* is aided by *Fusobacterium necrophorum*. Other bacteria, including a *Treponema* spirochete, are often present but have not been demonstrated in the development of the disease.
• Carrier sheep serve as reservoirs for *D. nodosus*. Such animals may not show symptoms but carry a pocket of infection beneath underrun horn. Survival by *D. nodosus* in the environment is generally limited to a few days and certainly no more than 2 weeks.
• Prolonged wet conditions allow colonization by *F. necrophorum* resulting in a local dermatitis called "ovine interdigital dermatitis" or "foot scald."
• Resultant hyperkeratosis facilitates infection with *D. nodosus*.
• Pili of *D. nodosus* allow attachment to foot epithelium.
• Benign footrot results from *D. nodosus* strains with little keratinolytic ability; virulent footrot is caused by keratinolytic strains resulting in more severe clinical signs.

SIGNALMENT
• Footrot is primarily a disease of sheep.
• Similar clinical signs may be seen in goats infected with *D. nodosus* but hoof separation is generally less severe than in cases of virulent footrot in sheep.
• Cattle can also be affected but lesions are primarily limited to the interdigital space.
• Incidence and lesion severity increase with increasing age although all ages are susceptible to infection.
• No sex predilection.

PHYSICAL EXAMINATION FINDINGS
• Sheep usually present for acute onset of severe lameness.
• Multiple legs are often affected. Animals may graze or walk on their knees.
• Redness, swelling, and moistness of the interdigital epithelium.
• Foul-smelling exudate in the interdigital space.
• The outer wall of the hoof becomes underrun and separated from underlying tissues. In severe cases, attachment of the hoof is limited to the toe and lateral coronary band.
• Benign footrot is limited to interdigital lesions but may be hard to distinguish from early cases of the virulent form.

GENETICS
• Merino-type sheep are the most susceptible to infection. British breeds are more resistant and exhibit milder signs of disease.
• Individual variation within flocks is believed to be genetically determined, and selection for resistance by selective breeding has been demonstrated.

CAUSES AND RISK FACTORS
• The disease is caused by *D. nodosus* in conjunction with *F. necrophorum*.
• Wet and warm conditions are a major risk factor for transmission and development of clinical signs. Thus, disease is often seasonal when environmental conditions are conducive to pathogen transmission.
• Environments conducive to irritation or abrasions of the interdigital space.
• Congregation of sheep in small areas (e.g., handling areas, communal feeding and drinking areas).
• Introduction of carrier sheep.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Bluetongue
• Contagious ecthyma (orf)
• Contagious ovine digital dermatitis (CODD)
• Foot abscess
• Foot and mouth disease
• Laminitis
• Strawberry foot rot

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY FINDINGS
Gram's stain of the interdigital exudate can be performed to tentatively identify *D. nodosus*.

OTHER DIAGNOSTIC PROCEDURES
• Underrunning and separation of the hoof wall accompanied by interdigital inflammation and malodorous exudate is diagnostic for contagious footrot.
• PCR tests can be used to identify particular bacterial strains.
• Fluorescein-stained antibody assay is available.
• Diagnostic assays are often not available at diagnostic laboratories outside major sheep-producing areas.

PATHOLOGIC FINDINGS
Necropsy is not warranted for diagnosis of foot rot.

TREATMENT

THERAPEUTIC APPROACH
• Treatment is aimed at temporary control or complete eradication.
• Antibiotic therapy is most effective early in the course of disease before development of horn lesions.
• Long-acting parenteral antibiotic therapy in conjunction with topical therapy improves recovery.
• Individual animal topical therapy requires complete removal of underrun horn although some research has questioned the value of hoof trimming.
• Footbaths are commonly used for treatment and control of herd outbreaks. Effective solutions include 10% zinc sulfate, 5% copper sulfate, and 5% formalin.
• Feet should be soaked for 30–60 min.
• Aerosol sprays have been used in lieu of footbaths but are generally less effective than foot soaking.

MEDICATIONS

DRUGS OF CHOICE
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Most cases respond to appropriate treatment.
• Nonresponders should be identified and culled to decrease environmental pathogen load and the source of future infections.

PATIENT CARE
• Repeated treatments may be necessary to clear infection from the herd.
• Animals that do not respond to several treatments should be culled.

PREVENTION
• Introduction of outside animals is discouraged and should only occur after quarantine.

FOOT ROT: SMALL RUMINANT (CONTINUED)

• Facilities or vehicles used to hold or transport affected animals should be disinfected or avoided.
• Vaccination is used in both treatment and control. Efficacy of vaccination is dependent on the homology of field and vaccine strains.
• Routine foot baths at 10-day intervals during the transmission season will help prevent outbreaks.
• Limit congregation of animals in wet areas.
• Separate affected animals during outbreaks.
• Previous disease does not provide immunity against further infection. Thus, returning treated animals to contaminated environments will result in further outbreaks of disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS

CODD is an emerging disease of sheep characterized by acute-onset lameness and extensive underrunning of hoof horn. In contrast to footrot, interdigital lesions are absent but proliferative or ulcerative lesions are seen at the coronet. Response to traditional footrot treatments is poor. *D. nodosus* and *F. necrophorum* are often present but the primary cause of CODD is believed to be a spirochete similar to bovine digital dermatitis.

AGE-RELATED FACTORS

All ages are susceptible to infection; incidence and lesion severity increase with increasing age.

BIOSECURITY

• Quarantine new arrivals and introduce to the herd only after inspection of the feet for underrun horn and evidence of infection with *D. nodosus*.
• Separate affected and unaffected animals during outbreaks and house in separate pastures.

PRODUCTION MANAGEMENT

• Eradication can be attempted in sufficiently dry areas (annual precipitation <20 inches).
• Eradication hinges on the identification of all affected animals. Examine the feet of all animals and separate the affected and unaffected sheep.
• Unaffected animals are run through a footbath and placed in clean pasture, with or without long-acting antibiotic treatment.
• Affected animals may be culled immediately or treated with antibiotic therapy and weekly footbaths. After at least three soakings, the feet are reexamined and affected animals culled.
• Any animals not showing lameness during the subsequent wet period can be reintroduced to the clean flock.

ABBREVIATION

CODD = contagious ovine digital dermatitis

FREEMARTINISM

BASICS

OVERVIEW
• A disorder of sexual development which occurs in pregnancies with male and female fetuses.
• The condition has been reported in several species of ruminant and camelid. However, it is mainly a production problem in cattle.
• 80–95% of female calves born co-twin to a male are affected.
• Affected female calves may be born singleton if the male twin perished in utero.
• In sheep and goats, it is more likely to occur with increased numbers of fetuses (i.e., 4 or 5) compared to twin and triplet pregnancies.

INCIDENCE/PREVALENCE
• Unknown but suspected to be increasing as the rate of twin pregnancy in cattle has increased.
• Although multiple mixed-sex births are common, incidence is rare in small ruminants (<2%). Reported incidence in sheep varies (0.8–1.9% in Romanov ewes and up to 7% in other breeds).
• In camelids, the condition is extremely rare.

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
Reproductive

PATHOPHYSIOLOGY
Vascular anastomoses lead to blood chimerism (XX/XY) and variable effects on each sex. In the female, effects of anti-Mullerian hormone and testosterone lead to variable masculinization of the external and internal reproductive tract. Effects on the male have been sporadically reported, with diagnoses of spermatozoa defects, decreased fertility, and testicular degeneration described.

HISTORICAL FINDINGS
• Female born co-twin to a male.
• Ambiguous external genitalia or abnormal urination.
• Abnormality of the reproductive tract discovered during AI (bovine).
• Male-like behavior has been described in ewes.

SIGNALMENT
Freemartinism has been reported in cattle, sheep, goats, camelids, and cervids.

PHYSICAL EXAMINATION FINDINGS
• The degree of masculinization of female offspring is highly variable.
• In many females, the external genitalia may appear normal. In other cases, abnormalities may include increased anogenital distance, enlarged clitoris, and coarse hair around the vulva.
• Internal genitalia may be characterized by a short blind vagina, small underdeveloped uterus, hypoplastic ovaries, ovotestes, and varying degree of development of male reproductive tract structures, including epididymides, ductus deferens, pampiniform plexus, and cremaster muscle. The gonads may be located abdominally, inguinally, or subcutaneously in the inguinal region. Affected females may show persistent estrus, anestrus, or male-like behavior. Affected males typically do not show outward abnormalities in anatomy or behavior.

GENETICS
Suspected in small ruminants. The risk for freemartinism is increased in breeds with high fecundity genes which carry litters of 4 or more lambs.

CAUSES AND RISK FACTORS
Twin pregnancies

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Other causes of abnormal sexual differentiation
• Physical examination of external genitalia

CBC/BIOCHEMISTRY/URINALYSIS
N/A

OTHER LABORATORY TESTS
• Cytogenetics (karyotype) to diagnose blood chimerism (XX/XY)
• Molecular studies (PCR) to diagnose Y-chromosome specific genes (*SRY, AMELY, ZFY*)
• Serology for anti-Mullerian hormone

IMAGING
• Transrectal ultrasonography may be used for the evaluation of the uterus and gonads in large heifers suspected to be freemartin.
• In one study on ewes, ultrasonography of the gonads showed an echotexture of the gonads varying from normal testicular tissue to pseudohermaphrodite appearance with various degree of calcification or cystic anomalies.

OTHER DIAGNOSTIC PROCEDURES
Vaginal canal length and presence of the cervix can be examined in female calves.

PATHOLOGIC FINDINGS
Most affected ewes have small vaginal length and gonads that resemble testicles with degenerating sex cords or testicular tissue with defined tubular structures and interstitial regions.

FROSTBITE

BASICS

OVERVIEW

• Frostbite represents damage or injury to the skin and body tissues resulting from their freezing following exposure to excessive cold or windchill.
• Severe frostbite is a grave physiologic condition with potentially life-threatening consequences.
• Frostbite may be primary, or secondary to debilitating disease or malnutrition.
• The ears, tail, teats, scrotum, and distal extremities (hindlimbs > forelimbs) are most often affected.
• Tissue damage is substantially exaggerated if thawing is followed by refreezing.
• Tissue previously damaged by freezing is more prone to injury on subsequent exposure to cold temperatures.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

More common in geographic regions with temperatures that drop below freezing

SYSTEMS AFFECTED

Integument

PATHOPHYSIOLOGY

• Exact mechanism of tissue damage is difficult to define and reflects multiple pathologic mechanisms.
• Frostbite involves direct cellular injury from freezing, injury from progressive vasoconstriction and subsequent arterial thrombosis, and ischemic necrosis.
• Four phases describe the mechanisms of cell damage during freezing:
  ◦ Phase I (pre-freeze phase): congestion and leakage of fluid from vascular compartment due to arterial constriction and venous dilation.
  ◦ Phase II (freeze-thaw phase): extracellular ice crystal formation causes cell membrane rupture or cellular dehydration.
  ◦ Phase III (vascular stasis phase): more severe and persistent arterial spasm and venous dilation leading to arteriovenous shunting and tissue hypoxia.
  ◦ Phase IV (ischemia phase): neural tissue damage due to prolonged tissue hypoxia.
• Additional injury occurs during rewarming with return of blood flow and warming of affected tissue.
• Direct cellular destruction, release of catecholamines, and tissue anoxia have potentially significant secondary effects in severe frostbite, resulting in damage to other organs.

HISTORICAL FINDINGS

• Frostbite is uncommon in well-nourished animals when environmental temperatures are above 10°F (−12.2°C).
• Frostbite can occur when temperatures are at or below 0°F (–17.8°C) or when windchill provokes such low temperatures.

SIGNALMENT

Any species, breed, age, or gender can be affected; however, neonates are at greatest risk due to wet, thin skin at birth, minimal subcutaneous fat, and a high surface area : volume ratio.

PHYSICAL EXAMINATION FINDINGS

• Signs of chilling including piloerection, shivering, and peripheral vasoconstriction.
• Mild frostbite causes blanching of tissue and reduced sensation followed by painful erythema, scaling, and alopecia.
• Severe frostbite results in necrosis, dry gangrene, and sloughing of affected part(s); affected skin is usually anesthetic.
• Death can result from hypothermia if not reversed before vital organs are compromised.
• Frozen teats will initially appear reddened or pale, which can progress to scab formation over the distal half of the teat. As the teat heals the milk duct may become occluded.
• Milk-fed calves may show superficial muzzle sloughing.
• Pain occurs with rewarming of affected areas.
• A line of demarcation between viable and nonviable tissue usually appears within 3 days of rewarming affected areas. This line is initially diffuse and becomes more distinct within 7 days, but may take weeks to become clearly defined.
• Vesicles and blisters develop on affected areas.
• After sloughing, ears are rounded, alopecic, and have pinnae of variable length.

GENETICS

N/A

CAUSES AND RISK FACTORS

• Exposure to subnormal temperatures and wetness.
• Windchill accelerates evaporation and cooling of exposed areas.
• Wet neonates or adults with wet udders, teats, or testicles.
• Heifers with severe periparturient udder edema and reduced perfusion to teats.
• Poor nutrition.
• Hypoglycemic neonates.
• Previous tissue damage due to cold injury.
• Debilitated, sick, or dehydrated animals with reduced metabolic heat generation.
• Animals with heavily pigmented skin.
• Milking cattle and goats turned outside in cold weather with inadequately dried udders and teats.
• Animals with pre-existing vascular damage (e.g., ergotism, fescue toxicosis, vasculitis).

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Inherited, small pinna of American La Mancha goat
• Traumatic injury
• Previous tissue damage from ergot toxicosis

CBC/BIOCHEMISTRY/URINALYSIS

Findings might be consistent with metabolic acidosis, dehydration, hypoglycemia (neonates), secondary infection, organ compromise, and hypoalbuminemia (if a large area of tissue is damaged),

OTHER LABORATORY TESTS

N/A

OTHER DIAGNOSTIC PROCEDURES

Skin biopsy

IMAGING

N/A

PATHOLOGIC FINDINGS

• Gross necropsy might define decreased subcutaneous and perirenal fat deposits, subcutaneous hemorrhage of the tarsal region, edema, vesicles, or bullae over affected tissue, or skin and tissue necrosis.
• Histology identifies adipocytes filled with eosinophilic cytoplasm instead of lipid; tissue microthrombosis, vasculitis.

TREATMENT

THERAPEUTIC APPROACH

• Rewarming should be initiated as soon as possible once it is known that refreezing can be prevented; thawing and refreezing increases tissue damage.
• Incomplete or partial rewarming decreases chances for successful recovery.
• Rapid rewarming is painful but results in less cellular and tissue damage than slow rewarming.
• Thaw tissue rapidly in warm water (plain or with a dilute antiseptic solution).
  ◦ Recommended water temperature range: 100.2–111.1°F (38–44°C), ideally 104–106°F (40–41°C).
• Rewarming process should be repeated twice daily for 2–3 days.
• Application of lanolin or other bland, protective ointments or creams after rewarming completed.
• Leave damaged area exposed during healing and protect animal from cold until healing has occurred.

SURGICAL CONSIDERATIONS AND TECHNIQUES

• If necessary, debride necrotic tissue to facilitate healing and limit secondary infection.

FROSTBITE (CONTINUED)

• Postpone debridement or surgical excision of limbs until boundary between viable and nonviable tissue is clearly obvious, which may take 8 weeks.
• Frostbitten teats may require surgery to keep the teat duct patent.

MEDICATIONS

DRUGS OF CHOICE

• Nonsteroidal anti-inflammatory drugs provide analgesia and systemic anti-inflammatory effects, including flunixin meglumine; 1.1 mg/kg IV, q12–24h; or ketoprofen: 2.2 mg/kg/day IV or IM.
• Epidural analgesia during rewarming period may help with hindlimb pain.
• Broad-spectrum antibiotics may be indicated to prevent secondary infection.
• IV or oral fluids help correct dehydration and metabolic acidosis, assist rewarming, provide vascular support, reduce hyperviscosity, improve capillary circulation, and prevent hypovolemic shock that may occur after peripheral rewarming and subsequent fluid shifts.
• Apply aloe vera topically (anti-thromboxane, anti-inflammatory, and analgesic effects).
• Tetanus immunization is indicated in animals with extensive frostbite.
• A single dose of glucocorticoids may decrease capillary permeability, maintain microcirculation, stabilize cell membranes, and reduce induced histamine.

CONTRAINDICATIONS

N/A

PRECAUTIONS

• Avoid massaging or rubbing tissue during warming as this can prolong edema and recovery.
• Do not use occlusive bandages over damaged areas.
• Avoid premature debridement of affected areas; more tissue may be more viable than initially apparent.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Dependent on severity of injury

POSSIBLE COMPLICATIONS

Secondary infection, sloughing of extremities, organ failure

CLIENT EDUCATION

Frostbite may occur at less extreme environmental temperatures in compromised animals despite adequate housing and nutrition.

PATIENT CARE

• Provide a palatable high-protein, high-calorie diet with a vitamin supplement.
• Restrain to avoid self-mutilation.
• Edges of healthy and gangrenous tissue should be kept clean, protected, and allowed to slough naturally.

PREVENTION

• Avoid or adjust for the listed risk factors (see "Causes and Risk Factors").
• Dry off calves, kids, and lambs born in cold environments.
• Ensure susceptible body parts remain dry during exposure to subnormal temperatures.
• Provide adequate, clean, dry bedding to neonates to minimize heat loss by convection and evaporation.
• Provide easily accessible shelter and consistent feeding management.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Secondary bacterial infection

AGE-RELATED FACTORS

Neonates are at higher risk

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

• With ambient temperatures below 32°F (0°C) management should include:
  ◦ Dry udder and teats completely before animal leaves parlor.
  ◦ Provide adequate windbreaks and shelter.
  ◦ Dip just the teat end during very cold weather.
• Provide windbreaks and bedding for calving cows when windchill temperatures are below 10–20°F (–12 to –10°C).
• House calving cows and calves <1 day old when windchills are below 10°F (–12°C) and calves cannot be kept dry because of rain or snow.
• Keep dairy animals clean, dry, and out of the wind with adequate dry bedding daily when temperatures are subnormal.

SYNONYM

Cold-induced injury

FUNGAL TREMORGENS

BASICS

OVERVIEW
• Tremorgens are mycotoxins that have been reported to cause tremoring conditions in cattle, goats, sheep, deer, horses, and camelids.
• Clinical signs associated with ingestion of these neurotoxins are collectively known as "staggers" and include ataxia, muscle tremors, rigid stance, recumbency, and paddling convulsions. The tremors are accentuated by exercise and can lead to tetany and collapse.
• The mycotoxins are produced by fungal genera such as *Neotyphodium, Claviceps, Penicillium,* and *Aspergillus,* and are often associated with specific grasses, such as perennial ryegrass, dallisgrass, bahiagrass, and Bermuda grass (Table 1).

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
Worldwide where affected pastures are used for grazing livestock. Cases have been reported in Australia, New Zealand, Europe, South America, and throughout the United States.

SYSTEMS AFFECTED
Nervous

PATHOPHYSIOLOGY
• Grass staggers is a syndrome caused by a group of related mycotoxins found in toxic stands of various pasture grasses.
• The toxins exert their effects by inhibiting the inhibitory neurotransmitter, gamma-aminobutyric acid (GABA). The mycotoxins are structurally similar to GABA and bind to GABA receptors in the internuncial neurons, resulting in receptor inactivation.
• Loss of inhibitory neurotransmitters leads to increased neurotransmission and prolonged depolarization, resulting in the neurologic signs of incoordinated movements, ataxia, and muscle tremors.

Table 1

Grass Forages Associated with Staggers Syndrome due to Fungal Endophytes

Cynodon dactylon	Bermudagrass
Hilaria mutica	Tobosagrass
Lolium perenne	Perennial ryegrass
Paspalum	
P. dilatatum	Dallisgrass, large watergrass
P. distichum	Knotgrass, jointgrass
P. scrobiculatum	Indian paspalum, monagrass, kodo millet
Phalaris spp.	Canarygrasses

Source: Burrows, George E., Tyrl, Ronald J. Toxic Plants of North America (p. 902). Wiley. Kindle Edition.

SIGNALMENT
• All species can be affected. Reports of tremogenic mycotoxin intoxication have occurred in cattle, horses, goats, sheep, deer, and camelids.
• There are no species or breed predilections.
• While there are no age predilections per se, most cases occur in adult cattle and to a lesser extent, weaned animals.

PHYSICAL EXAMINATION FINDINGS
• Signs are initially mild and may be limited to fine head tremors.
• Signs may be minimal or absent at rest but are exacerbated by noise and sudden movements.
• Coarse and fine muscle fasiculations, particularly in the shoulder and flank areas, develop as the disease progresses.
• Stiff, hypermetric gait. When forced to run, movements appear jerky and uncoordinated.
• In severe cases, animals may collapse with opisthotonus, nystagmus, and flailing of the limbs. Generally, the attack subsides in a few minutes and the animal is able to regain its feet.

CAUSES AND RISK FACTORS
• Risk factors and inciting conditions vary between tremorgenic compounds.
• Perennial ryegrass staggers is caused by the endophyte *Neotyphodium lolii* which produces tremorgenic toxins known as lolitrems, notably lolitrem B. Late seasonal growth, warm ambient temperatures, and closely grazed pastures favor toxicity. Clinical cases are seen between June and September in the northern hemisphere.
• The seed heads of dallis- and bahiagrasses can be infected by *Claviceps paspali.* The fungus produces alkaloids including indole compounds derived from lysergic acid known as paspalitrems. Wet conditions following seed head formation result in increased toxin formation.
• Annual ryegrass staggers is caused by a corynetoxin. Toxin levels are highest as the plant dries and seeds ripen in the summer. Outbreaks are commonly seen after outbreaks of stormy weather.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Many of the fungal tremorgens present similarly. Diagnosis is based on forage identification in affected pastures.
• Other conditions that can cause similar neurologic signs include hypomagnesemia, rabies, tetanus, tremetol intoxication, yew toxicity, and selenium poisoning.

CBC/BIOCHEMISTRY/URINALYSIS
No specific changes in clinical pathology. An elevation in serum creatinine kinase or aspartate aminotransferase may be seen due to muscle cell damage from ataxia or incoordination.

OTHER DIAGNOSTIC PROCEDURES
• Presumptive diagnosis is made based on clinical signs and demonstration of exposure to susceptible forages.
• Analysis of forage to identify specific mycotoxins can be performed by most state diagnostic laboratories; but it is not commonly performed, and obtaining a forage sample with adequate mycotoxin levels is difficult.
• Extracts of the fungus-infected feed material can be analyzed by thin-layer chromatography, high-performance liquid chromatography, or bioassay.

PATHOLOGIC FINDINGS
• Mortality due to the fungal tremorgens is low. When deaths do occur, they often result from misadventure such as drowning.
• Pathologic findings reflect the cause of death and are not specific for the fungal tremorgens.

TREATMENT

THERAPEUTIC APPROACH
• There is no specific treatment or antidote for tremorgenic mycotoxin intoxication.
• Removal from affected pastures or contaminated forages and supportive care usually allows for recovery in 1–2 weeks.

MEDICATIONS

DRUGS OF CHOICE
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Removal from affected pastures at the time of development of clinical signs generally allows complete recovery within 1–2 weeks.
• Longer recovery times have been noted in cases of annual ryegrass staggers where neurologic deficits have resolved over a period of several months.

POSSIBLE COMPLICATIONS
Though mortality is low, severely affected animals may collapse into bodies of water or cast themselves, resulting in traumatic injury or death.

PREVENTION/AVOIDANCE
• Pasture management is key to preventing grass staggers.

FUNGAL TREMORGENS (CONTINUED)

• Disease can be avoided by removal from affected pastures.
• Overgrazing of perennial ryegrass increases the likelihood of toxicity.
• *Claviceps paspali* infects the seedheads of dallis- and bahiagrasses. Removal of the seedheads by mowing can prevent intoxication.

MISCELLANEOUS

AGE-RELATED FACTORS
Though no specific age predilection exists, most cases occur in adults and weaned animals.

PREGNANCY
Abortion is not a common sequela of disease.

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
N/A

SYNONYM
Grass staggers

ABBREVIATION
GABA = gamma-aminobutyric acid

GOSSYPOL TOXICOSIS

BASICS

OVERVIEW

• Gossypol is a toxic phenolic substance that occurs naturally in the cotton plant (*Gossypium* spp.).
• Whole cottonseed (WCS) and cottonseed meal (CSM) are a widely used source of energy, fiber, and protein in diets of adult cattle, calves, and sheep.
• Signs of gossypol toxicity are primarily manifested in the cardiac system and include anorexia, weakness, cardiac failure, and sudden death.
• Gossypol also causes reproductive failure, particularly in males.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide in areas feeding cottonseed meal

SYSTEMS AFFECTED

• Musculoskeletal
• Cardiac
• Reproductive
• Hemolymphatic
• Multisystemic

PATHOPHYSIOLOGY

• Gossypol is contained in variable amounts in whole cottonseed and cottonseed meal. Free gossypol is readily absorbed from the gastrointestinal tract.
• Gossypol binds to cellular constituents including phospholipids and lysine, inhibits dehydrogenases, and uncouples cellular phosphorylation.
• Spermatogenesis is impaired through inhibition of lactic dehydrogenase in testicular Leydig cells and acrosomal plasminogen activator in the sperm.

SIGNALMENT

• Potentially all ruminants feeding on cottonseed meal can be affected.
• Mature ruminants are more resistant to gossypol toxicosis as gossypol can be neutralized in the rumen by binding to soluble proteins. However, the protein-binding detoxifying mechanism in adult cattle can be overwhelmed if the total gossypol content is excessive, or low protein content is present in the rumen.
• Preruminant cattle such as lambs and calves are commonly affected.
• The reproductive effects are primarily seen in male animals although high levels of gossypol can also cause impaired reproductive performance in cows.

PHYSICAL EXAMINATION FINDINGS

• The clinical signs of gossypol toxicity include sudden death as well as physiologic and reproductive effects without death.
• Preruminant calves exhibit anorexia and signs related to congestive heart failure including dyspnea, coughing, jugular distension, brisket edema, and weakness.
• Adult cattle have reduced milk production, anorexia, weakness, and respiratory stress.
• Reduced spermatogenesis and impaired sperm motility associated with morphologic aberrations of the sperm midpiece.
• Reproductive signs in females are not regularly seen clinically but include irregular cycling and potentially early embryonic death.

CAUSES AND RISK FACTORS

• Consumption of diets containing excessive amounts of gossypol from whole cottonseed and cottonseed hulls or meal is the route of exposure that causes toxicity.
• The level predisposing the animal to toxicity depends on the species, rumen function, level of protein in the diet, and duration of consumption.
• Two isomers of gossypol exist in all cotton plants: the (+) isomer acts as an insect deterrent but is more toxic than the (-) isomer. Upland cotton, the predominant strain in the southeastern US, has a higher ratio of the (+) isomer than Pima cotton, which predominates in the western US.
• Solvent extraction of cottonseed oil leaves more free gossypol than heat extraction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Monensin toxicity
• Vitamin E and selenium deficiency
• Toxic plants such as *Senna* spp., oleander, white snakeroot, and yew

CBC/BIOCHEMISTRY/URINALYSIS

• Elevations in liver-specific isoenzymes are the most consistent change in the serum biochemical profile.
• Minimal changes in erythrocyte parameters are expected during toxicity. However, hemoglobinuria, anemia, and a decrease in hemoglobin content have been reported.

IMAGING

Imaging is rarely undertaken but abdominal or thoracic radiographs and ultrasound will demonstrate the presence of free fluid in the body cavities.

OTHER DIAGNOSTIC PROCEDURES

• Diagnosis is supported by demonstration of elevated gossypol levels in feedstuffs being consumed, clinical signs consistent with gossypol toxicity, and typical pathologic findings.
• Send representative samples of the cotton by-product (WCS or CSM) to a qualified laboratory for total and free gossypol analysis. Note that the standard analytic method will not give accurate results of gossypol levels in a total mixed ration (TMR) sample; therefore, the cotton by-products should be analyzed individually.
• High performance liquid chromatography (HPLC) can be used to detect gossypol levels in some tissue samples.
• Gossypol accumulates in the liver and kidneys which are the preferred tissue samples for postmortem analyses.

PATHOLOGIC FINDINGS

• Generalized edema.
• Gelatinous, yellow proteinaceous fluid in the thoracic and peritoneal cavities.
• Hepatomegaly secondary to congestive heart failure.
• Degeneration of the skeletal and cardiac muscle.
• Histologically there is centrilobular hepatic congestion and necrosis related to hepatic anoxia. There is also myocardial degeneration and necrosis.

TREATMENT

THERAPEUTIC APPROACH

• No specific treatment is available for acute gossypol toxicity. Prognosis depends on the severity of clinical signs and supportive care may not be warranted in the case of advanced disease.
• Administration of vitamin E may ameliorate some clinical signs but will not prevent gossypol toxicity.
• Experimentally, selenium supplementation alleviates the effect of gossypol toxicity in breeding males.

MEDICATIONS

DRUGS OF CHOICE

N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Because of the cumulative nature of the toxicant and the type of pathologic changes, deaths will often continue for several days following cessation of feeding of the toxic ration.

PREVENTION

• Avoid overfeeding of WCS and CSM. Consult a nutritionist for specific dietary recommendations for different species and production classes.
• Testing of gossypol levels in cotton-based commodities is available but not routinely performed. Knowledge of free gossypol levels in feedstuffs may assist in ration planning.

GOSSYPOL TOXICOSIS (CONTINUED)

MISCELLANEOUS

AGE-RELATED FACTORS

Stage of rumen development is critical in detoxifying gossypol. While the young ruminant is being fed milk, rumen development and function are minimal. During this time, the animal functions essentially as a preruminant and tolerable levels of free gossypol in the diet are similar to nonruminant species, which is 200 ppm.

ZOONOTIC POTENTIAL

Humans are susceptible to gossypol toxicity but the toxicity is not considered transmissible through milk or meat products.

PRODUCTION MANAGEMENT

- Consumption of diets containing excessive amounts of gossypol from whole cottonseed and cottonseed hulls or meal is the route of exposure that causes toxicity.
- The level predisposing the animal to toxicity depends on the species, rumen function, level of protein in the diet, and duration of consumption.
- When considering toxicity levels of free gossypol in ruminants, the source—whole cottonseed vs. cottonseed meal—should be considered. Detoxification of free gossypol in the rumen appears to be more efficient with whole cottonseed.
- Stress lowers the toxic threshold for gossypol toxicity. Thus, signs of toxicity may be seen when feeding gossypol at recommended levels if the animals are subjected to increased external stressors (e.g., poor nutritional plane, overcrowding).
- Guidelines for safe levels of gossypol intake should not exceed 20 g/day for lactating dairy cows, 8 g/day for breeding bulls.
- Detoxification can be achieved by cooking the CSM or by the addition of 1% calcium hydroxide or 0.1% ferrous sulfate.

ABBREVIATIONS

- CSM = cottonseed meal
- HPLC = high performance liquid chromatography
- TMR = total mixed ration
- WCS = whole cottonseed

GRASS TETANY/HYPOMAGNESEMIA

BASICS

OVERVIEW
• Magnesium (Mg) deficiency affects the central nervous system of ruminants.
• Mg is absorbed from the rumen and excreted in urine.
• High dietary potassium decreases absorption of Mg.
• Rapidly growing grasses may contain relatively high concentrations of potassium and most always have low concentrations of Mg.

INCIDENCE/PREVALENCE
Unknown

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Nervous
• Musculoskeletal

PATHOPHYSIOLOGY
• Mg is necessary for most major cellular metabolic pathways and is vital to maintenance of resting membrane potentials at synapses.
• Because adenosine triphosphate (ATP) requires Mg to form the high-energy bond between phosphates, Mg is required for all enzymatic reactions requiring ATP.
• Mg is also necessary for ATPase activity; therefore, myofibril contractions are sustained in hypomagnesemia, leading to tetanic spasms.
• Most Mg is present in teeth and bones, which is not readily mobilized.
• There is no direct hormonal control of Mg uptake, so daily intake is necessary.

SIGNALMENT
• Cattle, sheep, and goats; potentially all ruminant species.
• Most commonly seen in lactating beef cattle within the first 2 months of calving, particularly if grazing cool season grasses.
• Lactating dairy cattle are affected less commonly because of differences in nutritional management. Grazing dairy cattle would be at greater risk.
• A winter tetany associated with cattle in a dry lot with dry feeds.
• Ewes and dairy goats are also susceptible.
• Calves on all milk diets without added Mg may develop the disease as well.

PHYSICAL EXAMINATION FINDINGS
• Affected animals are often found dead.
• Anorexia and separation from the herd.
• Early in the course, ears will be erect and twitching and hyperesthesia will be noted.
• Alert, hyperexcitable, may be aggressive.
• Muscle fasciculations and head tremors may be noted.
• Nystagmus and fluttering of the eyelids.
• Ataxia.
• Recumbency.
• Clonic convulsions, opisthotonus, or tetanic muscle spasms.
• Elevated body temperature because of excess muscle activity.
• Increased heart and respiratory rate.

CAUSES AND RISK FACTORS
• Magnesium deficiency that can be result of low intake of Mg and/or higher output of Mg, particularly during lactation.
• Mature ruminants just prior to calving and during early lactation have the highest demand for Mg.
• Periods of rapid grass growth, particularly cool season grasses and cereal crops, are the most common time for clinical signs to occur (spring and/or fall).
• Heavy fertilization of pastures with increased potassium increases the risk of grass tetany. Use of recycled poultry bedding as a feed supplement or fertilizer has commonly been associated with an increased incidence of hypomagnesemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Hypocalcemia (serum Ca)
• Nervous ketosis (urine ketones)
• Urea toxicosis
• Nervous coccidiosis (fecal float)
• Heavy metal toxicities: for example, arsenic and lead (history of exposure to heavy metals, elevated blood, kidney or liver concentration of heavy metal)
• Salt poisoning (history, necropsy)
• Tetanus (response to therapy, necropsy)
• Rabies (necropsy)
• Viral encephalitides (history of herd and surrounding area, increasing antibody titers)

CBC/BIOCHEMISTRY/URINALYSIS
• Serum Mg <1.2 mg/dL
• Cerebrospinal fluid Mg <1.45 mg/dL
• Urine Mg <2.5 mg/dL
• Postmortem ocular Mg <1 mg/dL (within 24 hours of death)
• Affected animals are often hypocalcemic.
• After episodes of tetany, animals will often have elevated potassium, aspartate aminotransferase (AST), and creatinine phosphokinase (CK) due to muscle damage.

OTHER DIAGNOSTIC PROCEDURES
• Diagnosis is most often made on the basis of clinical signs or history because of the need for immediate treatment.
• Decreased serum, CSF, ocular or urine Mg concentrations are confirmatory.

PATHOLOGIC FINDINGS
• Grossly may note evidence of thrashing on ground around where the animal died.
• No gross findings directly attributable to hypomagnesemia.
• Trauma and bruising are common findings because of seizures.
• Rumen contents may be aspirated into lungs.
• Ecchymotic hemorrhages.
• Agonal pulmonary emphysema.
• Histologically, calves dying of hypomagnesemia may have microscopic calcium deposits in arterial walls of the heart, lungs, and spleen.

TREATMENT

THERAPEUTIC APPROACH
• Minimize handling to decrease the chance of initiating tetanic seizures.
• It may be necessary to administer intramuscular sedation prior to initiating Mg therapy to control seizure activity. Avoid intravenous sedative administration.
• Heart rate should be monitored closely while administering Mg solutions and treatment should be slowed or discontinued if heart rate drops substantially.
• Respiratory failure may occur if Mg solutions are given too quickly due to medullary depression.

MEDICATIONS

DRUGS OF CHOICE
• Animals with hypomagnesemia are often hypocalcemic as well and should receive therapy containing calcium.
• Administer intravenous calcium borogluconate solution containing 5% Mg (500 mL for adult cattle; 50–100 mL for calves and small ruminants).

CONTRAINDICATIONS
• Avoid potassium-containing solutions for therapy because they will interfere with Mg absorption.
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Therapy is often unrewarding, especially in cases where seizures have already occurred.

CLIENT EDUCATION
• Allowing animals access to only hay or mature grass for a portion of the day will increase Mg in the diet and may prevent further cases.
• Mg is unpalatable and will not be consumed in significant quantities unless mixed with some other dietary component.

GRASS TETANY/HYPOMAGNESEMIA (CONTINUED)

• Mg can be added to feed or water to encourage intake:
  ◦ If feeding Mg in water, animals must be given access to only supplemented water to ensure intake of Mg.
  ◦ Spraying or dusting pastures with Mg fertilizers in the spring will increase dietary Mg.
  ◦ Mg will be readily consumed in concentrate mixtures or molasses licks.

PATIENT CARE

• Many animals relapse several hours after treatment, so an additional source of Mg should be provided with initial treatment.
  ◦ Oral Mg salts: (1) 50% Mg sulfate solution (125–150 mL for adult cattle). (2) Mg oxide (60 g in gelatin capsule for adult cattle).
  ◦ Subcutaneous injection of 100–200 mL (for adult cattle) of a 20%–50% Mg sulfate solution. Limit to 50 mL per site to avoid tissue damage.
• Mg enema—60 g of Mg in 250–500 mL of water. Solution should not be more concentrated than this to avoid mucosal sloughing.

MISCELLANEOUS

AGE-RELATED FACTORS

• Most commonly seen in lactating beef cattle within the first 2 months of calving, particularly if grazing cool season grasses.
• Lactating dairy cattle are affected less commonly because of differences in nutritional management. Grazing dairy cattle would be at greater risk.
• Calves on all-milk diets without added Mg may develop the disease as well.
• Calves dying of hypomagnesemia may have microscopic calcium deposits in arterial walls of the heart, lungs, and spleen.

ZOONOTIC POTENTIAL

Hypomagnesemia is neither contagious nor zoonotic.

PRODUCTION MANAGEMENT

• Periods of rapid grass growth, particularly cool season grasses and cereal crops, are the most common times for clinical signs to occur (spring and/or fall).
• Heavy fertilization of pastures increases the risk of grass tetany. Use of recycled poultry bedding as a feed supplement or fertilizer has commonly been associated with an increased incidence of hypomagnesemia.

SYNONYMS

• Grass staggers
• Hypomagnesemia
• Tetany
• Winter tetany

GRAYANOTOXIN

BASICS

OVERVIEW
• This toxin is found in members of the heath or *Ericaceae* family. This family is known for showy ornamentals that characteristically grow in acidic soils.
• All parts of the plant contain the toxin.
• Leaves are simple and alternate, rarely opposite.
• Flowers in variety of colors.
• Fruits can be berries or capsules.
• Seeds are small.

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
Worldwide

SYSTEMS AFFECTED
• Nervous
• Cardiovascular

PATHOPHYSIOLOGY
• Grayanotoxins are heterocyclic diterpenes that exert their effects thru binding to sodium channels within the cell membrane leading increased sodium permeability of excitable membranes within the neurologic, cardiac, and muscular systems.
• Effects on sodium channels results in easily triggered depolarization and thus persistent action.
• Accumulation of intracellular sodium also results in exchange for extracellular calcium which is needed in neurotransmitter release.
• Toxins are found within leaves especially, as well as stems, flowers, and nectar.
• The amount of toxin within various members and the growing stage is unknown.

HISTORICAL FINDING
History of exposure to plants

SIGNALMENT
Bovine, ovine, and especially caprine

PHYSICAL EXAMINATION FINDINGS
• Develop within 6 hours of exposure
• Depression
• Severe salivation
• Abdominal pain
• Regurgitation, can be projectile
• Severe toxicosis
  ◦ Cardiac arrhythmia
  ◦ Hypotension
  ◦ Opisthotonus
  ◦ Pyrexia (reported as high as 106°F or 41.1°C)
  ◦ Seizures

CAUSES AND RISK FACTORS
• This toxin is found in members of the heath or *Ericaceae* family. Most common members of this family include:
  ◦ Azaleas and rhododendrons (*Rhododendron*)
  ◦ Heaths (*Erica*)
  ◦ Mountain laurels (*Kalmia*)
  ◦ Heathers (*Calluna*)
  ◦ Madrones (*Arbutus*)
• Members of this family exist as shrubs, subshrubs, herbs, and small trees. They can be evergreen or deciduous.
• The toxins are found in all parts of the plants, including nectar from the flowers.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Oleander
• Foxglove

CBC/BIOCHEMISTRY/URINALYSIS
• No characteristic changes on full blood count
• No characteristic changes on serum biochemistry/urinalysis

OTHER LABORATORY TESTS
Identification of grayanotoxin in feces and urine through use of liquid chromatography-mass spectrometry

OTHER DIAGNOSTIC PROCEDURES
• History of exposure to the plants
• Clinical signs
• Identification of plant in GI contents

TREATMENT

THERAPEUTIC APPROACH
• There are no specific antidotes.
• Atropine has been used with some success either alone or as reported in goats and cattle with a combination of atropine sulfate and sodium camphorsulfonate (see "Drugs of Choice").
• Because of the acute nature of the disease, oral administration of charcoal may be of some benefit in limiting absorption of the toxins.
• Supportive treatment.

MEDICATIONS

DRUGS OF CHOICE
10–20 mg atropine sulfate and 15–20 mL of 10% sodium camphorsulfonate given subcutaneously.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Recovery possible even with severe toxicosis

POSSIBLE COMPLICATIONS
Aspiration pneumonia

PREVENTION
Avoidance of the plant materials

MISCELLANEOUS

ASSOCIATED CONDITIONS

HAEMONCHOSIS

BASICS

OVERVIEW

• *Haemonchus* is a voracious blood-sucking, single-host parasite that causes anemia, hypoproteinemia, and death in ruminants (particularly small ruminants).
• In warm, moist environments, *Haemonchus* is typically the dominant gastrointestinal nematode of pasture production systems.
• *Haemonchus* species (*H. contortus, H. placei*, and *H. similis*) tend to be host-specific, with some potential for cross-infection.
• Populations of *Haemonchus* have developed resistance to almost all currently available anthelmintics.

INCIDENCE/PREVALENCE

When conditions are suitable for transmission, nearly 100% of pastured ruminants will be infected, but the prevalence of clinical disease will vary with the number of worms that are able to establish in specific individuals.

GEOGRAPHIC DISTRIBUTION

Animals grazing in humid tropical regions and regions with summer rainfall, with daily mean temperatures >15°C (>59°F) and monthly rainfall >50 mm.

SYSTEMS AFFECTED

• Digestive
• Hemolymphatic

PATHOPHYSIOLOGY

• Adult *Haemonchus* females have great fecundity, and an individual can release more than 5,000 eggs per day into the host feces.
• L1 and L2 stages survive on bacteria within manure; the L2 sheds its cuticle during development to the infective L3 stage, 5–10 days after eggs are released onto pasture.
• Ruminant hosts are infected by ingesting the L3 from pasture; this stage can only exit the fecal pellet and ascend vegetation in a film of moisture.
• The L3 stage exsheaths in the rumen and moves to the abomasum, enters gastric pits, and molts to L4.
• The L4 feeds on blood and molts to the L5 and then the adult stage which can mate and produce eggs approximately 3 weeks after being acquired. Adult worms can live for months in susceptible hosts.
• Adult worms produce so many eggs that some offspring will survive unfavorable conditions within or outside of the host. The L3 larvae maintain a protective cuticle that helps them avoid desiccation, and they can survive on pasture for weeks to months, depending on conditions.
• During prolonged periods of drought or winter weather, ensheathed larvae survive in the fecal pellet; they are inactive and apparently do not utilize stored energy; when rain occurs they rapidly exit the fecal pellet.
• The early L4 stage can undergo hypobiosis (arrested development) within the abomasum. These larvae are in a state of inactivity and are not affected by the host's immune system. They survive until conditions within the host or environment are more favorable before resuming their life cycle.
• Adults and developing larvae possess a buccal lancet that allows laceration of capillaries in the abomasal mucosa to facilitate feeding, and they have prolyl-carboxypeptidases which can act as anticoagulants to facilitate feeding.
• Loss of erythrocytes and serum protein causes clinical signs of anemia and hypoproteinemia which can be profound, to the point of causing severe morbidity and mortality.

HISTORICAL FINDINGS

• Clinical signs can vary from peracute, to acute or chronic in nature, and reflect variably severe anemia and hypoproteinemia.
• Diarrhea is an infrequent clinical sign.

SIGNALMENT

• All ages of sheep, goats, camelids, deer, and cattle can become infected but recently weaned and lactating small ruminants are at greater risk of disease.
• Until young ruminants have been exposed to *Haemonchus* and maturation of the immune system occurs (4–7 months), they do not develop resistance to the parasite.
• Affected hosts can vary depending on environment and vegetation consumed. Where sheep and goats graze on short grass and legumes, clinical disease is more often seen in goats. When there is plentiful browse, goats are unlikely to be exposed to large numbers of infective larvae.

PHYSICAL EXAMINATION FINDINGS

• Clinical signs primarily reflect anemia and hypoproteinemia.
• Peracute disease is typically reflected by sudden weakness, pallor, recumbency, and death, as the PCV falls to <10%. Typically only a few individuals in the flock will be affected in this manner; soft stool or melena may be observed.
• In acute disease, a larger number of individuals in the flock will be affected. Anemia, pale mucus membranes, and hypoproteinemia (bottle jaw) are the most common clinical signs. Constipation can occur, and wool break often occurs in sheep several weeks after acute clinical signs.
• Chronic disease is often reflected by ill thrift with poor-quality wool, weight loss or failure to gain, and anemia can become unresponsive due to iron depletion.

GENETICS

• There is genetic host resistance to haemonchosis, which usually manifests as acquired protective immunity (after exposure), with fewer worms establishing in these individuals, and established worms producing fewer eggs.
• The genetic aspects of resistance to gastrointestinal parasitism are not well understood. It appears that multiple genes are involved in the protective response and different genes may be more important at different times during the course of infection.
• Ruminant breeds and species that evolved in humid tropical areas are more likely to have genetic traits increasing resistance to infection, including Barbados sheep.
• Factors such as lactation, age, or nutritional status influence the course of disease in individuals.
• Production traits should be carefully measured against parasite resistance. There is no evidence that traits associated with increased production are linked to increased susceptibility, but caution is warranted when selecting animals for breeding.
• Genetic selection can be employed by choosing individual animals with a level of resistance to *Haemonchus* or those that have the capacity to rebound from the effects of parasitism. The offspring of resistant hosts have a higher likelihood of being more resistant.

CAUSES AND RISK FACTORS

• Warm, humid climactic conditions.
• Young or lactating animals; when animals are producing at their genetic maximum they are at greater risk of parasitic disease because they are immunologically and nutritionally challenged.
• Female ruminants are unable to mount a protective immune response against helminths during the periparturient period.
• Heavily stocked and grazed pastures.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Anemia related to other endoparasites, bacterial infections or toxic agents.
• Chronic copper poisoning in sheep may be differentiated by time of the year, age of

affected animals, presence of icterus, and access to sources of copper.
• Poisoning caused by sweet clover, pokeweed, or plants that cause intestinal or other bleeding may resemble haemonchosis. History of access, age of animals, and time of year may help differentiate.

CBC/BIOCHEMISTRY/URINALYSIS
• In acute cases, CBC reveals reduced erythrocyte count and blood hemoglobin concentrations with normal erythrocyte morphology. Surviving animals quickly mount evidence of a regenerative response.
• Chronic haemonchosis results in depletion of iron, cobalt, and copper; hence microcytic, hypochromic anemia may occur.
• Serum protein concentrations are reduced, with reduced albumin/globulin ratio.

OTHER LABORATORY TESTS
• Fecal flotation using saline or sugar flotation media with a specific gravity of 1.18 or higher will float the eggs of *Haemonchus* and other nematodes. Fecal examination will reveal strongylid, thin-shelled segmented eggs. However, visualization of eggs is not diagnostic for *Haemonchus* since other genera of strongylids produce visually identical eggs.
• A quantitative test such as the modified McMaster method allows strongylid egg identification and enumeration. There is a somewhat linear relationship between egg count and the number of adult worms. Fecal egg counts of more than 4,000 eggs per gram of feces are associated with haemonchosis in small ruminants (though this depends upon the time of examination after infection).
• Measuring egg counts before and then 7–10 days after anthelmintic treatment (Fecal Egg Count Reduction Test) can be vital in determining the level of anthelmintic resistance on a specific property.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
• Coproculture, the development of eggs to the infective L3 stage under laboratory conditions, enables specific identification of larvae but can take 10–14 days. This technique also has applicability in assessing anthelmintic resistance via *in vitro* larval development assays.
• A fluorescein-labeled peanut agglutinin test can provide rapid differentiation of *Haemonchus* eggs from those of other strongyles.
• PCR testing is being explored as a method of specifically identifying and quantitating *Haemonchus* infection, and for characterizing anthelmintic resistance in this parasite.
• FAMACHA© testing, the comparison of ocular mucus membrane color to a commercially available chart, allows evaluation of the severity of anemia in individuals. This facilitates selection for treatment of those animals with the highest worm burden to help protect pastures and reduces parasite selection for anthelmintic resistance.

PATHOLOGIC FINDINGS
• Gross postmortem examination identifies adult worms in the abomasum if performed within 24 hours of death. Adults are approximately 2 cm long; males are red and females have a characteristic "barber-pole" appearance arising from the combination of the blood-filled digestive tract against the white reproductive tract. Body cavities may contain transudate, and the abomasal mucosa may range from normal to markedly thickened and ulcerated. Intermandibular edema and pallor of mucus membranes is commonly evident. Feces may be normal, loose, or dark and dry. Bone marrow may appear red and hyperplastic.
• Histologic findings are associated with anemia, hypoxemia, hypoproteinemia, abomasitis, and bone marrow hyperplasia. There may be centrilobular hepatic necrosis, interstitial edema of organs, and infiltration of the abomasal mucosa with lymphocytes, eosinophils, and mast cells.

TREATMENT

THERAPEUTIC APPROACH
• Successful control of haemonchosis should rely on the use of multiple management strategies rather than sole dependence on the periodic administration of anthelmintics. Strategies can include pasture rotation, selective anthelmintic therapy based on fecal and clinical monitoring, and use of non-pharmaceutical control procedures such as administration of copper oxide wire particles, oral feeding of nematophagous fungi (*Duddingtonia flagrans*), and the feeding of condensed tannin forage sources such as *Sericea lespedeza*.
• Anthelmintic resistance in *Haemonchus* has occurred rapidly and is widespread in some areas. Selection by treatment rather than mutation appears to be the driving force in the establishment of resistance. Some of the features that contribute to the rise and spread of anthelmintic resistance include:
  ◦ Tolerant or resistant worms often accompany livestock being introduced into new areas.
  ◦ Underdosing of anthelmintic agents by underestimating body weight, dosing based on the average size of animals in a flock, and by dosing goats at recommendations for sheep (goats and cervids metabolize anthelmintics more quickly than do cattle or sheep).
  ◦ Providing anthelmintics via injectable form – as blood concentrations decline, parasites with some level of tolerance of the drug will be able to establish in the host.
  ◦ Use of cattle pour-on formulations in other species in which they are not as well absorbed.
• Techniques that might enhance the impact of anthelmintic therapy also exist:
  ◦ The effectiveness of benzimidazoles may be enhanced by dividing the dose over several days or by fasting the animals overnight in a dry lot.
  ◦ Combining anthelmintics by administration of two or more drugs from different classes simultaneously. Proprietary drugs using all three main families of anthelmintics are being used for *Haemonchus* resistance problems particularly in Australia and New Zealand.
  ◦ Selection of anthelmintics for individual properties based on those with the likely highest efficacy for that property.
  ◦ In regard to anthelmintic drug rotation, currently it is often suggested that rather than rotate products, a product should be used until it fails before switching to the use of a drug in another class.

SURGICAL CONSIDERATIONS AND TECHNIQUES
N/A

MEDICATIONS

DRUGS OF CHOICE
• *Haemonchus* in cattle and in small ruminants in cooler climates are currently still susceptible to some benzimidazoles, levamisole/morantel, or macrocyclic lactones if administered at an adequate dose via an appropriate route.
• Several new classes of anthelmintics are available in different geographic areas and include the aminoacetonitrile derivative Monepantel, the octadepsipeptide Emodepside, and a member of the Spiroindoles class, Derquantel.
• Drugs which are able to block the ability of *Haemonchus* to clear some anthelmintics are being evaluated.

CONTRAINDICATIONS
• Most of the currently available anthelmintics have a wide safety margin.

HAEMONCHOSIS (CONTINUED)

However, levamisole, especially when injected, can cause signs of nervous stimulation including salivation, lacrimation, urination, and defecation.
• Albendazole in early pregnancy can cause embryonic loss or teratogenic effects.

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
Animals surviving acute disease and treated appropriately are expected to recover, though short-term consequences such as wool break and decreased production may be observed. Peracute and chronically diseased animals have a poor prognosis for survival or return to optimal production.

POSSIBLE COMPLICATIONS
Hypoxemia, recumbency, death

CLIENT EDUCATION
Should support periodic fecal analyses and herd health assessments, pasture management, animal selection, and judicious use of anthelmintic medications

PATIENT CARE
N/A

PREVENTION
• Prevention programs should be based on individualized practices that fit with the environment and management practices of the operation in question. The most effective control programs comprise integrated strategies using a number of different approaches simultaneously.
• Programs that recognize that some individuals are much more at risk than others, and which strive to ensure that the at-risk population is exposed to fewer worms or, if exposed, are treated differently, have a greater potential for success.
• Programs based on chemical control alone are likely to fail unless the season of transmission is very short or new anthelmintics with completely different modes of action are employed.
• Management strategies:
  ◦ In warm humid climates, rapid pasture rotation (where pastures are vacated for as few as 30 days) may be of value during the hottest time of the year in high rainfall areas or on irrigated pastures.
  ◦ Utilizing pastures that have been cropped, especially in the last half of the grazing season, insures that larvae deposited on the cropland will not survive until the next grazing.
  ◦ Alternate or co-grazing with other species or classes of livestock may harvest *Haemonchus* larvae from the pasture, reducing infection of ruminants; typically, *Haemonchus* of sheep and goats does not do well in cattle and vice versa. However, recent observations question this assumption as some populations of *H. contortus* may thrive in calves. Horses do not share *Haemonchus* and can be safely grazed in areas dangerous to ruminants, and older cattle may become infected but are highly resistant to the effects of the worm burden, and can be used to clear larvae from a pasture.
  ◦ Zero grazing for a period of time after an outbreak may enable animals to recover both in terms of reestablishing a protective immune response and replenishing erythrocytes and serum protein.
  ◦ Provision of copper oxide (typically as wire particles) is postulated to alter the reproductive capacity of *Haemonchus* females, reducing fecal egg counts and ultimately decreasing infective larvae on pasture.
• Nutritional strategies:
  ◦ Providing sufficient protein is vital to supporting infected individuals and to facilitating recovery.
  ◦ Provision of increased dietary protein during the periparturient period can reduce egg production by gastrointestinal nematodes.
• Biological control strategies:
  ◦ Pastures in which plants are high in condensed tannins are safer for hosts as ingested larvae are adversely affected.
  ◦ The physical structure of some plants can present a challenge to larvae to ascend the vegetation.
  ◦ Browsing reduces the chance of acquiring larvae as the distance from the ground increases. Most infective larvae are found within two inches (50 mm) of the soil surface.
  ◦ Nematophagous fungi can kill larvae on the pastures. One species, *Duddingtonia flagrans,* is able to traverse the digestive tract and is present in the feces when the larvae hatch. Feeding spores or incorporating them into ruminal boluses has the capacity to lower pasture contamination.
• Vaccination:
  ◦ A vaccine, Barbervax®, was recently made available for use in Australia, where it is reported to have 75–95% efficacy against *Haemonchus* infection in sheep. The vaccine is directed against specific intestinal antigens of the parasite, and is administered as 4–9 subcutaneous injections at approximately 6-week intervals.
• Genetics:
  ◦ Individual animals that display some innate resistance or the capacity to rebound from the effects of parasitism can be selected for breeding, as some of these selection traits may be heritable.
  ◦ Immunity to *Haemonchus* is slow to develop, and cannot overcome exposure to large numbers of larvae; however, there may be an allergic response to massive larval exposure known as "self-cure," during which adult worms are expelled and the larvae that triggered the response may eventually take their place or are also eliminated.

MISCELLANEOUS

ASSOCIATED CONDITIONS
Diarrhea may be observed in some infected individuals.

AGE-RELATED FACTORS
Young and recently weaned animals are at greater risk of clinical disease.

ZOONOTIC POTENTIAL
N/A

PREGNANCY
Pregnant animals are less resistant to infection and more susceptible to clinical disease.

BIOSECURITY
N/A

PRODUCTION MANAGEMENT
This is the most economically significant parasitic disease of pasture-based small ruminant systems, and results in stock losses, reduced production parameters, and expense associated with anthelmintic treatments and potentially vaccination.

SYNONYM
Barber's pole worm

ABBREVIATION
PCV = packed cell volume

HEARTWATER (COWDRIOSIS)

BASICS

OVERVIEW

• A tick-borne rickettsial disease of domestic and wild ruminants is caused by *Ehrlichia* (formerly *Cowdria*) *ruminantium.* This rickettsial agent is transmitted by ticks of the genus *Amblyomma*, particularly the tropical bont tick (*A. variegatum*).
• At least two *Amblyomma* species found in North America are potential vectors and this poses the threat of the disease introduction. Introduction of the vector is also possible through importation of wildlife from endemic areas.
• It is colloquially called "heartwater" due to the common finding of hydropericardium in infected cattle.

INCIDENCE/PREVALENCE

• In areas with the vector the disease is enzootic. The mortality rate in susceptible livestock is in the range <10%–90%, depending on the animal's species, breed, and previous exposures.
• Morbidity and mortality rates are normally higher in non-native than indigenous breeds, and sheep and goats are usually affected more severely than cattle.

GEOGRAPHIC DISTRIBUTION

The disease is enzootic throughout sub-Saharan Africa, Madagascar, and the Caribbean islands of Guadeloupe, Marie-Galante, and Antigua. The disease is exotic to the United States.

SYSTEMS AFFECTED

• Cardiovascular
• Nervous

PATHOPHYSIOLOGY

• Once in the host, the organisms may replicate first within the regional lymph nodes with subsequent dissemination via the bloodstream to invade endothelial cells of blood vessels elsewhere in the body. In domestic ruminants, there seems to be a predilection for endothelial cells of the brain.
• During the febrile stage, and for a short while thereafter, the blood of infected animals is infective to susceptible animals if subinoculated.
• Signs and lesions are associated with functional injury to the vascular endothelium, resulting in increased vascular permeability without recognizable histopathologic or even ultrastructural pathology.
• The concomitant fluid effusion into tissues and body cavities precipitates a fall in arterial pressure and general circulatory failure.
• The lesions in peracute and acute cases are hydrothorax, hydropericardium, edema and congestion of the lungs and brain, splenomegaly, petechiae and ecchymoses on mucosal and serosal surfaces, and occasionally hemorrhage into the GI tract, particularly the abomasum.
• The typically straw-colored effusions are high in large-molecular-weight proteins, including fibrinogen; hence, this fluid readily clots on exposure to air.

SIGNALMENT

• Most domestic ruminants are susceptible. Sheep and goats are more susceptible than other ruminants.
• Among wild ruminants, water buffalo and bison are highly susceptible. Infection has been observed in eland, wildebeest, blesbuck, and Cape buffalo.
• Age resistance, or a reduction in severity of clinical signs after infection, occurs in very young animals (calves <4 weeks of age, lambs and goat kids <1 week), and results in immunity to reinfection with the same strain and a carrier state.

GENETICS

• Among sheep breeds, Persian and Afrikaner are more tolerant than European breeds. Angora goats are highly susceptible.
• *Bos indicus* breeds are more tolerant than *Bos taurus* breeds.

PHYSICAL EXAMINATION FINDINGS

• Incubation period following bite from infected tick is 9–29 days in cattle, 5–35 days in sheep.
• Signs can be peracute, acute (most common), subacute, or subclinical.
• Peracute signs include rapid development of fever, hyperesthesia, lacrimation, convulsions, and sudden death. This form occurs in susceptible breeds introduced into endemic areas and is the rarest form.
• Acute signs include several days of high fever, anorexia, depression, exaggerated gait, excessive blinking, chewing movements, circling, aggression, and most animals die. This is the most common form.
• The subacute form is characterized by mild fever and mild nervous signs and occurs in animals with some natural resistance.
• The subclinical form has been reported in animals with natural resistance including neonates.
• Hydropericardium (hence the name heartwater) and hydrothorax are some of the pathologic findings observed on necropsy.

CAUSES AND RISK FACTORS

• Cowdriosis is caused by *Ehrlichia* (formerly *Cowdria*) *ruminantium,* a rickettsial agent transmitted by ticks of the genus *Amblyomma.*
• Important tick species that transmit the organism are *A. variegatum, A. habraeum,* and *A. pomposum.*
• Naïve animals introduced to endemic areas are highly susceptible. Introduction of vectors carrying *E. ruminantium* may also result in outbreaks.
• In endemic areas, reduced tick populations may lower herd immunity through less-frequent challenge and thereby put herds at greater risk for an epidemic of illness when tick populations rebound.
• In the United States, Gulf Coast states from Florida to Texas are at risk for introduction of the tropical bont tick, and possibly *E. ruminantium,* from the Caribbean.
• Zebu breeds of cattle appear more resistant to infection than European breeds.
• Animals 3–18 months are most susceptible, while young calves, lambs, and goat kids exhibit age resistance.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• Differential diagnoses include diseases that cause sudden death (peracute form) or cortical signs. These include anthrax, lightning strike, polioencephalomalacia, salt poisoning, lead poisoning, and rabies.
• The acute form may resemble babesiosis, theileriosis, and trypanosomiasis, especially in endemic areas.
• Nervous system abnormalities may suggest other diseases such as rabies, hypomagnesemia, nervous ketosis, listeriosis, tetanus, meningitis or encephalitis, or poisoning by some toxins.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

• Serologic assays (e.g., ELISA) are available but suffer from cross-reactions with other rickettsia.
• PCR and LAMP can identify *E. ruminantium* in tissues at necropsy, or in the blood of live animals from just before the onset of the fever to a few days after recovery.
• Cowdriosis should be suspected when an animal is infested with *Amblyomma* ticks and develops fever and nervous signs and dies.
• In fatal cases, presence of characteristic gross lesions and demonstration of *E. ruminantium* colonies using Giemsa stain on endothelial cells of brain smears.

PATHOLOGIC FINDINGS.

Gross lesions include hydrothorax, hydropericardium, pulmonary edema, splenomegaly, petechiae, and ecchymoses on serosal surfaces.

TREATMENT

THERAPEUTIC APPROACH

• Tetracyclines are the treatment of choice but must be given early in the course of the disease.
• Chemoprophylaxis with tetracyclines has been suggested in animals introduced to endemic areas.

• Short-acting formulations of oxytetracycline, 10–20 mg/kg body weight, given two times at 24-hour intervals

MEDICATIONS

DRUGS OF CHOICE

• Tetracyclines are the drug of choice (see "Therapeutic Approach")
• Corticosteroids have been used as supportive therapy (prednisolone 1 mg/kg, IM), although there is debate as to the effectiveness and rationale for their use.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Animals with the neurologic form have a poor prognosis.
• Animals with the acute form of heartwater usually die within a week.
• Heartwater can also present as a subacute disease with milder signs such as a prolonged fever, coughing and mild incoordination. CNS signs are inconsistent in this form. Subacute cases are reported to be infrequent (although some cases might not be recognized if diagnostic testing is not done). In this form, the animal either recovers or dies within 1–2 weeks.

PATIENT CARE

Affected animals must be kept quiet in a cool area with soft bedding and be totally undisturbed; any stimulation can preempt a convulsive episode and subsequent death.

PREVENTION

• Various vaccines are available in endemic areas with varying success.
• Tick control is essential.
• Exposure of young animals may permit development of resistance.

MISCELLANEOUS

AGE-RELATED FACTORS

Young animals are more resistant to infection.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Heartwater has been associated infrequently with abortion in infected animals.

BIOSECURITY

Heartwater is a foreign animal disease in the United States. Contact appropriate animal health officials (e.g., USDA—APHIS Veterinary Services http://www.aphis.usda.gov/vs) for suspected cases.

Heat Stress

BASICS

OVERVIEW
• Disease syndrome in ruminants secondary to exposure to conditions of excessively high ambient temperature or combinations of high ambient temperature and high humidity.
• The thermoneutral zone for cattle is between 41°F (5°C) and 77°F (25°C).
• The temperature humidity index is a good tool to determine risk. A THI ≥72 indicates some degree of risk.

INCIDENCE/PREVALENCE
N/A

GEOGRAPHIC DISTRIBUTION
Heat stress can occur in any part of the world where ambient temperature rises above 75°F (24°C), particularly with high humidity.

SYSTEMS AFFECTED
• Multisystemic

PATHOPHYSIOLOGY
• The preoptic area of the anterior hypothalamus receives and processes information from thermosensors throughout the body.
• Hyperthermia arises from thermoregulatory malfunction. In cases of heat stress, malfunction arises due to an elevated thermal burden that the body is incapable of handling.

HISTORICAL FINDINGS
Temperature rises above 75°F (24°C), particularly with high humidity ± increased stress

SIGNALMENT
Potentially all ruminant species. Disease is more severe in heavily fleeced animals.

PHYSICAL EXAMINATION FINDINGS
• Signs may vary due to the severity of the disease.
• Decreased fertility, decreased signs of estrus in females, increased number of abnormal spermatozoa in males, depressed libido in males, early embryonic death if early in gestation.
• Dullness, lethargy, increased respiratory and heart rates, open mouth breathing may all occur.
• Congested conjunctiva as well as pupil dilation or constriction depending on severity of disease may be present.
• Weak pulses and electrolyte and acid-base disturbances may occur as the disease progresses.

GENETICS
N/A

CAUSES AND RISK FACTORS
• Breakdown of thermoregulatory function due to exposure to periods of high heat ± high humidity
• Environmental factors
  ◦ Temperature
  ◦ Humidity
  ◦ Air movement
  ◦ High nighttime ambient temperatures
• Animal factors
  ◦ Dehydration
  ◦ Exercise
  ◦ Dark coat color
  ◦ Heavy fiber in sheep and fiber goats
  ◦ Obesity
  ◦ Stage of production—pregnant and lactating are at greater risk
  ◦ Age—old and young are at greater risk
  ◦ Current or recent illness
• Nutritional factors
  ◦ Excess dietary protein—removing excess nitrogen requires energy and generates heat
  ◦ Poor-quality hay—increases the heat of digestion
  ◦ Selenium-deficient diets
  ◦ Vitamin- and mineral-deficient diets
  ◦ Salt-deficient diets
• Management factors
  ◦ Availability of fresh drinking water—water consumption increases with ambient temperature.
  ◦ Availability of shade.
  ◦ Availability of cooling water.
  ◦ Timing of stressful activity—early morning before the heat of the day is best. Evening is less preferable as animals are dissipating heat from the day at that time.
  ◦ Timing of feeding—late day feeding will allow for the heat of digestion to be during cooler nighttime hours.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES
• Infectious diseases that generate fever
• Pneumonia
• Rumen acidosis
• GI causes of colic
• Abomasal ulcers

CBC/BIOCHEMISTRY/URINALYSIS
• CBC often shows a mature neutrophilia with no left shift, platelet count may decrease with time.
• Biochemistry—abnormalities vary depending on organ systems involved. Increases can be seen in creatinine, urea nitrogen, AST, CK, bilirubin, and SDH. Hypoproteinemia may be present. Electrolytes (Na and Cl) may be decreased. Whole body potassium is often decreased, but serum levels may be increased in the presence of acidemia. Metabolic and respiratory acidosis also may be present.
• Urinalysis—initially increased specific gravity that may become isosthenuric if renal failure ensues, tubular casts may be present in individuals with severe disease, positive blood and protein also may be present.

OTHER LABORATORY TESTS
Clotting profiles—clotting times may be increased.

IMAGING
N/A

OTHER DIAGNOSTIC PROCEDURES
CSF—used to rule out other causes of neurologic disease

PATHOLOGIC FINDINGS
• Gross postmortem
  ◦ Autolysis beyond what is expected for time of death
  ◦ Hemorrhages and other signs consistent with DIC
  ◦ Serous atrophy of fat
• Histologic changes
  ◦ Renal necrosis
  ◦ Hepatic necrosis
  ◦ Coagulation necrosis of neurons
  ◦ Vascular congestion in the lungs, liver, spleen, and myocardium

TREATMENT

THERAPEUTIC APPROACH
• Cooling to within a normal rectal temperature—care should be taken as affected animals may lack the ability to warm themselves if overcooled. Intact fleece in sheep will help insulate the animal even when wet, so cooling water must soak through to the skin.
• IV fluids—correction of dehydration, electrolyte disturbances, and acidosis. Intranasal oxygen therapy if indicated.
• Shearing (sheep)—if not already shorn, will increase area for heat loss.
• Limit activity as muscle activity increases heat production.

MEDICATIONS

DRUGS OF CHOICE
• Anti-inflammatory agents
  ◦ Steroids—for shock
  ◦ Dexamethasone—0.05–0.1 mg/kg, IV or SC, q48h for 2 treatments
  ◦ Prednisolone sodium succinate—0.5–1.0 mg/kg IV or SC, q12–24h
  ◦ Nonsteroidal anti-inflammatory agents—flunixin meglumine 1.1 mg/kg or meloxicam (0.5 mg/kg SC, IV, or PO). NSAIDs should be used cautiously as many heat-stressed animals may have severe renal compromise at presentation.
• Antimicrobial agents—for prevention of secondary infection. May not be necessary in all cases.
  ◦ Oxytetracycline 200 mg/mL—18 mg/kg SC q72h. Use with caution in animals with renal compromise.

(CONTINUED) HEAT STRESS

- ° Ampicillin trihydrate—11 mg/kg IM q24h. Sodium ampicillin can be used q8h at the same dose.
- ° Penicillin—22,000 IU/kg IM or SC q12h. Potassium penicillin can be used IV q6h at the same dose.

• Antioxidant agents
- ° Vitamin E—immediate antioxidant activity: 1 mL/100 lb or 45 kg SC or IM (300 IU/mL)
- ° Selenium—antioxidant activity will take 7–10 days for effect: Bo-Se® (1 mg/mL selenium and 50 mg/mL vitamin E)—1 mL/50 lb; or 22 kg Mu-Se (5 mg/mL selenium and 50 mg/mL vitamin E)—1 mL/200 lb or 90 kg.

CONTRAINDICATIONS
NSAIDs should be used with caution because severe renal compromise is often present at presentation.

PRECAUTIONS
Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS
N/A

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS
• Prognosis varies from good to grave depending on condition at the time of admission.
• Early heat stress with no systemic complications will often resolve with cooling and several days in a cooler environment.
• Individuals with organ failure and other serious manifestations may not survive despite aggressive therapy.

POSSIBLE COMPLICATIONS
• Severely affected animals are more predisposed in the future.
• Infertility:
- ° Male—excessive heat is spermicidal to primary spermatocytes.
- ° Female—ovarian activity will decrease in times of high heat.

• Pregnancy loss
• Congenital abnormalities in the fetus

PATIENT CARE
• Rectal temperature should be monitored regularly until stabilized, then several times daily.
• Serum biochemistry should initially be monitored depending on severity of disease to assess progress and provide a basis for alteration in fluid therapy.

PREVENTION
• Clients should be educated on risk factors and prevention techniques as well as early recognition of affected animals.
• Adequate access to clean drinking water.
• Adequate access to a mineral and salt supplement.
• Provide shade, fans, and other cooling mechanisms for animals during high heat and humidity.
• Observe animals and institute immediate treatment at signs of trouble.

MISCELLANEOUS

PREGNANCY
• Steroid use during pregnancy may induce abortion.
• Thermal damage to the developing fetus may result in congenital abnormalities, particularly of the CNS.

ABBREVIATIONS
• AST = aspartate aminotransferase
• CK = creatine kinase
• CNS = central nervous system
• CSF = cerebrospinal fluid
• DIC = disseminated intravascular coagulation
• GI = gastrointestinal
• IM = intramuscular
• IV = intravenous
• NSAIDs = nonsteroidal anti-inflammatory drugs
• SC = subcutaneous
• SDH = sorbitol dehydrogenase

HEAVY METAL TOXICOSIS

BASICS

OVERVIEW

• The term "heavy metals" has been given a wide range of inconsistent meanings and has not been defined by any authoritative body such as IUPAC.
• Here "heavy metals" describes a group of metals and metalloids (semimetals), specifically arsenic (As), copper (Cu), lead (Pb), molybdenum (Mo), selenium (Se), and zinc (Zn), which have been associated with toxicity in ruminants under natural conditions.
• Toxicity arising from exposure (mostly by ingestion) to heavy metals.
• Injectable products containing minerals have the potential to contribute to toxicosis when not used according to the label.

INCIDENCE/PREVALENCE

• Incidence of heavy metal toxicosis is to some extent influenced by nutrition and other management factors, age, sex, and breed (see "Signalment").
• Arsenic toxicity is now less frequent because of reduced use of As-containing compounds as pesticides.
• Peak incidence of Cu toxicity occurs in the fall and winter while most cases of Pb toxicity are associated with seeding and harvesting activities.

GEOGRAPHIC DISTRIBUTION

• Heavy metal toxicoses can occur virtually anywhere.
• In the United States, Cu toxicosis is more common in western states.
• Mo is naturally high in soils in some US states (Florida, Oregon, California, Utah, Hawaii, Montana, Colorado, and Nevada) and in several areas of other countries around the world.

SYSTEMS AFFECTED

• As—digestive, nervous, respiratory, cardiovascular, multisystemic
• Cu—digestive, hemolymphatic, cardiovascular, multisystemic
• Pb—nervous, digestive, hemolymphatic, musculoskeletal, multisystemic
• Mo—digestive, hemolymphatic, musculoskeletal, nervous, cardiovascular, integument
• Se—integument, musculoskeletal, cardiovascular
• Zn—hemolymphatic, digestive, multisystemic

PATHOPHYSIOLOGY

• Arsenic (As)—exists in trivalent and pentavalent forms. Trivalent arsenicals bind to sulfhydryl (−SH) groups, leading to inactivation of enzymes and enzyme cofactors including those involved in cellular respiration (TCA cycle). They also impair capillary integrity resulting in plasma transudation into the GI tract. Pentavalent arsenicals uncouple oxidative phosphorylation, leading to cellular energy deficits.
• Copper (Cu)—acute exposure causes irritation and coagulative necrosis of GI mucosa. Chronic toxicity occurs when the capacity of the liver to regulate Cu (by sequestration and excretion) is exceeded. Excess Cu undergoes redox cycling ($Cu^{+} \Leftrightarrow Cu^{++}$) and generates reactive oxygen species that cause membrane lipid peroxidation and necrosis of hepatocytes. Cu is then released from necrotic hepatocytes to blood circulation and damages RBC, causing intravascular hemolysis and release of hemoglobin. Damage to RBC causes anoxia, more centrilobular hepatic necrosis, and more release of Cu, which accumulates in and damages the kidney. Cu also inactivates proteins and enzymes by binding to –SH groups and may displace other essential trace metals (e.g., Zn) from their proteins.
• Lead (Pb)—binds to –SH groups and inactivates several enzymes including those involved in heme synthesis, impairs nerve and muscle transmission by competing with calcium (Ca), displaces Ca in bone and Ca-binding proteins (e.g., calmodulin), impairs membrane-bound enzymes (e.g., Na^{+},K^{+}-ATPase) leading to RBC fragility and renal tubular injury, impairs vitamin D metabolism, and interferes with GABA production and activity in the CNS. Pb is also irritating (GI mucus membrane), toxic to germ cells (gametes), teratogenic, and immunosuppressive.
• Molybdenum (Mo)—interferes with Cu metabolism leading to Cu deficiency—Mo and sulfur (S) form insoluble thiomolybdates in the rumen, which bind and reduce absorption of Cu—and stimulate urinary loss of Cu. Some thiomolybdates increase hepatobiliary excretion of Cu, decrease blood Cu availability, and directly inhibit Cu-dependent enzymes. Mo may also alter Zn metabolism and impair myelin maintenance and function, leading to enzootic ataxia in lambs.
• Selenium (Se)—acts as an antioxidant, especially in conjunction with vitamin E. Necessary for glutathione peroxidase formation. Glutathione peroxidase catalyzes the reduction of hydrogen peroxide and lipid hydroperoxides, preventing oxidative damage to body tissues. A second selenium dependence enzyme is iodothyronine 5′-deiodinase. This enzyme catalyzes the deiodination of thyroxine (T4) to the more metabolically active triiodothyronine (T3) in tissues. Acute toxicity is associated with myocardial and secondary liver pathology. Chronic toxicity affects hooves and hair.
• Zinc (Zn)—exact pathophysiology of Zn toxicity in ruminants is unknown. However, Zn irritates the GI tract; antagonizes Ca, Cu, and iron (Fe) metabolism; and injures the pancreas and pancreatic ducts.

SIGNALMENT

• All ruminants are susceptible to heavy metal toxicosis.
• Sheep are very sensitive to Cu, while Pb most commonly poisons cattle.
• Ruminants are more sensitive than nonruminants to Mo.
• As, Pb, and Zn toxicities have no breed predilections.
• Cu—British breeds of sheep (e.g., Suffolk, Oxford, and Shropshire), Texel sheep, and Jersey cattle are more susceptible.
• Mo—Scottish Blackface and Finnish Landrace sheep are apparently more prone to develop swayback.
• Young and old animals are more susceptible to heavy metal toxicosis.

PHYSICAL EXAMINATION FINDINGS

• As—abdominal pain, weakness, staggering, ataxia, watery diarrhea, ruminal atony, weak rapid pulse and shock, oliguria, proteinuria, dehydration, uremia, and acidosis.
• Cu—*acute toxicity:* vomiting, anorexia, hypersalivation, abdominal pain, greenish diarrhea, dehydration, shock, collapse, and death. *Chronic:* sudden onset of hemolytic crisis with weakness, anorexia, thirst, depression, hyperventilation, trembling, anemia, hemoglobinemia, methemaglobinemia, hemoglobinuria (port wine urine), icterus, dyspnea, and death.
• Pb—depression, hyperesthesia, muscle tremors, convulsions, blindness, ataxia, seizures, incoordination, aggression, head pressing, spastic twitching of eyelids, bloat, tenesmus, diarrhea, teeth grinding, jaw champing, and death.
• Mo—sudden death, anorexia, severe diarrhea with gas bubbles, emaciation, reduced growth, anemia, lameness, ataxia, swayback in lambs, recumbency, protrusion of nictitating membrane, blindness, achromotrichia (depigmentation of hair/wool), rough hair coat, alopecia, deformity of limbs, muscular degeneration, decreased milk production, and decreased reproductive performance.
• Se—acute toxicosis causes anorexia, depression, abnormal posture, diarrhea, colic, increased pulse and respiration, frothy nasal discharge, moist rales, respiratory difficulty, weakness, dyspnea, garlicky odor to the breath, and sudden death in calves. Myocardial and hepatic pathology may be observed. Chronic toxicosis causes hoof deformation, hair loss, discoloration and general roughness of the coat.
• Zn—green-colored diarrhea, dehydration, anemia, jaundice, weakness, paresis, anorexia, reduced weight gain, decreased milk yield, subcutaneous edema, polydipsia, polyuria, polyphagia, depression, listlessness, chemosis, exophthalmia, convulsions, and death.

(CONTINUED)

HEAVY METAL TOXICOSIS

CAUSES AND RISK FACTORS

• As—grazing in areas around As mining and smelting sites, exposure to herbicides or old pesticides that have been improperly discarded or stored.
• Cu—excessive administration of Cu formulations or ingestion of improperly formulated rations, feeding sheep feeds formulated for other animals, consumption of vegetation or water contaminated with Cu (e.g., near mining/smelting operations or pastures amended with poultry or swine manure), consumption of forage/feeds low in Mo and S and grazing animals in areas containing hepatotoxic plants (e.g., plants containing pyrrolizidine alkaloids). Chronic toxicity is precipitated by stress (e.g., shipping, bad weather, deteriorating plane of nutrition, or lactation).
• Pb—consumption of forages contaminated by airborne emissions near Pb smelters or along roadsides, consumption of contaminated water or feed from Pb-lined pipes and drinking/feeding utensils, ingestion of Pb-containing products (automotive batteries, farm machinery grease or oil, paints, putties, and pesticides). In cattle, many cases are associated with seeding and harvesting activities when used oil and batteries are likely to be improperly disposed. Toxicity is exacerbated in animals deficient in Ca, Zn, iron (Fe), and vitamin D. The restricted use of leaded gasoline and oils has significantly reduced environmental Pb contamination.
• Mo—consumption of contaminated pastures (near mining or metal production plants) or forage grown with heavy application molybdic or phosphate fertilizers and lime. Low dietary Cu and high dietary S exacerbate the toxicity. High soil pH increases Mo absorption and decreases Cu absorption.
• Se—the only metal regulated by the Food and Drug Administration because of the low safety margin in feed. Only 0.3 ppm Se is allowed to be supplemented in the total diet. Injectable Se products may cause toxicosis if label directions are not followed. If two different types of injectable Se products are used there may be an overdose. Selenium-accumulating plants may also contribute to chronic selenium toxicosis. Elevated concentrations of organic or chelated Se sources may contribute to toxicosis. Injection of selenium at 0.2–0.5 mg/kg in young cattle and 1 mg/kg in mature cattle will cause acute toxicosis. Diets >50 ppm will cause acute toxicosis. Chronic toxicosis is observed when dietary concentration of Se is >20–50 ppm for >3 days.
• Zn—consumption of improperly formulated diets or zinc-contaminated forage (e.g., near galvanizing factories and mines), access to substances containing Zn, and careless use of Zn sulfate as a prophylactic and treatment of diseases (e.g., ovine foot rot, facial eczema, and lupinosis).

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

• As—Pb toxicity, insecticide poisoning, selenium (Se) toxicity, Mo toxicity, Cu toxicity, bovine viral diarrhea.
• Cu—infectious gastroenteritis, leptospirosis, arsenic or selenium toxicoses, phenothiazine and other anthelmintic poisonings, bacillary hemoglobinuria, nitrate/nitrite poisoning, postparturient hemoglobinuria, babesiosis, *Corynebacterium renale* infection.
• Pb—other diseases with nervous signs including rabies, PEM, TEME, listeriosis, ammoniated feed toxicosis, hepatic encephalopathy, nervous coccidiosis, tetanus, hypovitaminosis A, thiamine deficiency, sodium (Na) ion toxicosis, hypomagnesemic tetany, nervous acetonemia, As poisoning, brain abscess or neoplasia, *Haemophilus* meningoencephalitis.
• Se—acute toxicosis has to be differentiated from acute Se deficiency, anaphylaxis, ionophores, Japanese yew, gossypol, organophosphates and carbamates.
• Mo—primary Cu deficiency, enzootic ataxia, infectious gastroenteritis, internal parasitisms, leptospirosis, anthelmintic poisoning, As toxicosis, Se toxicosis.
• Zn—other causes of diarrhea or anemia, such as acute autoimmune hemolytic anemia.

CBC/BIOCHEMISTRY/URINALYSIS

• As—elevated hematocrit, BUN and urine specific gravity, and proteinuria.
• Cu—hemoglobinemia, methemoglobinemia, reduced blood glutathione, reduced PCV, increased WBC, AST, LDH, AP, GGT, SDH, and bilirubin.
• Pb—microcytic hypochromic to normocytic normochromic anemia, basophilic stippling, high nucleated RBC counts, mature leukocytosis, decreased myeloid/erythroid ratio, increased RBC fragility leading to anisocytosis, polychromasia, echinocytosis, poikilocytosis, and target cells. Also urinary ALA levels are elevated; RBC ALAD and porphyrin levels are reduced and elevated, respectively.
• Mo—microcytic hypochromic anemia, elevated AST, GGT, GDH, CK, SDH, bilirubin, creatinine, and Ca, and increased or decreased BUN (depending on the stage of the toxicosis).
• Se—with chronic Se toxicosis there may be increased PT, PTT, fibrinogen, GTH, ALT, AST, and ALP.
• Zn—anemia, neutrophilia, immature RBCs, uremia, reduced erythrocyte ALAD, elevated blood Na, glucose, LDH, GGT, AP, and SDH.

OTHER LABORATORY TESTS

• As—analyze for As concentration in liver, kidney, urine, GI contents, feces, and in suspected feeds.
• Cu—analyze for Cu concentration in serum, liver, kidneys, and in suspected feed.
• Pb—analyze for Pb concentration in whole blood (>0.6 ppm is diagnostic), kidney, and liver as well as urinary ALA.
• Mo—determine Mo concentration in blood, liver, and kidney. Blood levels that result in toxicity depend on dietary intake of Cu and S. Quantify Mo and Cu in feeds and forage.
• Se—analyze for Mn concentration in serum, whole blood or liver. Whole blood will reflect what the diet has been for the last 30 days.
• Zn—analyze for Zn concentration in serum and tissues (e.g., kidney, liver, pancreas) and urine. Special royal-blue top tubes are recommended for blood collection to avoid contamination.

PATHOLOGIC FINDINGS

• As—abomasum and intestines show redness and congestion of mucosa, submucosal edema, and epithelial necrosis.
• Cu—acute toxicity results in severe gastroenteritis with hemorrhage, edema, erosions, and ulcerations in the abomasum, faint-blue color of GI contents, generalized icterus, and swollen friable livers. In chronic toxicity, livers appear yellowish, swollen, and friable; kidneys are dark-red or bluish-black (gunmetal blue kidneys); and gall bladders are distended with greenish bile. Histopathology reveals centrilobular coagulative necrosis with fibrosis of portal areas and lymphocytic inflammation in liver, proliferation and apoptosis of bile ducts with bile stasis, necrosis of renal tubular and glomerular cells and hemoglobin in renal tubules, brown-black and enlarged spleen with numerous fragmented RBCs, and status spongiosus in the CNS white matter.
• Pb—emaciation, muscle wasting, and degenerative changes in the nervous system and kidney. Histopathology reveals laminar cortical cerebral necrosis, necrosis of renal tubules with high numbers of mitotic figures, and osteoporosis.
• Mo—emaciation, coarse and poorly pigmented hair/wool, osteoporosis and fractures, swollen friable livers, and swollen kidneys with perirenal edema. Histopathology shows hydropic hepatocellular degeneration and periacinar hemorrhagic necrosis, hydropic renal degeneration with tubular necrosis, lysis of cerebral white matter, and demyelination and degeneration of motor tracts in the spinal

HEAVY METAL TOXICOSIS (CONTINUED)

cord and neurons (in lambs with swayback).
• Se—acute myocardial and/or secondary hepatic necrosis. Acute toxicosis causes pulmonary edema, pulmonary congestion, pulmonary hemorrhage, hepatic necrosis, myocardial necrosis, myocardial hemorrhage, and renal necrosis. Chronic toxicosis may cause hoof abnormalities, degeneration of the joint cartilage and bone, and reduced fertility.
• Zn—poor body condition, abomasitis and duodenitis with greenish mucosa, submucosal edema in the rumen and abomasum, catarrhal enteritis and congestion of small intestines, subcutaneous edema, hydrothorax, hydropericardium, and pancreatic atrophy. Cattle also show pulmonary emphysema, pale flabby myocardium, severe hepatic degeneration, and lesions in the pancreas. Histopathology reveals fibrosing pancreatitis, renal glomerular and tubular lesions, multifocal granulomas in the liver, and proliferation of neck cells of gastric glands.

TREATMENT

THERAPEUTIC APPROACH

Stabilize the patient, eliminate source of heavy metal, decontaminate (e.g., by physical removal through rumenotomy, washing off topically or by administration of cathartics), administer antidote (chelation therapy), enhance elimination, and provide symptomatic and supportive care.

MEDICATIONS

DRUGS OF CHOICE

• As—dimercaprol (BAL) 3 mg/kg IM q8h (before clinical signs) or 6 mg/kg IM q8h (after onset of clinical signs) for 3–5 days; sodium thiosulfate (30–60 g PO q6h for 3–4 days).
• Cu—ammonium molybdate (50–500 mg PO q24h per head) and sodium thiosulfate (300–1000 mg PO q24h per head) for 3 weeks (an aqueous mixture of the two salts can be sprayed on the feed to reduce labor); three treatments of ammonium tetrathiomolybdate (sheep, 1.7–3.4 mg/head IV or SC) on alternate days; D-penicillamine (52 mg/kg/day PO for 6 days), but it is expensive for treating on a flock basis.
• Pb—diazepam (0.55–1.5 mg/kg IM) for seizures; Ca-EDTA (73.3 mg/kg slow IV, divided q24h or q8h) for 3–5 days; BAL (3–6 mg/kg IM q8h for 3–5 days). Thiamine 250–1000 mg q12h is a useful adjunct to Ca-EDTA.
• Mo—copper glycinate (60 mg/calf and 120 mg/adult cattle SC); 1000 mg copper sulfate per adult cow; copper sulfate (1–5% depending on Mo levels in the feed) in salt-mineral mix.
• Se—primarily supportive therapy. Adding arsenic-containing compounds may be helpful in chronic toxicosis. Feeding rations containing 50–100 ppm of arsanilic acid may be helpful for calves. This may accelerate the excretion of Se.
• Zn—chelation therapy with Ca-EDTA as for Pb and supplementation of ration with Cu.

CONTRAINDICATIONS

• Ca-EDTA and BAL—use with extreme caution and adjust dose in patients with impaired renal function.
• Ca-EDTA and BAL should not be used in patients with anuria and impaired liver function, respectively.
• Exercise extra caution when using Cu compounds in sheep (very sensitive to Cu).
• Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

• Ca-EDTA—use with caution with nephrotoxic drugs (e.g., aminoglycosides) and glucocorticoids.
• BAL—do not administer with Fe and Se salts (forms toxic complexes).
• Chelation therapy can cause depletion of essential minerals (e.g., Zn and Fe).

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

• Generally favorable in animals with mild to moderate signs provided that the source of the heavy metal can be identified and removed from the animal's environment.
• Guarded to poor in animals with severe signs (e.g., hemolytic crisis, severe CNS signs).

PREVENTION

Prevent access to sources of heavy metals and ensure correct mineral nutrition and proper pasture management.

MISCELLANEOUS

ASSOCIATED CONDITIONS

As and Pb toxicities—none; Cu toxicity—Zn deficiency, possibly Mo deficiency; Mo and Zn toxicities—Cu deficiency

ZOONOTIC POTENTIAL

• None. However, organ meat may contain levels of heavy metals that pose a risk to humans (e.g., livers containing >500 mg/kg Cu are considered a risk to public health).
• Lead and Mo are secreted in milk and can present a risk to humans.

PREGNANCY

• Pb crosses placental barrier and is secreted in milk and thus can cause fetal and neonatal poisoning.
• Zn exposure in ewes can cause fetal and/or neonatal Cu deficiency.
• Pregnant ruminants are more susceptible to Zn toxicity.

PRODUCTION MANAGEMENT

• Nutrition—Ca, Zn, S, Fe, and vitamin D supplementation can reduce incidence of heavy metal toxicity. For example, the maintenance of correct Cu-to-Mo-to-S ratio in feeds is imperative to reduce incidence of Mo toxicity.
• Pasture management—use of some fertilizers may induce mineral imbalances in forage, hepatotoxic plants increase toxicity of Cu, and some plants may reduce bioavailability of essential heavy metals such as Cu.
• Cu : Zn ratio in the feed should be 1:4, Cu : Mn ratio in the feed should be 2:1.

SYNONYMS

As toxicity—arsenic toxicosis. Other names for As-containing compounds include arsenicals, arsenites, arsenates, arsine
Cu toxicity—enzootic icterus of sheep, copper toxicosis, copper poisoning, copper sulfate poisoning
Pb toxicity—plumbism, saturnism, lead intoxication, lead poisoning, lead toxicosis
Mo toxicity—molybdenosis, molybdenum toxicosis, teart disease, peat scours
Zn toxicity—zinc poisoning, new wire disease (in birds), zincalism (in humans)

ABBREVIATIONS

• ALA = δ-aminolevulinic acid
• ALAD = δ-aminolevulinic acid dehydratase
• AP = alkaline phosphatase
• AST = aspartate aminotransferase
• BAL = British anti-Lewisite
• CK = creatinine kinase
• EDTA = ethylenediaminetetraacetic acid
• GABA = gamma aminobutyric acid
• GDH = glutamate dehydrogenase
• GGT = gamma-glutamyl transferase
• GI = gastrointestinal
• IM = intramuscular
• IUPAC = International Union of Pure and Applied Chemistry
• LDH = lactate dehydrogenase

(CONTINUED) HEAVY METAL TOXICOSIS

• Na^+,K^+-ATPase = sodium, potassium adenosine triphosphatase (sodium pump)
• PCV = packed cell volume
• PEM = polioencephalomalacia
• PO = per os (by mouth)
• SDH = sorbitol dehydrogenase
• RBC = red blood cell
• TCA = tricarboxylic cycle (Krebs cycle)
• TEME = thromboembolic meningoencephalitis
• WBC = white blood cell
