ceptible to direct sunlight and so they should be kept in

with pregnant or lambing sheep. The virus is fragile and

the shade.

does not survive more than a day outside the host.

There may be many distinct MCF virus forms.

The incubation period is shorter for the African form.

***Chronic heat stress** (see Chapter 8)*

Following infection, there is an eclipse phase of nine to

seventeen days, then viraemia continues until death.

The chronic or subacute form occurs more frequently

After a further three to fifteen days, signs develop, fol-

than acute heat stress. When exposed to high tempera-

lowed by death five to ten days after their onset. Trans-

tures cattle compensate by increasing their loss of heat

mission is probably by inhalation or possibly blood

by panting and sweating. They can also reduce heat pro-

transfusion.

duction by reducing food intake, drinking more and

reducing activity. Cattle are able to accept high midday *temperatures if the evenings and nights are cool.*

Signs

In chronic heat stress there is decreased milk pro-

duction, reduction in weight gain and sexual maturity.

Cases are sporadic. Animals are very ill with anorexia,

There is also some loss in fertility, particularly involving

pyrexia (40.5–41.5°C; 105–107°F), depression and loss

spermatogenesis in the bull. When animals are affected

of condition. An early pathognomonic sign is an intense

they should be provided with shelter or otherwise given

scleral congestion with bilateral keratitis and corneal

access to well-ventilated shady areas. Oestrus suppres-

opacity starting at the edge of the sclera, causing blind-

sion may also occur. When cattle are grazed in very hot

ness. Early lesions also involve the buccal mucosa, with

conditions grazing should be restricted to the evenings,

reddening of the lips, gingivae and muzzle. Erosions

nights and mornings. If necessary zero-grazing may

develop, including necrosis of the tips of the labial

need to be adopted. In such circumstances, where the

papillae and the mouth corners.

Other signs vary. They can include nervous signs such

or carbohydrates are fed, the calf may be unable to

Calves need to rest and sleep in order to recuperate

utilize them and if milk is acidified too much, calves may

and avoid danger. They need to use several postures

which include one in which they rest the head on the

legs and another in which the legs are fully stretched

out (de Wilt, 1985; Ketelaar-de Lauwere & Smits, 1989,

1991).

Exploration is important as a means of preparing for

the avoidance of danger and is a behaviour shown

by all calves (Kiley-Worthington & de la Plain, 1983;

Fraser & Broom, 1990). Calves need to explore and it

may be that higher levels of stereotypies (Dannemann

et al. , 1985) and fearfulness (Webster & Saville, 1981) in poorly lit buildings are a consequence of inability to

explore.

Exercise is needed for normal bone and muscle

development and calves choose to walk at intervals if *they can, show considerable activity when released*

from a small pen and have locomotor problems if con-

fined in a small pen for a long period (Warnick et al. , 1977; Dellmeier et al. , 1985; Trunkfield et al. , 1991).

Normal calf anatomical, physiological and behav-

ioural development occurs only if the calves have some

fibre-containing material to eat (van Putten & Elshof,

1978; Webster, 1984; Webster et al. , 1985a) so it is clear that they need fibre in their diet after the first few weeks

different from those of the closed herd.

makes it much more likely that the sick animal will

recover without the unwelcome attentions of the other

animals who will always tend to act as bullies. In nature, *the sick animal usually separates itself from the rest of*

Group size

the herd, but it is often impossible for the housed

One of the principal ways of putting the housing on a

animal to do this. Also, under the more intensive

firm footing is to keep the animals in groups of minimal

systems of management, more animals are likely to

size. At first sight this sounds an old-fashioned and even

suffer from the aggression of their pen-mates and it is

reactionary concept that may eliminate all those advan-

essential that such animals are removed to prevent

tages from automation that large units can give us, but

them from suffering or being killed. It is also easier,

this certainly need not be the case. If groups are small

with an isolated animal, to give it such therapy as it

it is easier to match the animals in them for size, weight

needs and to give it any special environmental condi-

and age. Under these circumstances it is well estab-

tions, such as extra warmth or adjustments to comfort

lished that fighting and bullying are kept to a minimum,

requirements. For new entrants to the farm it will also *if not completely prevented.*

enable such tests to be carried out to ensure the animals

fying job.

house uniformly, so they do in actual practice occupy

and use the whole area. Regrettably, this is very rarely

the case in practical experience and especially so when

Housing types and systems

large numbers are housed together without any subdi-

(see pp. 40–44)

vision at all. If the animals crowd in certain parts of the

building there may be grossly overstocked floor areas.

There are three essentially contrasting types of housing:

This is bad enough in itself but it has further unfortu-

‘climatic’, giving only a cover and protection to the

nate side-effects. If they crowd excessively in a part of

animals; ‘controlled environment’, which regulates the

the house, this part may become polluted with dung and

microclimate as completely as is required for the partic-

exhalations to an abnormal and harmful degree;

ular stock being housed; and the ‘kennel’, which is in a

For wide buildings, extended trunk to give better air flow and heat retention

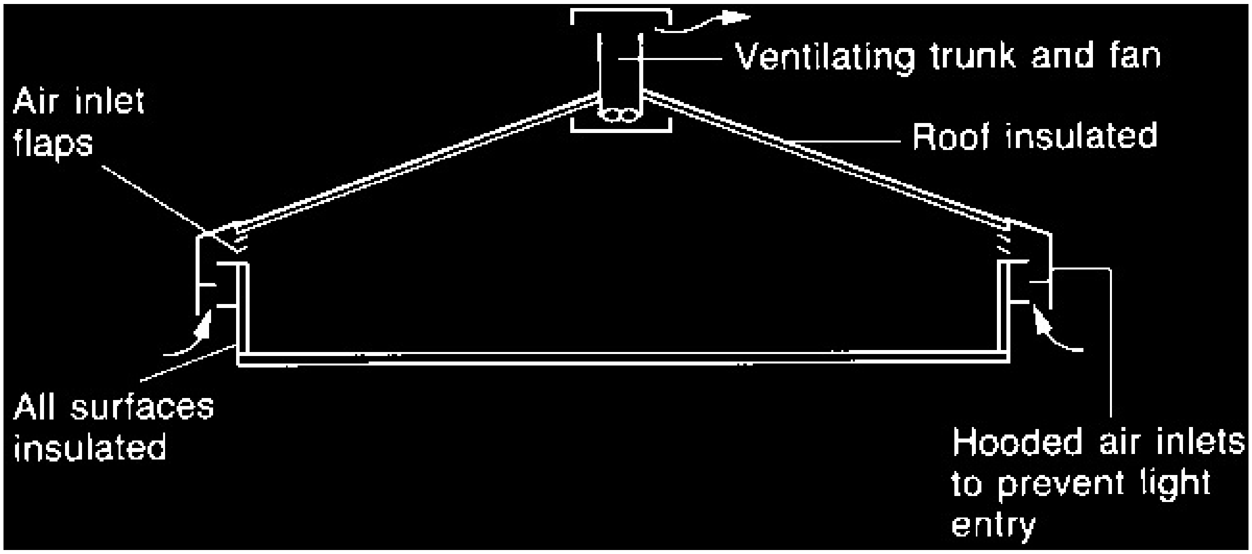

Fig. 56.1

Cross-section of 'climatic' livestock house with open ridge and baffled wall ventilators.

Fig. 56.3

Cross-section of a typical conventionally ventilated controlled environment house with roof fan extraction and hooded wall inlets.

In general, stocking densities tend to be half or less those in the controlled environment house. A major problem is created by agriculturists when they attempt to apply the high stocking rates that are suitable for the controlled environment house to the climatic house, as the building is unable to cope with the demands of the *stock and poor productivity and high disease incidence can result. Climatic housing is usually the correct choice for cattle over about six months of age. Such housing usually requires deep bedding for its success, particularly in cooler climatic areas.*

Controlled environment house *(Fig. 56.3)*

The controlled environment house is in great contrast. It has a limited use for cattle, being sometimes used for young calves and to a lesser extent for cattle kept on any bare surfaces, solid or slotted, without bedding. It is most economically viable with livestock that are fed largely concentrate food rather than substantial quantities of roughage, since the former is too expensive to be utilized as a form of energy. The housing is expensive and because of the cost it is usually necessary to

Fig. 56.2

organisms will be acted upon by antibiotics produced by non-pathogenic organisms that are normal inhabi- tants of the soil. Warm moist conditions will assist the action of such saprophytic agents.

Disinfection

The action of heat

The disinfection of a building implies the elimination from the house of all micro-organisms that are capable For many years heat has been used for disinfection, dry of causing disease, thus converting the place from a heat being used with the 'flame-gun' and moist heat in potentially infective state into one that is largely free the form of the 'steam-jenny', but both tend to be *from infection. A disinfectant is the agent that is*

preferably in the house, later to be taken out and aerated.

(5)

The floors and lower part of the walls should be cleaned with detergent disinfectant.

(6)

The house should then be treated in the same way as suggested in the previous section.

(7)

It may sometimes be advisable to skim off the top few inches of the soil around a heavily infected area.

(8)

The approaches to the building should be treated with disinfectant and foot-dips provided (Fig. 56.8).

Ventilation

There are few topics in animal husbandry where there have been more totally erroneous statements made *than on the reasons why housed livestock require ventilation or 'air-change'. For example, for many years it was accepted that the main deleterious effect of having too little ventilation was due to the build-up of harmful concentrations of the gaseous products of respiration, and in particular carbon dioxide, combined with a depletion in the oxygen content of the air. It is now known that this is far too simple and usually quite an incorrect hypothesis.*

Underlying principles and calculations

In any badly underventilated building the stagnant air gradually becomes both warmer and more humid and

Fig. 56.8

Using protective clothing and dipping boots in dis-

there is a rising concentration of dust, other particulate

infectant to reduce the risk of introducing infection.

matter, ammonia and other gases and any pathogenic

tective cap may be sufficient. But in other controlled-

microorganisms the livestock may be carrying. The end

climate accommodations far more control is needed *result is that the animals suffer from ‘heat stagnation’, and down-draughts, which can be common with the involving a susceptibility to chilling. Along with this will fixed open ridge, must be avoided. Experience has go poor productivity and a likelihood of disease, par- shown that for the latter, good results are obtained by ticularly respiratory, which modern experience shows to the use of a limited area of controlled outlet ventilation be of the greatest danger in intensive forms of housing. and for this purpose a simple chimney type or insulated In addition, in a badly ventilated building, condensa- ‘flue’ is satisfactory. It is good practice to have one or a tion on the surface is often likely and bedding and floors few outlets, but a much larger number of smaller air may become wet and the animals uncomfortable. This inlets, as the fresh air should come in slowly all round will tend to exacerbate the effect of disease conditions, the building, diffusely and carefully baffled. The basis respiratory or enteric in nature, or infections such as of a useful inlet system consists of hopper-type mastitis.*

windows, fitted with gussets to prevent direct draughts,

In recent years a new hazard to livestock and their

serving as principal inlets, and small baffled openings

attendants has been the risk of gaseous intoxication of

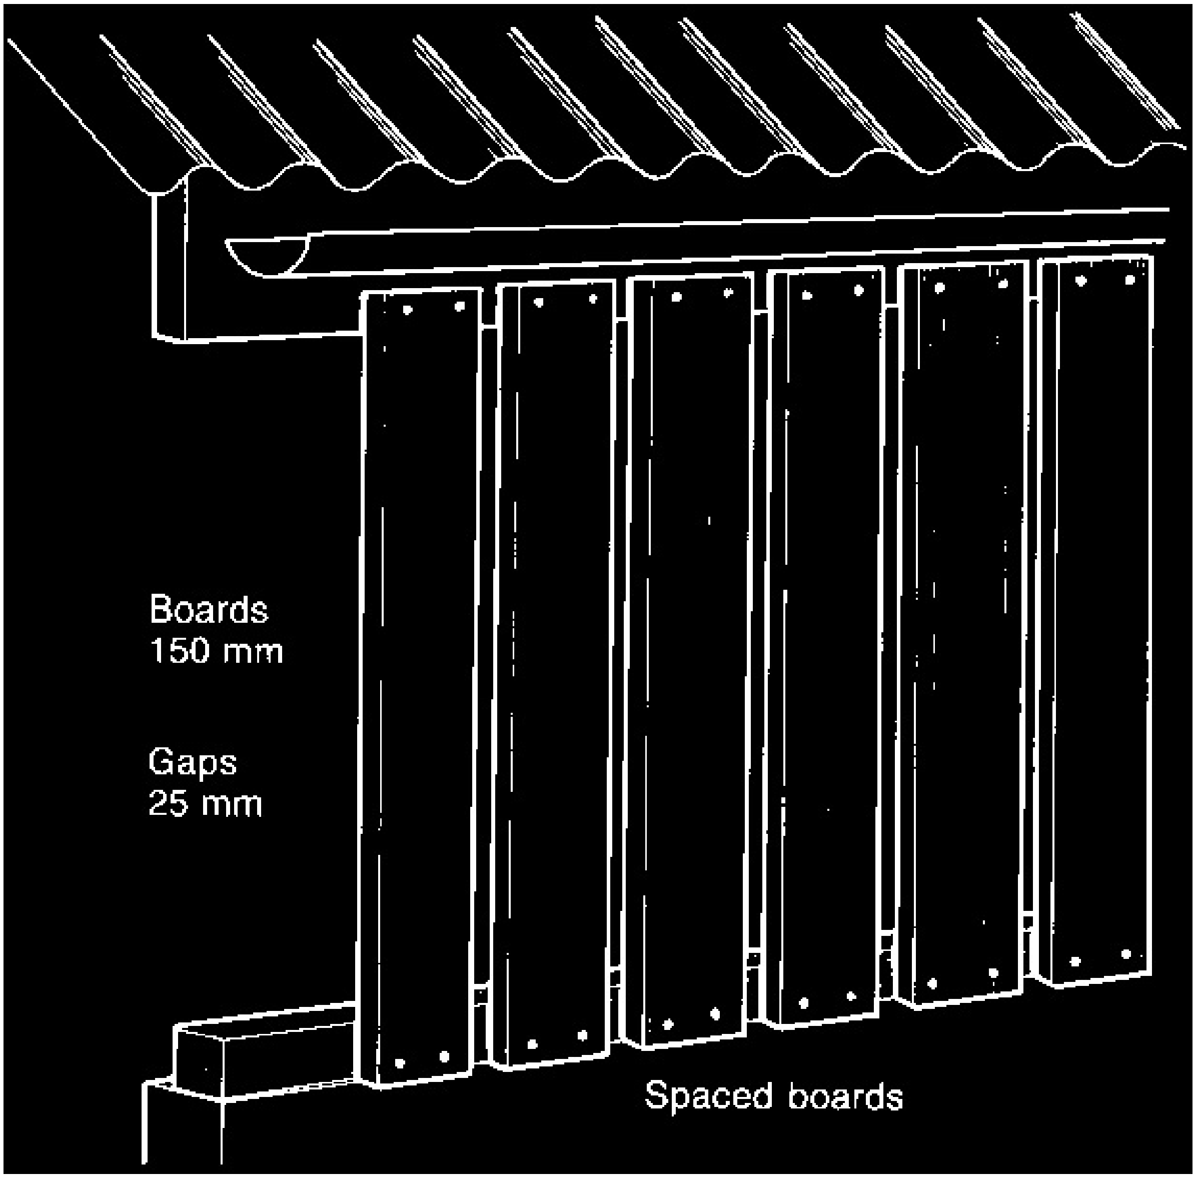
prevent down-draughts when they are switched off. All

prevent draughts and to give adequate control. The

fans should be speed controlled. Alternatively, a system *systems suggested are logical and generally understood*



air comes in than to open up the ventilation space in a sheltered site. Sometimes the proximity of other buildings makes it impossible to increase the airflow at all. Livestock yards are now often made very wide, of the *order of 40–50 m. These are invariably the most difficult units to ventilate. From the point of view of ventilation it is desirable to limit the span to some 30 m. Indeed, if the trend towards the use of thermal insulation continues, views on what constitutes an adequate cubic area may change. In an uninsulated yard a large cubic area helps to buffer the outside weather extremes. But in an insulated construction, the roofing area must be reduced to a minimum to cut costs and more economical dimensions would be a height of 3.6 m to eaves with a maximum yard span of 21 m. These recommendations widely used and required for cattle buildings apply, with only minor modifications, to climatic yard accommodation generally, including that for pigs, sheep and turkeys.*

Fig. 56.10

Wall ventilation with spaced boarding.

Open-fronted yards and kennels

A fundamentally different approach to climatic housing and easily controlled by the stockworker. available in

Clinical

Prophylactic

Laboratory

UK

examination

treatment

tests

BVDV

(+)

~

+

Yes

It is essential to test for BVD virus (up to 1.8% of cattle may be virus positive); serology also useful. Calve pregnant females in isolation and test calves at birth for virus if dam seropositive; or isolate calves and test when over 4 months of age for virus and antibody. Bulk milk tests available.

IBR (BHV-1)

(+)

~

+

Yes

Significance of adding seropositive (potentially infectious) animals depends on virus strain, vaccination type if used, existing herd status and possible implications for sale of cattle, semen and embryos. Bulk milk tests available.

Leptospirosis

(+)

+

+

Yes

Test animals using ELISA, 25 mg/kg dihydrostreptomycin given twice within 14 days of entry reduces risk of excretion. Bulk milk tests available. Zoonotic.

Salmonellosis

(+)

(+)

+

Yes

Repeated culture of faecal samples should help to detect carriers.

Positive SAT titre for S. dublin/ S. typhimurium on serum may indicate recent exposure. Zoonotic.

Johne's disease

(+)

~

(+)

Yes

Individual animal screening to detect subclinical infection is hampered by a lack of suitable tests. Tests such as adsorbed ELISA may be useful on a group basis. Request certification of clinical freedom in the herd of origin for a substantial period of time, e.g. 5 years. If diarrhoea develops in isolation examine faeces repeatedly for acid fast organisms and undertake culture. Consider rejecting animals with intermittent/

persistent diarrhoea regardless of test result. (Zoonotic?)

Streptococcus agalactiae

(+)

+

+

No

Should be readily preventable by using CMT, culturing positive quarters and/or treating. Bulk milk screening may be of use.

Digital dermatitis

+

(+)

~

No

Good clinical examination. If in doubt treat with topical antibiotic spray/

footbath.

Ectoparasites

+

+

(+)

No

Use appropriate treatment.

Gastrointestinal parasites

~

+

(+)

No

Use carefully selected, appropriate anthelmintics.

Lungworm

~

+

(+)

Yes

Use carefully selected, appropriate anthelmintics. Vaccine will not totally prevent infection.

Liver fluke

~

+

(+)

No

Use carefully selected, appropriate treatment.

Ringworm

+

(+)

(+)

Yes

Can cause quite serious problems in naïve herds, particularly amongst adult animals. Zoonotic.

Miscellaneous udder/skin

+

(+)

(+)

No

Troublesome and best avoided. Some are zoonotic.

conditions

Venereal campylobacteriosis

~

+

(+)

No

Treatment probably more cost-effective than laboratory tests, although not 100% effective especially in older bulls.

Trichomoniasis

~

~

(+)

No

Probably absent from UK, but check imported bulls and remain vigilant.

Tuberculosis

(+)

~

(+) Skin test

No

Increasing incidence in UK making the introduction of infected cattle into a herd more likely than in the past. Consider isolation and private testing.

Brucellosis

~

~

+

No

Present in Northern Ireland but absent from Great Britain except for a small outbreak in 2003.

Neospora caninum

~

?

(+)

No

Problematic, epidemiology complex and not fully understood. Consider not retaining calves from seropositive cows and not introducing seropositive cows or youngstock into a herd. Antibody titres wax and wane, likely to be highest around time of calving. Control dogs on farms.

Other exotic diseases, e.g.

Foot-and-mouth disease

+

~

+

No

Major threat if national biosecurity is breached.

Contagious bovine

(+)

~

+

No

Threat if national biosecurity is breached.

pleuropneumonia (CBPP)

Enzootic bovine leukosis

(+)

~

+

No

Threat if national biosecurity is breached.

(EBL)

Warble fly

(+)

+

+

No

Threat if national biosecurity is breached.

Biosecurity

CMT, California mastitis test; ELISA, enzyme linked immunosorbent assay; SAT, serum agglutination test.

genic stimulation; (ii) they can kill innumerable targets

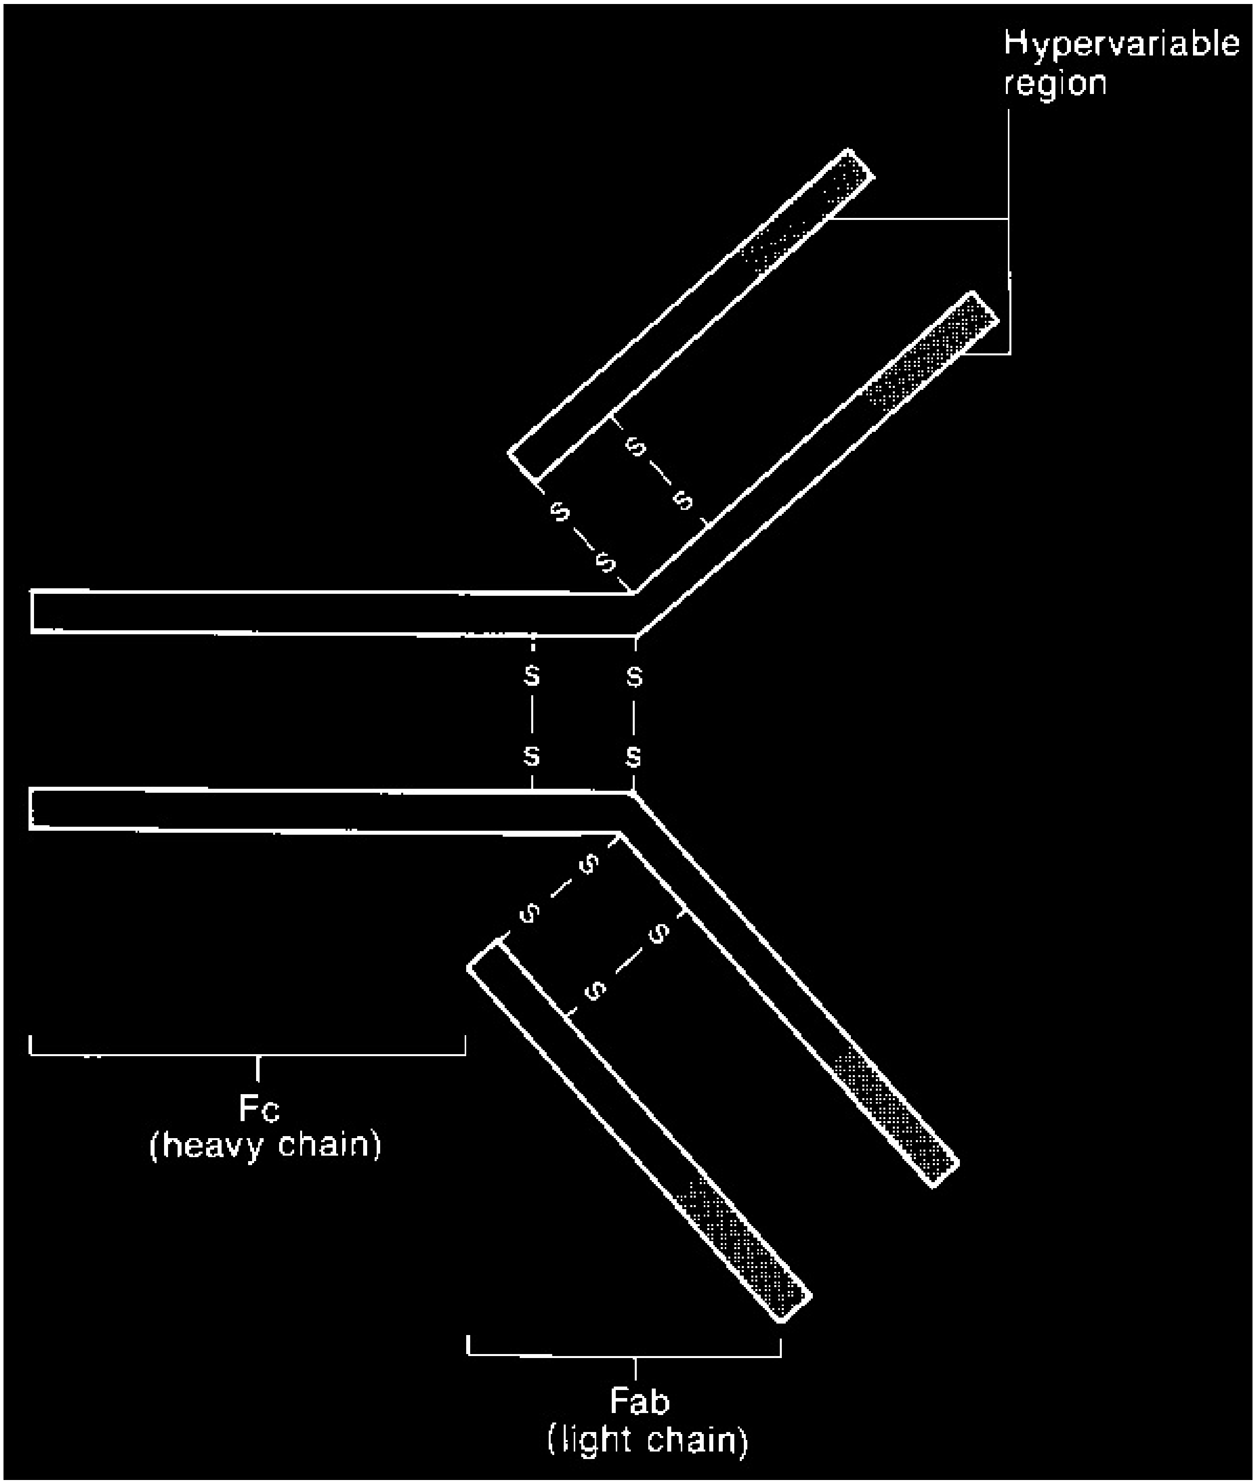
colostrum. The actual amount in bovine colostrum is

from virus-infected cells to tumour cells without the

about 6 mg/ml which drops to approximately 0.1 mg/ml

need for antibody. Therefore, they could operate a type

in milk. Interestingly the bovine fetus is quite capable



tions and stimulate B cells directly. Such antigens,

including bacterial lipopolysaccharides, normally stim-

ulate only IgM production. The efficacy of specific IgM

should not be underestimated. Not only is IgM highly

efficient at aggregating antigen, it can bind with the

secretory component (see below under IgA) and act as

a protective antibody at mucosal surfaces. In diseases,

such as Escherichia coli enteritis in calves, IgM has been shown to be a major protective mechanism.

In cattle suffering from infection with trypanosomes,

IgM levels can rise in serum to over 20 mg/ml, although

the majority of this overproduction is not particularly

useful against the trypanosomes. On the other hand, in

bovine leukaemia IgM levels can fall quite dramatically.

IgG

IgG predominates over other immunoglobulin classes

in serum and contributes in excess of 85 per cent of all

circulating immunoglobulins. Its structure is based on

the usual immunoglobulin model, and it has a molecu-

lar weight of approximately 180 000.

IgG occurs in two subclasses: IgG1 and IgG2. Adult

serum contains approximately 11 mg/ml of IgG1 and

Fig. 58.1

Descriptions used for immunoglobulins.

9 mg/ml IgG2. In colostrum the figure is well in excess

of 50 mg/ml IgG1 and 3 mg/ml IgG2; this reflects the

incredible selective concentration of IgG1 in colostrum

(more details are given in the section Maternal im-

after inoculation as it indicates that the vaccine has

A cheap, stable and safe vaccine that is unfortunately

'taken'. Johne's disease vaccine has a very short shelf

difficult to manufacture and produces variable degrees

life of 14 days.

of immunity.

***Rinderpest** (see Chapter 43d; pp. 707–10)*

Measles vaccine

Vaccination against this disease is common practice in

Measles, rinderpest and distemper are antigenically

areas where it is endemic. There are several good

related and human measles vaccine will produce good

vaccines available and in theory complete eradication immunity to rinderpest in all ages of cattle. It is espe-

is possible with a vaccination programme.

cially useful in very young calves, which can be vacci-

nated at an earlier age than with normal vaccines.

Tissue culture vaccine

Measles vaccine is not affected by the calf's colostral

immunity.

Attenuated vaccines manufactured from cell culture

have largely replaced other attenuated vaccines. They

are safe and effective and produce a long-lasting immu-

nity suitable for all cattle.

Brucellosis (see p. 580)

Abortion and infertility in cattle caused by Brucella

Goat-adapted vaccine

abortus can be very successfully controlled by

This is an attenuated vaccine that produces life-long

vaccination. There are two vaccines available, strain 19

treatment and control of parasite infections.

Introduction

ENDOPARASITICIDES

The control of parasitic diseases in cattle, as with other

Anthelmintics

domestic animals, relies heavily on the use of antipara-

sitic drugs. A vast array of drugs has been developed

Anthelmintics are widely used in both the treatment

for their antiparasitic activity and these are often clas-

and prevention of internal parasite infections of cattle.

sified according to the target parasites they control. For

Their use has been documented from ancient times

the purposes of this chapter, parasites are classed as

lesions, including sole ulceration, white line disease and acute digital tissue infection, leading to lameness. The pain component of inflammation arises from activation and sensitization of fine unmyelinated and some myelinated sensory fibres to the actions of chemicals released from a variety of sources during inflammation (Ferreira, 1983). Information from the periphery is conducted to the spinal cord and from there to the brain, where pain is perceived. Inflammation induces alterations in nociceptive information processing which may have serious consequences for the animal. Allodynia (perception of innocuous stimuli as noxious) and hyperalgesia (exaggerated responses to noxious stimuli) are common features of inflammatory pain (Coderre & Melzack, 1987; Nolan, 2000).

Mediators and modulators of inflammation

The characteristic pathophysiological changes of acute and chronic inflammation are produced by the action *of chemicals, either released from cells such as mast cells, macrophages and fibroblasts or formed by de novo synthesis. If there is an immune basis to the inflammatory response, lymphocytes are also involved. Compounds like histamine, that act directly to produce microvascular changes, or like bradykinin, to cause pain are called inflammatory mediators or, if their role has not been firmly established, they are termed putative mediators.*

The number of putative mediators identified is con-

Fig. 62.1

The inflammatory process.

siderable. Moreover, there are some species differences in mediators, so that, for example, 5-hydroxytryptamine (5-HT) is probably an acute inflammatory mediator in or even persistent chronic inflammation, with local pro-rodents only. Some mediators, such as complement liferation of connective tissue and mononuclear cell fragments C5a and C3a, not only act directly on the accumulation. The granulation tissue in chronic inflam-microcirculation but also cause mast cell degranulation, *mation comprises highly vascularized connective tissue.*

leading to histamine release and hence reinforcement

list is not comprehensive!

Table 62.1

Mediators and modulators of acute and chronic inflammation.

Putative mediator/modulator

Properties and source

Histamine

An amine produced from histidine by decarboxylation. Stored in mast cells, basophils and platelets. Mast cell degranulation leads to release into extracellular environment in immune and non-immune inflammation. Causes vasodilatation and increased permeability of small postcapillary venules. Local administration causes pain and itching 5-Hydroxytryptamine (serotonin) Another simple amine stored in platelets and mast cells. Increases permeability of small venules in rodents but probably at most a minor mediator in other species Bradykinin

A peptide containing nine amino acids that act on bradykinin receptors. Synthesized from plasma kinins de novo. Produces vasodilatation, increased vascular permeability and pain Neuropeptides

Main peptides involved are substance P, serokinin A (both tachykinins) and calcitonin gene related peptide. Induce mediator release, contract smooth *muscle and induce vasodilation Complement system*

Several complement components including C3a, C5a, C8, C9 exert proinflammatory actions, e.g. vasodilatation, increased vascular permeability, mast cell degranulation, leucocyte chemotaxis and cytolysis

Eicosanoids

PGE2

Derived from cell membrane phospholipid, following release of the precursor arachidonic acid.

Produces prolonged dilatation of small arterioles and potentiates the increased vascular permeability and pain produced by other mediators like histamine and bradykinin PGI2

A potent dilator of small arterioles. Possesses similar properties to PGE2 but with shorter duration of action

PGJ2

A derivative of PGD2. Believed to play a role as anti-inflammatory prostanoid in the resolution of acute inflammation

LTB4

Potent chemoattractant for polymorphonuclear leucocytes and mononuclear cells. Enhances vascular permeability produced by other mediators such as PGE2, PGI2 and bradykinin Lipoxin A

Produced from cell membrane phospholipid by polymorphonuclear leucoctyes. Stimulates leucocytes to generate superoxide radical and causes release of lysosomal enzymes. Lipoxins also possess anti-inflammatory properties and are probably involved in resolution of acute inflammation

Platelet activating factor (PAF)

An ether-linked analogue of phosphatidylcholine. Derived from cell membrane phospholipid.

Produces platelet and neutrophil aggregation, bronchoconstriction, vasodilatation, increased capillary permeability and chemotaxis

Interleukins and other

Produced by macrophages, chondrocytes and synovial cells.

cytokines, e.g. IL-1, TNF-a

Chemotactic for leucocytes and possess mitogenic and pyretic properties. Stimulate release of PGE2 and collagenase by chondrocytes, synovial cells and dermal fibroblasts. Possibly involved in cartilage breakdown. Other cytokines possess anti-inflammatory properties Enzymes

Lysosomal enzymes such as lysozyme and acid phosphatase concerned with lysis of foreign and host cells in acute and chronic inflammation. Non-lysosomal metalloproteinases such as stromelysin, concerned with proteoglycan breakdown in arthritis

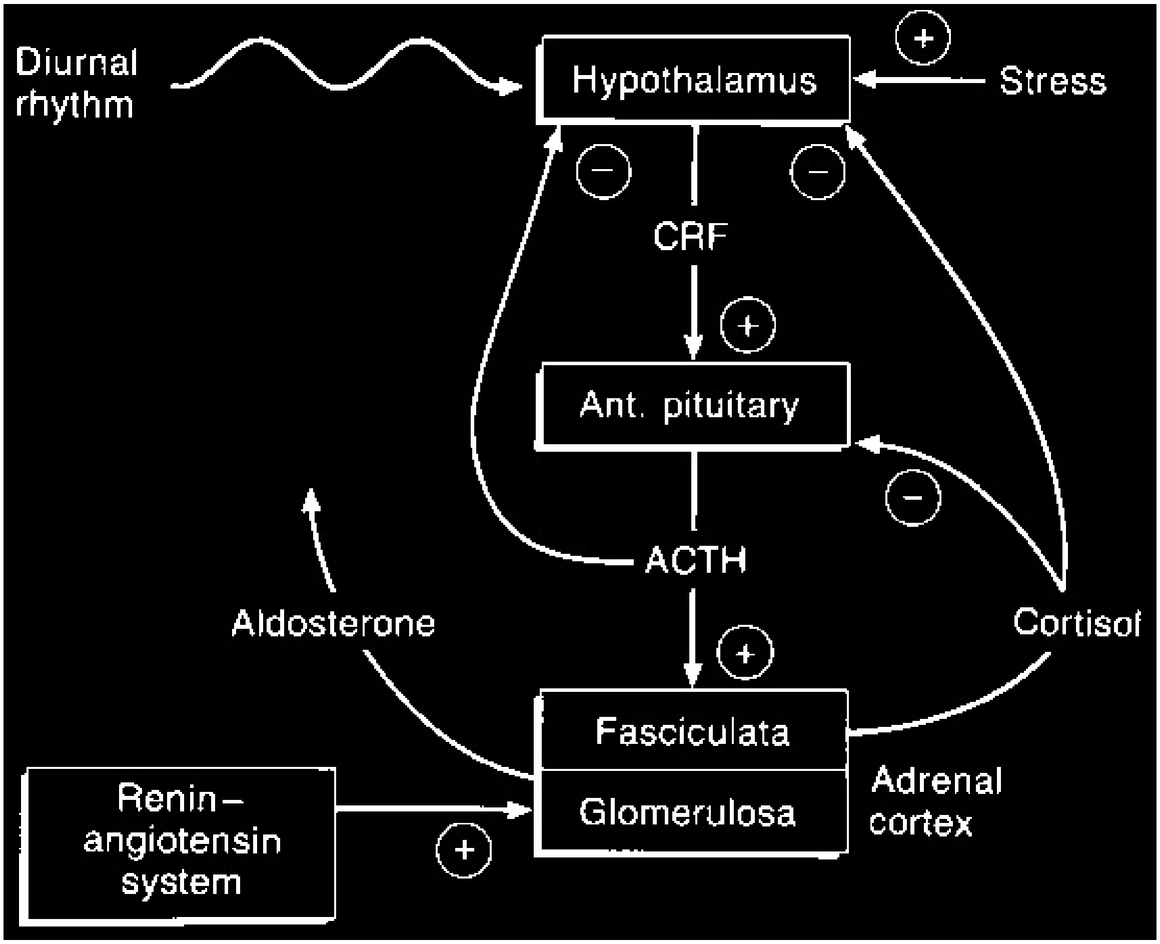
acute and chronic inflammation. Indeed, steroids are

lymphocyte and eosinophil numbers are reduced. In

the anti-inflammatory drugs 'par excellence'. Steroids

addition, glucocorticoids are depressant to lymphoid inhibit the vascular dilatation in the microcirculation



response. Because of this delay, it follows that any relationship between effect achieved and plasma or tissue drug concentration will be complex. Drug effects will generally outlast the period for which they can be detected in biological fluids. This may explain why dexamethasone, which has an elimination half-life of approximately 1 hour in horses and 2.5 hours in cattle

(Toutain et al. , 1982), possesses a 'biological' half-life of 36–54 hours (Table 62.4).

As discussed earlier, arachidonic acid may act as a substrate for two groups of enzymes, COX and LO. Through the production of lipocortins and consequential blockade of phospholipase A2 steroids can be expected to block the synthesis of COX-derived inflammatory mediators, including PGE2 and PGI2, and LO-derived HETE and leukotriene compounds. One of

significant increases in growth rates and feed utiliza-

tion, and Table 63.9, which shows significant increases

in dressing percentage, increased carcass lean.

OH

b-agonists are usually divided into two classes (Smith,

H

1998):

N

(1)

Halogenated aromatic ring. This class tends to

have a long serum half-life and when coupled with high

oral absorption and potency of action in humans there

HN

N

can be a real safety concern from residues in meat. An

Zilpaterol

example of such a compound is clenbuterol (pharma-

O

codynamic dose in man 10 mg/day – Meyer & Rinker,

1991); levels found in contaminated meat in the EU

becomes feasible in all stock. Such an achievement

and upholstery.

Intramuscular injection sites

Alternative siting of injections to that of the gluteal region is therefore desirable. The middle third of the neck, about one-third of the way down from the top, is *recommended (see Figs 64.1 and 64.2); this in itself does not reduce the incidence of abscessation or muscle scarring following the injection of drugs but trimming of this less expensive area reduces blemishing of the carcass. This area also tends to be cleaner than the hindquarters and so it is less likely that infection will be introduced with injection.*

The factors contributing to muscle damage and abscess formation must therefore be identified to allow the formulation of advice for veterinarians and animal owners to reduce such damage.

The efficiency of the host animal's inflammatory response in removing the foreign protein and devitalized tissue together with the persistence of the stimulus determine the size and progression of the abscess formation. In mild cases no abscess may form, but scar

Fig. 64.1

A growing calf being injected into the neck muscle.

tissue will mark the tissue damage. When an abscess has been formed and the inflammatory stimulus removed the abscess may persist for a prolonged period before *resolving to scar tissue.*

Methods of introducing

contamination

The introduction of foreign protein may occur in a

variety of ways.

Contamination of injected drugs: This is most likely to occur prior to administration as a result of poor

hygienic procedures employed. To obviate contamina-

tion of the contents of a bottle or vial a separate sterile

needle to that used for injection must remain attached

to the container and used only to refill the syringe.

In multiple dosing an automatic injection mechanism

avoids this requirement and results in a smoother

and more efficient operation. The manufacturer's

storage instructions should be followed; unused vaccine

should be discarded. When therapeutic agents such as

antibiotics are used they should be used up as quickly

Fig. 64.2

A bull adequately restrained before introducing an

four steps. The fourth is, in particular, a little surprising

in a positive way, in view of our modern culture's

opinion of the soundness of eighteenth century medical

beliefs and practices.

Know the remedies

A working knowledge of the 'provings' and actions of each individual 'remedy' or medicine is the basis of this stage. Obtaining this knowledge requires dedication. The remedies are written up in books of Materia Medica (e.g. Boericke, 1972; Clarke, 1982; Macleod, 1983; Vermeulen, 1997), which may run into several volumes. These books give an account of the properties of the remedies, in terms of source, general properties,

prescriber, to test the principles of homoeopathy and its

efficacy at an easier level, without immediately being

committed to long-term study or to large and therefore

Materia medica

expensive stocks of medicines.

There follows a brief summary of the properties of some of the homoeopathic remedies most commonly used in a farm context and some of their possible clinical applications. This is not intended to be an exhaustive source on the subject but an introduction to these 30 useful remedies. Fuller works on this material can be found in the Further reading section. Remedies are presented in alphabetical order for simplicity, not in order of importance nor grouped according to possible application. The way in which these remedies are presented shows the emphasis placed upon the 'picture' presented

The challenge of herd treatment

Much has been made, in the foregoing pages, of the need to individualize therapy for best results. This high ideal is frankly not practical in a herd or group situation. If we consider, for instance, a group of calves suffering from pneumonia, treating each on an individual basis is not possible. What is needed is a modification of principles, while maintaining the essence of homoeopathic philosophy and methodology. This short section can only be a summary of the techniques involved, in

by the disease rather than upon its usual name. Rem-

order to show the options. Clearly, homoeopathy will

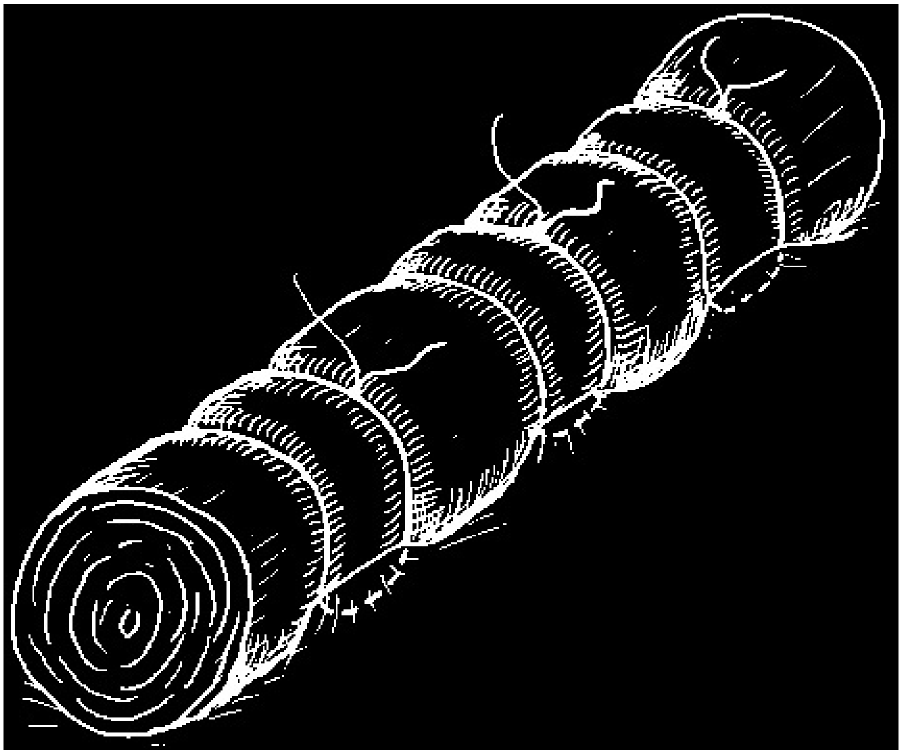
line can lead to local skin ischaemia, necrosis and death.

needed, one with two holes for abomasal and rumen



approaches and one for caesarean sections. The synthetic material used for tent making is now widely available and is ideal, being impervious to fluids, mouldable and capable of being sterilized. The use of drapes makes the maintenance of a clean site so much easier and imparts a professional air to the operation.

The choice of suitable dress for the surgeon is difficult. Abdominal surgery requires extensive intra-abdominal palpation or manipulation. A long-sleeved *gown is inconvenient in that the material abrades the*

wound edges and rapidly becomes sodden and uncom-

fortable; in a rumenotomy it also becomes severely

contaminated. For the same reasons the use of gloves

for these procedures is often impractical too. A good

line now lies several centimeters caudal to its abdomi-

the pericardium; a medial penetration could well result in the localized peritonitis affecting the vagus nerve and inducing 'vagus indigestion'. Bring out the offending wire, holding it firmly all the way, rinse the arm and explore the reticulum again. Further foreign bodies may be found within the silt that invariably lies on the reticulum floor as may all kinds of other, harmless items such as bolts, pebbles etc. Take the opportunity to examine all aspects of the reticulum, cardia, oesophageal groove, etc., for abnormalities and try to assess where the bulk of the adhesions lie. This is best *done by attempting to pick up folds of reticular wall. In the normal state this can be done fairly easily, but where induration of the wall and peritonitis exist it is impossible and attempts will be met by evidence of severe discomfort from the patient. The disposition of the inflammatory process also has implication for the prognosis; major involvement of the medial reticulo-rumen wall could well lead to damage to the stretch receptors located there.*

If no foreign body or penetrating wire is discovered at the first examination, the reticulum wall must be searched carefully, honeycomb by honeycomb. If no trace of a wire is then found (and fresh adhesions are present) it must be assumed that either the wire has

believed to be. When one of these cuts is made in the

animal often kicks after about 50 per cent of the solu-

tion is injected and frequently the needle pulls out of

the vein.)

Once injection is completed, full analgesia will *usually develop in about 10 minutes or so. However, before starting the incision, this must be checked. Within a volume of tissue subjected to IVRA the initial effects are random, with blocks of anaesthetized tissue lying adjacent or deep to other tissue blocks which are fully sensitive. It is therefore essential to check, not just by skin pricking, but by driving a needle down to the bone all the way around the claw. (It needs little imagination to picture the consequences of completing half the operation only to find the deep layers of tissue are entirely sensitive!) The interdigital cleft and especially its caudal aspects seem to be the last tissue to be affected and these areas should be carefully checked. If anaesthesia has only been partially achieved after 10–15 minutes, repeat the intravenous injection using the same amount of local anaesthetic solution. If it is still*

This will prevent the repeatedly irrigated with saline and antibiotic solution. skin necrosis that can occur deep to them if they are Although not disastrous, this finding is a poor prognos- subjected to too great an inward pressure.*

Once the bandage is secure, the tourniquet can be removed. By this stage it will probably have been on for at least a half to three-quarters of an hour. This does not seem to be harmful in any way and the author has often seen tourniquets in situ for an hour or more without deleterious effect. Remove the hobbles and assist the patient onto her sternum. Do not force her to her feet, rather let her get up in her own time. As soon as she puts weight on the foot blood is frequently forced *through the weave of the bandage – if this is minor it*

can be ignored, but if it persists for 10–15 minutes or is

excessive in amount, apply a second elastic adhesive

bandage over the first and, if necessary a third. Do not, under any circumstances, remove the existing bandage.

Leave the bandage in place for four to five days. If

it is taken off before that time the fragile clot is easily

disturbed and haemorrhage can be severe. Thereafter,

change it every five to seven days depending on the

amount of exudate produced by the healing wound.

The wound cavity will begin to contract about seven

to ten days after surgery rather like a flower closing and

the wound area diminishes rapidly. Concurrently, gran-

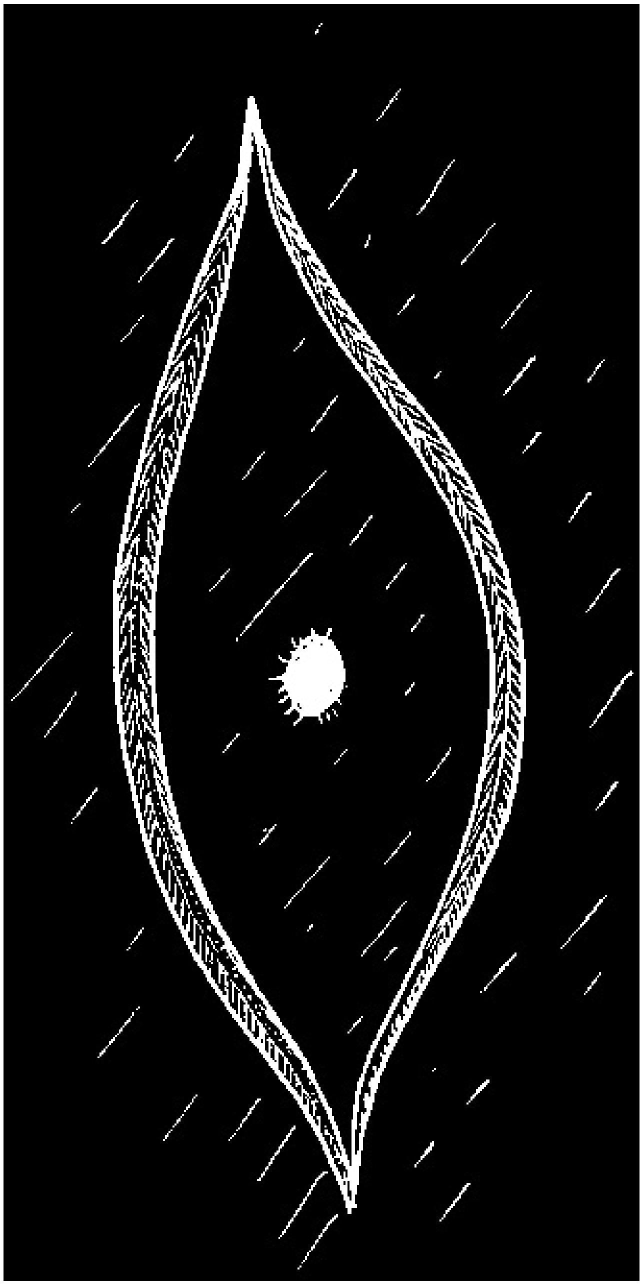
skin centred on the cicatrix at the hernial apex. Try and



sac can be inverted into the abdomen. There is no need to suture the sac, only to close the now enlarged ring in the usual way.

For closure, use strong, non absorbable suture mate-

rial which forms a secure knot. Monofilaments are not ideal and the author prefers a sheathed multifilament type of suture. There is no need to use any complicated suture patterns to overlap the ring margins, e.g. the so-called 'vest-over-pants' technique, as a simple apposition with simple interrupted sutures is entirely sufficient. The former creates a bulky mass of tissue which in turn creates a poor cosmetic effect. Also there is no need to 'freshen' the ring edges.

Insert the first suture some 1 cm beyond the caudal or cranial ring edge, then progress along the ring laying sutures every centimetre or so to finish one centimetre beyond the ring edge at the opposite pole (Fig. 66.10). Use the finger of the 'spare' hand to protect the abdominal viscera from the point of the needle. Lay all the sutures before tying and clamp each pair of free ends with artery forceps to prevent them from pulling out

1147

The two neuroendocrine axes have the capacity to alter

metabolism and to redistribute metabolites to help the

animal maintain homeostasis as it responds to stressors.

Introduction

While these feedback systems are capable of coping

with the many uncomplicated and discrete stressors

It is generally believed – and frequently repeated in the

that animals encounter every day, it has been realized

literature – that 'stress' is the major challenge to the

that the operating characteristics of typical feedback-

welfare, health and productivity of animals in intensive

controlled homeostatic systems are too narrow to *commercial cattle enterprises. However, when it comes account fully for the complexity of the interactive to drawing practical conclusions from the literature it responses that culminate in stress-related pathology. By becomes clear that scientists have been working with definition, homeostatic responses serve to maintain the paradigms of animal stress that have done little to help constancy of the internal environment; each strives to the industry to cope with the biological imperatives that return a regulated parameter to a set point that repre- it must address as it seeks to manage intensive units sents the central tendency of that activity. For instance, with the minimum of animal distress. There is a lack of a fall in serum calcium concentration elicits an imme- unanimity and clarity about which stimuli are so stress- diate increase in the secretion of parathyroid hormone, ful that, on occasion, they can undermine the dynamic which should promptly bring the calcium concentration equilibrium established and maintained by a battery of back to set point, its 'normal value'.*

homeostatic responses. Any stimulus that challenges

Many stress disorders may not be amenable to such homeostasis can be described as a stressor. It is a con- a straightforward resolution. Stressors may create per- dition of life that homeostasis is under constant turbations within several interacting organ systems and challenge by a multitude of stressors. Most of those they may require compensatory responses that elicit encountered by cattle in a well-managed enterprise are changes in the activities of other body systems that are amenable to the routine coping strategies of the governed by other regulatory actions. In those circum- animals; however, there are occasions when particular stances, the regulatory systems must have sufficient stressors seem to overwhelm the homeostatic flexibility to enable them to recalibrate operating set responses, to the detriment of welfare, health and points and to adjust the dynamic ranges of compensa- production. Apparently, the amount of stress an animal tory processes so that the interactions between the perceives depends on the intensity and duration of chal- brain, the autonomic nervous system and the endocrine *lenging stimuli and on the animal's physiological and*

Fig. 67.2

A schematic representation of cross-talk between the neural, endocrine, and immune systems when challenged by stressors. The cell bodies of the peptidergic neurones that govern the hypothalamic-pituitary-adrenal (HPA) axis are located principally in the paired paraventricular nuclei (PVN) within the hypothalamus. They secrete corticotrophin-releasing hormone (CRH) and arginine vasopressin (AVP; also known as ADH), both of which stimulate the release of adrenocorticotrophic hormone (ACTH) from the anterior pituitary gland. ACTH stimulates the adrenal cortex to release glucocorticoids (principally cortisol). The glucocorticoids exert negative feedback at hypothalamic and pituitary levels of the HPA axis and they counter-regulate the activities of both the sympathoadrenal (SA) neurones in the brain stem (locus coeruleus-noradrenaline: LC/NA) and (but not shown) the central humoral messengers that modulate the stress response. Neurones in the PVN and in LC/NA mutually innervate and activate each other. The SA axis releases noradrenaline within the brain (not shown), adrenaline and noradrenaline from the adrenal medulla and noradrenaline from peripheral sympathetic nerves. The cells of the lymphoid tissues release various cytokines that interact extensively with the neural and endocrine systems (see Fig. 67.6). Solid lines represent activation; dashed lines represent inhibition.

sion of the production of food from cows by paying

attention to their comfort.

As long as FMD exists somewhere in the world, the

Knowledge of diseases, and especially knowledge of their cause and aetiology, the consequent knowledge to prevent problems and the skills to prevent a decline of milk production and disasters on dairy farms must be an essential characteristic of veterinarians in the next decade. Veterinarians may also contribute to the achievements of dairy farmers by increasing the quotient milk production versus manure per surface unit. Two aspects for veterinary prevention programmes must be considered: prevention of the introduction of

risk of introduction of the virus into Western Europe by food products from infected animals remains real. Intensive traffic movements of people over the world increase the risk of accidental introduction of contaminated food products. When the FMD virus is introduced into a West European country, the risk of an epizootic depends on the time lapse between introduction of the virus and the diagnosis, and of the number of animal movements over the country or to other countries during that period (see p. 705).

This provides a peaty type of bedding which is com-
breaks between shifts for cleaning and routine main-
tenance. A farm of this size has a total staff of about
145 men, including everyone from the farm manager to
cooks and administration staff. Rolling herd average
milk yield in the best units is over 12 000 litres per head.
Lactating cows are housed in groups of 300 and con-
siderable effort is spent to ensure that this number of
animals calves in as short a period as possible to fill the
house quickly. The spread of calving dates in the house

must be minimal so that they can be managed and fed

as a single group. First lactation cows are housed sepa-

rately from older cows.

The extremely high temperatures experienced both

day and night throughout the summer months make

careful control of the cows' environment essential.

Efficient milk production is difficult without effective

interpreting data this involves working closely with farm *their pivots free from livestock.*

staff at all levels to investigate problems as they arise.

Examples include the calving live birth rate, incidence of mastitis, conception rates, incidence of ketosis and cow and calf mortality. If any of these parameters fall below the set target investigations must start immediately.

Secondly, he must establish the optimal working practices for each team and produce written manuals to set these out in a clear and methodical manner. It is important to utilize the very best current knowledge available in an area and produce firm guidelines that can be applied simply on a very large scale.

Thirdly, he has the responsibility for the maintenance of herd disease security. There is probably no other situation in the world where herd disease security takes on such an important role. Foot-and-mouth disease (FMD) and rinderpest are a real risk and if either of these were to enter a large unit the results could be catastrophic.

FMD is endemic in the region and attempts to

Fig. 71.3

A farm gatehouse, which is controlled to reduce the

control it on a national scale are thwarted by the move-

risk of foot-and-mouth entering the farm.

Fig. 71.4

Loading ramp at the perimeter fence for livestock

Farm perimeter fence. Security is important in a

movement. Cattle are moved through a separate gate from the

region where foot-and-mouth is endemic. The perimeter fence is main entrance to ensure that cattle trucks do not enter the farm.

separated from the cattle housing by several hundred metres.

One feature of farming in this region is that a large

proportion of farm staff are expatriates from countries

such as the Philippines, Kenya, Sri Lanka, Nepal,

Pakistan, India, UK and Ireland. Most staff are resident

on site and this reduces the chance of staff coming

into contact with other local livestock.

Preventing the movement of cattle and personnel

does nothing to prevent the chance of airborne spread

between units. This is a particular risk if another dairy

unit in the region is suffering a clinical FMD outbreak.

The chance of infection by airborne spread appears to

be greatest when humidity is above 60 per cent.

The second component of FMD prevention is vacci-

nation. The antigenic components included in the

Fig. 71.6

4, 5 and 6 months old before joining the whole herd

while the disease remains endemic in the region.

schedule.

A fourth role is the development of effective control

Vaccination against FMD is a tremendous cost to any

and contingency programmes for a number of diseases dairy organization. Apart from the direct costs of vaccination and time involved, milking cows often suffer a significant but short lived reduction in milk yield. Typically total daily milk production may fall by an amount equivalent to between 0.5 kg and 2.0 kg per cow for a 24- or 48-hour period immediately following whole herd vaccination. This cost is, at present, an unavoidable loss associated with the keeping of dairy cattle in the region. Dairy companies do vary in the vaccination schedule employed depending on their own circum-

which may occur. FMD provides the most obvious example but other diseases such as mycoplasmal mastitis, brucellosis and tuberculosis, all of which may occur, need definite policies in place to deal with them. In the case of mycoplasmal mastitis a control programme must ensure that sensible precautions are in place to prevent it, that sampling and laboratory procedures are effective in continuously monitoring for the disease and that should an outbreak occur a well-organized response can be implemented immediately.

Other roles include the coordination of parlour
