Pharmaceutical Disclaimer

Formulary doses and pharmaceutical withdrawal periods in this textbook are derived from a number of literature and professional sources. As such they represent a joint effort to reflect the most up to date pharmaceutical delivery. It is the editors' suggestion that the practitioner refer to the approved labeling of the pharmaceutical product for additional information. While this textbook includes the use of non-approved (extralabel) drugs in food-producing animals, this does not imply that the authors, editor, or publisher endorse the use of such drugs. Drug brand names are occasionally cited in chapters. This in no way implies promotion or endorsement of these products. The authors, editors, and publisher assume no responsibility for or make no warranty with respect to the treatment regimes noted here. The authors, editors, or publisher do not necessarily endorse such drug uses, procedures, or dosages listed. Further, the authors, editors, or publisher shall not be held liable to any person whosoever for any damages, equivalencies, or by reason of any misstatement, error, or negligence otherwise obtained in this text. It is highly recommended that the veterinary practitioner obtain a copy of the booklet: "FDA and the Veterinarian." This booklet discusses extralabel drug use in food-producing species. The Web address is: <http://www.fda.gov/cvm/>.

1 2008

To Dr. Bernard “Bernie” Feldman, deceased Professor at Virginia Tech: mentor, friend, brilliant professor, and scholar. Bernie, your support in times of need to so many can never be repaid. You still remain my professional light. Thank you.

To Dr. Charles “Charlie” Hjerpe, Professor Emeritus at the University of California, Davis; feedlot antibiotic pioneer, mentor, gifted diagnostician, and friend. Charlie, you taught many of us through the years much more than bovine practice.

Thank you.

To Bette and Charles Haskell, in memory of my loving parents who taught me perseverance, compassion, and fortitude.

Thank you.

To Parlin Gale, my sister who consistently shows me warmth, intelligence, and support administered with humor. Thank you for your guidance on the journey.

To Annie, Sydney, and Lilly Haskell, my kindred spirits. You taught me compassion, unwavering devotion, and love. Thank you.

PREFACE

Keeping current is a difficult task for today's ruminant veterinary practitioner. The ability to stay current through veterinary literature and research is a daunting if not seemingly impossible task. Many of the research results and conclusions in the scientific literature are confusing and may be inconclusive to today's food animal practitioner. *Blackwell's Five-Minute Veterinary Consult: Ruminant* is designed to provide to the practicing veterinarian, veterinary student, animal scientist, extension specialist, and researcher a quick, concise, and practical review of many if not most of the important diseases and clinical problems facing ruminants and pseudoruminants in the new millennium. Our goal in creating this textbook in the Five-Minute format is to provide up-to-date information in an easy-to-use format. Emphasis has been placed on the diagnosis and treatment of problems and diseases commonly seen by the ruminant veterinarian.

Today's ruminant practitioners provide services that are not always taught at veterinary colleges. As reproductive specialists, they are asked to conduct breeding soundness examinations and give extensive reproductive support programs. Genetic evaluation and the selection of dams and sires are increasing in their importance. Vaccination and deworming program implementation and evaluation are daily encounters for the practicing veterinarian. Nutritional support and body condition scoring as well as foot care have become necessary tools for the competent practitioner. And finally, financial recommendations are becoming a common purview in ruminant practice. This text addresses these issues as well as leads the reader to suggested readings. Several good internal medicine and production medicine textbooks are available. The uniqueness and importance of *Blackwell's Five-Minute Veterinary Consult: Ruminant* are in its use as a quick reference guide.

Though this textbook is a treatise of ruminant production and diseases, camelids have been included due to their growing importance in domestic and international agriculture. Though camelids are technically pseudoruminants, their physiology and disease patterns are similar in many ways to true ruminants. The inclusion of selected camelid diseases here as a quick reference is important for the practicing veterinarian. Nondomesticated and semidomesticated ruminant species are more commonly found in multidimensional farming situations worldwide. Practitioners have little time to literature search the management and care of these species. In many cases, the information has not been readily available until this textbook. Research demands on practitioners have been increasing. Many practitioners now are called upon to design and implement field trials, on-farm vaccination evaluation programs, and independent epidemiologic evaluations as a necessary part of the busy practice.

Environmental issues will become the primary limitation to animal agriculture in many areas of the world in this millennium. Sections in this textbook alert the reader to important and practical considerations to the environmental concerns faced by animal agriculture today. Sustainability of animal agriculture for the future is being compromised. Emerging disease issues are also covered in the textbook. Today's events in agricultural biosecurity and disease introduction are an important component in veterinary medicine. Private practitioners are the frontline of defense and first responders in the protection against a large-scale disease outbreak.

I, the consulting editors, and the contributors are delighted, privileged, and honored to have been able to present this textbook. Over two hundred veterinary specialists have contributed. An expert wrote each chapter on the specified subject matter. I am indebted to the many contributors and the consulting editors, whose diligence and hard work allowed this textbook to be written and published. My goal is to revise this text every three years so that the contents will remain current, timely, and useful.

Scott R.R. Haskell
Davis, California

ACKNOWLEDGMENTS

I would like to thank the consulting editors and the contributors who by their knowledge and professional expertise have enhanced the quality of these writings. Without their exceptional writing capabilities and understandings of ruminant production medicine, this textbook would in no way reflect flare and topical issues. Their suggestions, input, and commitment made this text an exceptional diagnostic tool. Dr. Danelle Bickett-Weddle gave generously of her time and professional expertise in the foundation and progress to this text. Many thanks go to her and her tireless editing efforts.

ABOMASAL EMPTYING DEFECT (AED) IN SHEEP

BASICS

DEFINITION

Abomasal emptying defect (AED) is a syndrome of adult Suffolk sheep characterized by chronic, progressive weight loss and abomasal dilatation in the absence of mechanical obstruction.

PATHOPHYSIOLOGY

- The pathogenic mechanism for AED is unclear.
- The AED syndrome shares some characteristics of a human syndrome, chronic idiopathic intestinal pseudo-obstruction that affects children and adults. Affected individuals clinically appear to have a partial or complete gastric obstruction, but none is present.
- Morphologic investigations of human patients indicate degenerative changes in the smooth muscle or the tunica muscularis and/or neurons of the enteric plexus.

SYSTEMS AFFECTED

Gastrointestinal

GENETICS

Little information is available regarding genetic predisposition. A pedigree analysis performed on a flock in which 11 of 92 Suffolks were affected failed to show a hereditary pattern.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

Species

Sheep

Breed Predisposition

Suffolk is the predominant breed. The condition has also been reported in the Hampshire, Dorset, and Texel breeds. ***Mean Age and Range*** Adults that are at least 2 years of age.

Predominant Sex

This condition affects both males and females.

SIGNS

Historical Findings

- This condition usually occurs sporadically, affecting a single individual. Usually, affected flock management is excellent with the animals appearing healthy and in good body condition, except for the affected individual.
- The owners may report loss of weight in the individual, despite efforts to provide extra nutrition, anthelmintic treatment, and individual attention. Also, owners will report that animals appear “bloated” despite inappetence.

PHYSICAL FINDINGS

- Most typically body temperature is within normal limits unless there is concurrent disease present. Pulse and respiration rates may be normal to increased. Fecal consistency is usually normal, but fecal volume is often decreased.
- Careful examination of the abdomen is important and particular attention should be paid to the following:
 - Abdominal conformation—may be normal; bilateral, asymmetrical abdominal distention may be observed (distension high in the left paralumbar fossa and low on the right side when the animal is viewed from behind); unilateral distension may be present (low on the right ventrolateral aspect of the abdomen).

- Rumen contractions—may be normal, increased, or decreased. Rumen hyperactivity is very dramatic to visually observe in AED sheep because the left paralumbar fossa appears to be in constant motion, reflective of the almost constant rumen activity.
- Abdominal ballottement—Most AED sheep are in varying stages of cachexia and their abdominal wall feels “thin” or lacks tone due to muscle wasting. The gastrointestinal organs also may lack tone or give the impression of being fluid filled. In some instances, the caudal border of the abomasum may be outlined as it extends beyond the last rib on the ventrolateral aspect of the abdomen. The distended abomasum usually feels fluid filled rather than the doughy or firm consistency that is often associated with abomasal impaction in cattle.

RISK FACTORS

Unknown

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differential diagnosis for chronic weight loss in adult sheep includes caseous lymphadenitis or other chronic infection, Johne’s disease, malnutrition, dental problems, parasitism, and rarely neoplasia.
- The historical and physical findings, as described above, are fairly specific to AED.

CBC/BIOCHEMISTRY/URINALYSIS

- Hematological and serum chemistry analysis are usually normal.
- The typical metabolic alkalosis with hypochloremia and hypokalemia associated with proximal gastrointestinal obstruction (e.g., displaced abomasum in cattle) is not consistently noted with AED.
- Elevations in liver enzymes (SGOT/AST, SDH, GGT) may be noted; however, this can be misleading chemical data.
- Increased intra-abdominal pressure from a greatly distended abomasum may lead to secondary liver congestion and ischemia. This pressure can precipitate hepatic leakage of liver enzymes.
- Urinalysis is usually unremarkable.

OTHER LABORATORY TESTS

- An elevated rumen chloride concentration is probably the most useful test in supporting a diagnosis of AED.
- Normal rumen chloride in sheep is ≤ 15 mEq/L. Most often affected sheep will have at least a twofold increase. Rumen fluid samples are obtained most easily by percutaneous aspiration of the rumen from a site in the ventrolateral aspect of the left paralumbar fossa.

IMAGING

- Abdominal radiology may be helpful; however, unless the animal can be positioned for an oblique abdominal radiographic view, results will be difficult to interpret.
- Abdominal ultrasonography may be more useful than radiography in imaging the abomasum. A 3 to 5 MHz linear or sector scanner can provide adequate images of the abomasum. When placed on the lower right abdomen, the normal abomasum will not extend beyond the last rib. An animal’s abomasum with AED will usually appear two to four times normal size.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Gross necropsy finding: abomasum that is greatly distended with a patent pylorus.
- Abomasal contents are usually liquid but may be dry. Histopathologic changes in the abomasum include smooth-muscle degeneration, vacuolation, and varying degrees of necrosis. Degenerative changes have been reported in the celiacomesenteric ganglia.

TREATMENT

GENERAL CONSIDERATIONS

- The prognosis for recovery when intensive treatment is initiated is variable and dependant upon the duration of the abomasal dysfunction and distention. Medical therapy alone using various cathartics and laxatives and surgical therapy (abomasotomy) have had limited success.
- In animals that are good surgical candidates, abomasotomy followed by metoclopramide and supportive fluid therapy has provided some success.

SURGICAL CONSIDERATIONS

An abomasotomy is best performed under general anesthesia, although an anesthetic approach using a local line block can be used. The animal is placed in left-lateral recumbency and a right paracostal approach provides excellent access to the abomasum. Subsequently the abomasum is opened and its contents removed, and the organ is flushed and closed in a routine manner. Therapy with metoclopramide should be used as an adjunct to the surgery (see Medications section below). Also, fluid replacement and electrolyte correction therapy is critical to survival and success.

MEDICATIONS

DRUGS OF CHOICE

Metoclopramide (0.1 mg/kg, q 8 hrs, SQ) as an adjunct to abomasotomy has been reported to improve abomasal motility in selected cases. This medication should not be used if a gastrointestinal obstruction is suspected.

CONTRAINDICATIONS

- Neostigmine should not be used in affected animals.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING

- If intensive therapy is undertaken, the animal should be observed for attitude, appetite, volume of fecal production, and abdominal conformation. Positive signs of improvement following abomasotomy and during metoclopramide therapy may include improvement in attitude and an increased interest in eating.
- Fecal production should increase and abdominal distention should decrease if abomasal motility has returned.

PREVENTION/AVOIDANCE

Because the underlying cause of this condition is unknown, no recommendations can be made.

POSSIBLE COMPLICATIONS

- Complications related to abomasotomy: surgical dehiscence of the abomasal incision (especially if the abomasal wall has undergone degenerative changes) and dehiscence of the abdominal incision may occur (more likely to occur in a debilitated patient).
- Once the condition is recognized, if treatment is declined, euthanasia should be offered as a humane resolution.

EXPECTED COURSE AND PROGNOSIS

- The earlier the condition is recognized and treated, the better the prognosis; however, for long-term recovery, the prognosis is guarded.
- In certain circumstances such as a ram completing a breeding season, or a late gestation ewe completing her pregnancy, a fair to good prognosis may be offered if intensive treatment is provided early.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Other concurrent conditions may occur with this disease. Pneumonia and other organ failures are viewed as secondary to any chronic debilitating diseases.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

None

PREGNANCY

In spite of treatment, pregnant animals may abort. Pregnant animals (especially mid to late term) represent an increased surgical risk.

RUMINANT SPECIES AFFECTED

The condition has been reported in sheep only; however, the author has observed a similar syndrome in a geriatric crossbred dairy-type goat.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

This is usually observed in a single animal from a well-managed flock.

SYNONYMS

Abomasal dilatation and emptying defect

Abomasal impaction

Acquired dysautonomia

Functional pyloric stenosis

Ovine abomasal enlargement

SEE ALSO

N/A

ABBREVIATIONS

AED = abomasal emptying defect

AST = aspartate transaminase

GGT = gamma-glutamyltransferase

SDH = succinate dehydrogenase

SGOT = serum glutamic oxaloacetic transaminase

Author: Michelle Kopcha

ABOMASAL IMPACTION

BASICS

OVERVIEW

- Blockage of fluid and ingesta from the abomasum through the pylorus by feed, sand, gravel, or neurological deficit.
- Pyloric obstruction from improper placement of percutaneous fixation of left-sided abomasum (“roll and toggle”) can result in abomasal impaction.
- Signs can be acute or chronic and are characterized by loss of appetite, decreased or scant feces, distension of the abomasum, weakness, dehydration, metabolic alkalosis, and apparent abdominal pain.
- Found in cattle and sometimes sheep. Usually isolated cases but also may have low morbidity associated with low-quality forages. High mortality.
- Abomasal emptying defect (AED) is a disease syndrome that primarily affects Suffolk sheep and is characterized by distension and impaction of the abomasum.

PATHOPHYSIOLOGY

- Physical blockage of the outflow from the abomasum to the duodenum occurs. This may be due to the packing of straw or poor-quality roughages, sand, or gravel in the abomasum.
- Damage to branches of the vagus nerve from reticuloperitonitis or lymphoma can decrease the emptying ability of the abomasum. Failure of fluid to move from the abomasum to the intestines results in dehydration and starvation.
- Sequestration of hydrochloric acid in the abomasum can result in metabolic alkalosis.
- In sheep, no histologic lesion has been consistently associated with AED. There is no known etiology. In one study, histologic examination of celiacomesenteric ganglia from affected sheep revealed scattered chromatolytic or necrotic neurons, without inflammation. Chromatolytic neurons were observed more frequently in AED-affected sheep than in healthy Suffolk sheep. Neuronal necrosis was not observed in any of the healthy sheep. Neuronal lesions of AED resemble dysautonomic diseases of humans and other animals.

SYSTEMS AFFECTED

Gastrointestinal

GENETICS

N/A

INCIDENCE/PREVALENCE

Very low morbidity

GEOGRAPHIC DISTRIBUTION

Worldwide; seen more commonly where low-quality roughages or low-energy diets are fed.

Epidemiology

- Feeding chopped straw or low-quality forages has been associated with abomasal impaction. Excessive intake of such feeds in attempts to meet energy needs appears to predispose cattle.
- Feeding cattle on sand or gravel or including excessive dirt or gravel from feed storage areas into mixed feed.
- Late-gestation animals appear more frequently affected.

SIGNALMENT

Species Affected

Bovine, ovine

Breed Predilections

Suffolk sheep

Mean Age and Range

N/A

Predominant Sex

Commonly seen affecting pregnant females.

SIGNS

- Anorexia, weight loss, scant feces, dehydration, distension of the abomasum, decrease in rumen motility, recumbency
- Metabolic alkalosis in chronic cases
- In sheep, clinical signs consisted of chronic anorexia and weight loss. Also, laboratory analysis failed to show the hypochloremic, hypokalemic, metabolic alkalosis commonly found in cattle. Rumen chloride concentrations in sheep indicated reflux of abomasal contents into the rumen.

GENERAL COMMENTS

Reported most often in beef cattle fed low-energy, chopped forage diets in cold weather. Seen sporadically in dairy cattle.

HISTORICAL FINDINGS

- Cattle on poor pasture or fed chopped, low-quality forages with low dietary energy, especially in cold weather. Cattle eating on sand or gravel or excessive gravel from the feed storage area in the feed
- Pica

PHYSICAL EXAMINATION FINDINGS

Anorexia, depression, decreased rumen contractions. Distension of the abomasum may be determined by palpation or ballottement of the lower-right flank. Eventually, the animal has scant feces and becomes dehydrated.

CAUSES

- Physical blockage of the abomasum by low-quality chopped forages, sand or gravel, or “roll and toggle” sutures inadvertently placed in or near the pylorus.
- Damage to the vagus nerve

RISK FACTORS

- Cattle on low-energy diets being fed chopped forages, or fed on sand or gravel
- Certain lines of Suffolk sheep may be afflicted more than others.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Abomasal volvulus or torsion, reticuloperitonitis, lymphoma

CBC/BIOCHEMISTRY/URINALYSIS

- CBC usually normal
- Hypochloremic, hypokalemic metabolic alkalosis may be present in chronic cases.
- In sheep with AED, laboratory analyses failed to show the hypochloremic, hypokalemic, metabolic alkalosis commonly found in cattle. Rumen chloride concentrations in sheep indicated reflux of abomasal contents into the rumen.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

Laparotomy

GROSS AND HISTOPATHOLOGIC FINDINGS

Confirmation from laparotomy

TREATMENT

Surgical correction by abomasotomy; possible softening of impacted material by per os mineral oil once daily for 2 to 4 days.

Inpatient Versus Outpatient

Inpatient treatment may include correction of metabolic alkalosis.

CLIENT EDUCATION

Feed cattle to energy requirements, especially cattle in cold weather. Do not feed chopped poor-quality forages with low-energy diets. Feed cattle on surfaces other than sand or gravel.

MEDICATIONS

DRUGS OF CHOICE

Balanced electrolytes IV for 1 to 3 days to correct metabolic alkalosis.

CONTRAINDICATIONS

N/A

PRECAUTIONS

Lactated Ringer's solution should be used cautiously due to the possibility of metabolic alkalosis.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Pain or suffering, fecal output, hydration status, electrolyte balance

PREVENTION/AVOIDANCE

Feed energy balance feeds with long fiber length. Avoid feeding on sand or gravel.

POSSIBLE COMPLICATIONS

Abomasal rupture and peritonitis

EXPECTED COURSE AND PROGNOSIS

Grave prognosis; death from dehydration, metabolic alkalosis, or peritonitis

MISCELLANEOUS

PREVENTION

Feed good-quality, long forage with adequate energy supplementation. Avoid feeding on sand or gravel.

ASSOCIATED CONDITIONS

Reticuloperitonitis, lymphoma, displaced abomasum

ABOMASAL ULCERS

BASICS

DEFINITION

- Damage to the abomasal mucosa continuing from erosion through complete perforation. Often subclinical but may be clinical.
- Classified as type I (nonperforating ulcers), type II (nonperforating with severe blood loss), type III (perforating with localized peritonitis), and type IV (perforating with diffuse peritonitis).
- Clinical signs associated with abdominal pain, blood loss, and peritonitis. Causes are not known, but may be associated with stress. Not associated with particular abomasal bacterial infections.

PATHOPHYSIOLOGY

- Injuries to the protective mucosal layer allow acid and pepsin to diffuse into the mucosa.
- Type I nonperforating ulcers have incomplete penetration, little local reaction, and minimal bleeding.
- Type II bleeding ulcers erode into a major blood vessel in the submucosa. There may be distension of the abomasum and reflux of abomasal contents into the rumen. There is usually melena.
- Type III ulcers completely perforate the wall with leakage of fluid and local peritonitis. Adhesions form to viscera localizing the peritonitis.
- Type IV ulcers perforate completely and the subsequent fluid leakage is not contained by adhesions, resulting in generalized peritonitis.

SYSTEMS AFFECTED

Gastrointestinal

GENETICS

N/A

INCIDENCE/PREVALENCE

Low, less than 1 or 2%. May be higher in some types of calf-raising systems.

GEOGRAPHIC DISTRIBUTION

N/A

Epidemiology

- Has been associated with physical irritation from straw in veal calves and high-grain diets in feedlot cattle
- May be related to postpartum conditions in dairy cattle; not definitively associated with bacteria such as clostridia, salmonella, or helicobacter
- No association with hairballs in veal calves

SIGNALMENT

Species Affected

Bovine

Breed Predilections

N/A

Mean Age and Range

Occurs in calves and adults

Predominant Sex

N/A

SIGNS

Anorexia, depression, pyrexia, abdominal pain, abdominal distension, melena, blanched mucous membranes. Peracute death

common in adult cattle but not calves.

GENERAL COMMENTS

N/A

HISTORICAL FINDINGS

Changes in feeding, such as transition from milk to solid feed in calves or high roughage prepartum to high concentrate postpartum diets may be involved.

PHYSICAL EXAMINATION FINDINGS

- Melena or occult blood in feces; possible distension of abomasum detected by ballottement of ventral right abdomen; blanched mucous membranes (pallor) in cases with severe blood loss; painful abdomen
- Peritoneal emphysema may be detected during rectal exam.

CAUSES

Unknown in many cases, but can be related to feeds that irritate the abomasal mucosa, such as straw or almond hulls

RISK FACTORS

Sudden transition from milk diet to dry feed in calves, straw feeding in milk-fed calves, possibly high-concentrate diets

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Lymphoma, left displaced abomasum, abomasal volvulus or torsion, duodenal ulcers, hemorrhagic bowel syndrome

CBC/BIOCHEMISTRY/URINALYSIS

Acute hemorrhagic anemia in cases of severe gastric hemorrhage

OTHER LABORATORY TESTS

Abdominocentesis may identify abomasal fluid in abdomen in some cases. Testing for occult blood in feces may detect blood in feces before melena is seen.

IMAGING

Ultrasonography may show free fluid in abdomen.

OTHER DIAGNOSTIC PROCEDURES

Exploratory surgery

GROSS AND HISTOPATHOLOGIC FINDINGS

- Ulcers are most commonly found along the greater curvature and usually in the fundic area. Ulcers can be a few millimeters to several centimeters in size. They are often filled with debris or clotted blood. Perforating ulcers are usually adhered to the omentum.
- Cattle with type IV ulcers have abomasal fluid in the abdominal cavity and may have fibrinous peritonitis.

TREATMENT

- Usually unrewarding. Antacids may protect the abomasal mucosa.
- Transfusions may be beneficial if bleeding stops or is controlled.
- Surgical correction of perforated ulcers for valuable cattle

Inpatient Versus Outpatient

The opportunity for successful surgical correction and adequate transfusion is greater in clinic than on farm.

CLIENT EDUCATION

Gradual introduction of dry feed to calves is preferred to abrupt exposure to dry feed during the milk-fed period.

MEDICATIONS

DRUGS OF CHOICE

- Antacids such as magnesium oxide (500 g/400 kg body weight daily for 2 to 4 days) has been suggested.
- Per os kaolin and pectin mixture (2 to 3 liters twice daily to mature cattle) has been suggested.

CONTRAINDICATIONS

NSAIDs that interfere with the production of prostaglandin E series via the arachadonic acid cascade are not recommended because the prostaglandins are important to the protective coating of the abomasal mucosa.

PRECAUTIONS

ABORTION

BASICS

DEFINITION

Loss of the fetus from 60 days to term. Prior to 60 days is considered embryonic mortality.

PATHOPHYSIOLOGY

- Camelids rely primarily on the corpus luteum for production of progesterone and maintenance of pregnancy for the entire gestation.
- Maintenance of the corpus luteum requires normal pregnancy recognition and establishment of placentation.
- Abortion is caused by any factor that acts directly or indirectly on the corpus luteum to cause luteolysis:
 - Treatment with prostaglandin F2 alpha
 - Inflammatory or febrile affection
 - Endotoxemia
 - Stress such as heat stress, transport
 - Debilitating diseases
- Abortion can be caused by factors that compromise fetal viability or placental integrity:
 - Placentitis
 - Placental insufficiency (endometrial fibrosis, uterine capacity in maiden females, twinning)
 - Direct insult to the fetus (mechanical or infectious)
 - Fetal malformation/abnormal pregnancy
 - Hormonal insufficiency or unbalance

SYSTEMS AFFECTED

Reproductive—potentially all systems may be affected depending on the condition.

GENETICS

N/A

INCIDENCE/PREVALENCE

- Pregnancy loss ranges from 2% to 17%.
- Losses of up to 60% may be experienced in some leptospirosis outbreaks.
- Loss of 40–50% has been reported in maiden females under some management systems.

GEOGRAPHIC DISTRIBUTION

Potentially worldwide depending on camelid species and environment

SIGNALMENT

Species

Potentially all camelid species

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

Female

SIGNS

Historical Findings

- Return to receptivity after confirmation of pregnancy
- Bloody or mucopurulent vaginal discharge
- Protrusion of the placenta or fetus
- Premature development of the mammary gland and lactation

PHYSICAL EXAMINATION FINDINGS

History

A complete history should be taken from each aborting case and include the following:

1. Age of the aborting animal
2. Breeding technique
3. Individual cases vs. outbreak
4. Reproductive history
5. Stage of pregnancy
6. Treatments and vaccination in the last 2 weeks
7. Animal movement in the last month
8. Feeding management
9. Layout of the facilities, proximity to stagnant waters, runoffs from dairy or swine operations
10. Contact with wildlife, feral cats

Clinical Examination of the Dam

Body condition score

Physical examination (TPR)

Demeanor

Transabdominal ultrasound

Vaginal examination

Uterine biopsy may be indicated in some cases.

Serology

Samples should be taken from:

- Fetus (cardiac blood)
- Aborting dam (paired samples) at abortion and 2 to 3 weeks later
- At-risk females in face of an outbreak

Bacteriology

Samples should be taken from:

- Fetus—stomach content, fetal fluids
- Dam—vaginal discharge, uterine swab
- Placenta

Necropsy/Histopathology

- Fetal necropsy
 - Measurement of the crown-rump length
 - External evaluation of the fetus for developmental abnormalities or lesions
 - Internal evaluation of the fetus
 - Samples from liver, brain, spleen, kidney, stomach and lungs should be submitted fresh or fixed
- Placenta
 - External examination of the chorionic surface for signs suggesting insufficient development or lack of villi
 - Examination for signs of placentitis
 - Examination for developmental abnormalities or lesions of the umbilical cord

Hormone Assays

In habitual aborters, progesterone determination during pregnancy may be indicative of possible luteal insufficiency. Pregnant females with progesterone levels below 2 ng/ml should be considered suspicious. However, some females may be able to carry to term even if progesterone level is between 1.5 and 2 ng/ml.

CAUSES AND RISK FACTORS

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Infectious Causes of Abortion

Brucellosis (*B. melitensis* in alpacas and llamas, *B. abortus* in camels)

Listeriosis

Chlamydiosis

Toxoplasmosis

Leptospirosis

Trypanosomiasis (in camels)

Hemorrhagic disease (*Bacillus cereus*, in camels)

Noninfectious Causes of Abortion

Administration of PGF₂-alpha Trauma: Breeding during pregnancy Administration of corticosteroids (last trimester of pregnancy particularly, even topical corticosteroids may cause abortion) Progesterone insufficiency Hormonal imbalances, adrenal gland dysfunction particularly in fiber-producing animals Some vaccines (Some vaccines have been associated with abortion) Nutritional deficiencies Toxic plants anecdotal; no precise information

CBC/BIOCHEMISTRY/URINALYSIS

May be indicated depending on disease condition

OTHER LABORATORY TESTS

See diagnosis above.

IMAGING

Ultrasound may be a helpful adjunct.

OTHER DIAGNOSTIC PROCEDURES

PATHOLOGIC FINDINGS

TREATMENT

- Abortion due to luteal insufficiency

Requires progesterone supplementation

Anecdotal reports of successful maintenance of pregnancy by administration of progestogens in oil (150 mg to 500 mg every week or every other week until 2 weeks before due date), Norgestomet implants weekly or biweekly

The author's observation is that natural progesterone (50 to 100 mg daily or long acting 500 to 1000 mg every week) is the most helpful in these cases if they can be diagnosed accurately. Fetal viability should be monitored regularly if these treatments are implemented.

- Placental insufficiency

Early diagnosis and termination of twins

Early diagnosis and treatment of uterine infection

Early diagnosis of uterine fibrosis (uterine biopsy) and sexual rest

Adequate breeding management of young females (should be at least 15 months old and 65% of adult weight)

- Drug induced

Avoid use in animals that may be pregnant:

Prostaglandin F2 alpha or analogues, ecbolics, corticosteroids, multivalent clostridial vaccines Cautious use in animals that may be pregnant: Anesthetics, organophosphates

ABORTION: BACTERIAL

BASICS

OVERVIEW

- Many species of bacteria may cause septicemia and/or localized lesions in adult cattle with a subsequent abortion. These agents usually cause sporadic abortions.
- The route of infection is usually hematogenous rather than ascending as interruption of the cervical seal occurs less often in cows than in mares. Often, cows may be predisposed to abortion by these bacteria by some immunosuppressive condition such as bovine virus diarrhea (BVD).
- Two categories of bacterial abortion: (1) ubiquitous environmental organisms: *A. pyogenes*, *E. coli*, *Bacillus* spp., *Streptococcus* spp.; (2) abortion secondary to specific disease: *Pasteurella* spp., *Salmonella* spp., *Haemophilus somnus*

SYSTEMS AFFECTED

Reproductive

GENETICS

N/A

INCIDENCE/PREVALENCE

Cattle

- In a 10-year survey, specimens from 8995 bovine abortions and stillbirths were evaluated for bacteria. Bacteria were determined to be the cause of 1299 (14.49%) of the presenting abortion cases.
- The five bacteria most commonly associated with bovine abortion or stillbirth were *Actinomyces pyogenes*, 378 (4.22%); *Bacillus* spp., 321 (3.58%); *Listeria* spp., 121 (1.35%); *Escherichia coli*, 98 (1.09%); and *Leptospira interrogans*, 79 (0.88%). Twelve other genera of bacteria were associated with > or = 10 abortions or stillbirths, and 12 more species were associated with < or = 10 abortions or stillbirths.
- The diagnostic success for determining the cause of abortions may be low (25%–40%).

Sheep

- In a similar 10-year study, 1799 accessions of ovine abortions and stillbirths were evaluated for bacteria. Etiologic diagnoses were made in 786 (44%) of the submitted cases.
- Infectious agents were found responsible in 702 accessions (39%), and noninfectious causes were involved in 84 (5%). No diagnosis was made in 998 accessions (56%).
- Together, *Toxoplasma gondii*, *Campylobacter* spp., and *Chlamydia psittaci* caused approximately 25% of all abortions and stillbirths examined.

Goats

- In an 8-year study of 217 caprine abortions, infectious agents as the cause were found in 37% of the cases: bacterial agents were identified in 30.5%, viral agents in 2%, fungal agents in 0.5%, and protozoal agents in 4% of the cases submitted.
- The most common causes of abortions were *Chlamydia psittaci* and *Coxiella burnetii* infection, which accounted for 23% of all goat abortions. Mineral deficiencies were observed in 4%, fetal anomalies accounted for 3%, and leukoencephalomalacia of the brain (probable oxygen deprivation) accounted for 3% of the submissions. No diagnosis was made in 112 of the 211 submissions (53%). No lesions were noted in 104 of the submissions (49%).

GEOGRAPHIC DISTRIBUTION

Worldwide depending on environment

Epidemiology

In a study of 58,048 pregnancies from 111 herds, the respective abortion density, proportion of aborted cows, and abortions per confirmed pregnancy were 4.2%, 5.9%, and 10.2%. Heifers had the lowest, and cows of second parity the greatest risk

of fetal death. The greatest risk of fetal death was observed in the first, and the lowest in the second trimesters of pregnancy. Respective proportions of aborted cows with and without a previous abortion were 17.5% and 5.9%. Odds of aborting after twinning in multiparous cows in this study were 1.3 times greater than for those having a single calf. Risk of abortion in the autumn and early winter was greater than that in the summer months.

DIAGNOSIS

See under specific microbial cause below.

TREATMENT

See under specific microbial cause below.

MEDICATIONS

See under specific microbial cause below.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

See under specific microbial cause below.

MISCELLANEOUS

Common microbial causes of abortion:

Arcanobacteriosis

- *Arcanobacterium pyogenes* (*A. pyogenes*, formerly *Actinomyces* or *Corynebacterium*) is the bacterium most frequently isolated from bovine abortions.
- It is a common inhabitant of the nasal, conjunctival, vaginal, and preputial mucosa of normal animals. The organism may reach the uterus by a hematogenous route, resulting in sporadic abortions.

Diagnosis

Culture of the organism from fetal tissue and placenta

Prevention and Treatment

None

Brucellosis

- Once considered the most important abortion disease of cattle, brucellosis has been nearly eradicated in North America, with the exception being some small local areas.
- *Brucella abortus* in cattle and *B. melitensis* in sheep and goats are gram-negative, intracellular coccobacilli able to survive in phagocytes.

Pathogenesis

The agent is transmitted by oral route. Aborted material contains large numbers of *Brucella* spp. organisms and contaminates the environment. Following ingestion, the organism locates in chorioallantois and results in fetal septicemia and abortion.

Clinical Signs

- Abortion occurring after the fifth month of gestation
- Thick, leathery placentitis, necrosis of the cotyledon
- Cows may have retained placenta and metritis.

Diagnosis

- Culture of the organism from fetal tissue and uterine fluids
- Infected animals identified by serology

Control

- Vaccination of calves between 4 and 12 months of age
- This is a reportable disease in most of North America; herds with positive testing animals are quarantined and an eradication program enforced.

Zoonosis

Human infection occurs from handling infected tissue and ingesting infected milk.

Campylobacteriosis

- Bovine campylobacteriosis is primarily a venereal disease resulting in early embryonic death, repeat breeders, an extended breeding season, a high percentage of open cows at the end of the breeding season, and an extended calving season. It causes occasional abortions, usually in midgestation.
- The primary cause of reproductive wastage is *C. fetus* ssp. *venerealis*. It infects the prepuce of bulls, and is transmitted to cows during breeding.
- Bulls may remain infected for life or recover spontaneously. The organism survives in frozen semen if not properly treated with antibiotics.
- *C. fetus* ssp. *fetus*, an inhabitant of the intestine, will occasionally spread to the uterus via a hematogenous route, resulting in abortion in cows. It is a more common cause of abortion in sheep.
- *C. jejuni* rarely causes bovine abortion but does so in sheep. Abortion due to *Campylobacter* spp. occurs between 4 and 8 months gestation.

Diagnosis

- Culture the organism from the prepuce of infected bulls and the anterior vagina of infected cows.
- Virgin heifer mating test: culture cervicovaginal mucus 18 to 30 days postcoitus.
- Culture the organism from aborted fetal tissues, abomasal contents, and placental fluids.

Treatment

Bulls—preputial lavage with antibiotics

Prevention

- Proper vaccination program
- Proper herd management
- Implement an artificial insemination program

Chlamydia

- *Chlamydia* are obligate, intracellular organisms that multiply in the cytoplasm of eukaryotic cells.
- *Chlamydia psittaci* is associated with reproductive wastage in cattle, sheep, and goats. In cattle it causes sporadic, late-term abortion and stillborn or weak-born calves.

Pathogenesis

- Transmission is by ingestion or inhalation of contaminated material.
- Persistent intestinal colonization results in sporadic placental infection.
- Possible venereal transmission

Diagnosis

- Necrotizing placentitis
- Identification of the organism in fetal liver or placenta
- Paired serum samples show a rising titer

Treatment

Antibiotics (tetracycline)

Zoonosis

Organisms are shed from the reproductive tract of infected animals. Pregnant women are susceptible to infection.

Epizootic Bovine Abortion (Foothills Abortion)

- EBA is limited to the foothills region of central California, coinciding with the range of the tick vector *Ornithodoros coriaceus*, the Pajahuello tick. The cause appears to be a spirochete-like agent.
- Abortion occurs in naïve cows in late gestation.
- The abortion rate may be 30% to 80% in susceptible cows.
- Native cows from enzootic areas do not abort.

Treatment and Control

- Chlortetracycline (2–5 g/day in feed) will reduce the abortion rate.
- Exposure of susceptible animals to the tick before breeding
- Fall calving to avoid exposure of pregnant cows to the tick

Haemophilosis

- The importance of *Haemophilus somnus* as a cause of abortion and infertility is controversial. It is a normal inhabitant of the male and female reproductive tract but may be a minor cause of pregnancy loss.
- Pure culture of *H. somnus*, in the absence of other organisms, may indicate this diagnosis.
- Treatment with antibiotics will reduce infection and a vaccination program may be beneficial.

Leptospirosis

- Leptospire are motile, helical spirochetes. Infection occurs by penetration of the nasal, ocular, genital, or intestinal mucosa. The organism can survive outside the host in moist, warm environments with a neutral to slightly basic pH.
- Direct transmission occurs by contact with infected urine, infected tissue, and fluids following abortion and sexual transmission.
- Indirect transmission occurs from contact with a contaminated environment.

Pathogenesis

- Leptospire localize in the proximal renal tubules and reproductive tract of cows and bulls.
- Organisms are shed in the urine and intermittent leptospiuria may persist for the lifetime of the animal.

Clinical Signs

- May include hemolytic anemia, hemoglobinuria, hepatorenal disease, abortion, and photosensitization.
- Abortion occurs 4 to 12 weeks following infection.
- Abortion due to *L. interrogans* serovar *hardjo* occurs throughout gestation due to serovar *pomona* usually in the last trimester.

Diagnosis

- Isolation of leptospire from fetal tissue such as kidney, urine, thoracic fluid, and aqueous humor. The organism does not survive well in the autolyzed fetus.
- Culture of the organism from cow's urine
- Immunofluorescent staining of fetal kidney
- Serologic testing

Control

- Vaccination programs

- Environmental cleanup, control population of wild animals and rodents that contaminate the environment

Treatment

Antibiotics (oxytetracycline or streptomycin)

Zoonosis

An important zoonotic potential

Listeriosis

- *Listeria monocytogenes* causes encephalitis, abortion, and neonatal septicemia.
- Infected cows often have fever and anorexia prior to aborting, with postparturient complications including retained placenta, pyometra septicemia, and occasionally death. Central nervous system signs seldom occur simultaneous with abortions.
- Organism ubiquitous in soil, vegetation, water, feces.
- Exposure often from spoiled silage
- More common in winter
- Usually sporadic, occasionally in outbreak form
- Organism has a predilection for fetoplacental tissues resulting in placentitis and fetal septicemia.

Abortion

- Usually last trimester
- Fetus autolyzed when expelled

Diagnosis

- Culture of organism from fetal tissues and stomach contents, placenta, uterine fluids
- Culture from feces of infected animals

Control

- Avoid feeding spoiled silage and other contaminated feed
- Aborted tissues source of contamination to herd mates

Zoonosis

Important zoonotic potential, especially in pregnant women

Neosporosis

- Neosporosis is caused by the protozoan *Neosporum caninum*. It has worldwide distribution. Dogs are identified as the intermediate host.
- Abortion usually occurs during the second trimester but may occur throughout gestation.

Clinical Signs

- Infected cows show no clinical signs.
- Infected calves may be born prematurely and exhibit neurological signs.

Pathophysiology

- The route of infection is vertical transmission with congenital infection occurring in 80% of seropositive cows.
- Seropositive cows are more likely to abort than seronegative herd mates.
- Repeat abortions occur following recrudescence of latent infections or following a new infection.

Diagnosis

- Observation of characteristic histological lesions or identification of the parasite in fetal tissue, especially brain, heart, liver, and skeletal muscle
- Fetal serology if abortion occurs after 5 months gestation
- Serologic testing of cows

Control and Prevention

- Prevention of postnatal transmission, possibly feed contamination by feces of infected dogs
- Removal of seropositive cows from the herd
- Embryo transfer to break the vertical transmission cycle
- A vaccine is available.

Trichomoniasis

- Trichomoniasis is a venereal disease caused by the protozoan *Trichomonas foetus*. Infection is demonstrated as early embryonic death, repeat breeders, an extended breeding season, a high percentage of open cows at the end of the breeding season, and an extended calving season.
- It causes occasional abortions, usually in the first half of gestation.

Diagnosis

- Bulls—identification and culture of the organism from preputial smegma
- Cows—identification and culture of the organism from cervicovaginal mucus and uterine contents in pyometra cases
- Virgin heifer mating test—culture cervicovaginal mucus 12 to 19 days postcoitus
- Culture the organism from aborted fetal tissues and fluids.

Prevention

- Proper vaccination program
- Proper herd management
- Implementation of artificial insemination program

Ureaplasmosis

- *Ureaplasma diversum* is a normal inhabitant of the reproductive tract of cows and bulls. In clinical conditions, it may result in granular vulvitis in cows.
- If artificial insemination does not include a guarded, double rod technique, the organism may be carried into the uterus, resulting in early embryonic death or abortion. Abortion is usually sporadic.

Diagnosis

Culture of the organism from fetal tissue

Treatment and Control

- Proper insemination technique
- Postbreeding infusion of tetracycline

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Heifers had the lowest risk, and cows of second parity the greatest risk of fetal death.

ZOONOTIC POTENTIAL

Brucellosis, chlamydiosis, listeriosis, leptospirosis, and *Coxiella burnetii* are all potential zoonotic agents.

PREGNANCY

The greatest risk of fetal death was observed in the first, and the lowest in the second trimesters of pregnancy.

RUMINANT SPECIES AFFECTED

Potentially, all ruminant species are affected.

ABORTION: FARMED CERVIDAE

BASICS

DEFINITION

Loss of a fetus

Further Definitions

- Calf—cervid less than 1 year of age
- Hind—adult female cervid
- Stag—adult male cervid

PATHOPHYSIOLOGY

- The fetus may die due to a genetic or congenital abnormality.
- Infectious organisms may invade the fetus and lead to fetal death.
- Abnormalities or infections of the placenta or uterus may lead to placental separation, fetal death, and reabsorption or expulsion.
- Trauma, toxins, infections, malnutrition, metabolic disease, drugs, or other stress incurred by the hind may lead to fetal stress and abortion. Abnormalities of the hind's reproductive or endocrine system may lead to abortion.

SYSTEMS AFFECTED

Reproductive; other systems may be involved depending upon the underlying etiology of the abortion. The clinician may need to monitor other body systems for complications secondary to abortion.

GENETICS

N/A

INCIDENCE/PREVALENCE

The incidence of embryonic mortality in farmed deer is relatively low. Insufficient data available for other species.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

Depends upon underlying cause. Some cervids are more susceptible to infectious disease than others. When red deer hinds (*Cervus elaphus*) are crossbred with wapiti stags, there is a greater risk for dystocia and subsequent fetal death.

Mean Age and Range

First calving wapiti (*Cervus elaphus*) are more likely to deliver nonviable calves than are adults. Also, 2-year-old elk, fallow (*Dama dama*), and red deer have lower calving rates than mature animals.

Predominant Sex

Female only

SIGNS

HISTORICAL FINDINGS

- May be none evident, especially if the fetus is reabsorbed early in gestation
- Estrus detected on a hind previously diagnosed as pregnant
- Failure to produce an offspring (missed due date)
- Restlessness, solitude-seeking behavior, pacing, abdominal straining, and other signs of imminent parturition
- Discovery of expelled fetus

PHYSICAL EXAMINATION FINDINGS

- May be none—fetal resorption early in gestation may have no visible signs. Hinds that were previously diagnosed as

pregnant will later be found to be nonpregnant. If rectal palpation is done (in wapiti), the previously pregnant horn will cease to be enlarged. There will no longer be a fetal membrane slip.

- Late-term abortions in cervids living in large enclosures or parks may occur unobserved as the female usually eats the placenta and the dead fetus is consumed by predators.
- When clinical signs are present, they include:
 - Bloody or purulent vaginal discharge
 - Visibly expelled fetus and/or placenta
 - Premature udder development and dripping
 - If abortion is due to systemic disease, may see other nonspecific signs of illness such as depression, dehydration, pyrexia, anorexia, and weight loss.
- Brucellosis-induced abortion in female reindeer (*Rangifer tarandus*) is characterized by a retained placenta and metritis.

CAUSES

Degenerative

Anatomic/Congenital

Congenital abnormalities may lead to fetal death.

Metabolic

Febrile or severely stressed animals may abort.

Nutritional

- Inadequate nutrition—may cause a fetus to die or be born underweight and nonviable
- Iodine deficiency—may be caused by insufficient dietary intake, or be secondary to excessive calcium in the diet, overingestion of toxic plants such as *Brassica* spp., gross bacterial contamination of the feed, continuous intake of feeds containing cyanogenetic glucosides (i.e., white clover), or due to ingestion of canola (rapeseed and canola meal). An iodine deficiency can lead to goiter, prolonged gestation, and an increased incidence of stillbirth.

Infectious

Bacterial

- *Brucella abortus*
- *Brucella suis* type 4—most common cause of abortion in reindeer and caribou
- Leptospirosis—serovars found in North American cervids include *L. pomona*,

L. grippityphosa, *L. canicola*, and *L. pyogenes*. *Leptospira pomona* is believed to cause abortions in free-ranging white-tailed deer (*Odocoileus virginianus*) and red deer.

- Experimental infections in white-tailed deer have produced abortions, anorexia, fever, and death.
- Listeriosis—the septicemic form causes placentitis and endometritis leading to abortion in late-term pregnancy as well as the birth of weak, full-term young.

Fungal

Incidence of fungal infections in farmed wapiti and red deer is rare. However, fungal infections can cause abortions in other ruminant species. Therefore, it should not be excluded.

Parasitic

Toxoplasmosis—wapiti and red deer appear to be less susceptible to toxoplasmosis than other cervidae species.

Viral

- Bluetongue (orbivirus)—abortion and congenital deformities have been seen in white-tailed deer, but bluetongue has not been reported to cause serious clinical disease in wapiti or red deer.
- Bovine viral diarrhea virus—BVDV has not been reported as a clinical entity in wapiti or red deer, but virus has been isolated from red, fallow, and roe deer. Serological evidence of infection has been demonstrated in mule (*Odocoileus hemionus*), white-tailed deer, fallow deer, moose (*Alces alces*), and a Chinese water deer (*Hydropotes inermis*). Almost all of the reported BVD-related cervid cases involve a free-ranging animal, which makes it difficult to find aborted fetuses. Experimentally, BVDV isolated from a dead deer did cause stillborn fawns and mummified fetuses when injected into pregnant penned deer.

Traumatic

Congenital abnormalities, fetal oversize, or abnormalities of presentation at time of parturition may lead to dystocia and

subsequent fetal death.

Toxic

Locoweed causes abortions in sheep and cattle and may be a problem for cervidae as well.

Drugs

Prostaglandin F2 alpha has been used to induce abortion in wapiti but is probably ineffective if given less than 10 days after breeding. Prostaglandins also can cause luteolysis in reindeer.

RISK FACTORS

Febrile or severely stressed animals may abort. The most common stressors for cervidae are severe weather, inadequate nutrition, recent capture or transport, and concurrent disease. It would also be wise to avoid the use of products that are known abortifacients in other ruminant species.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of vaginal discharge
 - Normal term parturition
 - Vaginitis
 - Pyometra
 - Metritis
 - Uterine trauma or hemorrhage
 - Uterine or vaginal neoplasia
- Other reasons for failure to deliver on due date
 - Infertility (animal never became pregnant)
 - Incorrect due date
- Other causes of abdominal straining/discomfort such as colic

CBC/BIOCHEMISTRY/URINALYSIS

May be normal. It may also indicate systemic disease.

OTHER LABORATORY TESTS

Maternal Pregnancy Specific Protein B (PSPB)

Bovine pregnancy specific protein B antibody cross reacts with caribou, red, fallow, and white-tailed deer PSPB. Hence, the PSPB radioimmunoassay developed for domestic cattle can be used for pregnancy monitoring in some cervids. It is as effective as ultrasound in diagnosing the pregnant hind. In red and fallow deer, PSPB is present by 33 days after conception. It is nondetectable in open hinds.

Serum Progesterone Levels (P4)

Serum progesterone concentrations rise during pregnancy, but they also rise during the estrus cycle. Serial measurements can be done during the breeding season to determine if an animal is pregnant or in estrus. Otherwise, one can wait until the breeding season is over. A decrease in P4 levels in a previously pregnant animal suggests early embryonic loss.

Fecal Progesterone Levels

Reserved for use in free-ranging populations. This can be used for detecting pregnancy in elk during mid to late gestation. Several factors may influence fecal P4 excretion and therefore make this test less reliable.

Urinary PDG (pregnanediol-3alpha-glucuronide)

The simultaneous evaluation of urinary PdG and urinary estrogen conjugates was effective for estimating and tracking pregnancy stage in Pere David's deer. PdG excretions decreased to nadir concentrations between 1 and 2 weeks before abortion in the two hinds that aborted.

Paired Serology

To test for infectious disease

Testing Procedures for Specific Diseases

Bacterial

- Brucellosis—There are five serological tests available: complement fixation, tube agglutination, rapid card, buffered plate, and ELISA.
 - Leptospirosis
 - Paired serology
 - Dark field microscopy of the urine or aqueous humor on dead deer
 - ELISA test may become available.
- Listeriosis—Serological tests, but high number of false negatives occur

Viral

- Bluetongue serological tests include ELISA, immunodiffusion, radioimmunoassay, hemolysis-in-gel assay, and a genetic probe for detection of bluetongue viral DNA in fluids and tissues.
- Bovine viral diarrhea virus
 - Virus isolation from blood or nasal secretions
 - IFA or immunohistochemistry
 - ELISA
 - Paired serology (VN)

Protozoal: Toxoplasmosis

- Sabin-Feldman dye test (DT)
- Hemagglutination test (HA), may not be reliable for red deer.
- Direct agglutination

IMAGING

Transrectal Ultrasound

- Most practical method for diagnosing pregnancy in farmed deer
- Restraint in a crush is preferable, but manual restraint may work for some animals and handlers. In wapiti and red deer, the best time for pregnancy diagnosis is between 35 and 60 days gestation. This technique can be used as early as 33–35 days gestation in fallow deer.

Transabdominal Ultrasonography

To evaluate the fetus later in gestation

Radiographs

May be more practical for the smaller cervidae species

DIAGNOSTIC PROCEDURES

Bacterial culture and histological examination of the fetal, placental fluid and placental tissues. It may be difficult to obtain the placenta as the female usually ingests it. Also, secondary bacterial overgrowth is likely to occur prior to sample collection.

Bacterial

- Brucellosis
 - Bacterial isolation of *Brucella* spp. provides the only definitive diagnosis of this disease (caution: zoonotic risk, so wear gloves).
 - If index of suspicion is high, owner may elect to sacrifice the mother for culture of her major body lymph nodes and organs.
- Listeriosis—isolation of *Listeria* spp.
- Leptospirosis—can be isolated from urine or kidney cultures. If the hind has any swollen joints, these should also be cultured.

Fungal

Specific diagnosis may require culture of the organism.

PATHOLOGIC FINDINGS

Depends upon etiology

Bacterial

- Brucellosis—necrotizing placentitis characterized by a thickened placenta covered with a purulent exudate
- Listeriosis—in animals that abort, placentitis and endometritis occur.

Fungal

Gross pathology reveals discreet granulomas and raised circular areas on affected organs. Histopathology shows pyogenic inflammatory reaction, fungal hyphae.

TREATMENT

APPROPRIATE HEALTH CARE

- Depends upon underlying etiology—see specific disease chapter.
- None may be warranted
- Make appropriate changes in husbandry if condition was related to poor handling, sanitation, or malnutrition.

NURSING CARE

Supportive

ACTIVITY

N/A

DIET

If abortion was due to listeriosis or mycotoxins, make appropriate changes to silage feeding practices.

CLIENT EDUCATION

See Biosecurity and Production Management below.

SURGICAL CONSIDERATIONS

Reserved for dystocias when all else has failed

MEDICATIONS

DRUGS OF CHOICE

- Dependent upon underlying cause
- Antibiotics may be warranted for specific bacterial diseases, metritis, toxemia, and so on.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Depends upon cause

PREVENTION/AVOIDANCE

Establish a good nutritional and preventative health program.

Brucellosis

A test and removal program is ideal for intensively managed deer farms. It may not be possible in game or wildlife parks to round up all animals in the herd at one time for testing. In the United States, vaccination is used in cattle under strict regulations, but it is not used in deer. There is a vaccination program in place for reindeer in Alaska. The program uses a

killed, homologous vaccine in adjuvant, which provides protection for up to 4 years. Unfortunately, current testing methods cannot differentiate between vaccinated and infected animals. As such, special permission from the state veterinarian is required. A newer vaccine, strain RB51, is in use for bovidae. This vaccine does not cross-react with the test. Its efficacy in cervid species has yet to be determined. So far, experimental studies have shown that this vaccine failed to prevent abortion in elk. The best way to prevent brucellosis is to allow the introduction of only nonvaccinated, blood-test negative animals from known brucellosis-free herds.

Leptospirosis

Vaccine is available although its usage in cervidae species is extralabel in the United States.

Bluetongue

Use parasite control to decrease the number of arthropod vectors (e.g., *Culicoides* spp. or gnats). Vaccine is available for use in deer in affected areas, but its use would be extralabel in the United States. In endemic areas, young may obtain up to 3 months' protection from colostral antibodies.

BVDV

Isolation of virus from nasal swabs is evidence that deer via direct contact can transmit BVDV. Therefore, fencing of adequate height and double fencing are recommended in order to prevent direct contact and disease transmission between captive and wild cervids.

POSSIBLE COMPLICATIONS

Decreased fertility

EXPECTED COURSE AND PROGNOSIS

Dependent upon underlying cause

MISCELLANEOUS

ASSOCIATED CONDITIONS

Dystocia, reproduction management

AGE-RELATED FACTORS

In farmed deer herds—young females that are underweight for their age should not be subjected to the risks of pregnancy.

ZOONOTIC POTENTIAL

Brucellosis, toxoplasmosis, leptospirosis, listeriosis

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Cervidae: wapiti (*Cervus elaphus*), fallow deer (*Dama dama*)

BIOSECURITY

- Newly acquired animals should always be quarantined for a minimum of 30 days before allowing entry into the herd.
- Preshipment testing for infectious diseases is advisable. Avoid purchasing animals from regions where brucellosis is endemic.
- Double fences may be warranted to prevent direct contact with wildlife species.
- Keeping cats and wild animals out of feed storage areas and animal enclosures will help lower the risks of infection with toxoplasmosis and leptospirosis. See specific chapters for additional measures.

PRODUCTION MANAGEMENT

- In farmed animals, it is important to monitor age, weight, and previous reproductive performance of hinds within a herd in order to maximize reproductive performance and overall production capability.
- Good nutrition management is mandatory. Young females that are small for their age should not be bred. If more than one animal aborts, testing of the herd for infectious diseases is advisable. Stress reduction also plays a major role in lowering the risk for disease and abortion.
- Habituating animals to gates and chutes makes handling during physical exams and other routine procedures less stressful on the animals. Avoid shipping animals during insect/vector season. Last, gross and histopathologic examination should

always be performed on all dead fetuses and animals whenever possible.

SYNONYMS

N/A

SEE ALSO

- Brucellosis

Author: Melissa Weisman

ABORTION: SHEEP AND GOATS

BASICS

DEFINITION

- Fetal loss, fetal wastage: loss of conceptus at anytime during pregnancy
- Most commonly observed in the last 2 months of pregnancy

PATHOPHYSIOLOGY

- Abortion results from
 - Fetal death from invasion by microorganisms
 - Fetal expulsion subsequent to placental disease, insufficiency
 - Fetal expulsion following maternal compromise
 - Premature parturition
 - Fetal reabsorption, maceration, autolysis
- Can be caused by a variety of infectious and noninfectious agents.
- Infectious causes of abortion are the most economically significant.
- Most common infectious causes are *Chlamydia psittaci*, *Toxoplasma gondii*, and *Campylobacter* spp., which may represent up to one-third of all cases of abortions.
- Chlamydiosis is more common in goats.
- *Campylobacter* is less common in goats in North America.

SYSTEMS AFFECTED

- Reproductive
- Others depending on the etiology

GENETICS

Angora goat may be a habitual aborter.

INCIDENCE/PREVALENCE

- Should be less than 5% on a flock basis (less than 2% ideal)
- Abortion storms may occur in the case of specific infectious diseases.

GEOGRAPHIC DISTRIBUTION

- Worldwide
- Some diseases processes may be regional (presence of vector).

SIGNALMENT

Nonspecific

SIGNS

- Early pregnancy loss may not be detected.
- Clinical signs in the aborting female vary depending on the cause.
- Complications depend on cause (deterioration of health, retained placenta, metritis).

Clinical Signs in Dam

- Bluetongue: febrile, swollen tongue, ear, or face; lameness; ulcerative lesions on mouth
- Akabane virus disease
- *Campylobacteriosis*: aborting goats may show diarrhea.
- *Chlamydia*: pneumonia, keratoconjunctivitis, epididymitis, and polyarthritis; anorexia, fever, bloody vaginal discharge 2 to 3 days before abortion

- Brucellosis: *B. melitensis* in goats causes abortion, weak kids, and mastitis. *B. ovis* in sheep is rarely a cause of abortion but is responsible for poor reproductive performance and in the ram contagious epididymitis.
- Aborting goats may experience fever, depression, weight loss, mastitis, and lameness.
- Leptospirosis: anorexia, fever, marked jaundice, hemoglobinuria, anemia, neurological signs, abortion, occasionally may be fatal
- Salmonellosis: abortion, retained placenta, metritis, and various systemic signs (fever, depression, diarrhea). Mostly in overcrowded flocks
- Toxoplasmosis: generally none, immunocompromised females may present a neurologic form of the disease.
- Leptospirosis: septicemia, fever, decreased appetite, reduced milk production, abortion, and meningoencephalitis
- Mycoplasmosis (goats): mastitis, arthritis, keratoconjunctivitis, vulvovaginitis, and abortion in the last third of pregnancy

HISTORICAL FINDINGS

- Introduction of new animals
- Vaginal discharges
- Premature udder development
- Presence of fetuses
- Premature/stillbirths
- Increased congenital abnormalities

PHYSICAL EXAMINATION FINDINGS

- Vaginal edema
- Vaginal discharge
- Anorexia
- Other signs in flock

CAUSES

- Viruses
- Bacteria
- Rickettsia
- Protozoa
- Fungi
- Toxins

RISK FACTORS

- Lack of biosecurity measures
- Vector population
- Overcrowding

DIAGNOSIS

Brucellosis

- Isolation: best samples are vaginal discharges and milk, stomach contents.
- Indirect diagnosis: complement fixation, agglutination and precipitation tests may help identify carrier animals.

Chlamydiosis (Enzootic Abortion)

- *C. psittaci*, gram-negative intracellular organism
- Abortion and other signs
- Aborting females become immune
- Females infected after 100 days of pregnancy may not abort.
- Diagnosis
 - Generalized placentitis, abortion in the last month of pregnancy, high incidence in newly infected flocks

- Demonstrations of characteristic inclusion bodies on smear from cotyledons, vaginal discharge, fetal stomach content
- Culture from vaginal discharge, placenta, and fetal tissue
- Serology: paired samples from dam and fetal serum
- ELISA or Indirect Inclusion Fluorescence Antibody tests (IIFA)

Toxoplasmosis

- Goats more susceptible than sheep
- Diagnosis
 - Cotyledons are gray-white to yellow and present small, 1–3 mm focal area of necrosis and calcification. Intercotyledonary areas are generally normal. Macroscopic lesions: 2–3 mm necrotic foci on cotyledons, intercotyledonary allantochorion are generally normal. Fetus may be mummified or decomposed; chalky white necrotic brain lesions
 - Samples: placenta, fetal brain, fetal fluids, maternal blood, precolostral blood
 - Isolation from cotyledons, brain and fetal fluids, tissues (shipped packed in ice)
 - Histopathology: fixed cotyledons, fetal brain
 - Serology: presence of antibodies in fetal fluids or precolostral serum is the preferred diagnostic technique and indicate transplacental infection.

Q Fever (Coxiella burnetii)

- Placentitis, placental necrosis, thickening of the intercotyledonary areas, abortion, and stillbirth
- Isolation: placenta, vaginal discharges, fetal stomach content
- Demonstration of organism by Ziehl-Neelsen staining
- Complement fixation: need samples from several animals
- Fluorescent antibody test may be used to identify organism in frozen section of placenta.

Campylobacteriosis

- *Campylobacter jejuni* and *C. fetus*; most prevalent in sheep, rare in goats
- Gram-negative microaerophilic rods

Symptoms

- Abortion, stillbirths, and weak lambs, retained fetal membranes
- Placentitis, placental edema
- Fetus: hepatomegaly, hemorrhagic liver, necrotic foci of 1–3 cm
- Fetal subcutaneous edema, serosanguineous fluid in abdominal and thoracic cavity
- Fetus: bronchopneumonia

Isolation and Identification

- Samples: placenta and vaginal discharges, frozen fetal stomach content (-20°C)
- Transport medium required
- Isolation from placenta, vaginal discharge, fetal stomach contents
- Histopathology: necrotic areas of the chorionic villi, arterioles, and thrombosis of the hilus of the placentomes

Salmonellosis

- *Salmonella abortus-ovis*, *S. typhimurium*, *S. Dublin*, *S. Montevideo*, *S. arizonae*
- Direct diagnosis: culture from fetal tissues taken aseptically may be preserved at -20°C; placenta and uterine discharges
- Indirect diagnosis: seroagglutination

Listeriosis (Listeria monocytogenes)

- Gram-positive, non-acid-fast facultative microaerophilic organisms. *L. monocytogenes* affects sheep and goats; *L. ivanovii* affects sheep only.
- Direct diagnosis: placenta, fetal liver and spleen, fetal stomach content, vaginal discharge within 48 hours of abortion. Samples may be refrigerated if not cultured immediately.
- Indirect diagnosis: histopathology on placenta, fetal liver and spleen microabscesses (white pinpoint spots), and necrosis and macrophages and neutrophils infiltration. Gram stain reveals numerous gram-positive rods.

Leptospirosis

- Sheep and goats are generally less susceptible to leptospirosis than other species. Goats are more susceptible than sheep.
- Sheep: mostly *L. hardjo* sometime *L. pomona*, *L. ballum*, and *L. bratislava*; late-term abortion, stillbirths, and ill-thrift lambs
- Affected flocks are mostly reared indoors
- Agalactia
- Goat: *L. icterohaemorrhagiae*, *L. pomona*, *L. grippotyphosa*
- Clinical signs in case of acute infection
- Direct diagnosis: fetal tissue, fetal fluids, and placenta
 - Isolation is difficult
 - Demonstration by dark-field microscopy, immunofluorescence and silver stain
- Indirect diagnosis: serology—macroscopic agglutination test

Border Disease

- Goats are fairly resistant.
- Virus isolation (buffy coat) and antigen demonstration—heparinized blood from dam or hairy shaker lambs, fetal tissue (thyroid, kidney, spleen, cerebellum, placenta), hairy shakers (thyroid, kidney, spleen, cerebellum, intestine, lymph nodes)
- Histopathology: cerebellum, spinal cord
- Serology: flood from dam and hairy shakers
- Clinical: small cotyledon with focal necrosis, hairy shakers,

Bluetongue

Viral isolation: blood, semen, fetal brain and spleen unlikely cause of abortion in goats

Akabane Disease

Fetal malformation, positive antibody titer in live-born and aborted fetuses

Cache Valley Virus

- Congenital abnormalities
- Detection of antibodies in fetal fluids or precolostral serum

Mycoplasmosis

- Mycoplasma abortions (*M. mycoides*, *M. agalactia*) are significant in goats.
- Diagnosis: culture and serotyping of the isolate from milk, fetal fluids, and placenta

Noninfectious Causes of Abortion

- Genetic (goat) may be a habitual aborter
 - Angora goats with fine mohair
 - Abortion at 100 days
 - Adrenal dysfunction
- Energy protein deficiency
- Phenothiazine and levamisole in the last 2 months of pregnancy; corticosteroids in late gestation
- Prostaglandin F 2 alpha or analogues (goats)
- Plants that accumulate nitrates

CBC/BIOCHEMISTRY/URINALYSIS

May be indicated if aborting dam is clinically sick

OTHER LABORATORY TESTS

- Sampling is critical for the proper diagnosis of abortion.
- Placenta
 - Ideal for the isolation of most abortion-causing agents
 - Ideal for identification using specific staining techniques on histological section or impression smears
 - For isolation: need five or six cotyledons and section of intercotyledonary spaces both from healthy appearing and diseased areas
 - If needed, this tissue may be rinsed with sterile saline.
 - For isolation: need a transport medium (i.e., viruses; *Campylobacter*: FBP/glycerol; *Leptospirosis* 100 ml extender

with 1% BSA)

- For histopathology: 0.5 cm section of tissue in 10% formalin 1:10
- For bacteriology: impression smears
- Vaginal discharges
 - Collect in sterile manner
 - Vaginal/uterine swabs
 - Use of specific transport medium is preferred if a specific germ is suspected.
- Fetal tissues
 - Tissue samples from all fetal organs (spleen, liver, kidneys, brain, lymph nodes, spinal cord) should be taken in an aseptic manner immediately after abortion or death.
 - Handle in the same manner as for placenta.
- Fetal fluids
 - If fetus is not autolyzed
 - Stomach content
 - Peritoneal/thoracic fluids
 - Blood from the cardiac cavity
- Milk—Samples of milk are taken from both glands using aseptic techniques (clean the mammary gland, disinfect teats, and eliminate the first two jets).
- Blood
 - For isolation: immediately after/during abortion
 - For serology: paired samples immediately after abortion and 2 to 3 weeks later
 - In case of an outbreak, blood should be collected from aborting females as well as from lambs/kids before colostrum intake.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Abortion Associated with Deformities

- Bluetongue: hydranencephaly
- Akabane disease: arthrogryposis (dystocia), hydranencephaly, and mummification
- Cache Valley: arthrogryposis, brachygnathia, hydranencephaly, microencephaly, spinal cord hypoplasia, and mummification
- Border disease: cerebellar hypoplasia, hydranencephaly, brachygnathia, arthrogryposis. dark pigmentation of the fleece, hairy shaker
- Toxic plants: lupine, skunk cabbage, locoweed, and Sudan grass
- Iodine, copper, manganese deficiency

Assessing Disease Risk

- Toxoplasmosis—cat population
- Leptospirosis
 - Rodent population
 - Humid hot environment
 - Proximity to dairy and swine operation
- Salmonellosis
 - Source of infection: bird, cattle, wildlife
 - Predisposing condition: overcrowding, shipping, climatic changes
- Chlamydia
 - Infection transmission: placenta, fetal fluids

- Pigeon/sparrows are reservoirs, ticks or insects may play a role.
- Vaginal discharge in goat up to 2 weeks before abortion
- Reservoir: young maiden females
- Listeria
 - Organisms grow in poorly fermented silage.
 - Can survive in soil and feces for extended period of time
- Bluetongue: Culicoides gnat (cattle may be a reservoir)
- Akabane virus diseases: gnats and mosquito population
- Cache Valley virus: mosquitoes

Test Accuracy

- Diagnosis of a specific cause of abortion can be very challenging.
- Even if all samples are submitted adequately, the exact etiology will remain undiagnosed in half of the sporadic cases.
- Diagnosis of the cause of an outbreak is more rewarding.
- Most labs will run an abortion panel based on serology, histopathology, and culture tests described above.

TREATMENT

Treatment potential

- Campylobacter: penicillin or streptomycin or tetracycline in feed
- Chlamydia: tetracycline, tylosin
- Leptospirosis: tetracycline
- Toxoplasmosis: decoquinate, monensin
- Leptospirosis: tetracycline
- Mycoplasma: tetracycline and tylosin

CLIENT EDUCATION

- Establish good preventative program
 - Biosecurity measures
 - Vaccination
- Good nutritional programs
- Consider every case of abortion as a possible outbreak.
- Act quickly and help collect appropriate samples to be examined by a veterinarian.

MEDICATIONS

Daily tetracycline treatment of the flock may help with some of the abortion-causing diseases.

DRUGS OF CHOICE

FOLLOW-UP

PREVENTION/AVOIDANCE

- General prevention program for abortion
 - Quarantine new animals (4–6 weeks)
 - Nutrition
 - Vaccination: chlamydia, campylobacter (2 months and last month of pregnancy)
 - Feed chlortetracycline (200–400 mg/head/day), monensin (15 mg/head/day) during gestation
 - Keep feed, pasture, and water source free from contamination by runoff particularly from cattle and hogs.
 - Control rat, bird, cat population.
 - Act quickly on any abortion and assume it is an outbreak; submit complete samples.
 - Separate prepartum from postpartum females.
 - Keep good lambing/kidding facilities.
- Reduce stress due to poor nutrition, unsanitary environment, crowded conditions.

Vaccination

- Bluetongue: questionable
- Akabane virus: effective
- Cache Valley: effective
- Campylobacter: helpful
- Chlamydia: helpful
- Q fever: autogenous vaccines in conjunction with chlortetracycline may help.
- *B. ovis*: poor efficacy of killed vaccine
- *B. melientensis*: live attenuated good when permitted
- Salmonellosis: autogenous vaccine may be helpful
- Toxoplasmosis: may be helpful

POSSIBLE COMPLICATIONS

Dystocia, retained placenta, metritis, mastitis, male infertility (brucellosis, chlamydiosis), female infertility

ABORTION: VIRAL, FUNGAL, AND NUTRITIONAL

BASICS

OVERVIEW

- Abortion is the expulsion of the fetus prior to the end of the normal gestation period. Besides bacterial etiology, viral, fungal, parasitic, and nutritional causes are not uncommon.
- Abortions may occur near normal delivery time and it is difficult to determine whether the dam has aborted or whether a premature birth has occurred.
- Diagnostic success rates for abortions of only 25%–30% attained by diagnostic laboratories are common.
- Abortion frequently results from an event that occurred weeks or even months prior to the event, making diagnosis difficult in many cases.
- Fungal abortions are normally sporadic, and occur from 4 months to term.
- The incidence of fungal abortions in temperate climates is highest in the winter months. Severe infection of the placenta, characterized by a leathery thickening of the areas in between the cotyledons, is a common finding.
- Toxic, pharmacologic, and genetic factors causing fetal death and/or abortion are many times not discernible in the specimens available for examination.

SYSTEMS AFFECTED

Reproductive

GENETICS

N/A

INCIDENCE/PREVALENCE

Viral

In a 10-year South Dakota abortion survey, viruses were associated with 10.58% of samples. Bovine herpesvirus-1 (IBR) was detected in 5.41%, and bovine viral diarrhea virus (BVDV) was detected in 4.54% of diagnostic submissions. Bovine herpesvirus-4 was isolated from 0.52%; parvovirus, enterovirus, adenovirus, parainfluenza virus, and pseudorabies virus were isolated in much smaller numbers. Malignant lymphoid neoplasia abortion was assumed to have been caused by the bovine leukosis virus.

Mycotic

In one study, mycotic infection was diagnosed in 6.8% of 6858 cases of bovine abortion and stillbirth examined during a 9-year period. Aspergilli were associated with approximately 5% of all abortion cases and 71% of 446 cases that were cultured for fungi and diagnosed as mycotic abortion. *Aspergillus fumigatus* was the most frequent isolate (62%), followed by *A. terreus* (6.7%), *Emericella (Aspergillus) nidulans* (3.0%), *A. flavus* (2.9%), and *E. rugulosus* (less than 1.0%). Zygomycetes (*Absidia*, *Mortierella*, *Rhizomucor*, *Rhizopus*) accounted for 21% of the cases. *Pseudallescheria boydii* and yeasts (*Candida*, *Torulopsis*) were each identified in 2% of the cases. Fungi that uncommonly cause infection accounted for 2% of the cases and included *Curvularia geniculata*, *Exophiala jeanselmei*, *Hendersonula toruloidea*, *Lecythosphora hoffmannii*, *Talaromyces flavus* var. *flavus* (*Penicillium vermiculatus*), *T. (Penicillium) thermophilus*, and *Wangiella dermatitidis*. About 10% of the mycotic cases were mixed fungal infections involving *A. fumigatus* (87%), *A. flavus* (12.5%), or *E. nidulans* (12.5%) coexisting with *Absidia corymbifera* (72%), *Rhizomucor pusillus* (4.3%), or *Rhizopus arrhizus* (4.3%). In each mixed infection, both septate and nonseptate hyphae were observed in placental tissues.

GEOGRAPHIC DISTRIBUTION

Worldwide, depending on species, agent, and environment

Epidemiology

In an Israeli study of 58,048 pregnancies from 111 herds, the respective abortion density, proportion of aborted cows, and abortions per confirmed pregnancy were 4.2%, 5.9%, and 10.2%. Among parities, heifers had the lowest risk, and cows of

second parity the greatest risk of fetal death. The greatest risk of fetal death was observed in the first trimester, and the lowest in the second trimester of pregnancy. Respective proportions of aborted cows with and without a previous abortion were 17.5% and 5.9%. The potential of aborting after twinning in multiparous cows was found to be 1.3% greater than for those having a single calf. Risk of abortion was greater in the autumn and early winter than in the summer months.

DIFFERENTIAL DIAGNOSIS

Nonbacterial

Bovine Abortion

- Bluetongue
- Bovine viral diarrhea virus (BVD)-mucosal disease
- Drug induced
- Fetal abnormalities
- Infectious bovine rhinotracheitis (IBR)
- Iodine deficiency
- Malnutrition
- Maternal stress
- Mycotic abortions
- Placenta abnormalities
- Q fever
- Twinning
- Vitamin A deficiency

Ovine Abortion

- Border disease (bovine viral diarrhea—BVD)
- Copper deficiency
- Maternal stress
- Mycotic
- Nutritional deficiency/excess
- Parasitic
- Selenium toxicity
- Starvation
- Toxic plant ingestion

Caprine Abortion, Early

- Drug induced/iatrogenic (diazepam, xylazine, Acepromazine)
- Nutrition
- Progesterone deficiency

Caprine Abortion, Late

- Akabane
- Bovine viral diarrhea (BVD)
- Caprine herpesvirus
- Copper deficiency
- Corticosteroid administration
- Foot-and-mouth disease
- Malnutrition
- Selenium deficiency
- Stress
- Toxic plant ingestion
- Vitamin A deficiency

TREATMENT

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

MISCELLANEOUS

Bovine Virus Diarrhea

Caused by bovine virus diarrhea virus (BVDV)

Clinical Conditions

- Subclinical BVD—Most common form of infection
- Acute BVD—Generally mild with low mortality
- Persistently Infected (PI) Cattle—PI calves are infected in utero and are immunotolerant to the noncytopathic virus
- Mucosal Disease—PI calves become super-infected with a second, cytopathic biotype of BVDV resulting in a condition of low morbidity but high mortality
- Abortions
 - Fetal infection may result in either PI calves or abortion.
 - Abortion rates are higher in BVDV type II infections.
 - Infections near conception result in early embryonic death and infertility.
 - Infections between 42 and 125 days gestation with noncytopathic biotypes result in PI calves, fetal death causing abortion or mummification, or congenital defects.
 - Infection between 125 and 170 days gestation results in a lower incidence of abortion and congenital defects. Calves may have an antibody titer to BVDV.
 - Infection after 170 days gestation has little effect on the fetus.

Diagnosis

- Good history relative to the health of the herd
- Virus isolation and antibody detection from herd mates
- Lesions in aborted fetus compatible with BVDV infection, virus isolation, and fetal antibody detection.
- Abortions prior to 4 months' gestation will have characteristic lesions and virus while those aborted after 4 months may have congenital defects, fetal antibodies, or virus.
- Calves born with congenital defects may have precolostral antibodies.
- PI calves will have no titer (except from colostrum) and may be identified by virus isolation

Prevention and Control

- Impeccable herd management
- Identification and removal of PI animals
- Proper vaccination program

Herpesviral Abortion

- In cattle, the alpha-herpesviruses, bovine herpesvirus-1 (infectious bovine rhinotracheitis virus), and bovine herpesvirus-5 (bovine encephalitis virus), and a gamma-herpesvirus, bovine herpesvirus-4, have all been implicated as causes of abortion.
- Caprine herpesvirus-1 causes abortion or neonatal deaths in goats.

Infectious Bovine Rhinotracheitis Virus (Bovine Herpesvirus 1)

- IBRV or BHV1 is the most frequently diagnosed viral abortion disease. In addition to abortion it causes rhinotracheitis, conjunctivitis, pustular vulvovaginitis, balanoposthitis, and enteritis.
- Herpesvirus may produce latent infection, localizing in the trigeminal and sacral ganglion, resulting in a source of persistent infection following stress.
- Transmission is by direct contact to respiratory, conjunctival, or genital mucous membranes. It may be spread in the semen of carrier bulls.

Abortions

- Most abortions occur in the second half of pregnancy.
- May occur 2 weeks to 4 months after infection; typically occurs about 20 to 45 days after infection.
- Abortion rate may be sporadic or in storms, depending upon the susceptibility of the herd.
- Vaccination of pregnant cattle with MLV may cause abortion.

Infertility

Infection near the time of breeding, from infected semen or other exposure routes, may cause endometritis and oophoritis, resulting in temporary infertility or early embryonic death.

Diagnosis

- The entire fetus and placenta should be submitted for postmortem.
- Fetus usually autolyzed, obscuring gross lesions.
- Microscopic lesions include intranuclear inclusions of liver, lung, thymus, or adrenal gland.
- Diagnosis is confirmed by virus isolation or antibody determination in fetal tissue, with cotyledons being the preferred tissue in severely autolyzed fetuses.
- Maternal antibody titer is of limited use as the abortion may occur several months following exposure and the nature of the virus is ubiquitous.

Prevention and Control

- Impeccable herd management
- Proper vaccination programs
- Use of semen from IBR-negative bulls

Bluetongue Virus

- BTV rarely causes abortion in cattle and sheep.
- Infection is transmitted by the insect *Culicoides* spp. Infection may result in early embryonic death, abortion, mummification, or cerebral malformation. It is shed in the semen of viremic bulls.
- Although the virus is widespread throughout the world, it is not considered a major cause of bovine abortion.

Mycotic Abortions

- The fungi responsible for mycotic abortion in cattle include *Aspergillus*, *Absidia*, *Mucor*, *Rhizopus*, *Candida*, and *Mortierella*, with *Aspergillus fumigatus* being the most common.
- Abortions are sporadic, of low incidence, and usually occur in late gestation.
- Fungi seen in silver-impregnated sections of tissues could be placed into three categories designated *Aspergillus*, *Phycomycete*, and *Atypical*.
- Gross or microscopic examination or cultures of the placenta are valuable diagnostically but examination of the fetus is seldom of value as infection in most instances does not involve fetal tissues.
- Fertility following fungal abortion was apparently unimpaired.

Diagnosis

- A thick, leathery placentitis
- The fetus may be emaciated, with ringwormlike lesions on the skin.
- Identification of fungal hyphae in fetal tissues and placenta

Pathophysiology

- Route of infection is hematogenous spread from the respiratory or gastrointestinal tracts.
- Source of infection is often moldy feed.

Control

Reduction of exposure to fungal agents by proper stable environment and reduced consumption of spoiled feeds

Abortion Due to Nutritional Causes

- Several poisonous plants, including poison hemlock and locoweed, may cause sporadic abortion but more commonly cause a variety of congenital defects.
- Nutritional deficiencies have been implicated in embryo loss however a direct cause-and-effect relationship is difficult to establish. Beta-carotene, vitamin A, iodine, selenium, phosphorus, and copper deficiencies have been implicated.
- Usually, nutritional deficiencies will demonstrate primarily as reproductive problems other than abortion.

Pine Needle Poisoning

- Consumption of needles from ponderosa pine trees can cause abortion in the third trimester. Isocupressic and imbricatolic acids have been identified as the probable abortifacient agent.
- Ingestion of pine needles causes a progressive reduction in uterine blood flow resulting in abortion or premature parturition within 3 days, although occasionally within 3 weeks. The problem may be prevented by providing an alternative feed source.

Nitrate Poisoning

- Ruminants are susceptible to nitrate poisoning because of the nitrate-reducing potential of rumen microbes.
- Plants that accumulate high levels of nitrates include Sudan grass, oats, wheat, corn, pigweed, and Johnson grass.
- Heavy fertilization and cool growing conditions are conducive to nitrate accumulation. The ingested nitrates are converted to nitrites, which converts hemoglobin to methemoglobin. Methemoglobin is unable to carry oxygen, resulting in a hypoxic state. The hypoxemia may result in fetal death and abortion, or a stress-induced increase in fetal cortisol resulting in induction of parturition.
- Severe methemoglobinemia may cause death of the cow.
- Treatment is methylene blue IV.

Sweet Clover Hay

- Moldy sweet clover hay will produce toxic levels of the anticoagulant dicoumarol. Ingestion of toxic levels will cause pregnancy loss as well as death of adult animals.
- Removal of the moldy feed from the diet will prevent or terminate the loss.

ASSOCIATED CONDITIONS

- Infertility and return to estrus
- Infection near the time of breeding, from infected semen or other exposure routes, may cause endometritis and oophoritis, resulting in temporary infertility or early embryonic death.

AGE-RELATED FACTORS

Among parities, heifers have the lowest risk, and cows of second parity the greatest risk of fetal death.

ZOONOTIC POTENTIAL

Mycotic agents can be zoonotic.

PREGNANCY

- Abortions may occur near normal delivery time and it is difficult to determine whether the dam has aborted or whether a premature birth has occurred.
- Abortion frequently results from an event that occurred weeks or even months prior to the event making diagnosis difficult in many cases.
- The greatest risk of fetal death is observed in the first trimester, and the lowest in the second trimester of pregnancy.

RUMINANT SPECIES AFFECTED

Potentially, all ruminant species are affected.

BIOSECURITY

- Test and isolate prior to herd/flock introduction.
- Impeccable herd management

PRODUCTION MANAGEMENT

- Vaccination is an important tool in disease prevention.
- Impeccable herd management

ACIDOSIS

BASICS

OVERVIEW

- Rumen acidosis is a pathological condition that can be acute (i.e., leading to death) or chronic (i.e., leading to short-term or long-term production inefficiencies and illnesses).
- Acidosis results from consumption of excessive amounts of readily fermentable carbohydrates (RFC) and, therefore, it can be a major problem for ruminants on high-concentrate diets (e.g., feedlot cattle).
- Rumen pH of 5.6 and 5.2 are used as benchmarks for chronic and acute acidosis, respectively.
- In the feedlot, acidosis occurs during adaptation of animals to high-concentrate diets and also in animals adapted to these diets due to engorgement of large amounts of RFC.
- Acidosis occurs in grazing animals when large amounts of high-starch supplements are fed.
- In dairy cows, the incidence of acidosis is highest during the first month postcalving. This is due to adaptation to high-concentrate diets containing more RFC than the cows are accustomed to utilizing during the dry period. It is important to note that the cow's body is also unable to handle acid loads during early lactation.
- Sources of RFC include immature/rapidly growing forages (i.e., high in intracellular carbohydrates), tubers/root crops (i.e., high in sugars), and cereal grains (i.e., high in starch).
- Cereal grains are considered the most important source of RFC in animals with acute or chronic acidosis.
- Cereal grains vary in their rate of ruminal starch fermentation (e.g., wheat is more fermentable than corn or milo, therefore, ruminants will be more susceptible to acidosis when fed wheat than corn).
- Sheep appear to be more susceptible to acidosis than cattle.
- Acidosis is of high economic significance because a large number of cattle and sheep are finished on high-concentrate diets.
- The economic losses include death and/or performance of animals at much less than their genetic potential.
- Many animals on high-concentrate diets experience chronic acidosis for extended periods of time without the condition being detected.

PATHOPHYSIOLOGY

- When the amount of RFC is increased abruptly, rapid rumen fermentation occurs and large amounts of volatile fatty acids (VFA; mainly acetate, propionate, and butyrate) are produced.
- These acids are continuously absorbed through the rumen wall without significant negative effects on the rumen environment. However, when large amounts of RFC are consumed, production of VFA is increased, and the rumen pH is decreased due to their accumulation.
- The decreased rumen pH causes significant changes in the ruminal microbial population, especially a rapid increase in numbers of the amylolytic or sugar-utilizing bacteria such as *Streptococcus bovis*.
- Under low pH conditions, lactate-producing bacteria (e.g., *Lactobacillus* spp.) also grow faster, increase in number, and produce increasing amounts of D- and L-lactate.
- Ruminants can utilize L-lactate, as it is an intermediary metabolite. They can also use D-lactate.
- In rumen environments not experiencing significant pH reductions, the lactate produced is absorbed in the rumen and small intestine or is immediately metabolized by lactate-utilizing bacterial species (e.g., *Megasphaera elsdenii*, *Propionibacterium shermanii*, and *Selenomonas ruminantium*). Thus, lactate either is not found in the rumen fluid or is detected at very low concentrations ($< 5 \text{ } \Phi \text{ M}$).
- When large amounts of lactate are produced, the rumen ability to utilize it is exceeded and, as a result, it accumulates (up to $40 \text{ } \Phi \text{ M}$ as is the case in severe acidosis) and causes significant reductions in rumen pH.
- Under these low pH conditions, lactate-producing bacterial species outnumber lactate-utilizing species, the number of *S.*

bovis is decreased, and the number of *Lactobacillus* species is increased.

- The ability of lactate to decrease pH more drastically than a similar amount of other fermentation acids (e.g., acetate) is due to its lower pK (i.e., the point of maximum buffering) value (i.e., 3.8 vs. 4.8). It is important to note that total acid (VFA and lactate) load is responsible for acidosis and this acid load causes several ruminal and systemic effects.

SIGNS

HISTORICAL FINDINGS

- Marked reduction or cessation of feed intake (anorexia)
- Diarrhea or loose feces
- Lethargy
- Laminitis or founder
- Vomiting
- Decreased rate of body weight gain
- Distressed appearance
- Polioencephalomalacia (cerebrocorticonecrosis). The thiamine deficiency is triggered by thiaminases produced by rumen bacteria under low pH conditions.
- Cessation of rumen motility
- In acute acidosis, dehydration occurs in response to the increase in ruminal osmotic pressure and the decrease in extracellular volume. The consequences of dehydration include decreased cardiac output, decreased peripheral perfusion, decreased renal blood flow, shock, and death.
- Symptoms detected in dead or slaughtered animals include rumenitis, inflammation of the small intestinal tissues, and high incidence of abscessed livers.

Rumen Effects

- A significant increase in numbers of amylolytic, sugar-utilizing, and lactate-producing bacterial species
- A continuous decrease in rumen pH to 6 and 5.2, which are lethal to major microbial populations such as the rumen protozoa and cellulolytic bacterial species, respectively.
- A decrease in the rumen motility and fermentation
- An increase in the rumen osmotic pressure (> 300 mOsm) due to accumulation of solutes such as VFA, lactate, glucose, and minerals
- When the rumen osmotic pressure exceeds that of the blood, a rapid influx of water from the blood occurs to neutralize the rumen osmotic pressure. This action results in significant rumen wall damage (i.e., swelling of the papillae and stripping of epithelium patches).
- The rumen microbes responsible for liver abscess (e.g., *Fusobacterium necrophorum*) can freely cross the damaged rumen

wall and enter the blood.

- An increase in absorption of lactate
- In subclinical cases of acidosis (e.g., dairy cows in early lactation), the rumen pH drops daily to < 5.5 for a given period of time. This has negative effects on fermentation and the subsequent utilization of nutrients by dairy cows.

Systemic Effects

- An increase in blood lactate concentration
- A decrease in blood bicarbonate concentration
- A decrease in blood pH below 7.35 (i.e., a life-threatening situation)
- A decrease in urine pH
- A decrease in blood concentration of minerals (e.g., calcium) and electrolytes
- An increase in blood histamine concentration
- An increase in blood osmolality due to loss of water to the rumen
- An increase in concentration of blood components (e.g., increased packed cell volume)
- Uncontrolled elevation of blood pressure
- Inflammation of the small intestine
- Coma and death (e.g., the sudden death in feedlots)

Promoting Factors

- Mismanagement of feeding RFC sources such as cereal grains
- Cold weather promotes consumption of large amounts of feed and, therefore, it may dispose feedlot cattle to acidosis.

TREATMENT

Chronic Cases

- Increasing bicarbonate input from the diet and/or through salivation by increasing forage levels in the diet, especially long hay to stimulate rumination. Dietary or salivary bicarbonates increase pH and stimulate lactate utilization in the rumen.
- Increasing water intake causes dilution of rumen contents and reduction in rumen osmolality. This prevents water influx from the blood and helps maintain blood osmolality.
- Supplementation of B vitamins (i.e., B₁₂ and thiamin) that are involved in VFA metabolism to decrease their blood levels
- Drenching with electrolytes

Acute Cases

- Evacuating the rumen after a stab incision in the paralumbar fossa area
- Use of antibiotics such as oral dosing of chlortetracycline and water
- Inoculation with rumen fluid from healthy animals
- Removing the RFC source from the diet
- Feeding good-quality forages
- Intravenous infusion of bicarbonate buffer to eliminate acidity but not to induce alkalosis
- Intravenous infusion of electrolytes
- Intravenous infusion of saline solution

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Gradual adaptation of animals to high-concentrate diets. A 4-week adaptation period was found to provide an opportunity to induce a gradual change and stabilization of a final ruminal microbial population that can handle the increased amounts of lactate produced when high-RFC diets are fed.
- Dietary inclusion of roughages (e.g., long forages or by-products containing fiber) at 10% to 15% of dry matter to enhance rumination and to increase salivation. The buffering capacity of ruminant saliva can help in reducing the negative effects of fermentation acids.
- Dietary exclusion of cereal grains that promote acidosis such as wheat
- Dietary exclusion of fermented feeds (e.g., silages) that are known to increase the acid load in the rumen
- Management and close monitoring of feeding processed grains such as steam-flaked corn. The gelatinization of starch during steam flaking increases its rate of fermentation.
- Modulating starch intake by restricting feeding (e.g., 90% of ad libitum intake) to eliminate excessive consumption of starch
- Restricting feeding after working cattle or during weather change
- Fat supplementation at levels up to 6% of the diet
- Feeding high-protein diets to increase production of rumen ammonia (i.e., alkaline) and to decrease rumen acidity
- Dietary inclusion of sodium bicarbonate at 1% or 2% of dry matter to increase the buffering capacity of the rumen and to ameliorate the acidic conditions during early feeding of high RFC levels.
- Allowing access to fresh feed and water at all times. Animals will eat smaller meals more often.
- Using feed additives with rumen effects such as the ionophores monensin and lasalocid. These additives alter rumen fermentation and allow adaptation to high-starch diets by inhibiting lactate-producing bacterial species and stimulating lactate-utilizing species. The actions of these ionophores are achieved by their interference with the normal transport of ions across bacterial cell membranes.
- Using feed additives with systemic effects such as the antibiotics chlortetracycline, tylosin, and virginiamycin to decrease the incidence of abscessed livers.
- Close monitoring of daily intake of diets containing high RFC levels

ACTINOBACILLOSIS

BASICS

DEFINITION

Actinobacillosis is caused by *Actinobacillus ligniersii* infection of the soft tissues, usually in the tongue.

PATHOPHYSIOLOGY

- *Actinobacillus ligniersii* is a gram-negative rod, which normally inhabits the mouth and rumen of domestic ruminants, and is also found on plant awns.
- Mucosal lesions anywhere on the body, typically in the mouth, can be invaded by these bacteria, causing a localized lesion. Bacteria can also spread to different parts of the body via lymphatic drainage.
- A typical site of bacterial invasion is through small ulcers in the sulcus lingualis at the base of the tongue, leading to hard, painful, diffuse lesions of the tongue interfering with prehension of food, hence the synonym “wooden tongue.” The bacteria initially cause an acute diffuse myositis of the muscles of the tongue, followed by development of granules and fibrosis.

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Firm, pale, gritty granulomatous abscesses with multifocal necrotic foci containing mononuclear cells, neutrophils, eosinophils, and plant fibers

TREATMENT

ACTIVITY

N/A

DIET

Use of a soft feed will aid prehension during treatment.

CLIENT EDUCATION

See Diet above.

MEDICATIONS

- Sodium iodide
- Daily organic iodides orally in severe cases

DRUGS OF CHOICE

Sodium iodide 70 mg/kg IV as 10–20% solution; give once, repeat at least once at 7–10-day intervals.

CONTRAINDICATIONS

- Use sodium iodide with caution in pregnant cattle; see Precautions below.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

Anecdotal reports of association with abortion in cattle at high doses of sodium iodide

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

Penicillin, tetracycline, ceftiofur

FOLLOW-UP

May need surgical debulking of lesions in severe cases.

PATIENT MONITORING

If signs of iodism seen (dandruff, excessive lacrimation, inappetence, coughing, diarrhea), halt therapy until signs disappear.

PREVENTION/AVOIDANCE

Reduce access to abrasive feed and pastures with hard penetrating plant awns or thistles.

POSSIBLE COMPLICATIONS

Anecdotal reports of association with abortion in cattle at high doses of sodium iodide

EXPECTED COURSE AND PROGNOSIS

- Good prognosis if only the tongue is involved.
- Fair prognosis if atypical sites are involved.

MISCELLANEOUS

ASSOCIATED CONDITIONS

ACTINOMYCOSIS: LUMPY JAW

BASICS

OVERVIEW

Common, sporadic, chronic **granulomatous osteomyelitis** of cattle caused by non-spore-forming, filamentous, gram-positive, anaerobic bacterium *Actinomyces bovis*

PATHOPHYSIOLOGY

- *Actinomyces*
 - normal members of oral microbiota in cattle
 - same order as *Mycobacterium*
 - low virulence
 - only cause disease when mucosal barriers are compromised
 - gram-positive, branching/filamentous, nonencapsulated bacteria
- Trauma to oral mucosa from rough feed or foreign objects or dental alveoli permits entrance of *Actinomyces* into buccal tissues.
- Grows in anaerobic conditions associated with devitalized tissue, lack of phagocyte delivery.
- In mandible and maxillae, initially, painless, hard, *immovable* swellings. In weeks or months, swelling frequently develops along lower edge of bone and in intermandibular space.
- Abscess/granuloma formation, necrotic foci (mycetoma)
- Masses open through sinus tracts, lesions may become painful.
- Discharge of viscous, sticky, “honey- or whey-like,” odorless, yellowish pus from openings.
- Pus contains sandlike, firm, yellowish granules, which do not contain sulfur. The granule contains microcolonies of *Actinomyces* in an eosinophilic, amorphous matrix made of calcium phosphate/antigen-antibody complexes.
- Occasional involvement of soft tissues, especially of esophageal groove with spread to lower esophagus, anterior wall of reticulum, may cause peritonitis.
- Rare hematogenous spread to other organs
- Local lymph nodes usually not involved
- Teeth may loosen.
- Swelling may cause dyspnea.
- Trauma to digestive tract could introduce *Actinomyces* into regions below oral cavity.

SYSTEMS AFFECTED

Musculoskeletal; rare hematogenous spread to other organs; oral cavity

GENETICS

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide

INCIDENCE/PREVALENCE

Common, sporadic

SIGNALMENT

Species

Cattle; potentially all ruminant species

Breed Predilections

N/A

Mean Age and Range

Young cattle with erupting teeth, commonly

Predominant Sex

N/A

SIGNS**HISTORICAL FINDINGS**

Hard, immovable swellings of maxillae/mandible

- Draining fistulous tracts—yellowish, sticky, odorless pus
- Misaligned teeth, difficulty masticating
- Weight loss, periodic diarrhea, chronic bloat
- Dyspnea
- Less frequently partial tracheal obstruction, orchitis, brain/lung abscesses

CAUSES AND RISK FACTORS

- Eruption of teeth in young cattle
- Rough feeds containing awns, foreign objects
- Procedures causing oral lacerations

SIGNALMENT

- Young cattle, erupting teeth
- Cattle fed awn-containing feeds or subjected to oral trauma

Source of Infections

- Endogenous infections; oral microbiota
- If noninfected cattle present with oral lacerations, *Actinomyces* may be spread from infected animals to noninfected animals via contaminated draining pus.
- Normally not contagious

Transmission

Endogenous; oral lacerations permit entry into devitalized buccal tissues and subsequent spread

**DIAGNOSIS**

- Palpation of hard, immovable masses
- Draining tracts, odorless, sticky, yellowish pus with hard, small yellowish-white granules
- Microscopic exam of pus: mix with saline; crush granules between two glass slides; use Gram's stain. Rosettes of thin, filamentous, branching gram-positive rods seen at periphery of granule. May appear irregularly stained, "beaded." May be misidentified as fungi.
- Fastidious, slow-growing bacterium. Culture anaerobically 10–14 days or more.

DIFFERENTIAL DIAGNOSIS

- Cheek abscess, causes other than *Actinomyces* (movable, located in soft tissue)
- Impacted feed/foreign bodies between cheek and teeth
- Chronic peritonitis, causes other than *Actinomyces*
- Mandibular lymphosarcoma

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Culture and sensitivity of the lesion is indicated.
- Microscopic exam of purulent debris: mix sample with saline and crush granules between glass slides; use Gram's stain.

IMAGING

Radiographs should reveal changes consistent with osteomyelitis of the affected mandible.

TREATMENT

- Difficult to treat
- Surgical debridement/drainage. Pack wound with streptomycin or tincture of iodine soaked gauze.

DRUG(S) OF CHOICE

- Streptomycin, penicillin, sulfonamides
- Iodine therapy: (See Precautions below.) Some animals become distressed (restlessness, dyspnea, tachycardia). Stop when signs of iodism occur (lacrimation, anorexia, cough, scaling skin lesions). Subcutaneous iodine causes severe irritation and immediate swelling. Potassium iodine as drench. Sodium iodine IV as 10% solution.
- Isoniazid as adjunct to antibiotic/iodine therapy

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

Caution: abortion has followed iodine therapy in some animals.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PREVENTION

- Avoid feeds/procedures that could cause oral lacerations.
- Monitor young cattle for swelling of mandible especially following tooth eruptions.
- Isolate cattle with discharging lesions
- No vaccine

ACUTE COLIC—ABDOMINAL PAIN

BASICS

DEFINITION

- Acute colic is abdominal pain of < 48 hours duration.
- Once pain has exceeded 48 hours duration, it is considered chronic.

PATHOPHYSIOLOGY

- The gastrointestinal tract is the source of most acute abdominal pain, but any abdominal organ can be involved.
- Gastrointestinal pain can result from distension, displacement, torsion/volvulus, obstruction, smooth muscle spasm, and mesenteric tension, and may involve hypermotility, hypomotility, ischemia, and inflammation.
- Urinary tract pain can result from obstruction, inflammation, infection.
- Reproductive pain can result from parturition, abortion, dystocia, uterine torsion, inflammation, infection, or tumor.
- Peritoneal pain results from inflammation, infection, and penetrating metallic foreign bodies.
- Other abdominal organs are less likely sources of pain, but should be considered if the source of the pain cannot be identified.
- Gastrointestinal lesions can be strangulating or nonstrangulating.
- Strangulating lesions are by definition associated with reduced blood supply, which can result in necrosis.
- Nonstrangulating lesions result in less circulatory disturbance and as a result are not usually associated with necrosis unless chronic.
- Any interference with gastrointestinal function can result in endotoxemia due to the large volume of natural gastrointestinal flora.
- Lesions originating in one system or organ can eventually result in other organs being affected.

SYSTEMS AFFECTED

- Gastrointestinal
- Urinary
- Reproductive
- Cardiovascular
- Respiratory, if abdominal distension is severe

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide distribution

SIGNALMENT

- All ages and sexes can be affected.
- Certain etiologies may be more common for specific groups.

SIGNS

- Abdominal pain may be mild to severe.
- Early signs may be subtle and easily missed, progressing in severity.
- Cause is often obvious from a careful physical examination including rectal examination.
- Ruminants are often stoic animals, bearing much pain without overt signs of colic as seen in the horse.

- The veterinarian should be familiar with the location of the gastrointestinal components in cattle, and with associated areas of tympany (pings), which indicate a gas-fluid interface under pressure.
- Sometimes diagnosis is made by presumption in early stages, based on a particular signalment and a few clinical symptoms.
- Mild colic—slight depression, reduced interest in feed, slight reduction in manure output, restlessness
- Moderate colic—reduced interest in feed, reduced manure output, restlessness, stretching abdomen (sawhorse stance), teeth grinding, posturing to urinate or defecate without producing much
- Severe colic—kicking at belly, recumbency (esp. lateral recumbency), severe depression, vocalization, straining to urinate or defecate, severe restlessness (getting up and down repeatedly), extended head and neck, rolling (very rare in ruminants)

PHYSICAL EXAM FINDINGS

- Depression
- Increased heart and respiratory rates
- Abdominal distension
- Change in body temperature above or below normal
- Reduced gastrointestinal sounds
- Gastrointestinal hypermotility
- The presence of pings in the abdomen
- Lack of urine or feces
- Discharge of uterine fluids
- Palpably distended or displaced viscus on rectal exam
- Grainy or constricted rectal palpation (peritonitis)
- Vomiting (rare)
- Dry prepuce (with urinary obstruction)

CAUSES

Forestomachs

- Ruminal acidosis (grain overload), vagal indigestion, traumatic reticuloperitonitis, omasal impaction, ruminal fermentation (calves), bloat (gas or frothy)
- Abomasum
- Ulcers, impaction, left displacement (LDA), right displacement (RDA), right abomasal volvulus (RAV), right omasal-abomasal volvulus (ROAV), abomasal rupture, vagal indigestion, abomasal stricture

Small intestine

Enteritis, ileus, impaction, stricture, entrapment, segmental torsion, jejunal flange torsion, jejunal hemorrhage syndrome, intussusception, adhesions, fat necrosis, tumor, hernia (inguinal, umbilical, diaphragmatic)

Large intestine

Colitis, impaction, cecal tympany, displacement, torsion, volvulus, adhesions, fat necrosis, tumor, intussusception, atresia coli

Reproductive

Dystocia, parturition, abortion, tumor, peri-uterine abscess, testicular torsion, testicular trauma, penile/preputial trauma, vaginal prolapse, seminal vesiculitis, inguinal hernia

Urinary

Urolithiasis, cystitis, nephrolith, pyoureter, pyelonephritis

Other

Hernia, torsion of root of mesentery, peritonitis, hepatic inflammation, hepatitis, cholelith

RISK FACTORS

- Dietary change(s)
- Lack of access to water
- Pregnancy
- Stress
- Recent parturition

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Many diseases can cause signs resembling abdominal pain, including choke, rabies, tetanus, myositis, hypocalcemia, septicemia, and obesity

CBC/CHEMISTRY/URINALYSIS

- Increased WBC count with peritonitis or other inflammation
- Increased PCV and TP with dehydration
- Decreased Cl, K, Na with most intestinal obstructive lesions in adult cattle
- Increased fibrinogen in inflammatory conditions
- Metabolic alkalosis in most gastrointestinal obstructive lesions in adult cattle
- Acidosis with grain overload or severe, long-standing obstructions
- Azotemia with urinary obstruction or severe dehydration
- Urinalysis shows increased WBC, RBC, bacteria, crystals in urinary tract

OTHER LAB TESTS

Abdominocentesis

- Increased WBC, TP, turbidity
- Serosanguineous color indicative of obstruction
- Foul smell indicative of GI rupture or enterocentesis
- Plant material indicative of rupture or enterocentesis
- Urine smell with uroabdomen
- Volume increased with pregnancy, inflammation
- Can be hard to obtain fluid in ruminants—try the flank region

Rumen Fluid Analysis

- Decreased protozoal activity with poor rumen function or obstruction
- Decreased pH with acidosis and abomasal reflux
- Increased Cl with abomasal reflux
- Abnormal color or smell with acidosis, ruminal fermentation, rumenitis

IMAGING

Ultrasound

- May be helpful in examination of urinary and reproductive tract
- Can identify fluid pockets in abdomen
- New publications suggest use transabdominal to detect abnormalities of the GI tract

Radiographs and contrast radiology

- Not usually useful in adult ruminants due to size
- May be useful in examination of the urinary tract

DIAGNOSTIC PROCEDURES

- *Liptak test*: Transabdominal paracentesis of a viscus on the left side of the adult cow to differentiate a LDA from rumen. Low pH = abomasum, high pH = rumen
- *Laparotomy*: Often used as diagnostic procedure in cows. The problem can be identified and repaired in many cases by flank laparotomy.
- *Laparoscopy*: Can be used as diagnostic procedure, but most abdominal problems require laparotomy to repair.

TREATMENT

APPROPRIATE HEALTH CARE

- Colic should be considered an emergency and diagnosis and treatment initiated immediately.
- Affected animals should not be fed until the cause is determined.
- Often the organ system involved is readily obvious following physical exam and the choice of medical treatment vs. surgery quickly made.
- Indications for immediate surgical treatment include severe abdominal pain, severe abdominal distension, HR >80 bpm, presence of pings, abnormal abdominocentesis, urinary obstruction, uterine torsion nonresponsive to rolling or manipulation, fetal oversize causing dystocia, confirmed gastrointestinal torsion, displacement, or obstruction.
- Surgical approach to the abdomen in adult bovines is made in a standing position by right flank laparotomy. If the desired lesion is located on the left side, a left flank approach can be made, but there can be limited exploration of the right side of the cow from this approach. In exploratory surgeries, the right flank is almost always chosen.
- In small ruminants, flank or middling approach can be used.

Acute colic—abdominal pain

NURSING CARE

- IV fluids will be necessary in most cases. As alkalosis is present in most adult cattle with GI problems, a neutral or acidifying fluid is recommended. In cattle with grain overload, and any other animals with confirmed acidosis, an alkalizing fluid and/or bicarbonate are recommended.
- IV fluids should be supplemented to correct any electrolyte abnormalities.
- Oral fluids may be administered in certain cases, such as impaction, in order to provide a large volume of fluids to the GI tract.
- The use of oral fluids combined with hypertonic saline (1 ml/kg/min) has gained some favor as being cheaper than IV fluids, with similar effectiveness in restoring vascular volume.
- Caution should be used in supplementing calcium to endotoxemic cows, as endotoxin sensitizes the heart to potentially fatal arrhythmias.
- Animals with severe rumen bloat will require immediate ororuminal intubation to relieve the pressure.

ACTIVITY

N/A

DIET

- During the colic episode, feed should be withheld.
- Following resolution of the condition, refeeding should begin slowly to avoid recurrence or complications.

CLIENT EDUCATION

None

SURGICAL CONSIDERATIONS

None

MEDICATIONS

DRUGS OF CHOICE

Analgesics

- Flunixin meglumine: 1.1–2.2 mg/kg IV q24h or divided q12h
- Ketoprofen: 2 mg/kg IM q24h
- Phenylbutazone: 4 mg/kg IV or PO q24h
- The use of phenylbutazone is illegal in dairy animals and highly discouraged in all food animals.
- Butorphanol: 0.02–0.04 mg/kg IV *Laxatives*
- Mineral oil: 10 ml/kg given by ororuminal tube
- Magnesium oxide: 0.5–1 kg for adult cow given by ororuminal tube
- Dactyl sodium succinate: 10–30 mg/kg of 10% solution given by ororuminal tube

Antibloat Agents

- Mineral oil: 10 ml/kg given by ororuminal tube
- Poloxalene: 30–60 mL per animal (can be repeated) by ororuminal tube
- Detergent soap can be used in emergency.

Prokinetics

- None are truly effective for promoting forestomach motility.
- Metoclopramide 0.1 mg/kg SQ q6–12h may provide some abomasal stimulation.
- Bethanechol: 0.07 mg/kg SQ q8h may provide some cecal stimulation.

Antibiotics

Necessary in infective conditions or following surgery

Transfaunation

- 4–8 L of fresh rumen juice for repopulation of rumen microbes
- Probiotic gels and yeast can be used for substitute.

Endotoxemia

Flunixin meglumine: 0.25–1.1 mg/kg IV q6–12h

CONTRAINDICATIONS

- Prokinetic drugs should not be used if obstruction present.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

- Prolonged use of NSAIDs can cause ulceration of abomasum and renal damage.
- Use of butorphanol or xylazine for pain control will cause ileus.

FOLLOW-UP

PATIENT MONITORING

- Once stable, refeeding should begin slowly and the animal monitored for passage of manure.
- If the urinary tract was involved, urination must be monitored.
- Patient should be monitored for recurrence of signs of abdominal pain or distension, or deteriorating cardiovascular status.

PREVENTION/AVOIDANCE

- Avoid sudden feed changes.
- Ensure access to water in all weather and temperatures.
- Investigate signs of abdominal pain or distension early.
- Investigate cows not calving by their due date.

POSSIBLE COMPLICATIONS

- Peritonitis
- Adhesions
- Shock
- Endotoxemia
- Gastrointestinal or bladder rupture
- Fetal loss

EXPECTED COURSE AND PROGNOSIS

Varies with the condition

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- Young animals more likely to have intussusception.
- Old animals more likely to have tumor, fat necrosis.
- Pregnant animals have indigestion of pregnancy/pseudo-obstruction.
- Peripartum animals predisposed to LDA, RDA < RAV, ROAV, abomasal ulcers
- Animals < 18 months more likely to have urolithiasis

ZOONOTIC POTENTIAL

N/A

PREGNANCY

- Late gestation cows most likely to have indigestion of pregnancy/pseudo-obstruction, uterine torsion
- Parturition/abortion can resemble GI pain.

ACUTE RENAL FAILURE

BASICS

OVERVIEW

- Acute renal failure (ARF) is caused by decline of renal function over a period of hours to days.
- This rapid onset of renal failure may result from prerenal, intrinsic renal, or postrenal causes.
- Intrinsic renal problems are usually due to ischemic or toxic insults resulting from injury, disease, or certain therapeutic agents.
- The kidneys are particularly susceptible to toxic injury.

PATHOPHYSIOLOGY

- The kidneys receive approximately 20% of cardiac output, which exposes them to a high proportion of toxicants present in the blood.
- The surface area of the large glomerular capillaries allows for a significant area of cells in the proximal tubules and ascending loop of Henle makes them particularly susceptible to intoxication.
- Tubular epithelial cell resorption of toxins may cause excessive accumulation of toxins intracellularly.
- Tubule-concentrating ability may result in increased levels of toxicants in the distal portion of the nephron.

SIGNALMENT

All ruminants are susceptible to ARF if primary predisposing factors are present.

SIGNS

- Signs of acute renal failure are nonspecific in ruminants and may not be indicative of urinary dysfunction.
- Depending on the underlying cause, anuria, oliguria, or polyuria may be observed.
- Affected animals may present with depression, poor appetite, diarrhea, epistaxis.
- Saliva may have a strong ammonia odor.
- Severe cases develop muscular weakness and even recumbency due to electrolyte and acid-base abnormalities.
- Rectal palpation may not be remarkable although occasionally renal enlargement or perirenal edema may be detected.

CAUSES AND RISK FACTORS

- Risk of ARF is enhanced by dehydration, fever, sepsis, vasculitis, hypotension, electrolyte abnormalities, hypoalbuminemia, and exposure to nephrotoxic agents.
- Nephrotoxic agents include certain metals, antimicrobials, NSAIDs, toxic plants, hemoglobin, myoglobin, calcium oxalate, as well as other toxins.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Development of a differential list is difficult due to the nonspecific clinical signs in cases of ARF and because of the variety of primary disease conditions that may predispose ruminants to ARF.
- Differentials include those diseases causing epistaxis (coagulopathies and pulmonary abscesses), diarrhea, and recumbency.

CBC/BIOCHEMISTRY/URINALYSIS

- Increased BUN and creatinine
- Isosthenuria on urinalysis indicates azotemia of renal origin.
- Proteinuria, hematuria, and granular casts may be present on UA.

- Metabolic alkalosis, hypochloremia, and hypocalcemia are common findings in ruminants with ARF.
- Hyponatremia, hyperphosphatemia, hypermagnesemia may also be seen.

OTHER LABORATORY TESTS

Fractional excretion of sodium may be evaluated but the test should be compared to a normal animal (e.g., herd mate) of similar age, physiologic state, and nutritional status.

Imaging

Ultrasonographic evaluation may reveal enlargement of one or both kidneys or presence of perirenal edema.

DIAGNOSTIC PROCEDURES

Renal biopsy may provide diagnostic as well as prognostic information in cases of ARF.

PATHOLOGIC FINDINGS

Gross and microscopic findings depend on the initial cause of renal failure (ischemic, infectious, or toxic).

TREATMENT

- In cases of toxic nephrosis, the animal should be removed from the source of the toxin.
- If ARF is due to use of a nephrotoxic drug, treatment should be discontinued.
- Focus of treatment should be on IV fluid therapy for correction of acid-base and electrolyte abnormalities and encouragement of diuresis.
- Isotonic, sodium-containing fluids with added calcium and potassium, as indicated, should be utilized.
- Oral fluid therapy may be used if IV administration is impractical.
- IV or oral fluids should be administered at a rate of one-and-a-half to two times the adult maintenance rate of 60 ml/kg/day to encourage diuresis.
- Monitor hydration and plasma protein to avoid overhydration and edema formation.
- Once the animal begins to urinate, IV fluids should be maintained until the serum creatinine has returned to normal.
- Supportive care, which may be necessary for 2–3 weeks, includes rumen transfaunation and nutritional support.

MEDICATIONS

DRUGS OF CHOICE

- If fluid therapy does not promote diuresis, furosemide (1 mg/kg IV or IM, every 2–3 hours) may be beneficial.
- If anuria or oliguria persists, a dopamine drip (3–7 mcg/kg/min IV) should be considered.

CONTRAINDICATIONS

- With repeated use of furosemide, the patient's serum sodium and potassium must be monitored carefully.
- Drug withdrawal times need to be determined and maintained in food-producing animals.

FOLLOW-UP

N/A

MISCELLANEOUS

- ARF due to ischemic episodes generally results in a grave prognosis.
- Renal failure due to toxic causes may have a more favorable prognosis with early intervention and aggressive fluid therapy.

AESCULUS (BUCKEYE) TOXICOSIS

BASICS

OVERVIEW

- *Aesculus* is a toxic tree or shrub that may produce neurotoxicity in cattle or sheep. The tree is commonly observed in the eastern United States and in Europe in wooded areas or fencerows.
- Leaves are opposite palmately compound and consist of 5–7 leaflets.
- Fruit is a leathery capsule with or without spines (depending on species).
- Nuts are chocolate in color with a tan scar.
- Bark, leaves, and especially fruit are toxic, containing the glycosides aesculin and fraxin and neurotoxic saponins.

SIGNALMENT

Affects ruminant animals of all ages although cattle seem more often affected

SIGNS

- Onset of signs may be 12–16 hours after consuming buckeye.
- In calves, 0.5% body weight of nuts has produced poisoning.
- Initial signs in ruminants are staggering, weakness, muscle twitching, and an incoordinated gait.
- Recumbency may occur in severe cases followed by coma and death.
- Death is rare.

CAUSES AND RISK FACTORS

- Toxicosis may occur in the spring when young foliage is abundant.
- Toxicosis often occurs in the fall from ingestion of the nuts.
- Animals seldom eat the nuts if ample good-quality forage is available.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of CNS signs in cattle include hypomagnesemia, polio, *Claviceps paspali*, lead, arsenic, *Clostridium botulinum* type D, and insecticide poisonings.

CBC/BIOCHEMISTRY/URINALYSIS

- Blood glucose may be high.
- Glucosuria and proteinuria may be present in severe cases.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

EXPECTED COURSE AND PROGNOSIS

- Mild cases of buckeye toxicosis respond without treatment if the source of the toxin is removed.
- More severe cases respond quickly following treatment and may be normal in 12–24 hours.
- Prognosis is poor for recumbent animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Initial signs in ruminants are staggering, weakness, muscle twitching, and an incoordinated gait.
- Recumbency may occur in severe cases followed by coma and death.
- Death is rare.

AGE-RELATED FACTOR

In calves, 0.5% body weight of nuts has produced poisoning.

AGRICULTURAL CHEMICAL TOXICITIES

BASICS

OVERVIEW

This chapter focuses on the ingestion, inhalation, and/or topical exposure to agricultural chemical compounds resulting in morbidity and/or mortality. Compounds include the following:

- Chlorinated hydrocarbons—a group of insecticides that incorporate a chlorine molecule and are also known as organochlorines. They are mostly known for their environmental persistence and bioaccumulation (concentration levels of compound increase in animals higher up in the food chain).
- Herbicides—compounds used for weed control. Many are selective against specific plants or types of plants.
- Fungicides—compounds used to treat or prevent fungal infections in plants or animals
- Polybrominated biphenyls (PBBs)—chemicals that were primarily used in industry as fire retardants in the 1970s
- Dinitro compounds—herbicides that are highly toxic to all animals
- The mechanism of action in animals of most of these agricultural chemicals is unknown.
- Many of these chemicals, especially the herbicides, are frequently used in most agricultural crop enterprises today.
- Their widespread use can create opportunity for exposure.
- Toxicity typically occurs through oral or dermal exposure.
- The currently available fungicides appear to be some of the safest chemicals discussed here due to their inefficient digestive absorption as well as their low toxicity in mammals.
- Aerosol exposure to fungicides can cause irritation to the eyes and respiratory tract.
- Most of the highly toxic and environmentally persistent compounds are no longer available in the United States today, but can be found worldwide.
- Many of these compounds (especially many of the chlorinated hydrocarbons and all PBBs) are still present worldwide due to their previous extensive use and potential for bioaccumulation.
- Acute toxicities due to accidental exposures are the most common presentation.
- This exposure can occur either through contaminated feeds, access to stored chemicals or treated seeds for planting, or sometimes through exposure to fields or pastures recently treated with these chemicals.
- Fields treated with chemicals many times require livestock access to be limited for some period of time; always read and follow label directions.
- Acute toxicities will usually show up in the first 24 hours postexposure (ranging from a few hours up to a day or more).
- Systemic absorption will usually result in these compounds ending up in particular areas, especially the liver, brain, kidney, fat, and milk.
- Transplacental transmission can occur with some chemicals (especially the chlorinated hydrocarbons).
- Most toxicities will result in minimal or nonspecific manifestations.
- Carbamates are a type of herbicide with cholinesterase-inhibiting properties similar to organophosphates.
- Cerebral and spinal cord congestion are probably the most common presentation along with pulmonary congestion.
- Congestion of kidneys, liver, and spinal cord can also be seen.
- Liver injury can be common, especially with chronic exposure.

SYSTEMS AFFECTED

Systems affected vary with the different class of chemicals as well as a particular chemical within a class.

- Cardiovascular—methemoglobinemia (chlorate herbicides), cardiac arrest
- Endocrine/metabolic—pyrexia
- Gastrointestinal—anorexia, excess salivation, decreased rumen motility, bloat, digestive irritation and abdominal pain

(especially some herbicides), diarrhea

- Hepatobiliary—congestion, hepatic lipidosis or amyloidosis
- Herd health—decreased milk production (PBBs), tainted milk (chlorinated hydrocarbons and PBBs), chronic poor performance
- Musculoskeletal—incoordination, recumbency, anorexia, extended hoof growth (PBBs)
- Nervous—stimulation or depression, ataxia, apprehension, hypersensitivity, muscle fasciculation, seizures, coma, death
- Ophthalmic—irritation (aerosol exposure), nystagmus
- Renal/urologic—congestion, nephritis (PBBs)
- Reproductive—early embryonic death (PBBs); cross placental barrier (chlorinated hydrocarbons)
- Respiratory—tachypnea, dyspnea, congestion
- Skin—alopecia (PBBs)

GENETICS

None

INCIDENCE/PREVALENCE

Rare

GEOGRAPHIC DISTRIBUTION

- Widespread use of many of these chemicals in today's agriculture.
- Many chlorinated hydrocarbons and all PBBs have been banned from use in many countries.

SIGNALMENT

Species

Susceptibility among compounds varies between ruminant species.

Breed Predilections

None

Mean Age and Range

None

Predominant Sex

None

SIGNS

Clinical signs or death are commonly seen within 24 hours of an acute exposure.

HISTORICAL FINDINGS

- Whole herd or a large percentage of the herd will usually be affected.
- Individual clinical signs may differ, but there usually will be a common system affected.
- Severe signs, including death, will be more common in the very young or old.
- Usually a new feed batch or pasture recently treated can be identified.
- Chronic exposures can be very difficult to identify.

PHYSICAL EXAMINATION FINDINGS

Elevated temperatures can be recorded due to seizing or other excessive muscle movement.

PATHOPHYSIOLOGY

- Exposure to significant amounts of these chemicals
- Toxicity levels vary for each compound as well as for the species involved.

RISK FACTORS

- Improper storage or labeling of chemicals
- Proper disposal of chemicals should have been followed especially for those products with bioaccumulation capabilities (chlorinated hydrocarbons, PBBs).
- Age of animals—very young or very old are at higher risk.
- Preexisting health and nutritional status
- Amount of exposure and time before first identified
- Dependent on chemical used, concentration, and formulation

DIAGNOSIS

History of possible exposure to chemicals directly to affected animal or to area/pasture where they were applied is suggestive.

DIFFERENTIAL DIAGNOSIS

- Neurologic signs—rabies, polioencephalomalacia, nervous ketosis, nervous coccidiosis, infectious thromboembolic meningoencephalitis, lead as well as other poisonings
- Digestive signs—poisonous plants, coccidiosis, grain overload, frothy or gas bloat
- Respiratory signs—infectious respiratory complex, nitrate toxicity (chlorate herbicides), bloat, acidosis, or other poisonings

CBC/BIOCHEMISTRY/URINALYSIS

- Increased SGOT (PBBs)
- Mostly unremarkable CBC and panels
- Urine can be analyzed in some instances for chemicals or their by-products.

OTHER LABORATORY TESTS

- Chromatography or other specialized tests can be run on frozen samples of brain, liver, kidney, fat, stomach contents, and suspected samples. These tests cannot be run on formalin-fixed tissues.
- Normal workup to rule out the more common infectious agents

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Fat biopsies, urine, and milk samples sometimes can be used to determine possible exposure.

PATHOLOGIC FINDINGS

- Usually unremarkable
- Many times will have pulmonary, renal, hepatic, or brain and spinal congestion
- Petechial hemorrhages or blanching of the gastrointestinal tract
- Cardiac parenchymal petechial hemorrhages suggestive of sudden death

TREATMENT

APPROPRIATE HEALTH CARE

- Immediate removal of possible contaminated source
- Barbiturates, chloral hydrate, or diazepam for convulsing animals
- Activated charcoal (900 g/adult cow)
- Mineral oil drench
- For chloral hydrate herbicide poisoning and methemoglobinemia, use a 2%–4% solution of methylene blue at 10 mg/kg IV.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

NURSING CARE

Supportive care including IV fluids may be helpful.

ACTIVITY

Restrict activity and minimize stimulation.

DIET

Roughage diet may be needed if rumen motility was affected.

CLIENT EDUCATION

- Proper storage and disposal of chemicals as directed by labels
- Limit access of livestock to treated areas if indicated by label

SURGICAL CONSIDERATIONS

N/A

**MEDICATIONS****DRUGS OF CHOICE**

N/A

CONTRAINDICATIONS

Do not use corn oil or other type of digestible oil in drenching. These oils can increase the absorption of some chemicals. Only use mineral oil.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

**FOLLOW-UP****PATIENT MONITORING**

- Seizuring animals usually will do so only for the first 24 hours.
- Animal/milk testing may be needed to determine amount of contamination and expected time needed to clear their system based on half-life of chemical.

PREVENTION/AVOIDANCE

- Proper storage and disposal of all chemicals on farm
- Proper labeling of all chemicals
- Do not store chemicals next to feedstuffs.

POSSIBLE COMPLICATIONS

- Some animals may not recover.
- Some animals and/or their products (milk) may never be able to enter the human food chain.

EXPECTED COURSE AND PROGNOSIS

- Highly variable
- Severity of signs at any one point in time is not indicative of prognosis; must be able to monitor the progress before a better prognosis can be made.
- Poor future performance is possible.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

- There is potential for agricultural chemical exposure to animals from milk and meat of poisoned animals.

- In some states, there are restrictions on movement or marketing of cattle poisoned with agricultural chemicals.
- The veterinarian should consult the local diagnostic laboratory or department of public health for questions specific to their practice area.

PREGNANCY

Early embryonic deaths have been attributed to PBBs.

RUMINANT SPECIES AFFECTED

All ruminant species are susceptible to toxicosis.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Proper storage and disposal of all chemicals on farm
- Proper labeling of all chemicals
- Do not store chemicals next to feedstuffs.

SYNONYMS

Chlorinated hydrocarbons are also known as organochlorines.

Author: Alejandro Ramirez

AKABANE

BASICS

DEFINITION

Akabane, also known as congenital arthrogryposis-hydranencephaly syndrome, is a viral disease of ruminants that has the potential for serious economic losses. It results in abortions, stillbirths, premature births, and deformities of the fetus or newborn with no clinical signs in the dam during pregnancy.

- The Akabane virus is an arbovirus (transmitted by arthropods) in the family Bunyaviridae, genus *Orthobunyavirus*.
- The single-stranded RNA virus causes intrauterine infection of the fetus in pregnant cattle, sheep, and goats. After invading the endothelium of the placenta, the virus replicates in the trophoblastic cells and the fetus itself, resulting in death or deformities of the fetus or newborn.
- Akabane is similar to Cache Valley virus, which is found in the United States.
- The vector for Akabane virus has not been proven, however epidemiological evidence suggests that mosquitoes and gnats spread the virus.
- Akabane virus has been isolated from a number of mosquito species (*Aedes*, *Culex*, *Anopheles*) as well as *Culicoides* species (biting midges).
- Direct contact, infected tissues, exudates, body fluids, or fomites do not transmit Akabane.
- Ruminants do not appear to become long-term carriers of this virus.

SYSTEMS AFFECTED

- Reproductive—arthrogryposishydranencephaly syndrome, abortions, stillbirths
- Musculoskeletal—arthrogryposis (persistent flexion of joints)
- Neurological—hydranencephaly (absence of the cerebral hemisphere tissue, which becomes occupied by cerebrospinal fluid)

GENETICS

N/A

INCIDENCE/PREVALENCE

- Incidence for Akabane and the potential for epizootics is correlated with climatic factors, a distinct seasonal pattern (warm, moist summer and autumn months), the geographic distribution of competent vectors, and the availability of susceptible ruminant populations.
- In endemic areas, most animals are immune to Akabane virus by the time they reach sexual maturity.
- Surveys indicate that more than 80% of adult cattle in an endemic area are seropositive for the virus. However, following years of drought or times of reduced vector populations, native livestock may not be exposed prior to breeding age and therefore become susceptible.
- Data from Japanese and Australian outbreaks suggest that the virus subsequently may invade the fetus in approximately 30–40% of infected pregnant cows.

GEOGRAPHIC DISTRIBUTION

- Akabane is a foreign animal disease in the United States. It is, however, common in the tropics and subtropics. It is considered endemic in northern Australia, Japan, Israel, and Korea. Occasional outbreaks have occurred in southern Australia, Asia, the Middle East, and South Africa, when conditions are favorable for virus transmission.
- Outbreaks typically occur in areas where naïve and susceptible animals are located and when environmental conditions are favorable for the disease.
- Most epizootics occur at the northern and southern periphery of the endemic band or to susceptible animals introduced into endemic areas.
- Outbreaks usually occur in late winter, indicating that the peak of virus activity and fetal infections occurs during the

previous late summer and early autumn periods.

SIGNALMENT

Species

Disease from Akabane virus only occurs in cattle, sheep and goats; however, antibodies to the virus have been found in horses, buffalo, deer, camels, dogs, monkeys, and most recently pigs.

Breed Predilections

N/A

Mean Age and Range

- The disease primarily affects fetal or newborn cattle, sheep, and goats.
- Adult animals do not typically show any sign of the disease. However, there has recently been documentation of five adult cattle in Korea that have developed neurological signs (encephalomyelitis) due to the virus.

Predominant Sex

N/A

SIGNS

GENERAL COMMENTS

- Adult ruminants with Akabane infection are typically asymptomatic.
- Viremia usually occurs 1–6 days after infection and lasts for 1–9 days. Only during this limited time are viral titers sufficient for potential vectors.
- Long-term carriers of the disease are not believed to occur.

HISTORICAL FINDINGS

Cases will most likely be noted in naïve pregnant animals that have been introduced into an endemic area or have had exposure to competent vectors.

PHYSICAL EXAMINATION FINDINGS

- Congenital abnormalities of the fetus or newborn are the hallmark of this disease. Effects on the young vary depending on the stage of gestation reached at the time of infection.
- When infected late in the first trimester, animals are usually born bright and alert but are unable to stand, are ataxic, and may have one or more paralyzed limbs.
- Muscle atrophy, limb rotation, exophthalmos (protruding eyes), and abnormal vocalization may also occur.
- Animals infected during the second trimester have arthrogryposis at birth; most cannot stand. The joints are rigid and fixed in flexion and muscles are severely atrophied.
- Torticollis, scoliosis, and kyphosis may also be seen.
- When infected late in pregnancy, animals can usually stand and walk, but have behavioral abnormalities, such as slow or absent suckle reflex, depression, dullness, periodic hyperexcitability, incoordination, and blindness.
- Skull deformities can be common.
- Dystocia at parturition may occur due to the deformities of the fetus.

CAUSES

- Akabane virus is transmitted by arthropods (biting midges, mosquitoes) and the virus affects the developing fetus in ruminants.
- Outbreaks are typically related to seasonal conditions that enhance the vectors.

RISK FACTORS

The major risk factor for Akabane is exposure of pregnant ruminants (particularly naïve animals) to potential vectors in endemic areas.

DIAGNOSIS

A presumptive diagnosis of Akabane disease can be made on the basis of clinical and postmortem examination. Diagnosis is typically confirmed by serology.

DIFFERENTIAL DIAGNOSIS

- Cache Valley virus
- Bluetongue
- Bovine viral diarrhea
- Border disease
- Wesselsbron virus
- Nutritional, genetic, or toxic causes of abortion and/or fetal deformities

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Virus isolation should be done but is rarely successful unless the fetus and placenta were aborted before the fetus developed an immune response.
- Specimens to collect include the placenta, fetal muscle, cerebrospinal fluid, and fetal nervous tissue.
- Serology may be performed on fetal or precolostral serum and the serum from the dam.
- Histopathology of the spleen, liver, lung, kidney, heart, lymph nodes, affected muscle, spinal cord, and brain can also be done.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Arthrogryposis and hydranencephaly are the most commonly noted lesions.
- Most of the affected joints are ankylosed and cannot be straightened.
- Other neurological lesions may include hydrocephalus, agenesis of the brain, microencephaly, proencephaly, and cerebellar cavitation.
- Additionally, fibrinous leptomeningitis or ependymitis, spinal cord agenesis or hypoplasia, torticollis, scoliosis, brachygnathism, cataracts, ophthalmia (severe inflammation of the eye), hypoplastic skeletal muscles and lungs, or fibrinous polyarticular synovitis may be seen.

TREATMENT

APPROPRIATE HEALTH CARE

- There is no effective treatment for Akabane virus.
- Most affected neonates die or must be euthanized soon after being born.
- Animals with mild symptoms may gradually become more mobile, but most die by 6 months.
- Subsequent pregnancies of the infected dam will not be affected.

NURSING CARE

N/A

ACTIVITY

N/A

DIET

N/A

CLIENT EDUCATION

In endemic areas, advise clients of the risks to newly introduced animals, especially during late summer and autumn months.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Prevention of Akabane disease includes vector control measures and vaccination. Akabane virus does not appear to be transmitted between animals, except by arthropod vectors.
- Prevention efforts should include elimination of vector breeding sites, and repellants or screened housing for pregnant animals.
- Avoid breeding ruminants during the prime transmission season (late summer and autumn).
- An inactivated and an attenuated vaccine have been developed and used in Japan. An effective killed vaccine has been developed but not marketed in Australia. The vaccines must be used prior to exposure to the infected vectors. A vaccine is not currently available in the United States.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Most affected neonates die or must be euthanized soon after being born. Subsequent pregnancies of the infected dam will not be affected.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Akabane affects fetal or newborn cattle, sheep, and goats.

ZOONOTIC POTENTIAL

There is no evidence that humans can be infected by Akabane virus.

PREGNANCY

Effects of Akabane virus are dependent on the stage of pregnancy when infected. However, most affected neonates die or must be euthanized soon after birth despite the time of infection.

RUMINANT SPECIES AFFECTED

Cattle, sheep, and goats

BIOSECURITY

Suspected cases or outbreaks of Akabane outside of its endemic area (see geographical distribution), should immediately be reported to the proper governmental veterinary authorities (e.g., state or federal veterinarian).

PRODUCTION MANAGEMENT

- In endemic areas, avoid introducing naïve pregnant animal in summer and autumn.
- Implement vector control measures to reduce the potential transmission of the virus.
- Consider vaccination protocols prior to breeding.

ALOPECIA

DEFINITION

- Alopecia means partial or complete loss of hairs in an area where hairs are normally found.
- The terms “hair loss” and “alopecia” are often used interchangeably.
- The term “hypotrichosis” is a more accurate term for congenital or hereditary hair loss or alopecia because it refers to less than an expected amount of hair.

PATHOPHYSIOLOGY

- There are two major etiologies of alopecia or hair loss: *congenital or hereditary* and *acquired*.
- Acquired hair loss is the result of any disease that causes direct damage to the hair follicle or skin (e.g., dermatophytosis) or indirect damage (e.g., pruritus).
- Acquired hair loss may or may not be permanent depending upon the amount of follicular damage.
- Congenital alopecia may or may not be hereditary and it is caused by the lack of the development of hair follicles. These changes are permanent.
- Congenital alopecia is usually evident shortly after birth.
- Hereditary alopecia may be evident shortly after birth or may develop as the animal ages.

SYSTEMS AFFECTED

Skin

GENETICS

Hereditary and/or congenital alopecia are rare and several syndromes have been described (see Alopecia [Table 1](#)).

INCIDENCE/PREVALENCE

- Acquired alopecia is a common skin disease in ruminants.
- Hereditary and/or congenital alopecia is rare.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

- Congenital and/or hereditary alopecia may or may not be sex linked ([Table 1](#)).
- Congenital and/or hereditary alopecia is usually evident at birth or shortly thereafter ([Table 1](#)).
- The signalment of inflammatory causes of hair loss reflect those of the underlying disease.

SIGNS

- Alopecia may be focal, multifocal, symmetrical, or generalized.
- Alopecia may develop acutely or gradually depending upon the cause.
- Hyperpigmentation, lichenification, erythema, and pruritus are common findings in acquired alopecia.
- Acquired alopecia may also be complicated by bacterial infections and/or seborrhea.
- Congenital, hereditary, and endocrine alopecia is noninflammatory unless complicated by secondary infections or damage to the skin.

CAUSES

- Diseases that destroy or damage hairs/hair follicles include bacterial skin diseases, dermatophytosis, demodicosis, severe inflammatory diseases, trauma, burns, frostbite, poisonings, and parasites.
- Diseases that slow hair growth include poor nutrition and protein deficiencies.
- Pregnancy, lactation, severe illness, and/or fever can cause a temporary alopecia characterized by large amounts of shedding within a few days.
- Anagen defluxion occurs as a result of acute damage/cessation of growth in a growing hair shaft characterized by sudden massive hair loss.
- Telogen defluxion occurs as a result of stressful situations (fever, illness, shock, anesthesia, surgery, etc.) that cause cessation of anagen hairs and synchrony of hair follicles into telogen and loss of hairs 1–2 months post event.

- Any disease that causes pruritus (parasites, allergies, neoplasia) may result in hair loss.
- Friction can cause local hair loss.
- Alopecia areata is a rare disease that can cause focal noninflammatory alopecia in cattle.
- Follicular dysplasia can present as focal, regional, or diffuse adult onset slowly progressive noninflammatory hair loss.

RISK FACTORS

- Calves, kids, and lambs that develop severe illness and/or fevers are at risk for anagen defluxion.
- Animals undergoing stressful situations are at risk for development of telogen defluxion.
- Overcrowding, poor nutrition, and poor management may predispose animals to diseases associated with acquired hair loss.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Focal, regional, or generalized hair loss in a neonate—congenital or hereditary hair loss
- Focal inflammatory alopecia: dermatophytosis, dermatophilosis, demodicosis, parasitic diseases, and staphylococcal folliculitis
- Focal noninflammatory hair loss: alopecia areata
- Generalized acute alopecia—telogen or anagen defluxion
- Excessive generalized hair loss in spring—abnormal spring shed
- Patchy hair loss in individual animals that have normal skin—abnormal shedding
- Adult onset slowly progressive alopeciafollicular dysplasia

CBC/BIOCHEMISTRY/URINALYSIS

Routine laboratory tests are not usually very helpful in the diagnosis of alopecia.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Skin scrapings to look for mites
- Flea combings to look for macroscopic parasites (lice, keds, fleas)
- Fungal culture for dermatophytosis
- Skin biopsy can help differentiate between acquired and congenital/hereditary causes of alopecia.
- Skin biopsy is the most cost effective diagnostic test.
- Hair trichogram for differentiation of anagen versus telogen defluxion

PATHOLOGICAL FINDINGS

- Anagen defluxion hairs have irregular and dysplastic hair shafts, hairs break easily.
- Telogen defluxion hairs have a normal, uniform shaft diameter, clubbed nonpigmented root lacking a root sheath.
- Small or absent hair follicles with little or no inflammatory changes are present in skin biopsies from congenital and hereditary alopecia.
- Inflammatory changes characterize acquired alopecia; special stains may identify infectious agents (e.g., dermatophytes).
- Atrophic, distorted hair follicles with melanin clumping are seen in follicular dysplasia.

TREATMENT

- Depends upon underlying cause
- No treatment for congenital or hereditary hair loss

- Successful treatment depends upon the underlying cause and diagnosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

Some causes of acquired alopecia are of zoonotic importance.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Cattle, goats, sheep, llamas, camels; potentially all species

BIOSECURITY

Highly contagious parasitic diseases may require quarantine of specific animals or herds.

PRODUCTION MANAGEMENT

- Acquired causes of hair loss can cause decreased milk, meat, or reproduction depending upon the cause.
- Congenital and/or hereditary alopecia compromise the health of the animal because of the lack of normal protection.

Table 1 Summary of Congenital and/or Hereditary Types of Hypotrichosis

Source: Adapted from Scott, 1988.

Name	Breeds Affected	Mode of Inheritance	Clinical Appearance	Other
Lethal hypotrichosis	Holstein-Friesians Japanese	Simple autosomal recessive	Calves die within hours, hair present only on muzzle, eyelids, ears, tail, pasterns	Hypoplasia of thyroid can occur.
Semihairlessness	Herefords and Polled Herefords	Simple autosomal recessive	Calves viable at birth but have thin, short, curly coat; coat is wiry and thin as animal matures and skin is wrinkled.	Calves do not grow well, can have "wild temperament."
Hypotrichosis and anodontia	Maine-Anjou Normandy mixed cattle	Sex-linked recessive	Affected calves born hairless and toothless, develop fine downy hair coat	Have long protruding tongue, defective horns, hypoplastic testicles
Viable hypotrichosis	Guernseys, Jerseys, Holsteins, Hereford	Simple autosomal recessive	Nearly hairless at birth, varying amounts of hair develop as animal ages	Some animals have dermal arteriovenous anastomosis.
Variable hypotrichosis	Ayrshire, polled Herefords	Autosomal recessive	Animals born with fine, sparse, hair with thin epidermis, generalized but some regions (tail, distal limbs, eyelids, ears) may be less affected Affected calves cannot tolerate cold or extreme heat.	
Hypotrichosis and missing incisors	Holstein-Friesians, Maine-Anjou cross, Normandy	Trait linked and incompletely dominant	Patchy hypotrichosis on face and neck and lack 4–6 incisors Mild disease in cows with lusterless stubbly hypopigmented coats	
Streaked hypotrichosis	Female Holstein-Friesians	Sex-linked dominant, lethal to males	Animals lack hair in vertical streaks on hips, legs, sides.	
Tardive hypotrichosis	Female Holstein-Friesians	Sex-linked recessive	Animals normal at birth, develop hair loss at 6 weeks to 6 months of age	Hair loss is symmetrical, starts on face and neck, proceeds caudally.
Inherited congenital hypotrichosis	Polled Dorset sheep	Unknown	Hairs absent from face, ears, and lower legs, no eyelashes, skin is thickened, wrinkled, greasy, and scaly and erythematous	Excessive lacrimation
BVDV induced Hypotrichosis	Any	Viral In utero infection with BVDV	Thin hair coat	
Badly calf syndrome	Female Holstein-Friesians	Autosomal recessive, homozygous state is usually lethal to males.	Affected calves normal at birth but live only 6–8 months; at 1–2 months they lose condition and develop generalized hair loss. Male Holstein calves may enter veal market. before clinical signs are seen.	Affected individuals have persistent salivation; clinical signs may resemble zinc deficiency. Ears may curl.
Viable hypotrichosis	Polled Dorset sheep	Simple autosomal recessive	Hypotrichotic at birth especially on face	
Cross-related hypotrichosis (rat tail)	Simmental-Angus and Simmental-Holstein	Unknown	Color dilution, sparse and short curly hair, tail switch is poor, hence rat tail name OR Color dilution, short curly hairs that are not sparse	Decreased growth

ANALYTICAL TESTING

BASICS

OVERVIEW

- Energy status, protein values, liver function, macromineral levels, micromineral levels, vitamin status of domestic livestock and wild ruminants are important in the animals' ability to maintain a healthy immune system.
- Measuring serum levels as a diagnostic/prognostic indicator of health is a crucial tool in maintaining healthy animal populations.

SYSTEMS AFFECTED

Potentially all systems can be affected.

DIAGNOSIS

CBC/BIOCHEMISTRY/URINALYSIS OTHER LABORATORY TESTS

Energy Status

Energy balance is by far one of the most critical nutritional factors in animal health, lactation, and reproductive performance. Traditionally we have monitored changes in energy balance via body weight and condition changes over time. This procedure, however, may not be a sensitive enough tool when dealing with the transition cow.

- NEFA—Nonesterified fatty acids
- Serum NEFA concentration is directly associated with adipose tissue catabolism of triglycerides and is a measure of energy balance.
- Feeding of dietary fats can slightly elevate serum NEFA, but not significantly to alter interpretation of energy balance.
- Serum or plasma concentrations range from < 0.1 to 2.5 mEq/L (<0.1–2.5 mmol/L).
- Concentrations are higher prior to a major feeding bout and reduce significantly following feeding. There is less significant variation in total mixed ration fed farms.
- Reasonably stable in serum or plasma, but concentration greatly affected by hemolysis (lowers value)
- BHB— β -hydroxybutyrate

- One of three ketone bodies generated by partial oxidation of fatty acids
- Can be elevated due to dietary sources (dietary ketosis), primarily poorly fermented silages high in butyric acid; butyric acid converted to BHB by rumen epithelium
- Serum or plasma concentrations range from < 1 mg/dL (0.1 mmol/L) to > 40 mg/dL (0.38 mmol/L)
 1. Subclinical ketosis:> 14.5 mg/dL (1.4 mmol/L)
 2. Clinical ketosis:> 26 mg/dL (2.5 mmol/L)
- Greatest blood concentrations found 3–5 hours after feeding
- Very stable analyte, but hemolysis may artificially elevate value
- EXPECTED VALUES FOR METABOLIC PROFILING: Serum or plasma concentrations for NEFA and BHB in the periparturient dairy cow should remain below the concentrations shown ([Table 1](#)). Higher values are suggestive of potential energy balance problems.

Protein

There is no single measurable analyte that directly reflects protein status. As a result, a combination of metabolite parameters needs to be utilized, including serum or plasma UN, Cr, total protein, albumin, and Ck.

- Serum or Plasma UN
 - UN reflects dietary protein status and balance relative to rumen and animal needs and is intertwined with available dietary fermentable carbohydrate. Insufficient dietary protein or excessive fermentable carbohydrate relative to degradable protein will result in lower UN concentrations. Likewise, excessive dietary protein or insufficient fermentable carbohydrate results in high UN concentrations.
 - Cr is used to assess renal function and its impact on UN values.
 - Concentrations can range from near 0 to over 30 mg/dL (0 to 21.4 mmol/L) and vary with feeding. Highest values occur between 3 and 5 hours after a meal.
 - Very stable metabolite, not affected by hemolysis
- EXPECTED VALUES FOR METABOLIC PROFILING
 1. Dry cows should maintain a mean serum or plasma UN concentration between 10 and 12 mg/dL (7.14–8.57 mmol/L).
 2. Fresh cows should maintain a mean serum or plasma UN concentration between 12 and 14 mg/dL (8.57–10 mmol/L).
 3. Individual values below 8 mg/dL and above 16 mg/dL are of concern and should be investigated.
- Total protein
 - Concentration reflects dietary protein status, but due to half-life of protein molecules is not extremely sensitive to dietary changes.
 - Confounded by changes in gamma globulin in response to inflammatory conditions.
- EXPECTED VALUES FOR METABOLIC PROFILING
 1. Early dry cows: 6.5–8.3 g/dL
 2. Close-up dry cows: 5.8–7.7 g/dL
 3. Fresh cows: 6.1–8.8 g/dL
 4. Values below 6 g/dL and above 9.5 g/dL should be investigated.
- Albumin
 - Albumin has a relatively short half-life compared to other blood proteins and can reflect protein deficiency problems over a period of a month or two.
 - Physiologic concentrations range from 3.2 to 4.5 g/dL
 - Dehydration and protein-losing disease processes can confound interpretation of results.
 - Stable metabolite, even with hemolysis.
- EXPECTED VALUES FOR METABOLIC PROFILING
 1. Early dry cows: 3.5–4.0 g/dL
 2. Close-up dry cows: 3.3–3.8 g/dL
 3. Fresh cows: 3.5–4.2 g/dL
 4. Close-up dry and fresh cows with albumin concentration < 3.25 g/dL and < 3.5 g/dL, respectively, are at greater

risk for periparturient disease problems.

- Ck (Creatine kinase)
 - Released from muscle when it is catabolized or injured

Table 1

Period	Sample	NEFA	BHB	
		mEq/L (mmol/L)	mg/dL	mmol/L
Early dry	Individual	<0.325	<10.0	<0.96
	Group	<0.300	<6.6	<0.64
Close-up dry	Individual	<0.400	<10.0	<0.96
	Group	<0.350	<7.0	<0.67
Fresh (<30 DIM)	Individual	<0.700	<14.5	<1.40
	Group	<0.600	<10.0	<0.96

- Due to a tremendous range in values, provides little diagnostic value unless coupled with other parameters
- Concentrations between 400 and 1000 IU/L might suggest muscle breakdown and possible protein deficiency if coupled with corresponding changes in UN and albumin. **Liver Function**

Liver Function

- Enzyme activities (GGT, AST, SDH) and total bilirubin concentrations
 - Elevations in any of these parameters suggest some insult has occurred to the liver but are not specific to liver.
 - SDH is liver specific for ruminants, but elevations cannot be directly attributed to fat infiltration of the liver.
 - Bilirubin values are most specific to bile flow problems than overt hepatocyte damage.
 - Enzyme activities have a wide potential range in values and need to be interpreted in conjunction with other measures of liver function.
 - Most enzymes are sensitive to freezing and thawing. Hemolysis will lower GGT, but increase AST activities.
- EXPECTED VALUES FOR METABOLIC PROFILING
 1. AST: Dry cows: 46–83 U/L; fresh cows: 61–103 U/L
 2. GGT: Dry cows: 18–38 U/L; fresh cows: 20–49 U/L
 3. SDH: 6.4–58.5 U/L
 4. Total bilirubin: 0.1–0.3 mg/dL (1.71–5.13 mol/L)
 5. Enzyme activities exceeding the above ranges would be of concern and liver function should be further evaluated.
- Total cholesterol
 - Associated with various lipoprotein molecules in blood; provides an indicator for very low density lipoprotein (VLDL) production (fat export) by the liver
 - Serum or plasma concentrations are elevated with dietary fat feeding, which may confound interpretation.
 - Physiologic concentrations vary from < 70 up to 300 mg/dL (<2.0 up to 8.7 mmol/L) with lowest values observed around the time of calving.
 - Very stable metabolite, but artificially increased with hemolysis
- EXPECTED VALUES FOR METABOLIC PROFILING
 1. Early dry cows:> 80 mg/dL (>2.28 mmol/L)
 2. Close-up dry cows:> 75 mg/dL (>2.14 mmol/L)
 3. Fresh cows:> 100 mg/dL (>2.86 mmol/L)
 4. Liver's capacity to export fat is of concern whenever fresh cow cholesterol concentrations are less than close-up dry cows.
- NEFA: Cholesterol ratio
 - The liver takes up NEFA in direct relationship with their concentration in blood. Once in the liver, NEFA can either be

partially metabolized to ketone bodies or they can be used to synthesize triglycerides.

- High NEFA associated with low cholesterol is suggestive of a situation where fat will accumulate in hepatocytes, inducing fatty liver condition.

- Ratio is calculated on a molar ratio (mmol NEFA/mmol cholesterol).

1. $\text{mEq/L NEFA} \times 1 = \text{mmol/L NEFA}$

2. $\text{mg/dL cholesterol} \times 0.02856 = \text{mmol/L cholesterol}$

- EXPECTED VALUES FOR METABOLIC PROFILING

1. Calculated ratio ranges from 0.01 to

0.2 for healthy cows with increasing values from early dry to fresh period.

2. Close-up dry cows with ratios > 0.2 are at greater risk for experiencing one or more periparturient disease problems.

3. Fresh cows with ratios > 0.3 are at greater risk for having postpartum disease problems.

Macrominerals

- Macrominerals Ca, P, K, Mg, Na, Cl, and S are of extreme interest as to their status relative to their role in milk fever, alert downer cows, and weak cow syndrome.

- Most of these minerals are tightly regulated in the body through a variety of homeostatic processes.

- Blood concentrations of macrominerals are not reflective at all of dietary status when the homeostatic system is properly functioning.

- Phosphorus, K, Mg, and S are those macrominerals in which blood concentrations are somewhat sensitive to dietary intake.

- Macromineral concentrations need to be carefully interpreted in light of whether or not the homeostatic system is in proper operation.

- Mineral concentrations are very stable, but can be altered by prolonged exposure to the clot (serum sample) or hemolysis (P, Mg, K artificially elevated).

- EXPECTED VALUES FOR METABOLIC PROFILING ([Table 2](#))

Microminerals

- Microminerals are of interest relative to their role in modulating immune function as well as other important metabolic roles.

- Cu, Fe, Se, and Zn are routinely assayed in blood as their concentrations are within detectable limits with current analytical diagnostics.

- Blood or serum micromineral concentrations are buffered from acute changes as a result of dietary problems through mobilization of storage minerals, usually from the liver; thus blood concentrations may not adequately reflect nutritional status.

- Liver trace mineral status may be a better indicator of dietary adequacy, whereas measurement of a mineral-specific enzyme activity better reflects presence of overt clinical deficiency disease compared to blood concentrations.

- Many trace mineral concentrations in blood are influenced by disease. Bacterial infections induce sequestering of iron and zinc and elevation of copper, thus confounding interpretation of blood mineral status.

- Physiologic state and age influence blood and liver micromineral concentrations and must be accounted for in interpretation of concentrations.

- Minerals are very stable in blood, serum, or plasma, but hemolysis can greatly distort serum Se and Zn concentrations.

- EXPECTED VALUES FOR METABOLIC PROFILING (ADULT VALUES ONLY) ([Table 3](#))

Vitamins

- Vitamins A and E are of greatest potential interest for metabolic profiling relative to their role in immune function and association with mastitis, metritis, and retained placenta.

- Vitamin analyses are affected by hemolysis and are prone to oxidation (direct sunlight). Samples should be iced following collection and remain chilled or frozen until analysis.

[Table 2](#)

Mineral	Adequate range	Concern Levels	
		Individual	Group
Calcium	8.7–11.0 mg/dL (2.17–2.74 mmol/L)	<7 mg/dL (<1.75 mmol/L)	<8 mg/dL (<2.0 mmol/L)
Phosphorus	4.5–8.0 mg/dL (1.45–2.58 mmol/L)	<3.5 mg/dL (<1.13 mmol/L)	<3.8 mg/dL (<1.23 mmol/L)
Magnesium	2.0–3.5 mg/dL (0.82–1.43 mmol/L)	<1.5 mg/dL (<0.62 mmol/L)	<1.8 mg/dL (0.74 mmol/L)
Sodium	137–148 mEq/L ¹	<137 mEq/L	<139 mEq/L
Potassium	3.8–5.2 mEq/L ¹	<3.0 or >5.5 mEq/L	<3.5 or >4.8 mEq/L

¹mEq/L = mmol/L.

Table 3

Serum Mineral	Adequate Range		Concern Levels	
Copper	0.6–1.5 µg/mL	9.4–23.6 µmol/L	<0.45 µg/mL	<7.1 µmol/L
			>4 µg/mL	>63 µmol/L
Iron	130–250 µg/dL	23.3–44.8 µmol/L	<130 µg/mL	<23 µmol/L
			>1800 µg/mL	>322 µmol/L
Zinc	0.8–1.4 µg/mL	12.2–21.4 µmol/L	<0.5 µg/mL	<7.6 µmol/L
			>3 µg/mL	>45.9 µmol/L
Selenium, serum	70–100 µg/mL	0.89–1.3 µmol/L	<35 µg/mL	<0.44 µmol/L
			>800 µg/mL	>10.1 µmol/L
Selenium, whole blood	120–250 µg/mL	1.5–3.2 µmol/L	<50 µg/mL	<0.63 µmol/L
			>1900 µg/mL	>24 µmol/L

- Age and physiologic state influence serum and liver vitamin concentrations and reference values need to be adjusted accordingly.
- Vitamin A (total retinol)
 - Concentration of total retinol can be measured in serum (plasma) or liver tissue.
 - Serum concentration is less indicative of dietary status and can be influenced by Zn and protein status as they impact retinol-binding protein availability.
 - Serum concentration declines during late gestation.
 - Liver vitamin A concentration reflects the storage pool and is sensitive to dietary status.
 - Both serum and liver concentrations are diagnostic for disease problems.
 - EXPECTED VALUES FOR METABOLIC PROFILING (ADULTS ONLY) ([Table 4](#))

Table 4

Sample	Adequate Range	Deficient
Serum	225–500 µg/mL (0.79–1.74 µmol/L)	<150 µg/mL (<0.52 µmol/L)
Liver	300–1100 µg/g dry weight	<40 µg/g dry weight

- Vitamin E (α-tocopherol)
 - Concentration of α-tocopherol can be measured in either serum (plasma) or liver tissue.
 - Serum concentrations generally reflect dietary intake, but are influenced by variations in blood lipoprotein content.

- Serum concentrations decline in late gestation.
- Relating serum vitamin E to total cholesterol concentration reduces variation as vitamin E is carried on blood lipoproteins.
- Vitamin E to cholesterol ratio is calculated on a molar basis (μmol vitamin E/ μmol cholesterol) and is unitless.
- Liver vitamin E concentration is reflective of the storage pool and reflects nutritional status.
- Both serum and liver vitamin E concentrations are diagnostic for disease problems.
- EXPECTED VALUES FOR METABOLIC PROFILING (ADULTS ONLY) ([Table 5](#))

INTERPRETATION

- A complete understanding of underlying metabolic and physiologic mechanisms controlling blood metabolite concentrations is necessary to properly interpret metabolic profiles and their application.
- Unlike the interpretation of individual cow clinical chemistry profiles, interpretation of metabolic profiles requires appreciation of statistical probabilities and acceptable level of risk.

Table 5

Sample	Adequate Range	Deficient
Serum	3–10 g/mL	<3.0 g/mL
Vitamin E: Cholesterol ratio	2.5–6.0	<1.5
Liver	20–40 $\mu\text{g/g}$ dry weight	<10 $\mu\text{g/g}$ dry weight

- Reference values for each metabolite need to be refined to minimize inherent variability due to effects of age, physiologic state, production level, and other cow-specific factors on analyte concentration and improve sensitivity of analyte to environmental (i.e., nutritional) influences.

REFERENCE VALUES

- Interpretation of metabolic profiles requires some standard reference values for comparison.
- Analyte reference values should represent the population mean and variation from a defined population of animals clinically evaluated to be free of disease and other health problems.
 - Each population mean needs to be statistically analyzed for a normal population distribution.
 - Median values should be used in place of means for metabolites not showing a normal distribution.
 - Abnormal metabolite values are defined as those outside of the predefined normal reference range.
- At present, few laboratories have specialized blood analyte reference criteria that are adjusted for age, physiologic state, and time relative to calving effects.
- Research is currently under way to develop appropriate metabolic profiling reference criteria.
- Until more specific criteria are developed, use of current reference ranges adjusted to α 1 or 1.3 standard deviation have been used for interpretation.

ASSESSMENT

- Metabolic profile results must be correlated with animal and dietary evaluations.
- Mean comparison to reference range
 - Individual samples within groupings
 1. Mean values and standard deviation for all analytes are calculated for each sampled individual within a defined group.
 2. Means and associated statistical variation are compared to reference range.
 3. Sampled populations where 10–25% of individuals are outside the reference range might be considered to be subclinical. If more than 40% are outside the range, then there is a greater risk of clinical disease.
 - Pooled samples within groupings
 1. Pooled analyte values are compared to reference range mean or median.
 2. Pooled values should be within α 0.5 standard deviations of reference mean to be considered normal.
 3. As pooled values deviate further from the reference mean, potential for subclinical and clinical disease will increase.
 4. More research is needed to better define pooled sample interpretation.
- Comparison across groups

- Besides comparing individual group means to reference ranges, tracking metabolite concentrations across physiologic groups within a herd may provide useful information.
- This assuming there have not been any major feed changes within group rations over a period of time.
- This process is useful in evaluation of transition cow problems. Compare analyte values across early dry, close-up dry, and fresh cow groups.
- Changes in group means are correlated with observed clinical signs, body condition changes, and ration evaluations to come up with some interpretation and recommendations.
- Mean comparison within groups over time
 - Statistical process control—statistical method used by industry to track quality control in manufacturing
 - Same concepts can be applied to repeated measures of analytes within a defined group over time.
 - Determine overall mean and statistical variation within and between time periods.
 - Track means graphically identifying individual tests outside of control limits or three or more consecutive means above or below overall average.
- Proportion comparison within groups
 - Compare individual samples to analyte reference value.
 - Identify all individuals that have values exceeding or below defined threshold value.
 - Determine proportion of individuals with abnormal values.
 - With increasing proportion of individuals with abnormal values, there is an increasing risk of subclinical to clinical disease problems.

ANAPHYLAXIS

BASICS

DEFINITION

- An anaphylactic reaction is a pathological immune response that occurs following exposure of a sensitized animal to a specific antigen. This exposure results in urticaria, pruritus, and angioedema, followed by vascular collapse, shock and often life-threatening respiratory distress.
- Anaphylaxis has now been included under type I (immediate) hypersensitivity.

PATHOPHYSIOLOGY

- Anaphylaxis is an acute systemic manifestation of the interaction of an antigen (allergen) binding to IgE antibodies, which are bound to mast cells and basophils. This binding of antigens to cell-bound IgE antibodies triggers the release of chemical substances from the mast cells and basophils.
- The major biologically active mediators produced by mast cells and basophils include histamine, leukotrienes, the eosinophilic chemotactic factor, platelet-activating factor, kinins, serotonin, and proteolytic enzymes. These chemicals directly affect both the vascular system, causing vasodilatation and increased vascular permeability, and smooth muscles, causing contraction of the bronchi and respiratory distress.

SYSTEMS AFFECTED

Cardiovascular, pulmonary, urinary, gastrointestinal, integument

GENETICS

There have been reports of higher incidence in certain lines and breeds of cattle.

INCIDENCE/PREVALANCE

Sporadic, dependent on exposure to inciting antigen

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Bovine, ovine; also reported in many other species of ruminants

SIGNS

- Sudden, severe dyspnea, muscle tremors, anxiety, occurs within a few to 10–15 minutes following exposure to the antigen; Muscle tremor may be severe and temperature may rise to 105°F
- History of injection in the previous hour
- Occasionally profuse salivation, mild bloat, diarrhea, urticaria, angioneurotic edema, and rhinitis
- Laminitis rarely occurs in ruminants.

PHYSICALEXAMINATION FINDINGS

Auscultation of the chest—vesicular murmur, crackling if edema is present, and emphysema in the later stages if dyspnea was severe

CAUSES

- Common agents causing anaphylaxis include blood transfusions, vaccines, horse sera, insect bites, heterologous enzymes and hormones, and certain drugs, such as penicillin and lidocaine.
- Milk allergy occurs occasionally in cows. This can happen when there is increased intramammary pressure to a point that normally sequestered milk components, notably casein, gain access to the circulation; these “foreign” proteins induce a type I hypersensitivity.

RISK FACTORS

Previous exposure to antigens (i.e., previous treatment with blood or blood products or vaccines)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acute Bloat

A history of introduction to new forage and/or concentrate diet. Obvious distention of the rumen occurs suddenly, and the left flank may be so distended that the paralumbar fossa protrudes above the vertebral column; the entire abdomen is enlarged. Dyspnea and grunting are marked and are accompanied by mouth breathing, protrusion of the tongue, and extension of the head.

Acute Bronchopneumonia

A history of recent episodes of stress (i.e., weaning, transport, vaccination) within the last 2–7 days. Clinical signs of bacterial bronchopneumonia are often preceded by a viral infection of the respiratory tract. With the onset of secondary bacterial pneumonia, the severity of clinical signs increases and is characterized by depression and toxemia. There will be fever (104–106°F); serous to mucopurulent nasal discharge; moist cough; a rapid, shallow respiratory rate and dyspnea. Auscultation of the lung field reveals increased bronchial sounds, crackles, and wheezes. In severe cases, pleurisy may develop, which is characterized by an irregular breathing pattern and grunting on expiration.

CBC/BIOCHEMISTRY/URINALYSIS

Increase in PCV, high plasma K^+ , neutropenia

CLIENT EDUCATION

Clients may be instructed to have epinephrine on hand so it can be administered as soon as signs are noted.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

- Anaphylactic shock is treated with an IV injection of epinephrine.

- Corticosteroids potentiate the effects of epinephrine and may be given following the administration of epinephrine.
- Antihistamines have no effect once signs are present.

CONTRAINDICATIONS

N/A

PRECAUTIONS

When treating food-producing animals, drug withdrawal times must be determined and maintained.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Animals need to have their respiratory system monitored for the next 24 hours to detect any emphysema.

PREVENTION/AVOIDANCE

Discuss the situation associated with the onset with the producer. Certain products may need to be avoided.

POSSIBLE COMPLICATIONS

Emphysema may result from severe dyspnea and violent muscle spasms.

EXPECTED COURSE AND PROGNOSIS

Animals treated promptly usually return to normal within 12 to 24 hrs.

ANAPLASMOSIS

BASICS

OVERVIEW

- Anaplasmosis is a hemoparasitic disease with a worldwide distribution, most common in tropical and subtropical areas.
- Upon infection, *Anaplasma* organisms double in number every 24 hours for the first several days.

PATHOPHYSIOLOGY

Infected red blood cells are destroyed by the reticuloendothelial system (spleen) leading to extravascular hemolysis and anemia.

SYSTEMS AFFECTED

Hemolymphatic

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide distribution

SIGNALMENT

Species

Primarily cattle but also sheep, goats, and many wild ruminants

Breed Predilections

N/A

Mean Age and Range

- Cattle under 6 months of age generally show no clinical signs.
- In cattle from 6 months to 3 years of age, signs are progressively more severe.
- Mature cattle (over 3 years of age) are the most susceptible to severe clinical manifestations of the disease. Mortality in this age group can be as high as 50% in naïve herds.

Predominant Sex

N/A

SINGS

- In the early stages of the disease, cattle may appear lethargic, be anorexic, have decreased milk production, and develop fever.
- Pale or icteric mucous membranes will be present.
- Other signs include depressed rumination, constipation with dark brown mucous-covered feces, dry muzzle, and weight loss.
- Hemoglobinemia and hemoglobinuria are *not* seen with anaplasmosis.
- Infected cattle subsequently develop varying degrees of anemia, which can be fatal if untreated.
- Cattle exhibiting signs of anaplasmosis should be handled with caution.
 - Cerebral anoxia can cause aggressiveness.
 - Severe anemia coupled with stress may precipitate sudden death.
- If anemia is severe, abortions may occur due to fetal anoxia.
- If animals survive the initial infection, they generally become carriers, maintaining a low level of infection without overt clinical signs.

CAUSES AND RISK FACTORS

- Three species of *Anaplasma* have been identified.
 - *Anaplasma marginale* is the most common cause of disease in cattle.
 - *Anaplasma centrale* can cause mild disease in cattle.
 - *Anaplasma ovis* causes mild disease in sheep.
 - There is some cross-protection between species.
- Other species of *Anaplasma* are suspected but have not been definitely identified in ruminants.
- Strains of the organism vary in pathogenicity.
- The disease is spread biologically and mechanically.
 - Biological transmission occurs with *Dermacentor* spp. ticks.
 - Mechanical transmission occurs with tabanid flies and blood-contaminated instruments (such as needles, tattooers, dehorning, and castrating equipment).
- Transmission is highest during heavy tick and fly seasons.
- Moving naïve adults into an endemic area or carrier animals into a nonendemic area often results in outbreaks of the disease.
- Black-tailed deer are effective reservoirs of *A. marginale* and complicate control of the disease in some areas. White-tailed deer are uncommon reservoirs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

- Babesiosis—presence of hemoglobinuria, identify typical piriform organisms on Giemsa-stained blood smear
- Leptospirosis—elevated titers, identification of organism in urine by dark-field microscopy
- Bacillary hemoglobinuria or *Clostridium novyi* infection—presence of hemoglobinuria, liver enzyme elevation; identify organisms on impression smear of liver on freshly dead specimen
- Hepatotoxic plants, for example: *Senecio* spp., *Crotalaria* spp., *Lantana camara*—evidence of plant ingestion, marked elevation of liver enzymes, histopathology of liver
- Severe intestinal parasitism—fecal examination
- Copper toxicity, most commonly in sheep—methemoglobinemia, hemoglobinuria, elevated serum, liver and kidney copper concentrations, elevated renal and hepatic enzymes

CBC/BIOCHEMISTRY/URINALYSIS

- Blood collected from animals showing clinical signs will appear thin and watery.
- The packed cell volume will be severely decreased (less than 30%).
- A regenerative response will appear leading to anisocytosis, basophilic stippling, poikilocytosis, polychromatophilia, and reticulocytosis.
- A blood smear stained with Wright's, new methylene blue, or Giemsa stain will definitively diagnose *Anaplasma* organisms. The organisms will appear darkly stained on red blood cells. *A. marginale* is typically at the periphery of the cell and *A. centrale* is at the center.
- A biochemical panel will generally show increased serum urea nitrogen, total and direct bilirubin (BILI), and aspartate aminotransferase (AST).
- Hemoglobinemia and hemoglobinuria are *not* seen in anaplasmosis.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Cytology on a direct, Giemsa-stained blood smear is the most common method of diagnosis in animals showing clinical signs.
- Rapid card agglutination and complement fixation tests are commonly used to diagnose the carrier stage.
- Recent research suggests that a nested polymerase chain reaction (PCR) test is better at accurately detecting the carrier

stage than complement fixation.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- Tissues will have an anemic pallor.
- Icterus may be present later in the course of disease.
- Splenomegaly is common.
- Hepatomegaly is found in some cases.
- Petechiae are occasionally found in pericardial tissues.

HISTOPATHOLOGICAL FINDINGS

- Staining of tissues may reveal organisms infecting blood cells in capillaries.
- Hepatic changes may include swelling of parenchymal cells, centrilobular necrosis with bile retention and hemosiderosis
- Renal changes may include degeneration of tubular cells and protein infiltrates in tubular lumens and the capsular space.

TREATMENT

- Handle affected animals with caution, as anoxia can lead to aggressiveness or sudden death.
- Other than antibiotic therapy, only supportive care is needed.
- If PCV is below 12%, a blood transfusion may be warranted.

MEDICATIONS

DRUGS OF CHOICE

If cleanup of carriers is attempted, animals should be retested 6 months after treatment.

- Oxytetracycline is the treatment of choice for anaplasmosis infections and can be used according to labeled dosages.
- For treatment of acute disease, administer 11 mg/kg intravenously once daily for 3–5 days.
- A long-acting (or depot) form of oxytetracycline can also be used for treatment of acute disease at 20 mg/kg intramuscularly every 72 hours for one to two treatments.
- In endemic areas, control can be achieved with
 - 6.6–11mg/kg of the nondepot form or 20 mg/ml of the depot form of oxytetracycline every 21–28 days from the start of the vector season until 1–2 months after vector season ends.
 - Chlortetracycline in feed at 0.22–0.55 mg/kg daily year-round
 - Chlortetracycline in feed at 1.1 mg/kg daily during the vector season
- Clearance of the carrier state can be achieved with
 - Four treatments utilizing a depot form of oxytetracycline at 20 mg/kg intramuscularly or subcutaneously every 72 hours
 - Chlortetracycline in feed at 1.1 mg/kg daily for 120 days or 11 mg/kg daily for 60 days
- Observe appropriate meat and milk withdrawal times.

CONTRAINDICATIONS

- If the carrier state is cleared using antibiotic therapy, cattle will become susceptible to reinfection. In endemic areas, it may not be advisable to clear the carrier state.
- Drug withdrawal periods for meat and milk must be followed.

FOLLOW-UP

If cleanup of carriers is attempted, animals should be retested 6 months after treatment.

MISCELLANEOUS

There have been vaccines available at various times for use in controlling losses associated with anaplasmosis, however, their efficacy has generally been poor. A search of the Internet using the words “anaplasmosis vaccine” will enable you to find current products. Vaccines are not approved for use in all areas.

- Vaccination does not prevent disease but does decrease the severity of clinical signs when animals are infected.
- Some vaccines have been associated with the development of neonatal isoerythrolysis in calves so caution should be exercised when vaccinating late gestation females.

ANEMIA, NONREGENERATIVE: BOVINE

BASICS

DEFINITION

- Anemia in adult cattle is indicated by a PCV (or Hct) of less than 23%.
- Beef cattle have higher hemoglobin, RBC, and PCV than dairy breeds.
- Anemias may be nonregenerative or regenerative. The lack of reticulocytes and polychromasia with normal red cell distribution width (RDW) is indicative of a nonregenerative response or erythropoietic depression.
- Lactating dairy cattle tend to have lower values than nonlactating cows.
- Bulls tend to have greater RBC counts than cows.
- Environmental, seasonal, and physiological differences may affect the hemogram.
- Diminished oxygen tension at elevated altitudes stimulates erythropoiesis resulting in increased RBC counts.

PATHOPHYSIOLOGY

- Anemia results from decreased production, or increased destruction (hemolysis) or loss (hemorrhage) of erythrocytes. Nonregenerative anemias are caused by decreased erythropoiesis.
- The onset of anemia and its related signs is insidious unless there is concurrent hemolysis or hemorrhage.

Anemia of Chronic Inflammation

- Established inflammation results in bone marrow depression due to alterations in iron metabolism, which results in sequestration of iron into the cells of the mononuclear phagocytic system. It is hypothesized that the iron sequestration is a nonspecific bacteriostatic process.
- This functional iron deficiency causes decreased erythropoiesis. However, the depression rarely results in the classic microcytic, hypochromic anemia of dietary iron deficiency or iron deficiency resulting from chronic hemorrhage.

Iron Deficiency

- Iron deficiency may be due to dietary iron deficiency or to chronic blood loss. Dietary iron deficiency is seldom recognized in cattle because soil contains a sufficient amount of iron to maintain hematopoiesis. It is possible that calves raised on concrete with a diet consisting exclusively of milk could have dietary iron deficiency.
- Chronic blood loss such as with certain intestinal helminth infections may result in enough loss of iron to cause iron deficiency. Other chronic bleeding conditions, such as intestinal tract ulcers or hemorrhaging tumors (e.g., lymphoma), can also cause iron deficiency.
- Classically, iron deficiency results in nonregenerative anemia (no reticulocytes or polychromasia) that has a microcytic, hypochromic erythrocyte profile.

Space Occupying Lesions Of The Bone Marrow

- Myelophthisis is rare in cattle, perhaps because few cattle live to older age when an animal is more likely to develop tumors. Tumors that metastasize to the bone marrow would produce a depression anemia, which is most likely to have a normocytic, normochromic erythrocyte profile.
- Cancerous lymphocytes of lymphoma do not frequently multiply in the bone marrow, but occasionally this may occur. If sufficient amount of the marrow is involved, depression anemia can be an unusual secondary feature of bovine lymphoma.

Copper Deficiency

Copper deficiency causes nonregenerative anemia due to impaired absorption and utilization of iron. The majority of copper in the blood is bound to ceruloplasmin, an enzyme that is required for the binding of iron to the transport protein, transferrin. Copper deficiency may be either primary due to deficient intake or secondary due to high molybdenum content of soils and forage. Copper deficiency results in microcytic, hypochromic anemia for the reasons outlined above for iron deficiency.

Cobalt Deficiency

Cobalt is an essential component of Vitamin B₁₂ (cyanocobalamins). Ruminant stomach microflora synthesizes vitamin B₁₂. Cobalt deficiency results in the depression of the vitamin B₁₂-containing enzyme 5-methyltetrahydrofolate homocysteine methyltransferase, which causes a reduction in folate metabolism and impeded DNA synthesis in developing erythrocytes. Anemia occurs late in the course of cobalt deficiency and may be normocytic or macrocytic.

Organ Dysfunction or Failure

- Nonregenerative anemia often occurs with chronic kidney diseases. This is due to decreased erythropoiesis as a result of decreased erythropoietin production. In addition, erythrocyte lifespan is decreased probably because uremic substances directly affect erythrocyte integrity (structural substances and/or metabolism).
- Nonregenerative anemia may occur with liver diseases. The processes that cause the anemia are unknown, but they may be the result of decreased absorption, distribution or use of elements necessary for erythropoiesis.

Peracute and Acute Hemorrhage or Hemolysis

- Apparent nonregenerative anemia may be suggested by hemogram findings for several days after rapid onset hemorrhage or hemolysis.
- Hypoxia stimulation of erythropoietin production occurs rapidly, but several days of increased erythropoiesis are required before evidence of increased erythropoiesis is evident in the hemogram.

Bracken Fern Toxicosis

- Chronic ingestion of bracken fern (*Pteridium aquilinum*) causes bladder hemorrhage and hematopoietic depression in cattle and sheep. The hemorrhage may be of sufficient magnitude and duration to cause severe anemia. Hemogram features often reveal a nonregenerative response, which is due to marrow hematopoietic suppression.
- Because of the bone marrow depression, thrombocytopenia and neutropenia may be evident. Moderate to severe thrombocytopenia likely contributes to the magnitude of the bladder hemorrhage and exacerbates the anemia due to bone marrow suppression.

SYSTEMS AFFECTED

- Hematopoietic: erythropoiesis is depressed. Bone marrow evaluation will reveal increased M:E (myeloid to erythroid ratio) because the myeloid activity is normal or increased, while the erythroid activity is depressed.
- Cardiovascular: hypoxia causes tachycardia. Decreased blood viscosity and turbulent blood flow may occasionally result in an auscultable heart murmur.
- Respiratory: hypoxia causes tachypnea.
- Central nervous system, liver, and kidney are particularly sensitive to hypoxia. Clinical and laboratory features suggestive of effects on these systems may be recognized.

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

- Potentially worldwide
- Chronic blood loss due to intestinal parasitism may have an increased prevalence in areas endemic to associated parasites.
- Copper and cobalt deficiencies are often associated with soil deficiency of these minerals. Functional copper deficiency may occur when there are excess amounts of molybdenum, zinc, and some compounds.

SIGNALMENT

Species

All cattle are susceptible to anemia.

Breed Predilections

N/A

Mean Age and Range

- Anemia due to chronic gastrointestinal blood loss secondary to abomasal ulcers or intestinal parasites may occur in cattle of all ages.
- Anemia due to other causes may affect any age animal.

Predominant Sex

There is no sex predilection.

SIGNS

N/A

HISTORICAL FINDINGS

Nonspecific signs of anemia include weakness, lethargy, anorexia, dyspnea, tachypnea, dark feces (melena), pica (especially with mineral deficiencies). Decreased growth and productivity may occur in iron-, copper-, or cobalt-deficient animals; diarrhea may be found in copper- and cobalt-deficient animals; and faded hair coat occurs in copper-deficient animals.

PHYSICAL EXAMINATION FINDINGS

Pale mucous membranes, tachycardia, tachypnea, melena occasionally observed in animals with gastric ulcers, unthrifty appearance. Faded hair coat may be seen with copper deficiency.

CAUSES AND RISK FACTORS

Anemia of Chronic Inflammation

Inflammation of any cause may result in anemia provided that the inflammatory condition is present for sufficient time. The degree of anemia will depend upon the duration of inflammation. Generally, mild anemia can be recognized by laboratory evaluation within 1 to 2 weeks after onset of inflammation.

Iron Deficiency Anemia

Any form of chronic external blood loss; blood loss in cattle most commonly results from loss through the gastrointestinal tract. Gastric ulcers and trichostrongylosis are frequent causes of GI blood loss. Neonates on all-milk diets without access to soil may develop anemia relatively rapidly because their erythrocyte mass is expanding as they grow.

Copper Deficiency Anemia

- Primary copper deficiency may occur in milk-fed animals or in animals pastured on copper-deficient soils.
- Secondary copper deficiency can occur with excess dietary molybdenum, sulfates, or zinc.

Cobalt Deficiency

- Primary cobalt deficiency occurs in areas of cobalt-deficient soils or on pastures heavily fertilized with limestone, which reduces cobalt availability.
- Secondary cobalt deficiency may occur with excess manganese, zinc, or iodine, which apparently antagonizes use of cobalt.

Anemia Secondary to Organ Dysfunction

- Chronic renal failure and hepatic dysfunction may result in depression anemia.
- Peracute and acute hemorrhage or hemolysis
- Early (approximately the first 3 to 5 days) in any hemolytic crisis of hemorrhagic condition, hemogram often suggests erythropoietic depression because several days are required before hypoxic stimulation of erythropoiesis is manifested as recognizable features of polychromasia, reticulocytosis, etc., in the blood.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- On the hemogram, nonregenerative anemia is distinguished from regenerative anemia in the lack of reticulocytosis and polychromasia. Hemogram features in the early stages of hemolysis or hemorrhage may be similar to those of depression anemia (see above, Peracute and Acute Hemorrhage or Hemolysis).
- In iron deficiency, microcytosis and hypochromasia are usually evident.
- In cobalt deficiency, macrocytosis may be evident.

CBC/BIOCHEMISTRY/URINALYSIS

Anemia Due to Chronic Inflammation

CBC

- Generally there are mild decreases in RBC, Hgb, and PCV (anemia is rarely severe).
- The hemogram reveals normocytic, normochromic, nonregenerative anemia (no reticulocytes or polychromasia with

normal RDW).

- Often an inflammatory leukogram consisting of neutrophilia, \pm left shift, \pm toxic change (often indicates bacterial etiology), \pm monocytosis (presence indicates inflammation of some duration or tissue damage/necrosis is present).
- Lymphopenia may indicate stress (endogenous corticosteroid release).
- Thrombocytosis may be found.
- Hyperfibrinogenemia is often found with active inflammation.

Serum Biochemistry

- Hyperglobulinemia is often found in chronic inflammation, particularly when infectious agents such as bacteria cause the inflammation.
- Hypoalbuminemia may be present with active inflammation especially if there is marked hyperglobulinemia.

Anemia Due to Iron or Copper Deficiency

CBC

- There are mild to marked decreases in RBC, Hgb and PCV.
- Microcytosis (low MCV) is often found
- Hypochromasia (low MCHC) also occurs.
- There may be either regenerative or nonregenerative response to the anemia; the latter is more common.
- Characteristic changes in erythrocytes observed on blood films include increased central pallor (hypochromasia), anisocytosis and moderate to marked poikilocytosis such as dacrocytes (tear-drop shape).
- Thrombocytosis is common; this may be extreme.

Serum Biochemistry

Hypoproteinemia with both hypoalbuminemia and hypoglobulinemia is a consistent finding if iron deficiency is due to sustained gastrointestinal blood loss.

Anemia Due to Cobalt Deficiency

CBC

- There are mild decreases in RBC, Hgb, and PCV.
- Usually the RBCs are normocytic (MCV in reference range) to occasionally macrocytic (increased MCV), normochromic (reference range MCHC), and nonregenerative anemia.
- There may be a stress (corticosteroid) leukogram.

Serum Biochemistry

- If ketosis develops secondary to anorexia, ketone bodies may be detected in the serum.
- There may be increased liver enzyme activity—AST, SDH, GGT.

Urinalysis

If ketosis develops secondary to anorexia, ketone bodies are detectable by urine dipstick.

Anemia Due to Secondary Organ Failure/Dysfunction—Chronic Renal Failure

CBC

- There are mild to moderate decreases in RBC, Hgb, and PCV.
- The anemia is normocytic, normochromic, nonregenerative.

Serum Biochemistry

With kidney failure there will be increased BUN (not as striking as in monogastric animals), creatinine, and possibly phosphorus with variably low bicarbonate, sodium, and chloride.

Urinalysis

Isosthenuria (Sp. Gr. 1.008—1.012) with variable proteinuria is found.

Anemia Due to Secondary Organ Failure/Dysfunction—Liver Disease

CBC

- There are mild to moderate decreases in RBC, Hgb, and PCV.
- The anemia is normocytic, normochromic, nonregenerative.

Serum Biochemistry Increased SDH, LDH, AST, GGT; variably high bilirubin; occasionally low BUN; decreased total protein with decreased albumin are some features of liver damage.

OTHER LABORATORY TESTS

Chronic Blood Loss/Iron Deficiency

- Hypoferremia (serum iron $< 30 \mu\text{g/dL}$) is consistently found.
- Transferrin saturation is decreased.
- Total iron binding capacity is increased.
- Fecal flotation may suggest intestinal parasites (*Trichostrongylus* spp.) as the cause of blood loss.
- Fecal occult blood test may reveal location of blood loss (*caution*: some plant peroxidases can result in a false positive).
- Space occupying lesions of the bone marrow
- Examination of the bone marrow may reveal neoplastic lymphocytes.

Copper Deficiency

Plasma copper levels are decreased.

Cobalt Deficiency

Low serum cobalamin (vitamin B₁₂) concentration. (Cobalt concentration is not reliable.)

OTHER DIAGNOSTIC PROCEDURES

Chronic Blood Loss/Iron Deficiency

Cytological evaluation of bone marrow specimen stained with Prussian blue for iron particles should reveal the absence of hemosiderin. Marrow evaluation for iron is only recommended when documentation of iron deficiency by other means is difficult.

PATHOLOGIC FINDINGS

Chronic Blood Loss/Iron Deficiency

Intestinal parasitism with mucosal petechiation; abomasal ulcers.

TREATMENT

- Successful treatment of nonregenerative anemia usually revolves around correction of the underlying cause(s).
- Treat with appropriate antimicrobials, anthelmintics, or correct dietary insufficiencies.

ACTIVITY

Restrict activity until the animal(s) can exert themselves without developing significant dyspnea.

DIET

Treat with appropriate antimicrobials, anthelmintics, or correct dietary insufficiencies. (Refer to specific chapters for types, dosages, and amounts.)

Chronic Inflammation

Determine source of inflammation and treat with appropriate antimicrobials if bacterial or fungal etiology. Hot pack external abscesses.

Chronic Blood Loss/Iron Deficiency

- Identify and correct the cause of external blood loss.
- Treat with appropriate anthelmintic based on specific parasite(s) detected by fecal evaluation.
- Iron may be provided as an oral supplement or as a feed additive. Iron dextran injections should be avoided in cattle because it can cause anaphylaxis, especially if used repeatedly. Injected iron may cause acute iron overload resulting in massive hepatic necrosis leading to death in cattle. Injectable iron should be used with caution in cattle.

Copper and Cobalt Deficiencies

Addition of copper or cobalt to diet by feeding free-choice trace mineral/salt mix is effective, but the animals consume the mix frequently.

Renal Failure

If possible, stabilize the animal and rehydrate with fluids.

Early Peracute and Acute Hemorrhage or Hemolysis

- Treat the specific condition.

- In valuable animals, transfusions may be used to maintain oxygen carrying capacity until effective erythropoiesis contributes to increased oxygen-carrying capacity of the blood.

MISCELLANEOUS

- See specific chapters on infectious diseases, parasitism for appropriate drugs and dosages.
- See specific chapters on mineral deficiencies for supplementation and dosages.

DRUGS OF CHOICE

- Appropriate antibiotics for inflammatory conditions with infectious etiologies
- Appropriate anthelmintics for parasitism

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING

- Respiration and heart rates and mucous membrane color are useful for recognizing the success of therapy.
- In patients with severe anemia, CBC or PCV with a blood smear examination should be performed every 1–2 days until a significant erythropoietic response is recognized.

PREVENTION/AVOIDANCE

See specific chapters for nutritional deficiencies, intestinal parasites, etc.

POSSIBLE COMPLICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Injected iron can cause anaphylaxis (iron dextran) or liver necrosis.

EXPECTED COURSE AND PROGNOSIS

Clinical course and prognosis vary and are associated with the underlying disease condition causing the nonregenerative anemia.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Young animals on milk diets are susceptible to iron deficiency.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

A mild anemia may be observed in some pregnant animals due to dilution of RBC mass by a high blood volume.

RUMINANT SPECIES AFFECTED

Potentially, all ruminant species are affected.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- In areas of mineral-deficient soils, feed should be appropriately supplemented or it should contain commodities (grain,

hay, etc.) grown on properly supplemented land.

- Preventative anthelmintic therapy should be practiced in areas of endemic parasitism.

ANEMIA, NONREGENERATIVE: CAMELIDS

BASICS

DEFINITION

- Anemia in adult llamas and alpacas is indicated by a PCV of less than 25%. A PCV of $\leq 28\%$ in camels is indicative of anemia.
- High concentrations of erythrocytes are observed in healthy camelids, but because the cells have a small mean cell volume, the PCV, or Hct, is relatively low.
- Anemias may be nonregenerative or regenerative. The lack of polychromasia, reticulocytes, and nucleated erythrocytes is indicative of depression or a nonregenerative response.

PATHOPHYSIOLOGY

Anemia may result from either decreased production or increased destruction of erythrocytes. Nonregenerative anemias are most often associated with decreased erythropoiesis. The onset of anemia and its related signs is insidious unless there is concurrent RBC destruction or loss. ***Anemia of Chronic Inflammation***

- Decreased production of erythrocytes is often associated with established or chronic inflammation in camelids, but iron or copper deficiency may also cause nonregenerative anemia. A mature neutrophilia ($>25,000$ neutrophils/ μL) \pm hyperfibrinogenemia (>400 mg/dL) is consistent with inflammatory disease. The presence of immature neutrophils (e.g., left shift) is supportive of active inflammation. Inflammatory disease results in cytokine-mediated disturbances in iron metabolism and decreased availability for erythropoiesis. Lack of polychromasia and reticulocytes indicates nonregenerative anemia.
- Mild, normocytic, normochromic, nonregenerative anemia has been reported in juvenile llamas affected with juvenile llama immunodeficiency syndrome (JLIDS). Anemia is probably a result of chronic and repeated infections resulting in decreased iron availability.

Iron Deficiency Anemia

Iron deficiency may be primary or secondary. In either case, iron deficiency results in moderate nonregenerative anemia due to insufficient iron for hemoglobin synthesis. Erythrocytes are microcytic (decreased MCV) due to an additional cell division during development. Hypochromasia (decreased MCHC) results from decreased hemoglobin concentration in the erythrocytes. Chronic blood loss can result in iron deficiency and nonregenerative anemia. *Trichostrongylus* infection causes a mildly regenerative, normocytic, normochromic blood loss anemia. Bleeding gastric ulcers can result in chronic blood loss.

Copper Deficiency Anemia

Copper deficiency causes nonregenerative anemia due to impaired absorption and utilization of iron. The majority of copper in the blood is bound to ceruloplasmin, an enzyme that is required for the binding of iron to the transport protein, transferrin. Copper deficiency may be either primary due to deficient intake or secondary due to high molybdenum content of soils and forage. Copper deficiency results in microcytic, hypochromic anemia for the reasons outlined above for iron deficiency.

Cobalt Deficiency

Cobalt is an essential component of vitamin B₁₂ (cyanocobalamins). Camelid stomach microflora are presumed to synthesize vitamin B₁₂. Cobalt deficiency results in the depression of the vitamin B₁₂-containing enzyme 5-methyltetrahydrofolate homocysteine methyltransferase, which causes a reduction in folate metabolism and impedes DNA synthesis in developing erythrocytes. Anemia occurs late in the course of cobalt deficiency and may be normocytic or macrocytic.

Secondary Organ Failure

- Renal failure results in decreased production of erythropoietin necessary for erythropoiesis. RBC lifespan is decreased. Uremic acids inhibit hemostasis.
- Hepatic failure may result in decreased absorption, distribution, or utilization of elements necessary for erythropoiesis.
- Hypothyroidism leads to decreased erythropoiesis probably through decreased tissue O₂ requirements as well as a direct

effect on erythrocyte production.

SYSTEMS AFFECTED

- Hemic/Lymphatic/Immune
- Hepatobiliary—chronic hypoxia due to marked anemia results in centrilobular necrosis. Mild hyperbilirubinemia may occur due to decreased hepatic function and mass.
- Cardiovascular—hypoxia causes tachycardia; decreased blood viscosity and turbulent blood flow may occasionally result in an auscultable heart murmur.
- Respiratory—hypoxia results in tachypnea.
- Renal/urologic—chronic hypoxia may lead to renal tubular necrosis.
- Gastrointestinal—colic may occur secondary to gastric ulcers.

GENETICS

Young llamas affected with JLIDS are often anemic. Although there are apparent familial links in affected llamas, reliable genealogical information is not available and a definitive genetic basis has not been established.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Chronic blood loss due to intestinal parasitism may have an increased prevalence in areas endemic to associated parasites.

SIGNALMENT

Species

All camelids are susceptible to anemia. Llamas and alpacas may be more susceptible to iron and copper deficiency anemias than camels, but the condition is uncommon in all species.

Breed Predilections

N/A

Mean Age and Range

- Anemia due to chronic gastrointestinal blood loss secondary to gastric ulcers may occur in llamas and alpacas of all ages including nursing animals.
- Median age of llamas affected with JLIDS and that are anemic, 13.8 months; range 6 months–4 years.
- Anemia due to other causes may affect any age animal.

Predominant Sex

No sex predilection

SIGNS

HISTORICAL FINDINGS

Nonspecific signs of anemia include weakness, lethargy, anorexia, dyspnea, tachypnea; reddish-brown urine (hemoglobinuria) if anemia is severe; dark feces (melena); pica, decreased growth and productivity may occur in iron-, copper-, or cobalt-deficient animals; diarrhea in cobalt-deficient animals.

PHYSICAL EXAM FINDINGS

Pale mucous membranes, tachycardia, tachypnea, icterus if anemia is severe; melena occasionally observed in llamas with gastric ulcers; unthrifty appearance and poor hair coat reported with cobalt deficiency.

CAUSES AND RISK FACTORS

Anemia of Chronic Inflammation

- Any cause of inflammatory disease including internal or cutaneous infections, infectious diseases, traumatic tissue damage, or fractures
- Active malignant neoplasia—lymphosarcoma, squamous cell carcinoma, mammary and uterine adenocarcinoma
- Juvenile llama immunodeficiency syndrome (JLIDS)

Iron Deficiency Anemia

- Any form of chronic external blood loss
- Blood loss in adult camelids most commonly results from loss through the gastrointestinal tract
- Gastric ulcers and trichostrongylosis are frequent causes of GI blood loss
- Copper deficiency can lead to secondary iron deficiency

- Neonates on all-milk diets without access to soil
- Hemostatic defects

Copper Deficiency Anemia

- Primary copper deficiency—milk-fed animals, pastured animals on copper-deficient soils, pregnancy may exacerbate deficiency.
- Secondary copper deficiency—dietary molybdenum, sulfates or zinc excess (inhibits copper absorption).

Cobalt Deficiency

- Primary cobalt deficiency—cobalt-deficient soils or pastures heavily fertilized with limestone reduces cobalt available to plants and animals.
- Secondary cobalt deficiency—manganese, zinc, and iodine may antagonize utilization of cobalt.

Anemia Secondary to Organ Dysfunction

Chronic renal failure; hepatic dysfunction—hepatic lipidosis, ketosis, infectious hepatitis; endocrine disorders—hypothyroidism

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Specific features in the erythrogram are used to identify not only nonregenerative (depression) anemias from regenerative anemias, but also some specific causes of the anemia such as iron deficiency.

CBC/BIOCHEMISTRY/URINALYSIS

Anemia Due to Chronic Inflammation

CBC

- Normocytic, normochromic, nonregenerative anemia
- Mild decreases in RBC, Hgb, and PCV (anemia is rarely severe)
- Inflammatory leukogram—neutrophilia, \pm left shift, \pm toxic change (indicates bacterial etiology), \pm monocytosis (presence indicates inflammation of some duration or tissue damage/necrosis)
- Lymphopenia may indicate effects of stress (endogenous corticosteroid release)

\pm Thrombocytosis (reactive)

- Hyperfibrinogenemia often observed with more acute or active inflammatory conditions

Serum Biochemistry

- Hypoalbuminemia if active inflammation
- Hyperglobulinemia if chronic inflammation
- Hypoglobulinemia often observed in llamas with JLIDS, especially in the face of chronic and repeated infections

Anemia Due to Iron or Copper Deficiency

CBC

- Microcytosis indicated by a low mean cell volume.
- Hypochromia indicated by low mean corpuscular hemoglobin concentration.
- Mild to moderate decreases in RBC, Hgb, and PCV
- Anemia, either regenerative or nonregenerative; the latter is more common.
- Characteristic changes in erythrocytes observed on blood films include increased central pallor (hypochromia), anisocytosis, and moderate to marked poikilocytosis such as dacrocytes (teardrop shape).
- \pm Thrombocytosis

Serum Biochemistry

Hypoproteinemia is a consistent finding if iron deficiency is due to sustained gastrointestinal blood loss. Hypoalbuminemia and hypoglobulinemia.

Anemia Due to Cobalt Deficiency

CBC

- Normocytic to occasionally macrocytic, normochromic, nonregenerative anemia
- Mild decreases in RBC, Hgb, and PCV
- Stress (corticosteroid) leukogram

Serum Biochemistry

- If ketosis develops secondary to anorexia, ketone bodies may be detected in the serum.
- Increased liver enzyme activity—AST, SDH, GGT.

Urinalysis

If ketosis develops secondary to anorexia, ketone bodies (primarily acetoacetate) are detectable by urine dipstick.

Anemia Due to Secondary Organ Failure/Dysfunction—Chronic Renal Failure

CBC

- Normocytic, normochromic, nonregenerative anemia
- Mild decreases in RBC, Hgb, and PCV
- Inflammatory leukogram if suppurative nephritis present

Serum Biochemistry

High BUN, creatinine, \pm phosphorus; variably low bicarbonate, sodium, and chloride

Urinalysis

Isosthenuria (Sp. Gr. 1.008—1.012); variable proteinuria and active sediment

Anemia Due to Secondary Organ Failure/Dysfunction, e.g., Hepatic Lipidosis

CBC

- Normocytic, normochromic nonregenerative anemia
- Mild to moderate decreases in RBC, Hgb, and PCV
- Inflammatory leukogram if suppurative hepatitis present

Serum Biochemistry

High glucose, ketone bodies, SDH, LDH, AST, GGT, triglycerides, creatinine; variably high bilirubin; variable high or low BUN; low potassium, total protein, albumin, \pm phosphorus; variably low bicarbonate, sodium, and chloride.

Urinalysis

- Ketone bodies (note: acetoacetate and acetone are normally present in urine from pregnant alpacas, trace amount present in llama urine)
- Variable specific gravity variable proteinuria and active sediment

OTHER LABORATORY TESTS

Chronic Blood Loss/Iron Deficiency

- Hypoferremia (serum iron $\leq 60 \mu\text{g/dL}$)
- Decreased transferrin saturation
- Fecal flotation to rule out intestinal parasites (*Trichostrongylus*) as cause of blood loss
- Fecal occult blood test (caution: some plant peroxidases can result in a false positive.)

Copper Deficiency

Plasma copper levels

Cobalt Deficiency

Low serum cobalamin (vitamin B₁₂) concentration (cobalt concentration is not reliable).

Hepatic Lipidosis

High serum bile acids, nonesterified fatty acids (NEFA), beta-hydroxybutyrate

IMAGING

Chronic Blood Loss/Iron Deficiency

Radiographic or ultrasonographic imaging may reveal evidence of gastrointestinal disease accounting for blood loss.

OTHER DIAGNOSTIC PROCEDURES

Chronic Blood Loss/Iron Deficiency

- Gastric endoscopy may reveal evidence for gastric ulceration.
- Cytologic evaluation of bone marrow specimen stained with Prussian blue for iron particles should reveal the absence of

hemosiderin. Marrow evaluation for iron is only recommended when documentation of iron deficiency by other means is difficult.

PATHOLOGIC FINDINGS

Chronic Blood Loss/Iron Deficiency

Intestinal parasitism with mucosal petechiation; gastric ulcers

TREATMENT

The successful treatment of nonregenerative anemia usually revolves around correction of the underlying cause. General treatment and supportive care recommendations follow. See specific disease chapters for detailed treatment information.

ACTIVITY

Restrict

DIET

Correct dietary insufficiencies as described below and within specific nutritional deficiency chapters.

Chronic Inflammation

Determine source of inflammation and treat with appropriate antimicrobials if bacterial or fungal etiology. Hot pack external abscesses.

Chronic Blood Loss/Iron Deficiency

- Identify and correct the cause of external blood loss.
- Oral supplementation of iron is less effective than parenteral administration if anemia is severe, but a safe and effective dose for injectable iron dextran has not been established in camelids.
- Incorporation of ferrous sulfate into a mineral mix advised for prevention.

Copper and Cobalt Deficiencies

Addition of copper or cobalt to diet by feeding free-choice trace mineral/salt mix—effective only if animals consume the mix daily.

Renal Failure

- Increase RBC mass (blood transfusion) if patient is symptomatic for anemia ($PCV \leq 15\%$).
- Stabilize azotemia and carefully rehydrate with appropriate fluids.
- Correct electrolyte and acid-base imbalances with appropriate fluid therapy and supplementation when necessary.

CLIENT EDUCATION

Conditions associated with severe nonregenerative anemia or pancytopenia generally carry a guarded to poor prognosis and may require long-term therapy without complete resolution.

MEDICATIONS

DRUGS OF CHOICE

Specific therapy for increasing RBC mass:

- If anemia is unusually severe ($PCV \leq 15\%$), transfusion may be required to treat life-threatening anemia. Whole blood, 0.1 ml/kg at a rate of 5–20 ml/kg/hr.
- Numerous blood types are present in the llama and alpaca. However, incompatibility reactions are very rare with the first transfusion. Subsequent transfusions increase the risk for an adverse reaction. Blood cross matching is advised for repeated transfusions.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

Oxyglobin has been used successfully in dogs, cats, and horses. If packed RBCs or whole blood is not available, Oxyglobin may be a suitable alternative in cases of severe anemia or until whole blood products are available.

FOLLOW-UP

PATIENT MONITORING

- Respiration and heart rate, mucous membrane color
- In patients with severe anemia, CBC or PCV with blood smear examination every 1–2 days
- In stabilized animals with a chronic disease or slowly improving disease course, reevaluation every 7–10 days

PREVENTION/AVOIDANCE

See specific chapters for nutritional deficiencies, intestinal parasites, etc.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Clinical course and prognosis vary and are associated with the underlying disease condition causing the nonregenerative anemia. Other cytopenias in addition to the anemia typically warrant a guarded to poor prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

The mean age of llamas affected with JLIDS is 13.8 months.

ZOONOTIC POTENTIAL

ANEMIA, REGENERATIVE: BOVINE

BASICS

DEFINITION

- Anemia in adult cattle is indicated by a PCV (or Hct) of less than 23%.
- Beef cattle have higher hemoglobin, RBC, and PCV than dairy breeds.
- Anemias may be nonregenerative or regenerative. The presence of reticulocytes, polychromasia, and increased red cell distribution width (RDW) is indicative of a regenerative response.
- Lactating dairy cattle tend to have lower values than nonlactating cows.
- Bulls tend to have greater RBC counts than cows.
- Environmental, seasonal, and physiological differences may affect the hemogram.
- Diminished oxygen tension at elevated altitudes stimulates erythropoiesis resulting in increased RBC counts.

PATHOPHYSIOLOGY

- Anemia results from decreased production or increased destruction (hemolysis) or loss (hemorrhage) of erythrocytes. Regenerative anemias are caused by hemolysis or hemorrhage.
- Anemia caused by hemolysis or hemorrhage and the related signs may be insidious or acute.
- Recognition of the indicators of erythropoietic response (reticulocytosis, polychromasia, and increased RDW) to hemorrhage- or hemolysis-induced hypoxia will not be evident for 3 to 6 days after the onset of anemia because the proliferation and differentiation of precursor cells of the erythropoietic series must occur. These events require several mitotic events and considerable protein, especially hemoglobin, synthesis. A single precursor cell may give rise to 16 to 32 mature RBCs.

Hemorrhagic Anemia

Hemorrhage is caused by vessel injury or disease. It may be internal (within the body) or external. With external hemorrhage, blood cells and their iron are lost from the system. Thus, the regenerative response is typically mild to moderate. Chronic external blood loss (e.g., GI bleeding) often leads to a nonregenerative anemia due to iron depletion. In peracute and acute hemorrhage, response to anemia-induced hypoxia will not be recognized by CBC parameters for 3 to 6 days after the initial hemorrhage.

Hemolytic Anemia

Hemolysis results from intravascular, extravascular (primarily in the spleen and/or liver), or a combination of both intravascular and extravascular destruction of RBCs. In contrast to hemorrhagic anemia, the regenerative response to hemolytic anemia is quite vigorous since iron is retained and is readily utilized for erythropoiesis. Extravascular hemolysis occurs as a result of erythrocyte sequestration in the spleen or liver where they are phagocytosed or lysed by the mononuclear phagocytic system. Hemolysis may be antibody and/or complement mediated, associated with infectious agents, drugs, or alterations in the immune system. Infectious agents may alter membrane antigens, form immune complexes that adsorb to the RBCs and fix complement, or cross-reacting antibody may be formed in response to the infectious agent. Less frequently, alterations in immune function may be secondary to some lymphoid malignancies. Intravascular hemolysis may be secondary to complement-mediated lysis such as with IgM-involved immune mediated anemia, neonatal isoerythrolysis or incompatible transfusions. Traumatic injury to the RBCs from intravascular fibrin deposition due to DIC or vasculitis can cause intravascular hemolysis. Oxidative injury to hemoglobin results in Heinz body formation that may cause RBC membrane damage sufficient to cause hemoglobin leakage and hemoglobinemia

SYSTEMS AFFECTED

- Hemic/lymphatic/immune—moderate to marked erythrocyte hyperplasia in the bone marrow. Splenomegaly can be a feature of extravascular hemolysis.
- Hepatobiliary—hypoxia due to marked anemia results in centrilobular necrosis. Hyperbilirubinemia may occur due to hypoxic hepatic injury and decreased hepatic functional mass, but icterus in patients with hemolytic anemia is primarily

prehepatic.

- Cardiovascular—hypoxia causes tachycardia; decreased blood viscosity and turbulent blood flow may occasionally result in an auscultable heart murmur.
- Respiratory—hypoxia results in dyspnea and tachypnea.
- Renal/urologic—chronic hypoxia may lead to renal tubular necrosis. Additionally, free hemoglobin may precipitate in tubules and lead to renal failure.
- Central nervous system, liver, and kidney are particularly susceptible to hypoxia.

GENETICS

- Congenital erythropoietic porphyria is inherited in an autosomal recessive manner in Holstein cattle. It has also been recognized in shorthorn and Jamaican cattle.
- Coagulation factor VIII deficiency is inherited in a sex-linked recessive manner in Hereford cattle.
- Coagulation factor XI deficiency is inherited in an autosomal recessive manner in Holstein cattle.
- *Bos indicus* breeds exhibit resistance to babesiosis.

INCIDENCE/PREVALENCE

Anaplasmosis and babesiosis are endemic to locales with the proper tick vectors.

GEOGRAPHIC DISTRIBUTION

- Hemorrhagic and hemolytic conditions occur worldwide.
- Certain toxicosis and deficiencies are confined to specific regions depending upon geological origin, ecological features, or agricultural practices.
- Hemolytic anemia due to infectious organisms such as *Babesia* and *Anaplasma* species occur in areas endemic for the vectors associated with these organisms.

SIGNALMENT

Breed Predilections

- Hemorrhage and hemolysis may occur with cattle of all types.
- Cattle on range in endemic areas for some infectious agents that cause anemia are more likely to be affected than confined cattle in the same geographic area.
- Coagulation factor VIII deficiency is inherited in a sex-linked recessive manner in Hereford cattle.
- Coagulation factor XI deficiency and erythropoietic porphyria are inherited as autosomal recessives in Holstein cattle.

Mean Age and Range

- Anaplasmosis and babesiosis occur most frequently in adult cattle.
- Neonatal isoerythrolysis occurs within 24 to 48 hours after birth.
- Erythropoietic porphyria is usually recognized during the first 10 days after birth.
- Inherited coagulopathies are recognized in very young cattle. They may first be manifested after castration or minor trauma.
- Anemia due to other causes may affect any age animal.

Predominant Sex

Factor VIII deficiency is sex-linked. Therefore, it is a disease of newborn males.

SIGNS

HISTORICAL FINDINGS

- Signs of anemia include weakness, lethargy, depression, inability and reluctance to exercise, decreased milk production, and anorexia.
- With anaplasmosis, there may be a history of recent movement of cattle from a nonendemic area.

PHYSICAL EXAMINATION FINDINGS

- Pale or icteric mucous membranes, tachycardia, tachypnea, melena in animals with intestinal bleeding, frank external bleeding, petechia, ecchymosis, icterus, hemoglobinuria
- Frank, extreme, external bleeding is obvious, but intestinal or internal bleeding may be difficult to recognize.
- Icterus is often seen with intravascular and extravascular hemolytic anemia, but hemoglobinuria occurs only with intravascular hemolysis. Icterus may not be recognized with some cases of hemolytic anemia.

CAUSES AND RISK FACTORS

Anaplasmosis

- Anaplasmosis is a hemolytic disease caused by the rickettsial organisms *Anaplasma marginale* and *Anaplasma centrale*. Transmission between animals is generally by ticks (*Dermacentor andersoni* in western North America), but mechanical transmission by biting flies, mosquitoes, hypodermic needles, dehorning, castrating, and ear tagging can occur.
- *A. marginale* are small (0.5–1 μ m diameter) inclusions along the margin of mature erythrocytes. *A. centrale* are of similar size but are found near the center of the erythrocytes. Generally, a single organism is found, but two or more organisms can be found occasionally especially in severe cases.
- *A. marginale* causes extravascular hemolytic anemia in adult cattle 3 years old or older. Animals less than 1 year old are resistant. Anemia develops through an immune reaction wherein antibody binds to infected erythrocytes, which are subsequently removed by mononuclear phagocytes of the spleen, liver, etc.
- Major clinical features are those of hemolytic anemia including pale mucous membranes, icterus, dyspnea, tachypnea, tachycardia, fever, lethargy, and reluctance to move.
- Diagnosis is based on finding organisms associated with erythrocytes or by card agglutination test.
- Laboratory features include moderate to severe anemia with evidence of response including reticulocytosis, polychromasia, microcytosis (increased MCV), hypochromasia (decreased MCHC), and increased RDW along with hyperbilirubinemia.
- Two vaccines are currently used to produce immunity in cattle. One consists of modified-live organisms and the other contains killed organisms. The live vaccine is only available in California. It should only be given to calves under 11 months of age. The killed vaccine can be given to cattle of any age. Two doses must be given in order to obtain full immunity. A killed vaccine that is no longer on the market has been implicated in producing neonatal isoerythrolysis (NI) in calves born to cows that were vaccinated in the last trimester. Apparently neither of the current vaccines has been evaluated for the potential for producing NI. (It is unlikely that the live vaccine would do so since it should not be used in animals of reproductive age.)
- Affected cattle are typically treated with tetracycline antibiotics.
- Also, tetracyclines can clear carrier cattle of *A. marginale*. From two to five treatments with LA-200 (long-acting tetracycline injectable product) given at 7-day intervals will clear the anaplasmosis organism from infected carrier cattle. However, cattle that are cleared will be susceptible and can be re-infected.

Babesiosis

- Babesiosis is a hemolytic disease caused by the protozoan organisms *Babesia bovis* and *Babesia bigemina*.
- *B. bovis* and *B. bigemina* are piroplasm (piriform, teardrop shaped) bodies found in erythrocytes that are approximately 2 μ m (*B. bovis*) or 4 μ m (*B. bigemina*) in diameter. Usually there are pairs of organisms, but greater numbers (usually multiples of 2) can be found occasionally.
- *Babesia* species cause intravascular hemolysis, which may cause visually detectable hemoglobinuria and hemoglobinemia.
- Major clinical features are those of hemolytic anemia including pale mucous membranes, icterus, hemoglobinuria, hemoglobinemia, dyspnea, tachypnea, tachycardia, fever, lethargy, and reluctance to move.
- Diagnosis is based on finding piriform organisms in erythrocytes. Capillary blood has higher numbers of organisms than does large vessel blood. Additionally, the infected erythrocytes are in greater numbers at the edge of blood smears than they are in the central, monolayer area. Thick blood smears improve the likeliness of finding organisms.
- Laboratory features include moderate to severe anemia with evidence of response including reticulocytosis, polychromasia, microcytosis (increased MCV), hypochromasia (decreased MCHC), increased RDW, hyperbilirubinemia, hemoglobinuria, and hemoglobinemia.
- Imidocarb has been used for therapy.
- An attenuated vaccine has been produced and successfully used in Australia for the prevention of *B. bovis*.
- *Bos indicus* breeds exhibit resistance.

Eperythrozoonosis

- *Mycoplasma wenyonii* (basonym *Eperythrozoon wenyonii*) occurs worldwide as a latent infection in healthy cattle. It causes hemolytic anemia only in critically ill cattle.
- Significant parasitemia without anemia but with hind limb edema and lymphadenopathy has been reported in cattle.
- On blood smears, *E. wenyonii* are small (0.5 μ m diameter) basophilic, pleomorphic organisms. They vary from ring forms to cocci to rods.
- General signs of anemia may accompany those of other diseases that allowed the organisms to cause hemolysis.

Theileriosis

- *Theileria parva* and *Theileria annulata* are pathogenic for cattle. *T. parva* causes East Coast fever in Africa, and *T. annulata* causes tropical theileriosis in the Mediterranean area, the Middle East, and Asia.
- *T. annulata* causes hemolytic anemia with hemoglobinuria.
- Pleomorphic merozoites of approximately 1 μ m diameter and varying from ring- to comma-shaped are found within erythrocytes.

Trypanosomiasis

Several trypanosomes cause hemolytic and/or nonregenerative anemia in cattle. ***Bacillary Hemoglobinuria***

BACILLARY HEMOGLOBINURIA

- Bacillary hemoglobinuria is a highly fatal disease caused by *Clostridium haemolyticum* in damaged liver tissue.
- Often there is an association with massive liver fluke (*Fasciola hepatica*) migration, but liver damage from toxins, inflammation, and biopsy can cause the development of hypoxic areas that allow the anaerobic organisms to grow and produce toxins (including β toxin) that cause hemolysis.
- Generally, the disease is rapidly fatal and diagnosis is made from history of sudden death and postmortem lesions. Postmortem lesions include pale and icteric mucous membranes, large volumes of red-tinged fluid in abdominal and thoracic cavities, hemoglobinuria, hemoglobin casts, and liver lesions that may include the presence of liver flukes, necrotic biopsy site, or other indicators of liver damage.

Other Bacterial Diseases That Cause Anemia

- Many bacterial infections may cause anemia. Generally, the anemia is due to the erythropoietic depression that occurs with inflammation (see Anemia, Nonregenerative).
- Infection with *Leptospira* species may cause hemolytic anemia in calves.

Postparturient Hemoglobinuria

- Sporadic cases of anemia accompanied by hemoglobinuria occur throughout the world in dairy cows during the first month after calving. The anemia is often severe and may be regenerative if the cow has been anemic for several days.
- Although it is not completely understood, hypophosphatemia due to loss in milk is thought to disrupt erythrocyte energy metabolism, which results in erythrocyte lysis.
- Treatment is with sodium phosphate solution or transfusions (if economically reasonable).

Copper Toxicosis

- Copper toxicosis most commonly causes hemolytic anemia in sheep. However, calves may develop massive hemolytic anemia when copper accumulated through long-term ingestion is released from liver storage. Copper interacts with membrane proteins leading to lysis of the cells.
- Massive hemolysis leads to sudden death. Hematological features suggesting response to anemia are not found because the extreme peracute hemolysis does not allow sufficient time for the hypoxic stimulus to produce new erythrocytes.

Heinz Body Anemia Toxicosis

- Heinz bodies form through oxidation of sulfur containing amino acids of hemoglobin and other proteins of erythrocytes, which denatures the proteins and results in inclusion bodies in erythrocytes. These inclusion bodies are called Heinz bodies, and they are most readily detected by microscopic examination of smears of blood that have been incubated with new methylene blue.
- Erythrocytes containing Heinz bodies are removed from the blood by the mononuclear phagocyte system. This extravascular hemolysis can result in severe, rapidly developing anemia.
- Numerous oxidative substances have been implicated in the production of Heinz bodies. Some oxidants include wild or domestic onions and members of the Brassica family (turnips, kale, and rape). The cause of anemia of copper toxicosis is oxidation of erythrocytes.
- Animals from selenium-deficient areas are of increased risk to develop Heinz body anemia because selenium is a vital component of the erythrocyte enzyme glutathione peroxidase, which participates in the antioxidant activity of erythrocytes. Blood glutathione peroxidase activity has been used as an indicator of selenium deficiency in cattle, but this method has been replaced by trace mineral analysis.
- Heinz body formation may cause massive hemolysis leading to sudden death. Hematological features suggesting response to anemia are not found because the extreme, peracute hemolysis does not allow sufficient time for the hypoxic stimulus to produce new erythrocytes.

- Animals with Heinz-body-mediated anemia may be icteric and have hyperbilirubinemia provided they live long enough for hemoglobin to be catabolized to bilirubin.

Water Intoxication Toxicosis

- Intake of large amounts of water can result in intravascular erythrocyte lysis due to extreme, rapidly developing blood hypotonicity.
- Milk-fed calves may develop severe anemia when first given access to unlimited amounts of water.
- Cattle given sudden access to water after being deprived of water such as with extreme cold when all supplies are frozen may suddenly develop severe anemia.
- Features of severe water toxicosis include severe anemia, hypoproteinemia, hemoglobinuria, hypotonicity with decreased electrolyte concentrations.

Congenital Erythropoietic Porphyria

- Congenital erythropoietic porphyria (CEP) is an inherited disease of cattle, particularly Holsteins.
- CEP is caused by a defect in production of the heme portion of hemoglobin. In addition to decreased erythrocyte production, toxic porphyrin products are present in high concentrations in erythrocytes.
- The abnormal porphyrins in high concentrations are toxic to the erythrocytes resulting in hemolysis. In addition, hemoglobin production is decreased, which results in decreased erythrocyte production.
- Affected calves develop severe photosensitivity in the light parts of their hair coat. Teeth are dark and fluoresce under ultraviolet light. Urine is often dark and also fluorescent.

Traumatic or Ulceration Induced Hemorrhage

- Bleeding is generally obvious with external hemorrhage, but internal hemorrhage into cavities or the intestines may be difficult to recognize.
- Dark-colored feces may indicate bleeding in the upper gastrointestinal tract; red-stained feces suggest bleeding in the lower GI tract.
- Red urine may be due to hemoglobin, which is suggestive of intravascular hemolysis, or hematuria (erythrocytes in urine), which is suggestive of hemorrhage into either the urinary tract or the genital system.
- Chronic ingestion of bracken fern (*Pteridium aquilinum*) causes urinary bladder hemorrhage in cattle and sheep. (See Anemia, Nonregenerative: Bovine.)

Inherited Coagulopathies

- Factor VIII deficiency (hemophilia A) has been described in Hereford cattle in Australia. Hemophilia A is inherited in a sex-linked recessive manner; therefore, it is essentially a condition of males. Clinical features include profuse bleeding and death after surgery such as castration. Diagnosis depends upon determination of prothrombin time (normal), partial thromboplastin time (markedly prolonged), and factor VIII levels (markedly decreased).
- Factor XI deficiency has been described in Holstein cattle. It is inherited as a simple autosomal recessive. Spontaneous bleeding is rare, and delayed (12–14 hours), often severe hemorrhage occurs following surgery or trauma. Diagnosis depends upon determination of prothrombin time (normal), partial thromboplastin time (markedly prolonged). Specific diagnosis requires determination of factor XI levels.

Vitamin K Antagonist Rodenticide Toxicity Coagulopathies

- Damaged or moldy sweet clover hay and coumarin and indandione anticoagulant rodenticides and pharmaceuticals cause bleeding by inhibiting the production of functional coagulation factors II (prothrombin), VII, IX, and X. Hemorrhages may occur in the cerebral vasculature, abdominal cavity, pericardial sac, mediastinum, thorax, subcutaneously, or into joints. Outward signs of hemorrhage may not exist.
- Diagnosis depends upon determination of prothrombin time (prolonged) and partial thromboplastin time (prolonged) along with history, laboratory analysis for detection of specific anticoagulants in biological fluids, or analysis of suspect hay or silage for dicumarol content.
- Therapy consists of injectable vitamin K₁ (1–3 mg/kg BW). Because there is great variation in the duration of activity of the various rodenticides, it may be necessary to maintain therapy for several weeks. In small animals and humans, the coagulation test PIVKA (proteins induced by vitamin K absence or antagonism) has been successfully used to determine when vitamin K therapy can be stopped.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- On the hemogram, regenerative anemia is distinguished from nonregenerative anemia by the presence of reticulocytosis, polychromasia, increased RDW, microcytosis, and hypochromasia.
- Anemia due to either hemolysis or hemorrhage may be distinguished by evaluation of bilirubin and protein concentration. Frequently, hyperbilirubinemia occurs in hemolytic anemia. Hypoproteinemia is a common finding in external hemorrhage. However, internal hemorrhage may not cause significant decrease in plasma protein concentration.
- Specific etiologic diagnosis requires evaluation of blood smears for organisms, culture of tissues, immunology-based testing, and possibly PCR for specific gene sequences.

CBC/BIOCHEMISTRY/URINALYSIS

Anaplasmosis

CBC

- Moderate to marked decreases in RBC, Hgb, and PCV
- Regenerative anemia with numerous typical inclusion bodies on RBCs
- Inflammatory leukogram—neutrophilia, \pm left shift
- Lymphopenia may indicate effects of stress (endogenous corticosteroid release).

Serum Biochemistry

- Hyperbilirubinemia
- Normal plasma protein
- Increased liver enzyme activity—AST, SDH, GGT

Babesiosis

CBC

- Moderate to marked decreases in RBC, Hgb and PCV
- Regenerative anemia with occasional, typical inclusion bodies in RBCs
- Inflammatory leukogram—neutrophilia, \pm left shift
- Lymphopenia may indicate effects of stress (endogenous corticosteroid release)

Serum Biochemistry

- Hyperbilirubinemia
- Normal plasma protein
- Increased liver enzyme activity—AST, SDH, GGT

Urinalysis

Hemoglobinuria

Heinz Body Anemia

CBC

- Moderate to marked decreases in RBC, Hgb, and PCV
- Either nonregenerative or regenerative anemia depending upon the duration of the condition.
- Many typical inclusion bodies in RBCs that are best revealed with new methylene blue staining

Serum Biochemistry

- Hyperbilirubinemia depending on the duration of the condition
- Normal plasma protein

Postparturient Hemoglobinuria

Serum Biochemistry

Hypophosphatemia in affected cows and in other cows of the dairy

Water Toxicosis

CBC

Nonregenerative anemia

Serum Biochemistry

- Decreased plasma protein concentrations
- Hyponatremia, hypochloremia, decreased osmolarity

Hemorrhage

CBC

- Regenerative anemia but generally not as robust as in hemolytic anemia
- Variable decreases in RBC, Hgb, and PCV

Serum Biochemistry

- Hypoproteinemia especially with external bleeding
- Increased liver enzyme activity—AST, SDH, GGT

Urinalysis

Hematuria (intact erythrocytes in urine) if bleeding is urogenital

OTHER LABORATORY TESTS

Anaplasmosis

In addition to recognizing organisms on erythrocytes, diagnosis is through the CF (complement fixation) or RCA (rapid card agglutination) tests.

Babesiosis

- Complement fixation and indirect fluorescent antibody tests are available from National Veterinary Services Laboratories (USDA: APHIS).
- A PCR method has been developed for detecting *B. bovis* carrier cattle. Its sensitivity is significantly improved over that of current methods.

Heinz Body Anemia

Possible low blood selenium concentrations

Bacillary Hemoglobinuria

Culture of liver; however, caution must be used when interpreting the results because *Clostridium* species often proliferate in tissues after death.

Copper Toxicosis and Selenium Deficiency

Trace metal analysis

Congenital Erythropoietic Porphyria

Blood or urine porphyrin analysis in animals of proper breed and with skin and teeth lesions

OTHER DIAGNOSTIC PROCEDURES

Bone Marrow Evaluation

Cytological evaluation of bone marrow specimen is not indicated when response to anemia-driven hypoxia is recognized by hematological features (reticulocytosis, polychromasia, macrocytosis, hypochromasia, and increased RDW).

PATHOLOGIC FINDINGS

Hemolytic Anemias

- Enlarged spleen and liver may be found with many hemolytic anemias especially those of extravascular pathogenesis.
- Tissues may be pale or have a red appearance. In massive hemolytic anemias (e.g., copper toxicosis), the kidneys may be dark and have a “gun metal” appearance.
- Hemoglobinuria indicates extravascular hemolysis.
- Liver lesions including liver flukes, biopsy site necrosis may be suggestive of bacillary hemoglobinuria.
- Discolored bone and teeth in congenital erythropoietic porphyria

Hemorrhage

Large amounts of blood in intestines, thorax, abdomen, joints, etc.; petechia and ecchymosis of skin, sclera, urinary tract, mucous membrane; and ulcers of the intestinal tract may be found with various causes of hemorrhage.

TREATMENT

- Successful treatment depends upon specific therapy for the underlying cause of the anemia. Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Transfusion may be used with animals that are of sufficient value to make the procedure economically feasible. Generally, it is unlikely that a recipient that has never received a transfusion will experience a transfusion reaction. Therefore, almost any adult bovine can be used as a donor. Occasionally, transfusion reactions may occur because of J antigen incompatibilities.

ACTIVITY

Restrict activity until the animal(s) can exert themselves without developing significant dyspnea.

DIET

Correct dietary insufficiencies such as selenium deficiency or excess copper in the diet.

CLIENT EDUCATION

- Advise clients in anaplasmosis-endemic areas to purchase replacement cows from anaplasmosis-endemic areas or purchase heifers that were vaccinated for anaplasmosis as calves.
- Advise clients to use proper anthelmintic therapy for liver flukes.

MEDICATIONS

DRUGS OF CHOICE

- Cattle with anaplasmosis are typically treated with tetracycline antibiotics.
- Also, tetracyclines can clear carrier cattle of *A. marginale*. From two to five treatments with LA-200 (long-acting tetracycline injectable product) given at 7-day intervals will clear the anaplasmosis organism from infected carrier cattle. However, cattle that are cleared will become susceptible and can be reinfected.
- Imidocarb has been used for therapy for babesiosis.
- If economically feasible, anticoagulant rodenticide toxicity can be treated with injectable vitamin K₁ (1–3 mg/kg BW). PIVKA can be used to determine when therapy can be discontinued.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

Cattle treated with tetracycline antibiotics at dosages that clear *Anaplasma* organisms are susceptible to reinfection.

FOLLOW-UP

PATIENT MONITORING

- Respiration and heart rates and mucous membrane color are useful for recognizing the success of therapy.
- In patients with severe anemia, CBC or PCV with a blood smear examination should be performed every 1–2 days until a significant erythropoietic response is recognized.

PREVENTION/AVOIDANCE

- If animals are to be pastured on range endemic for anaplasmosis, they should be vaccinated or purchased from an endemic area. Modified-live vaccine should be used only in calves less than 11 months old.
- An attenuated vaccine has been produced and successfully used in Australia for the prevention of *B. bovis*. *Bos indicus* breeds exhibit resistance to *Babesia* species.
- Appropriate anthelmintic therapy should be used in order to prevent liver fluke parasitism.
- Possibly initiate phosphorus supplementation if soil or feed is deficient especially in high producing dairy cows.

- Possibly provide selenium supplementation if soil or feed is deficient.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Clinical course and prognosis vary and are associated with the underlying disease condition causing the anemia.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- Adult cattle that have neither been vaccinated nor raised in endemic areas are highly susceptible to anaplasmosis, but calves develop resistance.
- Adult cattle are more susceptible to babesiosis than calves.

ZOONOTIC POTENTIAL

ANEMIA, REGENERATIVE: CAMELIDS

BASICS

DEFINITION

- A syndrome characterized by decreased circulating RBC mass (anemia in adult llamas and alpacas indicated by a PCV $\leq 25\%$; in camels a PCV $\leq 28\%$ indicates anemia), together with an appropriate compensatory increase in RBC production by the bone marrow.
- The presence of polychromasia, reticulocytes \pm nucleated erythrocytes are indicative of an appropriate regenerative response.
- Because it takes the bone marrow 3–5 days for a maximum response, evidence for regeneration may not be apparent until several days after the onset of anemia.
- High concentrations of erythrocytes are observed in healthy camelids, but because the cells have a small mean cell volume, the PCV, or Hct, is relatively low.

PATHOPHYSIOLOGY

- Anemia may result from either decreased production or increased destruction of erythrocytes. Regenerative anemias are most often associated with two general mechanisms: blood loss (hemorrhage) or hemolysis. Chronic blood loss can result in iron deficiency and nonregenerative anemia. Trichostrongyle infection causes a mildly regenerative, normocytic, normochromic blood loss anemia.
- Hemolysis in camelids most commonly occurs secondary to anti-RBC antibodies formed against altered erythrocyte membrane antigens. Infectious organisms (e.g., *Leptospira interrogans*, *Trypanosoma*, hemotrophic *Mycoplasma*), exposure of previously unexposed antigens, or adsorption of antigen-antibody complexes to the erythrocyte membrane can alter RBC membrane antigens and render RBCs susceptible to accelerated destruction or removal by the mononuclear-phagocytic system of the spleen and/or liver (extravascular hemolysis). Certain bacterial infections (i.e., *Clostridium perfringens* type A) cause direct erythrocyte damage due to hydrolysis of membrane phospholipids. The result is marked intravascular hemolysis.
- RBC parasites such as *Candidatus Mycoplasma haemolamae* (formerly *Eperythrozoon* spp.) adhere to the surface of RBC membranes. Affected erythrocytes are removed by the mononuclear-phagocytic system of the spleen and/or liver. Young llamas and alpacas are more susceptible to acute infection and severe parasitemia with clinically significant extravascular hemolysis. Anemia may be nonregenerative or regenerative depending on the presence or lack of other clinical problems.

Hemorrhagic Anemia

RBCs are lost from the vasculature due to vascular injury or disease. Hemorrhage may be internal (within the body) or external. RBC lifespan is unaltered in this condition. Both blood cells and iron are lost from the body with external hemorrhagic anemia. Thus, the regenerative response is typically mild to moderate. Chronic external blood loss (e.g., GI bleeding) often leads to a nonregenerative anemia due to iron depletion.

Hemolytic Anemia

In patients with hemolytic anemia, the vasculature is typically intact. Hemolysis results from intravascular, extravascular (primarily in the spleen and/or liver) or a combination of both intravascular and extravascular destruction of RBCs. In contrast to hemorrhagic anemia, the regenerative response to hemolytic anemia is quite vigorous since iron is retained and is readily utilized for erythropoiesis. Extravascular hemolysis occurs as a result of erythrocyte sequestration in the spleen or liver where they are phagocytosed or lysed by the mononuclear phagocytic system. Hemolysis may be antibody and/or complement mediated, associated with infectious agents, drugs, or alterations in the immune system. Infectious agents may alter membrane antigens, form immune complexes that adsorb to the RBC and fix complement, or cross-reacting antibody may be formed in response to the infectious agent. Less frequently, alterations in immune function occur secondary to some lymphoid malignancies. Intravascular hemolysis may occur secondary to complement-mediated lysis such as with IgM-

involved immune-mediated anemia, neonatal isoerythrolysis, or incompatible transfusions. Traumatic injury to the RBCs from intravascular fibrin deposition due to DIC or vasculitis can cause intravascular hemolysis. Oxidative injury to hemoglobin results in Heinz body formation that may cause RBC membrane damage sufficient to cause hemoglobin leakage and hemoglobinemia. The unique shape and low osmotic fragility of camelid RBCs probably render a protective effect against hemolysis from oxidative injury, unless severe.

SYSTEMS AFFECTED

- Hemic/Lymphatic/Immune—moderate to marked erythrocyte hyperplasia in the bone marrow. Splenomegaly can be a feature of extravascular hemolysis.
- Hepatobiliary—hypoxia due to marked anemia results in centrilobular necrosis. Hyperbilirubinemia may occur due to hypoxic hepatic injury and decreased hepatic functional mass, but icterus in patients with hemolytic anemia is primarily prehepatic.
- Cardiovascular—hypoxia causes tachycardia; decreased blood viscosity and turbulent blood flow may occasionally result in an auscultable heart murmur.
- Respiratory—hypoxia results in tachypnea.
- Renal/urologic—chronic hypoxia may lead to renal tubular necrosis. Free hemoglobin is also nephrotoxic and can lead to renal failure.

GENETICS

Young llamas affected with juvenile llama immunodeficiency syndrome (JLIDS) are often anemic. Although there are apparent familial links in affected llamas, reliable genealogical information is not available and a definitive genetic basis has not been established.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Chronic blood loss due to intestinal parasitism may have an increased prevalence in areas endemic to associated parasites.

SIGNALMENT

Species

All camelids are susceptible to anemia. Llamas and alpacas may be more susceptible to RBC parasitism than camels are.

Mean Age and Range

- Anemia due to infection with *Candidatus Mycoplasma haemolamae* generally affects llamas and alpacas ≤ 1 year; range neonate to adult.
- Median age of llamas affected with JLIDS and that are anemic 13.8 months; range 6 months–4 years.
- Anemia due to other causes may affect any age animal.

Predominant Sex

No sex predilection

SIGNS

HISTORICAL FINDINGS

Nonspecific signs of anemia include weakness, lethargy, anorexia, dyspnea, tachypnea; reddish-brown urine (hemoglobinuria) if hemolysis is severe; dark feces (melena).

PHYSICAL EXAMINATION FINDINGS

Clinical signs of hemorrhage with blood loss; pale or icteric mucous membranes; tachycardia; tachypnea; melena occasionally observed in llamas with gastric ulcers

CAUSES AND RISK FACTORS

Blood Loss/Hemorrhagic Anemia

Blood loss may be subdivided into acute and chronic causes of hemorrhage.

Acute Hemorrhage

Trauma, lacerations, GI ulcers, and hemostatic defects such as DIC, spoiled sweet clover hay poisoning, anticoagulant rodenticides, and bracken fern poisoning.

Chronic Hemorrhage

Intestinal parasites, GI ulcers or tumors, hematuria, vascular neoplasm, vitamin K deficiency, and thrombocytopenia

Hemolytic Anemia

Many of the causes listed below have both intravascular and extravascular components, but are listed where the majority of the hemolysis occurs.

Intravascular Hemolysis

Leptospirosis, bacillary hemoglobinemia/hemoglobinuria, copper toxicity, molybdenum deficiency, propylene glycol, vitamin K₃, incompatible transfusions, hypophosphatemia.

Extravascular Hemolysis

Mycoplasma haemolamae (formerly *Eperythrozoon*), *Trypanosoma* spp., occasionally drugs such as penicillin, hemangiosarcoma, autoimmune mediated hemolytic anemia (uncommon in camelids).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Regenerative anemia is differentiated from nonregenerative anemia by increased reticulocyte count, polychromasia and \pm nucleated RBCs. Specific features of the erythrogram, biochemical profile, and urinalysis are used to differentiate among blood loss anemia and intravascular and extravascular hemolysis.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia in adult llamas and alpacas is indicated by a PCV of less than 25%. A PCV of $\leq 28\%$ in camels is indicative of anemia.
- High concentrations of erythrocytes are observed in healthy camelids, but because the cells have a small mean cell volume, the PCV, or hematocrit, is relatively low.

Anemia Due to Blood Loss/Hemorrhage

CBC

- If blood loss is chronic, one may observe normocytic to microcytic, normochromic to hypochromic anemia with mild reticulocytosis. Higher reticulocyte counts may be observed with internal hemorrhage compared to external blood loss.
- Acute blood loss may result in normocytic, normochromic, nonregenerative anemia if the bone marrow has not had adequate time to respond (usually 3–5 days).
- Mild to marked decreases in RBC, Hgb, and PCV (degree of anemia based upon severity and duration of blood loss). Internal hemorrhage is usually associated with less-severe anemia.
- Anisocytosis, polychromasia, poikilocytosis.
- Inflammatory leukogram—neutrophilia, \pm monocytosis (tissue damage/necrosis due to trauma).
- Lymphopenia may indicate effects of stress (endogenous corticosteroid release).

Thrombocytosis (reactive) Serum Biochemistry Hypoproteinemia is associated with chronic blood loss (e.g., GI bleeding).

Urinalysis Hematuria due to urinary tract hemorrhage. (Rarely is urinary tract hemorrhage alone severe enough to cause clinical signs of anemia.)

Intravascular Hemolytic Anemia

CBC

- MCV is normal to increased. MCHC is typically low, but a falsely increased MCHC may occur due to hemoglobinemia.
- Moderate reticulocytosis (counts are higher in hemolytic anemia than external hemorrhagic anemia).
- Moderate to marked decreases in RBC, Hgb, and PCV.
- Anisocytosis, polychromasia, abnormal erythrocyte morphology (e.g., Heinz bodies, RBC parasites, schistocytes, keratocytes)
- Inflammatory leukogram (neutrophilia with left shift, \pm monocytosis)
- \pm Thrombocytosis
- Normal to increased plasma protein concentration

Serum Biochemistry

- Hyperbilirubinemia

- Hyperproteinemia due to hyperglobulinemia

Urinalysis

Hemoglobinuria

Extravascular Hemolytic Anemia

CBC

- MCV is normal to increased. MCHC is typically low.
- Moderate reticulocytosis (counts are higher in hemolytic anemia than external hemorrhagic anemia).
- Moderate to marked decreases in RBC, Hgb, and PCV
- Inflammatory leukogram (neutrophilia with left shift, \pm monocytosis)
- \pm Thrombocytosis

Serum Biochemistry

Hyperbilirubinemia if magnitude of hemolysis exceeds liver capacity to process

Urinalysis

Hemoglobinuria is absent.

OTHER LABORATORY TESTS

Blood Loss/Hemorrhage

- Fecal flotation to rule out intestinal parasites (*Trichostrongylus*) as cause of blood loss
- Fecal occult blood test (Caution: Some plant peroxidases as part of the normal diet can result in a false positive.)
- Coagulation profile to rule out hemostatic defects

Hemolytic Anemia

- PCR analysis to confirm *Mycoplasma haemolamae* RBC parasitism
- Copper levels to confirm copper toxicosis
- New methylene blue stained blood smear to confirm presence of Heinz bodies

IMAGING

Blood Loss/Hemorrhage

Radiographic or ultrasonographic imaging may reveal evidence of gastrointestinal disease accounting for blood loss.

OTHER DIAGNOSTIC PROCEDURES

Blood Loss/Hemorrhage

- Gastric endoscopy may reveal evidence for gastric ulceration.
- Bone marrow evaluation reveals erythroid hyperplasia. Cytologic evaluation of bone marrow is only needed when there is not evidence of RBC responsiveness in the peripheral blood, but regenerative anemia is still suspected.

TREATMENT

- An emergency situation exists if anemia is severe or develops rapidly. Massive hemorrhage results in hypovolemic shock and hypoxia/anoxia.
- The successful treatment of regenerative anemia usually revolves around correction of the underlying cause.
- General treatment and supportive care recommendations follow. See specific disease chapters for detailed treatment information.

ACTIVITY

Restrict

DIET

Correct any dietary insufficiencies as described within specific nutritional deficiency chapters.

CLIENT EDUCATION

N/A

MEDICATIONS

DRUGS OF CHOICE

Specific therapy for increasing RBC mass:

- If anemia is unusually severe ($PCV \leq 15\%$), transfusion may be required to treat life-threatening anemia: whole blood, 0.1 ml/kg at a rate of 5–20 ml/kg/hr.
- Numerous blood types are present in the llama and alpaca. However, incompatibility reactions are very rare with the first transfusion. Subsequent transfusions increase the risk for an adverse reaction. Blood cross matching is advised for repeated transfusions.
- Fluid therapy to correct hypovolemia may be indicated early in the course of traumatic hemorrhagic anemia.
- Oral or parenteral iron supplementation may be of benefit in patients with external blood loss anemia.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

Oxyglobin has been used successfully in dogs, cats, and horses. If packed RBCs or whole blood is not available for transfusion, Oxyglobin may be a suitable alternative in cases of severe anemia or until whole blood products are available.

FOLLOW-UP

PATIENT MONITORING

- Respiration and heart rate, mucous membrane color
- Initially, in patients with severe anemia, CBC or PCV with blood smear examination every 24 hours. As regeneration increases RBC mass and polychromasia is apparent on blood smear evaluation, rechecks recommended at 3–5 day intervals.

PREVENTION/AVOIDANCE

See specific chapters for toxicants, nutritional deficiencies, RBC and intestinal parasites, etc.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Clinical course and prognosis vary and are associated with the underlying disease condition causing the anemia.
- Return to normal values is expected within 10 to 14 days following the initial insult if the underlying cause has been corrected.

ANESTHESIA AND ANALGESIA

BASICS

OVERVIEW

- Anesthesia: local, regional (epidural, intrathecal), or general; local and regional methods most commonly employed in ruminants
- Analgesia: local, regional, systemic, multimodal, short-term, long-term
- Pain: an unpleasant sensory and emotional experience associated with actual or potential tissue damage or described in terms of such damage
- Types: acute, chronic, visceral, and somatic
- Suffering: a reaction to the physical or emotional components of pain with a feeling of uncontrollability, helplessness, hopelessness, intolerability, and interminableness. Suffering implies a threat to the wholeness of patient comfort within the environment.
- Virtually all anesthetics and analgesics are *off-label use* in any ruminant species. Please see Suggested Reading below for guidelines on off-label use of analgesic and anesthetic drugs in ruminants. The relief of pain and suffering in ruminants can and should be accomplished within these guidelines.

SYSTEMS AFFECTED

CNS, musculoskeletal, respiratory

GENETICS

SIGNS

Pain Behaviors in Ruminants: vacant stare, loss of mobility, guarding or splinting of affected limb, altered avoidance patterns, vocalization, tachypnea, repetitive motor activities, loss of socialization, repeated attempts at lateral recumbency, inappetence, reduced grooming behavior, bruxism. Behaviors and degree of distress depend on species, breed, temperament, rearing, and housing.

CAUSES AND RISK FACTORS

- Acute pain: trauma, surgery, GI accident, urogenital injury/obstruction, pneumonia/pleuritis, husbandry practices
- Chronic pain: osteoarthritis including CAE-related arthritis in goats, neoplasia, chronic osteomyelitis, chronic hoof rot, husbandry practices

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Some pain behaviors are not pain-specific. However, for a given species, a behavior indicates pain if it is seen during and/or after a specific tissue-damaging injury, disease, or procedure, but is not seen in healthy or nondamaged animals, and not seen when local anesthesia or effective analgesics are delivered.

CBC/BIOCHEMISTRY/URINALYSIS

May be indicated as routine preoperative workup

TREATMENT

MEDICATIONS

DRUGS OF CHOICE

Anesthetics Used in Ruminants: General Anesthesia

- Often not necessary for some procedures with adequate local or regional anesthesia and sedation due to ruminant temperament
- Protecting the airway is essential whether inhalant or injectable anesthetics are used; an endotracheal tube with cuff is always recommended. Proper positioning of the head during recumbency allows regurgitation to flow from the mouth. Techniques for inhalant anesthesia and monitoring are covered in depth elsewhere.
- Injectable anesthesia may be administered as a single or repeated bolus, or by continuous infusion.
- An IV catheter (jugular v., cephalic v., ear v.) is advised for continuous infusion; 5% guaifenesin and thiopental must be administered via jugular catheter only. Although not necessary for many ruminants, use of a preanesthetic sedative and analgesic will smooth induction and recovery.
- Doses for commonly used agents are listed in [Table 1](#).
- Acepromazine is not an analgesic or a potent sedative, and has several adverse side effects in ruminants.

Analgesics Used in Ruminants

Choice of analgesic is defined by type of pain, location of pain, duration of pain, species, breed, husbandry, meat and milk withdrawal times, and other federal and state drug use restrictions. Combinations of analgesics allows lower dosing of individual drugs and better pain control. See [Table 2](#) for individual drugs.

Opioids

Inhibit pain transmission peripherally and in the spinal cord by binding mu or kappa receptors. All opioids are controlled substances in the United States. Cardiopulmonary, GI, sedative, and excitatory side effects are possible and dose- and drug-dependent. *Indications:* acute pain, moderate to severe, visceral or somatic. May be given parenterally or regionally; fentanyl may be given topically in patch form. Opioids and alpha-2 agonists are synergistic; combining these drugs gives greater analgesia at lower doses for both drugs.

Alpha-2 Agonists

Produce central analgesia, sedation, and muscle relaxation by binding alpha-2 receptors in the brain and spinal cord.

Cardiopulmonary, GI, and other side effects are dose dependent and can be severe. May cause abortion in late-term gestation. Use in sheep can cause severe arterial hypoxemia. *Indications:* acute pain, moderate to severe, visceral, may be given parenterally or regionally, commonly used premedication for anesthesia. Opioids and alpha-2 agonists are synergistic; combining these drugs gives greater analgesia at lower doses for both drugs.

Steroids

Not analgesics but potent anti-inflammatory agents. Pain due to inflammation may be treated in part with steroids. Concurrent use of both steroids and NSAIDs should be avoided due to additive adverse renal and gastric side effects. Steroids should not be used in pregnant ruminants.

Indications: Short-term adjunct therapy in nonseptic inflammatory conditions.

NSAIDs Weak organic acids, which inhibit cyclooxygenase (COX) and reduce release of prostaglandins and thromboxanes. Anti-inflammatory, central and peripheral analgesic, and antipyretic effects, as well as adverse GI and renal effects are possible, and may relate to the COX1 and COX2 selectivity of the drug.

Indications: acute and chronic pain, mild to moderate, visceral and somatic, and for pain and concurrent sepsis or fever, may be given parenterally or orally.

Local Anesthetics

Block sodium channels and inhibit nerve transmission. Motor as well as sensory transmission is blocked. Produce anesthesia at and distal to the site of application, may be analgesic when given parenterally by infusion. Cardiovascular and CNS side effects are possible with high doses.

Table 1 Anesthetic Induction Protocols

Note: IV = intravenous; IM = intramuscular; IV/IM = via both routes, LOWER dose IV; B = bovine; L = llama/alpaca; O = ovine; C = caprine.

Drug	Dose (mg/kg)	Route	Species
Xylazine, then Ketamine	0.05–0.2 2	IV/IM IV	B
Xylazine, then Ketamine	0.03–0.2 5	IV/IM IV	O, C (See <i>Caution</i>) ¹
Xylazine, then Ketamine	0.25–0.44 5	IV/IM IV	L
Xylazine, then Telazol	0.05–0.1 2–4	IV/IM IV (IM)	B, L, O, C
Diazepam, then Ketamine	0.1 4.5	IV IV	B, L, O, C
Diazepam, then Ketamine	0.25 7.5	IV IV	O, C
Medetomidine, then Ketamine	0.02 0.5–1	IV IV	B (calf), O, C
GKX: 1L 5% guaifenesin + 1000 mg ketamine + 50 mg xylazine	0.5–1.0 mL/kg to effect 1.5–2 mL/kg/hr to effect for maintenance	IV IV	B, O, C L: increase xylazine to 100 mg
1 L 5% guaifenesin + 2000–4000 mg thiopental	(Following sedation) 2 mL/kg to effect	IV	B, L, O, C
Detomidine, then Propofol	0.01 3–5	IM IV	O, C

¹Caution: xylazine and other alpha-2 agonists can cause severe hypoxemia and pulmonary edema in sheep.

Indications: acute pain, mild to severe, visceral and somatic, and for regional anesthesia, administered subcutaneously, over peripheral nerves, and epidurally or intrathecally.

Other Agents

DMSO

Free-radical scavenger with anti-inflammatory, diuretic, vasodilatory, and anticholinesterase properties. Acts as a carrier agent for other drugs when applied topically as it readily crosses skin. DMSO is only labeled for topical use and not labeled for use in food animals.

Hyaluronic Acid and Polysulfated Glycosaminoglycans

Reported effects include inhibition of inflammatory mediators in joints and analgesia and improved range of motion for

osteoarthritis pain; not licensed in food animals; oral and parenteral formulations. *Author's note:* parenteral hyaluronic acid and polysulfated glycosaminoglycans at one-fourth the equine dose improve the comfort and mobility of small ruminants (which are not intended for food) suffering from osteoarthritis.

Ketamine

NMDA receptor antagonist that can prevent or reverse wind-up pain at subanesthetic doses. Subanesthetic use of ketamine is still largely experimental in food animals; ketamine is not labeled for use in food animals. *Author's note:* ketamine administered IM at 0.25–0.5 mg/kg q 6–8 hours, along with opioids and NSAIDs may be helpful for severe pain such as burn injury, or for severe polyarthritis or osteomyelitis in small ruminants.

LOCAL AND REGIONAL ANESTHETIC TECHNIQUES

Note: IV = intravenous; IM = intramuscular; IV/IM = via both routes, LOWER dose IV; PO = oral; SQ = subcutaneous; B = bovine; L = llama/alpaca; O = ovine; C = caprine.

Local

- *Infiltration:* wound edges, incision line, inverted L block, ring block
- *Drugs:* lidocaine, mepivacaine, bupivacaine. Epinephrine, 0.1 mL of the 1 mg/mL (1:1000) solution to 20 mL of local anesthetic prolongs the duration of lidocaine and mepivacaine. Do not use epinephrine in limb blocks or wound edges as ischemia and tissue necrosis can occur.
- *Dosing*
 - B: 5 mg/kg lidocaine (125 mL of 2% solution for adult cattle), similar for mepivacaine, 2 mg/kg bupivacaine. *Toxic doses:* > 10 mg/kg lidocaine or mepivacaine, >4 mg/kg bupivacaine.
 - O, C: 2–5 mg/kg lidocaine or mepivacaine, diluting to 1% with saline extends volume without increasing dose, 1 mg/kg bupivacaine. *Toxic doses:* > 5 mg/kg lidocaine, mepivacaine, > 1 mg/kg bupivacaine. Combining lidocaine and bupivacaine 1:1 or 2:1 allows a long-term block with less bupivacaine volume. Toxic signs include excitation, sedation, recumbency, tonic-clonic convulsions, cardiopulmonary depression, and death.

Specific Nerve Blocks

- *Ocular, periocular:* ocular exam, topical treatment, enucleation, periorbital surgery.
- *Topical:* proparacaine 0.5%, 2–10 drops.
- *Auriculopalpebral block:* B, O, C—20–24 G 2.5 cm needle placed subcutaneously over the nerve (palpable in a notch of the zygomatic arch), 2–10 mL lidocaine for aknesia of eyelids (no analgesia).
- *Retrobulbar*
 - B: 15 cm 18G slightly curved needle passed through the dorsal or ventral lateral or medial eyelid behind the globe, 10–15 mL 2% lidocaine (with epinephrine) or 5–6 mL lidocaine and 5–6 mL bupivacaine injected following aspiration as the needle is advanced.
 - O, C: 3.75 cm 22G slightly curved needle, 3–5 mL 2% lidocaine (with epinephrine) (or equal volumes of lidocaine and bupivacaine as for B) injected following aspiration. *Risks:* bleeding, subarachnoid deposition of local anesthetic with possible severe neurologic side effects.

Table 2 Common Analgesics Used in Ruminants

Note: IV = intravenous; IM = intramuscular; IV/IM = via both routes, LOWER dose IV; PO = oral; SQ = subcutaneous; B = bovine; L = llama/alpaca; O = ovine; C = caprine.

Class	Drug	Dose (mg/kg)	Route	Interval (hour)	Species
Opioid	Morphine	0.1–0.5	IM	4	O, C
Opioid	Butorphanol	0.05–0.5	IV/IM	2–4	B, L, O, C
Opioid	Buprenorphine	0.005–0.01	IV/IM	8–12	O, C
Opioid	Fentanyl patch	10 mg and 5 mg patch/70 kg	Trans-dermal	3–4 days	O
Opioid antagonist (reversal)	Naloxone	0.01–0.02 (dilute and titrate to effect)	IV		
Alpha-2 agonist	Xylazine (See <i>Caution</i>) ¹	0.01–0.02	IV	2–4	B, O, C
		0.05–0.1	IM	(Once)	B, O, C
		0.1–0.5	IV/IM		L
Alpha-2 agonist	Detomidine	0.005–0.05	IV/IM	3–6 (Once)	B, L, O, C
Alpha-2 agonist	Medetomidine	0.005–0.04	IV/IM	3–6 (Once)	B, L, O, C
Alpha-2 antagonist (reversal)	Tolazoline	0.5–2 (Dilute and titrate to effect)	IV		B, L, O, C
Alpha-2 antagonist (reversal)	Yohimbine	0.1–1 (Dilute and titrate to effect)	IV		B, L, O, C
Alpha-2 antagonist (reversal)	Atipamezole	0.02–0.1 (Titrate to effect)	IV		B, L, O, C
NSAID	Acetylsalicylic acid	50–100	PO	12–24	B, O, C
NSAID	Phenylbutazone	2–4	PO	24	B
		10	PO	24	O
NSAID	Flunixin	1–2.2	IV, SQ, PO	24	B, L, O, C
NSAID	Ketoprofen	3	IV, IM	24	B, O, C
NSAID	Carprofen	1–2	IV, SQ, PO	24	B, C
		4	SQ	24	O
NSAID	Meloxicam	0.5	IV, SQ	72	B

¹Caution xylazine and other alpha-2 agonists can cause severe hypoxemia and pulmonary edema in sheep, and may cause abortion in ruminants.

- *Peterson Eye Block*: B—20–25 mL lidocaine subcutaneously and at the orbitotundum foramen for immobilization of the globe and anesthesia of the globe and orbit.

Dehorning

- B: 2.5 cm 22G or 25G needle, 5–10 mL lidocaine injected subcutaneously over the palpable cornual branch of the zygomaticotemporal (lacrimal) nerve between the temporalis and frontalis muscles midway between the lateral canthus of the eye and the lateral base of the horn.
- C: 2.5 cm 22G or 25 G needle, 1–3 mL lidocaine injected subcutaneously over BOTH the zygomaticotemporal nerve midway between the lateral canthus and the base of the horn, and the infratrochlear nerve between the medial canthus and medial base of the horn at the dorsomedian margin of the orbit. *For kids*: 0.5 mL 2% lidocaine diluted for a ring block at the base of the horn to reduce possible toxicity.

Proximal and Distal Paravertebral Block

Anesthesia of skin, musculature, and peritoneum of the flank on the side treated, spinal nerves T13, L1, L2 for standing abdominal procedures.

- *Proximal*
 - B: 2.5–5 cm from midline immediately in front of the transverse process of L1, L2, and L3. After desensitizing the skin, an 18G 4.25–15 cm spinal needle is walked off the cranial edge of the transverse process while aspirating then infusing 1–2 mL lidocaine. Following aspiration, 15 mL lidocaine are injected ventral to the intertransverse ligament, 5 mL are injected proximally with minimal resistance.
 - O, C: 1.5–3 cm off midline, 20G 4.25 cm spinal needle, 2–3 mL lidocaine per site. *Risks*: penetration of aorta, vena cava, or other vessels, caudal migration of lidocaine to L3 causing ataxia or recumbency.
- *Distal*
 - B: 18G 3–7.5 cm needle inserted ventral and dorsal to the tip of the transverse process of L1, L2, and L4. Up to 20 mL lidocaine is infused in a fanned-out pattern ventrally at each site, 5 mL injected dorsally.
 - O, C: 20G 3 cm needle, 1–3 mL lidocaine at each site

Regional

Caudal Epidural Anesthesia:

Obstetric and surgical procedures of the tail, perineum, anus, rectum, vulva, vagina, prepuce, and skin of the scrotum

- B: 18G 3 cm needle or 5 cm spinal needle midline at the S5-Co1 or Co1-Co2 junction following sterile prep and skin desensitization. After contact with the floor of the neural canal, withdraw needle slightly. Place lidocaine in the hub of the needle and slowly withdraw the needle until the lidocaine is aspirated from the hub by the negative pressure of the epidural space. Alternatively, 1 mL of air may be slowly injected as the needle is withdrawn until no resistance is felt. Inject 5–6 mL lidocaine slowly for a 450 kg animal.
- O, C: 20G 1.5–3 cm needle midline at the S4-Co1 or Co1-Co2 space. Administer 0.5–1 mL lidocaine/50 kg of body weight.
- L: 20 G 1.5–3 cm needle midline at the S5-Co1 space. Administer 0.22 mg/kg lidocaine.
- *Risks*: ataxia due to cranial spread of lidocaine, infection due to nonsterile technique
- Other epidural drugs
 - B: bupivacaine mixed with lidocaine 1:2 to extend the block duration, xylazine 0.03–0.07 mg/kg diluted to 5–7 mL with saline, xylazine 0.03 mg/kg plus lidocaine to a total volume of 5 mL. Morphine alone, 0.1 mg/kg diluted to 5–8 mL or combined with xylazine 0.01 mg/kg or detomidine, 0.01 mg/kg, may be useful for longer term analgesia.
 - O, C: bupivacaine as for cattle, xylazine as for cattle, but diluted to 1–2 mL, xylazine plus lidocaine as for cattle, but diluted to 1–2 mL
 - L: bupivacaine as for cattle, xylazine 0.17 mg/kg diluted with 2 mL/150 kg sterile water, xylazine 0.17 mg/kg plus lidocaine 0.22 mg/kg

Lumbosacral Epidural Anesthesia

Procedures performed caudal to the diaphragm in calves, sheep, and goats. The technique may be performed in cattle, but anatomic considerations and loss of sensory and motor function of the hind limbs preclude its routine utility. Cardiovascular depression can occur from sympathetic blockade.

- O, C: 20 G 5–7 cm spinal needle with the bevel pointing cranial inserted midline between L6 and S1, midway between the wings of the ileum and just caudal to the dorsal spinous process of L6, following sterile prep and skin desensitization. Advance slowly until the needle pops through the interarcuate ligament to lie in the epidural space. The absence of blood or CSF in the needle hub, aspiration of saline from the needle hub, and no resistance to injection of 1 mL air all indicate correct placement. If CSF is observed (intrathecal position), reduce the dose of drug(s) to one-fourth that for epidural administration.
- *Drugs*: lidocaine 1 mL/5–7 kg body weight, bupivacaine 0.75% 1 mL/10 kg, morphine 0.1 mg/kg diluted with saline or local anesthetic to 0.1–0.2 mL/kg. All drugs must be administered slowly.
- *Risks*: prolonged caudal paralysis, cardiovascular effects from segmental sympathetic blockade, caudal pruritis (morphine), and infection

Adjunct Therapy

Bandages, splints, physical therapy, heat therapy, cold therapy, hydrotherapy, massage, acupuncture, topical therapy (local anesthetics, DMSO, capsaicin, diclofenac, etc.), confinement, housing (deep bedding, padding for recumbent animals, slinging, temperature-controlled environments), social and environmental enrichment

CONTRAINDICATIONS

POSSIBLE INTERACTIONS

- Regulatory restrictions: See Web sites below for links to FDACVM and the AMDUCA flowchart for recommendations on the use of analgesics and anesthetics in food animals.
- Meat and milk withholding: See Web sites below for the link to FARAD for recommendations on meat and milk withholding times for analgesics and anesthetics in food-producing animals.

ANESTRUS

BASICS

OVERVIEW

Anestrus is the absence of behavioral signs of estrus activity or behavior, although follicular waves are generally still present.

PATHOPHYSIOLOGY

Cattle are polyestrous, but cyclicity may be influenced by factors such as:

- Nutrition
- Environment
- Physiological conditions
- Breed
- Management Anestrus in cattle can be a response to aberrant release patterns at the level of the hypothalamus (GnRH) or the pituitary (LH and FSH).

SYSTEMS AFFECTED

Endocrine/metabolic, reproductive

SIGNALMENT

Breed differences are related to

- Lactational status
- Nutritional intake
- Estrus intensity and duration

SIGNS

History of female estrous cyclicity and hormonal patterns may increase estrus detection efficiencies.

CAUSES AND RISK FACTORS

Other causes may include

- Anestrus females may actually be pregnant.
- Systemic disease
- Lameness
- Utero-ovarian disorders
- Postpartum anestrus period (1–3 months) is common.

DIAGNOSIS

Estrus behavior (and lack thereof) and observations can be supported by

- Estrus cyclicity records
- Lack of palpable CL
- No vaginal mucus discharge
- No mounting activity when placed with other estrous females or males
- Unresponsive to estrus synchronization treatments

DIFFERENTIAL DIAGNOSIS

General health/reproductive history

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Serum progesterone concentration > 2 ng/ml may confirm ovulation activity and presence of functional CL, < 2 ng/ml may confirm anestrus.

IMAGING

Ultrasonic imaging in an anestrus female should reveal:

- Small inactive ovaries
- Small dominant follicle (10–15 mm) or evidence of follicular activity may be present.

DIAGNOSTIC PROCEDURES

- Serum progesterone analysis
- Transrectal ultrasonography
- Rectal palpation
- Visual observation

TREATMENT

- Correct nutritional intake.
- House anestrus females with actively cycling females.

MEDICATIONS

DRUGS OF CHOICE

- GnRH (200 μ g) followed by PGF2alpha (according to label) treatment (7 days apart) may initiate cyclicity.
- CIDR treatment (7 days) followed by estrus detection (1–7 days)
- MGA (0.5–1.0 mg/head/day) for 10–14 days followed by estrus detection (1–7 days)

CONTRAINDICATIONS

N/A

PRECAUTIONS

PGF2alpha is a vasoconstrictor known to cause abortions and respiratory complications (cattle and humans).

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Behavioral activity
- Transrectal ultrasonography
- Palpation
- Serum progesterone levels

POSSIBLE COMPLICATIONS

- Pyometra
- Endometritis
- Systemic disease
- Freemartin

EXPECTED COURSE AND PROGNOSIS

Anestrus females usually regain estrus cyclicity once nutritional, reproductive, and management issues are addressed.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Older females may exhibit reduced fertility and estrus cyclicity patterns.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Many females considered to be anestrus may be pregnant (with a viable or nonviable fetus) and may abort with PGF₂ treatment.

RUMINANT SPECIES

Cattle; other ruminants may be seasonally polyestrous.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

Consistently anestrus females in well-monitored operations with strong management and husbandry protocols should be considered for culling.

ANGULAR LIMB DEFORMITY

BASICS

DEFINITION

- Angular limb deformity (ALD) is a deviation from the normal axis of a limb (in the frontal plane) and is defined by the joint involved and the direction that the distal aspect of the limb is deviated.
- Valgus deformity: the limb distal to the lesion deviates *laterally*.
- Varus deformity: the limb distal to the lesion deviates *medially*.
- ALDs are further described by the location of the pivot point (axis of deviation) and by the location of the site of defective growth.
- Related conditions include flexural deformities, tendon injuries, joint luxations, and rotational deformities.
- Spider lamb syndrome (SLS) or hereditary chondrodysplasia (HC) is a hereditary condition in young lambs characterized by a number of skeletal deformities, including angular limb deformities.

PATHOPHYSIOLOGY

- ALDs are considered multifactorial in origin and have congenital/perinatal and developmental predisposing factors.
- Cattle and llamas have a complete osseous ulna. In llamas, the distal ulnar epiphysis fuses with the distal radial epiphysis. This unique development of the distal portion of the ulna is associated with forelimb valgus deformities in crias. The ulnar epiphysis extends distally, crosses the radial physis, and fuses with the radial epiphysis. This early fusion demands synchronous growth to ensure normal limb development.
- Most calves have a mild carpal valgus deformity of approximately 7 degrees, which does not require treatment. Varus deformities in cattle are abnormal and often need treatment.

SYSTEMS AFFECTED

Musculoskeletal, involving the tibia, radius, ulna, carpus/tarsus, and metacarpus/metatarsus

GENETICS

- The questions of heritability in angular limb deformities have not been definitively answered.
- ALDs in Jersey calves are genetically transmitted as a simple autosomal recessive trait.
- Hereditary chondrodysplasia, or “spider-lamb syndrome” (SLS), of Suffolk and Suffolk-cross sheep is inherited as a single, autosomal recessive gene that has been localized to the distal end of chromosome 6. A defect in the gene encoding fibroblast growth factor receptor 3 (FGFR3) is suspected. DNA tests (blood or semen) are available to identify homozygous and heterozygous animals.

INCIDENCE/PREVALENCE

Valgus and varus angular limb deformities (ALD) are common and well documented in horses but rare in ruminants.

GEOGRAPHIC DISTRIBUTION

ALDs are thought to occur worldwide.

SIGNALMENT

Species

Bovine (cattle), ovine (sheep), goats (caprine), South American camelids (especially llama crias), cervids—including fallow deer (*Dama dama*), red deer (*Cervus elaphus*), white-tailed deer (*Odocoileus virginianus*)—and a single case report of ALD in a giraffe calf (*Giraffa camelopardalis*).

Breed Predispositions

ALDs have been described in many different beef and dairy cattle breeds. SLS primarily affects black-faced breeds of sheep (Suffolk, Hampshire, Southdown, Shropshire, and Oxford).

Mean Age and Range

ALDs primarily affect young growing animals up to 7 months of age, but can be seen in older animals (e.g., trauma-induced ALD). SLS has two distinct clinical entities: lambs are either grossly abnormal at birth or develop the abnormal conformation at 4–6 weeks of age. Radiographic changes at birth are similar for both.

Predominant Sex

No apparent gender predisposition

SIGNS

A complete history including current age, birthing details, age at which the deformity was noticed, course and progression of deformity, and diets of affected animal and dam should be obtained.

PHYSICAL EXAMINATION FINDINGS

- The animal's conformation should be assessed first by having the animal stand in a symmetrical manner on a firm, flat surface and observing it from multiple angles. Affected animals may appear to be knock-kneed or bowlegged. All limbs should be palpated and affected limbs should be manually manipulated. Clinical signs such as abnormal bending of the affected limb, increased laxity, muscle atrophy, swelling, heat, pain on manual pressure, abrasions on lateral or medial side of hoof wall, presence of orthopedic injury, and abnormal gait and locomotion are indicative of ALD.
- Compensatory deviation (opposite that of the affected limb) is relatively common in the contralateral limb.
- If varus deformity is found unilaterally, the contralateral limb should be examined for a significant orthopedic injury as a cause of excessive weight bearing in the deformed limb/joint.
- Since cattle are considered to have a "normal" degree of medial deviation at the level of the carpus and hock, as well as normal external rotation of the lower limb, ALDs tend to be missed in the early stages of development.

SLS

In sheep affected with SLS, various degrees of angular limb deformities of fore- and/or hind limbs will be noted. Other physical exam findings include severe scoliosis/kyphosis of the thoracic spine, pectus excavatum, retarded growth rates, facial deformities such as angular deviation and/or shortening of maxilla, rounding of the dorsal silhouette, and Roman-shaped noses.

CAUSES AND RISK FACTORS

ALDs are often related to asymmetrical growth of the physis, ligament rupture, or orthopedic injuries.

Congenital Predisposing Factors

- Incomplete cuboidal bone ossification (carpal and/or tarsal)
- Physiological immaturity at birth
- Uterine malpositioning
- In utero bending stress and bone remodeling early in gestation
- Twin (or triplet) pregnancy
- Laxity of periarticular supporting structures
- Disproportionate osseous growth of medial and lateral aspects of long bones (e.g., distal radius, tibia, metatarsus)
- Nutritional imbalance during gestation
- Genetic causes

Developmental Predisposing Factors

- Conformational defects (causing abnormal weight distribution across a joint)
- Nutritional disorders (e.g., improper dietary calcium and phosphorus ratios; copper, zinc, manganese, iron, and molybdenum concentrations)
- External trauma (e.g., compression of or trauma to growth plate, malunion of fractures)
- Iatrogenic (e.g., assisted delivery)
- Excessive exercise
- Hematogenous osteomyelitis involving the physal region
- Rapid weight gain in heavy breeds
- Often, no specific cause is identified.

Camelids

- May see ALDs (usually carpal valgus) in growing camelids with hypophosphatemic rickets syndrome.
- Ill-thrift syndrome in llamas may be associated with ALDs as well as anemia, low serum iron concentrations, and

metabolic disorders (hypothyroidism). Underlying cause not established.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

SLS

- May be confused with arthrogryposis/hydranencephaly syndrome (AHS) in lambs, in which there is characteristic hyperflexion of forelimbs, cranial overextension of hind limbs, with a corkscrew deviation of the spine.
- In lambs with AHS, severe deformities result from primary abnormalities of the CNS (including hydranencephaly, micromyelia, hydrocephalus, and cerebellar hypoplasia) and not of the skeleton.

Camelids

True ALDs in llamas must be differentiated from valgus deformities of the forelimbs in newborn crias that self correct without surgical treatment.

CBC/BIOCHEMISTRY/URINALYSIS

There are usually no associated laboratory abnormalities with ALD.

SLS

May see slightly elevated serum alkaline phosphatase activity; insufficient for diagnostic purposes.

Camelids

- Ill-thrift syndrome: serum vitamin D (25-hydroxycholecalciferol) concentrations are often diagnostic.
- May also see hypothyroidism, anemia, erythrocyte dyscrasias, hypophosphatemia, and low serum iron concentrations.

OTHER LABORATORY TESTS

N/A

IMAGING

- Radiographs are critical in diagnosing ALDs—at least two views, 90 degrees apart, should be taken of the affected joint, including joints immediately proximal and distal to the affected joint.
- The dorsopalmar/dorsoplantar (DP) view is needed for examination of the anatomical location of the deformity and for measurements. The pivot point is defined as the intersection between lines drawn through the long axis at the center of the proximal and distal long bone using the dorsopalmar view. Location of the pivot point identifies the type of deformity. Measure the angle of deviation with a protractor.
- SLS: most consistent lesions include multiple islands of ossification of the anconeal process and malformed, displaced sternebrae. The anconeal lesions of HC are progressive, whereas similar lesions in other skeletal conditions of lambs regress.

DIAGNOSTIC PROCEDURES

- Bacterial cultures may be indicated in cases of septicemia, arthritis, or osteomyelitis.
- Toxicology (heavy metal and mineral analysis) and feed analysis may assist in diagnosis.

PATHOLOGIC FINDINGS

SLS

Histology (vertebrae and long bones): increase in width of the zone of proliferation and hypertrophy and unevenness of growth cartilage; failure to form or maintain orderly columns of chondrocytes.

TREATMENT

APPROPRIATE HEALTH CARE

Treatment of neonatal animals with incomplete ossification involves the application of tube casts or splints to the affected limb(s) until ossification is complete (based on repeated radiographs).

NURSING CARE

- Severely affected animals may be unable to rise to nurse and require additional supportive care. Protect limbs with thick,

soft bandages that fit well.

- Care should be taken to maintain a soft (padding), clean, and dry environment and to minimize decubital/pressure sores, open arthritis, muscle atrophy, umbilical infections, and septicemia.

ACTIVITY

Physical confinement (stall) is recommended for the management of ALDs to limit stresses placed on affected limbs.

DIET

- Nutritional imbalances have been implicated, such as ill-thrift in llamas. Treatment for this condition includes appropriate vitamin D supplementation.
- Other dietary imbalances should be corrected while treating cases of ALD.

CLIENT EDUCATION

- Examination and intervention of young animals with congenital angular limb deformities should be done as early as possible.
- Due to the possible hereditary link with ALDs, breeding of affected animals is not recommended.

NONSURGICAL CONSIDERATIONS/CONSERVATIVE TREATMENT

- Many cases of ALD will resolve without surgery if the underlying cause(s) can be identified and addressed and if the animal does not damage the affected physis or joints with vigorous exercise.
- Specific treatment methods are selected on the basis of age, degree of angulation, remaining growth potential of the involved physis, and experience of the veterinarian.
- Minor limb deviations may be conservatively treated by manual alignment and external support of the limb (e.g., rigid splinting, bandaging, or casting/tube casts) and/or hoof (claw) trimming.
- Hoof manipulations create growth-plate response to stress applied opposite the deformity, and self correction occurs. The hoof tends to turn in the direction of the longer claw or toward the side of the wider wall, resulting in straightening and derotation of the limb.
- Medial (varus) deformities can be treated by trimming the medial claw shorter than the lateral claw and by placing an acrylic (methyl methacrylate) wing on the weight-bearing surface of the lateral claw (to increase lateral contact with the ground).
- Treatment should be directed at the orthopedic injury when varus deformity is present secondary to a contralateral limb injury.

SURGICAL CONSIDERATIONS

- Surgery is recommended for older animals (near the end of active physal growth), for those that do not respond to conservative treatments, and for animals with bone malformations that require realignment (via osteotomy).
- The choice of surgical technique should take into consideration the economic value and age of the animal, severity of the deformity, and the joint involved.

Treatment Strategies Include the Following:

Growth Acceleration (Periosteal Stripping/Elevation)

In young calves and lambs with early cases of ALD, surgical growth stimulation via periosteal stripping on the concave aspect (shorter side) of the deformity has been used successfully. Based on the remaining growth potential in the physis, allow the animal to correct the deviation by physal growth.

Growth Retardation (Transphysal Bridging)

- Transphysal bridging is indicated for severe cases of ALD or in animals past the rapid growth phase of the radius and ulna (often recommended for animals older than 5 months of age).
- By creating a temporary transphysal bridge on the convex side of the deformity using staples or screws and wires, limb growth is slowed by restricting growth and allows the other side to continue growing, resulting in limb straightening.
- The surgical implants must be removed when the limb achieves normal conformation to prevent overcorrection. This can be used in combination with periosteal stripping to increase the likelihood of full correction in animals with severe deviations.

Corrective Wedge Osteotomy

- This procedure is indicated in mature animals with ALD and in neonates with congenital fracture malunion. If the growth plates are closed or if the growth plate is not involved in an ALD, a corrective osteotomy is recommended. This requires more experience and equipment and often is reserved for valuable animals when response to other therapies has failed.

- The site and orientation of the wedge should be determined by clinical and radiographic examination.
- The limb needs to be stabilized by internal fixation with a plate and screws for an extended postoperative period.

Camelids An ulnar osteotomy must be done in conjunction with the periosteal transection because the ulna spans the radial physis.

MEDICATIONS

DRUGS OF CHOICE

Nonsteroidal anti-inflammatory agents (NSAIDs) are recommended to reduce inflammation in some cases of ALD, especially those associated with physisitis.

CONTRAINDICATIONS

- Prolonged NSAID administration has been associated with gastrointestinal (abomasal) ulcers.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

Many of these affected animals are young; precautions regarding drug choices must take age into consideration.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

- Frequent physical monitoring and repeated radiographs should be done to assess the efficacy of corrective measures and to monitor progress.
- In cases of transphyseal bridging surgery, owner cooperation is required to determine when the limb has regained its normal conformation, at which time the implants must be removed to prevent overcorrection.

PREVENTION/AVOIDANCE

Avoid breeding affected animals.

POSSIBLE COMPLICATIONS

- In cases of valgus deformity, efforts should be taken to prevent compensatory varus in the contralateral limb. Persistence of hoof distortion is possible if the angular deformity is not corrected.
- Surgical: transphyseal bridging—overcorrection of the physis is possible. Owner cooperation is required to determine when limb has regained its normal conformation.
- Possible ALD surgical complications include muscle, tendon, and ligament atrophy/laxity, hyperextension of limbs, fibrous scar tissue development, and postoperative infection.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is guarded, yet reasonable for ALDs associated with growth plate imbalances, such as most valgus deformities.
- The prognosis for ALDs secondary to contralateral orthopedic injury (such as most varus deformities) is generally poor because it is usually centered over a joint and is dependent on the prognosis of the primary orthopedic injury.
- SLS-affected individuals rarely survive the neonatal period.
- Camelids: the prognosis for ill-thrift syndrome in llamas is poor; etiologic agent often not identified.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Conditions associated with ALDs include osteochondrosis of the physis, epiphysitis, and incomplete ossification of the cuboidal carpal bones.
- Hyena disease (premature physeal closure) has been reported in calves due to overdose of vitamins A, D₃, and E.
- Congenital lethal chondrodysplasia in Australian Dexter cattle = “Dexter bulldog calves.”
- Congenital chondrodysplastic dwarfism in Holstein calves
- Complex vertebral malformation is a familial syndrome of Holstein calves.
- Syndrome known as “bentleg” or “bowie” associated with ingestion of *Trachymene glaucifolia* (wild parsnip) by pregnant ewes in Australia and New Zealand

AGE-RELATED FACTORS

The majority of ALDs occurs during the active growth phase of the affected bone/joint.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

- Many of the causes of ALDs are congenital diseases in which the in utero environment is somehow disturbed (hormones, vascular supply, teratogens, mechanical factors, or prenatal virus infections).
- Cases of ALDs in goats pregnant with triplets have been reported.
- Contributing factors likely include stress and in utero malpositioning.

ANTHRAX

BASICS

DEFINITION

Anthrax is an almost invariably fatal septicemic disease caused by a large, gram-positive spore-forming bacterial rod *Bacillus anthracis*, which is part of the normal soil flora in most geographic areas, particularly those with alkaline soils.

PATHOPHYSIOLOGY

- Spores of the causal agent gain entry to the host by ingestion, by inhalation, or through skin lesions.
- Once the bacillus enters the body, it is ingested by macrophages and enters into lymphatic vessels and lymph nodes to cause lymphangitis and lymphadenitis.
- The spores germinate to a vegetative form, multiply extracellularly, and are disseminated throughout the host.
- The organisms produce toxins (lethal factor, edema factor, and protective antigen) that cause widespread damage of the vasculature and reticuloendothelial system to result in edema, tissue damage, shock, renal failure, anoxia, and ultimately death.

INCIDENCE/PREVALENCE

- In the United States, the disease is usually seen in one or only a few animals at a time and is sporadic.
- Both sporadic cases and outbreaks are often associated with disruption of the soil. This disruption brings bacterial spores to the soil surface where they are ingested. Similarly, animals grazing short grasses during drought periods may ingest spores.
- Outbreaks can occur over large areas if animals are fed contaminated feeds, such as meat and bone meal.
- Pastures can be contaminated by effluent from textile mills that were using animal products, such as wool, in the manufacturing process.
- Morbidity varies widely but case mortality is 90%–95%.
- Control efforts are successful in domestic species but wildlife can suffer large outbreaks.

GEOGRAPHIC DISTRIBUTION

The anthrax bacillus has a worldwide distribution but some areas have a higher rate of disease.

SIGNALMENT

- Anthrax can affect all livestock species but the major ruminant species—cattle, goats, and sheep—are more susceptible than horses and pigs.
- There are some reports of males being more susceptible than females and older animals being more susceptible than young animals but these probably reflect differences in stress and grazing habits rather than inherent differences in susceptibility.

SIGNS

- Many animals die suddenly and there are no clinical signs noted.
- Animals develop fever, depression, muscle tremors, dyspnea, diarrhea, and other signs related to septicemia. A smaller number of more chronic cases may develop subcutaneous edema, hematuria, rumen stasis, and decreased milk production with blood-tinged milk.

GENERAL COMMENTS

N/A

HISTORICAL FINDINGS

N/A

PHYSICAL EXAMINATION FINDINGS

N/A

CAUSES

- Anthrax is caused by *Bacillus anthracis*, a large, gram-positive, spore-forming bacterial rod.
- Infection can occur by ingestion, which is the most common route, by inhalation, or by contamination of skin wounds.
- Primary cases are usually due to ingestion but secondary cases on the same premises may be due to contact with infectious discharges from the primary cases or by ingestion of tissues from the primary case.

RISK FACTORS

- Anthrax cases are more common in years when there have been major climate changes (e.g., wet spring followed by a drought or a drought followed by heavy rains).
- Disruption of the soil can bring infectious spores to the surface where they are more easily ingested or inhaled.
- Close grazing of poor-quality, coarse feed can lead to oral trauma and predispose animals to infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Because the signs of anthrax are not specific, almost any disease can be considered in the differential diagnosis. Some that merit specific mention include acute toxicity, anaplasmosis, vena cava syndrome with exsanguination from the respiratory tract, blackleg, malignant edema, and bacillary hemoglobinuria.

CBC/CHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Because of the zoonotic risk of anthrax and the poor response to treatment, a full clinical workup is generally not warranted.
- Diagnosis is based on the demonstration of the causal organism in body fluids, and laboratory professionals best perform this testing function.
- Blood from an ear tip or jugular vein in the live animal (or one dead less than 12 hours) or aqueous humor or an entire eyeball from a dead animal are all acceptable samples for finding the organism.
- Bacteremia may not occur until just before death, and demonstration of the agent may be difficult in the live animal particularly if antibiotic therapy has begun.
- The organism on Giemsa or Wright stain is typically seen as a square-ended bacterial rod that occurs singly or in short chains and resembles “railroad boxcars.”

PATHOLOGIC FINDINGS

- Because of the danger of environmental contamination, if anthrax is suspected, a full necropsy is contraindicated.
- Animals that die from anthrax undergo rapid decomposition and generally do not develop full rigor.
- The carcass will be gas distended and have a “saw-horse” appearance.
- Natural body orifices may have an exudate consisting of dark, unclotted, tarry blood.
- On necropsy, there will be marked splenic enlargement (two to three times normal size), serosal and mucosal edema and hemorrhage, edema and hemorrhage in lymph nodes, unclotted blood, intramuscular edema, and possibly enteritis.
- In sheep and goats, the disease progresses very rapidly and there may not be localized lesions in the carcass.

TREATMENT

- The prognosis for animals with anthrax is poor but there are reports of animals that have survived.
- The anthrax bacillus is susceptible to a wide range of antibiotics but treatment will make demonstration of the organism

in body fluids more difficult.

- Streptomycin (8–10 g/day in 2 doses) or oxytetracycline (5 mg/kg/day) are recommended by some texts.
- Antibiotic treatment should be for a minimum of 5 days and preferably 10 days, and the first dose should be given IV if this is a possible route with the antibiotic chosen.
- An antiserum is available in some areas but is often quite expensive.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

CLIENT EDUCATION

- The client must be made aware of the potential of the organism to infect a variety of species, including humans, via skin wounds, ingestion, or inhalation.
- Carcass disposal can be problematic.
- The anthrax bacillus is generally destroyed during putrefaction of the carcass and if the carcass is not opened and if discharge of fluids into the environment does not occur, there will not be significant contamination of the site.
- Since treatment is typically not successful, prevention and control should be emphasized.

MEDICATIONS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Hygiene and carcass disposal are of paramount importance.
- Autolysis of the carcass destroys the vegetative forms of *B. anthracis* and, therefore, if carcasses are not opened up, the potential for contamination of the environment is minimized.
- Carcasses should be disposed of by burning or deep (>6 feet) burial that occurs well away from water sources.
- Burning may release spores into the rising heat column and disperse them, and therefore hot fires that take hold quickly are best. The risk from burning carcasses is probably less than not burning the carcass, however.
- Livestock can be vaccinated with Stern-strain spore vaccine. Booster vaccination is given 4–5 weeks following the initial vaccination, and then annually thereafter.
- The vaccine is a live nonencapsulated organism and therefore antibiotics should not be given within 7 to 10 days of vaccine administration.
- Following vaccination, there is a 60-day withdrawal time for the carcass, and milk should be discarded for at least 72 hours.
- There may be a localized reaction at the vaccination site and this can be quite severe in some animals.
- Spores are very resistant and can survive in contaminated soils for 15–30 years. Therefore, anthrax is still a potential danger in areas with historic cases.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Animals develop fever, depression, muscle tremors, dyspnea, diarrhea, and other signs related to septicemia. A smaller number of more chronic cases may develop subcutaneous edema, hematuria, rumen stasis, and decreased milk production with blood-tinged milk.

AGE-RELATED FACTORS

There are some reports of males being more susceptible than females and older animals being more susceptible than young animals, but these probably reflect differences in stress and grazing habits rather than inherent differences in susceptibility.

ZOONOTIC POTENTIAL

Anthrax is primarily a disease of herbivores, but all mammals, including humans, are susceptible and therefore care must be exercised when working in areas where spores are potentially present.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

All ruminant species are affected.

BIOSECURITY

- Anthrax is a reportable disease.
- Once anthrax is diagnosed, the farm will be quarantined, all carcasses and fluids will be destroyed, survivors will be vaccinated, and the farm will be isolated for at least 2 weeks.
- Because of the association between anthrax and disturbed soils and/or localized areas, animals surviving an outbreak may be moved to different pastures or holding pens in order to reduce the possibility of additional cases.
- Scavenger control is important to prevent the spread of the disease.
- Because of recent concerns about bioterrorism, the Federal Bureau of Investigation will likely become involved in any cases of anthrax in the United States.

PRODUCTION MANAGEMENT

- Hygiene and carcass disposal are of paramount importance.
- Autolysis of the carcass destroys the vegetative forms of *B. anthracis* and, therefore, if carcasses are not opened up, the potential for contamination of the environment is minimized.
- Carcasses should be disposed of by burning or deep (>6 feet) burial that occurs well away from water sources.
- Livestock can be vaccinated with Stern-strain spore vaccine. Booster vaccination is given 4–5 weeks following the initial vaccination, and then annually thereafter.
- Close grazing of poor-quality, coarse feed can lead to oral trauma and predispose animals to infection.

ARSENIC TOXICOSIS

BASICS

OVERVIEW

- Arsenic has been reported to be the second most common heavy metal intoxication of cattle after lead.
- Arsenic is still used in herbicides, defoliants, and wood preservatives.
- The use of arsenic-containing products has decreased in the recent past as other insecticides and herbicides become available.

SYSTEMS AFFECTED

- Gastrointestinal
- Renal
- Nervous (phenylarsonic compounds)

Sources

- Inorganic arsenic
 - Arsenate—natural, pentavalent form of arsenic
 - Trivalent forms are manufactured inorganic arsenic: arsenic trioxide (insecticide and herbicide); trivalent arsenic (arsenite)
 - Pressure-treated woods (green in color): chromated copper arsenate (CCA). Cattle have been poisoned by consumption of ashes from burnt pressure-treated wood.
 - Inorganic arsenic is more commonly associated with intoxication in cattle.
- Organic arsenic
 - 3-nitro, 4-hydroxyphenylarsonic acid (3 nitro)—a feed additive
 - Thiocertarsamine—heartworm therapy
 - Monosodium methanearsonate (MSMA)—herbicide
 - Disodium methanearsonate (DSMA)—herbicide

Toxic Dose

- Toxicity depends upon the formulation, route of exposure, and duration of exposure.
- Trivalent forms are 5–10 times more toxic than pentavalent forms.
- For most species, the toxic oral dose of sodium arsenite is 1 to 25 mg/kg of body weight.

GENETICS

 - Colic

CAUSES AND RISK FACTORS

N/A

**DIAGNOSIS**

- Clinical signs
- Possible history of exposure
- Chemical determination of arsenic in tissues
- Liver or kidney arsenic concentrations greater than 3 ppm
- Stomach content or urinary arsenic greater than 2 ppm
- Chemical determination of arsenic in water or feedstuffs

DIFFERENTIAL DIAGNOSIS

- Bovine viral enteritis (BVD)
- Bacterial enteritis (*Salmonella* spp.)
- Organophosphorus insecticides
- Other heavy metals (lead)
- Urea toxicosis

CBC/BIOCHEMISTRY/URINALYSIS

None specific to arsenic toxicosis

OTHER LABORATORY TESTS

N/A

PATHOLOGIC FINDINGS**GROSS FINDINGS**

- Gastrointestinal: generalized or localized reddening of the gastrointestinal mucosa; hemorrhage; erosions; submucosal edema
- Kidneys: pale, swollen

HISTOPATHOLOGICAL FINDINGS

- Multifocal hepatic and renal necrosis
- Dilation of intestinal capillaries
- Submucosal congestion and edema
- Intestinal epithelial necrosis
- Renal tubular necrosis

**TREATMENT**

Symptomatic and Supportive Therapy

- Very important, as animals may present late in the clinical course
- Fluid therapy
- Blood transfusion +/-

Antidotal Therapy—Chelation

- Thiocetic acid (lipoic acid or alpha lipoic acid)
 - More effective in cattle than dimercaprol
 - No commercially available source
 - 50 mg/kg divided into two to three injection sites
 - Administer q 8 hours
- 2, 3-dimercaptosuccinic acid (DMSA)
 - Also known as CHEMET or Succimer
 - Water-soluble analog of British Anti Lewisite (BAL)
 - Given orally
 - Commercially available product (humans)
 - 10 mg/kg per os q 8 hours (human and small animal dose)

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

ARTHROGRYPOSIS

BASICS

DEFINITION

- Congenital arthrogryposis is defined as a syndrome of persistent joint contracture (bilateral rigidity) present at birth and may involve one or multiple limbs (forelimbs and/or hind limbs).
- Arthrogryposis is often associated with cleft palate and primary CNS lesions such as hydranencephaly and syringomyelia.
- The arthrogryposis-hydranencephaly syndrome (AHS) is usually associated with flexural contracture of the limbs rather than angular limb deformities (ALDs).
- Crooked calf syndrome (CCD) is a congenital deformity condition widely recognized in western North America, characterized by arthrogryposis, scoliosis, torticollis, and cleft palate. CCD is observed in calves after maternal ingestion of lupines containing the quinolizidine alkaloid anagyrene during gestation days 40–100.
- Congenital arthrogryposis may be associated with denervation muscle atrophy.

PATHOPHYSIOLOGY

- Congenital arthrogryposis is considered multifactorial in origin and has multiple predisposing factors and etiologies.
- It can be caused by a number of etiologic agents including: plant teratogens (e.g., lupines), spinal dysraphism, prenatal viral infections (e.g., Akabane virus), and in utero hormonal and vascular defects.
- It may also be attributed to a decrease or lack of motion of the fetus during critical stages of development, such as malpositioning and overcrowding caused by the size of the fetus relative to the dam.
- Ingestion of teratogenic plants (e.g., *Astragalus* or *Oxytropis* spp. = locoweed; *Verratum californicum* = skunk cabbage; piperidine alkaloid-containing plants such as *Lupinus*, *Conium*, and *Nicotiana* species).
 - Repeated dosing or continuous low-level ingestion over time may result in cumulative intoxication and/or teratogenesis.
 - Teratogenic plant alkaloids may be transferred to the placenta and induce a sedative or anesthetic effect in the fetus.
- In CCD, there is often a lesion in the CNS that may result in reduced or complete absence of movement of the affected body parts in the developing fetus, especially during the period of rapid growth. Studies have demonstrated a significant reduction in number of α -motoneurons in the cervical spinal cord. May cause disruption in normal innervation of muscles leading to paresis and instability of the limb, or may result in hypotonic condition of extensor muscle and dysfunction of the radial nerve.

SYSTEMS AFFECTED

Musculoskeletal—involving forelimbs, hind limbs, or both. The carpal and phalangeal joints are most commonly affected, followed by metacarpophalangeal and metatarsophalangeal joints.

GENETICS

The questions of heritability in arthrogryposis have not been definitively answered.

Lambs

A congenital arthrogryposis exists in pedigree Suffolk and Australian Merino lambs as an inherited limb deformity.

INCIDENCE/PREVALENCE

- For CCD, there are reports of up to 40% of calves from a single herd being affected. The incidence of disease varies with year, area, and herd.
- Cattle records reveal that the disease usually affects < 10% of a herd.

GEOGRAPHIC DISTRIBUTION

- Arthrogryposis is thought to occur worldwide. Depending on the etiologic cause, the geographic distribution may vary (e.g., crooked calf syndrome is most common in western North America).
- Calf arthrogryposis has been reported from most parts of the world and in many breeds of cattle.

SIGNALMENT

Species

Bovine, ovine, caprine, camelids

Breed Predispositions

- Arthrogryposis has been described in many different beef and dairy cattle breeds. Certain syndromes are predominantly reported to occur in certain breeds (e.g., congenital arthrogryposis in Charolais cattle). CCD has been observed in most dairy breeds and in all breeds of beef cattle common to western North America.
- No breed predisposition or genetic susceptibility in cattle to the lupine-induced condition has been determined.

Mean Age and Range

- Arthrogryposis tends to affect young, growing animals. The incidence of CCD is highest in heifers at first calving, but the disease has been observed in calves from cows of all ages.
- For each species (cattle, sheep, and goats), there are specific periods of gestation when the fetus is susceptible to plant teratogens. The critical gestational period for exposure of cattle to lupines is 40–70 days with susceptible periods extending to 100 days.

Predominant Sex

No apparent gender predisposition

SIGNS

HISTORICAL FINDINGS

A complete history including age, birthing details, age at which the deformity was noticed, course and progression of deformity, diets of affected animal and dam should be obtained. The animal may be normal at birth and develop the flexural deformity within hours or days.

PHYSICAL EXAMINATION FINDINGS

- The animal's conformation should be assessed first by having the animal stand in a symmetrical manner on a firm, flat surface and observing it from multiple angles.
- Arthrogryposis in CCD is characterized by deformities of the limbs (rigid flexion of elbows and carpal joints), and spinal column (scoliosis, lordosis, kyphosis), and rib cage abnormalities. Affected calves occasionally have torticollis and cleft palate.
- The joints are often flexed and cannot be extended even after the flexor tendons are cut—distinguishing the disease from contracted tendons.

CAUSES

A number of etiological agents such as intrauterine infection with border disease virus (a pestivirus), Akabane virus, Cache Valley virus, and bluetongue virus, as well as teratogenic plant ingestion have been implicated in the pathogenesis of arthrogryposis (crooked limbs) in small ruminants.

Congenital Predisposing Factors

- Uterine malpositioning
- Genetic causes
- Ingestion of teratogenic plants by pregnant dam (e.g., *Astragalus* or *Oxytropis* spp. = locoweed; *Verratum californicum* = skunk cabbage; piperidine alkaloid-containing plants such as *Lupinus*, *Conium*, and *Nicotiana* species).
- Conditions associated with arthrogryposis include crooked calf syndrome/congenital arthrogryposis, spider lamb syndrome (hereditary chondrodysplasia), ill-thrift syndrome in llamas, metabolic, and neurovascular disorders.
- Leg deformities in young calves are most commonly associated with congenital contraction of the tendons. Flexural deformities involving contracted tendons and ligaments may be seen in many breeds of cattle and small ruminants.

RISK FACTORS

Predisposing factors for congenital arthrogryposis include male gender, posterior intrauterine presentation, and double muscling.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Arthrogryposis and CCD differ from contracted tendons; in animals with contracted tendons, the joints are usually properly aligned and the legs are not rotated. In calves with arthrogryposis, the articular and osseous changes are usually permanent and worsen as the calf grows.
- Congenital arthrogryposis rule-outs: BVD, IBR, bluetongue virus, Akabane virus, and Cache Valley virus
- Arthrogryposis-hydranencephaly syndrome (AHS) in lambs may be confused with spider lamb syndrome (SLS), in which there is characteristic hyperflexion of forelimbs, cranial overextension of hind limbs, with a corkscrew deviation of the spine. In lambs with AHS, severe deformities result from primary abnormalities of the CNS and not of the skeleton. Hydranencephaly, micromyelia, hydrocephalus, and cerebellar hypoplasia are also seen with AHS.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

- Radiographs can be used to diagnose angular limb deformities; at least two views, 90 degrees apart, should be taken of the affected joint.
- The dorsopalmar/dorsoplantar (DP) view is needed for examination of the anatomical location of the deformity and for measurements. Shoot with radiographic beam in line with the claws.

DIAGNOSTIC PROCEDURES

- Serology and virological diagnostic assays may aid in ruling out in utero viral infections (e.g., Cache Valley virus).
- Feed analysis and assessment of the availability of potentially toxic plants in the environment (pasture) may assist in diagnosis.

PATHOLOGIC FINDINGS

CCD

- No consistent primary lesion, rather a number of varied tissue responses are observed. It is likely that these findings are at least in part due to the animal's inability to stand.
- Histology: few lesions, restricted to muscles of the forelimb, external intercostalis muscle, or radial and femoral nerves—myositis, myodegeneration, muscle necrosis and atrophy, cellulitis, and perineuritis.

TREATMENT

APPROPRIATE HEALTH CARE

N/A

NURSING CARE

- Severely affected animals may be unable to rise to nurse and require additional supportive care.
- Protect limbs with thick, soft bandages that fit well.
- Provide good footing and allow for stretching of flexor tendons.
- Care should be taken to maintain a soft (padding), clean, and dry environment and to minimize decubital/pressure sores, open arthritis, muscle atrophy, umbilical infections, and septicemia.

ACTIVITY

Activity should be restricted until it is certain that the deformity is improving; however, some degree of exercise allows for stretching and lengthening of affected limb structures.

DIET

Correction of any dietary imbalances should be addressed while treating cases of arthrogryposis.

CLIENT EDUCATION

- Examination of young animals with congenital arthrogryposis should be done as early as possible to assess the degree of manual correction possible.
- Because of a possible hereditary component associated with some forms of arthrogryposis, breeding of affected animals

is not recommended.

NONSURGICAL CONSIDERATIONS/CONSERVATIVE TREATMENT

- Mildly affected animals may recover spontaneously.
- Weight bearing provides the necessary physical exercise to strengthen and lengthen affected tendons and musculature.
- Minor deformities may be corrected by manual alignment and external support of the limb (e.g., rigid splinting, bandaging, or casting/tube casts).

SURGICAL CONSIDERATIONS

- Surgery may be required for animals with severe deformities and for animals that do not improve with age or conservative management.
- Treatment of arthrogryposis includes surgery to improve the animal's posture sufficient for it to obtain slaughter weight (a salvage procedure).
- Surgical procedures include: transection of flexor tendon and suspensory ligament, joint capsule release, flexor tendon lengthening procedures, and joint arthrodesis.
- May require postoperative splinting or casting for support

MEDICATIONS

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Frequent physical examinations and assessing the efficacy of corrective measures should be done to monitor progress.

PREVENTION/AVOIDANCE

- CCD: Avoid breeding affected animals.
- Coordinate grazing times and alter breeding dates to minimize exposure. Avoid grazing the potentially teratogenic plants when pregnant cows are at the susceptible stage of pregnancy.
- Control teratogenic plant populations with herbicide treatment.

POSSIBLE COMPLICATIONS

Some severe cases of arthrogryposis cannot be corrected and full extension may not be possible postoperatively.

EXPECTED COURSE AND PROGNOSIS

- The prognosis is guarded for arthrogryposis, depending on the severity of the flexural deformity. Severe deformities requiring surgery often have a poor prognosis.
- For arthrogryposis in cattle, approximately 80% of surgically treated animals can be kept until they reach normal slaughter weight.
- If untreated, arthrogryposis is usually lethal in cattle, resulting in skin necrosis over the carpus, arthritis, and septicemia.

MISCELLANEOUS

ASSOCIATED CONDITIONS

A syndrome known as “bentleg” or “bowie” has been associated with ingestion of *Trachymene glaucifolia* (wild parsnip) by pregnant ewes in Australia and New Zealand.

AGE-RELATED FACTORS

The majority of arthrogryposis cases occurs during the active growth phase of the affected bone/joint.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

In cases of congenital arthrogryposis, the teratogenic plants are ingested by the pregnant dam and the compounds are passed to the fetus through the placenta.

RUMINANT SPECIES AFFECTED

Bovine, ovine, caprine, camelid

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Producers should be aware of the association between certain toxic plants (e.g., lupines) and angular limb deformities such as CCD.
- To reduce the incidence of crooked calf syndrome, graze lupines during their least hazardous growth period and reduce exposure of pregnant cows. Lupines are most hazardous when they are young or in the mature seed stage.
- Fence off heavily infested pasture areas and use intermittent, short-term grazing of lupine pastures.

ASPERGILLOSIS

BASICS

OVERVIEW

- *Aspergillus* spp. are ubiquitous environmental organisms that can cause disease in many mammalian species. This saprophytic fungus is present in the soil and other decaying matter.
- *Aspergillus* is an opportunistic pathogen and usually occurs secondary to chronic disease, immunosuppression, stress, or metabolic disturbances. It can also occur with chronic antibiotic or steroid use.
- In ruminants, *A. fumigatus* is the most common isolate involved in clinical disease.
- The disease can manifest in ruminants as one of several forms including pulmonary, intestinal, systemic, and/or as a cause of abortion or mastitis.

SIGNALMENT

- In cattle, aspergillosis is a major cause of mycotic abortion. Primary pulmonary infections are rare but can be caused by inhalation of spores from contaminated feedstuffs. It can occur secondary to concurrent disease in a pulmonary or intestinal form. Mastitis caused by *Aspergillus* has also occasionally been seen in cattle.
- Once infected, cattle may then develop a systemic aspergillosis due to invasion of blood vessels and dissemination of the organism throughout the body.
- Housed calves may be more susceptible to pulmonary infection.
- In sheep and goats, *Aspergillus* spp. may cause a primary mastitis. Disseminated aspergillosis may occur in conjunction with mastitis. Primary pulmonary infections are rare in sheep and goats.
- Pulmonary and disseminated aspergillosis have also been reported in llamas and alpacas, camels, American bison, and cervidae.

SIGNS

Pulmonary

- May cause few clinical signs. Mild respiratory disease and/or weight loss may be the only symptoms.
- Other respiratory signs may include fever, anorexia, cough, nasal discharge, tachypnea, dyspnea, and recumbency.
- Development of pneumonia may be acute.

Mastitis

Sheep and goats may have purulent mammary secretions, slight fever, and weight loss. The affected quarter becomes swollen and firm. Clinical signs from disseminated infection include depression, fever, and weight loss.

Abortion

- Bovine abortions due to *Aspergillus* spp. usually occur in the third trimester.
- Retained placenta and placentitis are seen.
- Fetal lesions may consist of bronchopneumonia and dermatitis.

CAUSES AND RISK FACTORS

- Chronic disease, immunosuppression, concurrent disease
- Viral erosive diseases, intestinal disease, metabolic disturbances
- Chronic stress, postpartum stress
- Antimicrobial therapy, chronic steroid or antibiotic use
- Unsanitary administration of intramammary antibiotics (dry cow treatment)
- Moldy feedstuffs

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Calves: enzootic pneumonia, tuberculosis, lungworms
- Cattle
 - Pulmonary form: shipping fever, mycoplasma bovis, tuberculosis, lungworms
 - Intestinal form: displaced abomasums, traumatic reticuloperitonitis, abomasal ulcers
- Sheep/Goats
 - Pulmonary form: caseous lymphadenitis, lungworms, pasteurellosis, tuberculosis, caprine arthritis/encephalitis virus (CAEV), ovine progressive pneumonia (OPP)
 - Mastitis form: bacterial mastitis
- Llamas/alpacas: third compartmental ulcers, bacterial pneumonia, intestinal impaction

CBC/BIOCHEMISTRY/URINALYSIS

- No specific findings for aspergillosis
- May aid in diagnosis of underlying disease

OTHER LABORATORY TESTS

- Fungal culture—identify organism; because of presence in environment, may be a contaminant.
- Transtracheal wash—identify organism; also potential to be a contaminant.
- Histopathology of lesions—demonstration of invasion into tissue
- Immunohistochemistry—along with clinical signs and other diagnostics

IMAGING

Thoracic radiographs may show evidence of multiple densities throughout all lung fields.

PATHOLOGIC FINDINGS

Pulmonary

- Severe fibrinous pneumonia (in calves) and multiple, small, white, discrete granulomas surrounded by necrotic tissue or with necrotic centers on gross pathology (ruminants)
- Alpacas infected with the pulmonary form of *Aspergillus niger* may demonstrate severe pyogranulomatous bronchopneumonia with bronchiectasis and the presence of calcium oxalate crystals.

Mastitis

- Nonspecific signs of mastitis
- Demonstration of septate branched fungal hyphae on histopathology

Intestinal

- Focal hemorrhagic and necrotic lesions in the omasum, rumen, reticulum, or small intestine
- Demonstration of fungal elements in the tissues

TREATMENT

MEDICATIONS

- Surgical resection of lesions
- Antifungal drugs, including intramammary application
- Antifungal drugs have not been approved for use in food-producing animals.
- Dosages for these agents have not been established in camelids.

- Prevention would involve avoiding moldy feed, and proper administration of intramammary antibiotics.

MISCELLANEOUS

ASSOCIATED CONDITIONS

ASPIRATION PNEUMONIA

BASICS

DEFINITION

Inhalation or accidental administration of large volumes of foreign liquids, aspiration of solids (foreign bodies, plant debris, dirt) resulting in gangrenous pneumonia, or, in the case of oils, lipid pneumonia.

PATHOPHYSIOLOGY

Gangrenous pneumonia develops due to either infectious or chemical irritants damaging the airways and lung parenchyma.

SYSTEMS AFFECTED

Primarily the respiratory system; secondarily, multiple organ system dysfunction/failure

GENETICS

N/A

INCIDENCE/PREVALENCE

Uncommon, usually accidental or due to inadvertent exposure to risk factors

GEOGRAPHIC DISTRIBUTION

Potentially worldwide, depending on species and environment

SIGNALMENT

- Calves, lambs, and kids receive accidental orotracheal intubation when feeding colostrum, or inhalation of meconium containing fetal fluids during difficult parturition.
- Necrotic laryngitis in calves resulting in altered (turbulent) airflow through larynx and subsequent aspiration of pharyngeal secretions
- Adult cattle, sheep, goats: esophageal obstruction, oropharyngeal trauma, abscesses, consumption of raw turnips, beets, oranges, or other by-product type feeds
- Parturient paresis associated with recumbency in recently fresh dairy cows
- Lead-poisoning-induced dysphagia
- Crude oil, fuel oil, or natural gas condensate ingestion by livestock
- Listeriosis or botulism resulting in cranial nerve dysfunction, regurgitation or dysphagia and aspiration of gut/pharyngeal contents

Species

Potentially all ruminant species

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Acute onset of depression, tachypnea, dyspnea, coughing, fever, foul breath odor.
- Adventitious lung sounds, pleural friction rubs auscultable. In severe cases or when associated with specific conditions, recumbency, shock, and sudden death may be observed.

HISTORICAL FINDINGS

RISK FACTORS

Improper administration of oral medications, dystocia, exposure to viral (IBR), bacterial agents or their products (listeria,

Clostridium botulinum), using by-product feed supplements, toxin exposures, use of dips on livestock (submerged dips)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acute bronchopneumonia, septicemia, toxic ingestion

CBC/BIOCHEMISTRY/URINALYSIS

Complete blood count may demonstrate leukocytosis, leukopenia with left shift, elevated total plasma protein, hyperglobulinemia, hyperfibrinogenemia, dehydration, and azotemia.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

TREATMENT

- Treatment is aimed at both gram-positive and gram-negative bacterial agents, removal (if possible) of primary problem (foreign body esophagitis/choke). Protection of airway from further injury.
- Prognosis often grave in cases where significant contamination of lungs with liquids has occurred.
- Nonsteroidal and steroidal anti-inflammatory agents should be administered to prevent mediator-induced inflammation and shocklike sequelae.

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Prognosis is often grave in cases where significant contamination of lungs with liquids has occurred.

ATYPICAL INTERSTITIAL PNEUMONIA

BASICS

DEFINITION

Atypical interstitial pneumonia is defined as disease(s) presenting with sudden onset of dyspnea (severe respiratory distress or difficulty breathing) due to congestion or edema, hyaline membranes, alveolar epithelial hyperplasia, and interstitial emphysema. This definition is limited for the purposes of this discussion to intoxication of cattle with L-tryptophan, 4-Ipomeanol, perilla ketones.

PATHOPHYSIOLOGY

3-Methylindole

Ruminal conversion of L-tryptophan to 3-methylindole, which is absorbed from the rumen and is metabolized in the lung resulting in bronchiolar, alveolar epithelial, and endothelial damage; pulmonary edema; hyaline membranes; lung cell hyperplasia; and interstitial emphysema (see [Table 1](#)).

4-Ipomeanol

- Formation of pneumotoxic 3-substituted furans (ipomeanine, 4-ipomeanol, 1-ipomeanol, and 1,4-ipomeadiol by *Fusarium solani*-infected sweet potatoes.
- These compounds are absorbed from rumen, and further metabolism of 4-ipomeanol and its analogs in the lung produces bronchiolar, alveolar epithelial, and endothelial injury by irreversible (covalent) binding to proteins within the cells.
- The loss of cellular function results in cell death, edema, and clinical signs associated with toxicity.

Perilla Ketones (*Perilla frutescens*)

- Cattle grazing dry grasses on sparse pastures in late summer in the southeastern United States and New Zealand (*Perilla maculata*). The tall, green plant is found along the edge of wooded areas in pastures and grows well in later summer when other plants are dry. Intoxication commonly occurs in drought years.
- Consumption of the plant results in absorption of perilla ketone and two related compounds causing lung injury associated with dyspnea and acute death.

SYSTEMS AFFECTED

Production management, nutrition, respiration

GENETICS

No breed predilection

INCIDENCE/PREVALENCE

- Descriptions from the United Kingdom, Canada, and the western United States (3-methylindole toxicity)
- Moldy sweet potato toxicity observed in southeastern United States.
- Perilla ketone toxicity observed in southeastern United States.

GEOGRAPHIC DISTRIBUTION

Worldwide, depending on plant species and environment

SIGNALMENT

Species

Potentially all ruminant species

Breed Predilections

N/A

Mean Age and Range

Adult ruminants. Generally, adult brood cows or bulls (> 2 years of age). Suckling calves generally not affected and yearlings less susceptible.

Predominant Sex

N/A

SIGNS

- Adult cattle moved from dry summer forage to irrigated or fertilized pastures in fall.
- Herd outbreak of severe expiratory dyspnea, open-mouth breathing, excessive salivation, head and neck extension, distress and anxiousness, with quiet lung sounds
- Affected animals do not generally cough. Animals forced to walk or move through alleys may collapse and die (see [Table 1](#)).

RISK FACTORS

Typical management conditions predispose to toxicity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Parasitic bronchitis
- Aspiration syndrome
- Atelectasis
- Pneumonia
- Pulmonary hemorrhage
- Congestive heart failure
- Endotoxemia/sepsis
- Metabolic (acidosis, hypoglycemia)
- Persistent pulmonary hypertension
- Severe anemia
- Tracheal collapse
- Anaphylaxis/allergy
- Postparturient hemoglobinuria
- Anaplasmosis

CBC/BIOCHEMISTRY/URINALYSIS

Stress leukogram, not generally helpful

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

Necropsy, demonstration of appropriate feedstuffs in rumen (perilla mint, moldy sweet potatoes), primarily lung lesions with lack of other organs affected.

PATHOLOGIC FINDINGS

- Typical lesions are confined to respiratory system. Lungs are heavy and wet and have rubbery consistency (do not float). Lungs may fail to collapse and maintain rib impressions after thorax is opened.
- Petechial hemorrhages in upper respiratory tract, foamy fluid in large airways, congestion, edema and hyaline membranes, hepatization of lung, interstitial emphysema, large bullae with marked accumulation of edema in interlobular septae, proliferation of alveolar epithelial cells.

TREATMENT

- Management practices that prevent abrupt exposure of animals to lush green forage. Provision of feed and minerals during latter parts of summer to limit consumption of toxic plants.

- Do not feed moldy sweet potatoes to livestock.
- In animals that are exposed to such management conditions routinely, prior treatment with monensin or lasalocid (200 mg/head/day) for 1 day (monensin) or 6 days (lasalocid) prior to placing them on suspect pasture. Maintain access to ionophore for at least 10 days after introduction to feed.

MEDICATIONS

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

FOLLOW-UP

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Endothelial damage, pulmonary edema, hyaline membranes, lung cell hyperplasia, and interstitial emphysema
- Bronchiolar, alveolar epithelial and endothelial injury
- The loss of cellular function results in cell death, edema, and clinical signs associated with toxicity.
- Lung injury associated with dyspnea and acute death

AGE-RELATED FACTORS

Adult ruminants—generally adult brood cows or bulls (> 2 years of age); suckling calves generally not affected and yearlings less susceptible.

[Table 1](#)

Intoxication with Perilla Ketone, 4-Ipomeanol, Parasitic Bronchitis

Toxin	Signalment	History	Clinical signs	Pathology	Treatment/Prevention
3-methylindole	Adult	Moved from dry, sparse feed, to lush green pasture, irrigated/fertilized aftermath	Open-mouth breathing, head and neck extension, frothing, sudden death. Multiple animals affected. Little coughing	Heavy, wet lungs, upper airway edema and hemorrhage, lung epithelial necrosis, hyaline membranes, epithelial proliferation, interlobular and subpleural emphysema	Ionophore in feed prior to changing diet. Aspirin, flunixin meglumine, furosemide.
4-ipomeanol	Adult	Provision or access to moldy sweet potatoes.	Open-mouth breathing, head and neck extension, frothing, sudden death. Multiple animals affected. Little coughing	Heavy, wet lungs, upper airway edema and hemorrhage, lung epithelial necrosis, hyaline membranes, epithelial proliferation, interlobular and subpleural emphysema	No effective treatment. Prevent access to moldy sweet potatoes.
Perilla ketone	Adult, older calves	Late summer/fall. Limited feed, access to open, wooded areas	Open-mouth breathing, head and neck extension, frothing, sudden death. Multiple animals affected. Little coughing	Heavy, wet lungs, upper airway edema and hemorrhage, lung epithelial necrosis, hyaline membranes, epithelial proliferation, interlobular and subpleural emphysema	No effective treatment. Prevent consumption of toxic plant by provision of quality feed and minerals in late summer/fall.

RUMINANT SPECIES AFFECTED

Potentially all ruminant species can be affected.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Management practices that prevent abrupt exposure of animals to lush green forage. Provision of feed and minerals during latter parts of summer to limit consumption of toxic plants.
- Do not feed moldy sweet potatoes to livestock.

AVOCADO TOXICOSIS

BASICS

OVERVIEW

Lactating animals that consume avocado leaves may develop noninfectious mastitis and agalactia.

Source

- Avocado plant (*Persea americana*)
- Leaves, fruit, bark, and seeds reported to cause toxicosis
- Drying the leaves does not reduce toxic potential.

Toxin

- Thought to be due to a “persin,” which has been identified as (Z,Z)-1-(acetyloxy)-2-hydroxy-12,15-heneicosadien-4—one that can be isolated from the leaves of the avocado plant.
- The exact mechanism of action of this toxin on target is not known.

Toxic Dose

Symptoms of noninfectious mastitis and agalactia have been noted with 60–100 mg/kg of the toxin in an experimental setting.

SYSTEMS AFFECTED

Mammary glands, cardiovascular (mouse model) at doses higher than those that cause agalactia

B VITAMINS

BASICS

OVERVIEW

- The B vitamins are a family of water-soluble micronutrients, which act primarily as coenzymes, and are essential to normal metabolism.
- The B vitamins are thiamine (B₁), riboflavin (B₂), niacin (B₃), pyridoxine (B₆), the cobalamins (B₁₂), biotin, folic acid, pantothenic acid, and inositol.
- Common feedstuffs usually contain substantial amounts of several of the B vitamins.
- Ruminal microorganisms synthesize B vitamins in quantities that, under most conditions, meet metabolic needs; therefore, there are no specific dietary requirements for B vitamins in animals possessing a functioning rumen.
- Preruminants are susceptible to deficiencies, but these are rare when the principle feed is milk.
- Under certain nutritional, management, or disease conditions, deficiencies may result in disease, the most clinically significant being polioencephalomalacia (PEM) associated with vitamin B₁ deficiency.
- The trace element cobalt (Co) is required for the synthesis of vitamin B₁₂ and a lack of this vitamin is responsible for the ill thrift associated with Co deficiency.

SIGNALMENT

B-vitamin deficiencies are noted in all ruminants, with growing animals most at risk. Sheep are most susceptible to vitamin B₁₂ deficiency.

SIGNS

- Vitamin B₁ deficiency—a history of acute neurologic disease in growing ruminants fed highly fermentable carbohydrate is suggestive. Clinical signs include excitability, circling behavior, abnormal vision, head pressing, followed by depression, convulsions and coma.
- Vitamin B₁₂ deficiency—often accompanied by a history of ill thrift in animals offered what would appear to be an adequate ration. Animals may have been fed a ration grown in a region known to possess Co-deficient soils. Clinical signs include retarded growth, muscular weakness, anemia, ketosis and general poor condition. In sheep, a syndrome termed ovine white liver disease has been identified that is characterized by ill thrift together with serous ocular discharge, fatty degeneration of the liver and sometimes photosensitization.
- Other B vitamin deficiencies—are extremely rare or unknown in ruminants under typical management conditions, but are most likely to result in nonspecific signs of ill thrift, poor growth, skin lesions, poor coat condition, and central nervous system abnormalities.

CAUSES AND RISK FACTORS

- Deficiencies of vitamin B₁ can occur when there is production or ingestion of inactive B vitamin analogs, or excessive destruction of B vitamins in the rumen. This occurs most commonly under conditions of ruminal lactic acidosis, induced by diets containing a high proportion of concentrate or other source of highly fermentable carbohydrate such as very lush pasture. A diet of highly fermentable carbohydrate can induce changes in ruminal flora so that rumen bacteria produce excessive amounts of thiaminase, reducing the amount of thiamine available for intestinal absorption. Some plants, such as bracken fern (*Pteridium aquilinum*) contain thiaminase.
- In vitamin B₁₂ deficiency, ruminal microorganisms are incapable of producing sufficient cobalamins due to a lack of Co. The concentration of Co in crops and forages depends on a variety of factors including Co concentration of the soil, plant species, rate of plant growth, and soil pH, drainage, and fertilization. Soils are generally considered Co deficient if they contain less than 2 ppm Co. Such soils are widely distributed throughout the world.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vitamin B₁ deficiency—clinical signs are nonspecific and may be confused with PEM associated with water deprivation and toxicosis due to sulfur, salt, lead, amprolium, lasalocid, and some anthelmintics. Differential diagnoses should include the following causes of encephalitis or meningoencephalitis: focal symmetric encephalomalacia (*Clostridium perfringens* type D); thrombotic meningoencephalitis (*Hemophilus somnus*); nervous coccidiosis; listeriosis; rabies, and herpes virus. Toxicoses due to ethylene glycol, lead and selenium, and deficiencies of vitamin A and magnesium should also be considered.
- Vitamin B₁₂ deficiency—differential diagnoses that should be considered are gross malnutrition; intestinal parasitism; paratuberculosis; and deficiencies of vitamin D, selenium, and copper. Diagnosis may be complicated by the fact that cattle are more susceptible to intestinal parasitism under conditions of vitamin B₁₂ deficiency.

CBC/BIOCHEMISTRY/URINALYSIS

No consistent abnormalities are observed.

OTHER LABORATORY TESTS

- Vitamin B₁ deficiency—antemortem diagnostic aids for thiamine deficiency include the following: blood concentrations of thiamine, lactate, and pyruvate; erythrocyte transketolase activity, and fecal thiaminase activity. Many laboratories do not offer these tests routinely and, due to the acute nature of the condition, postmortem diagnosis is more commonly performed (see below).
- Vitamin B₁₂ deficiency—diagnosis may be made by measuring serum or liver vitamin B₁₂ concentrations or serum methylmalonic acid concentration.

PATHOLOGIC FINDINGS

Gross pathologic signs of vitamin B₁ deficiency are symmetric and include cortical swelling and flattened gyri with thinning and yellowing of the cortex. Necrotic areas of the brain may autofluoresce under ultraviolet light. A diagnosis of PEM can be confirmed by histopathology.

TREATMENT

If clinical signs are noted in one or more animals, it is likely that a large proportion of the herd or flock is subclinically affected.

- Vitamin B₁ deficiency—provide good quality roughage and/or remove thiaminase-containing forage. Cease treatment with any medications that might be associated with PEM.
- Vitamin B₁₂ deficiency—supplementation is usually applied on a flock or herd basis.

MEDICATIONS

- Vitamin B₁ deficiency—thiamine hydrochloride solution 10–20 mg/kg IM or SC three times daily. The same dose can be given IV if diluted in isotonic intravenous fluids and administered slowly. Corticosteroids and diuretics to reduce cortical swelling may be useful.
- Vitamin B₁₂ deficiency—injection of vitamin B₁₂ solution SC at a dose of 100–300 µg weekly or 2000–3000 µg weekly for small and large ruminants, respectively, is effective.
- Weekly oral treatment with a dilute cobalt sulfate solution at 7 mg Co per animal (small ruminants), or 35–70 mg Co per head (large ruminants) is also effective.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Vitamin B₁ deficiency—provide adequate roughage in the diet to avoid lactic acidosis. Avoid feeding plants containing thiaminase. Add thiamine mononitrate to the ration at 125 g per tonne. Ruminants should be introduced to high-grain diets gradually and large variations in intake should be avoided.
- Vitamin B₁₂ deficiency—ensure Co is supplied at a rate of at least 0.1 mg/kg DM in the total ration. Rations supplemented at this level, or salt licks containing 0.1% Co (as cobalt carbonate), should prevent the disease. Oral administration of intraruminal boluses made of metal oxides or soluble glass, where available, provides supplementary Co for periods in excess of 1 year. Cobalt sulfate applied to pasture (1.5 kg/ha every 3–4 years) can be effective also. An injectable product containing microencapsulated vitamin B₁₂ has been developed in New Zealand for supplementation of sheep and is effective for up to 8 months after treatment.

EXPECTED COURSE AND PROGNOSIS

- Vitamin B₁ deficiency—response to treatment should be noted within minutes. Individuals that are recumbent and showing severe neurologic signs at the time of treatment have a poorer prognosis. Recovered individuals may be left with residual neurologic deficits.
- Vitamin B₁₂ deficiency—response to Co or vitamin B₁₂ supplementation is usually good and improvement is noted within days of treatment, however affected growing animals may never attain full mature weight.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Ruminal lactic acidosis in vitamin B₁ deficiency
- Intestinal parasitism in vitamin B₁₂ deficiency

RUMINANT SPECIES AFFECTED

All ruminant species are affected.

PRODUCTION MANAGEMENT

There is some evidence that the health and production of high-producing dairy cattle may be enhanced by supplementation of some B vitamins (niacin, biotin, and folic acid) and Co even though these cattle are not at risk of overt deficiency. Most researched is the effect of biotin on the incidence of lameness in dairy cattle.

BABESIOSIS

BASICS

DEFINITION

- Although it has been eradicated in the United States for 60 years, babesiosis remains an important disease in cattle throughout the world where the tick vector is prevalent.
- The causative agent is an intraerythrocytic protozoan that produces intravascular hemolysis in the ruminant host.

PATHOPHYSIOLOGY

- Babesiosis is contractible via inoculation of infected blood.
- Ticks are considered to be the principal vectors (see [Table 1](#)), although transmission may also occur via blood-contaminated needles or instruments.
- The organism is transmitted by several one-host ticks; the genus *Boophilus* is particularly important.
- Female ticks become infected during blood engorgement on infected cattle, with subsequent replication of the *Babesia* in the tick's embryos. As the tick embryos develop into larvae, nymphs, and adults, the *Babesia* persist and can be transmitted to new mammalian hosts during tick feeding. For *B. bigemina*, only nymph or adult ticks are capable of transmitting the disease. The infection does not persist beyond the larval stage in *B. bovis*.
- Although considered rare, vertical transmission within the mammalian host has been reported.
- Once inoculated, the incubation period is 2 to 3 weeks.
- In endemic areas, wherein passive humoral immunity is transferred from dam to offspring, clinical signs of disease are uncommon in cattle less than 6 months of age.
- Immunosuppressed or immunologically naïve individuals are susceptible to parasitemia, and clinical signs of disease develop. If an animal survives the initial episode of infection, active immunity rapidly ensues, thereby controlling parasitemia.
- Immunity to the disease after natural exposure may be as long as 1 to 2 years, however, the development of immunity may be insufficient to completely eliminate the organism, allowing for the persistence of the organism without clinical signs of disease (premunity).
- These subclinical "carriers" of *Babesia* serve as a silent reservoir for persistent infection within a herd.
- Carriers also may experience episodic clinical signs of recrudescence as protective immunity and the extent of parasitemia wax and wane.
- Although some individuals may eventually eliminate the infection, other chronic carriers eventually succumb to the disease.
- Upon inoculation, infective sporozoites enter red blood cells wherein binary fission occurs within 14 days of inoculation. When replication is complete, the organisms are released by erythrolysis to propagate infection in new red blood cells.
- Thus the predominant clinical signs of disease are fever and intravascular hemolysis. Other factors that may contribute to hemolysis include increased red blood cell fragility, removal of infected cells by the mononuclear phagocytic system, and the development of secondary autoimmune hemolytic anemia.
- Anemia develops, and in severe cases (typically immunosuppressed or immunologically naïve adults), death from hypoxemia may ensue.
- With *B. bovis* infection, the release of inflammatory mediators in response to infection may also lead to intense hypotension, cardiovascular shock, and disseminated intravascular coagulation.
- *B. bigemina* may also replicate within the endothelium of the cerebrum, causing local hypoxemia and the development of "cerebral babesiosis," characterized by acute onset of signs of cerebral disease.

SYSTEMS AFFECTED

- Hemic: regenerative anemia, intravascular hemolysis, disseminated intravascular coagulation, hemoglobinemia,

hemoglobinuria, icterus

- Cardiovascular: hypoxemia, hypotension
- Cerebral: ataxia, blindness, maniacal behavior

GENETICS

Zebu, Afrikaner, and Santa Gertrudis cattle are less susceptible to babesiosis than are other breeds of cattle.

INCIDENCE/PREVALENCE

- The disease is widespread in endemic areas.
- The existence of asystematic carriers obscures accurate estimate of the true prevalence of infection.
- Wide application of sensitive PCR testing will be necessary to establish the actual rate and distribution of infection.

GEOGRAPHIC DISTRIBUTION

- Cases have been reported throughout the world. The disease is endemic in tropical climates where the tick vectors flourish (see [Table 1](#)).
- Rigid measures to control the *Boophilus* tick population were primarily responsible for eradication of babesiosis from the United States.

SIGNALMENT

Species

Cattle and small ruminants are the principal hosts, but cases have been reported in other ruminants, such as water buffalo, reindeer, and the American bison.

Breed Predilections

N/A

Mean Age and Range

- Any age may be affected, but younger calves in endemic areas, wherein infected dams have provided passive immunity to their offspring, rarely develop infection prior to 6 months of age.
- Immunosuppressed, debilitated, stressed, or immunologically naïve adult ruminants are more susceptible to infection and often are more severely affected by the disease.

Predominant Sex

N/A

SIGNS

GENERAL COMMENTS

- Severely debilitated, immunosuppressed, or immunologically naïve individuals in endemic areas are most susceptible to disease.
- Seasonality of the disease is mostly dependent on the peak occurrence of the tick vector population.

HISTORICAL FINDINGS

Concurrent illness; progressive depression, weakness, and lethargy; poor growth; poor coat quality; separation from the herd; anorexia; tick infestation; hemoglobinuria; fever; and icterus

PHYSICAL EXAMINATION FINDINGS

- The onset of clinical signs depends on the size of the inoculum.
- Signs of disease can develop within 1 week of inoculation of infected blood, but may not be apparent for 2 to 3 weeks.
- High fever, depression, anorexia, and progressive weakness occur first.
- The predominant clinical signs develop with the onset of intravascular hemolysis that occurs as reproducing merozoites destroy erythrocytes in the circulation.
- Tachycardia and tachypnea may be profound and depend on the degree and rate at which the anemia develops. A low-grade systolic murmur may be present over the heart base as the viscosity of the blood decreases.
- Hemoglobinemia and pallor of the mucous membranes precede hemoglobinuria and the development of icterus. Pregnant cows often abort their fetuses.
- In severe cases, death occurs as a result of anoxic shock. If the infected animal survives the initial episode of hemolysis, convalescence is prolonged until anemia has regenerated (weeks to months).
- Emaciation, poor condition, and failure to thrive, and the existence of the carrier stage are common developments during convalescence.

- Infection of the endothelium of the central nervous system in cattle with *B. bigemina* may result in clinical signs of cerebral disease, including maniacal behavior, hyperexcitability, seizures, bruxism, opisthotonus, blindness, ataxia, and coma.
- The prognosis for this form of the disease typically is grave.
- A unique phenomenon of anal sphincter spasm in cattle infected with *B. divergens* may produce the additional clinical sign of pipe stream feces.

CAUSES

- Babesiosis is caused by infection with protozoa from the phylum Apicomplexa, order Piroplasmida, genus *Babesia*.
- There are at least six species of *Babesia* that affect cattle and two species that affect small ruminants (see [Table 1](#)). *B. bovis* is frequently considered to be the most pathogenic of the *Babesia* species; *B. major* and *B. ovate* are less pathogenic to nonpathogenic.

RISK FACTORS

Immunologically naïve (typically mature cattle) or immunosuppressed or otherwise debilitated individuals in endemic areas wherein the tick vectors reside are most at risk for contracting the infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any cause of intravascular hemolysis in cattle would result in similar signs including leptospirosis, bacillary hemoglobinuria, Heinz body anemias (onion, rape, kale toxicity), theileriosis, postparturient hemoglobinuria, and autoimmune hemolytic anemia.
- Differentials for extravascular hemolysis should also be considered.
- Copper toxicity should be considered as differential diagnoses in sheep.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia
- Regenerative anemia 5 to 7 days after onset (signs of regeneration include an increased MCV, anisocytosis, polychromasia, basophilic stippling, reticulocytes, Howell Jolly bodies, nucleated red blood cells)
- Hemoglobinemia (pink plasma, MCH, and MCHC increased)
- Hemoglobinuria (red-brown urine, urine dipstick positive for blood; positive for hemoglobin with saturated ammonium sulfate test)
- Hyperbilirubinemia (unconjugated)
- Hypokalemia
- Thrombocytopenia
- Metabolic acidosis

OTHER LABORATORY TESTS

- *Babesia* species may be seen within erythrocytes in a peripheral Wright- or Giemsa-stained blood smear. *B. bovis* is often difficult to find in the peripheral blood.
- The protozoa appear as nonpigmented, pyriform to irregular, round or amoeba-shaped organisms.
- Often, the protozoa appear in groups of two, with the “tops” of the pear-shaped organisms joined at an angle to form a “v.”
- Parasitemia is often low, or affected cells are removed from the circulation, therefore absence of visible protozoa does not preclude the diagnosis.
- The humoral response to *Babesia* can usually be detected within a week of infection.
- Numerous serologic assays have been developed to detect *Babesia*, but the complement fixation, ELISA, and the indirect fluorescent antibody tests are most commonly used.
- Because humoral immunity postinfection is long lived, it may be difficult to distinguish active infection from previous exposure.
- Highly sensitive and specific PCR assays recently have been developed as extremely useful tools in the diagnosis and

surveillance of active infection in both ticks and cattle.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Sudden death is not uncommon. Depending on the stage of the disease, diffuse pallor of the tissues or icterus is present.
- Splenomegaly, hepatomegaly, edema, body cavity effusion, petechial and ecchymotic hemorrhages on the heart and gastrointestinal tract, thin blood, thrombi, gallbladder distension, and the presence of red-brown urine in the urinary bladder are common findings.
- In chronically infected cattle, emaciation is an additional expected feature. *B. bigemina* tends to proliferate in peripheral vessels, whereas *B. bovis* multiplies in visceral blood vessels.
- Direct fluorescent antibody staining and PCR assay of blood or tissues are the most specific tests used to confirm the diagnosis postmortem.

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient or outpatient care

NURSING CARE

- If anemia is severe and clinical or laboratory evidence of hypoxemia is evident (intense lethargy or weakness, profound tachycardia or tachypnea, severe anemia, acidosis, increased anion gap), a whole blood transfusion is indicated.
- The normal total blood volume is approximately 8% of the body weight (i.e., 0.08 x body weight in kilograms equals the total blood volume in liters). Typically, transfusing one-fourth to one-third of the total blood volume is adequate.

ACTIVITY

Confined

DIET

N/A

CLIENT EDUCATION

- See Prevention/Avoidance below.
- Immunologically naïve cattle moving into endemic areas should be vaccinated prior to movement.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

- Numerous drugs have been used for the treatment of babesiosis.
- The most commonly used drugs include diminazene diaceturate (Berenil; 3–5 mg/kg IM), phenamidine diisethionate (Lomazine; 8–13 mg/kg, SQ or IM), imidocarb dipropionate (Imizol; 1–3 mg/kg, SQ or IM), and amicarbalide diisethionate (Diampron; 5–10 mg/kg IM). Imidocarb therapy may prevent reinfection for up to 2 months.
- Overzealous use of babesiocidal drugs may abruptly reduce parasitemia to a level that is inadequate for establishment of protective immunity.

CONTRAINDICATIONS

Meat and milk withdrawal periods must be maintained.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Heart rate, respiratory rate, attitude, appetite, PCV, body weight

PREVENTION/AVOIDANCE

- Most control programs are tailored to the particular circumstances of infection in the herd.
- Complete eradication in a herd within an endemic area leaves that herd susceptible to future reinfection from surrounding herds.
- Thus most control programs are aimed at balancing the degree of infection with an appropriate level of immunity. This is most effectively achieved by reducing the tick population with acaricides and vaccination with live or live-attenuated organisms to establish a state of premunition.
- As older animals are more sensitive to the effects of infection, vaccination with live organisms is often followed with babesiostatic drugs.
- Newer vaccines using cell culture or recombinant proteins are promising, but are not currently widely available. There is little cross protection between species of *Babesia*.

Table 1

Distribution and Vectors for <i>Babesia</i> in Ruminants			
Species	Geographic location	Reported vectors	Infective stage of tick vector
<i>B. bigemina</i>	South America, Europe, Africa, Australia, Middle East, Asia, West Indies	<i>Boophilus annulatus</i> , <i>B. decoloratus</i> , <i>B. microplus</i> , <i>B. calcaratus</i> , <i>Rhipicephalus evertsi</i> , <i>R. bursa</i> , <i>R. appendiculatus</i> , <i>Haemaphysalis punctata</i>	Nymphs and adults
<i>B. bovis</i> (also includes <i>B. berbera</i> , or <i>B. argentina</i>)	South America, Europe, Russia, Africa, Asia, Australia	<i>B. annulatus</i> , <i>B. microplus</i> , <i>Ixodes spp.</i> , <i>Rhipicephalus bursa</i>	Larvae
<i>B. divergens</i>	Europe, Africa	<i>Ixodes ricinus</i>	Larvae
<i>B. major</i>	Europe, Russia, North Africa, Middle East	<i>Haemaphysalis punctata</i>	Adults
<i>B. jakimovi</i>	Siberia, Asia	<i>Ixodes ricinus</i>	
<i>B. ovata</i>	Japan	<i>Haemaphysalis longicornis</i>	
<i>B. motasi</i> (sheep and goats)	Europe, South America, Africa	<i>Dermacentor silvarum</i> , <i>Haemaphysalis</i> , <i>Rhipicephalus bursa</i>	Adults
<i>B. ovis</i> (sheep and goats)	Europe, Russia, Asia, Middle East	<i>Ixodes ricinus</i> , <i>Rhipicephalus bursa</i> , <i>Dermacentor reticulatus</i>	Adults

POSSIBLE COMPLICATIONS

Death from hypoxemic anemia or cerebral babesiosis is not uncommon. Treatment frequently does not eliminate the carrier state.

EXPECTED COURSE AND PROGNOSIS

- Carriers and recrudescence are common in endemic areas. Infection with *B. bovis* is generally more severe than infection with other species.
- The presence of cerebral babesiosis warrants a grave prognosis.
- The mortality rate is high in adult immunologically naïve or immunosuppressed individuals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Younger cattle in endemic areas are rarely infected.

ZOONOTIC POTENTIAL

Although rare, immunosuppressed humans may be susceptible to infection.

PREGNANCY

Immunization of pregnant cows with live or live-attenuated vaccines may induce neonatal isoerythrolysis.

RUMINANT SPECIES AFFECTED

- Cases of babesiosis have been reported in cattle, small ruminants, white-tailed deer, American bison, water buffalo, reindeer, Asian elk, Tartarean roe deer, and African buffalo.
- Recent application of PCR techniques revealed that 16% of the cottontail rabbit population on Nantucket Island, Massachusetts, were carriers for *B. divergens*.
- The significance of this finding has not been fully determined, but widespread use of PCR assays may unveil a wider range of distribution of the organism.

BACILLARY HEMOGLOBINURIA

BASICS

DEFINITION

Peracute, highly fatal, anaerobic infection of cattle and other ruminants caused by rapid proliferation of *Clostridium haemolyticum* (*Clostridium novyi* type D) after hepatic insult and resulting in sudden death or fulminant disease with characteristic necrotic hepatic infarct, hemolysis, hemoglobinuria, and toxemia.

OVERVIEW

- Disease primarily of cattle and sheep caused by proliferation of and toxin(s) released by *C. lostridium haemolyticum* (*Clostridium novyi* type D)
- Spores of *Cl. haemolyticum* are normally found in the soil and GIT (liver, feces) and urine of healthy cattle and sheep grazing on contaminated pastures.
- Disease results when a hepatic insult or damage creates an area of anaerobiosis in the liver appropriate for spore germination and resulting vegetative cell multiplication and toxin production.
- Hepatic insult often results from migration of liver flukes (*Fasciola hepatica*, *Dicrocoelium dendriticum*, or *Cysticercus cellulosae*) or trauma (iatrogenic or spontaneous).
- Disease causes sudden death or fulminant toxemia.
- Clinical signs and pathologic lesions primarily due to toxin(s) produced by organism
- Organism produces at least three exotoxins.
 - Principle toxin, β -toxin, is a phospholipase C with lethal necrotizing (hydrolyzes lecithin and sphingomyelin) and hemolytic (hemolyzes erythrocytes) activity.
 - Tropomyosinase
 - θ -toxin: a lipase
- Toxins induce localized hepatic necrosis, toxemia, and intravascular hemolysis.
- Seasonal disease occurring mostly in summer and fall
- Outbreaks in feedlot cattle fed hay from infected fields
- Disease is spread from contaminated pasture to uninfected area by carrier animals, flooding or natural water drainage, or feeding of contaminated hay or bones of infected animals.

PATHOPHYSIOLOGY

- *Clostridium haemolyticum* is endemic in moist or swampy areas with a high soil pH (~8).
- Organism spores survive in soil and bones from affected animal carcasses for years.
- Once ingested by animal during grazing, spores are transported via lymphatic and blood to liver and tissue where they remain dormant.
- Asymptomatic but infected cattle harbor the organism in their GIT, liver, and tissues and may shed it in feces and urine.
- Any liver insult or damage that results in suitable anaerobic conditions fosters conversion of spores to vegetative organisms and bacterial proliferation.
- Vegetative growth associated with production and release of potent exotoxins, which induce hepatic necrosis, hemolysis, and severe toxemia
- A single ischemic pale hepatic infarct is highly suggestive of the disease.

SIGNALMENT

- Occurs in western United States, along the Gulf of Mexico, Wisconsin, Florida, New Zealand, Australia, Mexico, Venezuela, Chile, Great Britain, Ireland, Middle East
- High incidence in animals grazing irrigated or poorly draining alkaline pastures

- Usually affects mature cattle
- Highly conditioned cattle seem most susceptible.
- Mature sheep affected sporadically
- No sex or breed predilection

SIGNS

- Sudden death with no premonitory signs
- Duration of symptoms usually ranges from 12 hours to 4 days
- Peracute toxemia
 - High fever (103°F –106°F; 39.5°C–41°C)
 - Severe depression
 - Tachycardia
 - Abdominal pain
 - Ileus
 - Hypolactia/agalactia
 - Anorexia
 - Dark feces
 - Dysentery with blood and mucus
 - Arched-back stance
 - Grunting
 - ±Brisket edema
 - Abortion in pregnant cows
 - Recumbency
 - Shock
 - Death within 12 to 48 hours
- Intravascular hemolysis
 - Dyspnea
 - Progressive tachycardia
 - Hemoglobinuria
 - Red stain to perineal wool
 - Progressive anemia
 - Icterus
 - ± Tachypnea
- Immune carriers: animals exposed to subclinical infections

Pathologic Lesions

- Rapid onset of rigor mortis
- Anemic (pale) infarct of liver is virtually pathognomonic.
 - Usually a single infarct but occasionally multiple of varying size
 - Dark-red zone of hyperemia around infarcts
- Red urine in kidney and bladder
- Dehydration
- Icterus
- Anemia
- Subcutaneous gelatinous edema
- Petechial or diffuse subcutaneous hemorrhage
- Bloody fluid in abdominal, pericardial, and thoracic cavities
- Trachea has bloody exudate and mucosal hemorrhages
- Intestinal tract is hemorrhagic and may contain free or clotted blood.
- ±Subcutaneous edema

- ±Hemorrhages in renal parenchyma

CAUSES AND RISK FACTORS

- Pasturing of cattle in areas where liver flukes reside
- Geographic areas with wet or swampy conditions and high soil pH
- Irrigated pastures
- Hepatic insult(s) in cattle, which creates an appropriate anaerobic environment for germination of spores include migration of liver flukes, liver abscesses, septicemia, metabolic anoxia of liver, hepatotoxins, trauma, biopsy, and high nitrate diets.
- In sheep, telangiectasis, necrobacillosis, and *Cysticercus tenuicollis* are also precipitating factors.
- Unvaccinated cattle, sheep

DIAGNOSIS

- History of grazing cattle in pasture containing liver flukes or of a known insult to the liver
- Gross necropsy lesions
- Identification of large, gram-positive rods on impression smear from liver lesion
- Culturing of *Cl. haemolyticum* from tissue from the edge of liver infarct fresh carcass
- Demonstrate organism in liver by clostridial fluorescent antibody test (FAT) or immunohistochemistry
- Toxin identification
 - Demonstration of only β lecithinase in peritoneal effusion
 - Saline extract of liver infarct
- Definitive diagnosis by culture and GLC confirmation that isolate is *Cl. haemolyticum*
- Complete blood count
 - Evidence of hemolysis in plasma or serum
 - Anemia
 - Primarily leukocytosis ± left shift
 - May have leukopenia with left shift
- ±Anaerobic blood cultures (acute stage)
- Serum chemistry panel often reflects severe insult to liver and accompanying changes in other organ systems, hydration status, or hypophagia
 - Elevated liver enzymes (SDH, GGT, AST)
 - Hyperbilirubinemia
 - Azotemia
 - Elevated creatine kinase, if recumbent
 - Electrolyte abnormalities
 - Metabolic acidosis

DIFFERENTIAL DIAGNOSIS

- Leptospirosis
- Postparturient hemoglobinuria
- Hemolytic anemia from cruciferous plants
- Enzootic hematuria (bracken fern toxicosis)
- Anaplasmosis
- Chronic copper poisoning
- Black disease
- Acute pyelonephritis
- Hemorrhagic cystitis

CBC/BIOCHEMICAL/URINALYSIS

- Progressive anemia
- Leukocytosis with neutrophilia
- Hemoglobinuria

OTHER LABORATORY TESTING

IMAGING

Hepatic Ultrasound

- Infarct
- Disruption of normal parenchyma
- Vascular changes

DIAGNOSTIC PROCEDURES

- Caution interpreting Gram stains, culture, or FAT of liver
 - *Cl. haemolyticum* is a normal inhabitant of the liver
 - Cross reacts with *Cl. novyi* type B on FAT
- Ultrasound of liver
- Blood culture

TREATMENT

- Seldom successful
- High doses of aqueous potassium or sodium penicillin, intravenously (44,000 IU/kg QID) preferred
- High doses of procaine penicillin IM
- Tetracycline has also been recommended.
- Blood transfusion(s) as indicated; minimum of 4–6 liters for adult cattle
- Antitoxic serum, if available
- Intravenous fluids to maintain normovolemia, and electrolyte and acid-base balance
- Appropriate treatment of secondary organ disease or dysfunction
- If recovery, treat for liver flukes

MEDICATIONS

DRUGS OF CHOICE

- High doses of penicillin or tetracycline
- Blood transfusion
- Antitoxic serum
- Polyionic fluids

CONTRAINDICATIONS

- Monitor for blood transfusion reaction
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Mortality in untreated animals is 95%.
- Mortality in treated animals is high.

- On endemic farms, death losses may be as high as 25%.
- Heavy mortalities when naïve, unvaccinated cattle brought onto infected pastures
- Recovered animals may become poor doers: chronic weight loss, poor production
- Cattle surviving subclinical attacks of disease may act as immune carriers.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Toxemia, hypovolemia, and severe anemia may result in damage to other organs.
- Renal or pulmonary emboli
- Renal infarcts
- Cardiac arrhythmias
- Pigment nephropathy

ZOONOTIC POTENTIAL

N/A

RUMINANT SPECIES AFFECTED

- Cattle
- Adult sheep primarily
- Uncommonly elk, other ruminants

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Cattle should not be grazed on liver fluke infested pastures.
- Treat cattle with anthelmintics effective against liver flukes.
- Aquatic snails are intermediate hosts and needed for the flukes to complete their life cycle; use muskicide to remove snails, or fence cattle away from areas with standing water.
- Avoid feeding practices that induce ruminal acidosis or rumenitis to decrease liver abscess formation.
- In United States, vaccination recommended in spring; do not vaccinate within 21 days before slaughter.
- Calf vaccination
 - Commercial bacterin-toxoids *Cl. haemolyticum*
 - Vaccinate calves twice 3–4 weeks apart at 3–4 months of age
 - Booster annually or every 6 months in endemic areas
 - Deworm sheepdogs to reduce *C. tenuicollis* infection.
- Avoid pasture contamination by removing contaminated feces or properly disposing (burn, deep burial, remove from premises) of decomposing carcasses of affected animals.

BACKGROUNDING BEEF CALVES

BASICS

OVERVIEW

- The term “backgrounding” is used to describe many different systems in which cattle are grown after weaning but before being placed into a feedlot.
- Some people may use backgrounding and preconditioning interchangeably but backgrounding can include much more than just a preconditioning period.
- Backgrounding programs are often called stocker programs in the southern and southwestern United States.
- The ultimate goal of a backgrounding program is to enable calves to gain frame and muscle mass without gaining excessive condition.
- Most backgrounding programs rely on forage-based diets and may take advantage of inexpensive regional feeds such as grain by-products or crop residues.
- Backgrounding programs may provide more flexibility and market opportunity for producers and may give producers a good way to use available forages and/or feeds.
- Numerous backgrounding systems exist, and one system is not appropriate for all producers or all types of cattle.
- Backgrounding programs may be used for home-raised calves, or calves may be purchased from other producers and placed into a backgrounding program. Some producers provide custom backgrounding services for other producers.

Types of Backgrounding Systems: Preconditioning, Wintering, Growing, Grazing Wheat Pasture, Fast-Track Systems, Calf-Fed Finishing Systems

Preconditioning

- Preconditioning is a 30–45-day period occurring immediately after weaning in which calves are weaned, taught to eat dry feed from a bunk, and taught to drink from a water tank.
- Numerous health management practices such as vaccination, dehorning, implants, and castration can occur during this time.
- Efforts should be made to reduce stress as much as possible during this period so it is beneficial to perform the health management factors described above at least a few weeks prior to weaning.
- Preconditioning may be part of a larger backgrounding program or it may occur alone with calves being placed directly in the feedlot after the preconditioning period.
- Gains during this period are usually minimal.

Wintering

- This system focuses on using large quantities of forage (e.g., crop residues, hay, and dormant pastures) to carry calves through the winter.
- Targeted gains range between 0.5 and 1.5 lbs/hd/day.
- The overall goal is to minimize winter-feed cost and keep cattle healthy.
- Calves may be sold in the spring when prices are favorable or grazed through the summer to take advantage of additional cheap gains.
- Smaller framed British or British-cross cattle tend to fit this system well.
 - These cattle tend to have excess finish and light carcass weights if placed directly on feed after weaning.
 - Overwintering coupled with summer grazing allows these cattle to gain adequate frame and muscle prior to finishing so that their finished carcass weights better meet the industry standards.
- Large-framed exotic or exotic-cross cattle do not fit this system well because they become too large and finish with carcass weights that exceed the industry standards.

Growing

- This system targets higher rates of gain (1.5–2.5 lbs/hd/day) over a shorter period of time.
- This system utilizes a mixture of forage and grains and is a good way to utilize forages or grains grown on the farm.
- The cattle best suited to this system include moderate framed exotic and British breed cattle that may become too large in an overwintering system but become too fleshy if grown at a faster rate.

Grazing Wheat Pasture

- This system is the most common backgrounding system in the U. S. southern plains states.
- Calves are placed on wheat pasture around the middle of November and removed around the middle of March if wheat is to be harvested. If the producer elects not to harvest wheat grain, the pasture can be “grazed out” usually until the middle of May.
- The rates of gain and type of cattle are similar to those for other growing systems.

Fast-Track Systems

- These systems involve feeding rations that are quite similar to those fed in a finishing program.
- The goal is to get cattle to gain as fast as possible and gains should be 3 lbs/hd/day or more.
- The fast-track systems are best suited to large-framed exotic or exotic-cross cattle with genetic potential for rapid gains.
- They require a much higher level of management and have an increased risk of digestive problems.

Calf-Fed Finishing Systems

- These systems involve placing calves directly on feed after weaning or after a preconditioning program.
- Calf-fed finishing systems are better suited to commercial feedlots and are best suited for large-framed exotic cattle.
- This production system may get cattle finished earlier and allow the producer to take advantage of seasonal variations in price.

Backgrounding Facilities

Pens

- Pens should be designed to provide adequate space, protection from cold winds, adequate bunk space, adequate water supply, ease of handling, and safety.
- Calves in backgrounding systems generally require 150–300 square feet of space per calf.
- Pens should slope away from the feed bunk and have adequate drainage to reduce mud.
- Concrete aprons should be provided around feed bunks and waterers to reduce mud.
- Properly designed mounds should be included to provide calves a dry place to rest.
- Pen size should be no greater than 150 head per pen.

Feed and Water

- Calves fed once daily should have 18–26 inches of bunk space per calf.
- Calves fed twice daily should have 8–11 inches of bunk space per calf.
- If self-feeders are used, 3–4 inches of trough space per calf is required.
- Bunks should be easy to clean.
- Feeding on the ground should be avoided due to increased wastage and disease transmission.
- Placing waterers along fence lines will help new calves find the water.

Handling Facilities

- Handling facilities should be designed to promote smooth flow of calves through the system.
- Numerous publications are available describing facilities design.

Advantages of Backgrounding

- Calves can be grown to optimum size to increase feeding efficiency and maximize returns.
- Homegrown feed resources can be marketed through backgrounded calves.
- Backgrounding gives producers more flexibility and allows marketing of calves at times when demand and prices may be higher.
- Calves may be healthier and enter the feedlot with less stress when they have been backgrounded.

PATHOPHYSIOLOGY

- Stress is a major contributor to disease in weaning-age calves. Reducing the stress of weaning by performing health management practices prior to weaning should help reduce disease in these calves.

- Stress is also a major contributor to disease in cattle entering a feedlot.
 - Backgrounding programs may reduce the stress of feedlot placement by giving the calves the opportunity to learn to eat from a bunk and drink from a water tank. Getting calves used to eating dry feeds is also a benefit.
 - Properly backgrounded calves should have greater resistance to disease because of proper vaccination during the backgrounding period.
 - Increasing the age and maturity of calves through backgrounding prior to feedlot placement also should increase disease resistance.

SYSTEMS AFFECTED

The respiratory and gastrointestinal systems are most commonly affected by disease in weaned calves and cattle placed in the feedlot; production management

GENETICS

- Calf genetics play a very important role in deciding if and how to background calves.
- Numerous backgrounding systems exist and the system should be carefully matched to the type of cattle in order to take maximum advantage of the system.

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

- Most cattle are shipped to the Great Plains states for finishing and slaughter.
- Backgrounding programs may be performed on the farm or ranch of origin or calves may be purchased from several producers and shipped to a backgrounding program.
- Preconditioning calves on the farm or ranch of origin provides the best health benefits because stress and commingling are reduced at the time of weaning.

SIGNALMENT

- The type of cattle best suited for a particular backgrounding program depends on the genetics of the calf.
- See Types of Backgrounding Systems above for a description of the types of cattle best suited to each program.

SIGNS

- Calves should be watched very closely for signs of disease throughout a backgrounding period, especially during the preconditioning and early backgrounding phase.
- The most common diseases affecting calves at this time are respiratory and gastrointestinal diseases.

CAUSES

The causes of disease during the backgrounding period are numerous and most commonly include diseases of the respiratory and gastrointestinal tract.

RISK FACTORS

Stress and commingling with calves from other farms are two of most important risk factors for disease in calves during a backgrounding program.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

N/A

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Postmortem examinations should be performed on all cattle that die during a backgrounding program in order to make appropriate management decisions about disease prevention and treatment.

TREATMENT

APPROPRIATE HEALTH CARE

- If possible, management practices such as castration, dehorning, implants, and vaccination should occur prior to weaning.
- If necessary, these practices can be performed during the backgrounding, or preconditioning, period.
- These practices should not be performed at the time of weaning because of the increased stress to the calves. If performed during the preconditioning period, they should be performed after the calves have had some time to recover from the stress of weaning.

NURSING CARE

N/A

ACTIVITY

N/A

DIET

- Much of the advantage of a backgrounding program is gained from feeding forage-based diets to achieve moderate rates of gain.
- Depending on the type of backgrounding system and the type of cattle being fed, the diet will vary from mostly forage to diets that may be similar to those used in a feedlot.
- Adequate nutrition is very important to the success of a backgrounding system.
 - Calves must be provided adequate protein and energy to provide for maintenance needs as well as to provide the desired amount of gain.
 - A balanced mineral supplement should be available at all times because proper trace mineral nutrition is essential for optimum immune system function.
- Calves should have constant access to a clean water source and should be watched closely to make sure they are drinking adequately during the initial phase of the backgrounding period.
- Feeding management
 - Calves should be fed long-stemmed grass hay from the bunks for 4–7 days to help get them accustomed to the bunks. Once calves are eating from the bunks, a starter ration can be top dressed over the hay to get calves started on the ration.
 - Allowing waterers to run over for a few days will help calves find the waterers. The sound of running water will attract the calves.
 - Bunks should be kept clean and any old or moldy feed should be removed.
 - See the Suggested Reading list below for more information on feeding management.

CLIENT EDUCATION

N/A

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

- Calves should receive respiratory virus and clostridial vaccines prior to weaning or as part of the preconditioning program.
- Several antibiotics are labeled for metaphylactic (mass medication) use and may be beneficial in high-risk calves.
- Treatment protocols should be established to provide adequate and consistent treatment.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food producing animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- Young calves may be at increased risk of developing disease during the backgrounding period.
- Younger calves may also be less likely to respond to vaccines due to the interference of colostrum antibodies.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

- Calves should not be exposed to bulls during the backgrounding period due to the risks associated with pregnancy in feeder heifers.
- Many heifers will reach puberty during the backgrounding period and should not be pastured with intact bulls.

RUMINANT SPECIES AFFECTED

Cattle

BIOSECURITY

- Biosecurity should be considered in order to protect calves from as much disease exposure as possible.
- If calves from other sources are being backgrounded, they should be maintained separately, if possible, to prevent the introduction of disease in the home-raised calves.

PRODUCTION MANAGEMENT

Backgrounding systems should have a production management plan in order to provide and monitor production, nutrition, and disease occurrence.

BACTERIAL ENDOCARDITIS

BASICS

DEFINITION

An acute, subacute, or chronic infection involving one or more of the heart valves or parietal endocardium resulting in variably sized masslike lesions on or near the valves, valvular insufficiency or stenosis, and progression to heart failure.

OVERVIEW

- Most common valvular or endocardial disease in adult cattle but often unrecognized or misdiagnosed
- Vegetative lesions result from hematogenous infection of valvular or mural (parietal) endocardium
- Gram-positive organisms, *Arcanobacterium pyogenes*, α -streptococci, most commonly cultured from blood of affected cattle
- Tricuspid valve most frequently and severely affected in cattle
- Often more than one valve involved
- Initial clinical signs are vague and variable; later signs relate to cardiac insufficiency or septic thromboembolism
- Long-term antimicrobial and supportive therapy required
- General prognosis is guarded to poor for productivity and long-term survival

PATHOPHYSIOLOGY

- Unclear whether bacteria in bloodstream directly adhere to endocardium or valvular surfaces or enter hematogenously through capillaries at base of valve.
- Circulating bacteria enter endocardial surface(s) and initiate infection.
- Local proliferation of bacteria (bacterial colonies grow in laminar fashion).
- Endothelial damage exposes collagen and enhances platelets and fibrin; fibrin is a major component of the vegetative lesion.
- Certain bacteria synthesize polysaccharides (dextrans) and fibronectin, which enhance their ability to adhere to and colonize endothelial surfaces (vascular walls, heart valves) and thrombi.
- Bacteria adhering to valve surface activates coagulation cascade via release of tissue thromboplastin and extrinsic pathway.
- Reseeding of endothelial surface with continued bacteremia.
- Preexisting structural damage to endothelium (valvular or mural) and nonbacterial thrombi may or may not be required to initiate disease.
- Heart failure, right-sided more commonly than left-sided, may subsequently develop.
- In cattle, tricuspid valve is most frequently affected followed by mitral, pulmonary, and aortic valve, and endocardium adjacent to valves.
- Multiple valve involvement reported.
- Bacterial embolism to secondary organs is common.
- Lesions may be small to large enough to occupy most of adjacent heart chamber.
- Three histologic zones in lesions: (1) inner zone composed of fibrous tissue, (2) intermediate zone contains fibrin and bacterial colonies, and (3) superficial zone of fibrin and blood cells.
- Gross necropsy findings: (1) valvular lesions, often vegetative or fibrotic, thickening and distortion of valve leaflet, (2) embolic lesions to other organs, (3) signs of right-sided or congestive heart failure (e.g., hydrothorax, hydroperitoneum, passive congestion of liver, subcutaneous edema).

SIGNALMENT

- Seen worldwide

- Primarily in mature cattle
- More common in adult, small ruminants than in young
- No sex or breed predilection

SIGNS

- Frequently animal has history of temporary remission of clinical signs during antibiotic therapy.
- Clinical signs are often variable and vague.
- Tachycardia is the most consistent finding.
- Decreased appetite
- Weight loss
- Intermittent or constant fever
- Lameness, septic arthritis
- Hypolactia
- Heart murmur noted in ~50% of cattle cases
 - Primarily holosystolic or pansystolic on right side because of propensity for tricuspid valve to be affected
 - Diastolic and continuous also reported
 - Location, timing, and point of maximum intensity of murmur depends on valve(s) affected
 - ±Thrill
- Cardiac arrhythmias in ~10% of affected cattle
- ±Variable intensity of heart sounds
- ±Painful on palpation over heart region
- Less common signs: weakness, diarrhea, abdominal pain, pale mucous membranes
- As disease progresses, signs of heart failure, primarily right-sided, develop
 - Right-sided heart failure: ventral, mandibular, or brisket edema, jugular or mammary vein distention ± vein pulsation, tachycardia, hepatomegaly
 - Left-sided heart failure: tachycardia, tachypnea, dyspnea, coughing, abnormal lung sounds on auscultation
- Occasionally, affected cattle die suddenly without observed clinical signs
- Signs of secondary organ (lung, kidney) involvement (infection, infarction) or embolic disease

CAUSES AND RISK FACTORS

- At least eight bacterial species have been isolated from cattle with bacterial endocarditis.
- *Arcanobacterium (Actinomyces) pyogenes*, α -hemolytic streptococci are most commonly isolated.
- Other common isolates: *Escherichia coli*, *Micrococcus* spp., *Staphylococcus aureus*, *Pseudomonas* spp., *Klebsiella pneumoniae*, *Proteus mirabilis*, *Clostridium* spp., *Bacterioides* spp., *Fusobacterium necrophorum*.
- Uncommon isolates: *Mycoplasma mycoides*, *Erysipelothrix rhusiopathia*, *Helcococcus ovis*.
- Predisposing factors include chronic infection, chronic bacteremia, and underlying damage to valvular or endocardial surface.
- Risk factors include ruminal acidosis (acute, subacute, chronic), thrombophlebitis, infection site (mastitis, metritis, septic arthritis, tail infection, pneumonia, omphalophlebitis, abscesses, etc.), traumatic reticulopericarditis, decubital ulcers, traumatic myocarditis, indwelling intravenous catheter, iatrogenic lesions.

DIAGNOSIS

- Based on compatible history and clinical findings (murmur, persistent tachycardia), positive blood cultures, and confirmed by echocardiographic identification of consistent lesions
- History and physical examination
 - Tachycardia
 - ±Cardiac murmur
 - ±Fever

- ±Obvious sites of infection
- Hyperfibrinogenemia
- Hypergammaglobulinemia due to infectious or inflammatory process
- Aerobic and anaerobic blood cultures and sensitivity
 - Blood sample(s) obtained before antimicrobial therapy is initiated
 - Minimum of 10 ml of blood collected aseptically
 - Two to three cultures drawn 1–2 hours apart from separate venipuncture sites preferred but not often obtained
 - Culture in broth medium
 - Antimicrobial removal device (ARD) used if animal previously received antimicrobial drugs
 - Alternatively, if animal's condition permits, withdraw antimicrobial therapy for 24 to 48 hours before obtaining blood samples for culture
 - Failure to obtain a positive blood culture does not rule out the presence of bacterial endocarditis
- Examination of buffy-coat smears or leukocyte monolayer preparation stained with gram or Giemsa stain
- Echocardiography
 - Visualize and measure size of vegetative lesion on or around heart valve leaflets.
 - Lesions appear as echogenic shaggy, smooth, or cystic masses.
 - Valve thickening with ventricular hyperkinesis.
 - ±Enlargement of chambers on affected side.
 - ±Acoustic reverberation and production of microbubbles.

CBC/BLOOD SERUM CHEMISTRY/URINALYSIS

- Complete blood count
 - ±Nonregenerative anemia
 - Most commonly leukocytosis ± left shift; monocytosis
 - May have normal leukogram or leukopenia with left shift
 - Cattle have less consistent leukocyte response compared to other species
- Serum chemistry panel often reflects accompanying changes in other organ systems, hydration status, or hypophagia
 - Azotemia
 - Elevated GGT
 - Elevated creatine kinase if recumbent
 - Electrolyte abnormalities from anorexia
- Urinalysis if renal infection or infarct suspected

OTHER LABORATORY TESTING

- Electrocardiogram if arrhythmia present
- Transtracheal wash for cytology and microbiologic cultures if signs of pulmonic disease
- Thoracic radiographs of limited value in evaluating cardiac disease in cattle
- Arterial blood gas to evaluate oxygenation status
- Venous blood gas to evaluate metabolic status

IMAGING

- Echocardiogram: vegetative lesion on or near one or more heart valves, most commonly tricuspid valve, ± secondary chamber enlargement (right atrial).
- Negative study does not rule out diagnosis of bacterial endocarditis.

DIAGNOSTIC PROCEDURES

- Thorough history and physical examination
- Blood cultures
- Echocardiogram
 - Adult cattle: sector scanners, 3.5 mHz (or smaller) transducer
 - Young calf or small ruminant: 5.0 mHz
 - May need to scan adult cattle from both sides

DIFFERENTIAL DIAGNOSIS

Bacterial, viral, or protozoal myocarditis

Brisket disease

Cardiac lymphosarcoma or other neoplasm

Congenital cardiac abnormalities

Congestive heart failure

Cor pulmonale

Dilative cardiomyopathy

Endocardiosis

Nutritional myodegeneration

Parasitic endocarditis

Septic pericarditis

Toxic myocardial necrosis (ionophore toxicity, gossypol toxicity, plant toxicosis)

TREATMENT

- Long term and often costly
- Often palliative rather than curative
- Aimed at (1) sterilizing lesion and stopping spread of infection and (2) controlling signs of heart failure
- Ideally, antimicrobial therapy based on sensitivity of bacteria isolated from blood culture or other site of infection
- Parenteral administration of bactericidal antimicrobials required for a minimum of 4 to 6 weeks and often as long as 8 to 12 weeks
- Ideally, initial therapy includes broad spectrum antimicrobials given intravenously (IV) to provide maximum blood levels
- In cattle, penicillin and beta-lactam drugs are frequently first-choice therapy due to high percentage of gram-positive organisms isolated from affected animals
- Early withdrawal of therapy may result in relapse
- Often, extralabel use of antimicrobial is required because few are labeled for long-term therapy
- Anti-inflammatory/antipyretic agents: aspirin, flunixin meglumine
- Anticoagulants to limit enlargement of vegetative lesions and thromboembolic disease; bovine platelets respond poorly to antithrombotic effects of aspirin
- If signs of heart failure are present, diuretics and dietary sodium restriction are added to therapy
- Maintenance of normal blood electrolyte concentrations, acid-base status, and hydration
- Appropriate treatment of secondary organ disease or dysfunction
- Correct hypokalemia (\pm hypocalcemia) associated with anorexia and diuretic therapy
- Oxygen supplementation if hypoxemic

MEDICATIONS

DRUGS

- Penicillin: 22,000 IU/kg: Aqueous potassium penicillin IV QID or procaine penicillin IM BID
- Amoxicillin: 10 mg/kg IM BID
- Ampicillin: 20 mg/kg IV TID; 10 to 20 mg/kg IM BID
- Rifampin: 5 mg/kg PO BID, as adjunct therapy to enhance antibiotic penetration into lesion
- Anti-inflammatories: flunixin meglumine, aspirin
- Anticoagulants: aspirin, 30 to 100 mg/kg PO every 12 to 24 hours; heparin, 30 U/kg SC every 12 hours (of questionable value)

- Furosemide: 0.5 to 1 mg/kg IV every 12 to 24 hours
- Potassium supplement (50 to 200 g/day PO) if on potassium-wasting diuretics

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Most cases die or are culled due to poor prognosis and expense of therapy.
- One study reported 29% of affected cattle survived until discharge.
- Long-term survival rate and productivity level is not known.
- Prognosis is generally guarded to poor for recovery and productivity.
- Animals diagnosed early and treated aggressively with small or single lesions have a fair to good prognosis.
- Monitoring resolution of disease or lesion.
 - Regression of clinical signs
 - Return of fibrinogen and serum protein concentrations to normal
 - Echocardiogram to measure size of lesion(s)
 - Repeat blood culture 3–4 days after discontinuing antimicrobial therapy
- Reasons for therapeutic failure.
 - Advanced stage of disease at initiation of therapy
 - Premature withdrawal of therapy
 - Ongoing valvular thrombosis due to endothelial damage
 - Bacterial recolonization of valve
 - Change in sensitivity or type of infecting bacteria

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Cardiac arrhythmias including sinus tachycardia, premature ventricular contractions, and atrial fibrillation
- Septic arthritis
- Passive hepatic congestion
- Congestive heart failure
- Myocardial disease
- Most common sequelae include embolic pneumonia, renal infarction, suppurative arthritis, hepatic emboli
- Less common sequelae: cerebral and adrenal emboli, epididymitis, pleural effusion

ZOONOTIC POTENTIAL

N/A

RUMINANT SPECIES AFFECTED

- Mostly mature cattle
- Goats, sheep

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Observe appropriate milk and meat withdrawal times for drugs administered.
- Treatment of unregistered animals with bacterial endocarditis is often not undertaken due to costs.
- Genetically valuable animals often treated to enhance options for genetic salvage procedures (e.g., semen collection,

embryo collection, cloning).

- Infection results in decreased milk and meat production.

BACTERIAL MENINGITIS

BASICS

DEFINITION

- Meningitis is defined as a bacteria-associated inflammatory process that involves the meninges of the brain and/or spinal cord.
- Disease is most commonly seen in neonates but may also occur in older animals as a result of osteonecrosis induced by thermal cauterization during dehorning, extension of localized infection from skull fractures or coccygeal vertebrae (poor docking hygiene), or secondary to left-sided bacterial endocarditis.

PATHOPHYSIOLOGY

- Bacterial meningitis occurs by direct extension of an infectious agent into the calvarium or by hematogenous spread to the CNS from a distant site.
- The relative lack of bactericidal and opsonic activities in the CNS predisposes animals to meningeal infection.
- The inflammatory response resulting from bacterial invasion of the subarachnoid space is due in large part to the activity of host-derived mediators (cytokines), and it is this inflammatory response that is responsible for the long-term neurological sequelae and death associated with bacterial meningitis.
- Defects of cerebrospinal fluid (CSF) drainage occurring secondary to meningeal inflammation lead to hypertensive hydrocephalus.

SYSTEMS AFFECTED

Nervous system

GENETICS

None reported

INCIDENCE/PREVALENCE

The disease is common in neonatal farm animals. One survey reported a 43% prevalence of septic meningitis in necropsied calves (Green and Smith, 1992).

GEOGRAPHIC DISTRIBUTION

Worldwide occurrence

SIGNALMENT

Neonates of all species, especially calves

SIGNS

HISTORICAL FINDINGS

- There may be a history of prematurity, dystocia, or lack of colostrum intake.
- There may be a history of hyperesthesia, stiff neck, depression, seizures, or blindness, with or without a history of another illness, such as enteritis or polyarthritis.
- There may be a history of trauma, recent dehorning, or tail docking, or there may be information relating to the presence of a wound near the calvarium or vertebrae (usually older ruminants), or an infection of the sinuses, middle ear, or inner ear.

PHYSICAL EXAMINATION FINDINGS

Acute meningitis may or may not be accompanied by fever in the neonate.

Depression, anorexia, omphalophlebitis, polyarthritis, and ophthalmitis are frequent concurrent findings.

Neurological Examination Findings

- Ataxia, with or without spasticity and mild tetraparesis, hyperesthesia, neck pain, depression, wandering, star-gazing, and abnormal vocalization, may be seen.
- Lethargy, recumbency, anorexia, loss of suckle reflex, coma, opisthotonus, convulsions, tremors, and hyperesthesia are

the most common clinical signs in calves.

CAUSES

- Meningitis most commonly results from hematogenous extension of a preexisting bacterial infection, or results from traumatic penetration of the CNS.
- Failure of passive transfer of maternal antibodies predisposes to hematogenous meningitis.
- The bacteria involved most commonly are those associated with neonatal sepsis.
- Gram-negative bacteria are the predominant cause of infection in large animal neonates although polymicrobial infections also occur.
- *Escherichia coli* is the most common bacterium isolated. Other isolates include *Klebsiella pneumonia*, *Salmonella* spp. (*S. dublin* and *S. typhimurium*), *Staphylococcus* spp., *Streptococcus* spp., and *Bacillus* spp. in calves; *Klebsiella pneumonia*, *Salmonella* spp., *Streptococcus* spp., *Arcanobacterium pyogenes*, *Erysipelothrix rhusiopathiae*, and occasionally *Leptospira interrogans*, *Listeria monocytogenes*, *Mycoplasma* spp., and *Fusobacterium necrophorum* in sheep and goats in North America.

RISK FACTORS

Both maternal and neonatal factors contribute to the development of sepsis in the neonate. They include bacterial placentitis, perinatal stress, prematurity, dystocia, birth asphyxia, unsanitary or adverse environmental conditions, overcrowding, failure of passive transfer of maternal antibodies, contamination of the environment with pathogenic bacteria, and the presence of enteritis, omphalitis, or respiratory infections in the neonate.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Metabolic disease (e.g., hypoglycemia, hypomagnesemia)
- Cerebral edema
- Hydrocephalus
- Encephalitis (e.g., viral)
- Toxicity

CBC/BIOCHEMISTRY/URINALYSIS

- Leukocytosis with a left shift is common in calves.
- Respiratory acidosis, hypernatremia, hyponatremia, hyperkalemia, hypomagnesemia, and hypoglycemia may be observed also.

OTHER LABORATORY TESTS

- Low serum immunoglobulin concentrations may be observed.
- In the presence of neurological signs, a positive blood culture supports a diagnosis of bacterial meningitis secondary to neonatal infection. Other samples, such as synovial fluid, also may culture positive.

IMAGING

Radiographs and/or ultrasound may be indicated when trauma or extension of a localized infection is suspected.

DIAGNOSTIC PROCEDURES

Definitive diagnosis is based on the presence of a neutrophilic pleocytosis, xanthochromia, turbidity, high total protein concentration in the CSF, and, ideally, positive culture from the CSF. Although often unrewarding, Gram stain and culture should be attempted.

TREATMENT

APPROPRIATE HEALTH CARE

- Early diagnosis and aggressive treatment are imperative for a successful outcome. By the time clinical signs are present, treatment is often unrewarding.

- Within the herd, minimize perinatal stress, ensure passive transfer of maternal antibodies, and employ proper dehorning technique and hygiene during tail docking.

NURSING CARE

Provision of adequate nutritional support and a clean, comfortable environment; protection from self-inflicted trauma; and maintenance of body temperature, fluid, and acid-base balance are critical for a successful outcome.

ACTIVITY

N/A

DIET

N/A

CLIENT EDUCATION

Treatment may be expensive and mortality rate high despite appropriate therapy.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

Antimicrobials

NOTE: * = Not approved for use in food animals in the United States; ** = Approved for use in cattle, except lactating cows, in the United States; extralabel dose

- Antimicrobial therapy is the hallmark of treatment.
- Drugs that penetrate the blood-CSF barrier are lipid soluble, nonionized at physiologic pH, not extensively protein bound, and of low molecular weight. Drugs that satisfy these criteria and that are approved for use in food animals are limited, but include trimethoprim sulfa and sulfonamides (except lactating dairy animals). Inflammation markedly enhances CSF concentrations of penicillins, particularly cephalosporins, which normally penetrate poorly. Other drugs, such as aminoglycosides, do not penetrate CSF even in the presence of inflammation.
- Selection of an antimicrobial drug in ruminants should also be based on the pharmacokinetics and pharmacodynamics of the drug in neonates, the likelihood of antimicrobial resistance, and the potential for violative antimicrobial tissue residues.
- Bacteriocidal drugs are superior to bacteriostatic drugs.
- Where possible, the selection of antimicrobial drugs should be based on either smears stained by Gram stain or culture from infected areas. Treatment should not be delayed, however, until results of sensitivity testing are known. Empiric antimicrobial therapy should include gram-negative and gram-positive spectrum.
- Antibiotics should be administered by intravenous routes in order to attain maximum peak blood and CSF concentrations.
- The efficacy of specific antimicrobial therapy for treatment of meningitis in food animals is unknown because of the lack of CSF pharmacokinetic data in ruminants. Specific antimicrobial therapy could include, but is not limited to trimethoprim sulfa (30 mg/kg, IV, q 12 h)*; cefazolin (20 mg/kg, IV, q 6 h)*; florfenicol (20 mg/kg, IV, q 12 h)**.
- Relapses may occur as meningeal inflammation subsides and CNS concentrations of (nonlipophilic) antimicrobial drug(s) fall.
- Antimicrobial drug therapy should continue for at least 7 days after resolution of all clinical signs.

Anticonvulsants

The following drug doses have been extrapolated from recommended doses for equine neonates.

- Diazepam (5–10 mg/45 kg, slowly IV, repeated if necessary) is used for short-term control.
- If two to three doses of diazepam fail to control convulsions, a loading dose of phenobarbital (10–20 mg/kg diluted in 30 ml saline, IV over 15 minutes) should be given. Oral therapy (5–10 mg/kg, q8htoq12h) is then used for maintenance for long-term control.
- Pentobarbital (2–4 mg/kg, IV, slowly) has been advocated, but depth of anesthesia must be monitored to prevent respiratory arrest.

Other Treatments

- Consider DMSO (1 gm/kg, IV as a 10% solution in 5% dextrose or saline), corticosteroids (dexamethasone at 0.15 mg/kg 15–20 minutes before the first dose of antibiotic, then every 6 hours for 4 days), or a combination of both if progression is rapid.
- Following rehydration, nonsteroidal anti-inflammatory drugs may be beneficial (flunixin meglumine, 0.5–1.0 mg/kg, IV, q 12 h to q 24 h; ketoprofen, 2.2 mg/kg, IV, q 24 h; or aspirin, 100 mg/kg, PO, q 24 h in neonates)
- A plasma transfusion may be required.
- Additional therapy may be required to resolve secondary complications (i.e., antiulcer medications, ophthalmic drugs, etc.).

CONTRAINDICATIONS

- Acepromazine should not be used as a sedative due to its ability to lower the seizure threshold.
- Drug withdrawal times must be determined for all drugs used to treat food-producing animals.

PRECAUTIONS

Care should be exercised when dosing anticonvulsant drugs in neonates because of the increased permeability of their blood brain barrier.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Close monitoring of vital parameters and metabolic indices is warranted during antimicrobial therapy, especially in animals showing seizure activity.

PREVENTION/AVOIDANCE

- The key to prevention of meningitis in neonates is paying attention to the events leading up to and including parturition, and ensuring adequate colostrum intake.
- Proper dehorning technique and hygiene during tail docking will decrease the incidence of meningitis in older animals.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Prognosis in neonatal ruminants with septic meningitis is poor, despite treatment. The key to a successful outcome relies on early recognition of CNS involvement and institution of aggressive, appropriate therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Generalized sepsis typically accompanies septic meningitis in neonates.

AGE-RELATED FACTORS

Neonates are most commonly affected.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Diseases affecting the dam during gestation may predispose the neonate to partial or complete failure of passive transfer after birth.

RUMINANT SPECIES AFFECTED

All species are susceptible.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Measures taken that reduce perinatal stress will reduce the incidence of septic meningitis in the neonate.
- Proper dehorning technique and hygiene during tail docking will reduce the incidence of septic meningitis in older animals.

BEEF BULL MANAGEMENT

BASICS

OVERVIEW

- It is well known that the reproductive program in each herd has a major influence on productivity and is directly linked to profitability.
- Good reproductive performance requires diligent management of many important and interrelated factors.
- The performance of herd bulls during natural service is dependent upon not only their health and proper management but also the health of the females they will be breeding.
- To be successful, programs should start with good planning and genetic selection considerations for the important traits necessary for each herd and continue through the implementation stages of the breeding season.
- At the end of the production cycle, success is measured by overall reproductive efficiency and the performance of the offspring.

SYSTEMS AFFECTED

SIGNALMENT

Species

Beef cattle

Breed Predilections

All breeds

BULL MANAGEMENT PROGRAMS

- Bull management programs begin with the purchase of new herd sire prospects.
- The genetic direction of the herd is of obvious importance.
- In addition to inherent genetic traits, bulls must be healthy, fertile, and capable of expressing the desirable traits.
- Bulls should be purchased from seed-stock breeders that have documented herd health programs that minimize the likelihood of infectious diseases.
- The bulls should be immunized against common diseases and, if necessary, treated for parasites or tested for diseases indicated from a biosecurity standpoint.
- All bulls should undergo a complete breeding soundness evaluation (BSE) performed by a competent veterinarian to assess their general physical and reproductive soundness. This includes newly purchased bulls and a yearly reexamination of herd bulls.
- In addition to the general physical examination, it is important to collect semen and evaluate the sample for spermatozoal motility and morphology.
- Bulls should meet the minimum standards established by the Society for Theriogenology (BIF).
- Each component of the BSE such as scrotal circumference (SC) should be accurately measured and utilized within the context of age, weight, nutritional status, and contemporary group.
- SC is a good indicator trait for age at puberty in offspring; it is highly correlated with daily sperm production and is

mildly correlated with the percentage of normal spermatozoa.

- Body condition, structural correctness of feet and legs, and general soundness are also important factors for new sire prospects.

BULL TO FEMALE RATIO

The number of bulls required to adequately cover a given number of breeding females is related to a variety of factors. An arbitrary classification of some considerations follows:

Factors Influencing Bull to Female Ratio (BFR)

- Pasture or range conditions and cattle distribution
 1. Terrain
 2. Water availability and location(s)
 3. Carrying capacity
 4. Pasture adaptation
 5. Pasture size
- Individual bull variation
 1. Age
 2. Condition
 3. Fertility
 4. Mating ability
 5. Social behavior
 6. Injury
- Operation and management
 1. Length of breeding season
 2. Animal breeding and selection
 3. Reproductive disease
 4. Nutrition and body condition
 5. Management observation
- Defining the optimum BFR is difficult because certain factors influencing each set of circumstances are unpredictable.
- The expected number of estral females available to the bull(s) on any given day is an important point that must be considered.
- Anecdotal reports indicate that smaller breeding pastures with fewer animals are more efficient and provide more uniform distribution of bulls and females. This obviously limits the total number of females exposed to dominant bulls when compared to large multisire pastures where females congregate in a sexually active group. This is a group of estral females that band together from preestrus through standing estrus.
- The bull(s) join this group and are constantly moving throughout the pasture. This is of most concern in very large groups of females because the bulls tend to run together.
- It is possible for single bulls to cover 60 breeding females in limited breeding seasons and produce comparable reproductive rates to a much lower BFR.
- Generally, BFRs of 1:25 or 1:30 for mature bulls and BFRs of 1:15 or 1:20 for yearling bulls have been utilized for range areas with minimal observation and little breeding season management.
- This may be an important area of management consideration if optimizing efficiency and reducing expenditures is desirable.

Other Considerations

- The time each cow settles in relation to the start of the breeding season influences the weaning weight of her offspring and the ability to select replacement heifers with adequate age in a yearly production cycle.
- In limited breeding seasons, efficient management requires early conception and higher overall pregnancy rates.
- It is important to identify and optimize the use of bulls with preferred genetic traits, especially as producers move

toward value-based marketing through vertically coordinated programs.

- The use of frequent observation of breeding pastures and immediate detection and correction of problems is important.

Molecular Evaluation

- More recent technology utilizing a commercially available set of DNA microsatellite markers to identify each sire's progeny from multisire breeding pastures has been developed.
- Proteomics shows promise in terms of accurately identifying progeny. As new technology advances, it may reach an economic level that could permit its use in commercial herds.
- The identification of progeny in multisire breeding pastures will permit an accurate genetic evaluation system for a greater number of young sires.
- This potential could rapidly revolutionize bull selection programs and permit the ability to select and optimize the use of bulls with superior reproductive and genetic traits.

SELECTION GUIDELINES

- Select superior bulls from a genetic standpoint.
- Carefully screen the health of all new bulls.
- Conduct a breeding soundness evaluation on all bulls and select bulls that are above average in scrotal circumference, motility, and percent normal sperm morphology.
- Conduct breeding soundness evaluations on bulls yearly, preferably just before breeding season begins.
- Develop a method to identify some progeny of each sire.
- Observe mating ability of bulls during breeding at the start and several times during the breeding season.
- Utilize knowledge of social behavior, terrain, calving pattern, bull performance, and other factors to determine the number of bulls, bull to female ratio, and grouping of bulls.

BERSERK MALE SYNDROME/ABERRANT BEHAVIOR SYNDROME

BASICS

OVERVIEW

- Berserk syndrome or berserk male syndrome (BMS), aberrant behavior syndrome (ABS)
- As with any behavioral difficulty, there is a wide range in the severity of syndrome expression.
- A berserk male is a male camelid who has been improperly imprinted on humans, is extremely aggressive, and is very territorial. The extreme case is possibly incurable. However, most ABS camelids are not this severe and a more favorable prognosis is accorded.
- Territorial males typically direct their aggression toward other male llamas and their aggressiveness is misdirected at humans. In a domestic camelid, this syndrome is unacceptable for caretaker safety.
- Symptoms that indicate a camelid is at significant risk for developing ABS generally begin between 12 and 18 months of age; severe ABS begins between 2 and 3 years of age.
- Behavioral signs include: screaming, excessive spitting, attacking humans and other animals, charging, biting, butting, and lying on people.
- BMS/ABS is the result of a male llama being abnormally socialized to people at an early age. Common causes include bottle feeding, excessive handling, limited discipline of poor behaviors, removal from mother/peers, and isolation from the rest of the herd.
- Male crias are imprinted upon people and essentially see them as another llama in the herd.
- ABS crias communicate with people through behaviors like spitting, chest butting, and wrestling.
- Territoriality of males increases over time.

GEOGRAPHIC DISTRIBUTION

Worldwide in camelids

SIGNALMENT

Species

Camelids

Breed Predilections

N/A

Mean Age and Range

Symptoms that indicate a camelid is at significant risk for developing ABS generally begin between 12 and 18 months of age; severe ABS begins between 2 and 3 years of age.

Predominant Sex

Males

SIGNS

Clinical Signs

ABS camelids may have the following history:

- Bottle or tube fed/supplemented
- Separated from mother, generally early in life
- Separated from other camelid peers
- Early veterinary treatment, sometimes extensive
- Handled by numerous inexperienced people with the exclusion of camelid peers

Behavioral Signs

- Does not respond to training
- ABS camelids are usually under 4 years old.
- Regularly follow people within a 2-foot distance.
- Orge at humans
- Quite human aggressive
- Drop to a U-neck position near humans
- Flip tail over back into an aggressive positioning
- Aggressively pursue people and run up to people on sight

TREATMENT

- Castration is mandatory. Early castration is preferred. Castration generally helps and may in fact alleviate the syndrome in some cases. Once the syndrome is diagnosed, castration should be accomplished.
- Postcastration, remove the camelid completely from his territory. He should be moved into an established pasture of an aggressive older male. This should be done as soon as possible postsurgery. The new pasture should be out of the visual territory of the previous pasture. The animal should be maintained in this mixed pasture for several months prior to a training program.
- Training program with a qualified camelid trainer/behaviorist is necessary if a poor postsurgical/mature peer response occurs.
- In severe cases, euthanasia is indicated.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Raise young males with one or more assertive adult males/geldings. These animals will teach the young crias needed socialization and “manners.”
- Young intact males should be raised within the territory of an established male.
- Pushiness or aggressiveness should be firmly/positively corrected early on.
- Begin behavior training at an early age.
- Regular brushing/grooming while haltered allows socialization to humans.
- Do not allow crias to invade personal human space (2-foot distance rule).
- Halter training can begin around 2 months of age and is done slowly allowing camelid acceptance. All training should be directed toward eliminating cria aggression.
- Early camelid training must establish you as the alpha leader and the cria should learn to follow instructions.
- Do not allow attention at people’s feet by crias.

Genetic Selection

- Don’t breed from aggressive camelid stock; select less-aggressive dams and sires.
- Select against territorial instincts.
- Select away from guarding instincts, if possible.

- Keeping geldings away from females early on. Mixing can encourage possessive behavior and territoriality in ABS crias.
- Do not breed males before 4–5 years of age.
- Castrate all young males that show excessive fear, aggression, or territoriality or challenge adult animals/humans.

BESNOITIOSIS

BASICS

DEFINITION

- Infection with a coccidian protozoa of genus *Besnoitia*, family Sarcocystidae, which primarily affects the skin, subcutis, blood vessels, mucous membranes, and tissues of cattle, horses, goats, and other herbivores
- Organism is closely related to genus *Toxoplasma*.

OVERVIEW

- Chronic debilitating disease primarily of cattle, goats, and rarely horses
- Affects antelope, blue duiker, and blue wildebeest in Africa, caribou in Canada, and wildlife in Australia
- Endemic disease in some tropical and subtropical areas, sporadic elsewhere
- High morbidity, significant economic loss, and low mortality in endemic areas
- Reported in cattle in southwest Europe (France, Portugal), Africa, South America (Venezuela), Israel, Kazakhstan, South Korea, Asia, and Soviet Union
- Reported in goats in Iran, New Zealand, Africa
- Reported sporadically in horses in Africa, southern Europe, Mexico, and in two imported burros in the United States
- Not reported in cattle in North America
- Reported in North America in wildlife including opossum, caribou, reindeer, and mule deer; other wildlife that prey upon definitive host (i.e., cats) may also be affected.
- Three of the seven classified species occur in domestic livestock and four in wildlife.
- Life cycle involves a definitive host and an intermediate host.
- *Besnoitia* are host specific for intermediate hosts.
 - *Besnoitia besnoiti* in cattle
 - *B. bennetti* infects horses, donkeys, mules
 - *B. caprae* in goats (not sheep)
 - *B. tarandi* in reindeer, mule deer, and caribou
 - *B. jellisoni* and *B. wallacei* infect rodents
 - *B. darlingi* from lizards, opossums, and snakes
 - *B. sauriana* in lizards
- Cats are the definitive host for some *Besnoitia* spp. infecting wildlife; sexual reproduction occurs in the intestines of the definitive host.
- Transmission to wildlife may be fecal-oral route by ingestion of oocysts (contaminated feeds or water) shed in cat (final host) feces.
- Definitive host and mechanism of transmission for species affecting domestic livestock is unknown.
- Mechanical transmission via biting insects/flies (tabanids, tsetse, ticks) possible in cattle and goat; ingestion of feedstuffs or water contaminated with cat feces
- Transmission via semen suspected.
- Experimentally, can transmit some *Besnoitia* spp. by needle inoculation of cyst-containing tissues into suitable host.
- Organism localizes in thick-walled cyst(s) in the skin, blood vessels, mucous membranes of upper respiratory tract and subcutaneous and other tissues.
- Anasarca gives way to sclerodermatitis with loss of hair and epidermis and development of severe dermatitis.
- Condition may become generalized and disseminated

PATHOPHYSIOLOGY

- Upon entrance into a susceptible intermediate host, sporulated oocysts release sporozoites that produce tachyzoites via endodyogeny.
- Parasitemia is associated with tachyzoites (endozoites) replicating in the host's macrophages, fibroblasts, and endothelial cells.
- Tachyzoites are released from endothelial cells and reinvoke other endothelial cells causing vasculitis, increased permeability, anasarca, and thrombosis in capillaries and small veins of the dermis, subcutis, and testes (known as anasarca stage).
- Tachyzoites migrate into connective tissues and initiate cyst formation within endothelium and fibroblasts. They mature here to form bradyzoite cysts (cystozoites).
- Cellular destruction and release of inflammatory mediators during replication of organisms in endothelial, histiocytic, and other cells result in clinical signs and formation of large thick-walled cysts filled with bradyzoites.
- Connective tissue reaction around the cysts produces a thickening of the skin and resulting circulation disturbances, alopecia, and necrosis (scleroderma stage).
- Cysts are most commonly within the dermis, subcutaneous connective tissues, conjunctiva, sclera, scrotum, and mesentery.
- Location of cyst formation and size help determine which clinical signs predominate in any given case.

SIGNALMENT

No age, sex, or breed predilection

SIGNS

- Many affected animals are asymptomatic except for cysts in scleral conjunctiva.
- Cattle commonly have two stages of the disease: an acute stage associated with endozoite proliferation and a chronic stage with scleroderma and cyst formation.
- Incubation period in cattle is 6 to 10 days.

Cattle: Signs Seen During Acute Phase

- Fever
- Warm, painful ventral swellings and reluctance to move
- Anasarca (generalized edema of skin)
- Tachypnea
- Tachycardia
- Hypophagia
- Swollen lymph nodes
- Nasal discharge (rhinitis)
- Lacrimation
- ±Diarrhea
- Loss of condition
- Hypolactia
- Photophobia
- ±Orchitis
- ±Abortion
- Small whitish to clear pinpoint nodules on scleral conjunctiva and nasal, pharyngeal, and laryngeal mucosa

Cattle: Signs Seen During Chronic Phase

- Skin lesions progress to severe dermatitis over most of body
- Sclerodermatitis
- Infected cysts in the skin and subcutaneous tissue
- Subcutaneous lumps
- Variable alopecia
- Hyperpigmentation
- Skin thickens, wrinkles, and cracks
- Thickened folds of skin around neck, shoulders, rump

- Inspiratory dyspnea
- Secondary bacterial infection or myiasis of skin
- Bulls frequently become sterile: scrotal skin affected, and orchitis, epididymitis, periorchitis, vascular lesions in testes
- Teat lesions
- Mouth lesions in suckling calves
- Loss of hair, especially on face and lower legs in wildlife

Other Lesions That May Be Seen with Generalization of Disease

- ±Focal or disseminated myositis, keratitis, periostitis, endostitis, lymphadenitis, pneumonia, arteritis, perineuritis
- Severe weight loss

In Goats

- Rarely see acute stage
- Animals present in chronic stage with dermatitis and respiratory dyspnea
- Thickening, lichenification, alopecia, fissures, and oozing serum of legs (carpus/tarsus) and ventral abdomen
- Lesions severe on scrotum and fetlocks
- ±Subcutaneous papules over hindquarters

Postmortem Lesions

- Parasitic cysts in dermis, subcutaneous and other fascia
- Pharyngitis, laryngitis, tracheitis
- Cysts present in scrotum and testes of males
- Sandlike granules and cysts in nostrils and turbinates
- Sandlike granules in vascular endothelium
- Widespread vascular lesions
- Dermatitis
- Secondary lesions in skeletal and heart muscle, and lungs
- Histology: parasite evident in cystic lesions

CAUSES AND RISK FACTORS

- Endemic area
- Disease outbreaks in cattle and goats occur during fly/insect season
- Contamination of feedstuffs with cat feces
- High feral cat population

DIAGNOSIS

- Diagnosis is based upon history and geographical area.
- Appearance of cyst in scleral conjunctivas or nasal mucosa
- Identification of crescent-shaped bradyzoites surrounded by a collagen capsule in skin or scleral conjunctival scrapings or skin biopsy
- Ear-tip biopsy commonly used in goats
- Affected animals are often asymptomatic.

DIFFERENTIAL DIAGNOSIS

- Lumpy skin disease
- Sweating sickness
- Ectoparasites: ticks, fungi, mites

CBC/BIOCHEMISTRY/URINALYSIS

- No characteristic changes
- ±Hyperproteinemia, hypergammaglobulinemia

OTHER LABORATORY TESTS

- Serum antibodies by indirect immunofluorescence or ELISA
- Tests have only moderate sensitivity

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Scleral conjunctival or skin scrapings
- Skin biopsy

TREATMENT

- Isolate affected animals.
- No specific treatment; treat symptomatically.
- Supportive therapy; dermatitis, enteritis, fever.
- Reported clinical cure in donkey after prolonged administration of trimethoprim-sulfamethoxazole.
- Reportedly in rabbits, antimony and sulfanilamide complex prevented cyst formation.
- Oxytetracycline may have some value if given early in the course of the disease.

MEDICATIONS

N/A

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

- Case fatality about 10%
- Long convalescence period (many months)
- Sterility and infertility may be transient or permanent

MISCELLANEOUS

PREVENTION

- Reduce exposure to biting insects and ticks.
- Avoid exposure of wildlife to feces of infected cats.
- Avoid feed contamination with cat feces.
- Control feral cat population.
- Vaccine produced using *B. besnoiti* isolated from wildebeest and grown on tissue culture is effective.
 - Durable immunity in all vaccinates
 - Subclinical infection occurred at low level.

ASSOCIATED CONDITIONS

- Secondary bacterial or myiasis
- ±Focal or disseminated myositis, keratitis, periostitis, endostitis, lymphadenitis, pneumonia, arteritis, perineuritis

ZOONOTIC POTENTIAL

N/A

RUMINANT SPECIES AFFECTED

- Cattle
- Goat
- Wild ruminants: antelope, wildebeest

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Affected animals remain carriers for life.
- Chronic cystic stage results in severe production loss.
- Economic losses in endemic areas due to mortality (<10%), sterility (temporary or permanent), loss of condition, and lower market value, and damage to hide.
- Carcasses approved if localized lesions only, no systemic involvement
- Carcass condemned if disseminated lesions with emaciation

SYNONYMS

“Dimple” in goats

Globidiosis

BLACK LOCUST TOXICITY

BASICS

OVERVIEW

- There are two lectins present in the bark of the *Robinia pseudoacacia* (black locust) tree. They are the major lectin RPbAI and the minor lectin RPbAII. The seeds and leaves are also toxic.
- Plants from this family are in the same family as the *Abrus precatorius* (rosary pea) and the *Ricinus communis* (castor bean), as well as the *Phoradendron* (mistletoe) and *Phytolacca americana* (pokeweed).
- The lectins act as hemagglutinins and bind to mucous membranes, where they impair nutrient absorption and inactivate rRNA—particularly within the crypt epithelium. Also, due to the inhibition of protein synthesis, they impair the immune system and put the animal at risk for secondary bacterial infection.

GEOGRAPHIC DISTRIBUTION

These trees are typically found in the woods of the eastern United States but are also used as landscape trees throughout the United States.

SIGNALMENT

- Toxicity from the black locust is more prevalent in the summer and fall, when there is less forage available to grazing animals.
- Any ruminant on pasture can be potentially exposed to this toxin.

SIGNS

- Clinical signs can be acute or chronic and can consist of inappetance, bloody diarrhea, and salivation. Weakness and incoordination can be present due to posterior paralysis. There can be dyspnea, dehydration, laminitis, and recumbency. A weak pulse may be present due to systemic shock.
- Death is infrequent.

CAUSES AND RISK FACTORS

The major risk factor is animals grazing on sparse pasture in the late summer and fall.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Vomitoxin from moldy concentrates or arsenic toxicity as well as other causes of gastroenteritis

CBC/BIOCHEMISTRY/URINALYSIS

There will be increased hepatic enzymes—AST, ALT, LDH, GOT, and GGT. There can be increased BUN and creatinine. Decreased serum total protein, specifically albumin, can be present. There can be hemoconcentration (increased PCV and TP) due to the dehydration.

OTHER LABORATORY TESTS

RBC agglutination, precipitin test

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Presence of black locust seeds or plant materials in the forage or rumen contents upon necropsy is most diagnostic.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- Postmortem lesions are generally restricted to the GI tract.
- There can be fatty hepatic change and erosions of abomasal and intestinal epithelium.
- There can be pulmonary hemorrhage, edema, and emphysema.

HISTOPATHOLOGICAL FINDINGS

- You may find central lobular hepatic necrosis, lymphoid necrosis, and crypt cell epithelial necrosis.
- Histopathological evidence of pulmonary hemorrhage, edema, and emphysema may be evident.
- There may be necrosis of the renal convoluted tubules.

TREATMENT

Treatment consists of antiserum for ricinus toxicity, sedatives for convulsions, arecoline hydrobromide and saline cathartics.

MEDICATIONS

N/A

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING

The recovery period can be extensive.

PREVENTION/AVOIDANCE

Control black locust plants in pastures.

POSSIBLE COMPLICATIONS

Secondary bacterial infections due to impairment of the immune system.

EXPECTED COURSE AND PROGNOSIS

Prognosis is usually good once the forage is removed from the diet, but recovery can be prolonged.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Inappetance, bloody diarrhea, and salivation
- Weakness and incoordination due to posterior paralysis
- There can be dyspnea, dehydration, laminitis, and recumbency.

BLINDNESS

BASICS

DEFINITION

Loss of vision in one or both eyes

PATHOPHYSIOLOGY

Can be due to the blocking of light from entering the eye correctly (cataracts), retinal disease, optic nerve lesions, or brain lesions

SYSTEMS AFFECTED

Ophthalmic, CNS

GENETICS

- Congenital cataracts reported in cattle, sheep, rare in goats. Autosomal recessive in several breeds of cattle: Jersey, Hereford, Holstein-Friesian
- Albinism/subalbinism primarily in cattle and sheep, optic disc with dominant form of incomplete albinism in Hereford cattle
- Retinal degeneration of Toggenburg goats

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Cattle, sheep, goats, camelids; potentially all ruminant species

Breed Predilections

- Congenital cataracts have been reported in cattle, sheep, rare in goats.
- Autosomal recessive in several breeds of cattle: Jersey, Hereford, Holstein-Friesian cattle
- Albinism/subalbinism in cattle and sheep; dominant form of incomplete albinism in Hereford cattle
- Retinal degeneration of Toggenburg goats

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

HISTORICAL FINDINGS

- Inability to see, bumping into objects, unwilling or hesitant to move, eyes wide open, startles easily or overreacts when touched or when bumps an object
- Eyes may show an abnormal sheen due to degeneration of the retina. Determine if the disease is in a specific individual or multiple members of the herd/flock.
- Young animals may lack a menace response yet not be blind; need to watch them navigate an obstacle course.

PHYSICAL EXAMINATION FINDINGS

CAUSES AND RISK FACTORS

- Congenital cataracts can be associated with microphthalmia and retinal lesions from in utero exposure to BVD during days 76–150 of gestation, secondary to inflammation, toxins, and metabolic disease. In cattle can be secondary to IBK,

malignant catarrhal fever, IBR, or retinal dysplasia of cattle. In sheep, bluetongue is often associated with retinal detachment.

- Chorioretinitis: in cattle, it can be associated with neonatal septicemia, TEME, rabies, toxoplasmosis, tuberculosis, and listeriosis. In sheep, this can be associated with mycoplasmosis, listeriosis, elaeophorosis, toxoplasmosis, bluetongue, and scrapie.
- Retinal degenerations are more commonly acquired vitamin A deficiency in cattle.
- Bracken fern (*Pteris aquiline*) toxicity and PEM are common in sheep.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Causes:

Toxins

There are many plant and fungal toxins, the most common are listed here.

- *Stypandra glauca* (blind grass)—causes retinal degeneration and optic nerve neuropathy
- *Astragalus mollissimus* (locoweed)—causes dry eye and retinal degeneration
- Bracken fern (*Pteris aquiline*)—causes polioencephalomalacia and degeneration of outer retinal layers
- Sweet clover—coumarin causing intraocular hemorrhaging
- Lead toxicity
- Sulfur—see edema and decreased pupillary light response.
- Trauma to the brain
- Neoplasia—in the occipital cortices, lateral geniculate bodies, or optic radiations

Systemic Disease

- Meningitis/encephalitis—see pale swollen optic disc with hazy margins.
- Bluetongue in sheep—causes retinal dysplasia
- Listeriosis
- Neonatal septicemia
- Equine herpes type 1 virus in llamas—optic nerve and retinal degeneration
- Mycoplasmas—in goats can cause corneal opacification
- Diabetes mellitus in ram lambs can cause cataracts.

Parasitic

- Elaeophorosis, toxoplasmosis, trypanosomiasis—cause inflammation of fundus; elaeophorosis can cause cataracts.
- *Echinococcus granulosus*—hydatid cysts in the brain
- *Paraelaphostrongylus tenuis* (meningeal worm) in llamas

Deficiencies

- Thiamine
- Vitamin A
- Water deprivation
- CNS hypoxia—postanesthesia or other prolonged hypoxia

Congenital/Degenerative

- Retinal degeneration of Toggenburg goats
- Hydrocephalus
- Congenital malformations
- Glaucoma
- Cataracts
- Wool blindness of sheep

CBC/BIOCHEMISTRY/URINALYSIS

- Consistent with an underlying cause
- Ram lambs with diabetes mellitus–induced cataracts will have elevated glucose.

OTHER LABORATORY TESTS

- Practitioners use direct ophthalmoscopy more frequently than indirect ophthalmoscopy. It is important to view the tapetal fundus several inches from the patient and then move to 1–2 inches from the patient’s eye when the optimum focus is achieved and the animal has adapted to the restraint. The diopter setting is usually started at “0” and adjusted to between +3 to –3 diopters to provide the sharpest image possible.
- Indirect ophthalmoscopy complements direct ophthalmoscopy.

IMAGING

Ultrasound evaluation of the corneal surfaces, the anterior and posterior lens surfaces, the retina, and any abnormal intraocular material will aid intraocular diagnosis. This is especially useful when dense corneal opacity or mature cataract obscures the view of the fundus.

OTHER DIAGNOSTIC PROCEDURES

- Examination of the cornea is incomplete without utilization of topical ophthalmic stains.
- Fluorescein is used to demonstrate the presence or absence of corneal ulcers. For topical use, fluorescein-impregnated paper strips are preferred to fluorescein solution to insure sterility.

PATHOLOGIC FINDINGS

TREATMENT

- Ensure nutrition and management are adequate, remove from toxin sources.
- Remove objects that can cause ocular trauma.
- Affected animals will need to be hand-fed and watered separately due to inability to compete with the rest of the herd.

CLIENT EDUCATION

MEDICATIONS

DRUGS OF CHOICE

- Pharmaceutical choice depends on the specific etiology.
- Trauma—corticosteroids and IV DMSO may help decrease swelling.
- Polioencephalomalacia—thiamine HCl 6–10 mg/kg IM or IV, antibiotics

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Topical corticosteroids and anesthetics are contraindicated when the cornea retains fluorescein stain.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

FOLLOW-UP

PATIENT MONITORING

With optic nerve lesions, on initial exam the fundus may appear normal. It can take 4 weeks for the optic disc to become pale

and the retinal vessels to start regression.

PREVENTION/AVOIDANCE

POSSIBLE COMPLICATIONS

Permanent vision loss

EXPECTED COURSE AND PROGNOSIS

Prognosis for the return of sight is very guarded, but depends on the degree of damage and the etiology.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Note: animals with a disease causing mental dullness or vestibular signs may appear blind.

AGE-RELATED FACTORS

- Young animals may lack a menace response yet not be blind; need to evaluate them while navigating an obstacle course.
- Diabetes mellitus will induce cataracts in ram lambs

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Many diseases that cause blindness may also induce abortion.

RUMINANT SPECIES AFFECTED

Potentially, all ruminant species are affected.

BIOSECURITY

Quarantine new animals, isolate affected animals.

PRODUCTION MANAGEMENT

- Ensure nutrition and management are adequate; remove from toxin sources.
- Remove objects that can cause ocular trauma.
- Fence off toxic plants to prevent grazing.
- Minimize the incidence of nutritional PEM.

BLOAT

BASICS

DEFINITION

Gas distension of the rumen and reticulum. Primary, or frothy, bloat occurs when rumen gas is trapped in bubbles/froth, and cannot be eructated. Secondary, or free gas, bloat occurs because of physical blockage of the esophagus or from decreased vagal nerve function.

PATHOPHYSIOLOGY

- Normal rumen bacterial fermentation produces gases that are eructated from the rumen.
- Primary, or frothy, bloat occurs when the gas is trapped in bubbles/froth, and cannot be eructated. Immature legumes and clovers are rapidly fermented by rumen microflora, resulting in release of chloroplast particles that trap gas bubbles and prevent their coalescence.
- Additionally, liquid is trapped in the foam, reducing the passage of liquid from the rumen. This serves to enhance bacterial growth and increase gas and foam production. Feeding finely ground grains can also cause frothy bloat.
- Secondary, or free gas, bloat occurs because of physical blockage of the esophagus or from decreased vagal nerve function. Expansion of the rumen within the abdominal cavity eventually compresses the diaphragm decreasing lung volume and oxygenation and the venous return to the post cava causing hypovolemia.
- Young calves can bloat from fermentation of milk or milk replacer in the rumen.

SYSTEMS AFFECTED

Gastrointestinal, cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

- Normally very low incidence, generally less than 1%
- Incidence of primary bloat may be over 25% if animals are grazed on immature legumes/clover or fed excessive amounts of highly fermentable carbohydrates, such as finely ground grains.

GEOGRAPHIC DISTRIBUTION

Worldwide

Epidemiology

- Primary bloat is associated with grazing or feeding immature legumes/clover. Finely ground grain diets are also associated with frothy bloat.
- Secondary bloat is associated with feeds that can block the esophagus such as potatoes/beets and with masses that either block the esophagus or interfere with the vagus nerve in the mediastinum.
- Examples are tumors from lymphoma, enlarged lymph nodes from tuberculosis, and chronic bacterial pneumonia.

SIGNALMENT

Species Affected

Ruminants, especially cattle

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Distension of the left flank from gas accumulation, tachycardia from hypoxia. Rumen contractions may decrease but often remain normal. Abdominal discomfort is evident.
- Severe cases may show open mouth breathing and staggering. Animal may become recumbent from hypoxia.

GENERAL COMMENTS

Bloat should be considered a medical emergency due to potential death from hypoxia and hypovolemia.

HISTORICAL FINDINGS

Sheep and cattle grazing on lush pastures, especially young legumes or clovers; high-concentrate diets with finely ground grains; history of chronic pneumonia

PHYSICAL EXAMINATION FINDINGS

- Distension of the dorsal left flank. Cattle with chronic vagal indigestion may have concurrent distension of ventral right flank due to rumen emptying defect (“papple-shape”).
- Tachycardia often present

CAUSES

- Ingestion of immature legumes and clovers or finely ground grains
- Blockage of the esophagus or interference with the vagus nerve

RISK FACTORS

- Grazing or feeding early legumes or clovers; feeding finely ground grains or rapidly fermented carbohydrates
- Factors associated with the spread of tuberculosis or bovine leukemia virus; chronic bacterial pneumonia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ruminants often bloat postmortem. Necropsy signs of antemortem bloat include compression of blood and lymph flow in the neck and thorax, resulting in enlarged cervical vessels and lymph nodes. There is often a visible “white line” demarcation in the esophagus near the thoracic inlet from compression of the distal esophagus and congestion in the proximal esophagus.
- Lymphoma, enlarged lymph nodes from tuberculosis, and chronic bacterial pneumonia

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

Passing a stomach tube differentiates primary (frothy) from secondary (free gas) bloat. Esophageal blockages may often be detected while passing the stomach tube.

GROSS AND HISTOPATHOLOGIC FINDINGS

Distension of the rumen and reticulum with gas; congestion of cervical lymph nodes and vessels; “white line” demarcation in esophagus at interface of compressed and congested tissue

TREATMENT

- Depends on the cause and degree of hypoxia. Severely hypoxic animals should be intubated to relieve the free gas. The tube often plugs with froth or dips below the fluid level in the rumen, requiring clearing the tube by blowing into it or moving the end within the rumen.
- It may be necessary to place a rumen trocar in the dorsal left flank. Mild to moderate cases of frothy bloat often respond

to surfactants such as poloxalene (25–50 g per animal).

Inpatient Versus Outpatient

N/A

CLIENT EDUCATION

- Advise clients about the danger of grazing or feeding immature legumes/clovers especially to hungry animals.
- Discuss the importance of a functional rumen mat in cattle on high-concentrate diets.
- Discuss early recognition of bloat and treatments such as poloxalene and stomach tubing.

MEDICATIONS

DRUGS OF CHOICE

Poloxalene (25–50 g per animal) for primary bloat

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATE DRUGS

Mineral oil or vegetable oils may act as antifoaming agents.

FOLLOW-UP

PATIENT MONITORING

Watch for recurrence.

PREVENTION/AVOIDANCE

- Avoid feeding or grazing risk plants such as legumes or clovers. Do not overfeed finely ground grain or other highly fermentable carbohydrates.
- Prevent infections with bovine leukemia virus and tuberculosis.

POSSIBLE COMPLICATIONS

- Physical damage to the vagus nerve or branches of the vagus from excessive rumen distension may result in rumen dysfunction and possibly recurrence.
- Trocarization may result in localized or diffuse peritonitis.

EXPECTED COURSE AND PROGNOSIS

- Spontaneous recovery in mild cases and those patients sufficiently relieved by stomach tube/trocar or treated with poloxalene
- Death from hypoxia in severe cases

BLUE-GREEN ALGAE POISONING

BASICS

OVERVIEW

- Over 50 genera of freshwater blue-green algae (also referred to as cyanophytes or cyanobacteria) exist worldwide that produce two major types of toxins: neurotoxic alkaloids, such as anatoxins, and hepatotoxic peptides, such as microcystins.
- Very few cases of anatoxin poisoning (often produced by *Anabaena flos-aquae*) have been reported in cattle with clinical signs resembling organophosphorus insecticide poisoning (depolarizing neuromuscular blocking agent), such as muscle weakness and paralysis.
- Microcystin toxicosis is much more common than anatoxin poisoning and numerous cases have been reported in cattle and sheep worldwide. Therefore, microcystin toxicosis is discussed in detail.
- Microcystins are primarily produced by *Microcystis aeruginosa*, but many other cyanobacteria produce these peptides such as other *Microcystis* spp., *Anabaena* spp., *Oscillatoria* spp., and *Nostoc* spp.
- Microcystins are usually confined within the algal cells and are released only when cells are damaged (e.g., when cells encounter the acidic environment of the stomach).
- Microcystins enter the hepatocytes through a carrier-mediated transport system and cause inhibition of protein phosphatase (1 and 2A) in the hepatocytes. Dissociation and necrosis of hepatocytes lead to intrahepatic hemorrhage and diffuse centrilobular hepatocellular degeneration.
- Sudden death is possible as a result of hemorrhagic shock.
- Death in animals usually occurs within hours to days postexposure.
- Animals that survive the acute phase of poisoning can recover, but may develop clinical signs related to liver disease (e.g., hepatogenous photosensitization; drop in production).
- Respiratory—pulmonary edema and congestion have been reported in acute cases.

GENETICS

N/A

INCIDENCE/PREVALENCE

- Blue-green algae poisoning occurs seasonally during warm weather conditions. The blooms are most common in the summer and fall when bodies of water are stagnant and warm and contain ample nutrients.
- A breeze blowing across the water may help concentrate the organisms near a shore.

GEOGRAPHIC DISTRIBUTION

Worldwide

Epidemiology

- Not all animals in a herd may be affected. Several important factors are related to occurrence of poisoning. Favorable algae growth conditions are usually required to produce sufficiently high concentrations of algae in water. Nutrient pollution of lakes and ponds with phosphorus and nitrogen leads to eutrophication and accelerated algae growth.
- Long periods of sustained sunshine, which produce warm water temperatures, are usually necessary. A breeze blowing across the water has also been identified as critical in some situations for concentrating algae near a shore where cattle congregate on the leeward side during hot weather.
- Microcystins are the most prevalent hepatotoxins and are produced by several cyanobacteria genera including *Microcystis*, *Planktothrix*, *Anabaena*, and *Oscillatoria*. Anatoxins are produced mainly by *Anabaena* spp. in addition to *Aphanizomenon*, *Microcystis*, and *Oscillatoria* spp. Saxitoxin production is associated with a few specific freshwater cyanobacteria species found in the genera of *Anabaena*, *Aphanizomenon*, *Cylindrospermopsis*, *Lyngbya*, and *Planktothrix*.

SIGNALMENT

- All ruminant species are susceptible to blue-green algae toxins. Microcystin poisoning has been reported in cattle and sheep.
- Dead animals are often found close to water bodies that have a “painted green” or “scumlike” bloom.

SIGNS

- Animals exposed to blue-green algae toxins are often found dead near water that has a thick algal bloom. Cattle may have algae on their limbs.
- Abrupt onset of apprehension and distress occurs within hours of microcystin exposure.
- This is quickly followed by pale mucous membranes, ruminal atony, diarrhea, weakness, nervousness, ataxia, and anorexia. In severe cases, the animals become recumbent and comatose.
- Death may occur within 24 hours of exposure, but may be delayed several days.
- Animals that survive the initial toxicosis may develop hepatogenous photosensitization.

CAUSES AND RISK FACTORS

- Exposure to water contaminated with toxin-producing cyanobacteria
- Warm, dry weather and stagnant water and a breeze that blows across water, allowing the organisms to concentrate near a shore
- High concentrations of nutrients in the water, such as nitrates and phosphates from sewage, detergents, industrial pollution, and fertilizers increase the risk for a blue-green algae bloom.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other hepatotoxicants—metals (detection in liver and kidney, histopathological lesions), aflatoxins (detection in feed, often chronic), pyrrolizidine alkaloids (evidence of plant consumption, histopathologic lesions, chronic disease)
- Hepatopathy—serum clinical chemistry and liver biopsy
- Nitrate toxicosis—chocolate-colored blood, exposure to nitrate-accumulating plants
- Cyanide poisoning—mucous membranes are initially bright cherry red, evidence of exposure to cyanogenic plants, chemical analysis for cyanide in gastrointestinal contents, liver, or muscle
- Larkspur poisoning—mainly found in the western states; bloat is a common finding, evidence of exposure to *Delphinium* spp.
- Grass tetany—hypomagnesemia
- Electrocution or lightning strike
- Organophosphorus or carbamate insecticide exposure—commonly associated with gastrointestinal irritation and neurological signs, evaluation of cholinesterase activity, detection of pesticides in gastrointestinal contents
- Lead poisoning—determination of blood lead concentration
- Exposure to neurotoxic plants, such as poison hemlock, water hemlock, tree tobacco, lupine—chemical analysis for plant toxins in gastrointestinal contents, history of presence of plants in the environment
- Exposure to cardiotoxic plants, such as oleander, milkweed, and azalea—chemical analysis for plant toxins in gastrointestinal contents, history of presence of plants in the environment

CBC/BIOCHEMISTRY/URINALYSIS

Increased GGT, AST, SDH, and GLDH

OTHER LABORATORY TESTS

- Direct microscopic examination of water and gastrointestinal contents
- Mouse bioassay
- Detection of microcystins in water or rumen contents by high-performance liquid chromatography/mass spectrometry
- Analysis of suspect water by direct competitive ELISA

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Postmortem lesions in animals that died of exposure to microcystins include hepatomegaly, congested and hemorrhagic liver.
- Histopathologically, microcystin toxicosis results in centrilobular hepatocellular degeneration and necrosis; dilatation and engorgement of sinusoids; and loss of hepatic cords.
- Postmortem lesions are generally nonspecific in animals that died of exposure to neurotoxic blue-green algae toxins (e.g., anatoxins).

TREATMENT

- Treatment of animals exposed to blue-green algae toxins is primarily supportive and symptomatic. Supportive therapy should include administration of intravenous fluids, corticosteroids, and calcium.
- Poisoned animals should be removed immediately from the source.
- Adsorption of toxins with activated charcoal has been suggested.
- Rumenotomy or a rumen lavage may be considered in valuable animals.

CLIENT EDUCATION

- Create awareness for potential of blue-green algae toxicity, especially during sunny, warm weather and other favorable environmental conditions.
- A heavy water bloom of algae producing a surface scum is usually necessary for poisonings to occur.

MEDICATIONS

DRUGS OF CHOICE

- No antidote is available.
- Activated charcoal, mineral oil, or saline cathartics
- Corticosteroids
- Vitamin E and selenium supplementation

CONTRAINDICATIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

Hepatic uptake blockers, such as rifampicin and cyclosporin A, may be helpful, but their usefulness in the treatment of cardiac glycoside-poisoned ruminants has not been evaluated.

FOLLOW-UP

PATIENT MONITORING

- Monitoring of liver enzymes is helpful.
- Monitor serum electrolytes.

PREVENTION/AVOIDANCE

- Keep animals away from water bodies with visible algal blooms.
- Precipitation of algal cells:
- Lime (100–250 mg/l) to precipitate cells without rupturing them

- Suspend ferric alum block (1 kg/10,000 L)
- Suspend gypsum block (50 kg/1000 L)
- Algacide (lysis of algal cells): copper sulfate at 20–40 g/50,000 L (target concentration: 0.2–0.4 ppm). After treatment with copper sulfate, animals must be removed from the water source for approximately 7 days.
- Use of straw bales (100 g/1000 L) to control algal blooms has also been reported. Barley straw seems to be more effective when compared to wheat or other straws.

POSSIBLE COMPLICATIONS

Hepatogenous photosensitization

EXPECTED COURSE AND PROGNOSIS

- Animals poisoned with microcystins are often found dead.
- Microcystin poisoning progresses rapidly, and treatment is often too late. If animals exhibit clinical signs of liver failure, the prognosis is poor.
- Animals that survive 24 to 72 hours after exposure usually survive but may develop clinical signs associated with hepatic failure.

BLUETONGUE

BASICS

OVERVIEW

Bluetongue (BT) is an arthropod-borne, noncontagious viral infection of ruminants caused by BT virus (BTV), of the genus *Orbivirus* within the Reoviridae family.

- Transmission of BTV among susceptible hosts occurs through the bite of certain species of infected *Culicoides* or biting midges.
- The main vector of BTV in North America is *Culicoides sonorensis* (*C. sonorensis*; previously known as *C. variipennis*); in Australia, *C. brevitarsis*; and in Africa, Asia, and Europe, *C. imicola*.
- In the absence of a competent vector, transmission of BTV to cattle occurs occasionally by insemination with infected semen and transplacentally.
- Due to its potential for rapid spread across borders, and its capability to produce serious economic losses, the Office International des Epizooties (OIE) includes BT in their A list of diseases.

PATHOPHYSIOLOGY

Bluetongue virus infection presents initially with dyspnea and increased respirations followed by fever, hyperemia of the ears, lips, and muzzle, and ulceration of the oral mucosa. The tongue can become cyanotic and swollen, hence the disease name, bluetongue. Lameness and widespread muscle necrosis are additional sequelae.

SYSTEMS AFFECTED

- Cardiovascular—vascular injury leading to hemorrhages, congestion, heart failure.
- Musculoskeletal—intramuscular edema, hemorrhages, coronitis.
- Reproductive—infection during pregnancy can cause fetal loss or malformations.
- Gastrointestinal—vascular damage causes ulcerations and hemorrhages in the oral cavity, fore stomachs, and intestine.
- Respiratory—vascular damage leads to congestion and edema.

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

- Twenty-four BTV serotypes (BTV-1 to -24) have been found worldwide. Four of them are endemic in the United States (BTV-10, BTV-11, BTV-13, BTV-17). BTV-2, although not prevalent in the United States, has been isolated sporadically in the past.
- BTV infection occurs in tropical and temperate regions of Africa, Asia, Australia, and the Americas. Periodic incursions of the infection also occur in southern Europe.
- The distribution of BTV is limited by the distribution of the vector. BTV is considered to be present between approximate latitudes 35°S and 40°N. In some regions the presence of BTV may extend to 50°N. BTV transmission occurs only when weather conditions are favorable and adult vectors are active.
- In the United States, BTV infection is more prevalent in the southern and western parts of the country, and most infections occur in late summer and fall. Variations in weather patterns may affect the distribution of the vector and BTV transmission.

SIGNALMENT

- BTV infects a wide range of domestic and wild ruminants. Severe disease occurs almost exclusively in sheep and some species of deer, most notably the white-tailed deer of North America. Cattle commonly have inapparent infections.
- Mortality rates and severity of disease in sheep may vary, with fine-wool breeds and older sheep considered to be more

susceptible.

SIGNS

- BTV infection can cause inapparent infection or acute fulminant disease.
- Clinical disease is largely restricted to sheep and white-tailed deer; in cattle and goats, infection is usually asymptomatic. Infected bulls may shed BTV in their semen.
- The incubation period ranges from 2–15 days.
- The acute fulminant form is characterized by fever of up to 107.6°F (42°C), leukopenia, anorexia, weight loss, depression, with edema and swelling of the face, lips, muzzle, and ears, reddening of the oral mucosa, and salivation.
- Crusting and accumulation of mucopurulent discharge in the muzzle and nostrils are common. In a small percentage of cases, the tongue appears edematous and purplish-blue (hence the name of the disease) as a result of cyanosis.
- Hemorrhages, erosions, and ulcers in gums, cheeks, tongue, and nostrils are often present.
- Lameness, stiffness, and prostration may develop as a result of muscle degeneration and laminitis. Laminitis may manifest as swelling, hyperemia, and hemorrhage of the hoof laminae and coronary band. Lameness may progress to “knee walking” or recumbency.
- Death due to bronchopneumonia or secondary bacterial infections may occur 8 to 10 days after the initial signs appear. Some severely affected sheep may recover.
- BTV infection of pregnant sheep or cattle may result in abortion, stillbirths, fetal malformation, or the birth of live but weak offspring (dummy lambs/calves). These negative effects have been linked to the use of modified-live vaccines (MLV) rather than to natural infection with wild-type BTV. Ovine fetuses are more susceptible to the teratogenic effects when infection occurs during the fifth and sixth weeks of gestation.
- Pregnant sheep may abort during the acute phase of BT disease in the absence of fetal infection as a result of maternal stress.

CAUSES AND RISK FACTORS

Ruminants living in areas where the vector, *Culicoides*, and bluetongue virus coexist

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differential diagnosis includes other ulcerative diseases of the respiratory and digestive tracts of ruminants such as foot-and-mouth disease, orf, sheep pox, peste des petits ruminants, photosensitization, and diseases that cause stiffness and lameness including polyarthritis, and foot rot.
- In white-tailed deer, BT needs to be differentiated from epizootic hemorrhagic disease (EHD).
- The differential diagnosis of BTV fetal infection, malformations, and abortions includes infection with Cache Valley, Akabane, border disease, Rift Valley fever, Nairobi sheep disease, Wesselsbron disease, genetic defects, and ingestion of teratogenic plants.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

DIAGNOSTIC PROCEDURES

- Serological assays available for the demonstration of BTV antibodies include complement fixation, virus neutralization, the agar gel immunodiffusion (AGID) test, and several ELISA formats.
- Only the AGID and competitive ELISA (cELISA) are recommended by the OIE as prescribed tests for international movement of ruminants.
- Virus isolation can be done by inoculation of susceptible sheep or embryonated chicken eggs with heparinized blood or homogenized lymph nodes, spleen, or lung of infected animals. Subsequent adaptation to cell culture and serotyping of the virus may be necessary. Blood and tissue samples for diagnosis need to be preserved at 4°C, and not frozen.
- BTV can be isolated from blood of infected sheep and cattle for up to 11 and 49 days postinfection, respectively. BTV nucleic acids can be detected by reverse transcription-polymerase chain reaction (RT-PCR) for up to 222 days postinfection. However, blood from sheep and cattle is infectious for *C. sonorensis* for only 21 days after infection of the ruminant host.

- Sheep and cattle whose blood contains BTV nucleic acid as detected by RT-PCR, but not infectious virus as determined by virus isolation, are unlikely to play an important role in the epidemiology of BTV infection.
- BTV antibodies can be demonstrated in precolostral serum samples of lambs infected in utero. BTV virus also can be isolated in some of these lambs due to immune tolerance and persistent infection.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- BTV infection in sheep and white-tailed deer may result in extensive vascular injury that leads to congestion, edema, hemorrhage, disseminated intravascular coagulation, and tissue necrosis.
- The vascular damage results in ulcerations and hemorrhage of the tongue, oral mucosa, hard palate, dental pad, and sometimes fore stomachs and intestine.
- The lips, gums, and tongue may be edematous, congested, or cyanotic.
- There is subcutaneous and intramuscular edema and hemorrhages.
- The superficial lymph nodes may be enlarged and edematous.
- The most consistent lesion in sheep is hemorrhages in the tunica media at the base of the pulmonary artery. Hemorrhages are also present in the aorta, epicardium, endocardium, and myocardium.
- Pale areas as a result of necrosis may be found in skeletal and cardiac muscles.
- Pulmonary congestion and edema as a result of heart failure, and pneumonia due to secondary bacterial infections, may be present.
- Fetal lesions consist of hydranencephaly, poroencephaly, and arthrogryposis.

HISTOPATHOLOGIC FINDINGS

The characteristic lesion consists of microvascular thrombosis resulting in congestion, edema, hemorrhage, and tissue necrosis.

TREATMENT

There are no specific treatments for BT.

NURSING CARE/ACTIVITY/DIET

Secondary infections may be treated with broad-spectrum antibiotics. Anti-inflammatory and pain relief medications can be used to limit the symptoms. Affected animals should be placed in shaded pens protected from the environment and provided with clean water and good-quality hay or feed.

MEDICATIONS

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Modified live virus vaccines are available in some parts of the world.
- In the United States, MLV containing serotype 10 is available. In addition, MLV vaccines containing serotypes 10, 11, or 17 can be obtained for use only in California. Lambs can be vaccinated close to weaning and the breeding stock at least 3 weeks before breeding or after lambing. Pregnant animals should not be vaccinated because of the potential teratogenic effects.
- To induce protection, the BTV serotype of the vaccine must correspond to the serotype of the virus in the region.
- Limiting vector exposure by housing sheep during peak feeding times (from dusk to dawn) may reduce the risk of exposure, but vectors may be active during daytime when overcast.
- Reduction of the vector population through the use of insecticides or by making vector habitat unsuitable can aid in BT control.
- Many countries impose restrictions to the movement of livestock and germ plasm from infected areas.

MISCELLANEOUS

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

There is no evidence to indicate that BTV is infectious to humans.

PREGNANCY

Modified live BTV vaccines may cause pregnancy loss and teratogenesis.

SIGNS

HISTORICAL FINDINGS

PHYSICAL EXAMINATION FINDINGS

Body Areas to Be Assessed

- Dorsal aspect of the thorax, just caudal to the withers
- Fiberless area behind the elbows
- Region between the hind legs
- Brisket area

NOTE: Palpation of the pelvis is less than ideal due to the inherent thin skin, light muscling, and minimal fat cover in this area.

BODY CONDITION SCORES: GENERAL CONSIDERATIONS AND CAUTION

- Camelids have a great variability of body type and conformation even within the same species. Therefore weight alone is not a good indicator of body condition.
- Body condition scoring (BCS) does not replace actual weighing. Both should be considered if possible.
- A single score is usually not helpful. It is the variation of the BCS that needs to be stressed.
- Fiber coat may be misleading. Animals require direct palpation.
- Accumulations of adipose tissue characteristics are essential in assessing BCS. Evaluating adipose cover over the rib cage and the axilla region is important to the overall scoring process. It should be understood that body condition scoring is a

subjective measure of a herd nutrition and care program.

- Pelvic area is always bony.
- Neck is not a good indicator of body condition score.
- Characteristic regions of fat deposition in camelids: Shoulders; briskets; cranial ribs; inner thighs; perineum; camel: hump (or humps).
- Body condition scoring is a good management tool to evaluate if the nutritional demands required by specific physiologic situations (particularly lactation and late pregnancy) are being met.
- In addition, body condition scores allow monitoring animals through a change in feed or feeding systems.
- In range animals' changes in body conditions, scores are important in the evaluation of the nutritive value of pastures.

BCS Technique

BCS should be assessed at least four times and ideally six times a year.

Best times for assessment of body condition scores for the herd in general are

- Before winter
- In the middle of winter
- In spring
- In summer
- In fall

Best times for assessment of body conditions scores for breeding females are

- Early pregnancy
- Midpregnancy
- At parturition
- Six weeks after parturition (corresponds in general with the early pregnancy in rebred females)
- At weaning (corresponds in general to midpregnancy in rebred females) Technique for evaluation
- General appreciation from a distance for camels and camelids and if animals are sheared (llamoids).
- Depending on the body area, palpation evaluates fat deposit or both muscle mass and fat deposit.
- Palpate over the lumbar (loin) areas to feel the spinous and transverse processes and evaluate presence or absence of depression and its depth or roundness. Evaluating the angle from between the thumb on one side of the spinous process and the other fingers on the other side.
- Inspect and palpate the paralumbar fossa and evaluate the depth of the shelf created by the transverse process of the lumbar vertebrae.
- Palpate over the ribs to feel the fat cover in that region.
- Raise the tail and inspect the perineal area and the inguinal area for shape (curvature and fat deposition).
- Palpate the brisket for roundness and shape.
- Palpate the shoulders for fat deposit.
- In camels, inspect the size and shape of the hump.

Body Condition Scores

- Scores are given from 1 (emaciated animals) to 5 or 9 (obese animals) depending on preference.
- Generally, people using the 5-point system use intermediate scores in increments of 0.25 to 0.5.
- The ideal BCS

Males: 3 to 3.25 before the breeding season. Males will lose 0.5 to 1.0 points during the breeding season. Camels in free mating systems may lose up to 2 points during rutting season.

Females: 2.5 to 3.25 for open or lactating females; 3.25 to 3.5 in the last trimester of pregnancy. Lactating females should not lose more than 0.5 to 0.75 points.

Score 1: Emaciated Animal

Extreme loss of muscle mass

Thin face

Deep depression over the lumbar area

Gaunt, visible, tucked-in paralumbar fossa No perineal fat, sharp visible ischial tuberosities Inverted "V" inner thighs shape

Narrow prominent V-shaped brisket
Ribs easily identified, depressed intercostals area
Camels: flat back or flopped-over hump

Score 2: Thin

Muscle mass is minimal.
Lumbar area depression slightly filled in but easily palpable
Lumbar fossa prominent
Some fat deposition in the perineal area
Gradual filling of the inner thighs
Gradual filling on the brisket and loss of sharp edges of the sternum
Camels: moderate hump

Score 3: Moderate

Normal muscle mass and smooth appearance
Lumbar area depression palpable with slight pressure
Lumbar fossa not evident
Perineum filled in
Inner thighs rounded
Brisket: sternum still palpable but starting to become round
Ribs can still be palpated with some pressure. Camels: shoulder and rump muscles can still be delineated, hump normal size with angular dorsal edge

Score 4: Fat

Musculature not well defined—"buried in fat"
Lumbar area rounded to nearly flat
No shelf formed by the transverse process of the lumbar vertebrae
Perineum filled in, no depression under the tail
Inguinal area filled in
Brisket flat
Ribs can only be palpated with firm pressure.
Camel: hump round and wide at the base, shoulders very thick

Score 5: Obese

Smooth, rounded appearance due to excessive fat deposition
Lumbar area completely rounded
Bony structures difficult to palpate
Bulging perineum
Thick tail-head
Convex inguinal appearance
Rounded brisket
Camels: obviously fat on shoulders, hump very large and round

BORDER DISEASE

BASICS

OVERVIEW

- Neonatal condition of lambs as a result of a viral infection of the dam during pregnancy. The virus crosses the placenta and infects the lamb.
- The border disease virus (BDV) is closely related to other pestiviruses such as hog cholera virus (HCV), which causes classical swine fever, and bovine viral diarrhea virus (BVDV).
- Also called hairy shaker and fuzzy lamb disease

SIGNALMENT

- Sheep
- Goats
- Pregnant cattle inoculated early in gestation with border disease virus frequently abort and develop antibodies to bovine viral diarrhea. Swine may possibly be affected.

Species

Sheep and goats

Breed Predilections

N/A

Mean Age and Range

Clinical manifestations in the fetus depend on the stage of gestation when infection occurs.

Predominant Sex

N/A

SIGNS

Clinical signs are determined by the animal's age when infected.

- Animals infected as adults are subclinical. However, when the ewe is infected during pregnancy, the virus crosses the placenta and infects the fetus. Disease is suspected with increased numbers of barren ewes or ewes bearing mummified or malformed lambs.
- Clinical manifestations in the fetus depend on the stage of gestation when infection occurs.
- Placentitis occurs 10–30 days postinfection and may cause fetal expulsion, resorption, or mummification.
- Early gestational infections may result in immune tolerance in the lamb. These lambs are permanent carriers and shedders of the virus, but do not develop clinical signs of disease.
- Other surviving fetuses infected < 90 days gestation may not develop immune tolerance. These lambs develop the characteristic signs of border disease.
- Affected lambs are of small size with possible skeletal defects such as dropped pasterns or mandibular brachygnathia
- Involuntary tonic/clonic muscular tremors and ataxia

- Hypertrophy of primary hair follicles results in a long, coarse, and straight birth coat. It is sometimes described as “hairy.” The coat may also be pigmented.
- Kids and some rough-coated breeds of sheep do not demonstrate the characteristic hair changes.

CAUSES AND RISK FACTORS

The main sources of infection are the asymptomatic, persistently infected sheep. These animals shed the virus in saliva, respiratory secretions, urine, feces, or semen. Transmission occurs across mucous membranes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of abortion such as *Salmonella* spp., *Campylobacter* spp., *Chlamydia* spp., *Toxoplasma gondii*, and *Rickettsia* spp.
- In lambs other neurological conditions such as enzootic ataxia (swayback), bacterial meningoencephalitis, focal symmetrical encephalomalacia, and “daft lamb” disease

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY FINDINGS

Possibility of decreased levels of thyroid hormones contributing to growth retardation

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Fluorescent antibody tests for viral antigens performed on tissues of affected lambs. Tissues for collection include: abomasum, pancreas, kidneys, thyroid, testicles, and skin biopsies.
- Serology includes serum neutralization, agar gel immunodiffusion (AGID), and complement fixation tests of ewes. Ewes infected as adults develop serum neutralization (SN) titers ranging from 1:20 to 1:320. Animals with congenital infection may have negative SN titers or titers < 1:10.
- Precolostral blood cultures: colostral antibody can mask virus for up to 2 months.
- RT-PCR

PATHOLOGIC FINDINGS

GROSS FINDINGS

- Hydranencephaly
- Undersized cerebral cortex
- Severe cases may have cavitations or cysts of the cerebrum and/or spinal cord.
- Doming of the frontal bones of the skull
- Abnormal curvature of the ribs
- Brachygnathia
- Abnormal “hairy” appearance of birth coat due to increased proportion of primary hair follicles
- Abnormal skin pigmentation
- Placentitis and placental necrosis can occur.

HISTOPATHOLOGICAL FINDINGS

- White matter lesions in the CNS
- Increase in intrafascicular glial cells with myelinlike lipid droplet accumulation
- CNS and spinal cord hypomyelination
- Endothelial swelling and thrombotic occlusion of the vessels in the placenta

TREATMENT

No effective treatment

MEDICATIONS

None

CONTRAINDICATIONS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Serology should be performed. Most dams of affected lambs should have high levels of antibody and be immune to further challenge by the same strain of the virus in subsequent pregnancies. Ewes with negative antibody titers may be persistently infected. Blood cultures and examination of skin biopsies by fluorescent antibody tests should be performed on these animals to identify carriers.
- Pregnant noninfected ewes should be kept separated from the rest of the flock for the first 60 days of gestation.
- Infected lambs should be culled from the flock before breeding season.
- There are no approved vaccines for use against border disease virus in the United States. Bovine viral diarrhea vaccines for cattle are not recommended for use in sheep.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Affected lambs that survive the first few months will gradually resolve neurologic signs and fleece abnormalities.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Bovine viral diarrhea (BVD) and hog cholera virus (HCV) are very closely related pestiviruses.

AGE-RELATED FACTORS

Age at time of infection determines clinical signs in the individual.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Clinical disease or death in lambs is the result of infection of the dam during gestation.

SYNONYMS

Also called hairy shaker and fuzzy lamb disease.

SEE ALSO

Other causes of abortion such as *Salmonella* spp., *Campylobacter* spp., *Chlamydia* spp., *Toxoplasma gondii*, and *Rickettsia* spp. Other neurological conditions such as enzootic ataxia (swayback), bacterial meningoencephalitis, focal symmetrical

encephalomalacia, and “daft lamb” disease

ABBREVIATIONS

BDV = bovine diarrhea virus

HCV = hog cholera virus

SN = serum neutralization

RT-PCR = reverse transcription polymerase chain reaction

BORNA DISEASE

BASICS

OVERVIEW

- Borna disease is a sporadic, transmissible, progressive encephalitis.
- The virus does not have a direct cytopathic effect.
- Virally infected cells initiate a T cell immune response, which leads to tissue destruction.

SYSTEMS AFFECTED

CNS

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

- Borna disease was historically endemic to areas of Germany and Switzerland. Confirmed outbreaks of the disease have generally been in middle and eastern Europe and in horses in the Middle East.
- Clinically normal animals have tested positive for the RNA virus responsible for the disease in many areas of the world including the United States.

SIGNALMENT

- Natural infections occur in sheep and horses. Goats and cattle can also be affected.
- BDV has been experimentally transmitted to a wide range of animals including chickens, rabbits, rats, guinea pigs, and monkeys.
- Antibodies have been identified in monkeys, humans, and birds.

SIGNS

- Borna disease is a progressive neurologic disease.
- Initial signs are generally nonspecific and include anorexia, fever, excessive salivation, yawning, and chewing movements.
- Early neurologic signs include hyperesthesia, ataxia, head pressing, head tremors, muscle contractions, and depression.
- Transient signs of irritability, kicking, biting or compulsive movements may occur.
- In later stages of disease, animals may lean against objects or maintain a sawhorse stance. Convulsion or coma is possible.
- Nystagmus is observed in terminal cases.

CAUSES AND RISK FACTORS

- Borna disease virus (BDV) is an enveloped RNA virus from the Flaviviridae family.
- Actively infected, convalescent, and immune carrier animals shed the virus in nasal secretions, saliva, urine, or milk.
- Infection often occurs due to contaminated food and water.
- The virus moves to the CNS by intra-axonal transport via nerves in the nose and throat area.
- Disease outbreaks are more commonly seen in spring and early summer.
- The virus is transmitted between birds by the tick *Hyalomma anatolicum*. An arthropod vector is not necessary for transmission in other species.
- An outbreak of disease in horses in the Middle East was associated with a dense population of infected wild birds.
- Rodents have also been suspected as a source of infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other encephalopathies such as St. Louis encephalitis or West Nile virus
- Scrapie, bovine spongiform encephalopathy, chronic wasting disease in elk and deer
- Rabies
- Metabolic or digestive disorders—milk fever, nervous ketosis
- CNS tumor
- *Oestrus ovis* infestations in sheep
- Pseudorabies

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY FINDINGS

In some cases, serum and CSF may contain antibodies to BDV.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Polymerase chain reaction (PCR) viral amplification and in situ hybridization have been used to demonstrate viral RNA in neurons, astrocytes, Schwann cells, and ependymal cells.

PATHOLOGIC FINDINGS

GROSS FINDINGS

No characteristic gross lesions

HISTOPATHOLOGICAL FINDINGS

- Inclusion bodies in neuronal nucleus known as Joest or Joest-Degen bodies are found in ganglion cells of the hippocampus and olfactory lobes of the cerebral cortex. They are considered pathognomonic for Borna disease.
- Other lesions are characteristic of encephalitis including perivascular cuffing, ganglion cell degeneration, and gliosis.
- Neuronophagic nodules may be found.
- Lesions are typically found in gray matter of the cerebral hemispheres and brain stem. The most severe lesions are found in the olfactory bulbs, caudate nucleus, and hippocampus.
- Cerebellum is spared.

TREATMENT

- No specific treatment is available.
- Supportive therapy with mannitol may temporarily relieve cerebral edema. Anti-inflammatory medications may reduce discomfort.

MEDICATIONS

No specific medications

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING

Surviving animals may have permanent neurological deficits.

PREVENTION/AVOIDANCE

- Animals should not be fed and watered together in large numbers and should be kept separate from horses and cattle.
- Insect and tick control may be helpful.
- Incoming animals should be quarantined for 2 months due to the long incubation period of the disease, and tested twice during this period for the presence of antibodies.
- BDV is resistant to drying and other adverse environmental conditions.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Unlike other viral encephalitides, the incubation period can vary from 3 weeks to months or possibly years. The average incubation period is usually from 2 to 3 months.
- Duration of clinical illness is normally 1–3 weeks.
- Mortality rates can range from 60% to 95% in animals exhibiting clinical signs.
- Surviving animals may remain permanently neurologically impaired.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- The viruses of Borna disease and near eastern encephalitis are indistinguishable.
- Serologically distinct from the viruses that cause West Nile virus (WNV), eastern equine encephalitis (EEE), western equine encephalitis (WEE), Venezuelan encephalitis (VE)

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

BDV antibodies have been found in humans with various neuropsychiatric disorders such as schizophrenia. The actual significance of BDV in these disorders has yet to be determined.

PREGNANCY

N/A

SEE ALSO

Bovine spongiform encephalopathy Chronic wasting disease in elk and deer Metabolic or digestive disorders: milk fever, nervous ketosis *Oestrus ovis* infestations in sheep Other encephalopathies such as St. Louis encephalitis or West Nile virus Pseudorabies Rabies Scrapie

Author: Lisa Nashold

BOTULISM

BASICS

OVERVIEW

- Toxins produced by the bacteria *Clostridium botulinum* cause botulism.
- There are eight botulinum toxins produced by the bacteria. These toxins are antigenically distinct toxins and identified as types A, B, C₁, C₂, D, E, F, and G. Each of these toxins is found in different environments and affect different species of animals.
- Botulinum toxin types B, C, and D are the most common toxins to cause toxicity in cattle.

PATHOPHYSIOLOGY

- Intoxication by *Clostridium botulinum* is primarily by ingestion of the preformed toxin in a contaminated feed source. Spoiled oat, rye, and barley silage and hay are common sources for type B botulinum intoxication.
- The ingestion of poultry litter containing bird parts or the ingestion of other forages contaminated with toxin-laden animal parts is a source for type C botulinum toxin.
- Type D botulinum intoxication is common in phosphorus-deficient areas where toxin-contaminated bones are ingested. The ingestion of contaminated water (usually type C and D botulinum toxin) from nutrient-rich ponds has also been a source of intoxication.
- Wound infections can also lead to botulinum intoxication but is rare in ruminants.

SYSTEMS AFFECTED

- Ingestion of preformed toxin is the usual means of intoxication of ruminates.
- The toxin is absorbed by the intestines and distributed to the nerves that innervate the muscles (neuromuscular junction).
- The toxin attaches to the nerve and is incorporated into the cytoplasm where it acts as a metalloprotease that inactivates proteins needed to release the neurotransmitter acetylcholine.

INCIDENCE/PREVALENCE

- With modern production processes, the potential for animals ingesting toxin-laden food sources can occur, resulting in catastrophic consequences to the affected herd.
- Areas of the world where intoxication is a fairly common occurrence and is considered an endemic problem include Australia, South Africa, and South America.

GEOGRAPHIC DISTRIBUTION

The various botulinum toxins tend to have a unique geographical area of the world. *Clostridium botulinum* type B is commonly found in Europe and the eastern United States. *Clostridium botulinum* type C is commonly found in the western United States. *Clostridium botulinum* type D is commonly found in South Africa, South America, and Australia.

SIGNALMENT

- Most cases involve adult or young growing animals.
- Cattle are extremely sensitive to the toxins. Cattle have been determined to be 12.88 times more sensitive to botulinum toxin type C on a kilogram basis than the mouse. The median toxic dose for botulinum toxin type C in lactating dairy cows is 0.38 ng/kg.

SIGNS

- The rapidity of development of clinical signs depends on the amount of toxin ingested.
- Clinical signs develop usually between 48 and 72 hours after ingestion, but may appear as early as 24 hours and as late as 10–14 days after ingestion.
- Animals first appear to be constipated with dry feces and may seem uneasy on their feet. Over the next 24 to 48 hours, the animals become weaker with staggering and muscle fasciculation of large muscle groups. Animals will lean against fences and walls for support. When lying down they will remain in sternal recumbency.

- On clinical examination, the animals will usually lose tail tone with the tail easily handled and elevated. Animals lose tongue tone. An animal will remain alert and actively try to eat but cannot chew properly resulting in food being dropped from the mouth. The lack of tongue control causes the animal to be unable to clean its nose resulting in a dirty dry nose. Some animals will drool. When drinking water, the animal may stick its nose down deep into the water trough to get a drink.

- Labored abdominal breathing is usually seen in animals late in the course of the intoxication.

CAUSES AND RISK FACTORS

- Ingestion of spoiled hay or silage made from oats, barley, or rye is a common cause of intoxication for botulinum toxin type B.
- Ingestion of contaminated animal parts in hay, silage, or poultry litter is a common cause in botulinum toxin type C intoxication.
- In phosphorus-deficient areas of the world, ingestion of toxin-contaminated bones are a common source of intoxication particularly for type D botulinum toxin.
- Ingestion of water from shallow, warm, nutrient-rich ponds has been implicated in the intoxication of some animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Diagnosis of botulism can be difficult and is usually one of exclusion of other causes.

- Hypocalcemia, hypomagnesemia, and hypokalemia should be ruled out. However, there is a decreased chance of an acute outbreak involving multiple animals with a deficiency of calcium, magnesium, or potassium.
- Monensin and other ionophore toxicities can cause cardiac and skeletal muscle lesions leading to weakness in the animals.
- Gossypol toxicity can cause cardiac problems leading to weakness in the animals.
- Organophosphate and carbamate toxicity due to interference with neurotransmitters
- Chlorinated hydrocarbon (organochlorine insecticides) interferes with sodium and potassium channels leading to weakness, tremors, ataxia, and salivation.

CBC/BIOCHEMISTRY/URINALYSIS

CBC and blood chemistries should be normal in affected animals.

DIAGNOSTIC PROCEDURES

- Confirmation of a positive case of botulinum intoxication can be difficult.
- Feed samples from the previous 2 to 5 days should be immediately evaluated for botulinum toxin contamination.
- Animal samples to submit for botulinum toxin testing are serum, liver, rumen content, and cecal content. The testing procedure usually performed is the mouse protection bioassay. However, agar immunodiffusion testing and ELISA testing for the toxin can also be performed.
- Bacterial culturing of fresh rumen and cecal content from animals immediately euthanized or freshly dead for *Clostridium botulinum* organism can also aid in a diagnosis.
- The finding of preformed toxin in any of the feed or tissues submitted and/or the finding of *Clostridium botulinum* organisms present in the fresh rumen or cecal content suggests that the animal was intoxicated by botulinum toxin.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- Gross lesions are few. No histopathologic lesions are noted.
- The rumen may have a decreased fill of forage and forage in the rumen may be dry due to the animal's inability to swallow and drink water.

TREATMENT

APPROPRIATE HEALTH CARE

- The toxin is long acting and can affect the animal for several weeks, which makes treatment difficult.
- Treatment is mainly supportive with the animal receiving fluids for dehydration and hand-feeding to maintain the animal's caloric intake. Animals must remain in sternal recumbency or bloat will occur. Animals should be made to move and rise to prevent crush injuries to large muscle groups.
- The treatment of cattle with a pentavalent antitoxin has been of little success and is expensive.
- Avoid antimicrobials that potentiate muscle weakness (aminoglycosides, tetracycline, procaine penicillin)
- In some areas of the world, vaccination of cattle with a toxoid for types B, C, and D botulinum toxin has been successful in preventing outbreaks.

CLIENT EDUCATION

- The most common source of intoxication is through feed.
- Insure ensiled feed (e.g., rye, oat, and barley silage and hay) has been fermented correctly. No animal parts are present in the feed.

MEDICATIONS

CONTRAINDICATIONS

- Avoid aminoglycosides, tetracycline, and procaine penicillin for treatment of wounds since these can potentiate muscle weakness.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING

- Monitor cattle for dehydration and bloating. Keep animals in sternal recumbency so that bloat will not occur.
- Watch for muscle damage in recumbent animals.

PREVENTION/AVOIDANCE

Clients need to insure that silage is properly fermented and no animal parts are inadvertently incorporated into hay or feed.

EXPECTED COURSE AND PROGNOSIS

The prognosis is poor in most affected animals. Prolonged and intense supportive care is often needed lasting several weeks to months.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Most cases involve adult or young growing animals.

ZOONOTIC POTENTIAL

- Since this is an intracellular toxin bound to the nerves, the chance of individuals working with affected animals becoming intoxicated is minimal. Affected animals should be disposed of by burial or rendering.
- Animals should not be sent to slaughter for human consumption.
- No evidence of milk contamination with the toxin from intoxicated cows has been identified.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Cattle, sheep, and goats are most commonly affected.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

Insure ensiled feed (e.g., rye, oat, and barley silage and hay) has been fermented correctly. No animal parts are present in the feed.

BOVINE EPHEMERAL FEVER

BASICS

OVERVIEW

Bovine ephemeral fever (BEF) is a seasonal, arthropod-transmitted, viral disease of cattle and water buffalo that occurs in the subtropics or temperate regions of Africa, Australia, and Asia.

SIGNALMENT

- BEF is a seasonal disease whose severity varies from year to year and region to region. Epidemics may occur periodically and are characterized by rapid onset within days or a few weeks of many animals in a region.
- Ephemeral fever is most prevalent in the wet season in the tropics and in summer to early autumn in the subtropics or temperate regions when conditions favor the presence of biting arthropods. BEF disappears abruptly in winter.
- Morbidity may be as high as 80%; overall mortality is usually 1–2%, although it is higher in well-conditioned cattle (10–20%).

SIGNS

- The clinical signs occur suddenly and vary in severity. They include biphasic or polyphasic fever, shivering, inappetence, lacrimation, serous nasal discharge, drooling, dyspnea, atony of the fore stomachs, depression, stiffness and lameness, and a sudden decrease in milk yield. Cattle may also become recumbent and paralyzed for 8 hr to > 1 wk.
- After recovery, milk production often fails to return to normal levels until the next lactation.
- Abortion, with total loss of the season's lactation, occurs in ~5% of cows pregnant in months 8 and 9 of the last trimester.
- Bulls, market cattle, and heavily producing dairy cows are the most severely affected, but even so, spontaneous recovery usually occurs within a few days.

CAUSES AND RISK FACTORS

- The disease is caused by ephemeral fever virus, a Rhabdovirus (single-stranded, negative sense RNA in the same family as rabies virus).
- The virus can be mechanically transmitted by IV inoculation of blood from infected viremic cattle to susceptible cattle. The virus has been recovered from some *Culicoides* (biting midge) and mosquito species (*Anopheles* and *Culicine* spp.) collected in the field and has been shown to multiply in *Culicoides* and *Culex* mosquitoes in the laboratory. The role of the insect in mechanical transmission has not been established.
- Transmission by contact or fomites does not occur, and the virus does not appear to persist in recovered cattle.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Parturient paresis (milk fever, hypocalcemia) is an afebrile disease of mature dairy cows that occurs most commonly within 72 hours of parturition. The clinical signs progress through three stages: Stage 1, changes in attitude (i.e., hypersensitivity and excitability); Stage 2, generalized paresis; Stage 3, circulatory collapse, coma, and death.

CBC/BIOCHEMISTRY/URINALYSIS

Clinical cases have a neutrophilia with bands.

OTHER LABORATORY TESTS

Viral serum neutralization, complement fixation, and the blocking ELISA tests are used for serology. Virus isolation can also be done but isolation usually requires mouse inoculation.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Diagnosis of BEF is usually based on history and clinical signs (rapid onset of febrile signs for 2–5 days with spontaneous recovery).
- The clinical outbreak is confirmed by serology in paired serum samples collected during illness and 2–3 weeks later with a fourfold rise in antibodies.

PATHOLOGIC FINDINGS

- The gross lesions of BEF include polyserositis affecting joint, pleural, and peritoneal surfaces. Some lung edema is evident, atelectasis, cellulitis, and focal necrosis of skeletal muscle. The lymph nodes are edematous.
- The histological findings include neutrophilia, leukocytosis, and high fibrinogen deposition.
- Hemosiderosis of the lymph nodes and spleen from loss of erythrocytes early in infection has been observed.
- The venules and capillaries of the tendon sheath, synovial membranes, muscle, and fascia have perivascular neutrophilic infiltration, focal or complete necrosis of vessel walls, thrombosis, and perivascular fibrosis.

TREATMENT

- Complete rest is the most effective treatment, and recovering animals should not be stressed or worked because relapse is likely.
- Isotonic fluids can be administered IV to treat dehydration. Oral dosing should be avoided unless the swallowing reflex is functional.

MEDICATIONS

DRUGS OF CHOICE

- Anti-inflammatory drugs can be given early and in repeated doses for 2–3 days.
- IV or subcutaneous administration of calcium borogluconate has been found to be beneficial in some animals.
- Antibiotics can be administered to prevent secondary bacterial infections.

CONTRAINDICATIONS

During acute illness, no oral therapy should be given to avoid inhalation pneumonia due to the inability of the animal to swallow.

PRECAUTIONS/POSSIBLE INTERACTIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered.

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

- Animals should be encouraged to stand within 2–5 days. The animals should be rolled over several times a day to help avoid loss of circulation to the underside limbs, which will result in permanent muscle damage.
- The heavier the animal is, the more critical it is to get it back on its feet as quickly as possible.

PREVENTION/AVOIDANCE

A modified live vaccine is available that confers good protection. An inactivated vaccine is also available but it gives only 6 months of protection.

POSSIBLE COMPLICATIONS

Pneumonia, mastitis, hind limb paralysis, abnormal gait, abortion in late pregnancy, and temporary (up to 6 months)

infertility in bulls

EXPECTED COURSE AND PROGNOSIS

A complete recovery occurs in 95–97% of cases. BEF virus infection confers life-long immunity to cattle.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Pneumonia, mastitis, hind limb paralysis, abnormal gait, abortion in late pregnancy

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Infection in the last trimester can result in abortion.

RUMINANT SPECIES AFFECTED

Bovine and water buffalo

BIOSECURITY

The virus cannot be spread by direct animal-to-animal contact. However, it can be spread from infected animals to susceptible animals by injection, so single-use needles should be used.

BOVINE LAMENESS

BASICS

DEFINITION

Lameness is an alteration of gait. Clinically affected cattle are reluctant to move and may spend a great proportion of the day lying down. The affected limb typically has reduced contact time. Cattle will preferentially stand in such a manner that the affected limb bears little weight.

SYSTEMS AFFECTED

Musculoskeletal

GENETICS

N/A

GEOGRAPHIC DISTRIBUTION

Potentially worldwide depending on environment

SIGNALMENT

Species

Bovine

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

General Considerations

- Lameness is one of the most costly diseases of dairy cattle. Only mastitis and reproductive failure have greater economic impact.
- The vast majority of lameness can be localized to the hind limb.
- The vast majority of lameness in cattle is associated with hoof lesions.
- The vast majority of hoof lesions in the hind limb are located in the lateral claw.
- Hoof lesions are typically bilaterally symmetrical. Similar lesions are present in the right and left hoof.
- With the exception of interdigital cellulitis, parenteral antibiotics have little benefit in most lame cows.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

- Laminitis: acute laminitis, chronic laminitis, septic white line disease, horizontal hoof cracks, thimbles
- Sole ulcers
- Sole abscesses
- Corkscrew claw
- Interdigital cellulitis (foot rot)
- Digital dermatitis (heel warts)
- Heel erosions

- Vertical hoof cracks, sand cracks
- Interdigital fibroma

LAMINITIS

Definition

An inflammatory process that disrupts the junction of sensitive and insensitive lamina of the hoof. Acute disease will often cause permanent changes in hoof structure, which predispose to other hoof lameness.

- *Acute laminitis*—Clinical signs include hemorrhage at the white line, warm foot, softening of the coronary band, and prominent digital pulses. It is often difficult to localize the lesion to a specific hoof and most patients are lame in multiple hooves. Concrete floors accentuate gait abnormality. Hind limbs may be drawn under the body in an attempt to shift weight off the front feet
- *Chronic laminitis*—Loss of normal white line structure permits widening of white line and altered hoof angle and a loss of parallelism with P3. The toe becomes abnormally long. Weight is shifted onto heel and off of toe, potentiating abnormal hoof growth. The hoof wall often has raised horizontal ridges or rings; in severe cases horizontal fissures or thimbles may be present
- *Septic white line disease*—junction of sensitive and insensitive lamina is compromised and may separate permitting debris and infection to dissect along white line. Severe cases may have draining tracts erupt from coronary band.
- Diagnosis based on physical examination, radiographs rarely performed to document rotation of P3 and altered hoof angle

Cause

- Subclinical or clinical grain engorgement—a single episode can permanently disrupt laminar growth and integrity; grain engorgement is typically occult/subclinical in dairy and feedlot cattle; repetitive episodes will potentiate lesions and abnormalities; cattle with grossly abnormal hoof growth usually do not have clinical signs of acute laminitis; specific dietary causes include high proportions of easily fermented carbohydrates and short dietary fiber length.
- Septicemia—common primary causes include metritis, mastitis, peritonitis, and pneumonia.
- Trauma—heat (use of power sander on hooves), concrete floors

Treatment

- *Acute laminitis*—treat underlying diseases (septicemia or grain engorgement), place cows on softer surface (dirt vs. concrete) for 5 to 7 days, and administer nonsteroidal anti-inflammatory agents (flunixin meglumine).
- *Chronic laminitis*—perform corrective hoof trimming. Preferentially shorten the toe, altering the hoof angle. Remove all infected, underrun or unattached hoof.

Prevention/Management

- Dairy—limit concentrates to a maximum of 60% of diet. Insure adequate long-stem fiber in the diet. Screen total mixed rations on a routine basis to assess proportionate fiber length of feed. Monitor rumen pH to screen for subclinical grain engorgement. Consider inclusion of buffers in diet. Increase frequency of feeding. Eliminate component feeding. Provide routine hoof trimming. Recognize that a degree of laminitis is “normal” in dairy cows.
- Beef—attempt to limit frequency of severe disease. If possible and economical, adopt slow transition to high (>90%) concentrate diets. Consider inclusion of dietary ionophores and provide access to more comfortable footing.

SOLE ABSCESSSES

Definition

Abscesses located at the junction of sensitive and insensitive lamina.

Cause

This disease occurs when sensitive (living) tissues are exposed by a penetrating wound or separation of the white line (laminitis). Lesions are most common on the lateral claw of the hind foot. Structure of hoof wall limits drainage and host’s ability to clear infections.

Clinical Signs and Diagnosis

Infection dissects along the junction of sensitive and insensitive tissues forming a circumscribed abscess covered by a “false sole.” The history often includes fluctuating degree of lameness. Enclosed abscesses produce pressure and severe lameness. Drainage to the exterior will often cause short-term dramatic improvement in gait. Untreated infection may eventually involve deeper tissue (P3, navicular bone, flexor tendons, coffin joint, etc.), and cause irreparable damage.

Treatment

Pare out abscesses and underrun areas completely. If deep, sensitive tissues need to be debrided, consider a Baer block (distal intravenous anesthesia). Affix a wooden block to the unaffected digit making the lesion non-weight bearing. Lesions are typically not bandaged. If deep tissues are infected, consider soaking the foot one to two times a day for 10–15 minutes. Soak solutions typically contain betadine and Epsom salts (MgSO_4). Simple uncomplicated lesions do not require antibiotic therapy.

Prevention

Prevention of laminitis and trauma, routine hoof trimming

SOLE ULCERS (RUSTERHOLTZ ULCER, PODODERMATITIS CIRCUMSCRIPTA)

Clinical Signs and Diagnosis

- Sole ulcers are typically located at the juncture of the sole and heel on the lateral claw of the hind foot.
- Lesions typically consist of a circular defect in the sensitive layers of the sole with a mass of proliferative granulation tissue protruding through the defect. An intact sheet of insensitive sole typically covers early lesions. Later lesions may have a defect in the wall of the sole.
- The cause, origin, and pathogenesis of this disease are unknown. Postulated causes include laminitis, frostbite, and conformational defects.

Treatment

Excise sole wall overlying the defect in sensitive hoof wall and expose the defect in sensitive hoof wall. Remove the proliferative granulation tissue. Apply mild cautery or administer local treatment of lesions with compounds that kill living tissue (10% formaldehyde). Affix a wooden block to the unaffected digit making the lesion non-weight bearing.

Prevention

Design of specific preventative programs is difficult given unknown etiology. Routine hoof trimming recommended in dairy cattle.

CORKSCREW CLAW (SCREWCLAW)

Definition/Clinical Description

Corkscrew claw is an excessive growth of the abaxial wall of either the lateral hoof of the hind foot (most common) or medial claw of the front foot, which curves under the ventral surface of hoof. This growth pattern causes the toe to not bear weight. Long toes and an altered hoof angle usually accompany the rolling of the hoof wall.

Additionally, infected heel cracks and sole ulcers are commonly seen in cattle with screwclaw.

Cause

The conformation of cattle seems to predispose some beef cattle to this disorder. Affected beef cattle are usually heavily muscled with a wide rump. These cattle stand with their hind limbs abnormally close together and preferentially bear weight on the abaxial aspect of the lateral claw. Laminitis and preexisting damage to the hoof wall or coronary band are probably important predisposing causes.

Treatment

Corrective hoof trimming is the most appropriate treatment. Aggressive shortening of the affected abaxial hoof wall. Hoof trimming should provide a flat solar surface, which is perpendicular to abaxial hoof wall.

Prevention

Farmers should consider selection of breeding stock (especially bulls) for proper hoof conformation. The practitioner may consider aggressive corrective hoof trimming of young actively growing animals (less than 18 months of age). This procedure will force proper placement of feet, permitting animals to grow into a structure or conformation, which permits flat placement of hoof. Although this procedure may improve the health and survival of individual animals, it may mask conformational defects, which may have a genetic component.

INTERDIGITAL CELLULITIS (FOOT ROT, INTERDIGITAL PHLEGMON)

Definition

Infection of the skin and subcutaneous tissues of the interdigital cleft

Cause

Primary etiologic agent is *Fusobacterium necrophorum*, a gram-negative anaerobe. Trauma and abrasions of the interdigital skin are important predisposing factors.

Clinical Signs and Diagnosis

- Has the appearance of a wound with gray, devitalized edges. Lesion has a foul, necrotic odor characteristic of anaerobic

infections. The foot dorsal to the coronary band is often swollen, warm, and erythematous.

- Untreated disease or delayed treatment may result in deeper tissues being affected and cause irreparable damage.

Treatment

- Optimal treatment is systemic antibiotics. Common treatments include long-acting oxytetracycline (20 mg/kg IM) and procaine penicillin G (20,000 IU/kg IM). Some dairy clients will treat with ceftiofur (1–2 mg/kg) because this does not necessitate milk withholding. The author finds this treatment less efficacious.
- Topical therapy is less effective and unreliable.

Contraindications

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

Prevention

Avoid traumatic footing and irregular flooring surfaces like frozen mud, gravel, or grain stubble. Consider use of trace-mineralized salt containing organic iodine compounds.

DIGITAL DERMATITIS (HEEL WARTS, HAIRY HEEL WARTS)

Definition

A warty to verrucous lesion located on the bulbs of the heels or the caudal interdigital cleft

Cause

Disease appears to be caused by an as yet unnamed spirochete bacterium. Organism functions as a contagious pathogen and is readily passed among cattle in a herd. This disease is very common in dairy cattle and seen occasionally in beef cattle.

Clinical Signs and Diagnosis

- Lesions vary in appearance from warty and verrucous lesions to a raw, circumscribed granulation bed surrounded by a white to gray skin edge. Long hairlike fibrils often protrude from lesions.
- Lesions are confined to areas of haired skin and typically spare the hoof wall. These lesions are very painful when palpated.

Treatment

Large lesions should be debrided. Application of topical tetracycline or lincocin with or without bandages is effective. Dairy herds often spray the bulbs of the heel with topical antibiotic to either treat lesions or limit their severity.

Contraindications

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

Prevention

- Herds free of digital dermatitis should practice strict biosecurity to prevent introduction of the agent.
- Providing dry environment seems to limit the spread and severity of lesions. In endemically infected herds farmers may spray the bulbs of the heel with topical antibiotics to limit lesion severity. A vaccine is available; however, its efficacy has not been documented in controlled clinical trials.
- Farriers and hoof trimmers should disinfect hoof tools after treating affected cattle.

HEEL EROSIONS (SLURRY HEEL, HEEL CRACKS)

Clinical Signs and Diagnosis

- Deep erosive cracks that originate from the junction of heel and sole on the axial surface of hoof and extend caudally through the heel at a 45-degree angle.
- These lesions may extend as deep as the sensitive tissue and may become infected, dissecting cranial and caudal under the surface of the sole and heel.
- Lesions typically are present on both the medial and lateral claw of both hind feet. Lesions are predisposed by wet conditions and preexisting chronic laminitis.

Treatment

Completely pare out lesions. Consider corrective hoof trimming with particular emphasis on shortening the toe, which will shift weight off the heels and onto the toes. Affix a wooden block to the normal digit if only one claw is affected.

Prevention

Implement routine hoof trimming in dairy cattle. Avoid excessively wet conditions. Management of the diet to prevent laminitis.

VERTICAL HOOF CRACKS (SAND CRACKS)

Clinical Signs and Diagnosis

- Vertical cracks are typically located on the anterior to anterior-lateral surface of the hoof. They are most common on the front feet.
- Lesions are more common in beef cattle than dairy cattle. The underlying hoof wall is greatly thickened.
- Cracks that do not extend to the coronary band rarely cause lameness. Hoof wall adjacent to the crack may become underrun. In some instances, granulation tissue may protrude through the crack.
- Dry conditions and firm, hard footing may predispose, but the exact cause is unknown.

Treatment

- Pare out fissure (crack) completely. Thin (grind) hoof wall over and to either side of the fissure. This procedure will make that portion of the hoof non-weight bearing and shift weight onto the sole of the hoof. This procedure will limit flexing of hoof wall and coronary band, providing nearly immediate pain relief in many cattle.
- Normal hoof wall will grow out at a rate of approximately one-fourth inch/month. Replacement of entire edge of the hoof will require a minimum of 1 year. Repetitive hoof trimming may be needed to insure the affected portion of the hoof remains non-weight bearing.
- Protruding granulation tissue should be removed and its regrowth limited by topical application of 10% formaldehyde.

Prevention

Unknown

INTERDIGITAL FIBROMA (CORNS)

Proliferation of fibrous connective tissue and skin in the interdigital space. Most corns do not cause lameness. Corns that are not infected and not in contact with the ground rarely cause gait abnormalities. One should be careful not to attribute lameness to corns and miss other problems, which may cause irreversible damage if not treated. Laxity of intercornual ligaments probably predisposes.

Treatment

Surgical resection of corn

BOVINE LEUKEMIA

BASICS

DEFINITION

Bovine leukemia is a term used for two hematopoietic oncogenic diseases: sporadic bovine leukosis (SBL), which does not have an infectious cause, and enzootic bovine leukemia (EBL), a disease caused by a retrovirus, bovine leukemia virus (BLV).

PATHOPHYSIOLOGY

- Four clinical syndromes are recognized: calf, thymic, skin, and adult. The first three syndromes are called sporadic bovine leukosis because there is no evidence for the etiology.
- The adult form, enzootic bovine leukosis (EBL), is caused by infection of B cells with the bovine leukosis virus (BLV).
- BLV infections are lifelong infections. Thirty percent of the animals develop elevated lymphocyte counts (lymphocytosis). The development of solid tumors (lymphomas) from BLV occurs in a small percentage of animals.
- There is no relationship between lymphocytosis and the progression to lymphomas.
- Over 50% of the lymphomas contain a mutation in the p53 tumor suppression gene. These lymphomas develop most frequently in the lymph nodes, abomasum, heart, spleen, kidneys, uterus, spine, and retrobulbar lymphatic tissue.

SYSTEMS AFFECTED

Lymphoreticular system, skin

GENETICS

- There is a genetic component to BLV susceptibility.
- Cattle with the major histocompatibility complex allotype, BoLA-w8, have been shown at higher risk of being seropositive.
- The BoLA-DA12.3 allotype is prone to increased persistent lymphocytosis (increased numbers of B cells), while the BoLA-DA7 allotype is resistant to lymphocytosis.

INCIDENCE/PREVALENCE

- The three syndromes of sporadic bovine leukosis are very rare and usually occur in animals less than 2 years of age.
- Seroprevalence to BLV, the causative agent of EBL, varies from 0%–100% by herd. In 1996, 89% of dairy herds and 43.5% of dairy cows in the United States were BLV seropositive. In 1997, a survey of beef herds showed that 38% of all beef operations and 10.3% of all beef cows were BLV seropositive.
- The development of EBL following a BLV infection is a rare event.
- The incidence of animals developing EBL (leukemia/lymphosarcoma) varies among herds with the average annual incidence in infected cattle estimated to be 0.3%–1.0%.
- Most animals that develop EBL are > 2 years of age with peak incidence at 5–8 years of age.

GEOGRAPHIC DISTRIBUTION

- Sporadic bovine leukosis occurs worldwide.
- The geographic distribution of enzootic bovine leukosis is also worldwide but is dependent on the distribution of BLV. North and South America, Eastern Europe, Russia, and portions of Australia are BLV-endemic areas.

SIGNALMENT

- SBL is a disease mainly of young cattle.
- Three SBL syndromes are recognized: calf, thymic, and skin. The calf form usually appears in animals < 6 months old and results in generalized proliferation of lymph nodes, liver, spleen, and bone marrow and in lymphoblastic leukemia in about 50% of the animals. The thymic form occurs at 6–30 months of age and the primary neoplasm involves the thymus although lymph nodes and other organs can be affected also. Skin lymphosarcoma form is extremely rare. This syndrome has cutaneous tumors that spontaneously disappear and the animal appears healthy. The syndrome is usually only temporary and the skin tumors reappear along with lymphoid tumors in other tissues. All three SBL syndromes are

usually fatal.

- BLV infections are asymptomatic and can be recognized only by a serological test that detects BLV antibody. Animals become seropositive 4–12 weeks after exposure.
- Persistent lymphocytosis develops in ~30% of infected cattle, but this lymphocytosis is not associated with any clinical signs of disease.
- EBL occurs in 0.3–1.0% of BLV-infected animals. These animals will have enlarged superficial lymph nodes (retropharyngeal, mandibular, prescapular, subiliac, mammary) that are two to three times larger than normal size with no signs of inflammation. Lymphomas will infiltrate and affect the function of the abomasum, heart, spleen, kidneys, uterus, spine, and eyes [retrobulbar lymphatic tumor (exophthalmia)].
- The clinical signs may include weight loss, decreased milk production, loss of appetite, rear-limb weakness, fever, protruding eyeballs, gastrointestinal obstruction, and heart failure. These animals frequently suffer from anemia.
- Pregnant animals develop more rapid symptoms probably due to the immunosuppression associated with pregnancy.
- The lymphoma form of EBL is always fatal.

CAUSES

- There are no known etiological agents for SBL.
- Bovine leukemia virus, a C-type retrovirus, causes EBL. Retroviruses are enveloped, single-stranded RNA viruses. They integrate their genes into the B lymphocytes and the cattle are infected for life. This virus is highly cell associated and does not survive well outside the host.

RISK FACTORS

- Transmission of BLV occurs primarily by transfer of blood lymphocytes between animals. The use of common bleeding needles and surgical equipment (tattoo pliers, dehorers, castration knives, etc.) without proper disinfection are the most common mechanisms of transmission.
- Rectal palpation with a common sleeve is another high-risk practice.
- Virus is rarely present in nasal secretions, saliva, urine, or semen, except when those fluids are contaminated by blood or cellular exudate.
- Insects may act as mechanical vectors of blood. BLV can be transmitted to fetuses in utero, but usually < 10% of calves from infected dams carry the virus at birth.
- When embryos from cows infected with BLV are transferred to BLV-negative cows, the calves produced are routinely free of infection.
- Transmission of BLV to calves through colostrum or milk can occur but is rare because of the presence of BLV colostral antibody.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other tumors can be differentiated only by histology.
- Lumpy jaw caused by *Actinomyces bovis* causes hard swellings on the jaw and neck. These infections usually have some areas filled with purulent material and some of the abscesses may have already drained and may not have purulent material.

CBC/BIOCHEMISTRY/URINALYSIS

- Persistent lymphocytosis (PL), identified as absolute lymphocytosis in two consecutive complete blood counts obtained 3 months apart, occurs in approximately 30% of BLV-infected cattle.
- Circulating lymphocytes can be morphologically normal or exhibit morphologic features of “reactive” B cells.
- When bone marrow becomes lymphomatous in cattle with BLV-induced malignant lymphoma (ML), leukemia with lymphocyte counts as high as 100,000/ μ l can occur. In leukemic cattle, circulating lymphoid cells can appear “immature or blastic.”
- Some cattle with BLV-induced ML have lymphopenia, probably because circulating lymphoid cells are “trapped” in lymphomatous tissues.
- Lymphocytosis, usually in the 8000 to 20,000/ μ l range can also occur with other chronic infectious diseases, like

tuberculosis, trypanosomiasis, or brucellosis.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Two commercial serology tests for the detection of BLV antibody are available: the agar gel immunodiffusion (AGID) and the antibody capture ELISA. These two tests have similar sensitivity and specificities. However, they fail to detect between 35% and 39% of BLV serologically positive animals.
- Reverse transcriptase–polymerase chain reaction (RT-PCR) assays for the detection of the virus in milk and blood are available and are more sensitive and less likely to have false negatives seen with the serological tests. RT-PCR can also detect the infection prior to the presence of antibody.

PATHOLOGIC FINDINGS

- Grossly, EBL can be suspected when tumors of the visceral lymph nodes, uterus, abomasum, heart (especially right atrium), liver, spleen, and kidneys are found. These tumors are usually soft and gray-white, and can include friable areas of necrosis.
- Microscopically, massive lymphoid cell infiltration is observed in the affected organs as they replace normal cells.

TREATMENT

APPROPRIATE HEALTH CARE

Supportive treatment but prognosis is poor

ACTIVITY

N/A

DIET

N/A

CLIENT EDUCATION

Essential practices for controlling BLV infections are

- using hypodermic needles that are designed to be discarded after one injection
- using a different obstetrical sleeve to palpate each cow
- washing and then disinfecting any instruments that may be contaminated with blood. The use of two sets of instruments with one soaking in disinfectant while the other is being used should be encouraged.
- using electric dehorers rather than gouges or saws. The latter cause profuse hemorrhage and are difficult to sanitize.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- BLV-infected animals are a source of infection to all other animals.
- The low occurrence of clinical disease in herds with high seroprevalence to BLV frequently makes the priority of culling BLV seropositive animals low.
- Four essential practices for controlling BLV infections are listed above under Client Education.
- BLV eradication programs have been developed in Europe and in New York. The New York State Bovine Leukosis Virus Eradication and Certification Program (NYSBLVECP) was designed to help producers in establishing a BLV-free herd. The NYSBLVECP guidelines include the four practices outlined above along with many other steps for separation and rearing of infected animals and young stock.
- Although BLV-seropositive animals pose a risk to the herd, using only serology will lengthen the time to identify and eradicate BLV from a herd.
- BLV-positive animals with lymphocytosis are a larger risk because of their higher concentrations of BLV-infected lymphocytes. Removing these animals will have a faster impact on reducing the BLV risk in the herd.
- There are no commercial BLV vaccines available. Two experimental BLV vaccines, a modified-live gene deleted and a DNA vaccine, have been developed and prevented BLV infection in over 85% of the animals.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- With SBL, the prognosis is poor and the course of the disease from the first appearance of tumors will be only weeks to months.
- The vast majority of BLV infections are inapparent. Although 30% of BLV-seropositive animals will develop lymphocytosis, these animals are not at a greater risk for developing EBL.
- Animals with clinical signs of EBL have a poor prognosis and the course of the disease from the first appearance of tumors is short similar to SBL.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Animals < 2 years of age develop SBL. Most animals that develop EBL are > 2 years of age with peak incidence at 5–8 years of age.

ZOONOTIC POTENTIAL

No risk

PREGNANCY

The immunosuppression of pregnancy appears to accelerate the development of BLV lymphomas.

RUMINANT SPECIES AFFECTED

Bovine and ovine

BIOSECURITY

- BLV-infected animals have the potential of producing infectious BLV for life.

- BLV-seropositive animals need to be considered a reservoir of the virus.
- New arrivals should be tested prior to introduction for BLV antibodies.
- In a BLV-positive herd, testing for lymphocytosis also may be advisable to identify animals with higher numbers of BLV-infected lymphocytes that would pose a higher risk to the herd.
- The use of single-use materials (needles, gloves, etc.), as described above, along with proper disinfection of surgical instruments are essential components of a BLV biosecurity plan.
- Depending on the level of control desired, BLV seropositive and seronegative animals should be housed separately.
- Seronegative animals should always be processed before seronegative animals.

PRODUCTION MANAGEMENT

- The economic impact of BLV on dairy cows is \$59 per year per cow resulting from a ~3% decrease in milk production per cow.
- The overall economic impact of BLV on milk production for the United States is \$525 million per year.

BOVINE PAPULAR STOMATITIS

BASICS

DEFINITION

- A mild viral disease of calves characterized by proliferative lesions around the mouth caused by a parapoxvirus.
- Infections are usually asymptomatic, but raised papules may be observed on nasal planum, hard palate, nares, and occasionally on the esophageal or ruminal mucosa.
- There are no lesions at the coronary band.

SYSTEMS AFFECTED

Epithelium of nares, oral cavity, esophagus, and rumen

GENETICS

No association with breed or genetics observed; commonly observed in dairy calves and recent arrivals in feedlots

INCIDENCE/PREVALENCE

Worldwide distribution

SIGNALMENT

- Young dairy calves, feedlot calves shortly after arrival. Commonly observed in calves from 1 to 12 months of age
- Rare in adult cattle

SIGNS

- Acute lesions consist of 2–4 mm macules on the nares and muzzle that progress rapidly to papules with raised periphery and depressed center. Lesions later develop in the oral cavity.
- Lesion size may increase to 1 cm in diameter or greater (coalescence of multiple lesions) and regress within several days to weeks.
- Most animals are afebrile, eat normally, and have no clinicopathologic alterations associated with viral infection.

PATHOPHYSIOLOGY

- Viral infection results in early hyperemia and inflammation in focal regions of the nares and mouth. Secondary lesions may occur for up to 4 months.
- Histopathological evaluation of lesions demonstrates degeneration of epithelial cells and eosinophilic inclusions in degenerated cells.
- Hyperplasia of the papillae of the lamina propria is observed.
- Ulceration of lesions is accompanied by bacterial infection and sloughing of the epithelium.
- A chronic form of BPS has been described associated with more severe clinical signs (salivation, diarrhea, anorexia, and fever). The ulcers in chronic cases become encrusted with exudates.
- Similar to contagious ecthyma and pseudocowpox in sheep and goats, bovine papular stomatitis is zoonotic and common in veterinary personnel.

RISK FACTORS

- Calves born to cows affected by BPS when young
- Adult cows may serve as reservoir for future calf infection.
- Recent introduction of naïve animals to feedlot

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Foot-and-mouth disease, vesicular stomatitis, and bovine virus diarrhea/MD, pseudocowpox viruses. Lesions are not found at coronary band, and generally are asymptomatic.

CBC/BIOCHEMISTRY/URINALYSIS

No abnormalities consistently associated with viral lesions

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Polymerase chain reaction, electron microscopy and histopathology are useful in the diagnosis of BPS.
- Histopathological evaluation of lesions demonstrates degeneration of epithelial cells and eosinophilic inclusions in degenerated cells.
- Confirmation of BPS in a new area requires virus isolation and identification.
- Typical parapoxvirus virions can be seen using transmission electron microscopy of biopsy samples.

TREATMENT

MISCELLANEOUS

PREVENTION

- Symptomatic treatment of severely affected animals.
- Prevention can focus on biosecurity and production of vaccines using locally obtained viral strains.

ASSOCIATED CONDITIONS

N/A

- Young dairy calves, feedlot calves shortly after arrival; commonly observed in calves from 1 to 12 months of age
- Rare in adult cattle

ZOONOTIC POTENTIAL

Similar to contagious ecthyma and pseudocowpox in sheep and goats, bovine papular stomatitis is zoonotic and common in veterinary personnel. The mild clinical manifestations make the condition relatively minor; however, the occasional case may have more severe lesions.

Author: Jeff Lakritz

BOVINE PETECHIAL FEVER

BASICS

DEFINITION

- Bovine petechial fever is an infectious disease of cattle characterized by petechial and echymotic hemorrhages on mucosal membranes. The disease is also known as Ondiri disease.
- Bovine petechial fever is endemic in some parts of East Africa (Kenya and possibly Tanzania). The disease has not been reported in North America.

SIGNALMENT

- There is no sex or age predisposition. *Bos taurus* breeds are more susceptible than *Bos indicus*.
- The disease also has been reported in sheep, goats, and wild ruminants following experimental infection, but natural infection has been reported only in cattle.

SIGNS

- Affected animals have a fluctuating fever.
- The most consistent signs are petechiation and echymosis of mucous membranes. Unilateral conjunctival edema, hyphema, epistaxis, and anemia are present in some severe cases.
- Dairy cattle imported into endemic areas often exhibit a profound drop in milk production.

CAUSES

- The cause is *Ehrlichia (Cytoecetes) ondiri*. The organism is endemic in wild animals particularly the bushbuck (*Tragelaphus scriptus*) of highlands above 5000 feet in East Africa. Cattle acquire the disease when grazing on edges of thick, humid forests particularly when they are grazed in these areas at the end of the dry season.
- Bovine petechial fever is common in cattle that have been recently introduced to these areas while indigenous cattle appear to acquire resistance.
- The disease is thought to be transmitted by an arthropod vector. The vector has yet to be identified, but epidemiological findings suggest a tick vector.

RISK FACTORS

Grazing in or adjacent to thick, high elevation East African forests and the presence of the bushbuck, the reservoir of the organism, are important risk factors. Recently introduced animals are more susceptible.

DIAGNOSIS

Ehrlichia ondiri is diagnosed on demonstration of the organism in peripheral blood monocytes and granulocytes after Giemsa staining but cannot be cultured.

DIFFERENTIAL DIAGNOSIS

- Differential diagnosis includes bracken fern poisoning and tropical diseases including acute trypanosomiasis and theileriosis.
- Bracken fern poisoning is associated with pastures containing the plant and affected animals have hematuria.
- Trypanosomiasis occurs in the tropics where the vector, the tsetse (*Glossina* sp.) fly is found.
- Theileriosis is also common in areas where the tick vector *Rhipicephalus* sp. is present. Trypanosomiasis causes lymphadenopathy and the organism can be demonstrated in blood smears. Theileriosis causes lymphadenopathy and can be demonstrated in blood smears and lymph node aspirates.

TREATMENT

Tetracyclines are effective as a treatment. Recovered animals are immune to reinfection for at least 2 years.

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PROGNOSIS

- Prognosis is guarded. The mortality is up to 50% in affected animals.
- The disease is important in imported animals introduced into risk areas where significant losses are recorded.

PRODUCTION MANAGEMENT

- Bovine petechial fever is common in cattle that have been recently introduced to infected areas while indigenous cattle appear to acquire resistance.
- Grazing in or adjacent to thick, high elevation East African forests and the presence of the bushbuck, the reservoir of the organism, are important risk factors. Recently introduced animals are more susceptible.

BOVINE RESPIRATORY DISEASE COMPLEX (BRD)

BASICS

OVERVIEW

- Bovine respiratory disease (BRD) complex refers to the general development of respiratory disease in cattle. In most cases, it specifically refers to respiratory disease outbreaks among multiple animals. BRD most commonly occurs in cattle fed for slaughter, although it can also occur in cattle raised for milk production.
- BRD is commonly called “shipping fever.”
- It is estimated that over \$3 billion are spent annually on prevention, treatment, and production losses related to BRD in the United States fed cattle industry.
- The etiology of BRD is very often multifactorial, and may include viruses, bacteria, parasites, nutrition, environmental stressors, and host susceptibility. The severity of BRD outbreaks is often influenced by the relative combination of these factors.

SIGNALMENT

- BRD can occur in any age and class of cattle.
- Younger animals under stressful conditions are most at risk.

SIGNS

- Clinical signs may vary depending on the agents involved and the severity of infection.
- The first sign often recognized is a reduction in appetite. Cattle may not show typical enthusiasm for coming to the feed bunk when fed.
- Cattle off feed may have a sunken appearance in the left para lumbar fossa as a result of decreased rumen fill.
- Affected animals often separate from their herd mates.
- Movement of affected animals is typically slower than nonaffected herd mates. They may show a reluctance to rise.
- A general appearance of depression is often appreciated.
- Affected cattle often stand with their heads down and extended.
- Cattle may have a serous to mucopurulent nasal discharge.
- Serous ocular discharge is often present.
- Coughing is often evident, especially when cattle are forced to move.
- Depending on the severity, shallow to labored and rapid breathing may be evident.
- Cattle affected with BRD typically have a fever ranging from 103.5°F to 105.5°F.
- A cranial ventral distribution of lung sounds consistent with bronchopneumonia and lung consolidation is found on auscultation. Moist crackles are heard with bronchopneumonia when the bronchi contain watery secretion or exudation. As the exudate thickens, the sound changes to a dry crackle. Consolidated areas of lung associated with bronchopneumonia (or large abscesses) contain no air and are completely silent.

CAUSES AND RISK FACTORS

- Viruses commonly implicated in BRD include bovine herpesvirus 1 (BHV-1), bovine viral diarrhea virus (BVDV), bovine respiratory syncytial virus (BRSV), parainfluenza-3 (PI-3), bovine respiratory corona virus (BRCV), and adenoviruses.
- Bacteria commonly involved in BRD include *Mannheimia haemolytica* (formerly *Pasteurella haemolytica*), *Pasteurella multocida*, *Mycoplasma bovis*, *Haemophilus somnus*, and *Actinomyces pyogenes*.
- Environmental factors that increase the risk of BRD include poor sanitation, poor ventilation, overcrowding, lack of adequate feed bunk space, lack of adequate water availability.
- Stressful events such as transportation, mixing of cattle from multiple sources, castration, dehorning, vaccination, starvation, and weaning increase the risk of BRD developing.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Allergic interstitial pneumonia
- Pulmonary edema
- Pleuritis
- Pulmonary fibrosis
- Lungworms

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Culture and antimicrobial sensitivity are often done on lung samples collected at necropsy or following transtracheal bronchial alveolar lavage.

DIAGNOSTIC PROCEDURES

- Nasal swabs are of limited value, as many of the pathogens involved in BRD inhabit the nasal passages normally.
- Transtracheal bronchial alveolar lavage will identify pathogens most likely involved with pneumonic process.
- Necropsy provides the most useful information on the etiological agents and pathological processes involved. Necropsies on cases early in the course of the disease and prior to antibiotic therapy yield the best results.

GROSS FINDINGS

- Gross lesions will depend on the pathological agents involved in the BRD outbreak and the chronicity of the disease process.
- Necrotizing lesions of the upper respiratory tract and trachea may be present.
- Pneumonic lesions are typically distributed in a bilateral cranial ventral pattern, often with a sharp line of demarcation between the normal and abnormal lung.
- There may be varying degrees of pleural adhesion between lung lobes and to the chest wall.
- The lung parenchyma typically has a lobulated pattern that imparts a marbled appearance both on the pleural and cut surface.
- Affected parenchyma is firm in palpation and may range in color from pink to tan to red to red-black depending on the amount of necrosis present.
- Necrotic tissue may progress to abscessation.

HISTOPATHOLOGICAL FINDINGS

N/A

TREATMENT

- Antimicrobials directed against common BRD bacteria.
- Moving sick cattle to separate pens may be indicated to reduce the stress of competing with healthy cattle.

MEDICATIONS

- Common antimicrobial classes used for treatment of BRD include penicillins, cephalosporins, oxytetracyclines, floroquinolones, macrolides.
- Ancillary treatments such as nonsteroidal anti-inflammatory drugs, corticosteroids, antihistamines, and vitamin injections may be of value on a case-by-case basis, but in general have limited application in treatment of BRD.

CONTRAINDICATIONS

- Some antibiotics are not approved for certain classes of cattle, such as lactating dairy cattle.
- Meat and milk withhold times must be considered before administering any medication to food-producing cattle.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Daily observation of attitude and appetite will provide a good indication of treatment success.
- Gaining of weight is associated with a good prognosis while continued weight loss is a poor sign.
- Reduction of rectal temperature in 24–48 hours posttreatment is associated with a good prognosis.

PREVENTION/AVOIDANCE

- Immunization against common pathogens associated with BRD
- Minimizing stressful events
- Maintaining well-ventilated and sanitary environments with plenty of bunk space and water availability

POSSIBLE COMPLICATIONS

- Pericarditis
- Endocarditis
- Pleuritis
- Polyarthritis is often a sequela of *Mycoplasma bovis* and *Haemophilus somnus* pneumonia.

EXPECTED COURSE AND PROGNOSIS

- Prognosis is generally favorable if intervention occurs early.
- If intervention is started early, most cattle respond to treatment in 24–72 hours.
- Failure to respond to initial treatments generally indicates advanced disease and the prognosis should be guarded.

BOVINE RESPIRATORY SYNCYTIAL VIRUS

BASICS

DEFINITION

Bovine respiratory syncytial virus (BRSV) induces a mild to severe lower respiratory disease in cattle. This infection is one of the viral factors associated with bovine respiratory disease complex.

PATHOLOGIC FINDINGS

- BRSV induces damage to the respiratory epithelium with a concomitant influx of inflammatory cells (neutrophils and cytotoxic lymphocytes) and cytokines (tumor necrosis factor). This lowers arterial oxygen by 30%–40%.
- The damage to epithelium coupled with inflammatory changes increases the susceptibility of the lung to secondary bacterial infection.
- Severe BRSV infections can cause severe damage to bronchiolar and alveolar epithelial tissue resulting in the formation of bullae and interstitial emphysema.

SYSTEMS AFFECTED

Respiratory

GENETICS

N/A

INCIDENCE/PREVALENCE

- BRSV is endemic in cattle.
- BRSV is seldom seen in calves less than 2 weeks of age, and is most prevalent and severe in animals between 1 month and 8 months of age.
- BRSV disease is rarely seen in cattle > 9 months of age. Adult cattle can occasionally experience severe disease.
- Seroprevalence in herds is often > 90%.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

- BRSV infection results in respiratory signs. These respiratory signs can be mild, with increased respiratory rate and increased harshness in respiratory sounds, to severe, with dyspnea, forced expiration, and open-mouth breathing.
- Spontaneous cough can be easily induced and can vary from dry and nonproductive to moist.
- Nasal discharge can vary from none to serous to mucopurulent.
- Conjunctivitis and lacrimal discharge are seen infrequently. There is an increased rectal temperature (104–108°F [40–42°C]), depression, and decreased feed intake.
- Secondary pneumonia with bacterial pathogens (*Mannheimia haemolytica*, *Pasteurella multocida*, *Haemophilus somnus*) or *Mycoplasma bovis* is a frequent sequela.

CAUSES

BRSV is an enveloped, negative, single-stranded RNA virus in the pneumovirus group of the paramyxovirus family. The virus is easily inactivated by desiccation, heat, and disinfectants.

RISK FACTORS

- Stress (weaning, shipping, etc.) will increase the risk. Excessive levels of dust have been reported to increase clinical BRSV.
- Maternal antibody will inhibit vaccine response but will not prevent infection. However, it will lessen the clinical course of disease.
- Concurrent infection with other viral agents, particularly bovine viral diarrhea virus (BVDV), exacerbates BRSV clinical

disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Three other bovine viruses—BVDV, bovine parainfluenza-3 virus (PI-3), and bovine herpesvirus 1 (BHV-1)—commonly cause similar respiratory disease.
- BHV-1 is associated with rhinotracheitis and upper respiratory disease. BHV-1-infected calves frequently have mucopurulent discharge and conjunctivitis.
- BVDV is associated with oral ulcers, mucopurulent discharge, and upper respiratory disease.
- PI-3 infection is usually a mild lower respiratory disease.
- Bovine coronavirus (BCV) has also been associated with respiratory disease. In younger calves, it is seen in calves suffering from enteritis and diarrhea. BCV in 5–13-month-old cattle causes symptoms of dyspnea, nasal discharge, and increased respiratory rate.
- Atypical interstitial pneumonia (AIP) is characterized by sudden onset of disease with subsequent death. AIP animals have labored breathing with loud expiration, frothing at the mouth, and open-mouth breathing. They have harsh respiratory sounds with crackles and rhonchi. These animals usually have a recent history of grazing lush pastures or having a ration change in a feedyard.

CBC/BIOCHEMISTRY/URINALYSIS

BRSV causes a slight lymphopenia 3–10 days postinfection.

OTHER LABORATORY TESTS

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- BRSV is a very difficult virus to detect by virus isolation. Animals need to be sampled in the incubation or acute phase of infection (3–7 days).
- Transtracheal washes have been used to detect BRSV using polymerase chain reaction (PCR). Antigen detection kits have been developed and can detect BRSV antigen.
- Other procedures that have proved useful in detection of BRSV antigen are fluorescent antibody tests of fresh tissue and immunohistochemistry staining of cell cultures or formalin-fixed paraffin embedded tissues.
- Paired serum samples can be used in the diagnosis of BRSV infection. However, the antibody titer of animals with well-developed clinical disease may be higher in acute samples than the samples taken 2–3 weeks later.
- BRSV antibody response often develops rapidly, and clinical signs follow virus infection by up to 7–10 days.
- Single serum samples showing high antibody titers from a number of animals in a respiratory outbreak may be useful in making a diagnosis if coupled with clinical signs.
- Younger calves infected with BRSV in the presence of maternally acquired antibody may not seroconvert.

PATHOPHYSIOLOGY

- Gross lesions include a diffuse interstitial pneumonia with subpleural and interstitial emphysema along with interstitial edema. These lesions are similar to and must be differentiated from AIP.
- Regional suppurative bronchopneumonia of bacterial origin is usually present.
- Histologic examination reveals necrotizing and proliferative bronchiolitis with alveolitis that is sometimes proliferative along with hyaline membrane formation and edema.
- Syncytial cells are present in bronchiolar epithelium and lung parenchyma.

TREATMENT

APPROPRIATE HEALTH CARE

The therapy for BRSV is supportive. Severely diseased animals that are dehydrated may receive oral and/or intravenous fluids.

ACTIVITY

Handling of BRSV-infected animals should be minimized to decrease the risk of secondary bacterial infections.

DIET

Concentrate and silage should not be fed to severely diseased animals.

CLIENT EDUCATION

Minimize handling of animals, decrease animal exposure to high levels of dust, and use preventative vaccines.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

- Corticosteroids or nonsteroidal anti-inflammatory drugs (NSAIDs) may have some benefit to lessen the severity of BRSV disease.
- Antimicrobial treatment is utilized to reduce secondary bacterial infections.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Respiratory characteristics along with rectal body temperatures should be frequently monitored to assess BRSV clinical progression and also the development of secondary bacterial infections that would result in bovine respiratory disease complex (BRDC).

PREVENTION/AVOIDANCE

- Both modified-live-virus (MLV) and inactivated-virus BRSV vaccines are available.
- Vaccination is an important part of a BRSV control program.

POSSIBLE COMPLICATIONS

- Some formaldehyde-inactivated BRSV vaccines have been shown to increase the severity of BRSV disease. This method of inactivation is not currently used for commercial vaccines.
- Maternal antibodies in calves interfere with development of an effective BRSV immune response with MLV vaccines.

EXPECTED COURSE AND PROGNOSIS

- Uncomplicated BRSV infections will resolve in 10–14 days.
- Animals that have secondary infections usually will develop bronchopneumonia with varying levels of morbidity and mortality.

MISCELLANEOUS

ASSOCIATED CONDITIONS

BRDC is a frequent sequela to BRSV infections.

AGE-RELATED FACTORS

Younger animals (between 1 and 8 months of age) are usually affected.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Bovine, ovine

BIOSECURITY

- BRSV survives very poorly in the environment and is susceptible to UV light, desiccation, heat, and disinfectants. The virus will survive better in the winter.
- Animals exhibiting clinical signs of BRSV should be isolated from other cattle as transmission of BRSV occurs by the oronasal route.
- In pens of animals that have had a BRSV outbreak, it would be prudent to clean the water sources.

PRODUCTION MANAGEMENT

In herds with a history of BRSV in their calves, a BRSV vaccine program should be implemented.

BOVINE SPONGIFORM ENCEPHALOPATHY

BASICS

DEFINITION

Bovine spongiform encephalopathy (BSE) is a progressively fatal, neurodegenerative disease of cattle and is a type of transmissible spongiform encephalopathy.

PATHOPHYSIOLOGY

- Since its first diagnosis in the United Kingdom in 1986, different theories about the origin of BSE have been proposed.
- The most common theory is that BSE mutated from the scrapie agent found in sheep, and changes in the rendering processes for livestock feed allowed this prion to survive and be fed to cattle. Then further rendering of infected cattle carcasses to make meat and bone meal amplified the agent.
- Another theory is that BSE has always existed in cattle but went virtually unrecognized until 1986 when the outbreaks occurred in the UK.

SYSTEMS AFFECTED

Nervous

GENETICS

- Offspring of BSE-infected cattle seem to have an increased risk of developing BSE but exact etiology is unknown at this time.
- Vertical or venereal transmission has not been proven.

INCIDENCE/PREVALENCE

- Annual incidence data are only available for the countries in which BSE has been diagnosed and in cattle over 24 months of age because the incubation period is thought to be more than one year.
- The 2003 data range from as low as 0.16 cases per million bovines over 24 months of age in Canada to 137.19 cases per million bovines over 24 months of age in Portugal.

GEOGRAPHIC DISTRIBUTION

Infected indigenous cattle have been found in Austria, Belgium, Canada, Czech Republic, Denmark, Finland, France, Germany, Greece, Ireland, Israel, Italy, Japan, Lichtenstein, Luxembourg, Netherlands, Poland, Portugal, Slovakia, Slovenia, Spain, Switzerland, United Kingdom, and the United States. Imported cattle with BSE have been reported in the Falkland Islands and Oman.

SIGNALMENT

Species

Cattle, bison

Breed Predilections

NA

Mean Age and Range

Generally affects cattle between 3 and 6 years of age and the incubation period ranges from 2 to 8 years.

Predominant Sex

NA

SIGNS

HISTORICAL FINDINGS

Usually an insidious onset of neurologic signs in cattle older than 3 years of age.

PHYSICAL EXAMINATION FINDINGS

Slowly progressive, degenerative neurological disease. Cattle will often be ataxic, primarily on the hind limbs with

hypermetria. They will also have hyper-reflexia, muscle fasciculation and tremors, fall down, and behavior changes such as nervousness and frenzy. Over time, the animal will become anorexic and lose weight and body condition; dairy animals will have decreased milk production.

CAUSES

- The agent that causes BSE is smaller than most viruses and highly resistant to common disinfectants, heat, UV light, and ionizing radiation.
- While it has not been observed microscopically, there are three main theories as to the causative agent. First is that it is just an unconventional virus. Second is that it is an incomplete virus or virino. Third, and the most widely accepted theory, is that small prions, or proteinaceous infectious particles, cause normal prion proteins to change to an abnormal form and cause degenerative changes in the brain of infected cattle.

RISK FACTORS

Cattle consuming scrapie-infected meat and bone meal or other ruminant by-products that may be contaminated with the BSE agent

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Rabies, lead poisoning, nervous ketosis, listeriosis, polioencephalomalacia, hypomagnesemia, intracranial tumors, and spinal cord trauma

CBC/BIOCHEMISTRY/URINALYSIS

There is no antemortem test for BSE as the host does not mount an immune response to the agent.

OTHER LABORATORY TESTS IMAGING

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Gross lesions are restricted to carcass changes such as emaciation and damage to the hide from ataxia and nervousness.
- Histopathologic detection of neurodegeneration lesions in the brain (bilaterally symmetrical spongiform changes in the grey matter) will help confirm the diagnosis. Immunohistochemistry, immunoblotting, and ELISA to demonstrate accumulations of the prion (PrP^{Sc}) protein are needed for definitive diagnosis.

TREATMENT

APPROPRIATE HEALTH CARE, NURSING CARE, ACTIVITY

There is no treatment for this disease.

DIET, CLIENT EDUCATION

Restrictions have been put in place in many countries that preclude the feeding of ruminant products back to ruminants, but clients should be made aware of this as a risk factor and prevent contamination of any cattle feed on their farms.

SURGICAL CONSIDERATIONS

N/A

**FOLLOW-UP****PATIENT MONITORING**

N/A

PREVENTION/AVOIDANCE

Do not feed ruminant products to ruminants.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

This is a progressively fatal neurodegenerative disease and 100% of the cases will die.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

N/A

AGE-RELATED FACTORS

Most often seen in cattle between 3 and 6 years of age.

ZOONOTIC POTENTIAL

- There is evidence to suggest that persons consuming BSE-contaminated products may develop a disease called variant Creutzfeldt-Jakob disease.
- The exact incubation period for this disease is unknown but it is thought to be decades. It too is a progressively fatal neurologic disease with 28 years of age being the mean age at death of those affected with vCJD.
- Since the first discovery of vCJD in 1996 through November 2006, there have been 200 cases worldwide, with the majority of cases in the UK (164) and France (21). The United States has reported 3 cases, but the patients had resided in the UK (2) and Saudi Arabia (1) the majority of their lives.
- There are recommendations regarding blood donations, surgical equipment, and organ transplants from countries where vCJD has been diagnosed to prevent further spread of this disease.

PREGNANCY

Vertical transmission of BSE has not been documented but offspring of BSE-infected cattle are at higher risk for developing the disease; offspring are usually culled.

Authors: Danelle Bickett-Weddle and Neal Bataller

BOVINE VIRAL DIARRHEA VIRUS

BASICS

OVERVIEW

- Bovine viral diarrhea (BVD) is a multifaceted disease with complicated pathogenesis and one of the most significant viral infections of cattle.
- Bovine viral diarrhea virus (BVDV) is capable of infecting and causing pathology in many different organ systems.
- Cattle can become acutely infected with BVDV at any age. This is also referred to as primary infection or transient infection.
- Fetal infection prior to day 125 of gestation can result in the development of immunotolerance to the BVDV and the development of a persistent infection (PI) with the virus.
- Cattle persistently infected with BVDV shed large amounts of virus during their lifetime. They are the major source of virus spread within and between farms.

SIGNALMENT

All ages and classes of cattle are susceptible to infection with BVDV.

INCIDENCE/PREVALENCE

BVDV is a ubiquitous pathogen of ruminants with high seroprevalence worldwide (up to 60% of adult cattle have antibodies). Infections with BVDV are endemic in many countries and are often associated with severe economic losses for the cattle industry.

GEOGRAPHIC DISTRIBUTION

Worldwide

Species

BVDV was thought to be species-specific but is now known to cause infection in species other than cattle including llama, alpaca, pigs, sheep, goats, white-tail deer, and mule deer.

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Infections are mostly subclinical in nature. However, there has been an emergence of new virulent BVD viruses that cause thrombocytopenia and hemorrhagic disease.
- BVDV infection may result in subclinical acute infections; severe acute infections characterized by fever, leukopenia, and thrombocytopenia; persistent infections; reproductive disease presenting as congenital defects, repeat breeding, abortion, or mummification; enteric disease, respiratory disease; and immunosuppression. The severity of disease depends upon host and viral factors.
- Acute infection may be defined as the infection of an immunocompetent animal with BVDV.
- Following infection with BVDV, a short incubation period of 5–7 days is followed by viremia, which generally lasts for 1–2 days but may persist for 15 days.
- A mild, biphasic elevation in body temperature and leukopenia may be evident.
- Lactating cattle may have an associated decrease in milk production.
- Some strains are pneumotropic and may cause severe fibrinopurulent bronchopneumonia in the presence of *Mannheimia*

hemolytica.

- Mucosal disease is characterized by fever, anorexia, depression, profuse salivation, nasal discharge, severe diarrhea, hemorrhages and erosions in gastrointestinal tract, and a very high case fatality rate (see Mucosal Disease in this volume).
- BVDV subtype 2 is usually involved in severe acute BVD characterized by severe thrombocytopenia with hemorrhages (prolonged bleeding from venipuncture sites; hemorrhages on sclera of eye and inner surface of eyelids; hemorrhages on mucosal surfaces of cheeks, lower gingiva, tongue, and soft palate), fever, pneumonia, diarrhea, and sudden death in 10–100% of infected animals.
- BVDV can result in immunosuppression following acute infection resulting in secondary infections caused by opportunistic pathogens. BVDV has been implicated most often as an immunosuppressive component of the bovine respiratory disease complex.
- In calves: diphasic pyrexia, leukopenia, anorexia, diarrhea, immunosuppression
- In pregnant animals: early embryonic death, abortion, congenital infection (if infected within 45 to 125 days of gestation). At 12 days of gestation, infection usually results in the birth of PI animals. Signs may include cerebral hypoplasia, retinal atrophy, cataract, growth retardation, arrested bone development, and pulmonary hypoplasia.

CAUSES AND RISK FACTORS

- BVDV is an RNA virus and a member of the genus *Pestivirus* in the family *Flaviviridae*.
- The BVDV is antigenically related to classical swine fever virus (CSFV) of pigs and border diseases virus (BDV) of sheep. All pestiviruses are antigenically cross reactive.
- The subtypes of BVDV include BVDV 1a, BVDV 1b, BVDV 2a, and BVDV 2b. All of these viruses can be either cytopathic (cp) or noncytopathic (ncp); the cp strains have an additional nonstructural protein. Both virulent and nonvirulent strains have been reported. Virulence does not depend on biotype (cp or ncp) or genotype.
- The major risk factor for BVDV being introduced into a farm is the acquisition of new cattle. Other risk factors include sharing of pastures with other cattle (direct or fence line) and lack of a BVDV vaccination program.

Transmission

- The virus is shed in most secretions and excretions of infected animals including tears, milk, saliva, urine, feces, nasal secretions, and semen.
- Two main methods of virus transmission include postnatal horizontal transmission and gestational vertical transmission from a viremic dam to her fetus. Transmission may occur by aerosols, nose-to-nose contact, and via semen, rectal palpation, and embryo transfer. PI animals are much more efficient transmitters of BVDV than transiently infected animals because they shed large amounts of virus for a long period of time.
- Infection at 120–150 days of gestation may result in abortion, resorption, stillbirths, or PI animals.
- After 120 days, infection results in abortion, stillbirth, congenital defects, and normal appearing calves.
- Virus can survive for several days or even weeks in a cool, protected environment and hence fomites (nose tongs, halters, etc.) play a role in virus transmission.
- Flies can also transmit the virus.
- The virus can be present in milk and colostrums.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Differential diagnosis for calves with diarrhea as the result of BVDV includes any pathogen known to cause diarrhea in neonatal calves. In adult cattle, differential diagnoses would include winter dysentery and salmonella.
- Differential diagnosis for abortions caused by BVDV includes BHV-1, neospora, leptospirosis, and brucellosis.
- Differential diagnosis for thrombocytopenia induced by BVDV includes sweet clover poisoning, coumarol poisoning, and vitamin K deficiency.

CBC/BIOCHEMISTRY/URINALYSIS

- Severe leukopenia is characteristic in the early stages of acute BVD, with total leukocyte count in the range of 1000–5000/ μ l being common.
- Isolates of BVDV associated with hemorrhagic BVDV can result in severe thrombocytopenia and subsequently anemia.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Virus isolation from serum, whole blood, nasal swabs, or lymphoid tissue
- PCR on serum, whole blood, nasal swabs, or lymphoid tissue
- Identification of a fourfold increase in virus-neutralizing antibody titers in acute and convalescent serum samples
- Persistent infection with BVDV can be diagnosed by identification of virus from serial samples taken 3 weeks apart using virus isolation, antigen detection ELISA, or PCR, or identification of BVDV antigen in skin samples by immunohistochemistry.

Virus/Viral Antigen Detection

- Viral antigen can be found in brain, spinal cord, kidney, spleen, lymph nodes, testicular tubules, and endothelial cells of PI animals.
- High throughput methods are now available for whole-herd screening to identify and remove PI animals.
- For direct detection of viral antigen, cryostat sections of fresh tissues are stained with fluorescein-conjugated anti-BVDV antibody and then examined under a fluorescent microscope. The presence of apple-green fluorescence indicates a positive test.
- Immunohistological staining of formalin-fixed, paraffin-embedded skin biopsies (ear notch samples) using 15C5 monoclonal antibody has been used to detect PI animals and is often considered better than histopathology and direct immunofluorescence (DFA) of tissues.
- Antigen-capture ELISA (AC-ELISA) can be used for the detection of BVDV antigen in buffy coat cells, serum, and ear notch samples. Monoclonal antibody directed against a conserved antigenic domain of a nonstructural protein (NS2/3) of pestiviruses is used as a capture antigen followed by detection of antigen-antibody complex with enzyme-conjugated antibody. Serum can be used for the detection of PI animals by AC-ELISA. Acute animals are rarely detected by this test because the virus is present in the blood of acutely infected animal for only a short time.
- Bovine turbinate (BT) cells, primary bovine embryo kidney (pBEK) cells, and cell lines originating from bovine embryonic trachea (EBTr) and buffalo lung (IMR-31) can be used for the isolation of BVDV from nasal discharge, peripheral blood leukocytes (PBL), lungs, semen, blood, serum, fetus, and feces. The isolated virus can be confirmed/identified by DFA, immunoperoxidase monolayer assay (IPMA), monolayer enzyme-linked immunosorbent assay (M-ELISA), AC-ELISA, or RT-PCR. The presence of anti-BVDV antibody in serum and buffy coat samples may interfere with virus isolation.

Antibody Detection

- An indirect measure of virus infection is the detection of virus-specific antibodies in the sera of animals. Unfortunately, it is often difficult to differentiate among antibodies produced in response to acute infection, vaccination, or transfer of maternal antibodies from dam to offspring. In cattle, calves are usually born without antibody but seroconvert after colostrum consumption. These passive antibodies wane after 3–8 months. Hence, the presence of antibody in colostrum-deprived calves can be due only to active infection (either in utero or postnatal) or vaccination.
- Seroconversion of sentinel animals can be used as an evidence for possible exposure to PI animals. Many tests are available for the detection of anti-BVDV antibodies, namely, virus-neutralization (VN), indirect immunofluorescence (IIF) assay, indirect immunoperoxidase (IIP) assay, and ELISA tests.
- The virus neutralization (VN), also known as serum neutralization (SN), is considered to be the gold standard test for the detection of anti-BVDV antibodies and is used worldwide. The test can be used for the detection of antibodies against BVDV 1 or BVDV 2 depending upon the virus used in the test. In most situations, cp strains of BVDV are used in the test so that the presence of neutralizing antibodies can be detected by inhibition of viral infectivity as detected by the absence of viral cytopathology. Titers due to active infection can be differentiated from vaccination titers by demonstrating a fourfold rise in antibody titers using paired (acute and convalescent) serum samples. Virus neutralizing antibodies usually appear 3–4 weeks after infection and persist for years. Titers induced by vaccination may also persist for a long time. Passive antibodies decline at 105–230 days (but may persist for more than a year).
- ELISA tests have been developed for the detection of anti-BVDV antibodies in serum samples. The antigens used in ELISA tests include whole-virus antigen, nonstructural protein (p125/80), monoclonal antibodies, and peptides. The advantages of the ELISA test include its sensitivity, ease, and objectivity in reading results, nondependability on cell cultures.

- Indirect immunoperoxidase and indirect immunofluorescence tests also have been used for the detection of anti-BVDV antibodies.

Nucleic Acid Detection

- Detection by reverse transcription–polymerase chain reaction (RT-PCR) has been found to be more sensitive and rapid than virus isolation. In addition, contrary to virus isolation, RT-PCR is not affected by the presence of antibodies in serum samples.
- Due to its high sensitivity, RT-PCR is considered as an alternative to current standard methods for detecting BVDV, especially in pooled samples such as bulk tank milk. However, RT-PCR does not differentiate between nucleic acid from live or inactivated virus and may yield false positive results.
- The prolonged stability of viral nucleic acid as compared to the virus itself has led to a simple method for the collection, storage, transport, and testing of blood samples. In this procedure, 10 μ l of blood or serum is applied to a Whatman No. 1 paper, the sample is air dried and then tested.
- Several single- and two-tube RT-PCR assays have been described for the detection of BVDV RNA in serum, buffy coat cells, and fresh and formalin-fixed tissues (including ear notches).

Diagnosis by Testing Bulk Milk

- Screening of bulk milk for antibody or antigen has been used to detect BVDV infection in cattle herds. The milk is centrifuged to remove fat and undiluted skim milk is tested for antibodies using an ELISA test. There is an excellent correlation between the level of antibodies in the bulk-tank milk and the prevalence of BVDV-antibody-positive cows.
- RT-PCR assay to screen bulk milk samples for BVDV is also a sensitive and economic method for the detection of PI animals within a group because virus titers are usually higher in milk than in serum samples.

GROSS FINDINGS

- In most cases, acute BVDV presents with no gross lesions that are specific.
- Cattle may have lesions similar to those found with mucosal disease including erosions in the oral cavity, esophagus, rumen, abomasums, and small intestine, especially over areas of the Peyer's patches.
- Widespread petechial and ecchymotic hemorrhages may be present in cattle suffering from hemorrhagic syndrome.
- No specific lesions are seen in aborted fetuses.
- Cerebellar hypoplasia can be seen grossly in congenitally affected calves.

HISTOPATHOLOGICAL FINDINGS

Lymphoid depletion of the Peyer's patches, lymph nodes, spleen, and thymus are common with acute BVDV infections.

TREATMENT

- Cattle acutely infected with BVDV typically recover over time.
- In severe cases, supportive therapy is indicated.
- There is no treatment for cattle persistently infected with BVDV.

CLIENT EDUCATION

Eradication

- Sweden was one of the first countries to introduce a national BVDV control program in 1993, which now forms the basis for control programs in many other countries.
- The eradication programs are based mostly on detection and elimination of PI animals and immunization of breeding females prior to first gestation.
- Vaccination is not allowed in Denmark. Therefore, it is easy in that country to detect infected animals by testing for the presence of antibodies.
- The primary aims of eradication programs are the establishment of BVDV-free herds and prevention of reinfection of these herds so that there is a gradual decrease in the number of infected herds. This model works well in countries where cattle density is low and vaccination is not allowed but may not work in countries where both virus prevalence and cattle densities are high and where vaccination is permitted.

MEDICATIONS

N/A

CONTRAINDICATIONS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Implementation of a whole-herd vaccination program against BVDV is recommended.
- Vaccinations should include antigens against both type 1 and type 2 BVDV.
- Newly acquired cattle should be screened for persistent infection.
- Newly acquired cattle should be quarantined for a minimum of 3 weeks.

Vaccination

- Vaccination to prevent fetal infections is likely the most important measure to control the occurrence of PI calves.
- Effective vaccines against infectious agents must account for both antigenic and genetic diversity, and they should provide fetal protection.
- It should be remembered that colostral antibodies, which may last for 6 months, may interfere with vaccination.
- Both modified-live (MLV) and killed vaccines are available. Most vaccines in the United States include BVDV 1a cp strains, although some vaccines do contain BVDV 2 cp strains.
- Only a single dose of MLV vaccine is needed for initial immunization as opposed to killed vaccine that may require 2 or more doses. However, MLV vaccines are susceptible to inactivation by chemicals and/or exposure to higher temperatures. The MLV may also lead to mucosal disease when an animal persistently infected with an ncp strain is exposed to a closely related cp strain included in MLV.
- Because of multiple doses needed and the added cost of adjuvants, killed vaccines turn out to be more expensive. However, they are recommended for dairy herds where pregnant animals are always likely to be present. Killed vaccines are also recommended for bulls in AI centers.

POSSIBLE COMPLICATIONS

- The use of modified-live vaccines against BVDV in pregnant cattle is contraindicated unless specified by the product manufacturer.
- Modified-live vaccines may be immunosuppressive and therefore should be used with caution.

EXPECTED COURSE AND PROGNOSIS

Most cattle recover within 10 to 14 days.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Mucosal disease occurs in cattle persistently infected with BVDV following a superinfection with an antigenically related cytopathic BVDV strain.
- Cytopathic BVDV may also arise by mutation of the infecting ncp virus.

AGE-RELATED FACTORS

Colostral antibodies can protect newborn calves for 2–4 months.

ZOONOTIC POTENTIAL

BVDV is not considered a zoonotic agent.

- Fetal infection with BVDV can result in abortion, congenital defects, persistent infection, or seroconversion. The result of fetal infection is dependent on the virus strain and biotype and the stage of gestation when fetal infection occurs.
- In utero infection of the fetus with ncp BVDV prior to 120 days of gestation leads to immune tolerance and the birth of persistently infected (PI) calves that are unthrifty and poor doers and act as a source of virus for the rest of the herd. PI families can arise by breeding PI animals.

BRACKEN FERN TOXICITY

BASICS

OVERVIEW

- All ruminant species are at risk of developing toxicosis. Most cases of poisonings have been reported in cattle.
- Bracken fern, or brake fern (*Pteridium aquilinum*), is a native perennial fern, 1 to 6 feet tall, with triangular, coarse, pinnately compound fronds. It has a deep-seated, black, elongate, branched, hairy, horizontal rhizome. Spores develop late in the summer and are found rolled under the blade edges. This is the only *Pteridium* species that is considered toxic in the United States. Other *Pteridium* species have been shown to contain the toxic principle in other parts of the world.
- The plant prefers moist to dry woods and open slopes, with good drainage. It tends to occur naturally in very dense stands.
- The young plants and rhizomes are the most toxic part of the plant, green or dried.
- Disease in ruminants is generally seen following chronic exposures of variable concentrations of the plant in the diet.
- Poisonings with this plant are relatively uncommon.
- Diseases reported in ruminants include bone marrow suppression, enzootic hematuria, bladder and gastrointestinal carcinomas, and progressive retinal degeneration.
- Key to controlling the disease is prevention. Bracken fern is susceptible to a wide variety of herbicides.

PATHOPHYSIOLOGY

- Ptaquiloside is thought to be the main toxic principle. Other agents reported to be toxic include quercetin and shikimic acid. The species of animal exposed, and the dose and duration of exposure, are thought to be the limiting factors in determining which disease the animal succumbs to.
- Bone marrow suppression has been observed in clinically affected animals; there is suppression of all cell lines (radiomimetic effect).
- Clinically affected animals generally present with signs associated with thrombocytopenia and neutropenia; anemia may occur as a result of blood loss or later as the red cells disappear from circulation (long life span).
- Bovine enzootic hematuria ("red water") has been reported in cattle chronically exposed to bracken fern. This syndrome is linked to the development of bladder lesions, some of which are neoplastic. Hematuria and bladder neoplasms predominate in cattle, but papillomas, sarcomas, and carcinomas of the jaw and gastrointestinal tract can occur in sheep. Exposures of months or years are required to cause these types of changes. It has been speculated that viruses (bovine papillomavirus type 2 and type 4) may play a role in the development of neoplastic lesions.
- Experimentally, bracken fern exposure for 4 to 12 months has been associated with progressive retinal degeneration in sheep.
- Polioencephalomalacia has been reported in sheep chronically exposed to the plant (rare).

SYSTEMS AFFECTED

Bone marrow, urinary tract, gastrointestinal tract, and eye

GENETICS

N/A

INCIDENCE/PREVALENCE

Unpredictable and uncommon

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Cattle are most commonly affected.

Species

All ruminants appear susceptible; most poisonings have been reported to occur in cattle.

Breed Predilections

N/A

Mean Age and Range

Enzootic hematuria and tumors are generally observed in older animals, following months or years of exposure.

Predominant Sex

N/A

SIGNS

- Cattle afflicted with bone marrow suppression generally present with bloody nasal discharge, petechiation and ecchymoses, and weakness. Secondary bacterial infections are common (e.g., lung), and signs of dyspnea, decreased appetite, and hyperthermia can be observed.
- Red to brown urine is a common change in those cattle suffering from enzootic hematuria.
- Signs can be varied depending on the tumor site.
- Sheep suffering from retinal degeneration show bilateral pupil dilatation and have a glassy-eyed appearance (“bright blindness”).

CAUSES AND RISK FACTORS

- Poisonings can occur as a result of grazing the fresh plant (thought to be unpalatable) or following chronic consumption of contaminated hay.
- The plant is toxic green or dry; the most toxic parts of the plant are the young developing fronds (fiddleheads or crosiers) and rhizomes.
- Clinical disease is generally seen when animals consume significant amounts of plant material (up to 20% of their diet) for 30 days or more.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Thrombocytopenia has been reported with BVD virus infection.

CBC/BIOCHEMISTRY/URINALYSIS

- Thrombocytopenia and neutropenia; anemia is observed later on.
- Inflammatory leukogram, hyperproteinemia, elevated fibrinogen can be due to secondary infectious processes.
- Hematuria

OTHER LABORATORY TESTS

Prolonged bleeding times

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Examination of the bone marrow may reveal pancytopenia—risky procedure in compromised patients.

PATHOLOGIC FINDINGS

- Petechiation and ecchymoses, multiple hemorrhages throughout the tissues, pale bone marrow, edematous and ulcerated GIT
- Numerous neoplastic conditions of the GIT and urinary tract—papillomas, transitional cell carcinomas, squamous cell carcinomas, adenocarcinomas, hemangiomas
- Retinal degeneration and atrophy of the outer layers

TREATMENT

- Find and remove the suspect source or remove animals from the contaminated environment.
- Most animals respond poorly to treatment.
- Broad-spectrum antibiotic use, animal stress reduction, and good nursing care can be utilized.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

MEDICATIONS

N/A

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

N/A

PATIENT MONITORING

- Monitor platelet, neutrophil, and red blood cell values.
- Check for onset of secondary infections.

PREVENTION/AVOIDANCE

- Be able to recognize bracken fern in the field or in hay, and avoid excessive grazing.
- Herbicide application can be successful in eliminating the plant.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Animals suffering from bone marrow suppression almost never recover.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Monogastrics exposed to bracken fern suffer from neurologic disease that is thought to be related to a thiamine deficiency.

AGE-RELATED FACTORS ZOONOTIC POTENTIAL

Since ptaquiloside is a direct-acting carcinogen, people conceivably can be affected through direct consumption of the plant or ingesting meat or milk from exposed animals.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Cattle are most commonly reported to be affected; but there are reports of sheep, llamas, and other ruminants being affected.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Avoid feeding “weedy” hay.
- Avoid grazing in bracken dense areas, provide adequate forage, and instill appropriate stocking densities.

SYNONYMS

Bracken fern, brake fern

Bright blindness

BRASSICA SPP. TOXICITY

BASICS

OVERVIEW

- Ingestion of *Brassica* spp. can cause various diseases including goiter, enteritis, and Heinz body anemia in ruminant animals.
- Forages or roots of the genus *Brassica* include kale, rape, turnips, mustards, cabbage, brussels sprouts, and others. *Brassica* spp. contain glucosinolates, which have goitrogenic effects and induce gastrointestinal irritation.
- These plants also contain S-methylcysteine sulphoxide (SMCO), which causes Heinz body anemia.
- Other diseases associated with *Brassica* spp. ingestion include polioencephalomalacia, photosensitization, and acute bovine pulmonary emphysema and edema.
- There are three groups of glucosinolates, which can be enzymatically broken down into different metabolites: isothiocyanates, thiocyanate ion, and thiones.
- Isothiocyanates are found in mustard oils contained in plant seeds. These are irritants to the gastrointestinal mucosa causing enteritis and diarrhea.
- Thiocyanate ion can cause goiter when ingested in small amounts over extended periods of time, particularly if the dietary content of iodine is low. Thiocyanate ion reduces iodine uptake by the thyroid and can be treated with exogenous iodine.
- Thiones are a potent goitrogen, which interferes with the formation of thyroxine. Treatment with iodine does not alleviate clinical signs.
- “Rape blindness” has been observed in cattle and sheep grazing on rape. Other neurological signs such as head pressing and behavioral changes have been noted. These signs may be as a result of a mild degree of polioencephalomalacia or hepatotoxicity.
- Acute bovine pulmonary emphysema and edema have been observed in cattle on *Brassica* spp. plants. *Brassica* spp. forage may precipitate 3-methylindole-associated disease.

PATHOPHYSIOLOGY

- Thiocyanate ion can cause goiter when ingested in small amounts over extended periods of time, particularly if the dietary content of iodine is low.
- Thiocyanate ion reduces iodine uptake by the thyroid and can be treated with exogenous iodine. Thiones are a potent goitrogen, which interferes with the formation of thyroxine.
- Another toxin is S-methylcysteine sulphoxide (SMCO), which is converted to dimethyl disulphide (DMDS) by the rumen or gut organisms.
- DMDS interferes with disulphide exchange reactions, which results in changes in red blood cell membranes and hemoglobin. This can lead to Heinz body formation and anemia.
- *Brassica* spp. have also been associated with primary and secondary or hepatogenous photosensitization.

SYSTEMS AFFECTED

- Hemic
- Lymphoreticular
- Gastrointestinal
- Nervous
- Respiratory
- Integumentary

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Potentially worldwide depending on species and environment

SIGNALMENT

- *Brassica* spp. poisoning has been reported in cattle, sheep, goats, and pigs. Goiter may be seen in animals of any age. Feeding *Brassica* spp. to pregnant dams may result in neonates with goiter.
- Hemolytic anemia occurs after 1–3 weeks of ingestion of a diet consisting mainly of *Brassica* spp. plants. Enteritis can occur after ingestion of large amounts of rapeseed and *Brassica* spp. seeds containing mustard oils.
- Pulmonary emphysema has been reported only in cattle.

Species

Potentially all ruminant species

Breed Predilections

N/A

Mean Age and Range

Any age

Predominant Sex

N/A

SIGNS

HISTORICAL FINDINGS

- Clinical signs for goiter include thyroid enlargement, weakness, lethargy, and recumbency. Animals with goiter may show signs of weight loss or failure to gain weight.
- Animals in hemolytic anemia crisis may show signs of lethargy, anorexia, dyspnea, coffee-colored urine and mucous membranes, icterus, hypoxic abortion, and cardiovascular shock. Death results from respiratory failure secondary to anemia.
- Clinical signs associated with enteritis include diarrhea, dysentery, abdominal pain, salivation, and occasionally vomiting. Anorexia, ruminal stasis, and scant, sticky feces may also be noted with gastrointestinal disturbances.
- Signs of photosensitization include erythema and blistering of affected areas, particularly areas of light-pigmented skin.

PHYSICAL EXAMINATION FINDINGS CAUSES AND RISK FACTORS

- *Brassica* poisoning can be found in any commercial operation that provides *Brassica* plants or seeds as feed.
- Glucosinolate concentration can vary between *Brassica* plant species and can vary with season. The highest concentration of glucosinolates can be found in seeds, but are present in all parts of the plants. Plants become more toxic as they mature.
- The SMC content of *Brassica* plants also increases with maturity and the flowers and seeds are particularly toxic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- A nutritional deficiency of iodine can cause goiter. Goiter may also be caused by the ingestion of couch grasses (*Cynodon dactylon*, *C. nlemfuensis*) and white clover (*Trifolium repens*).
- Differential diagnoses for signs of hemolytic anemia include onion toxicity, red maple toxicity as well as leptospirosis, hypophosphatemia in postparturient cows, babesiosis, anaplasmosis, chronic copper poisoning, as well as immune-mediated and drug-induced hemolytic anemias.
- Differential diagnoses for *Brassica* spp.–induced signs of gastritis are numerous including ingestion of oak species, *Nerium* spp. (oleander), *Geigeria* spp., *Eupatorium rugosum*, and others, as well as parasitic, viral, and bacterial etiologies.
- Many species of plants, grasses, and blue-green algae can cause primary and secondary photosensitization.

CBC/BIOCHEMISTRY/URINALYSIS

- Assays of serum glucosinolate levels are available.

- Heinz bodies and decreased serum hemoglobin levels can be observed on complete blood counts.

TREATMENT

- There is no specific treatment for *Brassica* spp. poisoning. Removal of *Brassica* spp. feedstuffs and relocating animals away from pastures populated with *Brassica* spp. are recommended.
- Administration of iodine may be beneficial in cases of iodine deficiency. Blood transfusions may be necessary in cases of severe hemolytic anemia.

MEDICATIONS

DRUGS OF CHOICE CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

BREEDING SOUNDNESS EXAMINATION AND INFERTILITY IN MALE CAMELIDS

BASICS

DEFINITION

- Breeding soundness examination of the male camelid is becoming an integral part of many prepurchase examinations requested by breeders. This examination is not intended to measure fertility but to help identify males with reproductive problems.
- The reproductive system of the male camelid presents several anatomical and physiological peculiarities (see Camelid Reproduction). The practitioner should be familiar with these peculiarities in order to complete a thorough examination of a male.

SYSTEMS AFFECTED

Reproductive

GENETICS

N/A

INCIDENCE/PREVALENCE

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Camelids

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

Male

SIGNS

HISTORY AND PHYSICAL EXAMINATION

History and Signalment

- Age of the animal is important. Problems such as inability to mount or exteriorize the penis or even substandard fertility can be due to sexual immaturity
- Origin and type of management
- Breeding records
- Previous health problems
- Reason for examination

Physical Examination

- Reproductive performance of the male can be affected by diseases of other systems.
- Prolonged febrile condition or debilitating diseases can affect testicular function and spermatogenesis.
- A complete health history, including previous illnesses, vaccination, and recent treatments, should be taken.
- A general physical examination should be performed including general appearance and body condition of the animal.

During the sire-selection process, particular attention should be given to the presence of congenital or potentially heritable conditions.

Reason for Examination

- Reasons for examination can be generally divided into two categories: prepurchase examination of a herd sire and examination for infertility or obvious genital lesions.
- It is very important to define exactly the problem(s) to be addressed: existence of visible lesions, suspicion of infertility due to many unsuccessful breedings, or a change in the reproductive behavior (reduced libido).
- An approximate date of the onset of the problem should be obtained as well as conditions: did the problem appear suddenly or was it a slow, progressive process?

Examination of the Prepuce and Penis

- Examination should be done when there is an obvious problem at this level, such as an abnormally pendulous prepuce, presence of edema, or laceration.
- Examination of the prepuce may require sedation of the animal.
- Ability to exteriorize the penis is best observed during a live cover.
- The penis is normally extended when the male assumes the breeding position but full erection is completed intravaginally.
- Penile attachment to the prepuce is normal in young, prepuberal animals but can signal the presence of adhesions in the mature male. In llamoids, the penis should be completely free at 3 years of age.

Examination of the Testicles and Scrotal Content

- The scrotal region is examined from a distance to evaluate testicular descent and integrity of the skin in the area.
- Both testes should be present and visible within the scrotum in the perineal region.
- In older males, the scrotum may sometimes be pendulous.
- One of the testicles is usually situated slightly more ventral than the other, but both should be nearly equal in size (difference less than 15%).
- Testicles are predisposed to traumatic lesions including bites by other males.
- Palpation of the scrotum and its contents is necessary to appreciate the regularity of the contour of the testes as well as their consistency.
- The surface of the testes should be smooth and regular.
- The testes are normally resilient. They become hard and fibrotic or very soft in the case of degenerative changes.
- The scrotal sac should be free from fluid.
- The tail of the epididymis is palpable as a small hard nodule.
- Testicular size is an important indicator of sperm production capacity. Size of the testis can be evaluated by measuring its length and width using precision calipers or ultrasonography. In the llama, the long axis should measure at least 1.1 cm in a yearling and 3.2 cm by 2 to 3 years of age. In alpacas, the testes' long axis should be at least 3.5 cm in order to achieve good fertility in a herd. The length and width of the testicle in adult males should be 5–7 cm and 3–4 cm in llamas and 4–5 cm and 2.5–3 cm in alpacas.
- Ultrasound of the testicle should be part of the routine breeding soundness examination. It is preferably done with a linear 7.5 MHz transducer (see Camelid Reproduction).

Examination of the Accessory Sex Glands

- When examination of the accessory sex glands is required, transrectal ultrasonography is the best method to accomplish this.
- The bulbourethral glands are found just cranial and on each side of the anal sphincter.
- Following the pelvic portion of the penis cranially images the prostate.

Evaluation of Mating Behavior

- Mating ability of the male is best observed in the presence of a receptive female.
- During this evaluation, the succession of normal behavioral patterns is recorded as well as the times needed for each step: chasing, forcing down, mating, intromission, and duration of copulation.
- Behavioral problems at mating can be due to shyness, inexperience, or lack of libido.

Semen Collection

- Semen collection presents many difficulties due mainly to the nature of copulatory behavior and the slow (dribbling) process of ejaculation in camelids.
- Semen collection using an artificial vagina is possible but requires training and the use of a specially designed dummy mount fitted with a collection apparatus. The average duration of collection is about 30 minutes in llamas and 22 minutes in alpacas.
- Electroejaculation, using ram probes in llamoids and bovine probes in camels, has been accomplished under various degrees of sedation or anesthesia.
- Response to the electrical stimulus varies greatly from one individual to the other.
- Erection is possible during electroejaculation but failure to obtain an ejaculate or only a few sperm cells is common.
- The ejaculate obtained by electroejaculation is often of poor quality and contaminated with urine and cellular debris.
- In practice, the techniques most commonly used are vaginal aspiration and electroejaculation.
- Vaginal aspiration is accomplished by allowing a male to complete breeding with a receptive female. Upon completion of the mating an infusion pipette is introduced vaginally and the seminal fluid is aspirated using a 12 ml syringe.

Semen Evaluation

The major problem in interpreting semen analysis in the camelid is the lack of standard methods for collection and for examination.

Volume

- Ejaculate volume varies greatly depending on the method of collection used, duration of copulation, and male variation.
- Ejaculate volume ranges from 0.4 to 12.5 ml.
- Vaginal aspiration yields volumes ranging from 0.25 ml to 5 ml.

Color

- The color of semen varies according to sperm concentration.
- It is predominately milky white whether it is collected by electroejaculation or by other methodology, but can sometimes be creamy white.
- Ejaculate may be heterogeneous with some translucent material mixed with cloudy areas.
- Ejaculates collected by vaginal aspiration may be pink or red because of contamination with blood from the cervix.

Consistency and Liquefaction

- Camelid semen is viscous and requires some time to liquefy.
- The degree of viscosity depends on the individual male and on the proportion of seminal gelatinous fluid and tends to decrease with number of ejaculates.
- The time required for liquefaction varies from one male to another and from one ejaculate to another.
- Viscosity is attributed to the presence of mucopolysaccharides from secretions of the bulbourethral glands or the prostate.
- Liquefaction of camelid semen can be obtained by addition of trypsin or collagenase to the ejaculate.

Sperm Concentration

- Concentration of semen is best estimated using a hemocytometer technique after liquefaction.
- Sperm concentration is highly variable (82,000 to 250,000/mm³) and is affected by age, method of collection, and ejaculate rank.

pH

- The pH of semen varies between 7.5 and 8.1.
- Semen pH is affected by method of collection and rank of ejaculate.

Semen Motility

- Motility of semen is appreciated on nondiluted samples (mass activity) and on diluted samples (individual sperm motility).
- Mass activity is generally poor in camelidae semen unless the ejaculate is constituted exclusively by the sperm-rich fraction.
- In fresh nondiluted samples, only oscillatory movements are observed.
- Initial motility is very low (5%) and increases as the ejaculate liquefies.
- Progressive motility can only be estimated after liquefaction and dilution with a suitable extender.

Semen Morphology

- The head of camelidae spermatozoa is described as elliptical as opposed to ovoid in other species.
- Lengths of the head and middle piece are shorter than those of other animals.
- Morphology of the spermatozoa can be evaluated on smears stained with eosine-Nigrosin Hancock stain or Diff Quick (Giemsa) stains.
- A total of at least two hundred sperm cells from different fields should be evaluated from each sample.
- Morphological evaluation is done under phase contrast microscopy as for other species.
- The morphological abnormalities should be reported according to type and location.
- Effect of various types of abnormalities on fertility has not yet been determined.
- Total abnormalities should not exceed 50%.
- The most common abnormalities are proximal droplets, knobbed or swollen acrosome and tail, and midpiece reflex.

Endocrine Evaluation

- Information on endocrinological evaluation of the infertile male camelid is completely lacking. The only practical use of endocrine evaluation is in the differential diagnosis between cryptorchidism and castration.
- Presence of testicular tissue can be ascertained if there is at least a twofold increase in serum testosterone level within 8 to 24 hours after IV administration of hCG (3000 IU for alpacas, 5000 IU in llamas, 10,000 IU in camels).

Testicular Biopsy

Indications

- Testicular biopsy is not a routine procedure for the evaluation of the breeding soundness in the male.
- Testicular biopsy should be considered in males that have low fertility, testicular asymmetry, and abnormal testicular ultrasonography that is not consistent with hematoma or orchitis.
- This technique is useful for diagnosis of spermatogenic arrest, oligospermatogenesis, hypogonadism, inflammations, and neoplasm.

Techniques

- *Wedge biopsy*: an incisional or open biopsy requires general anesthesia. After surgical preparation of the scrotum, an incision (0.5 cm) is made over the skin, parietal vaginal tunic, and the exposed tunica albuginea avoiding vascular areas. Testicular tissue allowed to protrude from the rent in the tunica albuginea is ablated using a scalpel blade. The tunica albuginea, parietal vaginal tunic, and scrotal skin are closed with absorbable suture.
- *Trucut*: use under sedation or anesthesia. After surgical preparation of the testicles, the scrotum is incised using a sterile #10 surgical blade (alpacas) or #11 scalpel (llamas). The trucut (14-gauge self-firing) biopsy needle is inserted in the testicle through the tunica albuginea. The scrotum is closed with two skin sutures using 2-0 Vetafil. Results obtained with this technique are more reliable but hemorrhage at the biopsy site is more frequent.
- “Core” biopsy: A needle “core” biopsy can be performed using a 1 1/2 in., 16-gauge needle after heavy sedation of the animal. After surgical preparation of the scrotal skin, the needle is introduced into the testicular parenchyma and redirected by a gentle push-pull movement into two different sites. The needle is retracted from the tissue while a finder is placed over the hub to maintain the core sampled. A direct smear is prepared from the sample obtained.
- *Fine needles aspirate*: Fine needle aspirate cytology is a commonly used technique for the evaluation of azoospermia and testicular neoplasm in humans. It is rapid, simple, and inexpensive. Testicular tissue is aspirated with a 20-gauge needle and 12 ml syringe. A puncture is made and aspirates are taken in three to four directions making sure not to include the epididymis. Cytological smears stained with Diff Quick are interpreted based on the different types of spermatogenic cells.

Interpretations

- Interpretation should be done by an individual familiar with the technique and histology of camelid testes.
- Fine-needle aspirates are very difficult to interpret. The relative frequency of cell types provides a differential diagnosis between hypospermatogenesis, spermatogenic arrest, and normal spermatogenesis. A fine-needle aspirate from azoospermic animals consists of Sertoli cells alone, a few mature spermatozoa, and scant cell material or spermatid but no spermatozoa.
- “Core” biopsy provides more cellular material than fine-needle biopsy.
- Trucut or self-firing biopsy instruments are safe and provide a good amount of tissue for examination of seminiferous tubule spermatogenic activity.

- Presence of normal spermatogenic activity in cases of azoospermia may suggest the presence of segmental aplasia or other forms of obstructive azoospermia.
- Atypical spermatogenic cells are usually associated with testicular neoplasm (seminoma).
- No spermatogenic cells are obtained from atrophic testicles.

Complications

- Hematoma or hemorrhage
- Adhesions and inflammation
- Autoimmune reactions (development of antisperm antibodies)
- Degeneration of germinal epithelium and tubules
- Transient decrease in sperm output that lasts for several months
- Wedge biopsy is the most unsafe of all methods
- Complication risk increases if the technique is not performed correctly and quickly

Reproductive Disorders in the Male Camelid

Impotentia Cuendi

- Inability to complete mating may be due to poor libido, erection or ejaculation failure.
- Poor libido may be associated with endocrinological disorders, systemic diseases or diseases of other organs (including megasophagus!) and high ambient temperature.
- Young male may be too shy to perform particularly in clinic setting.
- Erection failure may be due to neurological disorders, painful conditions, or preputial stenosis.
- Incomplete mating may be due to obesity or abdominal pain.

Impotentia Gerandi

- Inability to achieve fertilization
- May be due to azoospermia or severe oligospermia of testicular (hypoplasia, degeneration) or epididymal (stenosis, segmental aplasia) origin
- Asthenozoospermia (lack of motility)
- Teratospermia (increased rate of abnormalities)

Diseases of the Penis and Prepuce

- Infections of the prepuce and the penis are relatively rare in camelidae because they are well protected due to their anatomic position.
- Preputial swelling is due to local inflammation caused by contact with chemical or physical irritants, parasitic infestation, or rupture of the urethra.
- Preputial swelling can also be part of a large ventral edema in some animals suffering from heat stress.
- Preputial prolapse is often seen in alpacas. It may require surgical correction.
- Paraphymosis can become complicated by the presence of dirt in the preputial opening and lead to a balanoposthitis, sometimes with necrosis of the tip of the penis.
- Early detection of paraphymosis and treatment will avoid these complications.
- In llamas, paraphymosis and balanoposthitis can be due to the presence of “hair rings” if the females are not clipped before breeding.
- Urolithiasis: most calculi occur at the level of the distal part of the urethra or at the level of the sigmoid flexure. Relief of the condition can be attempted via urethrostomy. Recurrence of obstruction is common even after urethrostomy.

Diseases of the Testis

- Scrotal trauma
 - Bites from other males are a common complaint in the male camelid.
 - Prognosis for the reproductive life of the individual male depends on the extent of the injury and the time elapsed until detection.
 - The affliction should be differentiated from orchitis or hydrocele.
 - Deep lacerations are frequently complicated by testicular hemorrhage, infection, and development of schirrous cord and require urgent surgical intervention (castration).
- Hydrocele

- Due to an inflammatory or noninflammatory process.
- The scrotal sac becomes pendulous and increased in size.
- Initial diagnosis is based on palpation of the scrotum and its content.
- The scrotum is not painful and the testes are usually free within the scrotal sac and fluid can be isolated in one area.
- Confirmation is done by visualization of the fluid by ultrasonography.
- Moderate hydrocele is sometimes observed in summer. The condition resolves progressively with decreasing ambient temperature.
- Hydrocele can develop following obstruction of the normal blood flow in the spermatic cord.
- Hydrocele may be due to the presence of an abscess at the level of the external inguinal ring.
- Long-standing hydrocele affects the thermoregulation of the testes and decreases the quality and quantity of semen.
- Orchitis
 - Usually caused by hematogenous route.
 - Systemic antimicrobial therapy is indicated but is generally not efficacious.
 - Castration of the affected testicle in valuable males may increase the chance of salvaging the nonaffected testicle and the reproductive life of the animal.
- Testicular degeneration
 - The most common cause of infertility in camelids.
 - The degenerated testicles are smaller than normal and either soft or hard and fibrous.
 - Semen shows increased abnormalities and the presence of spheroid (round) germinal cells.
 - Partial or total testicular hypoplasia or atrophy
 - Testicular hypoplasia is common in camelids.
 - Differential diagnosis between hypoplasia and atrophy requires histopathological techniques.
 - Semen may show increased abnormalities and poor concentration.
- Cryptorchidism
 - Relatively rare in camelids.
 - Can be unilateral or bilateral and is suspected when inspection of the perineal region shows a flat or absent scrotum.
 - The undescended testicles are usually found close to the internal inguinal opening but could also be found intra-abdominally, caudal to the kidney, or within the inguinal canal.
 - Cryptorchidism was reported in related vicuñas, which suggests that the affliction may be hereditary.
 - Should be differentiated from anorchism (absence of a testicle), which is generally accompanied by absence of the kidney on the same side.
 - Differential diagnosis: endocrinology, laparoscopy, laparotomy.
- Testicular tumors
 - Rare
 - Seminomas are the most common
 - Sertoli cell tumors and teratomas are possible
- Testicular cysts
 - Found in 15% of all males examined by the author.
 - Can be detected ultrasonographically.
 - They can be located in the rete testis, seminiferous tubules, head or tail of the epididymis.
 - The effect on fertility varies from complete sterility (azoospermia) to subfertility depending on the size and location of the cysts.
 - Some males with small testicular cysts have normal fertility.

Diseases of the Epididymis

- Epididymitis is usually associated with orchitis.
- Epididymal cysts are common in alpacas and llamas.
- Cysts are found on the anterior aspect of the head of the epididymis and near the ventral border of the testis.
- Cysts vary in size between 1 mm and 50 mm.

- Large cysts may be due to segmental aplasia of the epididymal duct.

Subfertility or Infertility of Unexplained Origin

- Decreased fertility may be due to overuse or senile changes.
- The author has seen cases of infertility/sterility with normal seminal parameters and behavior.
- Molecular factors (immunologic or genetic) may be involved in males with unexplained infertility.
- Males have different abilities to induce ovulation (lack or reduced activity of the ovulation inducing agent present in seminal plasma).

MISCELLANEOUS

ASSOCIATED CONDITIONS

It is very important to define exactly the problem(s) to be addressed: existence of visible lesions, suspicion of infertility due to many unsuccessful breeding attempts, or a change in the reproductive behavior (reduced libido).

AGE-RELATED FACTORS

Penile attachment to the prepuce is normal in young, prepuberal animals but can signal the presence of adhesions in the mature male. In llamoids, the penis should be completely free at 3 years of age.

ZOONOTIC POTENTIAL

Brucellosis, though not common in camelids, is a zoonotic disease worth concern.

BREEDING SOUNDNESS EXAM: BEEF BULL

BASICS

DEFINITION

- A breeding soundness exam (BSE) is an evaluation of a bull's reproductive soundness based on a physical examination of the reproductive tract and semen evaluation.
- The primary focus is on the reproductive system but the musculoskeletal system and ophthalmic systems must be evaluated as well.
- Some examiners will include libido or serving capacity tests as part of a BSE.
- The BSE is not meant to be a general health exam.

PATHOPHYSIOLOGY

N/A

SYSTEMS AFFECTED

Reproductive, musculoskeletal, ophthalmic, behavioral

GENETICS

- Genetics play an important role in the onset of puberty.
- Large breed differences exist in age and weight at puberty and testicular size (scrotal circumference).

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

- All bulls should receive a BSE prior to the breeding season.
- A BSE is particularly important in young bulls prior to their first breeding season.

SIGNS

N/A

CAUSES

The causes of poor fertility that can be detected during a BSE are numerous and include:

- Late maturation
- Small testicles
- Poor semen quality
- Injuries to the penis, prepuce, or testes
- Lameness
- Poor or excessive body condition
- Infectious processes involving the testes or accessory sex glands
- Eye injuries
- Congenital reproductive anomalies

RISK FACTORS

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Infertility

- Deficiencies: iodine, manganese, vitamin A, zinc
- Environment: cold weather infertility, heat stroke
- Hereditary: Bulls cotwin with freemartin heifer, chromosomal abnormalities, inbreeding, segmental aplasia of reproductive tract
- Lameness
- Malnutrition
- Penis/prepuce: balanoposthitis; bovine herpes virus-1; dermatophilosis; hematoma, hematocele; loss of penile sensation; micropenis, hypoplasia; papillomatosis, warts; paraphimosis; penile deviation; penile hair ring; penile preputial adhesion; persistent penile frenulum; prolapsed prepuce; trauma
- Psychologic impotency
- Scrotum: abscess, dermatophilosis, frostbite, inguinal scrotal hernia
- Seminal vesiculitis
- Sperm: abnormalities of spermatogenesis, hemospermia, infectious bovine rhinotracheitis (IBR), bovine viral diarrhea (BVD) contaminated semen, sperm granuloma
- Testicles: cryptorchidism, degeneration, hypoplasia/atrophy, orchitis, trauma, tumors
- Urethra and erectile tissue: corpus cavernosum vascular shunts, urethral fistula, urolithiasis
- Varicocele
- Vertebral spondylosis

Lack of Libido

- Epididymitis
- Iodine deficiency
- Lameness
- Malnutrition
- Orchitis
- Penis/prepuce problems: trauma-hematoma, prolapsed penis, loss of penile sensation, corpus cavernosum vascular shunts, persistent penile frenulum, posthitis
- Psychogenic impotency
- Vertebral osteophytosis/spondylosis
- Zinc deficiency

Sexual Malfunction

- Penile/preputial problems: balanoposthitis; deviation; herpes vulvovaginitis; infectious bovine pustular vulvovaginitis; papillomatosis; paraphimosis; penile/preputial adhesions; penile hair ring; persistent penile frenulum; phimosis; ruptured urethra; trauma, hematoma, abscesses; urethral calculi
- Prepuce: abscess/cellulitis, foreign body, preputial stenosis, prolapsed prepuce, trauma
- Testicles, spermatic cord, and scrotum: brucellosis; cryptorchidism; epididymitis; segmental aplasia; sperm granuloma; spermatocele; testicular degeneration, hypoplasia, atrophy; testicular trauma; testicular tumors; varicocele; zinc deficiency

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Culture and sensitivity may be indicated when disease is suspected.

IMAGING

Ultrasound examination may be a helpful adjunct.

DIAGNOSTIC PROCEDURES

Physical Soundness

- Careful attention must be paid to the structural correctness of the feet and legs of a potential breeding bull.
- A bull must be able to cover large distances to search out and find cows in estrus.
- Pain in the limbs and/or back may prevent a bull from successfully servicing cows.
- Breeding bulls should be free of heritable abnormalities such as post-leggedness, sickle hocks, and corkscrew claw.
- The eyes should be examined since a bull primarily uses eyesight to detect cows in estrus.

Evaluation of the Scrotum and Testes

- Visual inspection of the scrotum reveals information about the symmetry, size, and shape of the scrotum.
- The scrotum should have a distinct neck above the testicles to allow adequate thermoregulation.
- Appraisal of the scrotal skin allows detection of scrotal dermatitis or frostbite, which may affect semen quality.
- The testicles should be equal in size, shape, and consistency and be freely moveable within the scrotum.
- Palpation of lumps, soft spots, or any other abnormality of the testicles should alert the examiner to the possibility of an abnormality that may affect semen quality.
- Scrotal circumference (SC) should be measured.
 - Changes in SC from year to year may be evidence of problems within the testes.
 - Most breed associations have established minimum SC measurements in order for yearling bulls to pass a BSE.
 - Some variability exists between breed associations but most have a minimum SC of at least 32 cm for bulls 12–15 months of age.
 - SC is measured by grasping the neck of the scrotum and firmly pulling the testes down into the scrotum. The thumb and fingers should be on the sides of the scrotum rather than between the testicles. The measuring tape should be looped around the greatest diameter of the scrotum.
 - Each epididymis should be evaluated by palpation.
- The head of the epididymis can usually be palpated on the craniodorsal aspect of the testicle.
 - The body of the epididymis can be palpated on the medial aspect of the testicles. Abnormalities of the body are rare.
 - The tail of the epididymis can be palpated at the base, or ventral aspect, of the scrotum.
 - Each epididymis should be evaluated for side-to-side differences, swellings or masses, firmness, warmth, or pain.

Palpation of the Penis and Prepuce

Palpation of the penis and prepuce should be performed.

- The penis should be palpated through the skin from the base of the scrotum to the glans. Detection of any swellings along the penis should alert the examiner to the possibility of an injury that may affect the bull's ability to service cows.
- The prepuce should be palpated from the preputial orifice to the reflection onto the glans. Special attention should be paid to the reflection of the prepuce onto the glans, as this is a very common site of preputial injury.

Transrectal Examination of Accessory Sex Glands and Inguinal Rings

Transrectal examination of the accessory sex glands and inguinal rings should be performed.

- The urethra is usually the first structure palpated. It is a firm tubular structure and usually becomes pulsatile upon palpation.
- The prostate is usually encountered next and can be palpated as a firm transverse ridge at the cranial aspect of the urethra.
- The vesicular glands, or seminal vesicles, can be palpated cranioventral to the prostate. These glands vary in size between bulls but should be uniform in size, lobulated, turgid, and moveable.
- The ampullae may be difficult to identify by palpation but they lie on the pelvic floor cranial to the prostate. Disease of the ampullae is rare.
- The ampullae can be followed to the ductus deferens, which enters the abdominal cavity through the internal inguinal rings.
- The internal inguinal rings can usually be palpated 15–20 cm ventral to the brim of the pelvis and 5–15 cm lateral to midline. One to three fingers can usually be inserted into the internal rings. Enlarged rings may predispose a bull to scrotal hernia.
- The bulbourethral glands are imbedded in the urethralis muscle and cannot be palpated.

- The most common abnormality found on rectal examination is enlargement, excessive firmness, or loss of lobulation of the vesicular glands.
- Seminal vesiculitis occurs most commonly in young bulls.
- Adhesions, abscessation, and development of a draining tract may occur in chronic cases.
- Purulent material may be grossly evident in a semen sample or neutrophils may be seen upon microscopic examination of specially stained smears.
- Samples for culture and sensitivity may be obtained by passing a long, sterile catheter up the urethra and massaging the vesicular glands per rectum.
- After completion of the rectal exam, the pelvic urethra should be massaged to prepare the bull for semen collection.

Collection and Evaluation of Semen Sample

Collection and evaluation of a semen sample is an integral part of a BSE.

- The nature of the bull, available facilities, response of the bull to previous collection attempts, and examiner preference should all be considered when attempting to collect a semen sample.
- Semen may be collected by transrectal massage of the pelvic urethra, by electroejaculation, or by use of an artificial vagina.
- Transrectal massage usually works well in calm bulls but requires at least two people, often does not result in protrusion of the penis, and is tiring to the person performing the massage.
- Numerous types of electroejaculation equipment are available.
 - When using electroejaculation, a bull must be properly restrained.
 - The amount of stimulation should be determined by the bull's response.
 - Stimulation should be low at first and gradually increased until the bull gains an erection and ejaculates. If maximal stimulation is reached without ejaculation, the bull should be allowed to rest for a few minutes and the collection attempted again. If collection is unsuccessful after two to three attempts, the bull should be retested on another day or by another means.
 - Some bulls will not ejaculate in response to electroejaculation and other means must be used.
 - A caudal epidural prior to collection attempts may reduce discomfort for the bull.
 - The semen sample should be obtained when the ejaculate becomes cloudy.
- Semen collection by use of an artificial vagina (AV) is primarily used in artificial insemination centers.
 - Safety for the bull, the mount animal, and the collection personnel must be considered.
 - Collection of semen using an AV may be useful for bulls that fail to ejaculate in response to electroejaculation.
 - It is important that a bull achieve erection and protrusion of the penis so that the penis and prepuce can be carefully evaluated.

Semen Sample Examination

The semen sample should be examined microscopically as soon as possible after collection.

- Equipment used in semen evaluation should be kept clean and warm in order to prevent a reduction in sperm motility.
- Contamination of a semen sample with urine, blood, pus, or chemicals may reduce sperm motility.
- The semen sample should be evaluated for both gross and individual motility.
 - Gross motility is evaluated according to the following:
 - Very good—rapid dark swirls
 - Good—slower swirls and eddies
 - Fair—no swirls but prominent individual cell motion
 - Poor—little or no individual cell motion
 - Individual motility is evaluated by preparing a wet mount by placing a drop of semen on a warm slide and placing a warm cover slip over it.
 - Individual motility is determined based on an estimate of the percentage of progressively motile cells.
 - Very good—80–100%
 - Good—60–79%
 - Fair—40–59%
 - Poor—< 40%

Sperm morphology is evaluated by mixing a drop of semen and a drop of stain on a slide and preparing a smear.

- Live-dead stains are most commonly used. With these stains, live cells appear clear while dead cells are stained pink.
- Sperm cell morphology has historically been evaluated based on the percentage of normal cells versus the percentages of primary and secondary abnormalities.
- Primary abnormalities have their origin in the testes during spermatogenesis while secondary abnormalities originate in the epididymis.
- Some variability exists in the classification of primary versus secondary abnormalities. Generally speaking, abnormalities of the head or midpiece are considered primary while those of the tail are considered secondary. There are exceptions to this rule of thumb and the reader is referred to the Suggested Reading list at the end of the chapter for a more detailed description of these abnormalities.
- Some authors question the validity of this classification system and propose a differential count of all abnormalities instead.
- Primary abnormalities are not more important than secondary abnormalities as both types will reduce the viability of the cell.
- Under most circumstances, a minimum of 30% progressively motile sperm and 70% morphologically normal cells are adequate to pass a BSE.
 - Bulls are classified as satisfactory potential breeders or unsatisfactory potential breeders, or classification may be deferred.
 - Bulls with poor semen quality but without obvious physical abnormalities should be deferred and retested.
 - Detection of a heparin binding protein known as fertility-associated antigen in bull semen may be an indicator of fertility. This test may be useful in further identifying subfertile bulls among bulls that pass a standard BSE.

Serving Capacity/Libido Test

A serving capacity/libido test may be included as part of a BSE.

- Bulls are exposed to restrained, estrus cows for specified time periods and are observed for sexual behavior and mating activity.
- Bulls may also be exposed to a small number of estrous cows in a small pen and be observed for mating activity.
- Most standard BSEs do not include a serving capacity/libido test.
- A rough estimation of serving capacity/libido can be obtained by observing the activity of bulls in a natural mating situation.

Classification Systems and Evaluation Forms

Different classification systems and evaluation forms are available but the most commonly used evaluation form is produced by the Society for Theriogenology.

PATHOLOGIC FINDINGS

N/A

TREATMENT

CLIENT EDUCATION

- Reproductive efficiency is the most economically important aspect of beef production.
- Scrotal circumference is closely related to age of puberty and fertility in daughter progeny.
- Each gram of testicular tissue produces roughly the same number of sperm cells so bulls with larger testicles produce a larger volume of semen.

BRUCELLOSIS

BASICS

DEFINITION

Brucellosis is a reproductive disease of cattle, bison, elk, yaks, sheep, and goats caused by a gram-negative, facultative, intracellular bacterium.

PATHOPHYSIOLOGY

- *Brucella abortus*, *B. melitensis*, and *B. ovis* can be shed in the blood, urine, milk, semen, placenta, fetus, and vaginal discharges of infected animals.
- Susceptible animals that come in contact with these fluids, either through ingestion, contact with mucous membranes, or skin abrasions, can develop a septicemia and abort if pregnant, deliver weak-born animals, and/or become a chronic carrier.

SYSTEMS AFFECTED

Reproductive in all ruminants, musculoskeletal (arthritis) in cattle affected with *B. abortus*.

GENETICS

N/A

- Incidence of brucellosis varies between countries.
- In the United States, since the implementation of the Bovine Brucellosis Eradication Plan in 1934, infection rate is less than 0.25% in two states (Class A status) as of May 2004.
- More than 50% of the bison and elk herd in Yellowstone National Park and Grand Teton National Park have tested positive for brucellosis.

GEOGRAPHIC DISTRIBUTION

- Can be found worldwide
- *B. abortus* has been eradicated from Japan, Canada, Northern Europe, Australia, and New Zealand.
- *B. melitensis* does not occur in northern Europe, southeast Asia, Australia, or New Zealand and is rare in the United States.
- *B. ovis* is seen in Australia, New Zealand, and the United States and is endemic in other sheep-raising regions of the world.

SIGNALMENT

Species

- Cattle, bison, water buffalo, sheep, goats—*B. abortus*
- Sheep—*B. melitensis*, *B. ovis*
- Goats—*B. melitensis*

Breed Predilections

N/A

Breed Predilections

N/A

Mean Age and Range

Reproductively active animals are susceptible, so age can vary depending on species.

Predominant Sex

N/A

SIGNS

HISTORICAL FINDINGS

- In cattle, weak or stillborn calves, abortions during the second half of gestation, and decreased milk production may be

the only clinical signs.

- In sheep, late-term abortions and retained placenta. Rams may develop orchitis, epididymitis, and impaired fertility.
- In goats, abortions can be noted during the fourth month, as well as mastitis and lameness. Bucks may develop orchitis and epididymitis.

PHYSICAL EXAMINATION FINDINGS

- Most often, systemic signs are rare with brucellosis infection.
- Upon physical exam, retained placenta, decreased milk production may be noted in females.
- Male sheep may have decreased sperm counts and swollen testicles.

CAUSES

Susceptible animals that come in contact with contaminated blood, urine, milk, semen, placenta, fetus, and vaginal discharges from infected animals, either through ingestion, contact with mucous membranes, or skin abrasions, can develop brucellosis infection.

RISK FACTORS

Contact with infected herd mates or wildlife.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- In cattle, BVD, IBR, leptospirosis, listeriosis, neosporosis, mycotic abortion, trichomoniasis, campylobacteriosis, chlamydiosis, epizootic bovine abortion (in California), bluetongue, parainfluenza-3, *Ureaplasma*, *Mycoplasma*, *Haemophilus somnus*, *Salmonella*, and *Arcanobacter pyogenes*.
- Noninfectious causes include heat stress, ponderosa pine needle ingestion, locoweed, broomweed, and mycotoxins.
- In sheep and goats, vibriosis (primarily sheep), enzootic abortion (*Chlamydia psittaci*), toxoplasmosis, listeriosis, salmonellosis, and leptospirosis in goats.
- Noninfectious causes are similar to those of cattle.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Serology can be used to diagnose brucellosis infection (*B. abortus*, *B. melitensis*) by card and plate agglutination (buffered *Brucella* antigen tests).
- ELISA tests can be used to detect *B. abortus* in milk and *B. abortus* and *B. ovis* in serum.
- The milk ring test can be used to detect *B. abortus* in bulk milk samples in cattle but not in small ruminants.
- Complement fixation can be used to identify *B. abortus* and *B. ovis*.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Brucella abortus can often be cultured from fetal membranes, vaginal discharge, milk, semen, or aborted fetuses.

PATHOLOGIC FINDINGS

- Aborted fetuses can be normal or autolyzed with evidence of bronchopneumonia.
- Placentitis in cattle and sheep consists of edema and necrotic cotyledons.
- In cattle, the cotyledons could also be normal, red, or yellow in color. The intercotyledonary area is leathery and thickened and has a wet appearance in cattle and sheep.
- Goats have a normal placenta.
- In the case of joint involvement, inflammatory lesions may be seen.
- Granulomatous lesions may be found upon slaughter in the reproductive tract, supramammary lymph nodes, and the mammary gland.

TREATMENT

APPROPRIATE HEALTH CARE

- All cases of brucellosis need to be reported to the state or federal veterinarian and the animals need to be eliminated from the herd.
- No treatment is effective.

ACTIVITY

DIET

N/A

CLIENT EDUCATION

Veterinarians should educate cattle owners regarding their state's recommendations regarding vaccinating young stock in keeping with the eradication program in the United States.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

- No treatment is recommended for cattle.
- In the case of valuable breeding rams, prolonged antibiotic therapy based upon culture and sensitivity can be used. However, fertility may never return to normal.

CONTRAINDICATIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING:

N/A

PREVENTION/AVOIDANCE

- Vaccination of female calves against *B. abortus* with RB-51 from 4 to 12 months of age in endemic areas increases resistance to infection.
- Adult cattle can also be vaccinated but only with permission of the state, provincial, or federal veterinarian. RB-51 is currently being used experimentally in bison, and disease status is being monitored to assess efficacy.
- Goats and sheep can be vaccinated with live, attenuated Rev-1 *B. melitensis* in various parts of the world, but it is not available in the United States.
- Rams have been immunized against *B. ovis* in New Zealand with some success; not available in the United States.

POSSIBLE COMPLICATIONS

- Brucellosis leads to abortions in ruminant species with fertility ramifications in sheep and goats.
- Contact with fetal fluids in infectious and carrier animals can spread the disease to all susceptible animals in a given herd/flock or geographic location.

EXPECTED COURSE AND PROGNOSIS

- Ruminants typically abort only during their first gestation, 80% in late gestation.
- Fertility can be permanently impaired in rams and bucks.
- Death is uncommon in adult animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Arthritis in goats

AGE-RELATED FACTORS

Breeding-age animals most susceptible

ZOONOTIC POTENTIAL

- Humans are susceptible to *B. melitensis* and *B. abortus* infection through direct contact with infectious fluids from animals and absorption across mucous membranes or breaks in the skin.
- Brucellosis infection can also result from consumption of unpasteurized milk or cheese products from endemic areas.
- There is concern with aerosolized particles being used as a bioterrorism agent and causing widespread disease in humans.
- Disease can range from asymptomatic infection to chronic complications such as arthritis, endocarditis, orchitis, osteomyelitis, and other bone lesions.

PREGNANCY

Naïve animals abort late gestation in cattle and sheep and fourth month in goats.

RUMINANT SPECIES AFFECTED

Cattle, bison, elk, camels, water buffalo, yaks, sheep, goats

BIOSECURITY

- Ensure newly purchased cattle have been vaccinated against brucellosis if they are coming from endemic areas. Do not introduce animals directly into the herd for at least 3 weeks.
- Perform breeding soundness examinations on all sexually active males to make sure they are clear of disease and abnormalities.

PRODUCTION MANAGEMENT

- Vaccination of female calves against *B. abortus* with RB-51 from 4 to 12 months of age in endemic areas increases resistance to infection.
- Adult cattle can also be vaccinated but only with permission of the state, provincial, or federal veterinarian. RB-51 is currently being used experimentally in bison, and disease status is being monitored to assess efficacy.
- Goats and sheep can be vaccinated with live, attenuated Rev-1 *B. melitensis* in various parts of the world, but it is not available in the United States.

BURN MANAGEMENT

BASICS

OVERVIEW

- Burns in livestock are not common but may occur by several mechanisms:
 - Thermal—fire (barn, brush, forest), heat (heat lamps, heating pads), hot solutions
 - Electrical—lightning, electrocution
 - Frictional—rope burns, abrasions
 - Chemical—caustic agents, topical medications
 - Ultraviolet—sunburn
 - Radiation
 - Freeze “burns”
- Burns in livestock commonly occur over back, face, udder, and teats, and over ventrum with brush fires.
- Classification of burns is based on depth to which burn penetrates skin and extent of body surface involved.
 - First-degree burn: involves superficial layers of epidermis; characterized by erythema, transient edema, and pain, and generally heals without complication or extensive scarring, prognosis good
 - Second-degree burn: partial-thickness burns involving all epidermal layers but spare hair follicles and sweat glands; characterized by erythema, pain, and vesicles (blisters), necrosis, and sloughing with superficial and eschar with deep second-degree burns; usually re-epithelialized with proper care, some scarring
 - Third-degree burn: full thickness burns involving entire epidermis, dermis, and appendages and exposing deeper structures, local blood vessels and hair follicles destroyed; characterized by necrosis, ulceration, anesthesia, eschar, and extensive scarring, require extensive wound care ± skin grafting
 - Fourth-degree burn: involve entire skin, subcutis, underlying fascia, muscle, and tendon
- The full extent of the thermal burn is difficult to predict immediately after injury.
- Burns are usually complex with body areas being affected to different degrees.
- The development of blisters, fluid separation of epidermis and dermis and eschars may not appear for several days.
- Thermal injuries caused by fire associated with more than skin pathology
 - Fluid shifts, hypovolemia
 - Electrolyte abnormalities
 - Hypoproteinemia (loss of plasma is maximal in first 12 to 24 hours)
 - Extreme stress
 - Smoke inhalation
 - Immune suppression
- Extracutaneous complications of burns may be cardiopulmonary, ocular, hematologic, renal
- Animals suffering burns and/or smoke inhalation need to be closely monitored and repeatedly examined as signs and lesion development may be delayed.
- Wound or burn infection is common in cattle and *Pseudomonas aeruginosa* is the most common organism to establish infection.
- Infection under eschars is a common problem.
- Animals with second-degree and third-degree burns over 50% of their body usually die.
- Poor prognosis if second-degree and third-degree burns affect more than 10% to 15% of body surface
- Sequelae to burn injuries
 - Hypoproteinemia from protein exudate from wounds

- Progressive edema
- Hyperkalemia
- Burn-induced immunosuppression
- Progressive anemia
- Secondary infections; pneumonia, skin infections
- Multiple system involvement, i.e., renal shut down, eye damage
- Scarring
- Damage to eyelids, conjunctiva, cornea, anterior uveitis, exfoliation of lens capsule
- Sunburn
 - White and light-skinned animals, lateral aspects of teats, ears, nose, areas covered with little hair are most susceptible to ultraviolet light, 290–320 nm.
 - White-faced sheep, especially ears and face
 - Exposure to sunlight is associated with skin tumor development especially on udder of white goats.
 - Erythema, pain, swelling, blisters, erosions
- Complications of teat burns include obstruction of teat orifice, distorted teats, mastitis

SIGNALMENT

- No age, sex, or breed predilection
- Sunburn: light-skinned or white animals, white-faced sheep

SIGNS

- Severity of burn determines signs present, maybe mild erythema and superficial scabbing to extensive tissue damage and necrosis with severe protein exudation
- Wool is fire-retardant; burns on sheep most commonly found on legs and around face
- Goats and cattle are likely to have burns on any part of body.
- Signs of sunburn
 - Erythema, swelling, crusting of skin
 - Headshaking, pruritus
 - Discomfort during milking or nursing if udder or teats burned
- Teat burns
 - Mild burns: erythema, sloughing of outer, white, paper-thin tissue; areas of sloughing, crusting, and discoloration of tissue; milk is apparently normal; teat pliable on palpation
 - Severe burns: teats tend to be dull brown or black, dry, and often corrugated; thick layer of tissue is sloughed, underneath is red hemorrhagic tissue; teat is leatherlike and lacks pliability ± distorted.
- Healing lesions may be very pruritic causing animals to scratch or lick at affected sites.

CAUSES AND RISK FACTORS

- Symptoms can be acute or subacute
- Nondermatological signs occur about 7 days prior to onset of skin lesions: pyrexia.

DIAGNOSIS

Diagnosis is based upon history and clinical signs.

DIFFERENTIAL DIAGNOSIS

Differentiate sunburn from photosensitivity.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTING IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Initial overall assessment of survivors—recumbent, obviously badly burned, suffering animals should be euthanized.
- Evaluation of animal's systemic and local injuries is essential.
- Repeat examination is necessary to determine response to therapy and development of delayed signs and lesions.
- Treatment is aimed at care of initial injuries, cardiovascular support, respiratory support, and prevention of secondary infection
- Goal of treatment is epithelialization of wound.
 - First- and mild second-degree burns should heal well by epithelialization.
 - Severe second-degree and most third-degree burns require skin grafts.
- Cool affected body areas to reduce heat retention and limit necrosis.
 - Hosing with cool water for 15 minutes
 - Wet cool towels
- Hosing also removes burnt hairs, crust, and debris.
- Blisters allowed to remain in place for 1–2 days on second-degree burns
- Burn wound care
 - Thorough cleaning with irrigation or dilute chlorhexidine solution (controversial); repeat two to three times daily
 - Daily hydrotherapy
 - Topical antimicrobial; use water-soluble emollient antimicrobial cream, silver sulfadiazine (Silvadene)
 - Use of hydrogel and nonadherent, absorbent dressings, which are not constrictive, may be indicated in some cases, must be kept clean and changed at appropriate intervals.
 - Avoid occlusive dressings, which produce closed wound with bacterial proliferation and delayed healing.
 - Eschar over large second- or third-degree burns should be left undisturbed until natural sloughing occurs or if infection develops under eschar.
 - Wound debridement after 24 to 36 hours if necessary
 - Wound allowed to heal by granulation
- Systemic antimicrobials fail to penetrate local burn wound infections, may permit growth of resistant organisms.
- Systemic antimicrobials reserved for use when documented site of infection (i.e., pneumonia)
- Analgesia as needed—nonsteroidal anti-inflammatory drugs (concern these may delay healing)
- Correct hypovolemia: rule of thumb—give 3 to 4 ml/kg of body weight for each percentage body surface involved.
- Maintenance of electrolyte and acid-base balance
- Plasma administration if severe hypoproteinemia
- Keep animal in clean environment.
- Provide adequate nutrition.
- Tetanus booster if indicated
- Prevent delayed healing and self-mutilation from scratching and licking as lesions heal (pruritus), sedation may be required.
- Eye damage
 - Cornea and eyelid damage are of particular concern.
 - With burns on face, cornea should be treated with artificial tears.
 - Gently remove debris from eye with saline-soaked cotton swab.
 - Inspect and fluorescein stain eye for ulcers.
 - Apply topical antibiotics with atropine.
 - Third eyelid flap if necessary to protect eye
- Teat burns

- Soothing, softening burn ointments, lanolin ointments, aloe vera
- Antimicrobial ointment if skin surface sloughs
- Maintain open teat orifice.
- Healing is slow, takes many weeks to months.
- Sunburn
 - Remove from exposure to sunlight.
 - Provide shelter.
 - Soothing burn ointments, topical human sunburn medications, or aloe vera, topical steroids
 - Application of pigmented teat dips
 - Contamination of milk should be avoided.
 - For secondary bacterial infection, use topical or systemic antimicrobial agents.
 - Prevention recommendations: see Production Management

MEDICATIONS

N/A

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

- Lesions can persist for up to 12 weeks.
- Recovered cattle have immunity for months.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Smoke Inhalation

Involves carbon monoxide toxicity and smoke toxicity

Three Mechanisms of Injury to Respiratory System

- First stage: heat damage to upper respiratory tract, injury from toxic chemicals in smoke and carbon monoxide toxicity; usually signs within first 6 hours
 - Inflammation, edema, and necrosis of nasal passages, pharynx, and larynx lead to airway obstruction \pm laryngospasm
 - Bronchoconstriction of lungs; inhalation of soot, noxious gases
 - Carbon monoxide toxicity: hypoxemia and tissue hypoxia in all organs, especially brain; level above 10% carbon monoxide is consistent with toxicity
 - Shock
- Second stage: formation of pulmonary edema
 - Within 12 to 72 hours after exposure
 - Damage due to inflammatory mediators (cytokines, proteolytic enzymes, oxygen free radicals)
 - Obstruction of small airway from deposition of smoke material and inflammatory debris
- Third stage: bronchopneumonia
 - Result of impaired immune system and exposure to pathogens

- May occur within 24 to 48 hours or 1 to 3 weeks after initial injury

Clinical Signs

- Many signs may not be apparent for 1 to 2 days after fire.
- Oral burns, nasal mucosal swelling, pharyngeal swelling, laryngospasm, conjunctivitis
- Hoarseness, expiratory wheezes, cough, stridor, tachypnea
- Tachycardia
- Bright mucous membranes with carbon monoxide toxicity may mask cyanosis.
- ±Cyanosis
- Signs of hypovolemia
- Signs of shock
- Depression, disorientation, irritability, ataxia, or even comatose

± Signs of septicemia or pneumonia

Treatment

- Depends on stage and severity of injury
- Oxygen support
- Maintenance of airway
 - Tracheotomy if upper airway obstruction
- Keep airways clean.
- Bronchodilators to counteract bronchoconstriction
- Diuretics and anti-inflammatory agents (nonsteroidal anti-inflammatory drugs) to reduce edema and inflammation
 - Use of corticosteroids is controversial.
- Analgesics
- Fluid therapy if hypovolemic, electrolyte imbalances, or acid-base derangements
 - Caution not to fluid overload if ongoing protein loss through burns or from vasculature
- Plasmas therapy if hyperproteinemia
- Strict hygiene, nursing care, and optimal nutritional support
- Prophylactic antimicrobials are not recommended.
- Appropriate antimicrobials based on culture and sensitivity from documented site of infection

ZOONOTIC POTENTIAL

N/A

RUMINANT SPECIES AFFECTED

- Cattle
- Goats
- Sheep
- Camelids
- Wild ruminants

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Recovery time is prolonged with teat burns and extensive burns.
- Need to determine which animals to be euthanized or culled due to poor prognosis for successful recovery
 - Animals with second- and third-degree burns over extensive area
 - Burnt teats that will not withstand milking; mastitis is inevitable.
 - Badly burned feet may slough claws.
 - Facial burns involving cornea may lead to permanent stromal opacities.
- Teat burns
 - Mild lesions have good prognosis.
 - Severe lesions prognosis variable; may have mastitis, occlude, or heal distorted

- Mature adult cows are more likely to return to full function than heifers.
- Prevention of sunburn
 - Gradual acclimation to exposure to sunlight
 - Provide shade
 - Application of sun blocking screens or ointments; use sunblocks with highest SPF available and those that are suitable for use in children; avoid PABA as it is not recommended as safe in children and little is known about its safety in animals.
 - Iodophor teat dips
 - Pet animals may wear fly nets on ears, hats, or bonnets.

CACHE VALLEY VIRUS

BASICS

OVERVIEW

- Cache Valley (CV) is a viral infection afflicting a wide variety of domestic and wild ruminants as well as humans.
- Cache Valley virus (CVV) belongs to the genus *Bunyavirus* in the family *Bunyaviridae*, the latter being the largest single family of animal viruses with more than 350 members.
- CV is endemic throughout the United States, Canada, and Mexico. Several CVV subtypes, such as E4-3484, CbaAr 426, and Fort Sherman, that are indistinguishable by neutralization tests from CVV, have been isolated in Central and South America.
- CVV transmission to vertebrates occurs through bites of infected mosquitoes, including several species of *Aedes*, *Psorophora*, *Anopheles*, *Coquillettidia*, *Culex*, and from *Culiseta inornata*.
- The majority of infections are subclinical, but embryonic mortality, fetal teratogenesis, and stillbirth may be common in sheep.
- In the southwestern United States, lambs born in December, January, and February are more likely to show CVV-induced teratogenesis. This period coincides with increased rainfall and mosquito activity.
- Fetal susceptibility to CVV-induced pathology is higher during the first 2 months of pregnancy.

SIGNALMENT

- Infection by CVV has been reported in humans, sheep, goats, cattle, horses, pigs, deer, mouflon, caribou, raccoons, foxes, black-tailed jackrabbit, woodchuck, and turtles.
- In sheep there is a positive relationship between seropositivity to CVV and age. This reflects the likelihood of exposure as the age of sheep increases.
- In pregnant ewes, the CVV can cross the placenta causing embryonic death, mummification, or fetal malformation.

SIGNS

- In most animals, CVV infection is subclinical.
- In pregnant ewes, CVV infection may result in embryonic mortality, fetal mummification, and various degrees of musculoskeletal or central nervous system (CNS) abnormalities.
- Experimentally, CVV-induced fetal malformation occurs when the virus infects the fetus between days 27 and 54 of pregnancy.
- After the second month of pregnancy, fetal infection results in the production of fetal neutralizing antibodies that control and eliminate CVV without apparent consequences to the fetus.
- Dystocia may be a sequela in ewes that deliver full-term malformed offspring.
- Ewes that are CVV seropositive at the time of breeding are resistant to reinfection with CVV.
- There is no cross-protection against other related bunyaviruses.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Main Drain, La Crosse, and San Angelo bunyaviruses induce similar fetal pathology.
- Bluetongue virus of vaccine origin and border disease virus also may result in fetal infection and CNS malformations in sheep.
- Akabane, Rift Valley fever, Nairobi sheep disease, and Wesselsbron viruses are exotic to North America but may cause

similar fetal pathology in sheep.

- Other causes of teratogenesis and pregnancy loss, such as genetic defects and teratogenic plants, need to be included in the differential diagnosis of CV.

DIAGNOSTIC PROCEDURES

- CVV can be isolated from blood during the acute viremic phase by intracranial inoculation of suckling mice or infection of susceptible cell lines such as Vero cells. Because viremia is short-lived, in most cases results are negative.
- CVV serum antibodies are more often demonstrated by serum neutralization, but ELISA, complement fixation, and hemagglutination-inhibition tests also have been used. In adult animals, serum antibodies are indication of previous exposure, but do not provide information regarding the infectious status of individuals.
- Malformed fetuses that survive in utero for some time develop neutralizing antibodies and eliminate the virus. In these cases, assaying precolostral fetal serum for the presence of CVV neutralizing antibodies does the diagnosis.
- In full-term malformed fetuses or newborns, virus isolation is always unsuccessful.
- Lack of CV antibodies in sera of ewes lambing malformed fetuses rules out CVV as the cause.

PATHOLOGIC FINDINGS

Macroscopic

- In sheep, CVV intrauterine infection during pregnancy may result in embryonic mortality, fetal teratogenesis, stillbirth, and/or oligohydroamnion.
- Congenital abnormalities include arthrogryposis, hydranencephaly, hydrocephalous, microcephalous, porencephalia, cerebellar hypoplasia, scoliosis, torticollis, and lordosis.
- In multiple pregnancies, the degree and type of fetal pathology may be different in each fetus. In some cases, one fetus may be normal while the others may show malformations.
- In other ruminants, fetal abnormalities as a result of natural CVV infection during pregnancy happen sporadically.

Microscopic

- Histologic lesions are more frequently observed in the brain, spinal cord, and skeletal muscle of malformed fetuses. In the CNS, microscopic lesions are consistent with the gross lesions. Some of the brain cavities contain blood, and evidence of neutrophil rarefaction and malacia may be present. In moderately affected lambs, muscle fibers are small, but in more severe cases, fibers are narrow and short with few nuclei and no cross striations.
- Affected lambs often have meconium in pulmonary alveoli as a result of intrauterine stress.
- Perivascular infiltration of neutrophils in placentas of affected ewes has been observed in some cases, but this is more likely an incidental finding and not a hallmark of CVV infection.

TREATMENT

There is no treatment for CVV infections.

MEDICATIONS

N/A

CONTRAINDICATIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

N/A

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- There are no vaccines available to protect animals against CVV infection.
- Ewes that are seropositive to CVV at the time of breeding are protected from subsequent infection with CVV and its adverse effects on pregnancy, but they are susceptible to infection by bunyaviruses of different serogroups, some of which may induce similar fetal pathology.
- Insect control is difficult because of the wide range of mosquito vectors and vertebrate hosts. Application of insecticides may not be ecologically admissible. Other insect control methods such as tire removal may greatly reduce the abundance of the vector.
- Breeding ewes after the first frost of the fall reduces the risk of fetal infection.

MISCELLANEOUS

ASSOCIATED CONDITIONS

The majority of infections are subclinical, but embryonic mortality, fetal teratogenesis, and stillbirth may be common in sheep.

AGE-RELATED FACTORS

The prevalence of CVV antibodies in sera of animals increases with age. This is a reflection of the likelihood of exposure in older sheep and not related to increased susceptibility of this particular age group.

ZOONOTIC POTENTIAL

- CV is an indirect zoonotic in which humans may get infected through the bite of infected mosquitoes but not directly from infected vertebrate animals. Infection also can occur through accidental puncture with infected needles.
- The great majority of CVV infections in humans are subclinical. However, fever, myalgia, chills, headache, vomiting and death have been reported in a few cases.
- There is no conclusive evidence that CV virus in humans causes fetal malformation or pregnancy loss.
- Further research is necessary to determine the role of CVV in human disease, particularly in human immunodeficiency virus (HIV)-infected individuals and those affected by other types of immune deficiencies.

PREGNANCY

- Pregnancy loss and/or fetal malformation are common in CVV-infected sheep.
- In pregnant ewes, CVV infection may result in embryonic mortality, fetal mummification, and various degrees of musculoskeletal or central nervous system (CNS) abnormalities.

CALF DIPHTHERIA

BASICS

DEFINITION

- *Fusobacterium necrophorum* infection of the larynx and pharynx of calves
- The organism is an opportunistic pathogen that causes numerous necrotic conditions (necrobacillosis), such as bovine hepatic abscesses, ruminant foot abscesses, and oral infections.
- Because of the unavailability of suitable immunoprophylaxis, the control of *F. necrophorum* infection has depended mainly on the use of antimicrobial compounds.

PATHOPHYSIOLOGY

- Injury to the mucosa of the pharynx and larynx allows *Fusobacterium necrophorum*, an oral commensal bacteria, to invade and infect the tissues. Inflammation can constrict the larynx, causing dyspnea.
- *Fusobacterium necrophorum* is a gram-negative, non-spore-forming anaerobe and is a normal inhabitant of the respiratory and alimentary tracts of animals.
- Two types of *F. necrophorum*, subspecies *necrophorum* (biotype A) and *funduliforme* (biotype B), have been recognized. These two biotypes differ morphologically, biochemically, and biologically.
- The pathogenic mechanism of *F. necrophorum* is complex and not well defined.
- Several toxins, such as leukotoxin, endotoxin, haemolysin, haemagglutinin, and adhesin, have been implicated as virulence factors. Among these, leukotoxin and endotoxin are believed to be more important than other toxins in overcoming the host's defense mechanisms to establish the infection.
- *F. necrophorum* is encountered frequently in mixed infections and, therefore, synergisms between *F. necrophorum* and other pathogens may play an important role in infection.

SYSTEMS AFFECTED

GI/respiratory

N/A

INCIDENCE/PREVALENCE

Low incidence

GEOGRAPHIC DISTRIBUTION

Worldwide

Epidemiology

- Occurs most commonly in calves up to 18 months of age, but can occur in older animals.
 - Abrasive feed, trauma to mucosa during oral medication, or other damage to the mucosa allows infection by the bacteria.
- Housed cattle and feedlot cattle are at higher risk.

SIGNALMENT

Species

Bovine

Breed Predilections

N/A

Mean Age and Range

Three to 18 months.

Predominant Sex

N/A

SIGNS

GENERAL COMMENTS

Clinical signs are associated with edema and inflammation of the pharynx and larynx, making swallowing difficult and painful. Obstruction of the larynx causes dyspnea and may lead to death.

HISTORICAL FINDINGS

Rough or abrasive feeds, unsanitary feeding areas, recent oral bolus medication

PHYSICAL EXAMINATION FINDINGS

- High fever (106°F); inspiratory dyspnea; difficulty swallowing; salivation; moist cough; anorexia; depression; swollen, painful pharynx
- Visual observation of the pharynx and larynx reveal inflamed and necrotic mucosa.

CAUSES

Fusobacterium necrophorum infection through abraded or damaged mucosa in the larynx and pharynx

RISK FACTORS

Rough or abrasive feeds, unskilled workers giving oral medications

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Foreign bodies or traumatic pharyngitis
- Aspiration

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Culture and sensitivity are indicated in economically valuable animals. The most common sites or conditions from which members of this genus are isolated are abscesses, the respiratory tract, and pleural and peritoneal cavities.
- Most specimen cultures contain a single *Fusobacterium* species. The most commonly isolated species is *Fusobacterium necrophorum*. Almost all of the specimens contain other obligate anaerobes together with facultative and obligate aerobes.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

Bacterial culture of lesions

GROSS AND HISTOPATHOLOGIC FINDINGS

Swelling and edema of laryngeal-pharynx area, sometimes with necrosis of the mucosal tissue

TREATMENT

Cases with severe swelling and dyspnea may require tracheostomy.

CLIENT EDUCATION

Minimize abrasive materials such as sticks and cockleburs in hays and pastures. Keep feed areas, mangers, and feed equipment clean.

MEDICATIONS

DRUGS OF CHOICE

- Broad-spectrum systemic antimicrobial therapy for several days. Early recognition is essential for successful therapy.
- Anti-inflammatory drugs such as corticosteroids or NSAIDs may be useful to reduce the swelling and dyspnea.

CONTRAINDICATIONS

- Oral bolus medications
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

CALVING-RELATED DISORDERS

BASICS

DEFINITION

- Calving-related disorders (CRD) occur during the transition period of dairy cows (21 days before expected parturition to 21 days postpartum).
- The most important CRDs are hypocalcemia, retained fetal membranes (RFM), metritis, displacement of abomasums (DA), ketosis, fatty liver, and udder edema.
- Other conditions such as lameness and mastitis are also related to the transition period but they can occur at any time during the production cycle.

PATHOPHYSIOLOGY

- The transition period is a very dynamic stage in the production cycle of the cow.
- During the prepartum, the fetus grows exponentially and cows start to decrease dry matter intake (DMI), especially during the last week of gestation. As a response, cows start to mobilize fat from body reserves. The result is an increase of nonesterified fatty acids (NEFA) in the blood. This is especially true in obese cows, and fatty liver may occur.
- Calving is a stressful process that results in metabolic and hormonal changes that contribute to immunosuppression and a subsequent decrease of host resistance to diseases. Mammary gland tissue starts to extract elevated levels of calcium from the blood supply. Therefore, there is a more intense negative calcium balance with development with a concomitant hypocalcemia.
- If calving is complicated, hypocalcemia worsens affecting uterine and gastrointestinal motility.
- Retained fetal membranes may occur, with consequent metritis if preventive measures are not considered.
- Displacement of abomasums may be also a consequence.
- When lactation advances, energy requirements increase dramatically and DMI recovers slowly. This creates a typical negative energy balance during the first weeks of lactation. In addition, mammary glands extract large amounts of glucose from the blood for lactose synthesis. Hypoglycemia may develop and ketosis may be established.

SYSTEMS AFFECTED

Systems affected will depend on the calving-related disorder: mammary, hepatic, cardiovascular, gastrointestinal, respiratory, reproductive, nutritional, and production management

GENETICS

Some CRDs may have a hereditary component (ketosis and somatic cell count).

INCIDENCE/PREVALENCE

- Incidences of CRDs are extremely variable and depend on factors such as season, geographical location, breed, type of housing, environment, and management.
- Reported incidences for some CRDs include clinical hypocalcemia 0.2%–2%, retained fetal membranes 8%–14%, metritis 6%–12%, ketosis 2%–6%, displacement of abomasums 2%–6%.

GEOGRAPHIC DISTRIBUTION

Worldwide where dairy farming occurs

SIGNALMENT

Related to the periparturient period of dairy cows; there may be breed predispositions for some CRD (Jersey cows and hypocalcemia).

SIGNS

Retained fetal membranes (visible membranes after 24 h postpartum), metritis (fever, foul-smelling discharge), hypocalcemia (musculoskeletal compromise), ketosis (decrease in milk yield, high ketones in blood, urine, or milk), displacement of abomasums (high-pitch sound at auscultation on left flank, last two rib spaces).

CAUSES

Inadequate management of the prepartum, calving, and postpartum period; improper nutrition, environment, and management

RISK FACTORS

Management, breed, genetic potential, nutrition, season, herd size, geographical location

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypocalcemia
- Retained fetal membranes (RFM)
- Metritis
- Displacement of abomasums (DA)
- Ketosis
- Fatty liver
- Udder edema
- Lameness
- Mastitis

CBC/BIOCHEMISTRY/URINALYSIS

- Important tools for ketosis diagnosis (ketones in urine, blood, or milk). CBC/biochemistry can be useful in determining hydration, calcium and potassium levels, liver function, and infection level.
- Urine pH should be monitored to evaluate anionic salts during prepartum period for the prevention of hypocalcemia. Urine pH should be between 6.5 and 7.0.
- Serum Ca, Mg, P, nonesterified fatty acids (NEFA), beta hydroxy butyrate (BHBA), glucose, insulin, T3 and T4, liver enzymes, and urea nitrogen all can be monitored depending on differential diagnosis.

OTHER LABORATORY TESTS

Liver biopsy can be helpful with the diagnosis of hepatic lipidosis.

IMAGING

Ultrasound imaging can be a useful adjunctive tool.

TREATMENT

APPROPRIATE HEALTH CARE

N/A

NURSING CARE

N/A

ACTIVITY

N/A

DIET

- Proper transition diet. Moderate energy and protein levels. Prepartum diet with a negative cation-anion difference. Appropriate amount and particle size of fiber.
- Fresh cow rations should be intermediate between the close-up and the high group rations.

- Cows should be fed ad libitum—that means a 5% to 10% feed refusal. If concentration of energy and protein are somewhat low in the ration fed right after calving, it is important not to leave the cows in this group for too long of a time.
- Rations should have at least 21% neutral detergent fiber (NDF) from forage and enough particle size to support good chewing activity and rumen fill.
- Diets should have 8% to 10% of particles on the top screen of the Penn State Particle Size Separator for both prefresh and fresh cows. Researchers suggest feeding 3 to 5 lb of high-quality long forage to maintain rumen function.
- Forage quality is very important in the transition period.
- As for the close-up group, it is important to feed adequate levels of copper, zinc, manganese, selenium, and vitamin E.
- Researchers suggest 2000 IU of vitamin E per day for fresh cows.

CLIENT EDUCATION

Proper nutrition and general management in transition cows is important.

SURGICAL CONSIDERATIONS

Considered important for displaced abomasum

MEDICATIONS

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

Feed additives to improve energy and mineral balance such as propylene glycol, niacin, calcium propionate, vitamin E, selenium

FOLLOW-UP

PATIENT MONITORING

- Monitoring of body condition score during dry period; cows should not lose condition or gain excessive weight during the transition period.
- Urine pH should be monitored to evaluate anionic salts during prepartum period for the prevention of hypocalcemia. Urine pH should be between 6.5 and 7.0.

PREVENTION/AVOIDANCE

Proper general and nutritional management

POSSIBLE COMPLICATIONS

Decreased milk production, infertility, and death

EXPECTED COURSE AND PROGNOSIS

N/A

MISCELLANEOUS

ASSOCIATED CONDITIONS

Calving-related disorders are intimately related to each other. Cows with hypocalcemia are more likely to develop retained fetal membranes. Cows with RFM are more likely to develop metritis. Cows with metritis are more likely to develop ketosis and cows with ketosis are more likely to develop displacement of abomasums.

AGE-RELATED FACTORS

Older cows are more likely to develop clinical hypocalcemia, ketosis, and displacement of abomasum.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Parturition management is critical for prevention of calving-related disorders. Enough feed bunk space, adequate shade, and comfortable environment are essential for parturition dairy cows.

RUMINANT SPECIES AFFECTED

Dairy cattle

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

Nutrition and feeding, housing, management

- Dry cows (7 to 9 month pregnant nonlactating cows) need adaptation to their next lactation diet. Preparation for parturition and avoidance of calving-related disorders is an important component of this program.
- Consequently, dry cows need to be moved to a parturition transition pen (close-up pen).
- Three weeks prior to freshening is sufficient for adult mature cows. However, 5 weeks should be considered for pregnant heifers because they are still growing and they have not experienced the challenges of calving and lactation before.
- Close-up heifers and cows should be handled in different pens.
- Parturition transition animals need a comfortable environment with adequate shade, bunk space, and good-quality water.
- Parturition transition pens must be situated in a strategic location of the farm, with easy labor access and planned handling.
- Transition pens must be monitored twice daily for cows showing signs of udder edema development and signs of impending parturition.
- Calving may occur either in the same parturition transition pen or in the maternity pen, depending on management criteria.
- The calving environment must be quiet, clean, and easy to access if calving assistance is needed.
- Major concerns of the parturition transition period and calving are udder edema, dystocia, and hypocalcemia.
- Udder edema must be addressed through proper nutritional management. Excess nutritional sodium and potassium are related to this metabolic condition.
- Dystocia is a multifactorial problem where proper assistance is the key. Good knowledge of parturition physiology and obstetric intervention are basic and needed.
- For the postpartum transition cow, the same recommendation of a good environment applies. The postpartum pen also should be in a strategic location.
- Cows need to be monitored for retained fetal membranes, metritis, ketosis, and abomasal displacement.
- A strategic plan should include monitoring cows during the first 10 days postpartum for fever development and ketone bodies either in urine or milk.
- If cows are either febrile, positive to ketones, or both, they should be separated and evaluated through a complete physical examination.
- Body condition of cows is important. On a scale of 1 to 5, they should be between 3.25 and 3.75.
- Overconditioned animals are more likely to experience dystocia and calving-related disorders. Therefore, energy density of dry cow diets must be consistent and adequate.
- Mineral content is important to the prevention of hypocalcemia and other related disorders.
- Typical parturition diets are rich in cations (sodium and potassium). Therefore, the difference in mEq/kg between $(\text{Na}+\text{K}) - (\text{Cl}+\text{S})$ should be positive ($\sim+150$ to $+350$ mEq/kg). This diet institutes an alkaline environment, which favors the development of hypocalcemia.

- Receptors for parathormone and vitamin D are altered structurally by alkaline environments.
- If the cow's acid-base status has shifted to a more acidic level, these receptors work more efficiently with a better bioavailability and absorption of calcium.
- A goal should be a urine pH between 6.0 and 7.0. This pH level has been associated with a lowered incidence of hypocalcemia.
- Dietary ingredients of the prepartum diet should be exactly the same as the postpartum lactation diet to insure a better rumen microbial adaptation.
- The diet should contain a higher level of effective fiber (NDF, neutral detergent fiber) with adequate particle size to stimulate rumination, avoid acidosis, improve rumen fermentation, and avoid abomasal displacement.

Close-up Cows

Feeding strategies needed during the close-up period to achieve these goals are:

- Condition should be maintained during the dry period. Excessive body condition at calving can increase incidence of ketosis and fatty liver.
- Increase grain feeding to 0.5%–0.75% of body weight.
- Target 35%–40% nonfiber carbohydrates as a % of DM.
- Feed high-quality forages with sufficient effective fiber.
- Limit fat to 1/4–1/3 lb per day.
- Feed low-potassium forages; balance for potassium concentration less than 1.5% of diet DM (get as close to 1% as possible).
- Provide adequate magnesium (0.4% of diet DM) and calcium (1%–1.2% of diet DM).
- Feed adequate selenium (0.3 ppm) and vitamin E (2000 IU per day).
- Supply extra trace minerals such as copper, manganese, and zinc to account for decline in feed intake.
- Feed adequate crude protein (cows need 12%–13%, heifers 15% of diet DM).

Fresh Cows

- Calving and the change to lactating status are very stressful in the life of a cow. They need a lot of care. Assign your best employee/person to monitor this group of cows.
- Maternity facilities must be clean, dry, well lit, well ventilated, and comfortable. After leaving the maternity pens, cows should ideally be moved to a fresh cow group. There is also benefit in having a separate heifer group, because heifers are smaller and do not compete as well at the feed bunk.
- The first 1 to 2 weeks after calving set the stage for the entire lactation. Studies have shown that for each 1 lb increase in peak milk, there is a 220 lb milk production increase for the entire lactation.

Monitoring Progress

- After calving, it is important to optimize dry-matter intake as soon as possible.
- Monitor feed intake by rating how the cow consumes fresh feed on a scale of 1 to 4 (1 = 0%–33% consumed; 2 = 33%–66% consumed; 3 = 66%–90% consumed; 4 = all consumed). Cows off feed require special treatment. Observe chewing and rumination activity.
- Rumen movements should be monitored using a stethoscope—healthy cows have about 1.5 to 2 rumen movements per minute.
- Body temperatures should be recorded daily. The goal is to be below 103°F for mature cows and 102.5°F for heifers.
- Uterine discharges should be checked and a ketone test on the cow's urine or milk is recommended.

CAMELID TOOTH ROOT ABSCESSSES

BASICS

DEFINITION

Tooth root abscess is a localized osteitis, pulpitis, and/or alveolar periostitis around one or more tooth roots, often draining purulent exudates by a fistulous tract through the skin overlying the abscess.

PATHOPHYSIOLOGY

- The adult camelid dental formula is: (I 1/3, C 1/1, PM 1-2/1-2, M 3/3) × 2 for 30 to 32 teeth.
- The upper incisors are actually found caudally in the region of the canine teeth.
- Cheek teeth can be numbered from 1 to 5 (rostral to caudal), or labeled according to the dental chart (PM1&PM2, M1 to M3).
- The upper premolars have three roots each; lower have two roots each.
- The upper molars have four roots each; lower M1 and M2 have two roots, M3 has three roots, but two are fused.
- Tooth fracture, gingival penetration, or infundibular decay and infection can result in tooth root abscess. Often the source is unknown.
- Periostitis and osteitis of the mandible secondary to tooth root abscess can spread along the mandibular canal.

SYSTEMS AFFECTED

- Gastrointestinal
- Musculoskeletal

GENETICS

None

INCIDENCE/PREVALENCE

- Unknown
- Mandibular molars 1 and 2 are most often affected
- Maxillary teeth are rarely affected
- Canine teeth may be affected: incidence appears to be decreasing with change in methods for trimming fighting teeth.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

- All camelids can be affected.
- Rarely seen in very young animals, usually >12 months of age
- Median of 5 years

SIGNS

- Firm swelling of the jaw
- Drainage of exudates from mandible or maxilla
- Reluctance to eat
- Dropping food
- Strange chewing habits
- Nasal discharge if sinus affected.
- Quidding

CAUSES

- Gingival penetration along alveolus

- Infundibular decay
- Tooth fracture or trauma
- Mandibular/maxillary fracture

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mandibular osteitis
- Subcutaneous abscess/cellulites
- Fracture
- Sinusitis
- Tumor
- Actinomycosis
- Osteomyelitis
- Salivary gland disease

CBC/CHEMISTRY/URINALYSIS

- Not usually useful
- May see slight elevation in WBC count in chronic periostitis/osteitis

OTHER LABORATORY TESTS

Culture of exudates may sometimes indicate the bacteria involved, but is rarely necessary as tooth removal and flushing resolves the problem in most cases.

IMAGING

- Radiology is essential for diagnosis of tooth root(s) involved.
- Multiple oblique open-mouth views are often necessary, so sedation or anesthesia is usually required.
- Mandibular abscesses are easier to image than maxillary abscess.
- Contrast agent may be injected into a draining tract if the affected root is not obvious.
- Extent of osteitis/periostitis can be determined from radiographs also
- Bone lysis
- Loss of lamina dura
- Periodontal sclerosis
- Periosteal reaction
- Fistulous tracts

DIAGNOSTIC PROCEDURES

None

PATHOLOGIC FINDINGS

If seen at necropsy, localized purulent exudates, necrotic bone and alveolus, fistulous tract, loose teeth, and bony proliferation may be seen around the affected tooth roots.

TREATMENT

APPROPRIATE HEALTH CARE

- Tooth root abscesses require surgical care (nonemergency) and subsequent medical treatment.
- Extraction is generally required.
- Teeth can be removed by several methods in the anesthetized camelid.
- Oral extraction may be appropriate for premolars, canines, and incisors.
 - Elevation from the alveolus may be difficult by oral approach due to the limited excursion of the jaws in these species.

- Ensure all roots are removed.
- Some curettage of alveolus will help remove necrotic bone.
- Repulsion of the cheek teeth has been recommended by some.
- Extreme care must be taken due to the fragility of the mandible and maxilla, which can be easily fractured.
- Trephine openings are made as in horses—landmarks are described in references.
- Motorized burr has been very successful for removal of an affected tooth, especially mandibular teeth.
- Incision is made along the ventral or ventrolateral aspect of the mandible, resecting draining fistula if possible.
- Periosteum and overlying musculature are elevated along the lateral aspect of the mandible to the level of the gingival attachment.
- If a draining tract is present, it can be followed to the tooth using the burr to remove the overlying bone on the lateral aspect.
- If no draining tract is present, the affected tooth is identified by oral palpation and an approach is made through the lateral alveolar plate to the tooth.
- Following removal of the overlying bone, the tooth and roots are carefully elevated and removed.
- Care must be taken not to damage adjacent normal tooth roots. Knowledge of anatomy and study of radiographs are essential.
- In some cases, resection of the single affected root using the burr can be effective in resolving the problem without complete extraction.
- A ventral opening in the incision is left for drainage, closing the remainder of the incision.
- The empty alveolus can be packed with gauze or acrylic if desired, and may be necessary in the maxilla. In the mandible, it is not deemed to be necessary.

NURSING CARE

- Following surgery, daily or twice daily flushing of the tract with dilute chlorhexidine solution to remove food particles
- Flush until closed completely.

ACTIVITY

No restriction

DIET

- No change required
- Animals will usually begin eating within hours of anesthetic recovery.

CLIENT EDUCATION

- Early signs of dental disease should be investigated immediately.
- Subcutaneous infection can occur.
- Osteitis prolongs treatment.
- Packing of cavity with food will promote infection and prolong healing.
- Proliferative bone may remain present for the life of the animal.
- Animals are often chronic at the time of presentation because the masses are difficult to detect if heavy face fleece is present.
- Palpation or close observation of jaw lines when handling may allow for earlier recognition.

SURGICAL CONSIDERATIONS

None

MEDICATIONS

DRUGS OF CHOICE

- Flunixin meglumine 1.1 mg/kg IV q24h for postsurgical pain; rarely required for more than 48 hours
- Procaine penicillin G 20,000 U/kg IM q12h for 7–10 days or longer if required by infection severity
- Other antibiotics can be used if cultures indicate.

- Oxytetracycline—18 mg/kg SC q 48 hours
 - Postoperatively—5–10 days of treatment
 - Medical treatment—14–30 days treatment
- Ampicillin—2.5 mg/kg IM q 12 hours
 - Postoperatively—5–10 days of treatment
 - Medical treatment—14–30 days treatment

CONTRAINDICATIONS

None of the drugs listed are approved for use in camelids and do not have established withdrawal times associated with their use.

PRECAUTIONS

None

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUGS

Any broad-spectrum antibiotics effective against *A. pyogenes* and common oral bacterial inhabitants

FOLLOW-UP

PATIENT MONITORING

- Daily monitoring for cavity flushing will be required.
- Further follow-up care is rarely required unless another abscess occurs.

PREVENTION/AVOIDANCE

- Not much can be done
- Avoiding stemmy hay and foxtail may be helpful.

POSSIBLE COMPLICATIONS

- Ongoing osteitis and drainage
- Damage to adjacent tooth roots
- Infection of alveolar packing material
- Electrolyte loss and/or dehydration if salivary drainage through ventral drainage opening is excessive

EXPECTED COURSE/PROGNOSIS

- Healing will occur over several weeks, preferably healing from the inside out.
- Prognosis is excellent; good if bony infection is severe.
- Bony proliferation may be permanent.

Surgical Tooth Removal—Excellent

- Short term (<30 days)
 - Decreased size of facial swelling within 1 week postoperatively
- Long term (>30 days)
 - Resolution of facial swelling
 - Additional abscesses at adjacent teeth possible if extent of disease not identified at initial exam

Medical Treatment—Excellent-Good

- Short term (<30 days)
 - Decreased size of facial swelling
 - Progression of disease possible in minor number of patients
- Long term (>30 days)
 - Resolution of disease in most
 - Recrudescence possible: may respond to additional round of medical therapy

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Retained tooth root
- Fracture
- Recurrence at adjacent teeth

Medical Treatment

- Failure to respond
- Recurrence

CAMPYLOBACTER

BASICS

DEFINITION

- Campylobacter is a group of small, curved or spiral-shaped, gram-negative bacterial rods that can cause significant reproductive disease and loss in ruminant species.
- *Campylobacter fetus* subspecies *fetus* is responsible for abortions in sheep. Bovine venereal campylobacteriosis is due to *C. fetus* subspecies *venerealis* and results in decreased fertility, early embryonic death and less often, midterm abortions.
- In addition, *Campylobacter jejuni* and *C. coli* can cause minor, self-limiting enteritis and diarrhea in ruminants.

PATHOPHYSIOLOGY

Campylobacter Fetus subsp. *Fetus*

- Between outbreaks of abortion, the agent is present in the gallbladder and intestine of apparently normal sheep and then spreads to susceptible ewes via contamination of feed and water.
- Bacteremia in the ewe allows the agent to reach the fetus via the circulation where it results in systemic infection of the fetus with hepatitis.
- Ultimately, *C. fetus* subsp. *fetus* can cause late-term abortions, stillbirths, and birth of premature lambs.
- *C. fetus* subsp. *fetus* can also cause abortions in cattle due to localization of a systemic infection in the dam in the pregnant uterus with the production of endotoxins.

Campylobacter Fetus subsp. *Venerealis*

- Cattle are the primary host and main reservoir of *C. fetus* subsp. *venerealis*, which is an obligate parasite of the bovine reproductive tract that cannot survive outside the host for any extended time.
- Transmission is via the venereal route and can approach 100% from an infected bull to an uninfected cow.
- Transmission between cows can also occur via unsanitary artificial insemination and cows can be infected with contaminated semen.
- In cows, the bacteria initially infect the vagina and cervix and then spread to the uterus and oviducts.
- The embryo is not directly affected but instead the agent results in endometritis and salpingitis that in turn causes early embryonic death.
- *C. fetus* subsp. *venerealis* establishes itself in the prepuce of the male but does not interfere with semen quality or breeding ability.

SYSTEMS AFFECTED

In ruminants, *Campylobacter* causes disease primarily in the reproductive system but can, much less commonly and with only minor significance, cause disease in the gastrointestinal system that results in mild diarrhea.

INCIDENCE/PREVALENCE

- *Campylobacter fetus* subsp. *fetus* and *C. fetus* subsp. *venerealis* are both widely distributed but the incidence and prevalence of reproductive disease within a geographical region is widely variable depending primarily on management factors such as vaccination and herd dynamics.
- *Campylobacter jejuni* and *C. coli* often can be isolated from healthy ruminants but the underlying factors that lead some animals to develop enteritis and diarrhea are not certain.
- Tend to see the diarrhea cases due to *C. jejuni* and *C. coli* in herds with better hygiene and this probably reflects lack of prior exposure and immunologic experience

Worldwide

SIGNALMENT

Species, Breed Predilections, Mean Age and Range, Predominant Sex

- *Campylobacter* diarrhea can occur in ruminants of any age but young animals are more commonly involved.
- Reproductive disease due to *Campylobacter* is encountered as abortions or poor reproductive performance in females but males are not clinically affected.
- With *C. fetus* subsp. *venerealis*, bulls are not clinically affected but serve as an important reservoir and vector for spreading the agent among cows.

SIGNS

GENERAL COMMENTS

- Calves experimentally infected with *C. jejuni* and *C. coli* had thick mucoid feces with flecks of blood; sheep had feces of normal consistency but also with flecks of blood. Animals may develop a minor fever.
- Ewes that abort with *C. fetus* subsp. *fetus* only rarely have systemic disease (diarrhea, depression, fever, vaginal discharge) but they may develop endometritis due to the retention of fetal membranes and secondary bacterial infections.
- Cows infected with *C. fetus* subsp. *venerealis* may develop a mucoid to mucopurulent vaginal discharge.

HISTORICAL FINDINGS

Campylobacter Fetus subsp. *Fetus*

- Outbreaks of *C. fetus* subsp. *fetus* abortion in ewes generally start with only a few affected animals but progressively larger numbers are affected.
- If the flock consists of large numbers of young or maiden ewes, the abortion rate may approach 70%.

Campylobacter Fetus subsp. *Venerealis*

- In cows infected with *C. fetus* subsp. *venerealis*, the main historical sign is infertility with longer interestrus intervals, increased numbers of repeat breedings, and late calvings.
- Infected herds have low fertility and early in the process this may be as low as 15–20%.
- In more chronically infected herds, newly introduced animals will have very poor reproductive rates.
- Cows with chronic infection have minimal clinical signs and these may only consist of a mucopurulent vaginal discharge in a small percentage of cows.
- Abortions due to *C. fetus* subsp. *venerealis* are unusual and may occur in less than 10% of affected cows and are typically mid- to late-gestation abortions.

PHYSICAL EXAMINATION FINDINGS

N/A

CAUSES

N/A

RISK FACTORS

- There is not significant venereal transmission of *C. fetus* subsp. *fetus* and the major risk factor for an abortion outbreak in sheep due to this agent is widespread pasture contamination.
- The major risk factor for the introduction and maintenance of *C. fetus* subsp. *venerealis* in a cattle herd is the frequent purchase of adult bulls and cows from herds of uncertain health status.

DIAGNOSIS

DIAGNOSTIC PROCEDURES

- In sheep, agents other than *C. fetus* subsp. *fetus* that need to be considered in abortion storms include *Chlamydia*, *Coxiella*, and *Toxoplasma*.
- In cattle, the major differential for the herd-level reproductive problems with Campylobacteriosis is *Tritrichomonas foetus*.
- In both sheep and cattle, *Campylobacter jejuni* causes sporadic abortions rather than outbreaks.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- For both *C. fetus* subsp. *fetus* and *C. fetus* subsp. *venerealis*, the definitive diagnosis is by culturing the causal organism.
- With *C. fetus* subsp. *fetus*, the aborted fetus is the most likely source from which to isolate the agent.
- With *C. fetus* subsp. *venerealis*, the aborted fetus and preputial washes from infected bulls are the most likely sources from which to isolate the agent. The agent can sometimes be isolated from infected cows if the animal is early in the course of the disease.

PATHOLOGIC FINDINGS

On postmortem examination, animals with *Campylobacter enteritis* will have an ileum and perhaps jejunum with a thickened somewhat reddened mucosa.

Campylobacter Fetus subsp. *Fetus*

- Aborted lambs are generally in the last 6 weeks of gestation.
- About 20–30% of fetuses will have multifocal areas of hepatic necrosis, which consist of pale areas up to 2–3 cm in diameter with a reddened margin. There is also fibrinous polyserositis in some fetuses.
- Cotyledons will have necrosis and edema and intercotyledonary areas will appear edematous.

Campylobacter Fetus subsp. *Venerealis*

- Cows will develop a mucopurulent endometritis with lymphocytic infiltrates; salpingitis and cervicitis may also occur. Bulls do not have significant lesions.
- Aborted fetuses will often have fibrinous pericarditis, pleuritis, and peritonitis on gross necropsy. Histologically, the fetus often has hepatitis and suppurative bronchopneumonia.
- The cotyledons are often edematous and have a tan/brown discoloration. Histologically, these areas have necrosis, vasculitis with fibrinoid degeneration of blood vessels, and mixed inflammatory infiltrates with a predominance of neutrophils.

MEDICATIONS

DRUGS OF CHOICE

- Ovine abortion storms due to *C. fetus* subsp. *fetus* can be treated with streptomycin, penicillin, and/or oral chlortetracycline.
- Treatment of individual cattle for *C. fetus* subsp. *venerealis* with antibiotics is often extralabel and is not warranted on a herdwide basis if adequate control measures are instituted.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

- Convalescent immunity may occur in sheep flocks with *C. fetus* subsp. *fetus* and prevent infection and abortions for the next 2 to 3 years resulting in cyclical abortions.
- Cows infected with *C. fetus* subsp. *venerealis* develop immunity and generally clear the infection over 3 to 6 months, although a long-term carrier state is possible.
- Bulls infected with *C. fetus* subsp. *venerealis* develop a long-term carrier state with the organisms surviving in the deep crypts of the preputial epithelium. Because younger bulls have shallower crypts, they are less likely to develop persistent infection than are older bulls.
- Over time, the reproductive efficiency of the herd infected with *C. fetus* subsp. *venerealis* will improve and approach a normal rate as cows develop immunity and clear the infection.

MISCELLANEOUS

RELATED CONDITIONS

- Campylobacter is a group of small, curved or spiral-shaped, gram-negative bacterial rods that can cause significant reproductive disease and loss in ruminant species.
- *Campylobacter fetus* subspecies *fetus* is responsible for abortions in sheep. Bovine venereal campylobacteriosis is due to *C. fetus* subspecies *venerealis* and results in decreased fertility, early embryonic death, and, less often, midterm abortions.
- *Campylobacter jejuni* and *C. coli* can cause minor, self-limiting enteritis and diarrhea in ruminants.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

C. jejuni is the most frequent cause of food-borne enteritis and diarrheal disease in humans in the United States. Raw milk and contaminated meat are the primary sources.

PREGNANCY

See Related Conditions above.

RUMINANT SPECIES AFFECTED

Potentially all ruminant species

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Vaccines exist but to be most effective against *C. fetus* subsp. *fetus* abortion storms they need to be given before the outbreak. If the abortion outbreak has already begun, then animals that have not yet been exposed can be vaccinated.
- Control of *C. fetus* subsp. *venerealis* involves elimination of carrier bulls with two or more years of artificial insemination (since cows can be chronically infected) followed by use of young bulls that have previously been tested for *Campylobacter* and *Tritrichomonas*.
- Semen used in artificial insemination must be free of *C. fetus* subsp. *venerealis*, and extenders that include antibiotics are recommended.
- Vaccination is effective and is the best method of prevention and control of *C. fetus* subsp. *venerealis* in bull-bred herds. Vaccination is initially given prior to the breeding season and boosted 2–4 weeks later so that the series is completed about 2–4 weeks prior to the start of the breeding season. Vaccination is then given annually.

CANDIDIASIS

BASICS

DEFINITION

Yeast infection of mammals most commonly caused by *Candida albicans* and primarily involving the intestinal, reproductive, and respiratory tracts of compromised animals

OVERVIEW

- Organism is found worldwide.
- Yeasts are not highly pathogenic and rarely cause disease in healthy animals.
- Considered normal microflora of intestinal, oral, upper respiratory, and reproductive tracts of mammals especially *Candida albicans*
- Commonly found in the feces of animals
- Opportunistic invader of skin, mucocutaneous areas, and external ear canal
- Superficial infection of the oral mucomembranes is the most common form of candidiasis in mammals having been reported in humans, dogs, cats, horses, cattle, swine, and nonhuman primates.
- In susceptible animals (immunocompromised, malnourished), *Candida* spp. may cause systemic disease affecting one or multiple organ systems.
- Primary causal agent is *Candida albicans*; most infections are endogenous.
- *C. tropicalis*, *C. pseudotropicalis*, *C. krusei*, *C. parakrusei*, *C. parapsilosis*, *C. guilliermondii*, and *C. stellatoidea* may also cause disease.
- Candidal dermatitis is uncommon in large animals.
 - Reported in goats, cattle, feeder pigs, horses
 - Commonly, animals are immunocompromised or malnourished.
 - Chronic moisture and skin maceration predispose to yeast invasion.
- Goats: generalized exfoliative dermatitis
 - Reported in protein-deficient goats
 - Evaluate affected goat(s) for chronic wasting disease or for trace-mineral deficiency.
 - Yeast may represent secondary opportunist.
- Cattle: ulceration, erosion, scaling, crusting, papules, pustules, and secondary alopecia
- Feeder pigs: *C. albicans* caused exudative dermatitis.
- Horse
 - *C. guilliermondii* caused generalized nodular skin disease with mastitis reported in mare.
 - *C. albicans* caused oral candidiasis in immunodeficient foals.
 - Generalized candidiasis in debilitated and immunocompromised foal undergoing intensive care
- Systemic mycotic disease due to *Candida* spp. occurs less frequently.
- In cattle, systemic disease may affect gastrointestinal tract, lungs, liver, kidney, brain, udder, or reproductive tract.
- Peracute septicemic infections reported in newborn calves.
- Calves
 - Diarrhea in young calves following prolonged use of antimicrobials
 - Oral candidiasis
 - Mycotic pharyngitis and gastroenteritis in calves result in white pseudomembranes at back of pharynx and extending down to stomach and diarrhea.
- Mycotic omasitis, rumentitis, and enteritis reported in adult ruminants; forestomach lesions include acute hemorrhagic

mucosal necrosis.

- Mycotic pneumonia in young calves and lamb raised indoors in intensive housing units
- Mycotic pneumonia and pulmonary abscess in ruminants; pulmonary candidiasis reported as outbreak in feedlot cattle.
- *C. parapsilosis* most commonly reported in bovine mycotic abortion.
- Yeast mastitis in cattle and goats due to *C. andida* spp.

PATHOPHYSIOLOGY

- *Candida* spp. are yeasts that propagate by budding.
- Prominent cell shape is oval and buds are single or multiple.
- Form blastoconidia, pseudohyphae, and true hyphae in culture and in tissues
- Following nutritional or atmospheric alterations in habitat environment, *Candida* spp. on mucus-containing membranes or in the invasive phase of infection (when actively invading tissue) undergo spore germination to form mycelium or form pseudomycelium by cellular elongation and filament formation.
- *Candida* spp. produce acid proteinases and keratinases, which degrade the stratum corneum, and phospholipases, which aid in penetration of tissues.
- *Candida* spp. may induce serious local or systemic infections.
- In systemic mycosis, the alimentary tract is most common route of entry of the organism, which then spreads hematogenously to other tissues.

SIGNALMENT

- Most common in young or debilitated animals
- Neonates are most prone to develop candidiasis of oral mucous membranes.
- Commonly occurs as complication of antimicrobial therapy
- Can complicate any open wound near oral mucosa, genital, or respiratory tract

SIGNS

- Depends on which organ(s) is (are) affected
- Fever (104–107°F, 40–40.5°C)
- Abortion
- Mastitis: transient and self-limiting to severe; udder spongy and swollen
- Dermatitis
 - Goats: nonpruritic dermatitis with alopecia, scales, crusting, greasiness, and lichenification; lesions were fairly symmetrical.
 - Feeder pigs: exudative dermatitis of distal limbs, thighs, abdomen; surface exudate was gray, skin was lichenified and bluish.
- Oral candidiasis characterized by white pseudomembranous plaque and ulcer over tongue and gingiva
- Calves: chronic diarrhea
- Cattle with omasitis, rumenitis, and enteritis may show nonspecific signs including lethargy, hypophagia, decreased milk production, decreased ruminal and intestinal motility, ± fever, ± low-grade abdominal pain.
- Feedlot cattle with chronic pneumonia, dyspnea, moderate fever, brown-streaked nasal discharge, diarrhea, and lacrimation

CAUSES AND RISK FACTORS

- Disruption of normal cutaneous or mucosal barriers
- Exposure to chronic moisture and skin maceration
- Compromised immune system: inherent or disease-induced
- Prolonged antibiotic therapy or heavy oral dosing
- Glucocorticoid or immunosuppressive therapy
- Feeding of poorly formulated or administered artificial diets to newborns
- Malnutrition
- Use of intramammary infusion tube may be risk for development of candida mastitis

DIAGNOSIS

- Diagnosis is based upon history, clinical signs, and lesions.
- Isolation of organism from infected material
- Identification of mycelial and pseudomycelial yeast forms in Gram-stained smears of infected material
- Direct smears stained with new methylene blue or Diff-Quik reveal budding cells and pseudohyphae.
- Periodic acid-Schiff or Gidley and Gomori methenamine silver techniques make organisms easily discernible.
- Skin scraping cytology or impression smears: budding yeast or pseudohyphae on cytology best taken from edge of lesion
- Culture of skin biopsy: Sabouraud's dextrose agar incubated at 30°C
- Skin biopsy: superficial perivascular dermatitis and/or folliculitis; identify form of organism and demonstrate it is invading tissue.
- Fecal smears and cultures in calves with chronic diarrhea and history of antimicrobial therapy

Lesions

- Superficial form
 - White pseudomembrane overlying skin or mucous membranes
 - Pseudohyphae, septate, hyphae, and budding yeast organisms in membrane
 - Invades epithelium but rarely beyond basal layer
 - Neutrophilic, lymphocytic infiltrate beneath epidermis
 - Systemic form: lesions depend on organ(s) infected

DIFFERENTIAL DIAGNOSIS

- Other fungal skin infections
- Other systemic mycoses
- Common causes of diarrhea, mastitis, pneumonia in ruminants

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

In systemic mycosis to identify pathogen

- Polymerase chain reaction
- Murine monoclonal rabbit polyclonal antibodies in histochemistry
- Immunoblotting
- ELISA of antibodies in serology

IMAGING

N/A

- Direct smear: cytology of lesion exudate
- Culture of infected material or lesion exudate
- Skin biopsy

TREATMENT

- Treatment of underlying condition
 - Remove from excessive moisture
 - Provide adequate and balanced nutrition
 - Treat underlying disease process if present
 - Withdrawal of immunosuppressive drugs

- Withdrawal of antimicrobial drugs, if possible
- Focal lesions: clip, dry, and apply topical antifungal agents.
- Topical therapy for mild dermatitis
 - Only use approved drugs in food animal.
 - Apply two to three times a day until lesions are healed.
 - Nystatin (100,000 U/gm)
 - 2% Miconazole (topical small animal products)
 - 1% Clotrimazole (Over-the-counter vaginal creams can be used.)
 - Potassium permanganate (1:3000 in water)
 - Enilconazole
- Treatment for severe dermatitis: may require administration of oral or parenteral antifungal agents
- Systemic antifungal agents not approved for use in food animals
- Efficacy of oral antifungal agents in ruminants is not well known
- Treatment of systemic mycosis is often unrewarding.
 - Amphotericin B has been the primary drug previously used but is no longer advocated, as there are less toxic and more efficacious products available.
 - Enilconazole (topical agent, not available in United States)
 - Fluconazole
 - Itraconazole
 - Ketoconazole (generic drug available, therefore most cost-effective systemic agent, 5–10 mg/kg PO once daily)
- No specific treatment for young calves with enteric (diarrheal) candidiasis
 - Supportive care
 - Withdrawal of antimicrobial therapy
 - Depending on age, probiotics or transfaunation with normal rumen flora

MEDICATIONS

N/A

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS

- Many of the suggested drugs for therapy are not approved and therefore should not be used in food animals.
- Confirm safety of drugs in species to be treated before initiating therapy.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

- If underlying condition is an inherent immunodeficiency, prognosis may be guarded to poor.
- Systemic mycosis may not respond well to therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Immunocompromise: inherent or disease-induced

- Malnutrition
- Exposure to excessive moisture
 - Intensive care therapy including prolonged antimicrobials

ZOONOTIC POTENTIAL

N/A

RUMINANT SPECIES AFFECTED

- Cattle
- Goats
- Potentially, all species of ruminants may become affected.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Keep animals in dry, clean environment.
- Provide adequate and appropriate nutrition.
- Avoid prolonged use or inappropriate use of antimicrobial agents and corticosteroids.
- Use appropriate hygiene and technique when infusing intramammary medications into udder.

CAPRINE ARTHRITIS ENCEPHALITIS

BASICS

OVERVIEW

- Caprine arthritis encephalitis (CAE) is a disease characterized by signs of chronic degenerative polyarthritis, chronic indurative mastitis, and/or chronic pneumonia in adult goats and less frequently by acute paralysis in young kids.
- CAE is one of the most important diseases affecting dairy goats in industrialized countries.
- In the United States, seroprevalence of CAEV antibodies ranges from 38% to 81% in dairy goatherds.
- The disease is caused by caprine arthritis-encephalitis virus (CAEV), a species of the ovine/caprine lentivirus group in the *Lentivirus* genus of the family Retroviridae.
- CAEV is closely related to other human and animal lentiviruses, particularly visna maedi virus (VMV) of sheep.
- CAEV replication cycle includes the reverse transcription of the viral RNA genome into a DNA copy called the provirus. During cell division the provirus integrates into, and becomes part of, the host cellular DNA. As a result, once infected with CAEV, goats remain infected for life.
- Ingestion of CAEV-contaminated colostrum or milk by newborns is the most common form of disease transmission.
- Feeding pooled colostrum or unpasteurized milk and bad hygiene practices during milking increase the risk of CAEV transmission.
- Transmission by close contact between infected and noninfected goats particularly during lactation and parturition also may occur.
- CAEV-PCR-positive cells have been found in oviductal flushing media samples from CAEV-positive goats and shedding of CAEV in semen has been reported. Therefore for control purposes, the venereal and transplacental routes of transmission should be considered as potential sources of CAEV.
- Economic losses are associated with decreased productivity as a result of clinical disease. Diminished production is related to secondary infections, animal deaths, and the potential loss of international markets due to trade barriers.

SIGNALMENT

- Goats are the natural host of CAEV infection. Sheep can be infected experimentally with CAEV. Phylogenetic analyses indicate that cross-species transmission of small ruminant lentiviruses (CAEV and VMV) occurs regularly under natural conditions.
- Infection by CAEV is more common in dairy goats. Host genetics may influence the clinical outcome of CAEV infection. Goats of the Saanen breed that carry the CLA Be7 specificity are less likely to develop arthritis after CAEV infection than goats missing this specificity.
- CAE infection rates among meat and hair goat breeds in North America seem to be low. This may reflect differences in management practices between dairy and meat/hair goats that prevent transmission rather than differences in breed susceptibility.
- Mouflon-domestic sheep hybrids are susceptible to experimental infection with CAEV.
- Clinical signs of CAE-associated arthritis, mastitis, and/or pneumonia are manifested more often in goats 2 years of age or older. Chronic progressive paralysis has been described occasionally in adult goats. Paralysis that follows a rapid clinical course in kids 2 to 6 months of age also has been reported.

SIGNS

- Differences in virus strain, individual host susceptibility factors, and the presence of concurrent infections may influence the clinical outcome of CAEV infections.
- In the majority of CAEV-infected goats, the infection is subclinical.
- In approximately 25% of seropositive goats, arthritis, mastitis, and/or pneumonia are manifested only several years after CAEV primary infection (clinical latency). More than one clinical manifestation may be observed in the same animal.

- Chronic, proliferative arthritis (“big knee”) in mature goats is the most common clinical manifestation of CAE. Goats with CAE-associated arthritis show swelling of the joints, particularly the carpi and less frequently the stifle, hock, hip, and atlantooccipital joints. The onset of arthritis is insidious, with short periods of swelling followed by periods of remission. Eventually, affected animals show pain, decreased range of articular motion, stiff gate, “knee walking,” and chronic weight loss.
- The majority of CAE arthritic goats also show chronic indurative mastitis (“hard bag”). In these cases, the mammary gland is firm on palpation and symmetrically enlarged. Although normal in appearance, milk production may be reduced. In more severe cases, there is agalactia that occurs at the time of parturition.
- Some CAEV-infected goats develop chronic nonsuppurative pneumonia with signs of dyspnea and weight loss.
- Although unusual, neurological involvement in adult goats can occur. Initially, these goats show slight aberration in gait. Over the course of several months, the clinical course progresses to complete paralysis.
- Once CAEV-infected goats show clinical signs of the disease, death months or years after primary infection is the end result, usually as a consequence of secondary infections.
- A different clinical presentation of CAE, characterized by a rapid clinical course and afebrile paralysis in kids 2 to 6 months of age has been described. The paralysis starts in the rear legs and progresses toward the front of the animal. Affected kids continue to be alert and eat if hand-fed, but often develop bloating and urinary retention as a result of recumbency. A few affected kids show blindness or circling. During the acute stages of the disease, affected kids develop severe pleocytosis with up to 100,000 mononuclear inflammatory cells per cubic millimeter.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- CAE needs to be differentiated from other causes of chronic weight loss, such as caseous lymphadenitis, paratuberculosis (Johne’s disease), internal abscesses, scrapie, chronic parasite infestations, and malnutrition.
- In goats with arthritis, bacterial, chlamydial, and mycoplasmal polyarthritis (contagious agalactia) need to be included in the differential diagnosis of CAE.
- The differential diagnosis of the chronic respiratory form of CAE should include chronic bacterial and verminous pneumonia and lung abscesses.
- The neurologic form of CAE needs to be distinguished from trauma of or abscesses in the brain or spinal cord, meningitis, parelaphostrongylosis, vitamin E and Se deficiency, copper deficiency, listeriosis, scrapie, rabies, and bacterial polyarthritis.

DIAGNOSTIC PROCEDURES

- CAEV replicates in the presence of antiviral immune responses and persists for life in cells of infected goats. For this reason, determination of anti-CAEV antibodies in sera is the method most commonly used to identify infected goats.
- Serum antibodies can be detected as early as 3 to 6 weeks after exposure, but some infected goats may remain seronegative for 8 months or more in spite of being virus and PCR positive.
- The agar gel immunodiffusion (AGID) test and the enzyme-linked immunosorbent assay (ELISA) are the two most commonly used assays to detect CAEV-infected goats. None of these tests is standardized across diagnostic laboratories, and their sensitivity and specificity may vary widely. Consequently, unnecessary culling of false positive goats from, or the retention of false negative goats in herds during eradication programs may occur.
- A competitive ELISA (cELISA) with high sensitivity and specificity is commercially available.
- Because of the high cost of cELISA, it is recommended that the AGID test be used for the first round of testing, after which all positive reactors should be segregated from the herd. Then, the more sensitive cELISA can be used for subsequent testing at 3- to 6-month intervals. Once all animals in the herd give a negative result in at least two consecutive tests, annual retesting and the purchase of replacement animals from CAEV-free flocks should be implemented.
- Virus isolation from “buffy coats” is the most definite way to confirm CAE. However, this method is expensive, cumbersome, and often unsuccessful. For these reasons, this technique is not recommended as a routine diagnostic test for CAE.
- Although PCR is a highly sensitive technique, its usefulness for the detection of CAEV in clinical samples from naturally infected goats still needs validation.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- Affected goats may be thin to emaciated and have long, coarse, dull hair coats.
- Swelling of carpi and less frequently the stifle, hock, hip, and atlantooccipital joints are present in goats affected with arthritis. The swelling also affects associated tendons, bursa, and adjacent periarticular tissues. In early stages, the synovial fluid is increased but remains translucent. Mineralization of periarticular tissues and erosion of articular cartilage are found in more advanced cases.
- The mammary gland in goats affected with mastitis is symmetrically enlarged and firm on palpation.
- In most CAEV goats with pulmonary involvement, lung lesions are imperceptible.
- The lymph nodes draining affected joints, mammary gland, or lung may be enlarged.

Microscopic Findings

- Histologic lesions in joints of goats with CAE-induced arthritis are characterized by various degrees of infiltration of lymphocytes, plasma cells, and macrophages in the synovium, and proliferation of villi. As the disease progresses, degeneration of the articular cartilage, fibrosis, mineralization of the joint capsule, and periosteal replacement growth become evident.
- In the mammary gland of CAE goats with mastitis, there is interstitial infiltration of lymphocytes, and plasma cells in the interstitium surrounding lobular ducts. Often, macrophages can be seen in the luminal epithelium.
- Pulmonary lesions are typical of lymphoid interstitial pneumonia and are characterized by the presence of numerous mononuclear cell aggregates and lymph follicles adjacent to bronchioles and small blood vessels. In more severe cases, there is thickening of the interalveolar septa due to infiltration of mononuclear cells and fibrosis.
- In goat kids affected by the neurological form of CAE, there is chronic, nonsuppurative inflammation of the brain accompanied by destruction of myelin and proliferation of glial cells.

TREATMENT

There are no specific treatments available for CAE.

MEDICATIONS

N/A

CONTRAINDICATIONS

N/A

FOLLOW-UP

N/A

PREVENTION/AVOIDANCE

- There are no commercial vaccines available to prevent CAEV infection.
- Serological testing and segregation of positive reactors can achieve eradication of CAE from a herd.
- Some CAEV-infected goats may remain seronegative for weeks or months after infection. These goats may shed the virus in milk and other body secretions at irregular intervals, thus representing a major problem in CAE control and eradication programs.
- For these reasons, retesting every 3 to 6 months with elimination of new positive reactors is necessary until three to five consecutive tests result in 100% of the goats being seronegative. Then, yearly testing and acquisition of replacements from CAE-free flocks are recommended.
- Separation of offspring from their mothers before the ingestion of colostrum and the use of heat-inactivated colostrum

(56°C for 60 min) and milk substitutes have been used in the past with limited success. The method is labor intensive and not always effective.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- Clinical signs of arthritis, mastitis, and pneumonia are seen more often in goats 2 to 3 years old or older.
- Acute leukoencephalomyelitis, although uncommon, is seen in 2- to 6-month-old kids.

ZOONOTIC POTENTIAL

There is no evidence to indicate that CAEV is infectious to humans.

PREGNANCY

Vertical transmission from mother to fetus does not seem to be an important event in the epidemiology of CAE.

BASICS

OVERVIEW

- Capture myopathy (CM) is also known as postcapture myopathy, overstraining disease, transport myopathy, exertional rhabdomyolysis, exertional myopathy, and leg paralysis.
- Has been reported in numerous species of mammals and birds, often associated with capture and or restraint.
- Has been reported in animals captured by a variety of methods, including short or long-distance chases, chemical immobilization, drop netting, net gunning, boma capture, handling, and restraint in chutes
- Rarely reported in carnivores
- Appropriate capture method of wild species governs outcome and development (or not) of CM.
- Habituation of captive animals to handling is an important tool in prevention.
- CM can be broadly divided into four categories according its physical manifestation. These are peracute, acute, subacute, and chronic. It should be remembered that these are phases in a continuum, and that the borders are not rigid.

N/A

Predominant Sex

N/A

CAUSES AND RISK FACTORS

- Several factors can act alone or, more commonly, in combination, to lead to the development of CM.
- These factors include restraint methodology, overexertion, hyperthermia, isometric exercise, drug effects, alterations in the muscle pump activity.
- Species predisposition and individual variation
- Season and effects upon dietary intake and ambient temperature
- Physical fitness (training)
- Fear, habituation, and familiarity with events, environment, and personnel

DIAGNOSIS

- Clinical signs and history are important components in the diagnosis; in peracute and acute cases, there will be little or no opportunity for laboratory tests before death supervenes, although serum potassium and lactic acid are elevated.
- Acute or subacute cases may show lameness or be recumbent.
- In long-term chronic cases, wasting and debility may occur.

DIFFERENTIAL DIAGNOSIS

- If the precipitating factors are known, there may be little that should be confused with CM, but the clinical picture may be similar to conditions such as enzootic ataxia or acute central nervous system disease.
- In areas where selenium deficiency is recognized, CM can closely resemble white muscle disease, which may occur in calves born to selenium-deficient mothers, or in other age groups taking sudden exercise.
- Fracture or other traumatic injuries
- In long-term chronic cases, wasting and debility may occur.

CBC/BIOCHEMISTRY/URINALYSIS

- Early in acute phase serum pH, lactic acid and serum potassium are elevated.
- Once muscle and organ damage becomes evident, serum enzymes such as aspartate aminotransferase and creatine kinase are elevated, but serum pH, lactic acid, and serum potassium may have returned to normal. Myoglobinuria is often evident.
- Little information exists about effects of long-term chronic CM or repeated low-level stimuli that can lead to kidney damage. However, severe damage could lead to impaired renal function, which could include azotemia and inappropriate urine-specific gravity.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

History, clinical signs, serum chemistry, urinalysis

PATHOLOGIC FINDINGS

GROSS FINDINGS

- Peracute—few postmortem signs
- Acute—include pulmonary edema, severe congestion of the small intestine and liver, muscle hemorrhage or rupture, often in the gastrocnemius muscle.
- Subacute to chronic—areas of pale muscle or muscle groups. The muscle lesions are usually bilateral, but not necessarily symmetrical and may involve almost any muscle or even part of a muscle. Kidney damage and dark brown urine containing myoglobin may be seen in the bladder.
- Chronic—kidney and widespread muscle damage

HISTOPATHOLOGICAL FINDINGS

Varying degrees of damage and loss of striation in skeletal muscle may be seen. Deposition of hemoglobin and myoglobin in the glomeruli may occur.

TREATMENT

- Seldom effective in acute cases or those severely affected
- Prevention is important.
- In affected animals, a considerable variety of treatments including vitamins and anti-inflammatory and pain relieving drugs have been tried, usually with little success.

- Their success is dependent upon both the type of CM that is involved and the extent to which treatments can be administered without exacerbating existing conditions.
- Vitamin E/Se injections are used routinely to treat cattle and sheep with white muscle disease. White muscle disease has some similarities to certain forms of CM.

MEDICATIONS

Prophylactic use of taming or sedative drugs has been employed to prevent the development of capture myopathy syndromes, especially in African species captured from the wild and destined for game ranches. Combinations of a variety of these products, collectively known as long-acting neuroleptics (LANs), have been shown to greatly reduce morbidity and enhance the capture and translocation of several species.

CONTRAINDICATIONS

- If wild animals are to be released after capture, the use of LANs may be contraindicated as reduced perceptiveness may lead to an increased risk of predation.
- LANs are not licensed for use in food-producing animals.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING PREVENTION/AVOIDANCE

- Choice of the most suitable method of restraint is vital. This will depend upon the needs of the situation.
- One of the simplest forms of prevention is to ensure that the animals are dealt with in the training, taming, & tempo (TT&T) methods of handling.
- Training means that all the animals can be trained to use the corrals and handling systems to the point where they feel little or no stress.
- Taming involves acclimatization to humans by regular feeding from a vehicle, or by the use of special calls at feeding time. Animals should not be handled when strangers are present.
- Tempo—animals should never be rushed; handlers must be alert to animal responses, and working in unsuitable conditions should be avoided (windy days, high temperatures).
- LANs where appropriate

POSSIBLE COMPLICATIONS

Animals can apparently recover from a handling incident, but have long-term muscle damage (e.g., cardiac) and can succumb to subsequent adverse stimuli.

EXPECTED COURSE AND PROGNOSIS

Usually fatal in all but chronic forms. When chronic, slow debility and decline leads to loss of productivity or failure to breed.

CARBAMATE TOXICITY

BASICS

OVERVIEW

- Carbamates are anticholinesterase insecticides commonly found in crop insecticides.
- The binding of carbamates is reversible and temporary, unlike the mechanism of another class of anticholinesterase insecticide, the organophosphates, which is irreversible.

PATHOPHYSIOLOGY

Anticholinesterase insecticides bind with and inhibit acetylcholinesterase, the enzyme that breaks down the neurotransmitter acetylcholine. These compounds cause acetylcholine to accumulate at nerve junctions and cause excessive synaptic activity. The effects are in the parasympathetic nervous system and at neuromuscular sites.

SYSTEMS AFFECTED

CNS, production management

N/A

SIGNS

Muscarinic Symptoms

Result from stimulation of the parasympathetic nervous system and are described by the acronym SLUD:

- Salivation
- Lacrimation
- Urination
- Defecation

Other Possible Muscarinic Signs

- Vomiting
- Myosis
- Bradycardia
- Dyspnea

Nicotinic (Neuromuscular) Signs

- Muscle tremors
- Ataxia
- Progressive paresis to paralysis

Central Nervous System (CNS) Signs

- Depression
- Seizures
- Behavioral changes

CAUSES AND RISK FACTORS

- Domestic animals are usually exposed to carbamate insecticides due to drift, accidental ingestion, or improper treatment by owners. Carbamate insecticides are used primarily on crops and other plants. They were previously commonly used for ectoparasite control.
- Carbamates are anticholinesterase insecticides commonly found in crop insecticides.
 - Carbaryl—LD50 in rats is 307 mg/kg orally and > 500 mg/kg dermally.
 - Carbofuran—Minimum toxic dose in sheep and cattle is 4.5 mg/kg, becoming lethal for sheep at 9 mg/kg and for cattle at 18 mg/kg.
 - Methomyl—LD50 in rats is 17 mg/kg orally.
 - Propoxur—LD50 in rats is 95 mg/kg orally and in goats is > 800 mg/kg orally.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rabies
- Other pesticides including organophosphates, rodenticides, metaldehyde (snail bait), haloxon anthelmintic
- Other toxins such as strychnine or lead
- Numerous plant toxicities cause tremor or ataxia.
- Metabolic disturbances such as nervous ketosis
- Gastrointestinal causes of diarrhea

CBC/BIOCHEMISTRY/URINALYSIS

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Diagnosis is often based on known exposure to carbamate and response to treatment with atropine.
- Prompt testing is necessary due to the temporary binding of carbamate toxins. Cholinesterase activity may return to normal before or during laboratory testing.
- Cholinesterase activity in whole blood, retina, or brain that is 25%–50% of normal for the species being tested indicates cholinesterase inhibitor toxicosis. If less than 25% of normal, clinical correlation of symptoms is required for diagnosis.
- Check with the laboratory before submitting blood samples because some testing methods may require serum instead of whole blood samples.
- Half of the brain should be submitted for homogenization, as cholinesterase activity varies in different brain regions.

PATHOLOGIC FINDINGS

GROSS FINDINGS

None

HISTOPATHOLOGICAL FINDINGS

None

TREATMENT

- Provide supportive care for SLUD or secondary clinical signs such as dehydration.
- Wash the animal with soap and water if dermal exposure occurs to decrease absorption. Clipping may be advisable in long-haired animals.
- Administer activated charcoal at a dose of 1–2 lb PO per 500 kg animal.
- Atropine should be given at a dose of 0.1–0.5 mg/kg to competitively bind acetylcholine. Give one-fourth of the initial dose IV and the rest subcutaneously or intramuscularly. Dosage can be repeated in 6 hours if clinical signs recur.

MEDICATIONS

- Activated charcoal
- Atropine

CONTRAINDICATIONS

- Oximes such as pralidoxime chloride (2-PAM) that are used to release the acetylcholinesterase-organophosphate bond are *not* used due to the reversible nature of carbamate binding to acetylcholinesterase.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

- Heart rate
- Respiration
- Fluid and feed intake

PREVENTION/AVOIDANCE

- Closely follow instructions for dilution and application found on carbamate insecticide label.
- Premises should be washed and contaminated soil removed. Runoff can poison fish and aquatic animals.
- Avoid use of carbamate insecticides for ectoparasite control especially on sick or debilitated animals.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Good prognosis if treated promptly

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

- Carbamate toxicity is not a transmissible disease; however, humans are also susceptible to toxic exposures.
- Follow labeled instructions and precautions when handling carbamate insecticides.
- Use caution when washing poisoned animals.

CARDIOMYOPATHY

BASICS

DEFINITION

- Diseases of the heart resulting from primary myocardial dysfunction of unknown etiology and are characterized by dilation and/or hypertrophy
- Secondary cardiomyopathies include myocardial disease of known cause and other cardiovascular disorders which lead to dilation and/or hypertrophy of the heart

OVERVIEW

- Uncommon condition in large animals
- Sporadic occurrence
- Holstein cattle seem most sensitive
- Three forms of cardiomyopathy
- Dilated or congestive cardiomyopathy is characterized by
 - Cardiomegaly
 - Dilatation of all chambers and atrioventricular rings
 - Increased ventricular mass
 - Reduced myocardial contractility
 - Decreased systolic function
 - Outcome is heart failure.
 - Dilated cardiomyopathy described in Canadian black and white Holstein
 - Etiology: idiopathic, familial, secondary
- Hypertrophic cardiomyopathy
 - Diastolic disorder resulting from decreased ventricular myocardial compliance
 - Hypertrophy of left ventricular free wall and septum results in reduced distensibility, impaired relaxation of ventricle, and decreased diastolic flow from and dilation of left atrium
 - Symmetrical or asymmetrical chamber or septal hypertrophy
- Restrictive cardiomyopathy is characterized by impeded diastolic relaxation and reduced left ventricular filling.
- In cattle, inherited myocardial disease is a primary dilated cardiomyopathy.
- Two cases of hypertrophic cardiomyopathy have been reported in Holstein cattle.
- Disease in sheep and goats is due primarily to secondary cardiomyopathies.

PATHOPHYSIOLOGY

General

- Progressive loss of myocardial contractility
- Decrease in cardiac output
- Blood volume and pressure increases within chambers causing them to dilate
- Constant sympathetic stimulation of the heart leads to arrhythmias and myocytes death
- Renin-angiotensin-aldosterone release causes vasoconstriction and sodium and water retention
- Signs of congestive heart failure develop

SIGNALMENT/INHERITED SYNDROMES

Holstein-Friesian Cattle

- Reported in Holstein-Friesian cattle in Canada, Great Britain, Japan, Austria, Germany

- Reported in Simmental-Red Holstein crosses and black spotted Friesians in Switzerland
- Autosomal-recessive trait
- Cattle may be genetically linked by presence of red Holstein gene.
- Affected cattle range from 1.5–6 to 7 years old
- Most affected have clinical signs by 3 to 4 years of age.
- Stress (late pregnancy, early lactation) often precipitates onset of clinical signs.
- No sex predilection
- Initially, left ventricle fails to compensate leading to pulmonary hypertension, hypertrophy of right ventricle, and right heart failure.
- Lesions: cardiomyopathy, ventricular and atrial dilatation, variable hypertrophy, necrosis, and fibrosis, ± hepatomegaly (congestion and fibrosis), systemic cardiac edema, interstitial nephritis

Japanese Black Cattle

- Inherited: autosomal-recessive trait
- Affected calves usually die by 30 days of age; may survive 120 days
- Lesions: extensive myocardial necrosis with cardiomegaly and marked left ventricular dilation leading to congestive heart failure (pulmonary edema, ascites, hydrothorax)

Australian Polled Herefords

- Inherited; single autosomal recessive gene
- Associated with dense, tight, curly (wooly) haircoat
- Survival time reported as up to 3 months or 6 months of age
- Calves often die by 7 days of age.
- Arrhythmias noted included multifocal ventricular premature contractions, ventricular tachycardia, bigeminal rhythms.
- Lesions: myocardial necrosis; fibrosis and mineralization; vascular congestion of liver, spleen and lung; diffuse streaking of myocardium
- Also reported in horned Herefords

SIGNS

Holstein-Friesian Cattle

- Initially, clinical signs are indistinct and slowly progressive: cows are weak, unable to track with herd, and low-milk producers.
- Once cardiac signs are evident, disease progresses rapidly with cattle dying or culled within days or weeks.
- Signs of right heart failure:
 - Submandibular, brisket, and ventral edema
 - Muffled heart sounds
 - Tachycardia, gallop rhythm
 - Jugular and mammary vein distention and pulsation
 - Hepatomegaly
 - Pleural or pericardial effusion

Japanese Black Cattle

- Signs of progressive heart failure
- Severe dyspnea prior to death

Australian Polled Hereford Calves

- Rapid growth rate
- Short curly coat
- Moderate bilateral exophthalmia
- Exercise intolerance
- Sudden death, usually precipitated by stress
- Dyspnea
- Blood froth from nose

- Congestive heart failure

Pathologic Lesions

- See above under each syndrome.
- Lesions of congestive heart failure

CAUSES AND RISK FACTORS

- Etiology—unknown
- Genetic predisposition in some cattle breeds
- Stress may precipitate clinical signs

DIAGNOSIS

- History and clinical signs of heart failure
- Echocardiography
 - To rule out other causes of cardiac disease
- To document heart chamber dilatation \pm hypertrophy
 - Electrocardiogram if arrhythmias are present.
- Thoracic radiographs in calves to document cardiomegaly
- Arterial blood gas

DIFFERENTIAL DIAGNOSIS

- Ionophore toxicity
- Gossypol toxicosis
- Selenium- vitamin E deficiency
- Plant toxicosis: *Cassia occidentalis*, *Phalaris* spp.
- Viral-induced
- Myocarditis
- Endocarditis
- Primary or secondary copper deficiency
- Cardiac neoplasia: lymphosarcoma, fibrosarcoma
- Generalized glycogenosis type II

CBC/BIOCHEMISTRY/URINALYSIS

- CBC: normal or stress leukogram
- Serum electrolytes: normal or hyponatremia, hypokalemia, hypochloremia due to anorexia or retention of fluid in vascular space
- Serum chemistry changes reflect secondary organ involvement
 - Elevated GGT due to passive congestion of liver
 - Elevated creatine due to renal hypoperfusion

OTHER LABORATORY TESTS

- Hepatic ultrasound: \pm hepatomegaly
- Transferrin: serum and urinary concentrations increased in cattle with bovine dilated cardiomyopathy

IMAGING

- Echocardiography
- Thoracic radiographs
- Ultrasound of abdomen or chest

TREATMENT

- Short-term management only
- Cardioglycosides: Digoxin
- Diuretic: Furosemide, if pulmonary edema present
- Dietary restriction of sodium
- Dietary supplementation of potassium chloride (KCl)
- Monitor blood acid-base, electrolyte, and hydration status

MEDICATIONS

DRUGS OF CHOICE

- Furosemide: 0.5–1.0 mg/kg IV, IM BID
- Digoxin
 - 0.86 μ g/kg per hour IV (valuable hospitalized animals) or 3.4 μ g/kg IV every 4 hours; greater risk of inducing digoxin toxicity
 - Supplement with KCl if animal is inappetent.
- Dietary restriction of sodium in older calves
- KCl: 5 to 10 g per day PO in older calves; 50–200 g daily PO for adult cow/bull
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

- Plasma/serum digoxin concentrations to monitor for toxicity
- Monitoring of blood electrolyte and acid-base status
- Monitoring of hydration status
- Monitoring of weight gain or loss

EXPECTED COURSE AND PROGNOSIS

- 100% mortality in long term
- Holstein-Friesian and Simmental-Red Holstein may survive up to 6 to 7 years.
- Japanese black cattle often die by 1 month but may survive to 4 months of age.
- Australian polled Hereford calves usually succumb by 3 months but may live until 6 months of age.

CARDIOTOXIC PLANTS

BASICS

OVERVIEW

A large group of unrelated plants can be cardiotoxic to livestock; the majority contains cardiac glycosides. Other cardiotoxic plants that have resulted in livestock poisoning include yew (*Taxus* spp.), grayanotoxin-containing plants, death camas (*Zigadenus* spp.), and avocado (*Persea* spp.).

Cardiac Glycoside-Containing Plants

- Plants containing cardiac glycosides include oleander (*Nerium oleander*), summer pheasant's eye (*Adonis aestivalis*), foxglove (*Digitalis purpurea*), lily-of-the-valley (*Convallaria majalis*), dogbane (*Apocynum* spp.), and some species of milkweed (*Asclepias* spp.).
- Oleander is cultivated widely in the southern United States and is most commonly associated with plant poisonings in livestock. Therefore, oleander is discussed in detail as a representative of plants containing cardiac glycosides.
- Cardiac glycosides cause poisoning by inhibiting the cellular membrane Na^+/K^+ -ATPase, which results in an indirect increase in intracellular Ca^{2+} concentrations and a subsequent positive inotropic effect. In addition, direct effects on the sympathetic nervous system are seen.
- All parts of oleander are extremely toxic, whether the plant is fresh or dried. Ingestion of dried oleander clippings is a common source of poisoning in livestock.
- The median toxic dose of oleander leaves in cattle is 45 mg of plant material per kg body weight or approximately 12 averaged-sized leaves.

Yews

- Yews are popular shrubbery used as a hedge or foundation planting. Several *Taxus* species are found in the United States with *T. baccata* (English yew) and *T. cuspidata* (Japanese yew) most commonly reported in poisonings. However, all species of *Taxus*, including *T. brevifolia* (Pacific or western yew) should be considered toxic.
- Yews contain taxine alkaloids (major alkaloids are taxine A and taxine B) that cause an increase in cytoplasmic calcium by interfering with both the calcium and the sodium ion channel conductance across the myocardial cells. This results in the depression of cardiac depolarization and conduction of the heart.
- All parts of the plant, green or dried, with the exception of the red fleshy part surrounding the seed (aril portion), are toxic. Ingestion of yew clippings is most often the cause of poisonings.
- The minimum lethal dose in adult cattle is estimated to be approximately 200 g of dried leaves.

Grayanotoxin-Containing Plants

- Plants containing grayanotoxins include *Rhododendron* spp. (rhododendron, azalea, rosebay), *Kalmia* spp. (mountain laurel, sheep laurel, lambkill, sheepskill, dwarf laurel, calico bush), *Pieris* spp. (Japanese pieris, mountain pieris), *Leucothoe* spp. (dog hobble, dog laurel, fetter bush, black laurel), and *Lyonia* spp. (fetter bush, maleberry, staggerbush).
- Grayanotoxins are diterpenes that exert their toxic effect by binding to sodium channels in excitable cell membranes. The resulting increase in membrane permeability to sodium ions maintains excitable cells in a state of depolarization. Accumulation of intracellular sodium results in an exchange with extracellular calcium and plays an important role in the control of transmitter release. The membrane effects caused by grayanotoxins account for the observed responses of skeletal and myocardial muscle, nerves, and central nervous system.
- Toxicosis usually occurs when animals are offered plant trimmings or stray into wooded areas during adverse weather conditions and little else is available to eat.
- In cattle and sheep, ingestion of 0.2%–0.6% of an animal's body weight is considered toxic. Goats can be poisoned by the ingestion of fresh foliage in the amount of 0.1% of the animal's body weight.

Death Camas

- Many species of death camas occur across the United States and are seasonal with the greatest abundance being in the spring.
- Death camas contains steroidal alkaloids, such as zygacine and zygodenine. The alkaloids decrease blood pressure, slow the heart rate, and lead to respiratory depression.
- Leaves during the early stages of growth pose the greatest risk for poisoning. Seeds and fruits as well as the dried plant in hay are also toxic.
- The minimum lethal dose of the green plant in sheep is approximately 1% of the animal's body weight, but serious illness may be seen with as little as ingestion of 0.2% of an animal's body weight. Cattle are equally or possibly more susceptible than sheep.

Avocado

- Avocado is extensively cultivated in California and Florida, but can also be found as an ornamental in the gulf coast areas.
- The Guatemalan race and its hybrid ("Fuerte") are reportedly toxic to livestock. The Mexican race has low toxicity and no reports of poisoning in livestock exist.
- The toxic compound is called persin, but the exact mechanism of action remains unclear.
- The leaves are especially toxic, but ingestion of fruit and seeds can also result in poisoning.
- In goats, ingestion of 30 g/kg body weight of fresh leaves can result in cardiac effects. At exposures greater than 20 g/kg body weight of fresh leaves, lactating goats can develop severe mastitis. Even though goats seem to be particularly sensitive to avocado poisoning, cattle and sheep are also affected.

SIGNALMENT

Cardiac Glycoside-Containing Plants

All species are susceptible to cardiac glycoside-containing plants. Oleander poisoning is commonly seen in llamas and alpacas. Severe losses have also been reported in cattle.

Yew

Most poisonings with yew have involved cattle, but sheep, goats, and wild ruminants are also susceptible. Deer are able to tolerate considerable amounts of yew during the winter months, probably because of lower concentrations of taxine alkaloids in newly grown shoots.

Grayanotoxin-Containing Plants

Grayanotoxin poisoning has been reported in cattle and sheep, but most reports of poisoning involve goats.

Death Camas

Sheep are at highest risk, especially when hungry, because they are most likely to eat the death camas in early spring when little alternative forage is available. However, cattle have also been poisoned.

Avocado

Goats are highly susceptible to the mammary-induced effects of avocado poisoning, although all lactating animals can develop noninfectious mastitis and agalactia. With respect to cardiotoxic effects of avocado, all animal species are considered susceptible.

SIGNS

- Animals exposed to cardiotoxic plants are often found dead.
- If animals are presented alive, clinical signs of colic (abdominal pain) are often seen within hours of exposure. Progression of disease is rapid and animals develop weakness, tremors, excessive salivation, incoordination, dyspnea, and sometimes convulsions.
- In cardiac glycoside poisonings, animals often have an irregular, fast pulse with tachycardia, ventricular arrhythmias, or gallop rhythms.
- Animals exposed to avocado develop subcutaneous edema of the neck and brisket, submandibular edema, respiratory dyspnea, and cardiac arrhythmias. Lactating animals exposed to a low dose of avocado develop noninfectious mastitis and agalactia within 24 hours of exposure.

CAUSES AND RISK FACTORS

- Ingestion of cardiotoxic plants presents a great risk to ruminants. Plants most commonly associated with acute poisoning are oleander, yew, and rhododendron.
- Hungry animals are most likely to receive toxic exposures.
- Young and rapidly growing plants often contain highest concentrations of toxins.

- Fresh plant material of cardiotoxic plants is often considered to be of low palatability. However, animals frequently eat the leaves readily, if no other forage is available.
- Plant trimmings present the most common source for oleander and yew poisoning.
- Plant trimmings of cardiac glycoside-containing plants and yews remain toxic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nitrate toxicosis—chocolate-colored blood, exposure to nitrate-accumulating plants
- Cyanide poisoning—mucous membranes are initially bright cherry red; evidence of exposure to cyanogenic plants, chemical analysis for cyanide in gastrointestinal contents, liver, or muscle
- Larkspur poisoning—mainly found in the western states; bloat is common finding, evidence of exposure to *Delphinium* spp.
- Grass tetany—hypomagnesemia
- Organophosphorus or carbamate insecticide exposure—commonly associated with gastrointestinal irritation and neurological signs, evaluation of cholinesterase activity, detection of pesticides in gastrointestinal contents
- Lead poisoning—determination of blood lead concentration
- Exposure to neurotoxic plants, such as poison hemlock, water hemlock, tree tobacco, lupine—chemical analysis for plant toxins in gastrointestinal contents, history of presence of plants in the environment
- Exposure to the plant “fly poison” (*Amianthium muscaetoxicum*)—found only in the eastern United States, most commonly seen in the spring, history of presence of plants in the environment
- Exposure to star-of-Bethlehem (*Ornithogalum* spp.)—mainly found in the Northeast and Midwest, severe diarrhea, history of presence of plants in the environment
- Nonprotein nitrogen (NPN) toxicosis—history of NPN supplements in the feed ration, detection of toxic levels of ammonia in rumen content and blood
- Ionophore antibiotics—history of ionophores (e.g., monensin) in the feed ration, detection of toxic concentrations of ionophores in the feed, histologic lesions

CBC/BIOCHEMISTRY/URINALYSIS

- Serum chemistry changes are limited.
- Myocardial damage may result in hyperkalemia, and elevated LDH, CK, and AST activities.

OTHER LABORATORY TESTS

- Detection of oleandrin, gitoxin, digitoxin, grayanotoxins, strophanthidin, or other cardiac glycosides or aglycones in blood, rumen, cecal, or colon contents, and liver
- Detection of taxine alkaloids in rumen contents
- Visual and microscopic examination of rumen or intestinal contents for plant fragments

IMAGING

PATHOLOGIC FINDINGS

- In peracute cases, no lesions are found.
- Postmortem lesions are generally nonspecific in animals that died of exposure to cardiotoxic plants. Lesions include reddening of the mucosa of the gastrointestinal tract and congestion of organs.
- Cattle with oleander poisoning have evidence of fluid in the bowel and thrombosis and hemorrhage in the heart.
- There are no or very few lesions in cases of yew, grayanotoxin, or death camas poisoning.
- Avocado poisoning can result in fluid accumulation in the pericardial sac and in the thoracic and abdominal cavities. Edema of the gallbladder and perirenal tissues and a flabby, pale heart have been observed. Mammary glands are edematous with clots in the large ducts.

TREATMENT

- Immediate removal of the toxic plant material to prevent further exposure. Provide the animals with good-quality feed.
- Treatment of animals exposed to cardiotoxic plants is primarily supportive and symptomatic. Supportive therapy should include administration of intravenous fluids, antiarrhythmics, and antibiotics if indicated.
- Adsorption of toxins with activated charcoal has been suggested.
- Rumenotomy may be considered in a valuable individual animal if ingestion is known and clinical signs have not yet developed.
- Passing a stomach tube, if necessary, should relieve bloat.
- Any possible stress or trauma should be avoided.
- If edema is present in avocado poisoning, administration of diuretics is recommended.
- Atropine should be considered in cases of severe bradycardia. Additionally, it may be warranted in severely poisoned animals that do not respond to decontamination procedures and fluid therapy alone.

MEDICATIONS

DRUGS OF CHOICE

- Lidocaine, phenytoin, or propranolol to treat tachyarrhythmias
- Atropine to treat bradyarrhythmias
- Activated charcoal

CONTRAINDICATIONS

- Do not administer potassium in fluids if hyperkalemia is present.
- Avoid calcium-containing solutions and quinidine.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

ALTERNATIVE DRUGS

Anticardiac glycoside Fab antibodies have been used in humans and small animals, but their usefulness in the treatment of cardiac glycoside-poisoned ruminants has not been evaluated.

FOLLOW-UP

PATIENT MONITORING

Monitor progression of clinical signs.

PREVENTION/AVOIDANCE

- Prevent hungry animals from accessing new pasture, especially in the spring when only limited (and often toxic) forage is available.
- Animals should be denied access to landscaped yards and discarded clippings.
- Suspect forage should be inspected for the presence of cardiotoxic plants before allowing ruminants to graze.
- Hay should be inspected carefully for weeds, as many cardiotoxic plants remain toxic when dried (oleander, death camas, yew).

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Animals poisoned with cardiotoxic plants are often found dead.

- Cardiotoxic plant exposure progresses so rapidly that treatment is often too late. In most cases, the affected animals have a poor-to-grave prognosis.
- If treatment is initiated promptly after the onset of clinical signs, the prognosis is fair.
- Animals that survive the acute poisoning may suffer from myocardial damage and may be more prone to stress.

CASEOUS LYMPHADENITIS (CLA)

BASICS

DEFINITION

An endemic, infectious contagious disease caused by *Corynebacterium pseudotuberculosis*, characterized by caseous abscessation of the internal and external lymph nodes and internal visceral organs of sheep, goats, and rarely camelids.

PATHOPHYSIOLOGY

- Bacteria invade through wounds, unbroken or abraded skin, or mucous membranes.
- Animal may contract bacteria through contaminated fomites (particularly water, feed, soil, or housing) or directly from animals with draining abscesses, or from pulmonary abscesses from coughing.
- The bacteria then travel through lymphatic system or blood stream to local lymph nodes and organs.
- Phospholipase D (PLD) exotoxin, secreted by the bacteria, causes the breakdown of the endothelium and is leukotoxic. This enables the spread of the bacteria through tissues.
- The cell wall is thick with a high lipid content, which enables the bacteria to resist phagocytosis.
- Thus, abscesses form generally first in the lymph node(s) draining the site of initial infection, but may form anywhere in the body.
- Abscesses may rupture (through skin or into bronchi) or regress. New abscesses may form months later in the same or different location.

SYSTEMS AFFECTED

- Most commonly affects the lymphatic system (lymph nodes) in any location and lung parenchyma (respiratory system)
- In North American and European housed sheep and goats, most commonly affects parotid, submandibular, and cervical lymph nodes as well as the respiratory system
- In range flocks in Australia, mostly affects the respiratory system (parenchyma and mediastinal lymph nodes) and popliteal lymph nodes.
- Less commonly but not rare, abscesses are formed: externally in the prescapular, prefemoral, or mammary lymph nodes; internally in the liver, kidney, adrenal glands, pituitary gland, or vertebrae.

GENETICS

NA

INCIDENCE/PREVALENCE

- Common in all sheep- and goat-raising countries in the world
- Flock / herd prevalence likely greater than 75% in adult animals if no control program
- Flock / herd incidence varies depending on management and level of surveillance, but likely > 15%
- Prevalence of abscesses found at abattoirs estimated at 17% to 24% in adult sheep
- Recognized as an important cause of carcass condemnation and trim

GEOGRAPHIC DISTRIBUTION

- Widely distributed in North America.
- Mostly in terminal sire flocks in the UK

SIGNALMENT

Species

- Sheep (domestic and wild)
- Goats (domestic and wild)
- Camelids (llamas and alpacas)

Breed Predilections

None reported

Mean Age and Range

- Can affect lambs and kids as young as 6 weeks of age but mostly a disease of animals > 3 months
- Generally found in higher prevalence in adults than in young stock

Predominant Sex

None reported

HISTORICAL FINDINGS

- Most commonly, producers will report finding a lump under the skin or a ruptured abscess.
- Many abscesses may be missed because of long wool or hair coat.
- Occasionally, an adult may present with chronic weight loss with no external evidence of disease.
- Less commonly, an affected animal may present with respiratory difficulty from either an enlarged retropharyngeal lymph node or from extensive involvement of the respiratory system.
- Rarely an animal may present acutely off-feed and with cellulitis at the site of primary infection.
- Occasionally, an animal is found dead with no previous signs of disease, although there is usually a history of disease in the flock or herd.
- Although most cases of the disease do not adversely affect the general health of the animal, owners may be very concerned with the negative aesthetics of the sight of draining abscesses, particularly in purebred show sheep.

PHYSICAL EXAMINATION FINDINGS

- Affected animals are generally bright, alert, afebrile, and have a good appetite.
- The external abscess is initially discreet, cool, and firm to the touch, but as it matures it becomes soft.
- Prior to rupture, the hair is lost from the center of the lesion and the overlying skin thins.
- The purulent matter expressed from the abscess is thick, cream colored to slightly green, and has no discernable odor.
- Abscesses in sheep often have several concentric layers like an onion skin, but in goats, this feature is absent.
- When the abscesses affect the internal organs, physical findings are nonspecific. Often even with severe pulmonary involvement, there are no signs referable to the respiratory system.
- Animals with chronic wasting due to CLA will often be afebrile but have unexplained weight loss. Appetite is variable.
- Rarely animals experience acute swelling and pain with a high fever (>40°C) when initially infected. It is believed that this is due to the effects of the PLD exotoxin.
- At the flock level, decreased weight gains and wool growth have been reported.

CAUSES

- The bacteria *Corynebacterium pseudotuberculosis*, a small gram-positive rod, is the only etiology of CLA.
- *C. pseudotuberculosis* is a facultative intracellular parasite and produces PLD exotoxin.
- There are two biotypes classified on nitrate requirements: those isolates that are nitrate negative are responsible for CLA, as well as some cases of ulcerative lymphangitis in cattle; those that are nitrate positive are the etiologic agent of ulcerative lymphangitis of horses. Nitrate positive isolates do not cause disease in sheep and goats.
- The bacteria can survive several days in water, several weeks on fomites such as wooden feeders, and several months in soil. Cool moist conditions improve its survival.

RISK FACTORS

- Gathering the flock for shearing allows transmission of the bacteria by coughing (pulmonary abscesses).
- Nicking an abscess during shearing contaminates the shears, thus allowing transmission to others shorn later. Shearers that do not clean their equipment or clothing between flocks have been shown to bring the disease to unaffected flocks.
- Broken or abraded skin, which can occur during shearing, increases the risk of transmission, although the bacteria can penetrate unbroken skin.
- Draining abscesses that contaminate feed, water, and feeders are an important source of infection.
- Fighting between rams or bucks has also been shown to transmit the bacteria.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- External abscesses
 - Many bacteria cause abscesses that may or may not be associated with a lymph node.
 - Most common in sheep and goats are abscesses of the cheek or jaw associated with trauma from feed, although any trauma may result in an abscess. A wide variety of bacteria has been isolated from these including anaerobes (e.g., *Fusobacterium necrophorum*), *Mannheimia haemolytica*, *Staphylococcus aureus*, many species of streptococci, and *Escherichia coli*. They may have a watery content, with or without gas, and a foul odor and often do not involve a lymph node.
 - Sterile abscesses are found in about one-third of animals recently vaccinated with a multiway clostridial vaccine.
 - Abscesses on the back of the neck are often caused by sheep crawling under wooden feeders that then become infected secondarily with *S. aureus*.
- Chronic wasting
 - Diseases in which a few individuals in the flock are clinically affected: dental disease; competition; paratuberculosis; ovine progressive pneumonia (OPP), also known as maedi visna (sheep); caprine arthritis; encephalitis (goats); and scrapie
 - Diseases in which a large proportion of the flock is clinically affected: gastrointestinal parasitism, nutritional deficiency
 - Respiratory disease: Bacterial pneumonia, lung worm (*Dictyocaulus viviparus* or *Muellerius capillaris* in goats only), sheep pulmonary adenomatosis, transmissible nasal carcinoma
 - Lymphosarcoma may present as external and/or internal masses, cause chronic wasting, and/or be space occupying in the thorax.

CBC / BIOCHEMISTRY / URINALYSIS

Generally, no specific abnormalities are seen.

OTHER LABORATORY TESTS

- Culture of abscess prior to rupture. This is best done by using a sterile needle and syringe to aspirate, or by lancing the abscess with a sterile scalpel and collecting abscess material in a sterile container. Submit for routine culture.
- Serology. A variety of serological tests has been developed to detect antibodies to important antigens. Most commonly the tests detect antibody to PLD, for example, the synergistic hemolysin inhibition (SHI) test and many different ELISA tests. Sensitivity on a flock basis is good but only fair on an individual animal level, likely because the bacteria are walled off after initial infection. Titers may be higher and more persistent in goats than in sheep. Vaccines that contain PLD toxoid interfere with interpretation, (i.e., reduce specificity).
- IFN gamma ELISA. Using whole blood, this assay detects CMI. Response does not appear to decrease with time postinfection and vaccination will not interfere with interpretation.

IMAGING

In cases of chronic wasting or respiratory disease: ultrasound or radiograph of the thorax will reveal number and size of abscesses affecting the respiratory system.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Abscesses may occur in any lymph node or visceral organ. Routine culture will determine if *C. pseudotuberculosis* is the causative agent.
- In cases of sudden death, cut down the trachea and bronchial tree to check for evidence of an abscess rupturing into and occluding an airway.

TREATMENT

APPROPRIATE HEALTH CARE

- No treatment regime has been shown to influence the course of disease.
- Many months or years may pass between abscess events in an animal, but once an animal exhibits an abscess, it should

be considered to be infected for life.

- Although the bacterium is sensitive to many antibiotics, including penicillin, abscess formation prevents effective therapy.
- To hasten recovery and prevent contamination of the environment, isolate animals with abscesses until healed.
- Isolation facility should have the following features:
 - No shared waterer or feeder with other animals
 - Ideally, in a separate air space
 - Pen must be dedicated to housing animals with abscesses (e.g., not used for lambing or for housing animals sick with another disease)
- Lance abscess with sterile scalpel blade when it becomes soft. Wear disposable gloves. Catch all material in a container (e.g. rectal sleeve) to prevent environmental contamination. Clean abscess wound with iodine or chlorhexidine. Repeat twice per day until wound is scabbed and dry. In cases of chronic and/or repeated episodes of abscess development, strongly consider culling so as to reduce the risk of infection of the rest of the flock or herd.

NURSING CARE

Keep in isolation pen until abscess is healed

ACTIVITY

N/A

DIET

N/A

CLIENT EDUCATION

CE needs to focus on what a diagnosis means to the flock/herd so that control measures can be instituted as quickly as possible. See Prevention/Avoidance section below.

SURGICAL CONSIDERATIONS

- Retropharyngeal abscesses may be surgically drained under anesthesia if animal value warrants it.
- Surgical removal of an external lymph node has been done in selected cases.

MEDICATIONS

DRUGS OF CHOICE

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

If the owner elects not to cull, the animals should be checked at least once / month for new abscesses.

PREVENTION/AVOIDANCE

A control program is based on:

- Reduction of environmental contamination with the bacteria:

- Routine palpation of external lymph nodes whenever sheep and goats are handled
- Isolation of affected animals and appropriate treatment
- Disinfection of shearing blades and pieces whenever an abscess is nicked
- Routine washing of hands with chlorhexidine soap when handling infected animals
- Use feeders that reduce contact of the head and neck with the feeder (e.g., bars or keyhole feeders).
- Cull all affected animals if economics allow.
- Cull all repeat offenders.
- Reduction of risk of transmission to uninfected animals:
 - Rear young stock away from adults (e.g., remove at birth and rear artificially in another barn).
 - Shear young sheep first and older and infected sheep last.
 - Milk affected does last and wash down parlor with disinfectant afterward.
 - Limit purchases of breeding stock from flocks of unknown health status.
 - Shearers should wear clean clothing (including footwear) that has not been worn to another flock without laundering. For best biosecurity, producers should purchase their own shearing equipment.
 - Treat all shearing wounds immediately with iodine or other topical disinfectant.
- Improve the immune status of uninfected animals:
 - Commercial vaccines that contain PLD toxoid and some cell components are licensed for use in sheep but not goats. The vaccines are marketed as a combined clostridial-CLA vaccine.
 - The vaccine works best if administered before chance of infection and after colostral immunity has waned (around 3 months of age).
 - A vaccination program involves vaccination of young stock with a primary series (e.g., vaccinate at 3 and 4 months of age) and an annual booster.
 - For breeding ewes, this annual booster can be administered 1 month prior to lambing, so as to optimize transfer of colostral immunity to offspring.
 - The vaccine will not cure existing infections and works best when combined with other control measures as it will reduce risk of infection but will not totally prevent. Routine vaccination, when combined with culling of affected sheep, can reduce flock prevalence to < 2% (cull ewes at the abattoir).
 - Vaccine efficacy may be improved by increasing the frequency of vaccination to every 3 to 6 months, particularly if sheep and goats are housed all or part of the year.
 - No vaccine is licensed for use in goats and some cause adverse reactions in goats that are already infected, so extreme caution should be used when vaccinating this species.
 - Autogenous vaccines have been employed in the past, but if the PLD toxin is not totally inactivated, severe illness and death may occur.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Most infected animals do not experience severe disease.
- The disease is more important at the herd level where it can cause chronic wasting, sudden death, premature culling, and carcass condemnation and trim.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

C. pseudotuberculosis infection of humans has been reported but is not common. Suppurative granulomatous lymphadenitis

may occur secondary to wound contamination when treating or handling infected animals or contaminated materials. It is important to wear gloves when lancing abscesses and wash hands with chlorhexidine soap after treating this disease.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Primarily sheep and goats and less common camelids; llamas are most often reported as they are used frequently as guard animals with sheep.

CASTOR BEAN TOXICITY

BASICS

OVERVIEW

- Castor bean, or palma christi (*Ricinus communis*), is grown for the commercial production of castor oil.
- The leaves are large, mottled, and usually a light brown; seeds resemble engorged ticks and weigh approximately 0.3 g each.
- The castor bean is a semiwoody plant with large, alternate, starlike leaves that grows as a tree in tropical regions and as an annual in temperate regions. Its flowers are very small and inconspicuous. Its fruits grow in clusters at the tops of the plants.
- All parts of the plant are very poisonous to eat.
- The poisonous principle of castor beans is ricin, a water-soluble, proteinaceous material that is concentrated in the seeds.
- This plant is found in all tropical regions and has been introduced to temperate regions.
- The plant can be found in any location in North America.

SYSTEMS AFFECTED

Gastrointestinal, CNS, cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Potentially worldwide, depending on the environment

SIGNALMENT

Species

- All animals
- Sheep and cattle are more resistant to its effects.
- Humans and horses are most susceptible.

Breed Predilections

N/A

Mean Age and Range

N/A

SIGNS

- There is a characteristic latent period from ingestion to onset of clinical signs, which can be as long as 2–3 days.
- Acute signs are seen when large quantities are ingested.
- Profuse catarrhal to hemorrhagic diarrhea (cattle)
- Neuromuscular signs may be observed and include a swaying gait, recumbency after brief exercise, and muscle tremors. Increased salivation and exaggerated chewing may be observed.
- Depression
- Seizures can occur.
- Increased thirst (polydipsia)
- Colic
- Elevated heart rate and/or temperature

- Clinical signs are progressive and may increase in severity with time.

CAUSES AND RISK FACTORS

- The seed is one source of toxicity. It has a hard capsule and has little taste unless the coat is broken.
- Ricin, the active principle of the seed, belongs to the group of plant toxins known as phytotoxins and is absorbed from the intestine.
- Phytotoxins are found in all parts of the plant but seeds are especially toxic.
- Heat reduces but does not eliminate the toxicity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of enteritis

CBC/BIOCHEMISTRY/URINALYSIS

Leukopenia with a marked left shift and an elevated PCV has been detected approximately 10 hours postingestion.

OTHER LABORATORY TESTS

- Microscopic examination for castor seeds
- Hemagglutination test
- Precipitin test on extracts of excreta or intestinal contents

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Gut contents are fluid or semifluid.
- Hemorrhages on the serosal and mucosal surfaces of the stomach, intestines, and bladder
- Hepatic necrosis
- Enlarged mesenteric lymph nodes
- Liver, lung, and spleen are all affected—may appear edematous upon postmortem examination.

TREATMENT

- Specific antiserum is the ideal antidote.
- GI decontamination may be useful.
- Symptomatic treatment
- Adequate nursing care for recumbent animals

MEDICATIONS

- Maintain body fluid and electrolyte balance
- Sedatives
- Arecoline hydrobromide followed by saline cathartics may be helpful.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered.

CECAL DILATION AND VOLVULUS

BASICS

DEFINITION

- Cecal dilation is primarily a disease of high-producing adult dairy cattle occurring within the first 1–2 months postpartum.
- It is believed to share similar epidemiologic and physiologic characteristics as abomasal dilation and displacement, however research may challenge this relationship.
- Cecal dilation is also reported in calves less than 6 months of age, the majority of which are fed high-concentrate diets for purposes of early slaughter.

PATHOPHYSIOLOGY

Cecal Dilation

- The presence of excess gas from the digestion of fermentable substrates and decreased intestinal motility
- When animals are fed diets high in concentrates and containing inadequate roughage, high levels of fermentable carbohydrates pass beyond the forestomachs into the lower intestine. Lower intestinal flora digest the excess carbohydrates into volatile fatty acids (VFAs), methane, and carbon dioxide. Increased VFAs present in the cecum and ascending colon are believed to cause a reduction in intestinal motility.
- Decreased intestinal motility may also result from decreased levels of ionized calcium.

Cecal Volvulus

The exact cause of cecal volvulus is unknown, however it is believed to be predisposed by, and therefore be a sequela to, the occurrence of cecal dilation.

SYSTEMS AFFECTED

Mean Age and Range

Adult cattle within 2 months postpartum

Predominant Sex

Female

SIGNS

HISTORICAL FINDINGS

- Cattle suffering cecal dilation typically present with mild to moderate anorexia and decreased milk production.
- Cattle suffering cecal volvulus typically demonstrate abrupt anorexia, rumen stasis, and significantly decreased milk production.

PHYSICAL EXAMINATION FINDINGS

- Cattle with cecal dilation have an area of increased resonance (“ping”) that is auscultated over the right paralumbar fossa. The right paralumbar fossa may be distended, and cattle may exhibit mild to moderate signs of abdominal pain.
- Fecal output is normal to decreased and fecal consistency is typically more fluid.
- During rectal examination, a gas distended cecum is usually palpable with the apex located in or near the pelvic inlet.
- Cattle with cecal volvulus have moderate to severe abdominal pain (colic).
- Animals are often tachycardic and tachypneic, and produce little to no feces.
- Rectal examination usually reveals a markedly distended cecum containing both gas and fluid. The apex of the cecum is often not palpable as it is positioned cranially. The area of resonance in the right paralumbar fossa is generally much larger than that noted with simple cecal dilation. Increased resonance may even be noted over the caudal dorsal left paralumbar fossa.
- Mild to moderate anorexia and decreased milk production are commonly seen.

CAUSES/RISK FACTORS

Postpartum cattle fed low-roughage, high-concentrate diets are predisposed, also, those suffering from hypocalcemia, metritis, mastitis, or indigestion that could result in gastrointestinal ileus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Right displaced abomasum or abomasal volvulus, small intestinal obstructions, intussusception

CBC/BIOCHEMISTRY/URINALYSIS

- Serum biochemical profile, blood gas analysis, and complete blood count are typically unremarkable, though a stress leukogram may be observed in cecal dilation cases.
- Depending on the severity and duration of cecal volvulus, cattle may present with moderate to severe acid-base and electrolyte derangements. Hypochloremic, hypokalemic metabolic alkalosis is most commonly observed, however, mixed acid-base abnormalities (concurrent metabolic acidosis and alkalosis) can also occur.

OTHER LABORATORY TESTS

N/A

IMAGING

Ultrasonography via the right abdominal wall at the level of the tuber coxae may be useful in the diagnosis.

DIAGNOSTIC PROCEDURES

Rectal palpation

PATHOLOGIC FINDINGS

N/A

TREATMENT

APPROPRIATE HEALTH CARE

- Cecal dilation is usually treated successfully via medical management. Large volumes (20 liters) of oral fluids containing electrolytes (8 oz NaCl, 2 oz KCl), calcium (12 oz calcium propionate), and cathartics (12 oz Mg-hydroxide, Mg-sulfate) can be given one to two times daily. Intravenous fluids can also be administered.
- Transfaunation with rumen liquor (10–20 liters) can be used to stimulate rumen motility and appetite. Finally, intravenous or subcutaneous calcium borogluconate solutions (20 grams in 500 ml) can be useful in lactating cows.

ACTIVITY

N/A

DIET

Animals should be provided access to a palatable, coarse, high-fiber diet.

CLIENT EDUCATION

Warranted in cases that are induced by inappropriate diet

SURGICAL CONSIDERATIONS

- In cattle with recurrent cecal dilation, preventative typhlectomy may be indicated.
- Cattle with cecal volvulus typically require surgical intervention along with appropriate fluid therapy to correct fluid, acid-base, and electrolyte abnormalities. A right paralumbar approach is typically used. Decompression via typhlotomy may be necessary to remove excess fluid and gas and to facilitate correction of a volvulus. In the event that ischemic necrosis is severe, a typhlectomy may be required.

MEDICATIONS

DRUGS OF CHOICE CONTRAINDICATIONS POSSIBLE INTERACTIONS ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Increased appetite and milk production with manure production are all good signs that treatment is working.

PREVENTION/AVOIDANCE

Pre- and postpartum management of dairy cattle to maximize adequate intake of a forage-based diet, minimize infections of the uterus and vagina by calving in a clean environment, and minimizing the risk of gastrointestinal upset

POSSIBLE COMPLICATIONS

Cecal torsion leading to rupture and peritonitis in severe untreated cases

EXPECTED COURSE AND PROGNOSIS

- For patients with normal heart rate, some manure production, a small appetite, no dehydration, and minimal abdominal distension, medical treatment is usually successful.
- Patients with elevated heart rates, no appetite or manure production, dehydration, and a distended abdomen with colic signs, surgery is indicated. Prognosis depends upon the degree of ischemic compromise to the cecum and adjacent bowel, successful correction of acid-base and electrolyte derangements, and appropriate surgical technique.
- Postsurgical prognosis is dependent on the degree of ischemic compromise to the cecum and adjacent bowel, successful corrections of acid-base and electrolyte derangements, and appropriate surgical technique.

CERVIDAE TUBERCULOSIS (MYCOBACTERIUM BOVIS)

BASICS

OVERVIEW

- A common problem that affects the captive and wildlife deer population is the presence of *Mycobacterium bovis*, otherwise known as tuberculosis.
- Deer seem to show an increased sensitivity to mycobacterial infections compared to other animals; thus, the ramifications of this disease are higher.
- In the United States, most notably in the northern parts of Michigan, the deer serve as a reservoir host of *M. bovis*. This makes eradication of this disease among domestic livestock and other wildlife impossible since the tuberculosis cannot be controlled among the wildlife population.
- *M. bovis* is also a zoonotic disease that can affect humans, so a correct diagnosis is critical when tuberculosis is suspected.
- The most common lesions are found in the medial retropharyngeal lymph nodes and the thorax. In many situations, hunters submit the head of the deer for a tuberculosis diagnosis so that the medial retropharyngeal lymph nodes may be inspected (among other cranial lymph nodes).

SIGNS

N/A

HISTORICAL FINDINGS

- There are differences in host response to *M. bovis*.
- The New Zealand red deer tends to produce external draining sinuses from the infected lymph nodes. This fluid is most likely responsible for the transmission of the disease. In contrast, white-tailed deer were not found to have draining lesions, thus they lack this mode of transmission. Other bodily fluids, such as saliva, nasal secretions, urine, and feces, were found to be contaminated with *M. bovis* in white-tailed deer.

PHYSICAL EXAMINATION FINDINGS CAUSES AND RISK FACTORS

- *M. bovis* is a gram-positive rod-shaped bacterium.

- Tuberculosis in deer can be seen as a pulmonary disease, where the bacteria are inhaled and proliferate into a focal region.
- The bacteria may also seed into a lymph node and spread via the lymphatic system. This infection can cause rapidly disseminated tuberculosis, which causes an acute disease.
- *M. bovis* may lie dormant and become reactivated in the face of an immunocompromised state. Once it becomes reactivated, it progresses to the disseminated form.
- Its modes of transmission include inhalation or ingestion.
- One study suggests that *M. bovis* persists in the tonsillar crypts for prolonged periods of time. Thus, *M. bovis* may be shed into the saliva and nasal secretions. These secretions serve as sources of transmission to other animals and humans.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Progressive pneumonia
- Caseous lymphadenitis lesions
- Other causes of chronic respiratory disease—chronic lung abscesses, aspiration pneumonia
- Other causes of chronic weight loss and ill thrift—Johne's disease, parasitism

CBC/BIOCHEMISTRY/URINALYSIS

There are no specific clinical pathology data typical for this disease in cervidae.

OTHER LABORATORY TESTS

IMAGING

Depending on the location of the suspected lesion, radiography and ultrasonography may demonstrate the presence of tubercles within the body and are used to evaluate the extent of the infection.

OTHER DIAGNOSTIC PROCEDURES

- If tuberculosis is suspected in deer, there are several ways to diagnose the disease.
- The intradermal tuberculin test is widely used to diagnose tuberculosis among cattle; the injection is normally placed in the caudal tail fold. This location is not reliable in the deer, whereas the single cervical tuberculin test (SCT) has proven to be more diagnostic. If the deer responds positively to the injection, then it is retested with the comparative cervical tuberculin test (CCT).
- The CCT consists of injecting both bovine purified protein derivative and avian purified protein derivative. The response to both injection sites is compared.
- Another option besides the CCT is the blood tuberculosis test (BTB), a test that has been reported with > 95% sensitivity and > 98% specificity.
- Other immunodiagnostic tests include the lymphocyte transformation test, ELISA, gamma interferon assay, and the Ag85 blot immunoassay.
- If there is a positive reaction to either the CCT or BTB, then that animal is classified as a reactor.
- All herds that contain a reactor are immediately quarantined and/or depopulated.

PATHOLOGIC FINDINGS

- A Michigan study on tuberculosis lesions in white-tailed deer counted 58 positive cultures for *M. bovis* out of 19,500 total samples. In the majority of the samples, only the head was submitted. The rest of the samples consisted of the extracranial portions of the deer carcass.
- The cranial gross lesions were mostly found in the medial retropharyngeal lymph nodes. In addition, solitary unilateral parotid lymph node lesions were found. Extracranially, most of the lesions were in the thoracic region.
- Other sites included the liver, spleen, rumen, and mammary gland.
- In another study conducted in New Zealand, *M. bovis* was isolated from 14 of 116 deer. Nine out of the 14 had lesions consistent with tuberculosis (medial retropharyngeal lymph node and lung were mostly affected). However, 5 out of the 14 had no gross lesions, yet *M. bovis* was cultured. This study indicated that examination of only the lymph nodes and the lungs could significantly underestimate the prevalence of tuberculosis among the deer population.
- Disease manifestation varies by the cervid species involved. One study compared lesions from cattle, fallow deer, Sitka

deer, and elk (red deer). Elk lesions showed scattered peripheral mineralization rather than central mineralization. These lesions also contained more neutrophils and fewer giant cells than the bovine lesions. The fallow deer lesions showed more giant cells; otherwise, the lesions were similar to the elk/red deer lesions. The Sitka deer lesions had more giant cells, but fewer neutrophils than the bovine lesions. The giant cells were also larger and contained more nuclei than the giant cells of other species. These histopathological differences could perhaps serve as aids in diagnosis.

TREATMENT

- Since tuberculosis is a contagious disease of both animals and humans, the most effective and recommended way of handling this disease is by control and eradication (test and slaughter).
- There have been only isolated incidents where treatment was attempted on exotic herds. The treatment consisted of a three-drug regimen of isoniazid, rifampin, and ethambutol.

ALTERNATIVE DRUGS

FOLLOW-UP

PATIENT MONITORING

PREVENTION/AVOIDANCE

- Usually, treatment is not warranted. The only practical steps to take are control and prevention.
- A vaccine for tuberculosis has not been produced.
- A test and slaughter method could be used for captive deer, but this would not be possible among free-roaming deer.
- One management goal is to decrease deer density, which would in effect also decrease the amount of deer-to-deer transmission.
- Decreasing the amount of supplemental feeding that occurs during the winter months could greatly decrease the deer density. Supplemental feeding causes an increase in the number of deer that tend to congregate in one area.
- Transmission through aerosol or contaminated feed could easily occur, thus eliminating supplemental feedings should help decrease transmission.

POSSIBLE COMPLICATIONS

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Tuberculosis in deer can be seen as a pulmonary disease, where the bacteria are inhaled and proliferate into a focal region.
- The bacteria may also seed into a lymph node and spread via the lymphatic system. This infection can cause rapidly disseminated tuberculosis, which causes an acute disease.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

- Cervidae tuberculosis is zoonotic. Care must be taken in the collection of laboratory samples and the diagnosis of affected animals.
- The presence of tuberculosis within the deer population, wild and captive, poses a major health concern.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

All cervid species can be affected.

BIOSECURITY

- Isolation and quarantine of new stock entering the herd/flock
- Test and cull reactor animals prior to herd introduction.

PRODUCTION MANAGEMENT

- When cleaning a facility after the elimination of positive reactors, the facility can be decontaminated using 2% cresylic compounds or phenol derivatives. Before repopulating the facility, it is recommended to disinfect twice at 14- to 21-day intervals.
- All personnel involved with the facility and deer handling should wear respirator masks and be properly tested for tuberculosis.

CESAREAN SURGERY: INDICATIONS

BASICS

DEFINITION

- A cesarean operation is a surgical procedure whereby the fetus is removed from the uterus through an abdominal and uterine incision in the dam.
- The operation is indicated when vaginal delivery is impossible or cannot be done without causing fetal death or damage to the maternal reproductive tract.

PATHOPHYSIOLOGY

- The indications for a cesarean operation for cattle are similar to other species.
- There is an inability to deliver the fetus vaginally due to a fetopelvic disproportion, dead or emphysematous fetus, failure of the cervix to dilate, fetal malposture, fetal monster, or uterine torsion that cannot be corrected manually.
- An elective cesarean operation can be undertaken when severe preparturient conditions exist, such as ketosis, fetal dropsy, prolapse of the vagina, or to deliver valuable fetuses from small recipients in cases of embryo transfer.
- The operation can be performed in dams that carry a live or dead fetus. However, when the fetus is dead, the clinician must weigh the risk of complications such as peritonitis in comparison to performing a fetotomy. In the author's experience, a fetotomy is indicated in the case of a decomposed or emphysematous fetus.

SYSTEMS AFFECTED

- Endocrine/metabolic
- Herd health
- Musculoskeletal
- Reproductive

GENETICS

- Bulls whose daughters have too small a pelvis to deliver calves of normal size or those whose offspring are oversized in comparison to the breed average.
- Small breeds of goats such as the French Alpine.

INCIDENCE/PREVALENCE

- The incidence varies according to clinician preference in performing a fetotomy versus a cesarean in cases where the fetus is dead.
- About 5%–7% of dystocia cases in dairy cattle and goats are delivered via a cesarean. In beef cattle, the figure is slightly higher.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Bovine, ovine, caprine

Breed Predilection

- The overall incidence of dystocia varies with the species and with breeds within species.
- The bovine species is most often affected but ewes and does when carrying twins may show a high incidence.
- In the Belgian blue cattle breed, 80% of parturitions are delivered by cesarean.

Mean Age and Range

Similar to dystocia the incidence of cesarean operation is higher in primiparous than in multiparous animals.

SIGNS

GENERAL COMMENTS

- Defects in the components of the parturition process, the expulsive forces, the birth canal, fetus, and torsion of the uterus must be considered when assisting a case of dystocia.
- Before proceeding with a cesarean section, the clinician must be comfortable that the fetus cannot be delivered manually or by forced extraction after following the guidelines to determine whether or not the fetus can be delivered vaginally.

HISTOPATHOLOGICAL FINDINGS

- Lack of progress after initiation of parturition
- Continuous violent abdominal contractions without visualization of fetal parts.
- Unsuccessful attempts by either an owner or herdsman to deliver the calf.

PHYSICAL EXAMINATION

First, a vaginal exam must be performed to determine the presentation, position, and posture of the calf within the birth canal. Second, malposition or malpresentation is corrected and calf viability is determined. Last, the clinician should attempt to deliver the calf and determine whether or not a vaginal delivery is possible after applying the appropriate guidelines for either an anterior or posterior presentation.

RISK FACTORS

- Obesity
- Twins
- Hypocalcemia
- Small frame size
- Small pelvic diameter
- Large calf

DIAGNOSIS

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGICAL FINDINGS

In cases of dystocia caused by hydroallantois, adventitial placentation is commonly found.

TREATMENT

APPROPRIATE HEALTH CARE

A cesarean procedure is a surgical case that may require hospitalization. However, most procedures are performed on-farm provided that there are suitable restraining or handling facilities and that appropriate care can be given to the patient.

NURSING CARE

Administration of postsurgical treatments such as antibiotics, ecbolic agents, energy and calcium supplements. Appetite, vaginal discharge, and temperature should be assessed regularly.

ACTIVITY

No restrictions

DIET

No restrictions

CLIENT EDUCATION

- Management practices to prevent risk factors for dystocia
- Training in observation strategies and techniques for prompt and correct diagnosis of dystocia

SURGICAL CONSIDERATIONS

- The surgical approach for a cesarean depends on the experience of the clinician, facilities, cause of the dystocia, and condition of the dam and fetus.
- The surgical risk is greatly increased when the patient is recumbent in mud or other inconvenient situations. Preferably, the surgery should be performed in a location of the farm or stable that offers less risk for complications.
- The surgical instruments listed below are recommended:
 - 4 to 12 towel clips
 - A scalpel
 - 6 to 10 hemostats
 - A needle driver
 - 2 pairs of Glock's uterine forceps
 - Blunt-point scissors
 - 2 pairs of Allis peritoneal forceps
 - Rat-toothed forceps
 - 2 short obstetrical chains and handles
 - No. 3 or 4 chromic catgut or polyglycolic acid suture material
 - Size 4 silk nonabsorbable suture
 - Suture needles
 - Iodine-based solution for surgical scrub
 - Alcohol
 - 4 × 4 cotton gauzes (30)
 - Bucket with antiseptic for the chains and handles
- There are three main approaches for the cesarean operation in the cow: left flank, ventrolateral, and ventral midline.
- Routine surgical procedures should be followed when incising the flank or abdomen and entering into the peritoneal cavity. In addition, the following surgical considerations are important:
 - Epidural anesthesia with 2% lidocaine hydrochloride can be used to obviate abdominal contractions that are usually present.
 - The skin incision in the flank or abdomen should be located in a site where the uterus is accessible, and should be long enough to remove the fetus through it.
 - Exteriorize the gravid uterine horn into the incision site as much as possible.
 - Make the uterine incision in the greater curvature, avoiding incising a placentome, and make it large enough to extract the fetus without causing tearing.
 - Close the uterus using an absorbable suture with a continuous inverting pattern such as the Cushing and the Lembert patterns or the Utrecht uterine suture pattern, which is a modified Cushing.
 - A single layer is sufficient if the uterine wall is healthy and not septic.
 - Placental tissue should not be included in the suture.
 - The muscle layers and skin are sutured in a routine fashion.
 - Administer 2–40 U/kg of oxytocin postoperatively to help expel the placenta.
- Cesarean procedures in sheep and goats can be done with general anesthesia. However, most clinicians prefer to position the ewe/doe in right lateral recumbency with rope restraint and perform the incision through a left flank approach and a local anesthesia similar to that in cows. The incision is made in vertical direction in the left flank paralumbar fossa.
- Multiple births are common in sheep and goats and they can be delivered through the same uterine incision. However, an incision in the contralateral horn is often necessary.

- Keep in mind: goats are more sensitive to lidocaine and xylazine than are cows.
- The same surgical considerations and postoperative care given to cows should be followed for sheep and goats.
- Paravertebral anesthesia can be used to desensitize the paralumbar fossa if a left flank approach is selected.
- Local anesthetic solution can also be injected subcutaneously and deep into the abdominal musculature dorsal and cranial to the proposed incision site in the shape of an inverted L.
- In addition, a line block can also be used in a similar fashion desensitizing the proposed incision site. As much as 50 ml of lidocaine may be required in the mature cow depending on the incision length.

MEDICATIONS

DRUGS OF CHOICE

- The drug of choice for desensitization of the incision site is lidocaine. A balance anesthetic plane can be achieved by using xylazine at a dose of 0.02 mg/kg (bovine dose) in conjunction with the lidocaine blocks.
- A variety of broad-spectrum antibiotics are recommended postsurgically to prevent peritonitis and septic conditions. Label recommendations to avoid antibiotic residues in saleable milk should be followed when systemic antibiotics are used.
 - Penicillin or a synthetic analog: 20,000 to 30,000 U/kg bid
 - Ceftiofur: 1–2.2 mg/kg bid
- Some cases may require supportive treatment with fluids, electrolytes, and anti-inflammatory agents.

CONTRAINDICATIONS

- Xylazine may induce uterine contractions and make exteriorization of the gravid uterine horn difficult.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

If the operation is performed on a standing animal, care must be taken not to overdose with lidocaine in the epidural or xylazine for sedation, to prevent the animal from becoming recumbent.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

Acetylpromazine maleate at a dose of 0.044–0.088 mg/kg IM or IV can be used to achieve sedation. However, acetylpromazine is generally not recommended in ruminant species due to its negative effect on rumen motility and subsequent bloat.

FOLLOW-UP

PATIENT MONITORING

Animals should be monitored for signs of septicemia and peritonitis.

PREVENTIVE AVOIDANCE

- Proper management of the prepartum cow
- Genetic considerations to help reduce fetal size
- Training of farm personnel in proper observation of preparturient animals.

POSSIBLE COMPLICATIONS

- Peritonitis
- Wound dehiscence
- Retained fetal membranes
- Toxic metritis
- Incision site abscess
- Uterine adhesions

EXPECTED COURSE AND PROGNOSIS

- Survival depends on the degree of uterine-content contamination of the peritoneum, closure of the uterine wall, and overall surgical technique. In addition, cows placed on systemic antibiotics have a more favorable prognosis.
- A recovery rate of 70% should be expected in uncomplicated cases. However, the majority of cows that have a cesarean operation experienced reduced fertility postpartum.

CHLAMYDIOSIS

BASICS

DEFINITION

Chlamydia are intracellular bacteria that constitute one of the most important causes of small ruminant abortion in most parts of the world (also denoted enzootic abortion of ewes) as well as a number of other disease syndromes in sheep, goats, cattle, and llamas.

OVERVIEW

- Chlamydiosis may occur as a variety of disease syndromes, depending on the strain of *Chlamydia* and the animal species involved.
- The most important of these are reproductive diseases
 - Third-term abortion, endometritis, and infertility in females
 - Orchitis and seminal vesiculitis in males
- Other diseases include pneumonia, enteritis, encephalomyelitis, polyarthritis, and conjunctivitis.
- Infection may be unapparent or present with severe clinical disease affecting most of the herd or flock.
- Two distinct *Chlamydia* species have been implicated in ruminant disease: *Chlamydophila abortus* (previously *Chlamydia psittaci* biotype I) and *Chlamydophila pecorum* (previously *Chlamydia pecorum*).
- Aborted fetuses, placentas, and uterine discharges are the main sources of *C. abortus* infections.
- In-utero infection may lead to fetal death or perinatal disease.
- Although cattle strains may infect sheep and goats and vice versa, avian *Chlamydia psittaci*, strains from humans, cats, and other mammals are not generally associated with disease in ruminants.
- *C. abortus* is zoonotic and has been reported to cause abortion in women.

PATHOPHYSIOLOGY

- *Chlamydophila abortus* strains are invasive as opposed to *C. pecorum*, which tends to colonize mucosal surfaces causing clinically inapparent or mild local infections.
- Both strains may be harbored in the alimentary tract and transmitted through feces, although the main source of *C. abortus* is aborted infected tissues and fluids.
- Infection is usually oral-nasally after which proliferation in the lymphoid tissues and the gastrointestinal mucosa leads to *Chlamydia* that are usually cleared after 7–10 days.
- Inhibition of chlamydial replication by the immune system may keep the disease quiescent until past midpregnancy when hormonal changes or immunosuppression are thought to permit replication in the placental trophoblasts.
- The production of proinflammatory chemokines, cytokines, and other modulators by the infected cells seems to be the cause of increased chlamydial proliferation and the intense tissue reactions that lead to necrotizing lesions.
- Migration of the bacteria from the placenta to the fetus induces fetal pathology that may culminate in abortion or the premature birth of weak lambs.
- Chlamydial invasion of the endometrial epithelium results in endometritis characterized by necrosis and mucosal sloughing.
- In cases of polyarthritis, the inflammatory reaction in the synovium, tendon sheaths, and subsynovial tissues induces fibrosis and both articular and periarticular damage.
- In young calves and lambs, diffuse interstitial bronchopneumonia may be seen with thickened alveolar septae and focal neutrophilic bronchiolitis and alveolitis. Disease is often concurrent with other pathogens, which exacerbate the syndrome.
- Sporadic bovine encephalitis (SBE) results from generalized chlamydial infection. Inflammation of the vascular endothelium, mesenchymal tissue, and most serosal membranes leads to organ damage, while nervous signs are a result of brain edema and hyperemia.

SIGNALMENT

- Chlamydiosis in ruminants has been reported in most parts of the world. In New Zealand, the disease has not been described, and in Australia, abortion from this agent is rare.
- *C. abortus* causes sporadic third-term abortion in cattle or abortion storms after 90 days gestation in sheep and goats.
- All Naïve animals are susceptible, but the strong immunity that develops after abortion will prevent further fetal loss.
- In a newly infected sheep flock, between 30% and 60% of the pregnant animals may abort. Storms of 60%–90% abortions in goats have been reported.

Mean Age and Range

- In an endemic herd or flock, the animals in their first gestation are of highest risk to abort.
- Enteritis, pneumonia, and polyarthritis are generally limited to young stock below 6 months of age with a morbidity ranging from 2% to 75%.

Predominant Sex

N/A

SIGNS

- Third-term abortion storms in sheep and goats; dark red or clay-colored placental cotyledons
- Sporadic abortions in cattle
- Inflammation of the seminal vesicles, epididymitis, or testicles, which may become atrophic
- Stillbirth, perinatal weakness, or death
- Coughing, depression, dyspnea, mucoid or mucopurulent nasal discharge in young stock; may be fever
- Shifting lameness, stiffness, pyrexia, and anorexia; painful joints, which may or may not be swollen but contain grayish-yellow synovial fluid with fibrin clots. Stiffness often seems to improve with forced exercise.
- Hyperemia of the conjunctiva and sclera, serous discharge that may become purulent due to secondary infection; small corneal ulcers may develop.
- SBE is characterized by depression, anorexia, pyrexia, dyspnea, and nasal discharge. Increased salivation and diarrhea may be seen; stiff gait, circling, staggering, and paralysis; up to 60% mortality. Survivors perform poorly.

CAUSES AND RISK FACTORS

- The main sources of *C. abortus* are the fetal membranes, tissues, and uterine discharges of animals that have aborted.
- Both *C. abortus* and *C. pecorum* may be harbored in the alimentary tract and transmitted through feces.
- Venereal spread may be due to infected semen from males with seminal vesiculitis or orchitis.
- Vertical transmission may lead to infected offspring.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Causes of third-term or late gestation abortion associated with placentitis: toxoplasmosis, Q fever, *Campylobacter jejuni* or *C. fetus fetus*, brucellosis, listeriosis, salmonellosis, aspergillosis, leptospirosis
- Generalized stiffness and lameness: Lyme disease, mycoplasmosis, caseous lymphadenitis, infectious or septic tenosynovitis, tendonitis, synovitis, *Histophilus somnii*, louping ill (UK), monensin, lasalocid or ionophore toxicity, white muscle disease, foot-and-mouth, bluetongue
- Diarrheic syndrome in calves: feed related, BVD, salmonellosis, rotavirus, coronavirus, coccidiosis, nematodes
- Keratoconjunctivitis: *Mycoplasma* spp., *Moraxella bovis*, IBR, environmental irritants

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Serology

- Generally, complement fixation (CF), but also ELISA or other methods
- Most labs use MOMP (major outer membrane protein) antigens, which produce serological titers that do not discern between *C. abortus* and *C. pecorum*.
- A large proportion of the ruminant population will exhibit titers without clinical disease.
- Newer synthetic or soluble antigens have been developed that can identify *C. abortus* or *C. pecorum*; not commonly used by most laboratories.
- In most labs, CF titers of 1:16 to 1:32 are considered positive.
- Most animals that have aborted from chlamydiosis will have a titer of 1:80 or higher that peaks 2–3 weeks after abortion.
- Serology is generally not useful for individual animal diagnosis.
- It cannot be used to detect infection in rams or latently infected animals.
- High titers in a group that aborted as opposed to negative or low titers in a parallel group that had normal parturition is indicative of *C. abortus*.
- Serological titers due to vaccination cannot be distinguished from those due to infection.
- Fetal serology, although less sensitive than detection of chlamydial LPS antigen, may be of particular use when placenta is not available.

Culture

Not generally performed for veterinary diagnostic purposes as is only possible in cell culture or embryonated hen's eggs.

Microscopy

Staining by modified Ziehl-Neelsen (Stamp, Gimenez, or Macchiavello) or Giemsa may give a tentative indication but is not specific.

Immunofluorescence/Antigen ELISA

Diagnostic when positive on placentas or other pathological material

PCR

- This test is becoming more common in regional and central laboratories.
- Due to its high sensitivity and the prevalence of fecal and environmental *Chlamydia* species, samples must be taken and processed extremely carefully.
- False negative results may occur due to inhibitors in the samples.

PATHOLOGIC FINDINGS GROSS FINDINGS

- Placenta: raspberry or clay-colored cotyledons, leathery intercotyledonary areas
- Fetus: usually fresh but may be autolyzed. Often excess fluid is seen in the abdominal cavity, as are small necrotic foci in the liver.
- Joints: may be swollen due to periarticular fibrosis and subcutaneous edema, but even in nonenlarged joints, excessive grayish-yellow turbid synovial fluid with fibrin plaques may be present.

HISTORICAL FINDINGS

Abortions

- Grossly, there is thickening and yellow to red-brown discoloration of the placenta, especially in the intercotyledonary areas; necrotizing vasculitis and thrombosis with mononuclear and neutrophilic infiltration.
- Microscopically, necrotizing placentitis is accompanied by nonsuppurative vasculitis. There are no specific gross postmortem lesions in the fetus, but nonsuppurative meningoencephalitis, necrotizing hepatitis, and proliferation of mononuclear cells in spleen and lymph nodes may occur.

Polyarthritis

Synovial joint fluid is nonpurulent and may be off-color with flakes of fibrin. There is no change to the cartilage, and mononuclear cells predominate in the synovial fluid. The tendon sheaths and subsynovial tissues exhibit primarily an inflammatory reaction, which extends to involve the synovial membranes.

Pneumonia

- Bronchopneumonia is characterized by edematous septae and thickened bronchioles that produce turbid exudate on compression. There may be consolidation of cranial lung lobes with interstitial changes and intracytoplasmic elementary bodies within alveolar macrophages.

- Lungs: peribronchiolar lymphocytic cuffing, bronchiolitis, and alveolitis.

Keratoconjunctivitis

- Conjunctival hyperemia can progress to lymphoid follicle formation, and corneal vascularization and corneal edema may be present. Conjunctival epithelial cells are often necrotic.
- Conjunctival smears show numerous neutrophils and some lymphocytes; as the disease progresses there are more neutrophils and fewer mononuclear cells.

Placenta

Fetus: often few lesions seen but occasionally multifocal necrosis in the liver or spleen or mild interstitial pneumonia in the lungs. Chlamydial inclusions may be seen in the abomasal mucosa.

Brain

Perivascular cuffing and inflammatory cell infiltration evenly distributed through most parts of the brain.

TREATMENT

- Abortions—various protocols suggested
 - Long-acting oxytetracycline (OTC) (20 mg/kg) at 10–14-day intervals from midgestation until parturition.
 - 400–450 mg OTC/head/day orally (abortions in goats)
 - 200 mg tylosin/head/day orally (abortions in goats)
- General chlamydiosis
 - Single long-acting OTC (20 mg/kg)
 - Three treatments at 3-day intervals suggested
 - 150–200 mg tetracycline/head/day orally for lambs or kids

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PREVENTION/AVOIDANCE

Vaccination

- Killed whole cell bacterins given prior to breeding will significantly reduce the level of abortion but do not eliminate the carrier state or excretion.
- In the midst of an abortion storm, antibiotic treatment is the only course available, as most vaccines are not licensed for use during gestation.
- A temperature-sensitive avirulent vaccine for use in sheep is produced and marketed in Europe. It is claimed to prevent both abortions and shedding.

Management

- Closed flock management is advised.
- Stud males should be screened or treated prior to breeding.
- All aborting animals should be segregated from the flock to prevent transmission to other stock. Aborted fetuses, placental membranes, bedding, and other contaminated materials should be removed and destroyed.
- In cases of synchronized breeding, the flock should be divided into small groups that have close parturition dates.
- Judicious use of disinfectants should be geared toward preventing manual transmission of the disease through boots,

clothing, and instruments from aborting or lambing animals to those still pregnant. Newborn lambs may be infected.

- As animals that aborted may continue to excrete the organism, breeding rams that have been with them should not have access to other clean stock.
- Antibiotics and vaccines should be incorporated into a flock-management program.

POSSIBLE COMPLICATIONS

The avirulent live vaccine for use in sheep may have zoonotic implications.

EXPECTED COURSE AND PROGNOSIS

- After the initial outbreak, good management techniques combined with judicious use of antibiotics and/or vaccines should reduce the rate of abortion to negligible levels.
- Animals that have aborted are immune from further abortions.

MISCELLANEOUS

ZOONOTIC POTENTIAL

- *C. abortus* may cause abortion in pregnant woman who should, therefore, not work in a flock with this disease.
- The avirulent live vaccine for use in sheep may have zoonotic implications.

CHRONIC WASTING DISEASE

BASICS

OVERVIEW

- Chronic wasting disease (CWD) is a transmissible spongiform encephalopathy (TSE) that affects free-ranging and captive cervids including mule deer, white-tailed deer, and Rocky Mountain elk.
- CWD was first recognized in captive mule deer in Colorado in the 1960s and later identified as a TSE in 1978.
- TSEs are a group of diseases characterized by the accumulation of a misfolded normal host prion protein in the brain.
- Additional TSEs in other species include BSE in cattle, scrapie in sheep, kuru, CJD, and vCJD in humans, and feline spongiform encephalopathy.
- CWD has been detected in wild populations in Wisconsin, Nebraska, South Dakota, New Mexico, western Colorado, and Saskatchewan, Canada. CWD has been diagnosed in captive populations in numerous other states.
- Horizontal spread of the disease by oral exposure to infected carcasses, excretions, secretions, or other tissue source has been proven by epidemiological studies.
- Clinical signs of CWD include changes in behavior, weight loss, loss of muscle mass, and salivation. The average age of affected animals ranges from 3 to 5 years.

PATHOPHYSIOLOGY

- Transmission of CWD within wild populations appears to be via exposure to infected carcasses, secretions, and excretions.
- Dead and decaying carcasses, placenta, and placental fluids are suspected to be common sources of infection.
- Analysis by immunohistochemical studies of the tissue distribution of prions in CWD-infected cervids identified the agent in the brain, spinal cord, eyes, peripheral nerves, and lymphoreticular tissues.
- Distribution of the CWD agent outside of the brain seems to be less widespread in elk than in deer.
- Involvement of the tonsils and peripheral nerves early in the course of experimental and natural prion infection suggests the possible involvement of the lymphoreticular and peripheral nervous systems in the pathogenesis and transmission of the disease.
- A unifying feature of all the prionoses is their neuropathology. CWD affects the grey matter of the central nervous system (CNS), producing neuronal loss, gliosis, and characteristic spongiform change. In addition, plaques with the typical staining properties of amyloid (e.g., apple-green birefringence after Congo red staining when viewed under polarized light) are observed. These amyloid plaques are immunoreactive with antibodies to the prion protein and do not immunoreact with antibodies to other amyloidogenic proteins, such as the amyloid-beta.
- CWD and other TSEs are believed to be caused by a pathogenic effect on neurons of an abnormal isoform of a host-encoded glycoprotein, the prion protein.
- The pathogenic form of this protein appears to be devoid of nucleic acids and supports its own amplification in the host. TSEs in animals primarily occur by transmitting the etiologic agent within a species, either naturally or through domestic husbandry practices. A notable exception among the human TSEs is the variant form of Creutzfeldt-Jakob disease (vCJD), which is believed to have resulted from the foodborne transmission of bovine spongiform encephalopathy (BSE) to humans.
- Although CWD does not appear to occur naturally outside the cervid family, it has been transmitted experimentally by intracerebral injection to a number of animals, including laboratory mice, ferrets, mink, squirrel monkeys, and goats.
- In an experimental study, the CWD agent was transmitted to 3 of 13 intracerebrally injected cattle after an incubation period of 22 to 27 months. In ongoing experimental studies, after > 6 years of observation, no prion disease has developed in 11 cattle orally challenged with the CWD agent or 24 cattle living with infected deer herds.

Figure 1. The geographical distribution of CWD in free-ranging deer in the United States and Canada.

- In addition, domestic cattle, sheep, and goats residing in research facilities in close contact with infected cervids did not develop a prion disease.

SYSTEMS AFFECTED

CNS, musculoskeletal

GENETICS

N/A

INCIDENCE/PREVALENCE

- The low prevalence and lack of large-scale surveys has hampered identifying genetic profiles of susceptible populations and the use of geno-typing to identify susceptible populations.
- Epidemiologic modeling suggested that chronic wasting disease might have been present among free-ranging animals in some portions of the disease-endemic area several decades before it was initially recognized.
- This disease can be highly transmissible within captive deer and elk populations. A prevalence of > 90% was reported among mule deer in facilities where the disease has been endemic for > 2 years.

GEOGRAPHIC DISTRIBUTION

North America, potentially worldwide (see [Figure 1](#))

- Chronic wasting disease appears to have been introduced into Canada through the importation of infected farmed elk from the United States in the late 1980s and early 1990s, at a time when little was known about the disease.
- Eradication efforts in Canada have led to the control of the spread of CWD in the farmed elk industry.
- Immunohistochemical (IHC) staining of the retropharyngeal lymph nodes and obex with a monoclonal antibody is considered the gold standard for postmortem diagnosis of CWD. Lymph node staining has been approved as a valid diagnostic procedure. There is currently no antemortem diagnostic test.
- CWD appears host specific and will not readily transmit to humans, sheep, swine, cattle, or other wildlife.
- Increasing spread of CWD has raised concerns about the potential for increasing human exposure to the CWD agent. The foodborne transmission of bovine spongiform encephalopathy to humans indicates that the species barrier may not completely protect humans from animal prion diseases.
- Conversion of human prion protein by CWD-associated prions has been demonstrated in an in vitro cell-free experiment, but limited investigations have not identified strong evidence for CWD transmission to humans.

National Programs

- State and national programs have been implemented to reduce the spread of CWD.

- Many states have mandatory identification and postmortem testing of all captive cervids. In addition to testing, some states have restricted movement of deer and elk across state boundaries.
- Captive herds with a CWD-positive animal are typically eliminated.
- CWD, like other prion proteins, can survive in contaminated environments for many years.
- In Canada, CWD was first detected in free-ranging cervids (two mule deer) in 2001 in Saskatchewan; a few additional deer tested positive in 2002 and 2003. Saskatchewan Environment has implemented a herd-reduction program using “control permits” to prevent further spread of the disease among free-ranging cervids.

SIGNALMENT

Species

Both free-ranging and captive white-tailed deer (*O. virginianus*), Rocky Mountain elk (*Cervus elaphus nelsoni*), mule deer (*Odocoileus hemionus*) have all been diagnosed with CWD.

Breed Predilections

N/A

Mean Age and Range

- Most affected cervids are greater than 2 years of age and many are 3 to 5 years old.
- In captive cervids, most cases occur in animals 2–7 years of age; however, the disease has been reported in cervids as young as 17 months and as old as > 15 years of age.

Predominant Sex

N/A

SIGNS

HISTORICAL FINDINGS

- Many cervids diagnosed with CWD are asymptomatic. The more chronically affected animals have progressive fat and muscle loss over a period of weeks or months.
- Additional clinical signs include changes in behavior, which can include loss of fear to humans, increased salivation, and atrophy of muscles around the head leading to droopy ears.
- There are no gross pathognomonic changes in cervids with CWD. Gross exam of the brain is unremarkable in cervids with CWD. Additional postmortem changes in chronically affected animals are nonspecific, but can include emaciation, serous atrophy of fat, abomasal ulcers, and aspiration pneumonia.

PHYSICAL EXAMINATION FINDINGS

- Clinical manifestations of CWD include weight loss over weeks or months, behavioral changes, excessive salivation, difficulty swallowing, polydipsia, and polyuria. In some animals, ataxia and head tremors may occur.
- Most animals with the disease die within several months of illness onset, sometimes from aspiration pneumonia. In rare cases, illness may last for ≥ 1 year.
- The mode of transmission among deer and elk is not fully understood; however, evidence supports lateral transmission through direct animal-to-animal contact or as a result of indirect exposure to the causative agent in the environment, including contaminated feed and water sources.

DIAGNOSIS

- Histopathological lesions of chronic wasting disease include spongiform change of the grey matter; neuronal intracytoplasmic vacuolation, degeneration, and loss; and astrocytosis in the absence of a host inflammatory response.
- Immunohistochemical (IHC) staining of the retropharyngeal lymph nodes and obex with a monoclonal antibody is considered the gold standard for postmortem diagnosis of CWD. The recent development of an ELISA-based diagnostic test on fresh retropharyngeal lymph has been used to test large numbers of wild cervids in a short time frame.
- There is currently no approved antemortem test for CWD.

OTHER DIAGNOSTIC PROCEDURES

- Two major types of the proteinase-K-resistant prion protein fragment have been identified on the basis of their molecular size by one-dimensional immunoblot analysis: type 1 migrating at 21 kDa and type 2 at 19 kDa. N-terminal protein sequencing indicated that the cleavage site of the type 1 fragment is generally at residue 82 and that of type 2 is at

residue 97.

- Prion strain diversity is believed to be encoded in the three-dimensional conformation of the protein, which determines the cleavage site and molecular size of proteinase-K–treated prion fragment, indicating that the difference in molecular size may correlate with strain differences. However, one-dimensional immunoblot analysis may not identify more subtle differences that may influence the conformation of different prion strains.
- Analysis of the glycoform ratios of prion fragments and application of a two-dimensional immunoblot may help further identify these subtle differences.
- On one-dimensional immunoblot analysis, the prion fragment from several CWD-infected deer and elk migrated to 21 kDa, corresponding to the type 1 pattern. This specific type has been identified in most cases of sporadic CJD in the United States. However, the deer and elk prion fragment differs from that in sporadic CJD cases in the glycoform ratio.
- In the CWD-associated prion fragment, the diglycosylated form was predominant, but in the CJD-associated prions, the monoglycosylated form was predominant.
- Preliminary analysis using two-dimensional immunoblot indicates that the CWD-associated prion fragment exhibited patterns different from that of the CJD-associated prion fragment from a human patient with the type 1 pattern.

PATHOLOGIC FINDINGS

Histopathological lesions of chronic wasting disease include spongiform change of the grey matter; neuronal intracytoplasmic vacuolation, degeneration, and loss; and astrocytosis in the absence of a host inflammatory response.

CICUTA SPP. (WATER HEMLOCK) TOXICITY

BASICS

OVERVIEW

- Water hemlock poisoning in ruminants, particularly cattle, is not an uncommon occurrence.
- Four species (*C. bulbifera*, *C. douglassi*, *C. maculata*, *C. virosa*) can be encountered in North America.
- These plants are members of the Apicacea family and all have similar physical characteristics—perennials with tall (3–10 feet), erect, stout, hollow stems (except at the nodes). The leaflets are lance shaped, with the majority of the secondary veins terminating at the small notch at the leaf edge. The small white cluster of umbrella-shaped flowers is located at the tips of the branches. The root is bulbous (similar to a potato with sprouts) and is often located very close to the surface.
- Cicuta plants are always found in wet areas, along streams, ditches, and in marshy areas.
- The lower stem, tuber, and roots ooze a yellow resinous liquid between hollowed out chambers.
- The toxin present in the resin can cause acute onset of salivation, tachypnea, muscle tremors, and convulsions.
- Death is typically within a few hours of ingestion.

PATHOPHYSIOLOGY

- Cicutoxin is the primary toxin concentrated in the yellow resin of the tubers, roots, young shoots, and green seeds.
- Definitive mechanism of action is yet unclear; possibilities include interference with sodium and potassium channels, interference with GABA, and effects on the brain stem.

SYSTEMS AFFECTED

Nervous and cardiopulmonary systems

GENETICS

N/A

INCIDENCE/PREVALENCE

Not uncommon in many areas of the United States and Canada, more prevalent in wet areas

GEOGRAPHIC DISTRIBUTION

Throughout North America

SIGNALMENT

All ruminants, particularly cattle

Species

All ruminants appear to be susceptible; most cases seem to be reported in cattle.

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Animals found dead
- Muscle twitching, excessive salivation, tachycardia, dilated pupils, and tachypnea are some of the earlier signs seen within 30–90 minutes of ingestion, depending on dose.
- Rapidly followed by recumbency, excessive chewing movements, and violent convulsions; death may quickly follow due to respiratory paralysis.

CAUSES AND RISK FACTORS

- Most poisonings occur in animals ingesting the tuber, roots, and very young shoots. This can occur any time of year; however, most cases occur in the early spring when the tubers are sprouting. The roots are very near the surface and are easily accessible.
- Reported lethal doses of tuber are greater than 1.2 g fresh tuber/kg BW in sheep, and 0.1% in cattle. Lethal doses of fresh green plant material have been reported to be 2 ounces for sheep and 10–12 ounces for adult cattle; field cases indicate that fatal doses may be much less than this.
- Animals grazing the immature seeds can be susceptible to poisoning.
- It is possible that animals can be poisoned by drinking out of water puddles where the green seeds have concentrated or plant material has been trampled.
- The remainder of the plant is low in toxicity, and drying the plant greatly reduces the toxicity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Bacterial or viral meningitis or encephalitis, lead poisoning, Dicentra poisoning, nitrate toxicity, hypomagnesemia, rabies, nervous coccidiosis

CBC/BIOCHEMISTRY/URINALYSIS

- No specific or diagnostic changes have been reported.
- Elevation of AST, LDH, and CK may be indicative of muscle pathology.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- One can often readily identify pieces or whole tubers/roots within the rumen or reticulum during necropsy.
- Rumen/reticulum contents can be tested for the presence of cicutoxin (not very stable; samples need to be collected within 24 hours of death). This analysis can be extremely difficult to perform on other tissues due to the short half-life of the toxin.

PATHOLOGIC FINDINGS

- Nonspecific evidence of generalized congestion, and signs of a terminal convulsion
- Myocardial degeneration and necrosis of the heart and skeletal muscle may be observed in those animals with severe and prolonged seizure activity.

TREATMENT

- Treatment is generally not possible due to the short time course of clinical signs.
- Can attempt oral activated charcoal and saline cathartic (magnesium sulfate).

MEDICATIONS

- Control the muscle tremors or seizures with valium or phenobarbital/pentobarbital.
- Barbiturate-induced anesthesia prior to the onset of seizures can lead to complete recovery.

CONTRAINDICATIONS

N/A

FOLLOW-UP

Recovery is potentially possible if the animal is still alive 2–4 hours following ingestion.

PATIENT MONITORING

Monitor respiratory function, and control seizure activity.

PREVENTION/AVOIDANCE

- Avoid access to the plant. This is unlikely to be hay-related poisoning.
- Dig up and remove the roots, or control chemically with appropriate herbicides.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Most clinically affected animals are expected to die.

Author: Patricia Talcott

CIRCULATORY SHOCK

BASICS

DEFINITION

Circulatory shock is defined as severe insufficiency in capillary perfusion. Shock begins with a hormone-mediated *hyperdynamic phase* that is characterized by bounding pulses, tachycardia, and decreased capillary refill time of mucous membranes. This phase is transient and is quickly followed by the *hypodynamic phase* of circulatory failure. Usual causes of circulatory shock are marked depletion of extracellular fluid volume (*hypovolemic*), loss of effective cardiac pumping action (*cardiogenic*), and dysfunction of the small vessels (*vasulogenic*). In the most severe cases, it is often fatal if left untreated.

PATHOPHYSIOLOGY

The effective circulatory blood volume may be diminished by actual loss or sequestration of blood or plasma. Shock may result from diverse causes such as vascular and myocardial effects of circulating endotoxins from enteric organisms.

Hypovolemic Shock (Due to Reduction in Blood Volume)

- Loss of whole blood by external or internal hemorrhage
- Loss of plasma by exudation (e.g., burns) or into body cavities
- Loss of water and electrolytes by excessive sweating, diarrhea, diuresis, regurgitation, and transudation

Cardiogenic Shock (Due to Acute Changes in Cardiac Pumping Effectiveness)

- Interference with effective cardiac filling such as cardiac tamponade, constrictive pericarditis, and hydropericardium
- Restricted ventricular emptying such as acute cor pulmonale, increased vascular resistance, toxic myocardial depression, and cardiac dysrhythmias

Vasogenic Shock (Due to Changes in Venous Dysfunction or Peripheral Resistance).

- Endotoxins and vasoactive agents of anaphylaxis
- Vasomotor paralysis from CNS trauma or infection

SYSTEMS AFFECTED

- Cardiovascular—inability to provide sufficient circulating fluid volume leads to ischemia in other organs.
- GI—decrease in urine volume and mucosal necrosis as a result of microvascular thrombosis
- Lymphatic/immune—tendency toward thrombosis in the early stages, then hemorrhagic

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

SIGNALMENT

N/A

SIGNS

Clinical Signs

General Comments: Large varieties of clinical signs are associated with infection and include central depression, and altered cardiovascular status.

HISTORICAL FINDINGS

- Morbidity and mortality due to enterotoxemia or diarrhea
- Exposure to cardiotoxic plants, such as oleander (*Nerium oleander*), foxglove (*Digitalis purpurea*), lily of the valley (*Convallaria majalis*), yew (*Taxus* spp.), Indian hemp (*Apocynum cannabinum*), false hellebore (*Veratrum* spp.), milkweed (*Asclepias* spp.), avocado (*Persea americana*), oleander, caltrops (*Calotropis procera*), and red cotton (*Asclepia curassavica*)

- Exposure to calcium salts and ionophore coccidiostats

PHYSICAL EXAMINATION FINDINGS

- Visible weakness, obtundation, cold extremities, tachycardia with a weak pulse, decreased urination and defecation, cyanotic or pale mucus membranes, shallow breathing and prolonged capillary refill time.

CAUSES

- Sepsis, localized bacterial infection, myocarditis, dehydration, electrolyte and acid-base disturbances and cardiovascular anomalies
- Yew and false hellebore contain toxic alkaloids.
- Ionophore toxicity is known to occur in sheep and the use of ionophores for control of coccidiosis in goats is increasing.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Diagnosis is by recognition of characteristic clinical signs and clinicopathologic abnormalities.

CBC/BIOCHEMISTRY/URINALYSIS

- Depending on the organ system affected, laboratory evidence of hepatic, renal, or metabolic dysfunction, coagulopathy, and electrolyte imbalances may exist.
- Leukopenias with neutropenia, lymphopenia, or thrombocytopenia are often associated with severe sepsis and shock.

OTHER LABORATORY TESTS

- Arterial and venous blood gas analysis is helpful to evaluate pulmonary and metabolic function, respectively.
- Blood cultures are indicated when sepsis is suspected.

IMAGING

- Transabdominal, transrectal, or thoracic ultrasonography for assessment of fluid distribution
- Renal ultrasonography for assessment of cortical and or medullary sclerosis
- Echocardiography to assess cardiac function

DIAGNOSTIC PROCEDURES

- Thoracic radiographs help in recognition pulmonary edema.
- Direct or indirect blood pressure monitoring to assess hypotension

PATHOLOGIC FINDINGS

Generally reflect the primary underlying disease process

TREATMENT

APPROPRIATE HEALTH CARE

General Comments

This life threatening condition always warrants intensive care. Therapy should target the underlying infection and/or disease process and provide hemodynamic and pulmonary (oxygen) support and anti-inflammatory therapy.

Herd Management

Address historical problems resulting in shock

Individual Patient Care

Urgent repletion of circulating volume is of utmost importance

- Necessary volume of IV fluids should be calculated based on central venous pressure monitoring but levels should be increased to supranormal values as demands following clinical shock are markedly elevated.
- A shock dose of 8% of the animal's body weight should be administered as initial bolus. Homologous blood may be of value if significant hemorrhaging has occurred and should be administered with two to six times the volume of a balanced electrolyte solution.

- Arterial blood oxygen levels need to be at least 60% concentration. Oxygen can be administered by endotracheal tube, mask, bag, or nasal cannula.

ACTIVITY

Strictly limited

DIET

Total or partial parenteral may be required to meet increased energy and metabolic demands due to shock.

CLIENT EDUCATION

Generally positive, but if the condition deteriorates, the prognosis becomes progressively worse.

MEDICATIONS

DRUGS OF CHOICE

- Supportive tissue perfusion with polyionic IV fluids is mandatory.
- Amount of fluid administered over 24 hours should = excess fluid loss + maintenance (starting at 100 mL/kg per 24 hours for first 10 kg + 50 mL/kg per 24 hours for second 10 kg + 25 mL/kg per 24 hours for weight > 20 kg).
- IV glucose is administered to meet the metabolic demands induced by shock.
- Dextrose can be administered in a 5 or 10% solution and should achieve 0.1–0.2 gm/kg per hour (5–10 gm/hour for 50 kg patient).
- Flunixin meglumine (0.25 mg/kg IV BID or TID)
- Whole plasma transfusion (15–30 mL/kg) to restore low oncotic pressure in cases of hypoalbuminemia. If available, hyperimmune plasma with a higher titer of antitendotoxin antibody may be beneficial.
- When indicated, treat all cases aggressively with IV antibiotics approved for food animal use, which can be reviewed on the Internet: (www.farad.org).
- Pressor or inotrope therapy to increase effective circulatory fluid pressure. These drugs must be delivered by an IV pump to control their effect.
- Dopamine (5–20 µg/kg per min; usual starting dosage is 10 µg/kg per min)
- Dobutamine (5–40 µg/kg per min; usual starting dosage is 10 µg/kg per min)
- Epinephrine (0.1–3 µg/kg per min; usual starting dosage is 0.5 µg/kg per min)
- Norepinephrine (0.05–2 µg/kg per min; usual starting dosage is 0.5 µg/kg per min)
- Corticosteroid use is widely successful but only after circulatory volume has increased to a safe level because of their anti-inflammatory and membrane-stabilizing effects.
- Heparin may be used to prevent DIC in cases with acquired coagulopathies.
- Mannitol may be administered to increase urine flow and reduce cerebral edema.

CONTRAINDICATIONS

- Adrenergic drugs, especially catecholamines, are limited in success because they are vasoconstrictive, arrhythmogenic, and generally enhance tissue oxygen demands. The exception to this is anaphylactic shock in which they are critical for maintaining cardiac function.
- Drugs that cause or may exacerbate preexisting hypotension (e.g., acepromazine) should be avoided.
- Avoid potentially nephrotoxic drugs and those requiring hepatic metabolism.

FOLLOW-UP

PATIENT MONITORING

- Constant close attention during administration of therapeutic fluids and cardiac inotropic drugs until the animal has reached a stable condition is required.
- Physical examination every 2–4 hours with particular attention to heart and respiratory rate, temperature, urine output, presence of arrhythmias, pulse intensity, and mucous membrane coloration.

- Check PCV and TP every 12 hours during the initial treatment with IV fluid to expand the intravascular fluid volume and during equilibration with the extravascular pool.

PREVENTION/AVOIDANCE

Herd Management

Identify the primary disorder(s) and make necessary management changes and initiate specific therapies

Individual

Early detection and aggressive treatment of primary disease(s) Aggressive treatment of sepsis and localized bacterial infections that have progressed to the stage where fluid intake of the animal has been compromised

POSSIBLE COMPLICATIONS

Multiple organ dysfunction (MOD) such as heart and renal failure, respiratory distress syndrome, and DIC

EXPECTED COURSE AND PROGNOSIS

If treatment is early enough, the prognosis is very good; as the condition progresses, prognosis becomes increasingly worse.

MISCELLANEOUS

AGE-RELATED FACTORS

Immune system response time and effectiveness decreases from peak capability with age. The urgency of treatment is compounded with increasing age.

ZOONOTIC POTENTIAL

Depends on the pathogen involved. Infectious contagious enteritis, such as salmonellosis, has zoonotic implications.

CLEFT PALATE (PALATOSCHISIS)

BASICS

DEFINITION

- Cleft palate (palatoschisis) is a common congenital anomaly characterized by a midline fissure of the hard and soft palate.
- Bilateral cleft palate is most common. The lesion is symmetrical and the ventral edge of the nasal septum can be seen from an open mouth view.
- Cleft palate is an occasional congenital anomaly affecting ruminants and camelids.
- Unilateral cleft palate is asymmetrical; the ventral edge of the nasal septum (vomer) is not visible because it is fused with the palatal shelf of the normal side.
- Cleft lip is not usually associated with cleft palate in ruminants. The majority of cases of cleft palate in cattle are thought to be genetic but the mode of inheritance is uncertain and other environmental factors may be implicated.
- Cleft palate has been documented to occur in association with consumption of piperidine alkaloids contained in plants of the lupine, hemlock, and tobacco families in cattle, sheep, and goats during early gestation.

PATHOPHYSIOLOGY

- The hard palate is formed by fusion of symmetrical palatal “shelves” that divide the primitive stomadeum into nasal cavity and oral cavity. Caudally, the same is true for the soft palate, which divides the nasal pharynx from the oral cavity and oropharynx.
- Experimental work indicates that cleft palate results from mechanical blockage by the tongue preventing fusion of the palatal “shelves.”
- Any substance that inhibits normal fetal movement of the tongue during the critical period of palatal fusion will result in cleft palate.
- The critical period for palatal fusion is 35–40 days gestation in goats and sheep and 40–50 days in cattle.
- After the critical period, the edges of the palatal shelves are covered by epithelium that prevents fusion of the palatal edges with each other and the ventral edge of the nasal septum.

SYSTEMS AFFECTED

Potentially all depending on condition

GENETICS

- Cleft palate is a component of the inherited congenital neuromuscular syndrome of Charolais cattle.
- A familial history of progeny from dam or sire; having cleft palate may be present.

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Potentially all ruminant species

Breed Predilections

- Cleft palate is a component of the inherited congenital neuromuscular syndrome of Charolais cattle.
- The condition has a higher prevalence in the Saanen breed compared to other breeds of goat.

Mean Age and Range

- The condition is usually diagnosed in neonates when the defect involves the hard palate or hard and soft palates.

- Small soft palate defects may be clinically inapparent and go undiagnosed.

Predominant Sex

N/A

SIGNS

- Nasal discharge of milk while nursing.
- Periodic sneezing and occasional coughing during and after nursing
- Respiratory distress (if aspiration of milk occurs); complications including rhinitis and aspiration pneumonia are common.
- Failure to thrive with poor weight gains is a consequence of cleft palate.
- Reluctance to nurse or bottle-feed.
- General unthriftiness (if aspiration occurs)

CAUSES AND RISK FACTORS

Plants containing alkaloids have been shown to produce cleft palate when fed to ruminant dams during the critical period for palate fusion. These plants include poison hemlock (*Conium maculatum*), burley tobacco (*Nicotiana tabacum*), and wild tree tobacco (*Nicotiana glauca*). *Lupinus* spp. also have been associated with cleft palate when ingested by pregnant ruminants.

- In humans, genetic factors and certain environmental teratogens such as cigarette smoke and ethanol have been implicated as causes of cleft palate.
- Cleft palate occurs due to developmental errors of the facial embryonic segments with subsequent craniofacial skeletal and soft tissue abnormalities in the roof, wall, and floor of the nasal cavity and the boundary between the nasal and oral cavities.
- Genetic and environmental factors are proposed.
- Risk factors include forage or pasture access to piperine-containing oleoresin and alkaloids by dam during early to mid gestation
- Goats are more sensitive to these teratogens than sheep and tailcup lupine (*L. caudatus*) only affects cattle.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other causes of nasal regurgitation of milk and dysphagia in neonates
- Dysphagia in neonates due to white muscle disease (selenium deficiency)
- Oropharyngeal foreign body, esophageal obstruction, esophageal stricture, megaesophagus, pharyngeal trauma
- Neurologic causes of dysphagia and nasal regurgitation of feed (listeriosis, meningitis, cervical vagus injury) and retropharyngeal trauma
- Neuromuscular causes of dysphagia and nasal regurgitation of feed—botulism
- Nonpaltischic congenital oropharynx malformations, esophageal stricture due to persistent right aortic arch
- Toxicities causing dysphagia—organophosphates, oral irritants

CBC/BIOCHEMISTRY/URINALYSIS

- CBC, if aspiration pneumonia is suspected
- Laboratory diagnostics are generally not useful, affected neonates with aspiration pneumonia will have an inflammatory leukogram.

OTHER LABORATORY TESTS

- Generally unnecessary; cleft palate is a clinical diagnosis.
- Whole blood selenium levels to rule out white muscle disease
- Tracheal lavage cytology if pneumonia is suspected

IMAGING

- Radiographs may demonstrate foreshortening of the palatal tissues on lateral, dorsoventral, and intraoral films.
- Contrast radiography to demonstrate nasal access by oral contents may be performed in equivocal cases or those with very small, hard to visualize defects.

DIAGNOSTIC PROCEDURES

- The condition is easily diagnosed by visual inspection and palpation of the dorsocaudal oral cavity and oropharynx.
- Endoscopy of the oral cavity, oropharynx, and nasopharynx may be diagnostic with small defects.

TREATMENT

- While surgical repair is frequent in humans and occasionally done for foals, there is little or no justification for it in ruminants. Treatment for the main secondary problem, pneumonia, is covered elsewhere in this text.
- Attempts at surgical repair in calves have a very high rate of surgical dehiscence.
- Most affected animals are euthanized.
- Contrary to “conventional wisdom,” some young ruminants can thrive with cleft palate after early conversion to pail feeding or even when bottle-fed with a long nipple.

MEDICATIONS

Medical management of pneumonia is covered elsewhere in this text.

FOLLOW-UP

PATIENT MONITORING

- Owners who elect to raise a young ruminant with cleft palate must always maintain a vigil for aspiration pneumonia. Second, weight should be monitored before weaning to ensure that adequate milk is being consumed.
- Calves should get fluid milk equivalent to 10%–15% body weight/day and kids need 15%–20%.

PREVENTION/AVOIDANCE

- Care should be taken to avoid ingestion of known teratogenic plants mentioned above, especially during the first trimester of gestation.
- Eradication of poisonous plants with herbicides may be helpful.
- Until genetic factors are better understood, breeding of animals with cleft palate should be avoided.

POSSIBLE COMPLICATIONS

The main complication is aspiration. Careful feeding should minimize this risk. Leaky nipples should be avoided when bottle-feeding.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Since cleft palate has been shown to be associated with decreased fetal movement, it is often associated with multiple congenital contractions of the limbs but these may resolve during the postnatal period.
- Occasional cases may be associated with other congenital defects such as arthrogryposis (cattle, goats, and sheep), micrognathia (sheep), or the absence of ears (sheep).

AGE-RELATED FACTORS

Condition is congenital, only seen in neonates.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

- The dam/sire combination should not be repeated with subsequent breedings.
- Assess pasture type and forage consumption during early gestation for evidence of exposure to piperine-containing oleoresin and alkaloids.

RUMINANT SPECIES AFFECTED

Both ruminants and pseudoruminants (camelids) can be affected.

BIOSECURITY

CLOSTRIDIAL DISEASE: GI

BASICS

DEFINITION

Clostridial gastroenteritis is an acute inflammatory noncontagious disease of young ruminants that usually results in death.

PATHOPHYSIOLOGY

- Clostridial bacteria are ingested as spores from the environment or carrier animals and are considered normal bacterial flora.
- Factors favoring intestinal clostridial bacteria overgrowth, such as high-carbohydrate diets, result in rapid toxin production with subsequent clinical signs and death.
- Clinical signs depend on the predominate type of toxin produced although there is considerable crossover.
- There are four major lethal toxins (alpha, beta, epsilon, and iota) and five types (A–E). Alpha toxin (types A–E) usually results in an intravenous hemolytic crisis of the abdominal and thoracic cavities with or without subsequent icterus. Beta toxin (types B and C) results in necrosis and hemorrhage of affected tissues, especially the intestine. Epsilon toxin (types B and D) causes intestinal necrosis, and increases vascular permeability with subsequent hemorrhage and edema. Iota toxin (type E) causes increased vascular permeability.

SYSTEMS AFFECTED

The gastrointestinal tract is primarily affected with systemic involvement of most other systems especially cardiovascular and neurologic.

GENETICS

No genetic predisposition known

INCIDENCE/PREVALENCE

- The disease incidence has been reported to range from 0% to as high as 50% of calves (unsubstantiated) in the herd.
- *Clostridium perfringens* was diagnosed in 9.2% of calves with gastrointestinal disease or septicemia in a German study. On routine culture, type A is the most common type isolated from cattle. In a Montana study, type C was more common in clinical cases than type A. Type D may still occur in vaccinated feedlot lambs with an incidence up to 1%, whereas the incidence in unvaccinated feedlot lambs may approach 10%. As a disease syndrome, type D is probably the most common, especially in unvaccinated herds/flocks.

GEOGRAPHIC DISTRIBUTION

- Clostridial bacteria are common worldwide.
- *Clostridium perfringens* A, C, and D are considered problems in the United States. Type B (Europe, Africa, and Asia) is not considered a problem in the United States. Type E tends to be rarer but has been reported in calves in the United States.

SIGNALMENT

Acute onset of clinical signs followed by rapid death or sudden death in a healthy, rapidly growing young ruminant is classic. Type A typically affects calves and lambs less than 3 months of age. Type C is most typical in calves and lambs less than 2 weeks old, especially those with high-producing dams. Type D is more common in feedlot lambs and occasionally calves.

SIGNS

- Because there is considerable overlap in the clinical signs among *Clostridium perfringens* types, clinical signs are suggestive but not definitive in differentiating the type.
- Type A is most commonly associated with depression, abomasal bloat, and abomasitis. Early signs may present as abdominal pain with the patient kicking at the abdomen. The animal becomes increasingly depressed and uncomfortable as abdominal distension progresses. Eventually the young ruminant becomes recumbent and semicomatose.
- Type C has commonly been associated with acute fatal hemorrhagic enteritis in young calves and lambs. This bloody,

mucoid diarrhea has also been a consistent finding in goat kids.

- Type D, the agent of enterotoxemia also known as “overeating disease,” primarily affects young ruminants undergoing nutritional changes.
- Regardless of the type, many cases are simply found dead. If affected animals are found alive, most cases present with colic and/or neurologic signs such as convulsions and opisthotonus prior to death.
- Young ruminants surviving more than 4–5 hours may develop hemorrhagic diarrhea.

CAUSES

Clostridium perfringens types A, B, C, and D

RISK FACTORS

- Risk factors usually include a change of diet (usually from milk/forage to grain), feedlot animals on a high-grain diet, or offspring of dams that produce an abundance of milk. In addition, lush pastures may also predispose to the disease.
- Singles are more likely to be affected than twins. The healthy, rapidly growing young ruminant is most at risk.
- Copper deficiency may contribute to type pathology.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anything causing acute death: anthrax, various poisonings, other clostridial diseases
- Right displacement and torsion of the abomasum
- Salmonellosis
- Sarcina bacteria may be involved in abomasal bloat cases.
- Ruminal acidosis
- Leptospirosis
- Polioencephalomalacia

CBC/BIOCHEMISTRY/URINALYSIS

In sheep afflicted with type D, hyperglycemia (more than five times normal) and glucosuria may be present but are inconsistent findings.

OTHER LABORATORY TESTS

Culture and impression smears may be useful. Toxin identification is essential for control and prevention recommendations.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Intestinal contents may be stained and examined for large gram-positive rods. Culture and toxin typing would be necessary for definitive identification. It is important to note that *C. perfringens* is a normal inhabitant of the GI system, especially type A.
- Because clostridial organisms proliferate rapidly after death, intestinal contents should be collected immediately after death. Intestinal fluid for toxin evaluation should be placed in a cool environment or frozen until testing because the toxins, especially beta toxin, are fragile.
- ELISA and counter-immunoelectrophoresis tests are now offered and have proven comparable to the traditional mouse lethality tests.

PATHOLOGIC FINDINGS

- Type A (alpha toxin) necropsy findings show watery blood, icterus, hemoglobinuria, excessive fluid in abdominal and thoracic cavities, and evidence of hemorrhages on thoracic and abdominal viscera, yet these findings are not consistent among calves.
- Type B (alpha, beta, and epsilon toxins) necropsy findings tend to be restricted to the intestinal tract, liver, and adjacent lymphatics in which inflammation, ulceration, and necrosis are evident.
- Type C (alpha and beta toxins) presents with an acute hemorrhagic enteritis in which bloody diarrhea may or may not be present at death. An additional finding in type C disease is swollen and hemorrhagic mesenteric lymph nodes.

- Paintbrush hemorrhages of the subendocardium of the left ventricle are most typical of type D (alpha and epsilon toxins). Additionally, hydropericardium is considered one of the most significant lesions of type D.

TREATMENT

APPROPRIATE HEALTH CARE

- The response to treatment is usually poor. However, if right-sided bloat is evident, relieving the distention in the abomasum may benefit some patients.
- Intravenous or subcutaneous infusion of clostridium C and D antitoxin may be beneficial at doses ranging from 3 ml in lambs to over 30 ml in adult cattle. Dosages can be repeated every 3–4 hours provided improvement is seen. Anaphylactoid reactions may occur.
- Activated charcoal and mineral oil have also been suggested but have not been scientifically evaluated. Chelating agents, such as EDTA, have been reported to influence the disease outcome if given early in the disease.

NURSING CARE

Maintenance: alkalinizing IV fluids

ACTIVITY

N/A

DIET

If at all possible, eliminate oral nutrition during treatment to decrease bacterial substrate.

CLIENT EDUCATION

N/A

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

Procaine penicillin G (300,000 IU/ml) at 1 ml/11 kg (1 ml/25 lb) orally, IM, or subcutaneously is the drug of choice.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

Oral sulfadimethoxine has been recommended.

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Passive antibodies to *Clostridium perfringens* C & D can be protective.
- The C & D toxoid may be given to dams in late gestation or to neonates beginning at 10 days of age and 2 weeks later. Young stock should be revaccinated at weaning and prior to feed changes.

- Antitoxin may be given to neonates at birth during outbreak situations. In a reported outbreak, 5 ml of *C. perfringens* type C&D were administered subcutaneously to neonatal calves and no more cases occurred. Decreasing concentrate and increasing roughage may reduce feedlot deaths.
- Additionally, chlortetracycline may be added to concentrates to help decrease the incidence of type D. Type A is poorly antigenic; effective vaccines have not been developed, although autogenous vaccines have been used with mixed results. Suggested methods to prevent type A disease include proper animal husbandry, sanitation, and feeding.
- There has been some suggestion that when young ruminants ingest large amounts of milk, the milk backflows to the rumen leading to *Clostridium perfringens* type A overgrowth and subsequent disease. Therefore, avoiding excessive intake may be helpful in disease prevention of type A. Vaccines for type B have been developed and appear useful in countries in which the disease occurs.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

If the patient is still ambulatory when treatment is initiated, the prognosis is fair at best. If the patient is recumbent, the prognosis is guarded to grave. Mortality approaches 100% regardless of type.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

This is a disease of young, healthy ruminants although adults have been reported to be sporadically affected.

ZOONOTIC POTENTIAL

No known zoonotic potential

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

All ruminant species may be affected but best documentation is in sheep and cattle.

BIOSECURITY

The organism is widespread in the environment and within the gastrointestinal tract, thus biosecurity measures are of little benefit; however, carcasses should be disposed of properly by burial or incineration. A high concentration of bacterial spores may contaminate the area.

Author: Jerry R. Roberson

CLOSTRIDIAL MYOSITIS

BASICS

DEFINITION

Clostridial myositis is a term used to describe a group of acute diseases characterized by a rapid course of myonecrosis and high mortality.

PATHOPHYSIOLOGY

- Any muscle or muscle groups may be involved such as rear and forelimb muscle systems, abaxial muscles, the diaphragm, and the heart. When an area of muscle becomes anaerobic (such as a bruise or injury), the spore may convert to a bacterial toxin-producing state.
- The organisms then produce powerful exotoxins, which are responsible for the local necrotizing myositis and systemic toxemia.
- The predominant signs that develop depend on the predominant clostridial organism.

SYSTEMS AFFECTED

Musculoskeletal

GENETICS

None

INCIDENCE/PREVALENCE

- The incidence will rarely be more than 10% and only during outbreaks. The prevalence will be virtually zero because affected livestock usually die within hours of the disease onset.
- Some herds may go for many years without clostridial myositis cases.
- Most cases are seen in the late summer to early winter.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

- Clostridial myositis is typically a disease of young cattle and is relatively rare in other ruminants.
- Cattle over 2 years old appear to develop a natural resistance to the disease.

SIGNS

- Sudden death common
- If blackleg, there will be areas of subcutaneous emphysema.
- Affected cattle are usually downers or extremely lame.
- Affected areas may be cold to the touch and will appear be swollen and edematous (if malignant edema).
- Other common nonspecific signs are depression, anorexia, and lethargy.

CAUSES

- *Clostridium chauvoei* is the agent of classic blackleg.
- *Clostridium septicum* is the agent of malignant edema.
- The organisms exist as spores in the environment. Cattle are thought to eat these spores in the process of grazing. The spores then find their way to various locations within the bovine (exact mechanism not known but may be via tissue macrophages). The spores are also normal in bovine feces. Conditions causing anaerobic muscle allow the spores to convert to the bacterial toxin-producing state.

RISK FACTORS

- Animals on high planes of nutrition and in excellent body condition are most likely to develop the disease, the assumption being a larger muscle mass.

- Herds that are not vaccinated are most at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Conditions that result in sudden death in young, well-muscled ruminants should be considered as differentials. These include but are not limited to gunshot, anthrax, snakebite, *Clostridium perfringens*, taxus (Japanese yew), various toxicants (lead, arsenic), nitrate and cyanide poisoning.

CBC/BIOCHEMISTRY/URINALYSIS

Of little benefit

OTHER LABORATORY TESTS

Of little benefit

IMAGING

Of little benefit

DIAGNOSTIC PROCEDURES

- Diagnosis is usually based on characteristic signs and gross lesions; impression smears showing large gram-positive rods may be helpful.
- Aspirates from the affected tissue can be submitted for fluorescent antibody testing and anaerobic bacterial culture.

PATHOLOGIC FINDINGS

Necropsy should reveal an area of “black” muscle necrosis and subcutaneous gas (hence the name blackleg). The affected muscle may have an odor of rancid butter. Malignant edema tends to have more edema than subcutaneous gas.

TREATMENT

APPROPRIATE HEALTH CARE

If treatment is considered appropriate, supplying the animal with feed and water would be a necessity. Antitoxin for these clostridial organisms is not readily available.

NURSING CARE

As above

ACTIVITY

The animal would limit its own activity.

DIET

N/A

CLIENT EDUCATION

The most important client education is to convey the need to protect unaffected herd mates.

SURGICAL CONSIDERATIONS

None, short of serial fasciotomy of affected areas to allow aeration and drainage.

MEDICATIONS

DRUGS OF CHOICE

- Procaine penicillin G at high doses (24,000 IU/kg) IM; injecting PPG around the affected tissue may help stop the advancement of the clostridial organisms.
- Anti-inflammatory drugs may be administered for pain, shock, and inflammation.
- With blackleg, it has been recommended to place skin incisions within the affected area to allow oxygen to the area.

- Treatment is usually a moot point because most are found dead.

CONTRAINDICATIONS

- Because of the poor prognosis, humane euthanasia should be considered. Slaughter is usually not an option.
- Drug withdrawal time must be determined and maintained for the treated animal.

PRECAUTIONS

None

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUGS

Many other antimicrobials may be effective, but penicillin is the drug of choice.

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Vaccinate all young stock (< 2 years of age) at least twice a year. Valuable and purebred stock should be vaccinated 3–4 times a year. Protective immunity should occur by 2 weeks postvaccine.
- Vaccinate cows in late gestation to boost colostral immunity for neonates that won't be vaccinated until the next cattle working period.
- When faced with an outbreak, vaccinate all susceptible stock and administer PPG at the same time in an attempt to prevent further cases while you're waiting for protective titers to develop.
- Vaccines are economical and efficacious.
- One vaccine to a calf that is 1 or 2 months old will usually not lend protective immunity because of interference with passive immunity.
- Carcasses should be burnt or buried deeply and covered with lime, as they represent concentrated areas of clostridial spores.

POSSIBLE COMPLICATIONS

None

EXPECTED COURSE AND PROGNOSIS

Prognosis is guarded to grave at best. Even if the animal survives, it may be permanently disabled.

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

The disease appears to be most common among young ruminants between 3 months and 2 years of age.

ZOONOTIC POTENTIAL

None

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Predominantly bovine, however goats, sheep, and camelids may be affected.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

Vaccination should help prevent clinical disease.

CLUB LAMB DISEASE

BASICS

OVERVIEW

- Club lamb disease or club lamb fungus is another name for ringworm or fungal skin infection in lambs.
- Ringworm is a common problem in show lambs but is uncommon in commercial sheep and goat herds.

SIGNALMENT

- Round, raised skin lesions are most commonly noticed on the face and ears of show lambs but lesions may develop under the wool anywhere on the body.
- There is no age, breed, or sex predilection for ringworm, but the condition most commonly occurs during the summer show season when market lambs less than 125 pounds (60+ kg) are repeatedly shorn, washed, and transported to shows.

SIGNS

- Round, raised skin lesions appear on the face, ears, and neck.
- The wool over affected skin is raised above the surrounding fleece.
- Some lesions appear mildly pruritic.
- Alopecia develops from fungal invasion of the keratinized hair shafts.
- Crusts form from accumulation of fungal hyphae and epithelial debris.
- The underlying skin appears reddened, thick, and abraded.

CAUSES AND RISK FACTORS

- The more common fungal species involved are *Trichophyton verrucosum* and *T. mentagrophytes*.
- Ringworm is transmitted by direct contact with infected animals or indirect contact from contaminated equipment such as clippers, shears, hoof trimmers, hoses, and buckets.
- Repeated bathing and excessively short shearing of show lambs irritates the skin and makes the epidermis more susceptible to fungal infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Soremouth, also known as contagious ecthyma or orf
- Chemical burns
- Parasitic skin disease
- Photosensitivity

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Fungal culture on Sabourad's dextrose agar.
- Microscopic examination of wet mounts prepared with 20% potassium or sodium hydroxide from skin scrapings or hair shafts. *Trichophyton* spores appear as round or polyhedral, highly refractive bodies in chains.
- *Trichophyton* species do not fluoresce under Wood's lamp examination.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

N/A

TREATMENT

- Ringworm is highly contagious and affected animals should be isolated and confined separately until after the wool has grown back and the lesions have healed.
- Health certificates should not be written and travel should not be allowed for affected animals until after the lesions have healed.
- Ringworm is zoonotic.
- Ringworm is a self-limiting infection and most lesions heal within 4 to 5 weeks.
- Segregation and treatment of affected lambs may decrease spread to other animals and contamination of the environment.

MEDICATIONS

- Crusts and debris should be removed by scraping or brushing.
- Medication should be vigorously rubbed or brushed into the lesions.
- Medications used for daily local treatment of a few distinctly separate lesions (adapted from Pugh, 2002):
 - (1) Dilute topical iodine compounds (2–5%)
 - (2) 2% chlorhexidine solution
 - (3) 2 to 5% lime sulfur
 - (4) 3% captan
- Sprays and washes can be applied to the entire body surface daily for treatment of widespread infections or when prophylactic treatment of contacts may be desirable.
 - (5) 5% lime sulfur
 - (6) 3% captan
 - (7) 0.5% sodium hypochlorite
- Systemic treatment with oral griseofulvin produces variable results.

CONTRAINDICATIONS

- Ringworm is a self-limiting disease of animals that are used for food. An adequate withdrawal time must be established and followed for any medication applied topically or administered orally.
- Griseofulvin should not be used in animals intended for food in the United States.
- Captan should not be used in animals intended for food in the United States.

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Animals with club lamb disease should not travel to shows and should be segregated to prevent transmission to unaffected stock.
- Equipment such as trimmers and shears should be thoroughly cleaned between flocks to prevent the spread of ringworm.
- Housing facilities should be thoroughly cleaned and sprayed with 2.5 to 5% phenolic disinfectant, dilute iodine, 2% chlorhexidine, 5% lime sulfur, 5% formalin, 5% sodium hypochlorite, or 3% captan after the lesions have healed.

POSSIBLE COMPLICATIONS

Lambs in poor physical condition/BCS or with low nutritional status are susceptible to secondary bacterial infection of ringworm lesions. Poor physical condition or inadequate nutrition should be corrected with improved management.

EXPECTED COURSE AND PROGNOSIS

Club lamb disease is self-limiting and usually resolves in individuals within 4 to 5 weeks. The course of disease through the entire flock may run several months.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Club lamb disease is usually limited to market lambs.

ZOONOTIC POTENTIAL

Trichophyton species are readily transmitted to humans. Persons examining or treating affected animals should wear protective gloves and wash thoroughly after handling affected animals.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Sheep; occasionally goats housed with sheep

BIOSECURITY

- Club lamb disease is highly contagious and is easily spread through direct contact and indirect contact with contaminated equipment and facilities.
- Show lambs should be housed separately from the main flock for 4 to 5 weeks following return to the flock.

PRODUCTION MANAGEMENT

Lambs in poor body condition and low nutritional status are more susceptible to ringworm.

SYNONYMS

Club lamb fungus

SEE ALSO

Chemical burns

Contagious ecthyma, or orf

Parasitic skin disease

Soremouth

ABBREVIATIONS

BCS = body condition score

CNS: BRAIN LESIONS

BASICS

OVERVIEW

- Brain diseases often affect only one portion of the brain; however, multifocal lesions are possible.
- Disorders can be due to infectious, congenital, nutritional, toxic, metabolic, immune-mediated, neoplastic, and traumatic causes among other causes.

PATHOPHYSIOLOGY

Brain Abscess

Abscesses can be caused by direct spread of infection or septic embolism to cerebral vessels.

Meningitis

- Inflammation of the meninges
- Often due to infectious agents such as bacteria, viruses, fungi, protozoa, or parasites
- Other causes include chemical agents and immune-mediated diseases

Cerebellar Hypoplasia

Lack of development or loss of one or more layers of the cerebellar cortex usually occurs due to in utero viral infections.

Hydrocephalus

Accumulation of excess CSF within the ventricular system of the brain

SYSTEMS AFFECTED

CNS

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide in distribution

SIGNALMENT

- All species
- Bacterial causes of meningitis are more common in ruminants.
- Viral infections in cattle, sheep, and goats can result in hydranencephaly syndrome.

Species

All ruminant species

Breed Predispositions

N/A

Mean Age and Range

N/A

Predominant Sex

SIGNS

Signs of CNS disease in the brain depend on the location of the lesions (see [Table 1](#)).

Meningitis

- Earliest signs include anorexia, diarrhea, fever, stiff neck, and hyperesthesia.
- Signs progress to decreased sensation, propulsive walking, status epilepticus, and coma.

Brain Abscess

Signs are those of a steadily progressive mass lesion and can occur in any part of the brain.

Hydrocephalus and Cerebellar Hypoplasia

- Dome-shaped calvarium
- Often open fontanelle in neonates
- Congenital causes usually result in symmetric, nonprogressive signs.
- Degenerative causes of disorder such as demyelination diseases and spongiform encephalopathies have progressive signs.

CAUSES AND RISK FACTORS

Meningitis

- Neonatal ruminants
 - Sequela of septicemia caused by *E. coli*, *Salmonella* spp., or *Streptococci* spp.
 - Failure of passive transfer predisposes to oomphlophlebitis or enteritis, with hematogenous spread to the CNS.
- Adult animals
 - Thrombotic meningoencephalitis (TMS) in cattle due to *Haemophilus somnus* and septicemia in feeder lambs by *H. agni* spread to CNS via hematogenous route.
 - *Pseudomonas aeruginosa* mastitis of cattle and goats
 - *Pasteurella haemolytica* and *P. multocida* pneumonia or hemorrhagic septicemia.
 - *Listeria monocytogenes* infection ascends to the CNS via transaxonal migration in cranial nerves.

Brain Abscess

There is usually a history of concurrent infection such as inner ear or respiratory infection. Otitis interna infections may spread by extension to the brain stem. Respiratory and other infections spread hematogenously to any part of the brain.

Hydrocephalus and Cerebellar Hypoplasia

- Occasional idiopathic congenital malformation
- Prenatal viral infections with such viruses as akabane virus, bluetongue virus, bovine virus diarrhea virus are possible causes of hydrocephalus in ruminants.
- The akabane virus is spread by mosquitoes and the midge.
- Degenerative causes include demyelinating diseases, spongiform encephalopathies, and abiotrophies.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Meningitis

- Hypomagnesemia and hypoglycemia signs resemble meningitis. Neonates may have these conditions concurrently in cases of septic meningitis.
- Cervical vertebral fractures and luxations can result in similar neck stiffness and pain.

Brain Abscess

Other space-occupying masses in the CNS such as tumors

Hydrocephalus and Cerebellar Hypoplasia

Spongiform encephalopathies, demyelinating diseases, and abiotrophies

CBC/BIOCHEMISTRY/URINALYSIS

Meningitis

- Findings are inconsistent and are usually related to concurrent conditions such as septicemia, diarrhea, or overaggressive fluid therapy.
- Possible leukocytosis, left shift, toxic changes
- Hyperkalemia, respiratory acidosis, hypoglycemia, hyponatremia, or hypernatremia

Hydrocephalus and Cerebellar Hypoplasia

Normal findings

OTHER LABORATORY FINDINGS

Meningitis (Bacterial) and Brain Abscesses

CSF findings can include:

- Turbid and white-to-amber in color
- May foam when shaken
- May clot
- Increased protein concentrations (20–270 mg/dl)
- Xanthochromia
- Increased WBC count (avg. 4000 WBC/ml)
- CSF concentration of glucose often < 50% of the corresponding blood concentration
- Possible positive culture or using Gram stain may show high bacterial titers.

IMAGING

Advanced imaging with CT or MRI can identify many neurologic defects, but is of limited availability for large animals.

Table 1 Symptoms Associated with Neurological Lesions.

Brain stem lesions	Altered mentation—depression, stupor, coma Circling Ataxia, falling Hemiparesis or tetraparesis Cranial nerves III–XII—deficits Visual deficits (normal pupils)
Vestibular lesions	Loss of balance Head tilt Falling or rolling Circling Nystagmus Strabismus Cranial nerve deficits (possible V, VI, VII in central lesions and possible VII in peripheral lesions) Horner's syndrome possible in peripheral lesions Cerebellar signs of mental depression and hemiparesis with ipsilateral postural reaction deficits (ataxic) possible in central lesions.
Cerebellar lesions	Dysmetria, spastic, stiff-limbed gait with normal strength Truncal ataxia Intention tremors Broad-based stance Postural reactions delayed with exaggerated responses +/- Menace deficit with normal PLR +/- Anisocoria (pupil dilated contralateral to side of lesion) +/- Opisthotonus (rare) +/- Vestibular signs (rare)
Cerebral lesions	Altered mental status—most commonly depression, lethargy Occasional hyperexcitability Change in behavior Normal gait on level surface with postural defects (delayed) Circling, twisted head and trunk (pleurothotonus), head pressing Abnormal gait going up or down hill CP deficits Menace decreased or absent with normal PLR Seizures Coma

Hydrocephalus

- Some neonates with hydrocephalus have an open fontanelle, which can allow ultrasound examination of the lateral ventricles for dilation and increased fluid accumulation.
- Radiographs of the skull may indicate a thin and possibly dome-shaped calvarium.

DIAGNOSTIC PROCEDURES

Hydrocephalus and Cerebellar Hypoplasia

- Blood for virus isolation, serologic testing, and quantitative immunoglobulin determination can be useful in cases due to in utero viral infection.
- Presuckle serum samples may be seropositive for akabane or bluetongue virus.

PATHOLOGIC FINDINGS

GROSS FINDINGS

Meningitis

- Meningeal vessels are congested.
- Meninges are swollen, opalescent, and petechiated.

Hydrocephalus and Cerebellar Hypoplasia

- Domed skull
- Dilated lateral ventricles
- Thinning of cerebellar cortices
- Secondary skeletal changes may occur in viral diseases such as arthrogryposis, abnormally curved ribs, kyphosis, and brachygnathia.

HISTOPATHOLOGICAL FINDINGS

Meningitis

- Meninges infiltrated by neutrophils and lymphocytes
- Endarteritis of meningeal vessels
- Choroiditis
- Leptomeningeal hemorrhages
- Bacterial colonies around blood vessels, meninges, and brain parenchyma

Brain Abscesses

In chronic abscesses, fibrinous leptomeningitis may develop adjacent to the abscess.

Hydrocephalus and Cerebellar Hypoplasia

- If disease is a result of akabane virus infection in the neonate, there may be additional neurologic pathology such as nonsuppurative encephalomyelitis, necrosis, and endothelial proliferation.
- Thinning of periventricular white matter

TREATMENT

Treatment of brain disorders involves treatment of the specific disease if possible and supportive care and prevention of life-threatening complications such as brain edema.

Meningitis (Bacterial) and Brain Abscesses

Early recognition and treatment with appropriate antibiotic therapy are essential.

Cerebellar Hypoplasia and Hydrocephalus

No specific treatment is available.

MEDICATIONS

Meningitis (Bacterial)

- Appropriate antibiotic therapy based on Gram stain characteristics of sedimented bacteria and the initial 24-hour cultures to begin treatment as soon as possible
- CSF antibiotic concentrations should range from 10 to 30 times the MIC of the infecting bacteria. Note that some antibiotics more effectively cross the blood-brain barrier (BBB) than others. Bactericidal antibiotics are preferable to bacteriostatic antibiotics.

Meningitis (Protozoal)

May respond to sulfa/pyrimethamine combination or clindamycin therapy

CONTRAINDICATIONS

- In cases of infectious meningitis, glucocorticoids are usually contraindicated; however, a single high-dose short-term

course of dexamethasone or methylprednisolone may control complications such as acute cerebral edema.

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

FOLLOW-UP

PATIENT MONITORING

Monitor for progression of neurologic signs

PREVENTION/AVOIDANCE

Meningitis (Bacterial)

- Ensure appropriate colostrum intake by neonates
- Appropriate environmental sanitation
- Quarantine of new animals brought to farm to prevent spread of infectious disease

POSSIBLE COMPLICATIONS

Depends on underlying cause of disease

EXPECTED COURSE AND PROGNOSIS

Meningitis (Bacterial)

Ensure appropriate colostrum intake by neonates

Hydrocephalus

Neonates often die of secondary conditions such as malnutrition and septicemia due to inability to suckle. Animals that survive have permanent neurologic deficits.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Spinal cord lesions and peripheral nerve disorders

AGE-RELATED FACTORS

- Congenital hydrocephalus and cerebellar hypoplasia occur during fetal development.
- Secondary obstructive (adult onset) hydrocephalus is generally due to obstruction of CSF flow due to such causes as intracranial masses or impaired CSF resorption at arachnoid villi due to inflammation.

ZOONOTIC POTENTIAL

E. coli, *Salmonella* spp., and *Streptococci* spp. can be zoonotic. Care should be included in the handling of laboratory samples.

PREGNANCY

Cerebellar Hypoplasia and Hydrocephalus Most commonly occur in neonates due to in utero viral infections

SEE ALSO

CNS: NERVE LESIONS

BASICS

OVERVIEW

Peripheral nerve lesions are commonly due to traumatic injuries. The following conditions often occur in small ruminants and other large animals:

- Brachial plexus avulsion
- Suprascapular nerve (sweeney)
- Spastic paresis (elso heel)
- Radial nerve trauma
- Femoral nerve trauma
- Peroneal nerve trauma

PATHOPHYSIOLOGY

Depends on the specific condition

SYSTEMS AFFECTED

CNS

GENETICS

Predominant Sex

N/A

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

CNS lesions such as demyelination, encephalitis, parasitic visceral migrans, or other lesions

CBC/BIOCHEMISTRY/URINALYSIS

Usually normal

OTHER LABORATORY FINDINGS

Electrolyte abnormalities may occur and exacerbate muscular weakness:

- Hypocalcemia

- Hypokalemia
- Hypomagnesimia

IMAGING

- Radiographs may show bony changes that can occur with chronic disorders.
- Changes in chronic spastic paresis include osteoporosis, lipping of dorsal aspect of tibial epiphysis, excessive straightening of the tuber calcis, and plantar displacement proximal portion of the tibial diaphysis and epiphysis

DIAGNOSTIC PROCEDURES

Thorough neurologic evaluation

PATHOLOGIC FINDINGS

GROSS FINDINGS

Depends on underlying cause

HISTOPATHOLOGICAL FINDINGS

Depends on underlying cause

TREATMENT

- Reduce inflammation
 - Dexamethasone (0.05 mg/kg IV daily for 3 to 5 days)
 - Apply cold packs to the affected area during the first day after injury.
- Treat electrolyte abnormalities if present.
 - Calcium gluconate (500 ml SC daily)
 - Potassium chloride can be given in water via stomach tube.
- Relieve musculoskeletal pain.
 - NSAIDs such as banamine, phenylbutazone, or aspirin may be indicated.
 - Morphine
- Prevent secondary medical complications such as dehydration and malnutrition.
- Turn recumbent animals six to eight times daily to prevent decubital ulcers and pressure sores.
- Goats often tolerate dog slings to assist them to stand.
- Provide adequate dry bedding to allow traction and prevent further injury.
- Spastic paresis can potentially be treated surgically with tibial nerve neurectomy or superficial digital flexor tenotomy proximal to the tuber calcis. It is often not treated due to familial nature of the disorder.

MEDICATIONS

See Treatment above.

CONTRAINDICATIONS

- Do not use NSAIDs and steroids concurrently.
- Monitor drug withdrawal times for meat and milk.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food -producing animals.
- Do not use steroidal drugs with pregnant animals.

FOLLOW-UP

PATIENT MONITORING

Monitor for progression of neurologic disorder and secondary conditions such as dehydration, malnutrition, electrolyte abnormalities, or pressure sores in recumbent animals.

PREVENTION AVOIDANCE

- Prevent traumatic injuries using appropriate management, housing, and equipment.
- Use care when assisting with dystocia.

POSSIBLE COMPLICATIONS

Depends on cause of disease

EXPECTED COURSE AND PROGNOSIS

Depends on severity of injuries and neurologic impairment

MISCELLANEOUS

ASSOCIATED CONDITIONS

See [Table 1](#).

AGE-RELATED FACTORS

Spastic paresis can occur in calves or as an adult-onset condition.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Dystocia or trauma in assisted parturition can result in nerve damage.

Table 1 Symptoms and Causes Associated with Neurological Lesions.

Nerve/Condition	Common Causes of Injury	Signs
Brachial plexus avulsion	Traumatic injury Severe extension or abduction of thoracic limb causes stretching or tearing of the nerve roots from their spinal cord attachment.	Complete flaccidity and desensitization of the thoracic limb Unable to bear weight Triceps and biceps reflexes are absent Abduction of the elbow due to loss of pectoral nerve function Dropped shoulder Hyperextension of the elbow at rest and inability to flex the elbow due to musculocutaneous nerve paralysis Complete desensitization of thoracic
Radial nerve	Traumatic injury Direct trauma at lateral aspect of the elbow joint Prolonged anesthesia or restraint in lateral recumbency on hard surface	Signs depend of location of injury High radial nerve paralysis occurs with lesions near the elbow joint. Signs include dropped elbow, foot knuckled over at rest, scuffing of the toes, and flexion of joints distal to injury. The animal is unable to bear weight on thoracic limb. Low radial nerve paralysis results in knuckling of the carpus, fetlock, and pastern joints. The animal can bear weight if the metacarpus and elbow can extend. Triceps reflex is decreased or absent.
Femoral nerve	Traumatic injury Overextension of the hip and stifle joint commonly due to a fall or forced posterior delivery of calf	Inability to extend or fix the stifle Reciprocal apparatus cannot fix the hock causing collapse of the limb when attempting to bear weight. Metatarsal and tarsal joints remain in flexion. There is loss of sensation on medial aspect of the limb from the proximal thigh to medial malleolus of the tibia.
Peroneal nerve	Direct trauma as nerve crosses over the lateral condyle of the fibula Commonly seen after recumbency due to hypocalcemia or other causes	Extension of hock joint Flexion of the digits Decreased sensation of craniodorsal surface of foot, hock, and stifle Some animals can bear weight only if the limb is manually placed in the proper position.
Suprascapular nerve (weeney)	Trauma to the shoulder region	Instability of the scapulohumeral joint with outward bowing of the joint Neurogenic atrophy results in prominent appearance of scapular spine.
Spastic paresis (elso heel)	Etiology is undetermined. Not a result of insult to a single peripheral nerve and may be due to CNS lesions. Two syndromes—both are considered familial conditions and have been found in several breeds of cattle. In calves, clinical signs of lumbar lordosis and caudal extension of limbs are seen between 1 week and 1 year of age. In adults, clinical onset usually occurs between 3 and 7 years of age.	Extension of stifle and tarsus Spastic contracture of gastrocnemius and superficial flexor muscles as animal attempts to walk. Other muscles in pelvic limbs can also be affected. Limb is circumducted when walking to prevent dragging the foot. If untreated, the disease will progress. Often responds favorably to tibial nerve neurectomy.

CNS: SPINAL COLUMN AND CORD ANOMALIES

BASICS

OVERVIEW

Spinal cord anomalies can be the result of many disease processes including trauma, infection or inflammation, nutritional diseases, congenital disorders, degenerative diseases, toxins, and vascular diseases.

PATHOPHYSIOLOGY

- Vertebral body fractures
 - In large animals, vertebral fractures are a common cause of spinal cord injury.
 - Fractures can be due to trauma, nutritional deficiencies, or other pathologic causes.
- *Hypoderma bovis* (heel flies)
 - *Hypoderma bovis* are long, hairy, beelike flies. The female flies attach their eggs to the hair on the legs and lower body of cattle and bison.
 - The migration of the first stage larvae through the epidural fat along the spinal cord can result in inflammation and clinical signs of spinal cord disease.
- Vertebral spondylosis
 - Spondylosis is a disease of the intervertebral joints. There is ossification in the joint space between bone and ligament or tendon. There can be complete bridging (ankylosis) between vertebral discs. It can be due to progressive development of vertebral enthesophytes or secondary to degenerative joint disease.
 - Ankylosing spondylitis is a progressive inflammatory disease affecting joint tissue that can result in fusion of lumbar vertebrae in bulls and rams.

SYSTEMS AFFECTED

Musculoskeletal, CNS, skin, nutritional

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide distribution

SIGNALMENT

- Due to differences in management, temperament, and anatomy affecting regional strength of the spine, the common locations of spinal injury sites differ among species.
- Breeding injuries occur more commonly in cattle.
- Cattle and sheep incur pathologic fractures due to nutritional deficiencies or vertebral osteomyelitis.
- Vertebral spondylosis occurs in bulls and rams. Spondylosis results in culling of approximately 4% of Holstein bulls used for artificial insemination.
- All species of domestic livestock are susceptible to CNS disease resulting from nematode and insect larvae migration through the CNS. *Hypoderma bovis* infest cattle and bison. *Parelaphostrongylus tenuis* infestations occur in sheep, goats, and llamas.

Species

- All species
- Breeding injuries occur more commonly in cattle.
- Vertebral spondylosis occurs in bulls and rams.

Breed Predilections

Spondylosis results in culling of approximately 4% of Holstein bulls used for artificial insemination.

Mean Age and Range

N/A

Predominant Sex

Vertebral spondylosis occurs in bulls and rams.

SIGNS

The signs of any spinal cord injury are related to the level of the spinal cord segment(s) involved. Clinical signs can help localize the site of damage in the majority of cases with neurologic problems. (See [Table 1.](#))

Vertebral Fracture

- Acute signs may progress in unstable fractures or luxations. Progression to respiratory muscles results in death.
- Spondylosis most frequently affects the lumbosacral region.

Hypodermiasis

- The majority of *Hypoderma bovis* first-stage larvae lodges in the lumbosacral region of the spinal cord. However, larvae can potentially migrate to other parts of the spinal cord or even brain stem.
- Inflammatory process results in acute, often asymmetric, and progressive signs.
- Cattle may exhibit a stampeding behavior described as “gadding” when chased by the female *Hypoderma bovis* flies. This behavior can result in injury or decreased feeding.

CAUSES AND RISK FACTORS

Vertebral Fractures

- Abnormal bone mineralization may predispose to fractures. Common sites in calves are the C2–C4, T10–T13, and L3–L6 vertebrae.
- Nutritional deficiencies of copper, vitamin D, or calcium in 3–6-month-old ruminants can result in vertebral fractures.
- Traumatic cervical fractures may be caused by injuries sustained in falls, roadway accidents, butting of other animals, predation, or squeeze chutes.
- Pygmy goats may have traumatic luxations or fractures of the atlantooccipital and atlantoaxial joints when the horns are held during restraint.
- Chronic ankylosing spondylosis in mature bulls and rams can result in traumatic lumbar vertebral fractures.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Meningitis can result in stiffness and resistance to passive flexion of the neck as seen in cervical fractures.
- Osteoarthritis or degenerative joint disease (DJD)
- Nematodes other than *Hypoderma bovis* can migrate through the CNS. In cattle, *Setaria* spp. causes pathology. Small ruminants may become infected with *Parelaphostrongylus tenuis* when pastured where white-tailed deer also feed.

CBC/BIOCHEMISTRY/URINALYSIS

Normal

OTHER LABORATORY FINDINGS

- CSF findings in vertebral fracture—acute changes (< 1 day after injury) include high RBCs, normal to high WBCs, and high protein concentration.
- CSF findings in vertebral fracture—chronic changes (> 1 day) include normal to slightly increased WBCs, possible xanthochromia.
- CSF findings in hypodermiasis are variable. Increased eosinophils are suggestive but may not be present because the larvae infestations are extradural. The CSF changes reflect increased pressure. Mild xanthochromia and normal to increased WBCs may be present if there is vascular damage due to pressure changes.

IMAGING

Fractures

Survey and contrast radiography often identify vertebral fractures and luxations.

DIAGNOSTIC PROCEDURES

- Complete and accurate history
- Thorough physical examination with fullest neurologic examination possible including evaluation of cutaneous desensitization to pinprick can help localize the lesion.
- Evaluation of gait is very valuable for large animals. Ambulation while blindfolded and while walking up and down a grade may accentuate subtle gait defects.
- Evaluate neck and limbs for pain, muscle atrophy, and cutaneous trunci reflex.
- Electrodiagnostic testing for neuromuscular conduction abnormalities

PATHOLOGIC FINDINGS

GROSS FINDINGS

- Vertebral fracture with possible evidence of spinal cord hemorrhage or necrosis
- Bridging of vertebral bodies in cases of ankylosing spondylitis

Table 1 Symptoms Associated with Neurological Lesions.

Spinal Cord Segments	Principal Signs
C1–C5	Weakness or paralysis in all limbs or in limbs on one side of the body UMN signs of normal or increased reflexes and muscle tone in all limbs Extensor rigidity on the same side as the lesion in all limbs Conscious proprioceptive deficits on the same side as the lesion in all limbs Hyperesthesia at the level of the lesion The neck is held stiff. Affected animals resist passive flexion of the head. May refuse to lower the head and may kneel when trying to eat from the ground. Thoracic limb held in partial flexion or repetitive stamping Urinary incontinence Persistent scratching at the neck Possible Horner's syndrome Possible dyspnea Possible torticollis/scoliosis
C6–T2 brachial plexus (thoracic limb)	Weakness or paralysis in all limbs, limbs on one side of the body, or a single limb LMN signs of decreased reflexes and flaccid muscle tone in thoracic limbs UMN signs of normal or increased reflexes and increased extensor muscle tone in pelvic limbs CP deficits in one thoracic limb, limbs on one side of the body, or all limbs Hyperesthesia at level of lesion Cutaneous trunci reflex reduced or absent behind the level of the lesion (unilateral or bilateral) Persistent scratching at one side of the neck or shoulder region Horner's syndrome
T3–L3	Weakness or paralysis of pelvic limbs UMN signs of normal or increased reflexes and increased extensor muscle tone in pelvic limbs. Initially, there is no muscle atrophy in pelvic limbs. Hyperesthesia at the level of the lesion Cutaneous trunci reflex reduced or absent behind the level of the lesion Urinary incontinence Thoracolumbar kyphosis Possible dyspnea or respiratory paralysis in cases with descending myelomalacia Possible Schiff-Sherrington posture ¹
L4–S2 lumbosacral plexus (pelvic limb)	Weakness or paralysis of pelvic limbs Hyperesthesia at the level of lesion LMN signs of muscle atrophy in pelvic limbs, and decreased anal sphincter tone. CP deficits in one or both pelvic limbs Reduced sensitivity in perineal region, pelvic limbs, or tail Urinary or fecal incontinence
S1–Cd5	Urinary or fecal incontinence Reduced sensitivity in perineal region or tail

¹Schiff-Sherrington phenomenon is paraplegia with increased extensor tone in the thoracic limbs.

HISTOPATHOLOGICAL FINDINGS

- Vertebral fractures can result in spinal cord demyelination with secondary changes of ascending and descending necrosis of the spinal cord (myelomalacia) with possible evidence of compromised blood flow (hematomyelia).

- Parasite migration results in inflammation and tissue necrosis.

TREATMENT

FRACTURES

- Recovery after 4–6 weeks of stall rest is often possible if neurologic deficits are mild and the fracture or luxation is not unstable.
- Small ruminants with cervical fractures and luxations may be stabilized by casting. A fiberglass cast should extend from the middle part of the thorax to the tip of the nose.
- Raise feed and water sources to allow animals with cervical fractures to eat and drink without bending the neck.
- Dietary intake of copper, molybdenum, and calcium should be evaluated and measured if possible. Supplementation may be necessary to avoid additional pathologic fractures.
- Avoid restraint of animals with metabolic bone disease to avoid additional pathologic fractures.

HYPODERMA BOVIS

Parasitides should be administered to prevent further parasite migration in the CNS. This treatment can cause severe reactions associated with the death of the parasites, so concurrent heavy anti-inflammatory therapy is required.

MEDICATIONS

VERTEBRAL FRACTURES

- Spinal cord contusions generally recover spontaneously without medication.
- Acutely affected animals can be treated with
 - Dimethyl sulfoxide (DMSO) (0.25–1 g/kg IV in 5% dextrose as a 40% DMSO solution); do not use DMSO in concentrations > 20% in horses.
 - Dexamethasone (0.1–0.2 mg/kg given 4 times daily for 2–4 days)
- If extremely painful, narcotic agents such as morphine (0.2–0.4 mg/kg) may be administered. Another analgesic option is lumbar epidural injection of morphine (0.1 mg/kg in 10–20 ml of normal saline).
- Instead of dexamethasone, treatment with methylprednisolone within the first hours of injury may be helpful (30 mg/kg IV, followed 2 hours later by 15 mg/kg IV, followed 6 hours later by 15 mg/kg IV, every 6 hours for a total of 24 hours of treatment). Do not use NSAIDs in conjunction with corticosteroids.
- Meat and milk drug withdrawal times must be strictly enforced. Consult FARAD when possible.

HYPODERMA BOVIS

- Systemic organophosphates or other insecticides are the only way to eliminate migrating larvae. Avoid treatment with systemic insecticides when larvae are in the epidural space.
- Topical insecticides can be used to kill eggs and larvae on the hair and skin of the lower body and legs.
- Organophosphates must be used in strict accordance with label instructions to prevent toxicity to the host animal.
- Organophosphates are not permitted for use on lactating dairy animals.
- The following insecticides are available for use:
 - Cruformate (75 mg/kg as 13.5% Ruelene)
 - Trichlorfon (40 mg/kg PO)
 - Famphur (13.2% 1 fluid ounce 90 kg of body weight, not to exceed a total dosage of 4 oz for cattle)
 - Ronnel (100 mg/kg PO for cattle)
 - Ivermectin 0.5% (1 ml/10 kg, max 10 ml / injection site); recommend treatment immediately after the adult fly season
 - Fenbendazole and thiabendazole have been reported to be used but are not labeled for use against *Hypoderma* spp.
- If systemic treatment must be given when the larvae are in the epidural space, the potential adverse effects must be addressed with concomitant heavy anti-inflammatory treatment with corticosteroids or NSAIDs. Do not use steroids and NSAIDs concurrently.

- Dexamethasone (0.1–0.25 mg/kg IV every 6 hours) or
- Phenylbutazone (10 mg/kg once every 36 hours IV or PO in cattle)
- Aspirin (100 mg/kg PO 2–3 times daily for cattle)
- Flunixin meglumine (1–2.2 mg/kg IV given 2 times daily for cattle)

CONTRAINDICATIONS

- Avoid treatment with systemic insecticides when the larvae are located in the epidural space (October 1–March 1 in the northern United States). Dying worms can directly release toxic factors and can cause local immunologic responses. Neurologic disturbances are aggravated and can be potentially fatal.
- Tranquilizers should be administered with care to ambulatory patients because ataxia may result in a fall and worsen spinal cord damage.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Do not use steroidal drugs in pregnant animals.

FOLLOW-UP

PATIENT MONITORING

Monitor for progression of neurologic signs.

PREVENTION/AVOIDANCE

- Efforts should be made to differentiate nutritional deficiencies from traumatic causes to allow proper preventive measures for other animals.
- Treat with appropriate anthelmintics before larval migration of *Hypoderma bovis*.

POSSIBLE COMPLICATIONS

Treatment complications are possible. See Treatment section above.

EXPECTED COURSE AND PROGNOSIS

Fractures

- Guarded prognosis in recumbent animals
- Poor prognosis if deep pain perception is lost caudal to the lesion.

Hypoderma bovis

- The life cycle of the fly is complete in 1 year.
 - Eggs are deposited by the female fly in May–July in the northern United States.
 - The first-stage larvae travel down the hair shaft and penetrate the skin within 3–7 days.
 - Then they migrate through fascial planes between muscles, along connective tissue, or along nerve pathways to the region of the epidural fat between the dura mater and periosteum along the spinal canal where they accumulate for 2–4 months.
 - In early winter, the larvae begin to arrive in subdermal tissue of the back of the host. They make breathing holes through the skin and the “warbles” form around the first-stage larvae. The larvae go through the second and third stages within these cysts. The warble stage lasts 1–3 months.
 - The third-stage larvae emerge through the breathing holes in the skin, drop to the ground, and pupate.
 - Adult flies do not feed and live only 1 week.
- The prognosis is guarded because treatment results in potentially life-threatening complications. Dying worms release toxic factors and there is a local inflammatory response to dying worms, which aggravates neurologic conditions. Anti-inflammatory medications must be given at the time of treatment for the parasites.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Brain disorders and peripheral nerve disorders.

AGE-RELATED FACTORS

Immature animals (3–6 months of age) more frequently suffer pathologic fractures due to nutritional deficiencies.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Nutritional deficiencies in the dam can affect skeletal development of the fetus.

SEE ALSO

COCCIDIOIDOMYCOSIS

BASICS

OVERVIEW

- The dimorphic soil fungus, *Coccidioides immitis*, causes coccidioidomycosis.
- Inhalation of arthrospores frequently leads to asymptomatic infection.
- Mild respiratory disease may rarely lead to disseminated disease in some animals.

PATHOPHYSIOLOGY

- Soil mycelial phase release arthrospores, which can survive for many years in environment
- Arthrospores are inhaled and reach alveoli.
- Arthrospores form endospore-producing spherules.
- Spherules rupture, releasing endospores that form additional spherules.
- Spherules destroy tissue as they are formed and rupture.
- Frequently, infection is confined to respiratory tract and results in asymptomatic infection. In human studies, 60% of infected patients exhibit asymptomatic respiratory infection within 10–14 days of spore inhalation.
- Some animals develop mild respiratory disease with diffuse pulmonary infiltrates. In human studies, 40% of infected patients developed symptoms of mild or, infrequently, more severe flu-like respiratory disease (primary pulmonary disease). Fibrotic/cavernous lesions of lungs may be sequelae of primary pulmonary infection.
- Rarely will *Coccidioides* spread hematogenously.
- Phagocytic cells play crucial role in defense against *Coccidioides immitis*.
- Granulomatous lesions/abscesses may be found in lungs, bronchial and mediastinal lymph nodes; infrequently in submaxillary/retropharyngeal lymph nodes. In most cattle, carcass quality is not affected.
- Lesions may contain a creamy purulent material or be calcified.
- In disseminated disease, lesions may be found in other tissues including CNS, bone, joints.

INCIDENCE/PREVALENCE

- Of feedlot cattle, 5%–20% at slaughter exhibited lesions of coccidioidomycosis in one study (Arizona).
- Of human population, 3% converts to positive *Coccidioides* skin test annually in endemic regions.

GEOGRAPHIC DISTRIBUTION

- Lower Sonoran zones of the southwest United States, Mexico, Central and South America
- Arid/semiarid climates, low-elevation deserts, alkaline soils

SIGNALMENT

- All species of mammals, including humans, dogs, cattle, sheep, goats, swine, rodents, may be infected.
- In endemic areas, infection of cattle, humans, and dogs is common.
- Coccidioidomycosis should be part of differential diagnosis of chronically ill animals in endemic areas.

SIGNS

- Commonly causes asymptomatic infections
- Animals may exhibit chronic weight loss, persistent cough, fever.
- Granulomatous lesions/abscesses most commonly found in lungs and bronchial and mediastinal lymph nodes. *Source of Infection*
- Soil reservoir
- Although zoonotic potential, no transmission reported between animals or between animals and humans. *Transmission*
- Inhalation of spores, especially following dust storms
- Possible infection via ingestion (if devitalized tissue present)/skin abrasions

RISK FACTORS

- Exposure to spore-contaminated dust (spores resistant to heat, drying, salinity)
- Presence of devitalized tissue from preexisting disease
- Overuse of corticosteroids
- Granulocyte abnormalities
- Not contagious from animal to animal
- Highly infectious from environmental, laboratory culture mycelial phase

DIAGNOSIS

- Direct microscopic examination and culture of transtracheal wash, pus, pleural fluid, necropsy sample
- Samples should be placed in sterile containers and prevented from drying (small amount sterile water or 0.85% saline for biopsy/necropsy samples, no preservatives, antibiotics may be added to inhibit bacterial overgrowth).
- Formalin-fixed specimens cannot be used for culture but can be used for histological examination.
- Examine/culture within 1 hour or refrigerate
- Presence of spherules upon microscopic exam of tissues
- Spherules: round, nonbudding, thick-walled, 20–200 micrometer in diameter, endosporeulating
- Serum: complement fixation/precipitin/FA inhibition tests
- Intradermal sensitivity tests use coccidioidin extract (nonspecific). Inject 0.1 ml in flank skin fold intradermally. Positive test if after 48 hours, 5 mm edema/induration. Nonspecific cross-reactions with histoplasmin.

DIFFERENTIAL DIAGNOSIS

- Tuberculosis
- Caseous lymphadenitis (sheep/goats)
- Actinomycosis
- Actinobacillosis
- Nocardiosis
- Histoplasmosis
- Blastomycosis

TREATMENT

- No effective treatment
- Eukaryotic fungi are not inhibited by antibiotics.
- Amphotericin B and azoles used to treat human cases.
- In human cases, prognosis for primary pulmonary disease is good.
- Disseminated disease is usually fatal.

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PREVENTION/AVOIDANCE

- Reduce dust by planting grass/installing water sprinklers. In one study, 90% of visible particles collected from stable air studies were fungal spores/actinomycetes.
- Avoid clearing brush while animals are present.
- No vaccine is available.

COCCIDIOSIS

BASICS

DEFINITION

Coccidiosis refers to the clinical symptoms that result from an infection with one of several *Eimeria* species.

OVERVIEW

- Most ruminants are exposed to and infected with coccidia. Infection is usually asymptomatic and self-limiting with the development of species-specific immunity.
- Clinical signs develop when large numbers of oocytes are ingested or the host's immune system is suppressed.

Causative Agent *Eimeria* species infect ruminants. Coccidia are species specific. The most common coccidia in cattle are *E. bovis* and *E. zuernii*, in sheep *E. ovina*, and in goats *E. arloingi*.

- Oocysts are shed in the feces of infected animals, either those with clinical signs or older carrier animals. The oocysts sporulate in moist warm environments and become infective.
- During the developmental stages of the parasite's life cycle, intestinal cells are damaged. The number of infective oocysts ingested is related to the severity of clinical signs.
- Healthy nonimmune animals ingesting few oocysts may not show any clinical signs as intestinal damage is not significant and is quickly repaired. If a healthy nonimmune animal is exposed to many oocysts, widespread intestinal damage occurs with disruption of the intestinal mucosa.
- Mucosal damage results in alterations in gut function, loss of blood, fluid, protein, and electrolytes into the intestinal lumen resulting in diarrhea. Fecal material may contain pieces of sloughed mucosa and blood. Mucosal damage allows for bacterial invasion into and through the gut wall.
- Animals experiencing stress are more likely to exhibit clinical signs. Animals acquire active immunity to the species to which they are exposed.
- The pathophysiology of nervous coccidiosis is not fully elucidated but a neurotoxin is suspected to be involved.

SYSTEMS AFFECTED

- Gastrointestinal
- Nervous

GENETICS

N/A

INCIDENCE/PREVALENCE

Incidence of nervous coccidiosis is highest in the winter. Incidence of diarrhea is related to the buildup of infective oocysts within the animal's environment.

SIGNALMENT

Species

Bovine, caprine, and ovine

Breed Predilections

N/A

Mean Age and Range

- There is no specific age range for infection but clinical signs appear in animals as young as 16 days of age.
- Clinical signs are often associated with the stress of weaning and movement into a feed yard.

Predominant Sex

N/A

SIGNS

GENERAL COMMENTS

- The disease is primarily of young animals managed as groups in unsanitary conditions. Most animals in a group become infected but only a minority exhibits signs.
- Animals exhibiting clinical signs often have suppressed appetites and poor weight gains for several weeks after enteric signs resolve.

HISTORICAL FINDINGS

- Animals were recently weaned, moved from individual to group housing, housed in a crowded area that has a buildup of fecal material, and/or the housing environment has become wet or muddy.
- Owners may report poor feed intakes and weight gains.
- Cases of nervous coccidiosis—animal has recently exhibited signs of diarrhea, tenesmus, or hematochezia along with cold environmental temperatures.

PHYSICAL EXAMINATION FINDINGS

- Rough hair coat, poor body condition, and feces-stained perineum are common in young animals. Animals have varying degrees of dehydration, anorexia, and weakness.
- Depending on the severity of the infection, feces may contain mucus, strands of mucosa, and blood. Feces may be dark in small ruminants but hematochezia is rarely observed.
- Tenesmus is common with slight rectal prolapse.
- Nervous coccidiosis—initial signs of depression and incoordination are noted, progressing to muscle tremors, hyperesthesia, clonic-tonic convulsions, nystagmus, and blindness.
- The case fatality rate is high.

CAUSES

Eimeria species infect ruminants. Coccidia are species specific. The most common coccidia in cattle are *E. bovis* and *E. zuernii*, in sheep *E. ovina*, and in goats *E. arloingi*.

RISK FACTORS

- Changes in feed, weaning, and transport increase the development of clinical signs of disease.
- Housing that encourages buildup of fecal material such as crowded conditions and group housing
- Exposure to moist environments such as areas around leaking waterers or poorly drained feeding stations

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Enteric Coccidiosis

Salmonellosis, BVDV infection, abomasal or intestinal nematode parasitism, cryptosporidiosis

Nervous Coccidiosis

Polioencephalomalacia, lead intoxication, thromboembolic meningitis

CBC/BIOCHEMISTRY/URINALYSIS

Nothing particularly significant

CBC/BIOCHEMISTRY/URINALYSIS

- Hemoconcentration, although a slight anemia may exist but is masked by dehydration; a mild inflammatory leukogram if mucosal damage is severe.
- Plasma proteins are increased initially due to dehydration; however, plasma protein levels decrease due to leaking into gut and depressed feed consumption.

OTHER LABORATORY TESTS

- Fecal flotation
- Diarrhea may be present for 3 or 4 days prior to the presence of oocysts in the feces.
- Checking multiple individuals increases the chances of finding oocysts, as stages of oocyst development will vary among individual animals.
- Presence or absence of oocysts in a single fecal exam is neither diagnostic nor confirmatory for coccidiosis. An animal can

shed large numbers of oocysts; yet show no clinical disease because of immune status.

PATHOLOGIC FINDINGS

Mucosa of the ileum, cecum, colon, and rectum may be congested, hemorrhagic, and thickened. The mucosa may be sloughing and ulcerated in severe cases. Lumen contents may contain blood and pieces of the mucosa.

TREATMENT

APPROPRIATE HEALTH CARE

N/A

NURSING CARE

Fluid therapy, consisting of commercial oral or intravenous polyionic fluids may be needed to correct dehydration and restore electrolytes.

ACTIVITY

N/A

DIET

Because animals tend to be thin, feeding an appropriate amount of grain for that animal may be helpful.

CLIENT EDUCATION

- Clients should be made aware of the potential shedding of oocysts in feces and contamination of the environment.
- A preventive program, including coccidiostats, should be discussed and implemented as soon as possible to prevent future infections.

MEDICATIONS

DRUGS OF CHOICE

- Sulfamethazine 110 mg/kg for 5 days—cattle (may help control bacterial invasion and pneumonia). Resistance to sulfamethazine has been observed.
- Amprolium 10 mg/kg for 5 days—cattle
- Amprolium 50 mg/kg for 5 days—goats and sheep, extralabel

CONTRAINDICATIONS

- Use of amprolium may increase the risk of polioencephalomalacia.
- With the use of medications, the meat and milk withdrawal times must be maintained appropriately.

FOLLOW-UP

PATIENT MONITORING

Monitor attitude, appetite, fecal color and consistency, and hydration status.

PREVENTION/AVOIDANCE

- Cleanliness is the basis of prevention. Clean and disinfect animal holding facilities between groups of animals. Drying and exposure to sunlight increases die off of oocysts.
- Do not overcrowd animals. Reduce manure buildup. Eliminate muddy areas in the animal's environment. Feed up off the ground.
- Do not allow animals to defecate in water or feed. Feeding of coccidiostats in feed or in salt mixes:
 - Amprolium—5 mg/kg for 30 days cattle
 - Decoquinate—0.5 mg/kg for 30 days, cattle, goats, and sheep
 - Lasalocid—20–30 g/ton of feed, cattle and sheep, or 1 mg/kg per head per day

- Monensin—20 g/ton of feed, cattle and goats, or 1 mg/kg per head per day

POSSIBLE COMPLICATIONS

- Pneumonia has been associated with outbreaks of coccidiosis.
- Bacterial invasion through damaged gut wall may lead to septicemia.

EXPECTED COURSE AND PROGNOSIS

- Course of diarrhea is dependent on severity of infection. Feces begin to firm after several days of treatment with antimicrobials or amprolium.
- Prognosis is based on how debilitated the animal is at the time of presentation.
- Animals that are severely affected may have long-term reduction in weight gains, especially kids, as a result of damage to the intestinal lining.

MISCELLANEOUS

AGE- RELATED FACTORS

- Clinical signs of disease can occur anytime after 16 days of age.
- All ages are susceptible until immunity is developed.

ZOONOTIC POTENTIAL

None

RUMINANT SPECIES AFFECTED

Bovine, caprine, ovine

PRODUCTION MANAGEMENT

Do not overcrowd animals. Reduce manure buildup. Eliminate muddy areas in the animal's environment. Feed up off the ground.

COENUROSIS

BASICS

DEFINITION

Coenurosis is a condition in sheep caused by invasion of the central nervous system (CNS) by *Coenurus cerebralis* in its cystic larval stage, or metacestode stage of the tapeworm *Taenia multiceps* (bladder worm). This parasite normally inhabits the intestinal tract of carnivores when they eat infected sheep's brain (raw) or cyst-contaminated offal.

PATHOPHYSIOLOGY

Sheep become infected when they eat forage contaminated with tapeworm or *Taenia* eggs and then the embryos pass from the blood to the CNS. Lesions of the CNS may result from:

- The large numbers of immature/migrating worms entering and causing encephalitis
- Interference with cerebrospinal fluid drainage
- Large cerebral cysts compressing surrounding nervous tissue

Most signs are caused by the mature *Coenurus cerebralis*, which may be up to 5 cm in diameter after 6–7 months of development.

SYSTEMS AFFECTED

CNS

SIGNALMENT

Species

Most common in sheep (can also affect cattle, goats, and wild ruminants)

Breed Predislection

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

GENETICS SIGNS

- Acute conditions may occur due to migrating larvae approximately 10 days after ingestion. This is most common in young lambs (6–8 weeks of age). Signs may include:
 - Blindness
 - Ataxia
 - Muscle tremors
 - Nystagmus
- Chronically infected animals with mature *Coenurus cerebralis* that have hatched, migrated, and grown over 2–6 months may show signs of:
 - Solitude
 - Partial or complete unilateral blindness
 - Depression
 - Head pressing and incoordination
 - Gradual development of paresis/paralysis and recumbency if the spinal cord is involved

CAUSES AND RISK FACTORS

Ingestion of forage contaminated with *Taenia* eggs

DIAGNOSIS

- Presumptive diagnosis can be based on clinical signs and knowledge of *Taenia* presence in the area.
- Localization of metacestode in the brain or spinal cord is necessary for definitive diagnosis.

DIFFERENTIAL DIAGNOSIS

Coenurosis should be differentiated from other local space-occupying lesions in the CNS, including abscesses, hemorrhage, and neoplasia as well as listeriosis and bluetongue.

CBC/BIOCHEMISTRY/URINALYSIS

OTHER LABORATORY TESTS

N/A

IMAGING

Skull radiographs may be helpful in localizing the cyst.

PATHOLOGIC FINDINGS

- Thin-walled cysts are most commonly found on the external surfaces of the cerebral hemispheres.
- Local pressure atrophy of nervous tissue is usually apparent.
- Spinal cord lesions usually occur in the lumbar region.

TREATMENT

- Surgical drainage of the cyst may prolong life.
- Surgical removal of the cyst may lead to complete recovery.

MEDICATIONS

N/A

CONTRAINDICATIONS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- The spread of infection with *Taenia multiceps* is best prevented by controlling the mature worms in dogs through effective periodic deworming.
- Carnivores should not be given access to carcasses of animals infested with the intermediate stage of *Taenia multiceps*.
- Carnivores should be prevented from defecating in areas where ruminants graze to minimize exposure to *Taenia* eggs.

EXPECTED COURSE AND PROGNOSIS

Prognosis is poor without surgery, although surgery can be difficult depending on the location of the cyst.

MISCELLANEOUS

ZOONOTIC POTENTIAL

Human infection can occur but it is very rare. Proper hygiene (washing hands or wearing gloves) after handling dog feces or infected sheep carcasses helps prevent infection.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Sheep, goats, cattle, and wild ruminants

BIOSECURITY

Not allowing dogs to defecate on forages to be consumed by ruminants will help decrease exposure to *Taenia* eggs.

CONGESTIVE HEART FAILURE

BASICS

DEFINITION

Congestive heart failure is a syndrome, not a specific disease, resulting from a number of causes and occurring when the heart becomes weak and is unable to effectively contract and pump blood to organs and peripheral tissues resulting in congestion of the lungs and other tissues.

OVERVIEW

- Heart failure can involve the heart's left side, right side, or both sides.
- Occurs when any of the heart chambers lose their ability to efficiently pump the amount of blood flow returning to the heart
- May result from primary cardiovascular disease or secondary to disease in other organ(s) or systemic disease
- Left-sided or left-ventricular failure
 - Left ventricle loses ability to contract (systolic failure) and force blood into the circulation. Ventricle becomes dilated.
 - Left ventricle loses its ability to relax (diastolic failure) because muscles are stiff and the ventricle cannot fill properly with blood during the resting period. Ventricular wall thickens.
 - Congestion in pulmonary circuit (pulmonary edema)
 - Systemic blood pressure falls.
 - Fluid builds up in tissues of body (edema).
- Right-sided or right-ventricular failure
 - Occurs as result of left-sided failure or alone
 - Right ventricle cannot pump the volume of blood returned to it.
 - Congestion of systemic venous system, decreased output to lungs causes venous distention, hepatomegaly, splenomegaly, edema of the intestinal tract, and peripheral edema.
- Congestive heart failure is usually a chronic event, occasionally acute.
- Heart tries to compensate for changes occurring with heart failure by enlarging, developing more muscle mass, and/or pumping faster.
- Body tries to compensate for heart failure by vasoconstriction, diverting blood from less important organs to maintain flow to most important organs.

PATHOPHYSIOLOGY

- Cardiac contractility is compromised resulting in inefficient heart contraction and movement of blood through the heart and circulatory beds.
- As blood flowing out of the heart slows, blood returning to the heart via the veins backs up causing congestion in the tissues and frequently edema.
- Pulmonary edema may develop resulting in dyspnea and coughing.
- Secondary compromise of renal function results in retention of fluid and edema.

SIGNALMENT

- Uncommon, sporadic disease
- Cattle
- Goats, sheep

SIGNS

- Most affected animals presented for signs of heart failure
- Exercise intolerance

- Weight loss
- Hypophagia
- Tachycardia
- Muffled heart sounds
- Signs of left-heart failure: tachypnea, coughing, dyspnea
- Signs of right-heart failure: submandibular, brisket, or ventral edema, jugular and mammary vein distention, and pulsation with right-heart failure
- Heart sounds may vary in intensity.
- Fast and weak peripheral pulses
- Pulse deficit
- ± Heart murmur
- ± Arrhythmia
- ± Hepatomegaly
- ± Diarrhea

PATHOLOGIC LESIONS

- Right-sided heart failure: subcutaneous edema, ascites, hydrothorax, hydropericardium, hepatic congestion, hepatomegaly
- Left-sided heart failure: pulmonary congestion and edema
- Heart enlargement and dilation

CAUSES AND RISK FACTORS

- CHF may result from previous heart disease (e.g., myocardial degeneration, myocarditis, cardiomyopathy, endocarditis, valvular defect, ruptured valve or chordae), pericarditis, pericardial tamponade, congenital heart defects, hypertension, disease of the arteries supplying the heart muscle, or cardiac neoplasia.
- Pressure load (e.g., aortic or pulmonic stenosis, pulmonary hypertension)
- Left-heart failure: myocardial disease, aortic insufficiency, hypertension, cardiomyopathy
- Right-heart failure: left-heart failure, obstructive lung disease, congenital heart defects, neoplasia (lymphosarcoma) in right atria
- Arrhythmias
- Nutritional muscular dystrophy
- Ionophore toxicosis
- Ingestion of cardiotoxic plants (e.g., oleander, lily of the valley, yew, Indian hemp, false hellebore, milkweed, avocardo, caltrops, coffee weed, senna, etc.)
- In goats, CHF due to cor pulmonale secondary to pneumonia, mediastinal thymoma, and ventricular septal defect
- Gousiekte or “quick disease” in South Africa due to ingestion of plants in Rubiaceae family

DIAGNOSIS

- History and clinical signs of heart failure
- Auscultation: tachycardia, crackles over the lung fields
- Echocardiography
 - Assess valve function, heart wall and septum motion and contraction, overall heart size, presence of pericardial effusion
 - Document ventricular hypertrophy and dilatation
- Thoracic radiography: ± cardiomegaly, ± pulmonary edema
- Electrocardiogram for arrhythmias
- Cardiac catheterization to document increased pulmonary artery pressure
- Arterial blood gas

DIFFERENTIAL DIAGNOSIS

- Brisket disease or mountain sickness
- Cardiomyopathy
- Endocarditis
- Myocarditis
- Pericarditis
- Cardiac lymphosarcoma
- Cardiotoxic plants
- Ionophore toxicosis
- Selenium deficiency
- Gossypol toxicosis
- Parasitism

CBC/BIOCHEMICAL/URINALYSIS

- Normal or variable CBC changes depending on underlying causes
- Hyponatremia, hypochloremia due to dilutional effect following retention of fluid and anorexia
- Hypokalemia \pm hypocalcemia from anorexia
- Hypoproteinemia, hypoalbuminemia due to retained fluid or loss of protein into interstitial space, ascites, or intestinal tract
- Elevated γ glutamyl transferase (GGT) indicating biliary stasis due to passive congestion of the liver.

OTHER LABORATORY TESTING

Hepatic ultrasound

- Infract
- Disruption of normal parenchyma
- Vascular changes

IMAGING

- Echocardiography
- Radiography

DIAGNOSTIC PROCEDURES

As above

TREATMENT

- Treat specific underlying causes of CHF, if known
- Aimed at increasing the pumping ability of the heart, reducing the blood volume that must be pumped, reducing fluid retention, and management of vascular tone
- Short-term management only
- Stall rest
- Inotropics-digoxin: improve cardiac contractility; dobutamine
- Diuretic: furosemide, to aid elimination of excess fluid and salt from body
- Drugs to expand blood vessels and decrease resistance in vessels (efficacy in ruminants is unknown)
 - Vasodilators
 - ACE (angiotensin-converting enzyme) inhibitors
 - Calcium channel blockers
- \pm Beta blockers: improve contractility of left ventricle
- Antiarrhythmic: if arrhythmia present and serum electrolytes and calcium and acid-base and hydration status are normal
- Dietary restriction of sodium
- Dietary supplementation of potassium chloride (KCl) if needed

- Monitor and supplement calcium as needed
- Monitor blood acid-base and electrolyte status every other day
- Other supplements recommended when appropriate for specific conditions associated with heart impairment: vitamin E, selenium, thiamin, magnesium, L-carnitine
- Surgical therapy (pacemakers, heart valve replacement, transplant); not reported in ruminants

MEDICATIONS

DRUGS

- Furosemide: 0.5–2.0 mg/kg IV, IM BID, SID
- Digoxin
 - Initial loading dose of 2.2 mg/100 kg IV followed by 0.34 mg/100 kg every 4 hours
 - 0.86 µg/kg per hour IV (valuable hospitalized animals) or
 - 3.4 µg/kg IV every 4 hours; greater risk of inducing digoxin toxicity
 - supplement with KCl if animal is inappetent
- KCl: 50 to 150 g per day for adult cattle on potassium-wasting diuretics
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

100% mortality in long term

MISCELLANEOUS

ASSOCIATED CONDITIONS

CONIUM SPP. (POISON HEMLOCK) TOXICITY

BASICS

OVERVIEW

- Poison hemlock (*Conium maculatum*) toxicity in ruminants is an uncommon occurrence.
- Poison hemlock is a member of the Apiaceae family. It is a biennial. The first-year seedling plant contains leaves that are fernlike in appearance—three to four times pinnately divided, and the leaflets are 1/4 in. long and segmented. The foliage has a strong mousy, parsniplike odor.
- The mature plant is erect, 3–8 feet tall, with a stout hollow stem (except at the nodes) that is smooth and often purple splotched. The plant has a long white/yellow taproot, which resembles a carrot or parsnip.
- Small, white flowers are arranged in umbrella-shaped clusters at the tips of the uppermost stems.
- It is a commonly encountered weed throughout North America, sometimes forming heavy dense stands that are difficult to control.
- Two types of clinical conditions can be encountered—acute toxicities (nicotinic effects) and malformations in young exposed in utero (“crooked calf disease”).
- Treatment is nonspecific in nature, and emphasis should be placed on identification of the plant and preventing access to it.

PATHOPHYSIOLOGY

- The piperidine alkaloids have nicotinic-like effects—stimulate, then paralyze the nicotinic receptors. Large exposures cause neuromuscular block, hypotension, and bradycardia.
- Gamma-coniceine is thought to be the agent responsible for the malformations; inhibits fetal movement.

SYSTEMS AFFECTED

Nervous and musculoskeletal systems

GENETICS

N/A

INCIDENCE/PREVALENCE

Not very common; the plant is not generally considered palatable (particularly the mature plant) and animals don’t readily graze it unless forced to do so. Animals may acquire a taste for the plant.

GEOGRAPHIC DISTRIBUTION

Throughout North America

SIGNALMENT

All ruminants, particularly cattle (considered more susceptible)

Species

Cattle, sheep, and goats appear to be susceptible.

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Abrupt onset (within a few hours of ingestion) of muscle tremors, ataxia, muscle weakness, excessive salivation and lacrimation, mydriasis, and frequent urination and defecation

- This can progress to recumbency, depression, abdominal pain, respiratory distress, and death from respiratory arrest.
- Skeletal deformations observed when pregnant animals are exposed include arthrogryposis, cleft palate, microphthalmia, and spinal column deformities.

CAUSES AND RISK FACTORS

- Concentrations of the toxic alkaloids vary between parts of the plant and stage of maturity.
- All parts of the plant are potentially toxic, and toxicity is thought to increase as the plant matures.
- Approximate toxic and lethal dose for poison hemlock: cattle > 1.0 g fresh plant/kg BW; sheep > 5.4 g fresh plant/kg BW; goats > 7.8 g fresh plant/kg BW
- Some toxicity is lost in drying; but there have been cases where cattle have been poisoned as a result of ingesting contaminated hay.
- Contaminated grain by the seeds can be a problem as well.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Organophosphate or carbamate poisoning, poisoning with *Lupinus* or *Nicotiana* spp.

CBC/BIOCHEMISTRY/URINALYSIS

No specific diagnostic changes have been reported.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- One can attempt to confirm exposure through feed microscopy of the rumen contents.
- Alkaloids can be detected in the rumen contents or urine, also in liver, kidney, and blood.

PATHOLOGIC FINDINGS

- Renal tubule necrosis and skeletal muscle degeneration has been reported in fatal cases involving people.
- A mousy, parsnip odor can be detected from the freshly open rumen.
- Skeletal malformations include cleft palate, arthrogryposis, scoliosis, kyphosis, and torticollis.

TREATMENT

- Symptomatic and supportive in nature. Decontaminate the gastrointestinal tract with activated charcoal and saline cathartic.
- Providing adequate respiratory support would be next to impossible in the field.

MEDICATIONS

Atropine should be used with caution.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

N/A

PATIENT MONITORING

Monitor respiratory function.

PREVENTION/AVOIDANCE

- Avoid access to the plant.
- Control chemically with appropriate herbicides.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Highly dependent on the exposure dose or the severity of the malformations.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Depression, abdominal pain, respiratory distress, and death from respiratory arrest
- Skeletal deformations observed when pregnant animals are exposed include arthrogryposis, cleft palate, microphthalmia, and spinal column deformities.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Attempts should be made to prevent pregnant animals' access to the plant during susceptible periods (cattle—days 40–100 of gestation; sheep and goats—30–60 days of gestation).

RUMINANT SPECIES AFFECTED

All ruminants considered susceptible; most commonly reported in cattle.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Prevent animals from accessing the plant.
- Some toxicity is lost in drying; but there have been cases where cattle have been poisoned as a result of ingesting contaminated hay.
- Contaminated grain by the seeds can be a problem as well.

CONTAGIOUS BOVINE PLEUROPNEUMONIA

BASICS

DEFINITION

- Contagious bovine pleuropneumonia (CBPP) is a highly contagious bacterial disease of primarily cattle resulting in severe, acute pneumonia and occasionally a polyarthritis with high mortality.
- CBPP can be acute, subacute, or chronic in nature. It is caused by *Mycoplasma mycoides mycoides*.

PATHOPHYSIOLOGY

- Carrier animals of the bacterial agent *M. mycoides mycoides* small-colony type (SC type) shed the organism in respiratory secretions during periods of stress to susceptible cattle, resulting in severe respiratory disease and mortality in a herd. Secondary infections with other viral and bacterial pneumonias complicate disease presentation and diagnosis.
- *M. mycoides mycoides* large-colony type (LC type) is pathogenic for goats and sheep but does not affect cattle. *M. mycoides mycoides* (SC type) survives well in vivo, but is quickly inactivated by external environmental conditions.
- CBPP is often unilateral.

SYSTEMS AFFECTED

Respiratory and occasionally musculoskeletal

GENETICS

- Predominantly a disease of the genus *Bos*.
- Anecdotal reports suggest breed differences affecting susceptibility.
- European cattle breeds tend to be more susceptible than indigenous African breeds.
- The infection has been recorded in yak, bison, and the domestic buffalo (*Bubalus bubalis*).

INCIDENCE/PREVALENCE

- Incidence for CBPP varies worldwide.
- Morbidity often reaches 100% and mortality may be 10–70%.
- Mortality may depend on other herd-management decisions and concurrent disease processes.

GEOGRAPHIC DISTRIBUTION

- Endemic in most regions of Africa
- Regions of Asia, particularly India and China
- Europe (Spain, Portugal, and Italy)
- North America and the western hemisphere are currently free of contagious bovine pleuropneumonia.
- Reported in 25 countries during the years 2001–2004.

SIGNALMENT

Species

- Bovine: *Bos indicus* and *Bos taurus*
- Other susceptible species: yak, bison, antelope
- Water buffalo in Italy
- Sheep and goats in Africa and Portugal

Mean Age and Range, Predominant Sex

Some age resistance does appear evident. Cattle less than 3 years of age have been shown to be less resistant to experimental challenge.

SIGNS

HISTORICAL FINDINGS

- Severe respiratory disease in cattle with high morbidity and mortality within 7–10 days after clinical disease onset.

Contagious bovine pleuropneumonia is spread by inhalation of aerosolized droplets from a moribund coughing animal.

- The time from disease exposure to overt symptomatology varies but generally is quite prolonged. Animals introduced into a CBPP-infected herd may show signs of disease in 20 to 123 days.
- CBPP has been implicated in MAKEPS syndrome (mastitis, arthritis, keratitis, pneumonia, and septicemia)

PHYSICAL EXAMINATION FINDINGS

- Depression, inappetence, and pyrexia
- Coughing with concomitant thoracic pain, dyspnea, and increased respiratory rate
- Animals classically position themselves with elbows abducted to increase chest capacity.
- Thoracic auscultation reveals rales, crepitation, and pleuritic friction rubs; labored respiration attempts and open-mouthed breathing
- Occasionally in calves polyarthritis is evident.
- Frothy nasal discharge and continuous stringy salivation appear shortly before death. Chronic cases can recover and become carrier animals.

CAUSES

- The bacterial agent *M. mycoides mycoides* small-colony type (SC type)
- Disease spread is through direct contact and inhalation of infective aerosols.

RISK FACTORS

- Exposure to carrier animals shedding organisms after periods of stress, such as sudden climatic changes (heavy rains or cold spells), especially in close confinement or overcrowded conditions can predispose CCBP outbreaks.
- Introduction of carrier animals into previously uninfected herds
- Herd outbreaks usually occur as the result of animal importation/movement patterns into a naïve herd.
- Persistent carriers may develop after chronic infection and may harbor infectious organisms within a pulmonary sequestrum.
- Fomite transmission may be possible.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Pasteurellosis, other *Mycoplasma* spp. pneumonias, *Haemophilus* spp., and *Salmonella* spp., BVD, BRSV, IBR, PI3, East Coast Fever, hydatid cyst, TRP, *Mycobacterium bovis*, *Mannheimia hemolytica*

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Serological tests such as complement fixation (detects 99% of active cases and 70% of chronic cases), passive hemagglutination, and ELISA can be used on a herd basis to detect antibodies to CBPP.
- Polymerase chain reaction on lung, pleural fluid, urine, and cultured colonies
- Histopathology
- Immunohistochemistry

Diagnostic Specimens for Laboratory

Live animal samples

Nasal swabs, tracheal wash, thoracocentesis fluid, serum

Postmortem sample

Fresh lung, Pleural fluid, tracheobronchial lymph nodes, and synovial fluid

IMAGING

Although not commonly done, radiographs would reveal evidence of fluid in the thoracic cavity, pulmonary consolidation, and nodules.

DIAGNOSTIC PROCEDURES

Confirmatory diagnosis is made by culturing the agent from lung, pleuritic fluid, swabs of major bronchi, and tracheobronchial or mediastinal lymph nodes and identified by complement fixation or by growth or metabolic inhibition tests.

PATHOLOGIC FINDINGS

- Acute lesions: alveolar spaces infiltrated by edema fluid and accumulations of leukocytes. Fibrin thrombi are evident with intense inflammatory infiltration and concomitant necrosis of alveolar septae.
- Chronic lesions: lymphocytic infiltration with thickening along interlobular septae, fibrosis of interlobular septae and coagulative necrosis of lobules.
- Unilateral pleuritis and pneumonia. There is a decided “marbling” effect of lung tissue due to distended interlobular septae. Sequestra in pulmonary tissue are encapsulated with fibrosis.
- Acute through chronic stages are common in the same animal.
- There will be straw-colored fluid in the thorax. The lungs themselves will have a fibrinous pneumonia and pea-sized, yellow-colored nodules appear in early infection.

TREATMENT

- *Mycoplasma mycoides mycoides* (SC type) is susceptible to a variety of antimicrobials. These may include tetracycline, streptomycin, and chloramphenicol (where legal).
- Antimicrobial therapy may favor the formation of sequestra and create a carrier state.

APPROPRIATE HEALTH CARE, NURSING CARE

Due to the contagious nature of this disease, affected animals should be isolated and the entire herd placed under quarantine.

ACTIVITY

Animals should be isolated and activity restricted because of the exercise intolerance due to the severe respiratory disease.

DIET

Maintain a good plane of nutrition with fresh food and water daily.

CLIENT EDUCATION

Clients should be made aware of the seriousness of CBPP and the contagious aspects so as to protect their nonexposed susceptible animals on their facility.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

- Broad-spectrum antibiotics EARLY in the course of disease
- Macrolides, tetracyclines, and quinolones are active against *M. mycoides mycoides* (SC type) but do not always clear an animal of carrier status.
- Tylosin and oxytetracycline appear effective. Drug withdrawal periods for meat and milk are important to monitor when using antibiotic agents.

CONTRAINDICATIONS

POSSIBLE INTERACTIONS

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Respiratory distress is a large component of this disease, so monitor animals for signs of labored breathing and nasal discharge to ensure they have a patent airway.

PREVENTION/AVOIDANCE

- In Africa, routine vaccination against CBPP remains the primary control option.
- Current live attenuated vaccine performance is suboptimal. Low efficacy (33–67%) and a short duration of immunity (6–12 months) are recurring problems with this vaccine. Vaccination of animals with a live attenuated and inactivated vaccines have had varying degrees of success in parts of the world.
- Two vaccine strain types are currently used in Africa: strain T1 44 and T1 SR.
- Vaccination often generates a local quite extensive tissue reaction. Therefore, it is often given in the tail tip, which may become necrotic and slough.
- Quarantine of farms with testing and slaughtering of animals has been proven effective as a control plan in the event of an outbreak.
- Serologic testing of herds for importation is recommended.

POSSIBLE COMPLICATIONS

Cattle that recover maintain a long-term carrier status, leading to exposure of susceptible animals during periods of stress.

EXPECTED COURSE AND PROGNOSIS

Recovered animals can become long-term carriers of mycoplasma.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

CBPP is not a zoonotic disease.

CONTAGIOUS CAPRINE PLEUROPNEUMONIA

BASICS

DEFINITION

Contagious caprine pleuropneumonia (CCPP) is an extremely contagious bacterial disease of goats resulting in severe, acute pneumonia with high mortality. CCPP is considered to be the most devastating disease of goats worldwide.

PATHOPHYSIOLOGY

Carrier animals of the bacterial agent *Mycoplasma capricolum capripneumoniae* (mycoplasma biotype F-38) shed the organism in respiratory secretions during periods of stress to susceptible goats, resulting in severe respiratory disease and mortality in a herd. Infection with *Mycoplasma mycoides capri* (type strain PG-3) can occur but less commonly. Secondary infections with other viral pneumonias complicate disease presentation and diagnosis.

SYSTEMS AFFECTED

Respiratory

GENETICS

N/A

INCIDENCE/PREVALENCE

- Incidence for CCPP varies worldwide but infection with *Mycoplasma capricolum capripneumoniae* (mycoplasma biotype F-38) is more common and severe than *Mycoplasma mycoides capri* (type strain PG-3).
- Morbidity often reaches 100% and mortality may be 70–100%.

GEOGRAPHIC DISTRIBUTION

- While not found in the United States, CCPP has been reported in over 40 countries including Africa, Asia, Eastern Europe, the Middle East, and the former Soviet Union.
- Isolating the mycoplasma organism proves difficult in some countries and has been done only in Africa (Eritrea, Ethiopia, Kenya, Mali, Niger, Sudan, Chad, Tunisia, Tanzania, Uganda), Asia, and the Mediterranean (United Arab Emirates, Oman, Yemen).

SIGNALMENT

Species

Caprine

Breed Predilections, Mean Age and Range, Predominant Sex

N/A

SIGNS

HISTORICAL FINDINGS

Severe respiratory disease in goats with high morbidity and mortality within 7–10 days after clinical disease onset.

PHYSICAL EXAMINATION FINDINGS

- Infection with mycoplasma F-38 is respiratory in nature with a fever (106°F), cough, labored breathing, weakness, anorexia, leading to exercise intolerance and respiratory distress. Goats will stand with legs spread, neck extended downward, and tongue protruded.
- Frothy nasal discharge and continuous stringy salivation appear shortly before death. Chronic cases can recover and become carrier animals.
- Infection with type strain PG-3 results in a more generalized infection with respiratory signs (although less severe), reproductive signs, and gastrointestinal signs due to acute or peracute septicemia.

CAUSES

- The bacterial agent *Mycoplasma capricolum capripneumoniae* (mycoplasma biotype F-38) is the most common cause of

CCPP. It is also the most contagious and virulent.

- *Mycoplasma mycoides capri* (type strain PG-3) also causes CCPP in goats but less commonly and with a different clinical presentation.
- Disease spread is through direct contact and inhalation of infective aerosols.

RISK FACTORS

- Exposure to carrier animals shedding organisms after periods of stress, such as sudden climatic changes (heavy rains or cold spells), especially in close confinement or overcrowded conditions can predispose CCPP outbreaks.
- Introduction of carrier animals into previously uninfected herds

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Peste des petits ruminants, pasteurellosis, other *Mycoplasma* spp. pneumonias, *Haemophilus* spp., and *Salmonella* spp.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Serological tests such as complement fixation, passive hemagglutination, and ELISA can be used on a herd basis to detect antibodies to mycoplasma F-38.
- Whole blood or serum can be used for the latex agglutination test (most commonly done in Africa).

Although not commonly done, radiographs would reveal evidence of fluid in the thoracic cavity, pulmonary consolidation, and nodules.

DIAGNOSTIC PROCEDURES

Confirmatory diagnosis is made by culturing the agent from lung, pleuritic fluid, swabs of major bronchi, and tracheobronchial or mediastinal lymph nodes and identified by immunofluorescence or by growth or metabolic inhibition tests.

PATHOLOGIC FINDINGS

- With *M. capricolum capripneumoniae* infection, one or both lungs may be affected and may be adhered to the thoracic cavity due to thickened pleura. There will be straw-colored fluid in the thorax. The lungs themselves will have a fibrinous pneumonia and pea-sized, yellow-colored nodules appear in early infection.
- More advanced cases will have congestion surrounding the nodules. An entire lobe may become solidified or develop massive hepatization (appearance of liver). There is no thickening of the interlobular septa as in bovine pleuropneumonia.
- Histopathology reveals serofibrinous to fibrinonecrotic pleuropneumonia with infiltrates in the alveoli, bronchioles, interstitial septae, and subpleural connective tissue.
- Peribronchial lymphoid hyperplasia with mononuclear cell infiltration can also be seen.
- In the case of infection with *M. mycoides capri*, lung lesions are more likely unilateral with extensive pleuritis, fibrinous pneumonia with hepatization, most commonly of the cardiac and diaphragmatic lobes.
- The interlobular septa are dilated.
- Since this form of CCPP causes a more generalized infection, other lesions such as encephalitis/meningitis, lymphadenitis, splenitis, and genitourinary tract and intestinal changes will be seen.

TREATMENT

APPROPRIATE HEALTH CARE, NURSING CARE

- Due to the contagious nature of this disease, affected animals should be isolated and the entire herd placed under quarantine.
- Early in the course of disease, antibiotics may be warranted.

ACTIVITY

Animals should be isolated and activity restricted because of the exercise intolerance due to the severe respiratory disease.

DIET

Maintain a good plane of nutrition with fresh food and water daily.

CLIENT EDUCATION

Clients should be made aware of the seriousness of CCPP and the contagious aspects so as to protect their nonexposed susceptible animals on their facility.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

- Broad-spectrum antibiotics EARLY in the course of disease
- Macrolides, tetracyclines, and quinolones are active against *M. capricolum* subsp. *capripneumoniae* but do not always clear an animal of carrier status.
- Tylosin and oxytetracycline appear effective.

CONTRAINDICATIONS, POSSIBLE INTERACTIONS, ALTERNATIVE DRUGS

Drug withdrawal periods for meat and milk are important to monitor when using antibiotic agents.

FOLLOW-UP

PATIENT MONITORING

Respiratory distress is a large component of this disease, so monitor animals for signs of labored breathing and nasal discharge to ensure they have a patent airway.

PREVENTION/AVOIDANCE

- Vaccination of animals with a live attenuated and inactivated F-38 vaccines has had varying degrees of success in parts of the world.
- A lyophilized saponin-inactivated F-38 vaccine had 100% effectiveness in preventing contact exposure in field tests in Kenya. It is used in goat kids older than 10 weeks and is effective for approximately 1 year.
- Quarantine of farms with testing and slaughtering of animals has been proven effective as a control plan in the event of an outbreak.

POSSIBLE COMPLICATIONS

Goats that recover maintain a long-term carrier status, leading to exposure of susceptible animals during periods of stress.

EXPECTED COURSE AND PROGNOSIS

Acute disease has a morbidity of 70–100% with mortality reaching 100% in some goat herds. Recovered animals can become long-term carriers of mycoplasma.

COPPER DEFICIENCY OF SHEEP AND GOATS

BASICS

DEFINITION

A disease condition caused by either primary or secondary copper deficiency that is manifested in the neonate by congenital posterior paresis or paralysis and occasionally more severe neurological disease, and in the growing lamb/kid or adult with reduced growth or chronic wasting, anemia, lameness, changes to the wool/hair coat, and occasionally diarrhea.

PATHOPHYSIOLOGY

- There is a strong breed component to the susceptibility of sheep to Cu deficiency. Breeds such as the Scottish blackface and Finnish Landrace, are poor utilizers of Cu, very susceptible to Cu deficiency, and, conversely, resistant to Cu toxicity. Texel sheep require little Cu and are resistant to Cu deficiency but are very susceptible to Cu toxicity.
- This is not as well studied in goats but genetic variability is suspected between breeds.

GENETICS

- Primary copper (Cu) deficiency occurs because of insufficient copper in the diet of the pregnant ewe/doe (congenital) and/or the diet of the growing lamb/kid. Plant copper levels of < 5 mg/kg DM are dangerous and < 3 mg/kg DM are likely to result in primary Cu deficiency. Cu-deficient soils are generally sandy and poor quality.
- Secondary Cu deficiency occurs when levels of molybdenum (Mo) (most commonly), sulphur (S) (occasionally), or iron (Fe) or zinc (Zn) (rarely) are high in the diet. These minerals compete with Cu uptake and cause increased excretion of Cu. Forage levels of Mo > 10 mg/kg are associated with secondary Cu deficiency. Peaty soils are more often associated with excess Mo. S-containing fertilizers may exacerbate Cu deficiency.
- Cu is a necessary component of ceruloplasmin, an enzyme involved in the cytochrome oxidase system, and of other enzymes such as erythrocyte superoxide dismutase. Failure of these enzyme systems may cause poor tissue oxidation, which then interferes with cell growth and function.

SYSTEMS AFFECTED

Congenital Form

Present at birth in kids and lambs. White matter of the cerebrum is affected. Areas of fluid-filled cavities may be grossly evident in the most severely affected cases. ***Delayed Form***

- In kids and lambs within 2 to 4 months of age: affects the spinal cord and brain stem. Lesions are found in the large neurons of the red and vestibular nuclei, the reticular formation, and the ventral horns of the spinal cortex. In kids, may also affect cerebellum. Altered or reduced myelination is the primary feature.
- Acute delayed Cu deficiency has been reported in the UK, where lambs 2 to 4 weeks of age are suddenly affected with incoordination, tremors, frothing at the mouth, grinding of the teeth, and finally opisthotonus and death due to cerebral edema and herniation of the medulla and cerebellum through the foramen magnum.
- The delayed form may be caused by marginally low Cu in the pregnant adult, poor transfer of Cu stores to the fetus, and continued deficiency in the neonatal period. Severity and length of the deficiency dictates the severity of the disease in the young lamb/kid.

Young Stock and Adults

- Hemoglobin production for red blood cells is inhibited by the lack of Cu to aid in recycling of iron. This results in hypochromic anemia without hemolysis.
- Wool lacks keratinization and becomes straight and brittle (steely wool) and colored fleeces lack color. This impairment of keratinization also affects skin.
- With primary Cu deficiency: bone is affected with osteoporosis, widening of the long bones, and overgrowth of epiphyseal cartilage most notably at the costochondral junction. Osteoblastic activity is impaired. With Mo excess: most of the effect is at the epiphyses.

- Both humoral and cell-mediated immunity are impaired, as well as the nonspecific immune system. Resistance to parasites is decreased with Cu deficiency.

PATHOPHYSIOLOGY

- Overall not a common disease, but one that is generally associated with a specific geographic region.
- Excess supplementation of S, either on pasture or as a mineral supplement or water high in S, may cause an “outbreak” in a specific flock that was not noted previously to be at risk.
- Water high in iron may also contribute if Cu availability is marginal.

GEOGRAPHIC DISTRIBUTION

- Soil type determines the likelihood of Cu deficiency in the plants (e.g., sandy and limestone soils and soils that are washed out may have low Cu levels). A specific geographic area may be known to be risky. Many areas in the United States and Canada are known to be Cu deficient although there may be tremendous variation in Cu soil content within a small region, even on a given farm.
- Reclaimed swamps or peat bogs often are high in Mo.

SIGNALMENT

Species

Sheep and goat

Breed Predilections

See Genetics above

Mean Age and Range

- Congenital is present at birth.
- Delayed generally occurs between 2 and 4 months of age.
- Adult can occur at any age.

Predominant Sex

N/A

GENERAL COMMENTS

N/A

HISTORICAL FINDINGS

- A particular farm may have chronic problems due to Cu or Mo levels in the forages or S or Fe levels in the water.
- There may be a history of a change in feeding practices (e.g., addition of S to ration or to pasture).

PHYSICAL EXAMINATION FINDINGS

Congenital

Lambs or kids are born small, weak, and ataxic or unable to stand. Severe cases may be blind or show tremors. If not fed colostrum, they often die of septicemia secondary to failure of passive transfer.

Delayed

- Lambs or kids are born normally but may develop ataxia (paresis) or paralysis of the hind end or lameness.
- They are more prone to parasitic infections such as coccidiosis and haemonchosis.
- They may be found down in the pasture, but if they are still alert, the owner may note that the ewe/doe will still be nursing them.
- Fractures may occur secondary to osteoporosis. Fractures may be minute and may present as angular deformities.
- Lameness due to inflammation of the epiphyses

Adult

- Mildly to profoundly anemic
- Lameness due to minute fractures of the trabeculae, epiphysitis, or long bone fractures.
- The wool is straight, without crimp, may exhibit wool-break due to weakness of the fiber, and in colored fleeces and hair may lack color.
- Growth of young stock is reduced and in severe cases, animals may show weight loss.
- If Cu is secondary to Mo excess, diarrhea may develop (peat scours) although this is more common in cattle.
- Infertility may be linked to Cu deficiency but this is not well proven.
- New work shows an association between Cu metabolism and conformational changes in the scrapie prion protein in

susceptible sheep but the clinical significance of this is not well understood at this point.

CAUSES

- Forages deficient in Cu
- Forages containing excess Mo or S
- Water containing excess S or Fe (less common)

RISK FACTORS

- Susceptibility of breed (i.e., ability of breed to absorb Cu)
- Heavy parasitism will reduce Cu liver levels.
- Cu does not accumulate in the ovine fetal liver as well as in other species (e.g., cattle).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Congenital Form

Any disease that causes birth of weak lambs or kids (e.g., enzootic abortion, iodine deficiency)

Delayed Form

Tail docking abscess, traumatic fracture of a vertebra or long bone, CAE/MV (OPP), rickets due to vitamin D deficiency, down due to vitamin E selenium deficiency

Adult

- Poor growth due to parasitism, poor nutrition
- Anemia due to parasitism, chronic disease, blood loss
- Poor wool due to sulphur deficiency, external parasites

CBC/BIOCHEMISTRY/URINALYSIS

Anemia in lambs is hypochromic and microcytic, in adults is hypochromic and macrocytic.

OTHER LABORATORY TESTS

Sheep

- Serum Cu
 - Deficient—0.10–1.00 ppm
 - Marginal—0.40–1.00 ppm
- Plasma Cu: deficient—< 0.60 ppm
- Erythrocyte superoxide dismutase activity
 - Short-duration deficiency—youngstock > 0.5 and adult > 0.3 mg/g hemoglobin
 - Prolonged deficiency—youngstock < 0.3 and adult < 0.2 mg/g hemoglobin
- Tissue Cu
 - Liver—deficient 0.5–4.0 ppm WW
 - Liver—marginal 5.0–20.0 ppm WW
 - Fetal liver—deficient 1.0–10 ppm WW
 - Wool—deficient 0.5–2.5 ppm DW

Goat

- Serum Cu
 - Deficient—0.04–0.40 ppm
 - Marginal—0.40–0.80 ppm
- Tissue Cu
 - Liver—deficient 0.4–10.0 ppm WW
 - Fetal liver—deficient 1.6–20.0 ppm WW
 - Hair—deficient < 3.0 ppm DW

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

See Systems Affected above.

TREATMENT

APPROPRIATE HEALTH CARE

NURSING CARE

Lambs and kids that are severely affected with either the congenital or delayed form should be humanely euthanized.

ACTIVITY

N/A

DIET

Sheep

- If Mo 0.05–1.0 ppm, then Cu 5.0–10.0 ppm DW
- Cu:Mo ratio > 2:1 and < 20:1 (~ 6:1)
- Maximum safe level of Mo 8.0–10.0 ppm DW

Goats

Copper levels should be 10–23 ppm DW.

CLIENT EDUCATION

Inform client of balancing dietary needs with respect to Cu, particularly if secondary Cu deficiency.

SURGICAL CONSIDERATIONS

NA

MEDICATIONS

DRUGS OF CHOICE

- Oral treatment: 1.5 g Cu sulphate for ewes and 35 mg for lambs as a single dose
- Dosing ewes 8 and 4 weeks prior to lambing with 200 mg Cu sulphate can prevent the congenital form.
- 5 mg Cu methionate injection in lambs at 3 to 10 days of age to prevent delayed form
- Some injectable forms may be recommended (Cu calcium edetate or Cu methionate) but may cause tissue reaction.

CONTRAINDICATIONS

- If diagnosis is not correct, (i.e., not supported by analysis of Cu levels in the animal), then supplementation of Cu may result in toxicity.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

Excessive treatment with Cu may cause toxicity.

POSSIBLE INTERACTIONS

ALTERNATIVE DRUGS

FOLLOW-UP

PATIENT MONITORING

To monitor effectiveness of control program, may wish to monitor Cu liver levels or, in ewes, serum Cu levels.

PREVENTION/AVOIDANCE

Copper Supplement for Sheep

- Copper oxide wire particles or rods orally (1.25 g Cu to weaned lambs and 2.5 g Cu to adults) generally administered in a gelatin capsule, which dissolves in the abomasum. The Cu oxide rods or wires dissolve slowly.
- Copper heptonate as an intramuscular injection (25 mg Cu to weaned lambs and 37.5 mg Cu to adults) once every 3 to 9 months, respectively.
- Copper sulphate spread on pasture at 2.0 kg/ha.

Copper Supplements for Goats

Oral—2 g copper oxide needles to kids at 5 weeks of age and 4 g copper oxide needles to does in early pregnancy

POSSIBLE COMPLICATIONS

Diagnosis should be confirmed before preventive therapy is commenced.

EXPECTED COURSE AND PROGNOSIS

- Lambs and kids born with the congenital form will not respond to therapy.
- Lambs and kids that develop the delayed form may respond if clinical signs are mild. Certainly supplementation of the animals at risk may prevent additional animals from developing the delayed form.
- Adults will respond rapidly to supplementation, particularly wool growth will improve within days of supplementation and anemia will become less severe. Lameness may not improve or only improve marginally, however.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

If Mo is present at a high level in the diet, it may accumulate in the liver and kidneys. If this is the case, then animals intended for slaughter should have kidneys and liver discarded as unfit for human consumption.

PREGNANCY

Supplementation of pregnant ewes and does is critical to preventing the congenital and delayed form of this disease.

RUMINANT SPECIES AFFECTED

Primarily sheep but also goats and cattle

COPPER TOXICITY

BASICS

OVERVIEW

- Copper (Cu) is an essential trace element that is a component of several enzyme systems. The Cu-dependent enzymes are involved in critical metabolic and physiological functions such as iron (Fe) metabolism, elastin and collagen formation, melanin production, and integrity of the central nervous system (CNS).
- Cu is also a toxic element if consumed in excess amounts.
- The liver is considered the key organ in Cu metabolism, storage, and excretion.
- Ruminants store Cu in the liver during excess intake and deplete when Cu intake is low.
- Several elements have a negative impact on Cu absorption and its metabolism. These include molybdenum (Mo) and sulfur (S). The negative interactions between Cu and these elements significantly affect Cu availability and animal requirements. Consumption of high-Mo forages results in molybdenosis or hypocuprosis in grazing ruminants.

PATHOPHYSIOLOGY

- High concentrations of other minerals, especially Mo and S, have negative effects on Cu absorption and its metabolism. In the rumen, sulfate is reduced to sulfide that reacts with Mo to form thiomolybdate (MoS_4^{2-}). The thiomolybdate possesses a high affinity for Cu and is capable of rendering it insoluble and nonabsorbable by forming Cu thiomolybdate (CuMoS_4).
- Some of thiomolybdates are absorbed and affect systemic metabolism of Cu negatively. The absorbed thiomolybdates result in Cu being tightly bound to albumin in plasma and not available for biochemical functions.
- S alone at high levels affects Cu absorption negatively. This is due to formation of insoluble nonabsorbable Cu sulfide.
- High levels of Fe and Zn also decrease Cu absorption.
- Interference of Fe with Cu absorption is not well understood. This negative interaction was suggested to involve formation of ferrous sulfide complexes in the rumen that become soluble in the abomasum where the sulfide may dissociate and form insoluble complex with Cu.

SYSTEMS AFFECTED

Production management, skin, central nervous system, musculoskeletal, cardiovascular

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

- Worldwide depending on species and environment
- Cu deficiency in ruminants is common under natural grazing conditions in many countries, especially Australia, New Zealand, the Netherlands the UK, and the United States.

SIGNALMENT

Species

Potentially all ruminant species

Breed Predilections

- Sheep breeds appear to vary in their tolerance to high Cu levels (Merino sheep are known to be more tolerant than other sheep breeds).
- Chronic toxicity of Cu has been reported in dairy cows fed diets containing 37.5 mg/kg DM during lactation and 22.6 mg/kg DM dry cows.

- Simmental and Charolais cattle appear to have higher Cu requirements than Angus cattle.

Mean Age and Range

- In general, Cu is poorly absorbed by ruminants and the absorption rate is higher in suckling than in adult animals (i.e., 5%–10% vs. 1%–3%).
- Adult cattle are more resistant to toxicity than younger cattle.

Predominant Sex

N/A

SIGNS

HISTORICAL FINDINGS

Copper Deficiency

- Ruminants, especially sheep, are more susceptible to Cu deficiency than nonruminants.
- Cu deficiency is considered a severe limitation to grazing ruminants throughout the world. Cu deficiency is more frequent on pastures than in feedlots.
- Cu deficiency in ruminants can result from low Cu concentration in feeds (i.e., < 3 mg/kg DM) but most commonly occurs when Cu concentrations in forages are normal (i.e., 6 to 16 mg/kg DM) but unavailable due to high concentrations of Mo or S.
- With regard to Mo, Cu deficiency occurs when forage Mo concentration exceeds 3 mg/kg DM and Cu concentration is less than 5 mg/kg DM.
- Cu deficiency can occur under different dietary conditions such as low Cu (i.e., < 5 mg/kg DM), low Cu and high Mo (i.e., ratio 2:1), higher Mo (i.e., > 20 mg/kg DM), normal Cu and low Mo but with high levels of soluble proteins from lush pastures.
- Anemia results from the delay in maturation and shortening of the life span of red blood cells. Anemic ruminants have a hemoglobin level of 5.9 g/100 mL vs. 13.7 g/100 mL after Cu administration.
- The impaired keratinization of hair and wool
- The CNS disorders are attributed to the demyelination of the nerves.
- The symptoms of reproductive failure include low fertility, delayed or depressed estrus, fetal death and resorption, calving difficulties, retained placenta, and calves born with congenital rickets.
- Achromotrichia is a lack of tyrosinase (i.e., polyphenyl oxidase) activity. This results in breakdown in the conversion of L-tyrosine to melanin and the subsequent loss of pigments in hair and wool. Examples include lightening of hair coat in black or red animals, showing reddish tinge in the case of black animals behind the shoulder and on the lower quarters, and finally rough hair coat.
- Bone problems include development of fragile bones, especially long bones that break easily without an apparent cause. Cattle can have swelling or enlargement of the ends of the leg bones and, therefore, move like a pacing horse (i.e., pacing gait).
- Falling disease or sudden death in cattle is attributed to heart lesions.
- Negative effects of Cu deficiency on immune function
- Severe diarrhea is also a common symptom of Cu deficiency; however, diarrhea is less common in sheep than in cattle.
- Poor growth and/or loss of body weight are also common symptoms of Cu deficiency.

PHYSICAL EXAMINATION FINDINGS

Symptoms

- The symptoms of Cu toxicity include nausea, vomiting, salivation, abdominal pain, convulsions, paralysis, collapse, hemolysis, methemoglobinemia, hemoglobinuria, jaundice, icterus, widespread necrosis, and death.
- Additional symptoms include anemia, muscular dystrophy, decreased growth, and impaired reproduction.

CAUSES AND RISK FACTORS

Functions

- Cu is needed for several metabolic functions such as cellular respiration, bone formation, normal cardiac function, connective tissue development, myelination of the spinal cord keratinization, and tissue pigmentation.
- Additionally, Cu serves as a catalyst for hemoglobin synthesis. Cu also is needed for normal reproduction and immune function.

Sources

- Cu is distributed in feeds at various levels ranging from 1 to 50 mg/kg of dry matter (DM).
- The Cu content of feeds depends on geographical location, soil pH, climate, crop management, and plant species, maturity, and yield. Cu concentrations were reported to be highest for legumes (i.e., 15 mg/kg DM), lowest for grasses (i.e., 5 mg/kg DM), and intermediate for grains (i.e., 4–8 mg/kg DM).
- Several Cu salts (inorganic forms) are commonly used in ruminant diets to meet the requirements. These include (from highest to lowest in biological availability) cupric sulfate (CuSO_4), cupric carbonate (CuCO_3), and cupric oxide (CuO).
- Inorganic Cu sources such as CuO are used in a bolus form that provides long-term supplementation through the slow release of Cu in the rumen over an extended period of time.
- Chelated forms (organic complexes) of Cu have higher bioavailability than do inorganic sources.

Toxicity

- An extended period of time (i.e., weeks or months) is needed for development of Cu toxicity.
- Ruminants are more susceptible to Cu toxicity than nonruminants. This is due to the very narrow range between adequate and toxic Cu levels.
- Sheep are considered the most sensitive domestic animal species to Cu toxicity. This was illustrated in the marked elevation of hepatic Cu when sheep were fed diets containing Cu at 26–38 mg/kg DM, whereas rats tolerated diets containing Cu levels as high as 500 mg/kg DM.
- Significant differences were also shown between sheep and cattle in dietary Cu tolerance (i.e., 25 vs. 100 mg/kg DM). The sensitivity of sheep to Cu could be explained by comparing the adequate (i.e., 5–8 mg/kg DM) to the toxic (i.e., > 8 mg/kg DM) levels of their diets.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Iodine deficiency
- Rickets due to vitamin D deficiency
- Vitamin E selenium deficiency
- Parasitism (internal and external)
- Poor nutrition
- Anemia due to parasitism, chronic disease, blood loss
- Sulfur deficiency

CBC/BIOCHEMISTRY/URINALYSIS

Anemia—in young, hypochromic and microcytic; in adults, hypochromic and macrocytic

OTHER LABORATORY TESTS

IMAGING

OTHER DIAGNOSTIC PROCEDURES

Deficiency Diagnosis

- Analysis of feed for Cu, Mo, S, and Fe to assess the Cu status and possible availability. Forage containing < 8–10 mg/kg DM are Cu deficient. Forages containing Mo at > 1–3 mg/kg DM or having Cu:Mo ratios > 3:1 or 4:1 usually have low levels of available Cu.
- Measuring Cu concentration in plasma or serum. The normal range (i.e., 0.6–1.5 γ g/mL) is wide for cattle, sheep, and goats.
- Cu deficiency is commonly associated with decreased number of mineral elements in the liver and other organs (e.g., kidney and brain).
- Liver biopsies to assess the storage status of Cu. Normal concentrations range from 100 to 400 mg/kg liver DM.

Toxicity Diagnosis

- Increased serum glutamate oxaloacetate transaminase activity before death
- Increased serum arginase in liver damage

TREATMENT

Deficiency Treatment

- Cu deficiency is corrected by supplementation of Cu in the diet. This is possible through Cu inclusion in the concentrate mixture of feedlot diets. Grazing ruminants are supplemented with Cu compounds through dosing or drenching at intervals (e.g., monthly). The boluses used are usually slow-release forms of Cu compounds that provide the required amounts over time.
- Another method of Cu delivery is through subcutaneous or intramuscular injection of organic forms. Injectable forms of Cu (e.g., Cu glycinate and Cu EDTA) were suggested to be given at 3- to 6-month intervals to prevent deficiency.
- Cu also can be offered in a free-choice mineral mix containing 0.1%–0.2% Cu sulfate. Under severe deficiency, Cu sulfate could be increased in the mineral mix to 0.5%.

Toxicity Treatment

- For treatment of sheep, administration of Mo and S (e.g., 100 mg of ammonium molybdate and 1 g of sodium sulfate in 20 mL of water or in feed daily for 5 to 6 weeks) is recommended.
- Because high levels of Zn can protect against Cu toxicity, administration of Zn at 100 mg/kg DM will decrease liver Cu storage.

MEDICATIONS

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Injectable copper can be highly toxic in sheep and goats.

PRECAUTIONS

Ionophores (e.g., monensin and lasalocid) can increase Cu accumulation in the liver of ruminants with monensin having the greatest effect.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

PREVENTION/AVOIDANCE

Under certain conditions, the forages that cause Cu deficiency when they are grazed will not do so when harvested and fed as hay.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

MISCELLANEOUS

ASSOCIATED CONDITIONS

The Cu deficiency symptoms include anemia, severe diarrhea, bone disorders, neonatal ataxia, reproductive failure (e.g., temporary infertility), cardiovascular disorders (e.g., heart failure), achromotrichia (i.e., loss of pigmentation), nerve disorders, depressed immune function, poor growth, reduced appetite, keratinization failure in hair and wool, and weak, fragile long bones that break easily.

AGE-RELATED FACTORS

In general, young and growing ruminants have higher Cu requirements than older animals and both the requirements and tolerance are affected by the genetic makeup.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Abortion secondary to copper deficiency

RUMINANT SPECIES AFFECTED

Potentially, all ruminant species can be affected.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

Nutritional Requirements

- It is difficult to provide the exact dietary Cu requirements or to predict potential toxic levels of Cu for ruminants under different feeding programs. This is because Cu concentrations and availability vary significantly among feeds and even for the same feed (e.g., a forage species grown in different environmental conditions). Absorption rates of Cu are also affected by homeostatic controls and many dietary factors.
- Dietary Mo concentrations have the greatest impact on Cu requirements. Increasing dietary Mo, as is the case under certain grazing conditions, significantly increases Cu requirements.
- Although Mo is less of a problem in the feedlot, Cu requirements of cattle on high-concentrate diets are still not well defined.
- A Cu:Mo ratio of 4:1 was suggested to ensure meeting Cu requirements.
- Cu requirements are increased when intakes of Zn or Fe are high due to decreased Cu absorption.
- Dietary Cu levels of 8, 10, and 7–11 mg/kg DM were recommended to meet the requirements of beef cattle, dairy cattle, and sheep, respectively.
- Cu availability in feeds is a limiting factor, especially under grazing conditions. Thus, more supplemental Cu is required for grazing cattle than for those on high-concentrate diets.
- Because Cu availability in lush pastures is low and its level decreases with forage maturity, Cu supplementation should be increased at early and late maturity stages of forages to prevent deficiency.

COR PULMONALE

BASICS

DEFINITION

- An alteration in the structure and function of the right ventricle caused by a primary disorder of the respiratory system
- Collectively refers to conditions of right-heart hypertrophy, dilatation, and subsequent failure caused by pulmonary hypertension and increased pulmonary vascular resistance

OVERVIEW

- Sporadic disease that occurs most commonly in animals with chronic lung disease and ongoing lung pathology
- May develop secondary to a variety of cardiopulmonary diseases
- Regardless of cause, pulmonary hypertension is the common link between lung dysfunction and the heart in cor pulmonale.
- Pulmonary hypertension leads to right-ventricular hypertrophy, dilatation, or failure.
- Most common cause for pulmonary hypertension is chronic alveolar hypoxia and hypoxic vasoconstriction.
- Commonly has a chronic progressive course but may have an acute onset
- Sporadic disease that occurs most commonly in animals with chronic lung disease and ongoing lung pathology
- May develop secondary to a variety of cardiopulmonary diseases
- Regardless of cause, pulmonary hypertension is the common link between lung dysfunction and the heart in cor pulmonale.
- Pulmonary hypertension leads to right-ventricular hypertrophy, dilatation, or failure.
- Most common cause for pulmonary hypertension is chronic alveolar hypoxia and hypoxic vasoconstriction.
- Commonly has a chronic progressive course but may have an acute onset

PATHOPHYSIOLOGY

- Pathophysiologic mechanisms that lead to pulmonary hypertension and cor pulmonale include
 - Pulmonary vasoconstriction due to alveolar hypoxia or acidemia
 - Lung disorders (e.g., emphysema, thromboembolism, interstitial disease) resulting in anatomic compromise of pulmonary vasculature
 - Increased blood viscosity
 - Idiopathic primary pulmonary hypertension
- Pulmonary hypertrophy of medial smooth musculature within pulmonary arteries and arterioles results in increased work for the right ventricle.
- Right-ventricular hypertrophy predominates in chronic cor pulmonale.
- Right-ventricular dilatation occurs predominately in acute cor pulmonale.

SIGNALMENT

- Uncommon, sporadic disease
- No age or sex predelection
- Cattle: highly susceptible to brisket disease due to well-developed smooth muscle in pulmonary circulation
- Holstein dairy cattle may be particularly sensitive.
- Goats
- Sheep

SIGNS

- Signs generally are nonspecific.
- Early signs: subtle respiratory signs or exercise intolerance

- Exercise intolerance on exertion
- Fatigue
- Dyspnea
- Tachycardia
- Cough
- Syncope with exercise
- Later stages: signs of right-heart failure—ventral edema, mammary and jugular vein distension, jugular vein pulsation, passive hepatic congestion
- Heart sounds are normal or increased in intensity.
- ± Cyanosis
- ± Heart murmur: tricuspid valve insufficiency or pulmonic valve ejection
- ± Gallop rhythm
 - ± Atrial fibrillation (especially in goats)
 - ± Splitting of second heart sound
- ± Hemoptysis
 - Respiratory signs and thoracic auscultation reflect chronic and ongoing lung pathology

PATHOLOGIC LESIONS

- Lesions of underlying respiratory or cardiovascular disease
- Right-ventricular hypertrophy or dilation
- Enlargement of and wall thickening of pulmonary arteries and arterioles
- Lesions of right-heart failure (peripheral edema, hydrothorax, ascites, hepatic congestion)
- Lesions of locoweed toxicity in other organs

CAUSES AND RISK FACTORS

- Any condition that leads to prolonged high blood pressure in the arteries or veins of the lungs (pulmonary hypertension)
- Occurs most commonly in animals with chronic pneumonia, bronchiectasis, pulmonary abscesses, consolidated anterioventral lung lobes from previous pneumonia or chronic lung worm
- Mountain sickness (high-altitude disease); cattle exposed to high altitudes (elevation of 1600 m above sea level)
- Concurrent ingestion of locoweed (*Astragalus* spp. and *Oxytropis* spp.) enhances brisket disease in animals at high elevations
- *Pimelea* spp. toxicosis
- Hypoxia in neonatal calves
- Pulmonary hypertension secondary to pulmonary and bronchial arteritis and periarteriolar sclerosis reported in dairy calves presumably exposed to monocrotaline, a pyrrolizidine alkaloid
- Chronic interstitial pneumonia and emphysema
- Chronic obstructive pneumonia, chronic bronchitis, pulmonary interstitial fibrosis
- Obesity in feedlot cattle
- Primary pulmonary hypertension
- Pulmonary embolism
- Pulmonary vascular disease
- Smoke inhalation
- Air pollution
- Silicosis
- Chest wall disease
- Abnormal ventilatory drive
- Surgical resection of lung tissue

DIAGNOSIS

- History of chronic pulmonary disease or exposure to high altitude in animal with signs of right-heart failure
- Echocardiography
 - Rule out primary cardiac disease.
 - Document right-ventricular hypertrophy or dilatation.
 - Paradoxical interventricular septal movement during systole
 - \pm Thickening of interventricular septum
 - Tricuspid valve insufficiency or pulmonic valve ejection jet
 - Dilatation of pulmonary artery
 - Doppler echocardiography to measure pulmonary artery pressure
- Cardiac catheterization to document increased pressure in pulmonary artery, right ventricle, and right atrium
- Thoracic radiographs
 - Pulmonary disease
 - Evidence of pulmonary artery enlargement or right-heart enlargement
- Characterization of underlying pulmonary disease
 - Transtracheal wash—cytology, gram stain, culture, and sensitivity
 - Bronchoalveolar lavage—cell count and cytology
 - Thoracic ultrasound
 - Thoracic radiographs
- Baermann's technique to rule out lung worm
- Arterial blood gas: hypoxemia,
- \pm hypercapnia

DIFFERENTIAL DIAGNOSIS

- Brisket disease or mountain sickness
- Farmer's lung
- Parasitic pneumonitis
- Allergic pneumonitis
- Cardiomyopathy
- Endocarditis
- Myocarditis
- Pericarditis
- Congestive heart failure
- Cardiac lymphosarcoma

CBC/BIOCHEMISTRY/URINALYSIS

- Variable: Normal or reflect chronic inflammatory/infectious disease
- \pm Polycythemia
- \pm Monocytosis or hyperproteinemia from chronic infection

OTHER LABORATORY TESTS

- Hepatic ultrasound
 - Infract
 - Disruption of normal parenchyma
 - Vascular changes
- Electrocardiogram
- Pulmonary function tests

IMAGING

- Echocardiography
- Radiography
- Thoracic CT scan
- Pulmonary angiography
- Cardiac catheterization
- Magnetic resonance imaging

DIAGNOSTIC PROCEDURES

- Echocardiography
- Doppler echocardiography
- Thoracic radiography
- Cardiac catheterization
- Lung biopsy to determine underlying etiology

TREATMENT

- Treat primary lung disease when present
 - Antimicrobial agents for bacterial infections
 - Anthelmintics for lungworm infestations
 - Anti-inflammatories as needed
 - Diuretics: furosemide
 - ± Vasodilators; calcium channel blockers, prostaglandins; efficacy unknown in ruminants
 - ± Digoxin: use controversial
 - Oxygen therapy
 - Animals with brisket disease: treat with oxygen, move to lower altitude;
- ± phlebotomy recommended by some authors for polycythemia
- Bronchodilators if underlying obstructive pulmonary disease
 - Anticoagulant therapy if underlying thromboembolism
 - Dietary salt restriction
 - Appropriate milk and meat withdrawal times must be followed for all compounds administered to food producing animals.

MEDICATIONS

DRUGS OF CHOICE

- Furosemide: 0.5–1.0 mg/kg IV, IM Bid
- Digoxin: 0.86 µg/kg per hour IV (valuable hospitalized animals)

FOLLOW-UP

- Serum digoxin levels should be monitored to avoid toxicity.
- Monitoring of serum electrolytes and calcium, acid-base balance, and hydration status, if on diuretics

EXPECTED COURSE AND PROGNOSIS

- Guarded to poor prognosis depending on underlying cause
- Recovered animals may become poor doers: chronic weight loss, poor production.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Right-heart failure
- Hypoperfusion of vital organs (e.g., kidney, liver, gut)

CORKSCREW CLAW IN CATTLE

BASICS

DEFINITION

Corkscrew claw is an abnormal growth of the abaxial wall of the hoof, usually the lateral rear claw with concurrent misalignment of the phalanges. The abaxial wall grows beneath the claw and causes the sole to be displaced axially. The condition is thought to be hereditary.

PATHOPHYSIOLOGY

- The second and third phalanges are misaligned with the third phalanx becoming long and narrow.
- The abaxial wall grows longer than normal and curves under the claw to become the weight-bearing surface, displacing the sole axially.
- An exostosis may form at the abaxial border of the distal interphalangeal joint and may cause excess growth of the abaxial wall.

SYSTEMS AFFECTED

Musculoskeletal and dermatologic

GENETICS

- Condition is considered heritable and bulls exhibiting this condition should not be used for breeding.
- Cows with this condition should not be used for replacement heifers.
- Heritability is about 0.05.

INCIDENCE/PREVALENCE

Incidence is reported to be from about 3% to 18%.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Bovine

Breed Predilections

Reported mostly in dairy cattle

Mean Age and Range

Cattle older than 3.5 years

Predominant Sex

Both cows and bulls, but seen most often in cows

SIGNS

HISTORICAL FINDINGS

Lameness can be a feature of this disease due to overburdening of the lateral, rear claws.

PHYSICAL EXAMINATION FINDINGS

- Overgrowth of the abaxial walls on lateral rear claws causing the sole to be displaced axially.
- The claw looks like a “corkscrew.”
- There is often a palpable exostosis at the coronary band.
- Hemorrhage of the sole and white line, white line separation, and sole ulcers are commonly observed secondary lesions due to the increased weight bearing on the lateral claws.

CAUSES

RISK FACTORS

Poor hoof health management and improper or infrequent hoof trimming may play a role in incidence.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Chronic laminitis, “slipper foot,” “hooking” or “scissor claws” on the front claws, rotation of the medial claw in heifers

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Visual observation, characteristic appearance.

PATHOLOGIC FINDINGS

- Abnormal angulation of the second and third phalanges with the plantar surface of the third phalanx rotated axially.
- Exostosis of the abaxial distal phalangeal joint
- A groove may develop on the inside of the hoof capsule due to rotation of third phalanx, causing the abaxial sole to be thin. The third phalanx may be long and thin.

TREATMENT

APPROPRIATE HEALTH CARE

- Functional hoof trimming; however, trimming is a challenge due to the rotation of the third phalanx and thinning of the sole near the abaxial white line. It may be necessary to trim the lateral claw first to allow more weight bearing on the medial claw.
- The dorsal wall of the corkscrew claw should be straightened with a rasp or angle grinder and hoof-trimming wheel.
- If the lateral claw cannot be trimmed to match the medial claw, it may be helpful to apply an orthopedic block to the medial claw to help stimulate growth on the medial claw and take some of the weight off of the lateral claw.
- Cattle with this condition will need to be trimmed every 3–4 months.

NURSING CARE

If secondary conditions such as sole ulcer occur, they must be treated and reexamined after 1–2 weeks to determine if healing is occurring normally.

ACTIVITY

Cows that are lame should be moved closer to the milking parlor.

DIET

If incidence is high, diet and feeding management should be investigated, but if nutrition is a problem, we would expect to see an increased incidence of laminitis.

CLIENT EDUCATION

Clients should be educated about the possible heritability of this condition, and progeny from affected cows should not be kept for breeding stock.

FOLLOW-UP

PATIENT MONITORING

Monitor for lameness and occurrence of secondary laminitis lesions.

PREVENTION/AVOIDANCE

- Perform functional hoof trimming on all cows at dry-off and midlactation.
- Perform functional hoof trimming on heifers before they calve.
- Cows with corkscrew claw will have to be trimmed more often than other cows.

POSSIBLE COMPLICATIONS

Sole hemorrhage, sole ulcer, white line separation

EXPECTED COURSE AND PROGNOSIS

Corkscrew claw is irreversible, but proper trimming may prolong the cow's useful life.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Sole hemorrhage, sole ulcer, white line separation

AGE-RELATED FACTORS

Most common in cows over 3.5 years old.

CORNEAL ULCERATION

BASICS

DEFINITION

- Corneal ulcers can be caused by primary infections, can occur as secondary manifestations of system disease, or can be traumatic in origin.
- The vast majority of corneal ulcers in cattle are caused by infectious bovine keratoconjunctivitis (IBK), a specific disease caused by infection with *Moraxella bovis*.
- Debate exists regarding the role of several ancillary or potential pathogens in the development of corneal ulcers.

SIGNALMENT

- Infectious bovine keratoconjunctivitis occurs worldwide.
- The disease is most common in late spring, summer, and early fall. The seasonal pattern is probably associated with populations of the face fly, which serves as a mechanical vector.
- Young animals are most susceptible; however, cattle of all ages may be affected.

SIGNS

- The earliest clinical signs of corneal ulcers are epiphora and blephrospasm. Either one or both eyes may be affected. As lesions progress and mature, clouding of the cornea becomes apparent and vascular in-growth from the corneal scleral junction becomes visible.
- In cattle with *Moraxella bovis* infections, the ulcer is situated central in the cornea and later replaced by a raised white papilla, which includes inflammatory exudates.
- In severe cases, the integrity of the corneal lesions may be lost and a descemetocoele may be observed.
- Untreated, the clinical course may be as long as one month. A significant percentage of affected eyes will become nonfunctional with severe, permanent corneal opacity. Residual central corneal opacities are common.
- *Chlamydophila* sp., *Mycoplasma* sp., and *Branhamella* sp. in small ruminant species produce similar lesions.
- Viral keratitis generally produces multifocal to diffuse corneal lesions, the exception being malignant catarrhal fever (MCF) in which a zone of limbal or peripheral edema is the most consistent ocular sign.

CAUSES

- The most common cause of corneal ulcers in cattle is infectious bovine keratoconjunctivitis (IBK) caused by *Moraxella bovis*. Isolates of *M. bovis* vary greatly in their virulence. Virulence appears to be linked to the production of pilus adhesins, leukotoxins, hemolysins, and proteases.
- Occasionally, herd outbreaks of corneal ulcers have been associated with alternative pathogens. The virulence of these organisms is a subject of ongoing debate. At the very least, these organisms appear to increase the severity of IBK and under unique circumstances may serve as primary pathogens.
- Common infectious causes of corneal ulcers in sheep and goats include *Mycoplasma* sp., *Chlamydophila* sp. (formerly *Chlamydia* sp.), and infectious bovine rhinotracheitis virus (IBR, goats only).
- Other causes of corneal ulcers are usually JUST sporadic observations in single individuals.

RISK FACTORS

- Common risk factors for IBK include exposure to insect vectors (particularly face flies), ultraviolet light, dust, tall pasture grasses, recent additions to the herd, and carrier animals. *Moraxella bovis* will overwinter in the eyes of carrier cattle.
- Atypical herd outbreaks of corneal ulcers of non-IBK etiology often occur in the fall of the year. These atypical outbreaks often involve closely confined, recently weaned calves in open-herd settings in which feeder calves are continually added to a group. These groups often have a history of recurrent respiratory disease and/or polyarthritis. The author has identified a high prevalence of *Mycoplasma* sp. ocular infections in these outbreaks. Mature cows and neonatal

calves in close proximity to these open source groups occasionally experience continual flare-ups.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious bovine keratoconjunctivitis (*Moraxella bovis*, pinkeye)
- *Branhamella* sp. (small ruminants)
- Grass awns
- *Mycoplasma* sp.
- *Chlamydophila* sp.
- Viral keratitis (IBR, MCF, BVD, rinderpest)
- *Pasteurella multocida* (capsular type A)
- Trauma
- Exposure
- Neurogenic, loss of palpebral function (e.g., listeriosis, otitis interna, etc.)
- Exophthalmos, retrobulbar masses (e.g., lymphosarcoma, abscess, etc.)
- Parasitic (e.g., *Thelazia* sp., *Onchocerca* sp., *Elaeophora* sp.)
- Entropion

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Clinical exam is typically sufficient to permit a diagnosis. Application of a fluorescein stain will increase the sensitivity of ocular examinations.
- In the face of atypical or unresponsive outbreaks, microbiologic culture, virus isolation, and polymerase chain reaction assays (PCR) on ocular swabs may be considered.

TREATMENT

- Accepted treatments include subcutaneous long-acting oxytetracycline, topical therapy using ophthalmic ointments, or dry cow intramammary infusions and subconjunctival injections of penicillin with or without dexamethasone. Two treatments with long-acting oxytetracycline at 72-hr intervals have been reported to eliminate carrier states and demonstrated promise in terminating outbreaks.
- A number of other antibiotics including florfenicol have been demonstrated efficacious in the treatment of IBK; however, *M. bovis* is often resistant to tylosin, erythromycin, and lincomycin.
- In cattle, early recognition and treatment will typically limit the severity of disease and the degree of corneal scarring.
- Infectious corneal ulceration in sheep and goats appears more aggressive and less responsive to treatment.
- Treatment in sheep and goats typically consists of systemic administration of long-acting oxytetracycline because the vast majority of potential pathogens are at least nominally sensitive to this antibiotic.
- Anecdotal reports have suggested that aqueous ceftiofur is efficacious as a subconjunctival injection, and this approach is particularly appealing in lactating dairy cattle because milk withholding is avoided; however, the author is aware of no documentary evidence supporting this approach.
- When topical treatment is used, appropriate hygienic precautions should be employed to prevent transmission to additional animals.
- Adjuncts to treatment, which are occasionally used, include an eye patch covering the affected eye, third eyelid flaps to prevent impending corneal perforation, and use of topical or systemic anti-inflammatory agents.

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PREVENTION

- Prevention should include control of face flies (insecticide impregnated ear tags or residual fly sprays), clipping tall pastures, elimination of dusty environments, elimination of carrier cattle and vaccines.
- Animals with active clinical disease should be isolated from unaffected herd mates.
- Vaccine efficacy appears highly variable and difficult to predict due to the variation in the strain of IBK responsible for a given outbreak.
- Mass medication with oxytetracycline using either subcutaneous injections or the addition of antibiotics to salt or concentrates also will limit the severity of outbreaks and ameliorate the presence of carrier animals.
- It should be noted that mass antibiotic therapy may cure asymptomatic anaplasmosis carriers, rendering these cattle susceptible to clinical anaplasmosis if the disease is reintroduced.
- In herds with atypical fall or winter pinkeye, efforts should be made to reduce the severity of endemic respiratory disease (*Mycoplasma* sp.). These efforts should include preconditioning programs and restricting the continual addition of susceptible cattle to groups experiencing corneal ulceration.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- These groups often have a history of recurrent respiratory disease and/or polyarthritis.
- Mass antibiotic therapy may cure asymptomatic anaplasmosis carriers, rendering these cattle susceptible to clinical anaplasmosis if the disease is reintroduced.

AGE-RELATED FACTORS

Young animals are most susceptible; however, cattle of all ages may be affected.

ZOONOTIC POTENTIAL

The *Chlamydophila* sp. associated with ocular disease in small ruminants may be zoonotic.

PREGNANCY

Chlamydial and mycoplasmal species can cause abortion.

RUMINANT SPECIES AFFECTED

Potentially all ruminant species are affected.

BIOSECURITY

- Prevention should include control of face flies (insecticide impregnated ear tags or residual fly sprays), clipping tall pastures, elimination of dusty environments, elimination of carrier cattle and vaccines.
- Animals with active clinical disease should be isolated from unaffected herd mates.
- Restrict the continual addition of susceptible cattle to groups experiencing corneal ulceration.

PRODUCTION MANAGEMENT

- Reduce exposure to insect vectors, particularly face flies, exposure to ultraviolet light, dust, tall pasture grasses, recent additions to the herd, and carrier animals.
- Prevention efforts should include preconditioning programs and restricting the continual addition of susceptible cattle to groups experiencing corneal ulceration.

Author: Jeff Tyler

CORONAVIRUS

BASICS

OVERVIEW

- Disease of neonatal ruminants
- The causative agent is a coronavirus. All coronaviruses are of the same serotype.
- Pathogenicity is related to load of exposure, level of immunity to the virus, concurrent infection with other neonatal pathogens, and stress. Most infections are concurrent with other neonatal pathogens.
- The virus is ubiquitous with seroprevalence in the adult herd of 80–90%.
- Morbidity of coronavirus is estimated to be 15–25%. Mortality rate in uncomplicated cases is 5–10% but may reach 50% with concurrent bacterial or parasitic infections.

PATHOPHYSIOLOGY

- The virus is acquired either through the ingestion of feces-contaminated material or inhalation. Initially, villous epithelial cells are infected in the proximal small intestine with infection progressing caudally with time. The crypt cells of the small intestine are not affected.
- The infection extends into the colon resulting in infection of the epithelial cells of the ridges as well as the crypts.
- The virus is cytotoxic resulting in sloughing of epithelial cells. Coronavirus may also infect undifferentiated epithelial cells, fibroblasts, and endothelial cells of the lamina propria resulting in significant damage to the colon. Infected cells contain large numbers of virus and are desquamated into the lumen. Immature crypt cells replace the absorptive epithelium of the small intestine but denuded areas within the colon may take several days to heal.
- The loss of epithelial cells results in a maldigestive as well as a malabsorptive type of diarrhea.
- Undigested carbohydrates undergo bacterial fermentation resulting in an increase in osmotic pressure and water being drawn into the intestinal lumen. The crypt cells of the small intestine are not affected and continue to secrete fluid resulting in net secretion exceeding absorptive capacity.
- Diarrhea results due to increased osmotic pressure and decreased absorption. The physical loss of the epithelial cells results in increased susceptibility to other pathogens because of loss of the villous integrity and decreased secretion of lactoferrin and lysozymes as well as the release of inflammatory mediators.
- Damage predisposes the attachment of ETEC and attaching and effacing *E. coli* to the intestinal villi.
- The loss of electrolytes, bicarbonate, and water leads to dehydration and metabolic acidosis.
- The virus can also infect the respiratory epithelium resulting in a mild respiratory or subclinical respiratory infection.

SYSTEMS AFFECTED

Gastrointestinal, respiratory

GENETICS

N/A

INCIDENCE/PREVALENCE

Prevalence of coronavirus infections ranges from 15% to 25% with a great variation in mortality, 5–50% depending on concurrent bacterial and parasitic infections.

Seroprevalence in the adult herd may be close to 100%.

SIGNALMENT

Species

Bovine, ovine, caprine; potentially, all ruminant species can be infected.

Breed Predispositions

N/A

Mean Age and Range

- Most infections occur during the second week of life. Range is 3 days to 3 weeks.
- Calves as old as 3 months of age may be affected.

Predominant Sex

N/A

SIGNS

GENERAL COMMENTS

- Clinical signs are more severe than rotavirus-induced diarrhea.
- Acute onset of diarrhea varying from mild to severe, depression, and reluctance to nurse; feces may contain mucus, milk curds, and occasionally flecks of blood.
- Clinical signs last 3–5 days during which calves become progressively depressed, weak, and experience weight loss.
- Some calves may exhibit signs of abdominal pain. In the case of uncomplicated cases, diarrhea may exist for 2 to 3 days. In cases of secondary bacterial infection, diarrhea may last 3–5 days.

HISTORICAL FINDINGS

- Sudden onset of diarrhea that spreads rapidly through the neonatal population
- A few cases may have been noticed initially but the frequency of cases increases as the calving season progresses due to buildup of pathogen load.
- Increased number of cases observed following periods of stress such as a snowstorm or cold wet weather.

PHYSICAL EXAMINATION FINDINGS

- Mild to severe watery diarrhea with pieces of milk curd and flecks of blood; color, consistency, and composition will vary with coexisting infections.
- Dehydration and depression with degrees of inappetence or reluctance to nurse. Some animals may be weak to the point of recumbency.
- Bruxism and nasal discharge

CAUSES

Coronavirus. All cattle coronaviruses are of the same serotype.

RISK FACTORS

- Inadequate colostrum transfer of immunoglobulins resulting in agammaglobulinemia or hypogammaglobulinemia. Lack of local colostrum immunity in calves 5 days postpartum or in calves raised on milk replacers.
- Birthing areas contaminated with fecal material containing coronavirus
- Neonatal housing in which buildup of pathogen load occurs
- Neonates housed or maintained in a cold, wet environment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diarrhea may be caused by a variety of infectious agents as well as nutritional causes.
- *Clostridium perfringens* type C—acute death and hemorrhagic enteritis. *E. coli* infections are usually seen in calves less than 7 days of age. Cryptosporidia and rotavirus are hard to differentiate from coronavirus. Salmonellosis animals are usually febrile; coronavirus infections temperature will be variable.
- Nutritional causes of diarrhea may be differentiated from coronavirus diarrhea if history contains a dietary change or examination of the feedstuffs and identification of deficiencies or excesses.

CBC/BIOCHEMISTRY/URINALYSIS

- CBC: hemoconcentration, increased plasma proteins
- Serum chemistry: metabolic acidosis with low plasma bicarbonate. Glucose and electrolyte values will be low depending on severity of diarrhea.
- Urinalysis: depending on state of dehydration, urine will be concentrated resulting in an increased specific gravity.

OTHER LABORATORY TESTS

DIAGNOSTIC PROCEDURES

- Feces should be collected as soon as diarrhea is noted because exfoliation of virus-laden enterocytes is short-lived and occurs early in the disease process.
- Feces can be submitted for electron microscopy and identification of virus. A few drops of formalin can be added to 10 cc of feces, or feces can be frozen.
- Serology can detect seroconversion or a fourfold increase in serum immunoglobulin levels.
- Fresh sections of the small intestine, preferably mid ileum, and colon tied at the cut ends to contain intestinal contents can be submitted on ice for immunofluorescent microscopy.

PATHOLOGIC FINDINGS

- No specific gross lesions; distended bowel containing undigested milk and fluid. The mucosa may be congested and there may be petechial hemorrhages throughout the intestinal tract.
- Histologically, the villi will be shortened, covered with squamous to cuboidal epithelial cells.

TREATMENT

APPROPRIATE HEALTH CARE

N/A

NURSING CARE

- Fluid therapy is needed to correct dehydration, circulatory impairment, and electrolyte and metabolic imbalances.
- Fluid deficit should be calculated as well as maintenance requirement, 80–100 ml/kg, to determine volume of fluids needed during a 24-hour period. Fluid may be administered orally or intravenously. Commercial oral electrolyte solutions containing glucose and an alkalinizing agent are recommended if the neonate is still nursing. Although oral electrolytes are less likely to be absorbed due to enterocyte pathology, not all enterocytes are affected so some absorption may occur.
- Neonates without a suckle response need IV fluids. IV administration of lactated Ringer's solution is adequate. With severe acidosis, isotonic sodium bicarbonate solution (1.3%, 13 of sodium bicarbonate to 100 of distilled water) may be used. Dextrose solutions (2.5–5%) are indicated in cases of hypoglycemia.
- With hypoglycemia and an unknown electrolyte and acid-base status, a 2.5% dextrose and 0.45% saline solution has been recommended.

ACTIVITY

N/A

DIET

- Neonates with a suckle response should be left with the dam and allowed to nurse.
- Animals being reared artificially should remain on their diet or switch to whole milk or colostrum. If the diarrhea becomes worse or the calf becomes depressed, removal from the dam or milk is warranted. In case of hand-fed neonates that are depressed and not interested in sucking, or neonates not nursing the dam, neonates should receive a high-energy electrolyte solution at a rate of 10% of body weight divided into a minimum of four feedings.
- Once neonates are suckling, feed milk at a rate of 5% of body weight in four feedings a day, increasing the amount per feeding gradually so calf is back on full feed within 2 to 3 days.
- Calves should also receive 5% of their body weight in electrolyte solutions spacing 2 hours before or after milk feedings. Milk should not be withheld longer than 24 hours and can be given via an esophageal feeder. No more than 1 liter should be tubed at a time.
- Milk and electrolyte solutions can be altered as described previously with a minimum of 10% body weight of fluid per day.
- Oral electrolytes containing an alkalinizing agent, other than acetate, should not be fed when calves are receiving milk as milk digestion may be disrupted.

CLIENT EDUCATION

- Clients need to ensure the calves acquire an adequate amount of colostrum. Neonates should be kept dry and in a draft-free environment.
- Animals should be moved and fed in such a way as to reduce the buildup of mud and fecal material in the neonate's

environment. Diarrheic animals should be isolated from healthy neonates as they are sources for large numbers of pathogens.

- Owners should work with healthy calves before working with sick calves and should clean equipment, bottles, and nipples adequately between calf usage.
- Owners should be advised as to how to reduce pathogen transfer between calves in regard to clothing and shoes.

MEDICATIONS

DRUGS OF CHOICE

- Broad-spectrum antibiotics may be considered because of the potential for mixed infections as well as the loss of mucosal integrity. Oral amoxicillin trihydrate 10 mg/kg PO q 12h for nonruminating calves, 20-day slaughter withdrawal (extralabel in small ruminants). Amoxicillin trihydrate-clavulanate potassium 12.5 mg combined drug/kg PO q 12 h (extralabel usage) for 3 days.
- Parenteral ceftiofur 2.2 mg/kg IM/SC q 24 h for 3 days (extralabel usage) for 3 days.

Plasma Transfusion

Although not specific for corona viral infections, in cases of failure of passive transfer and depending on value of the animal, plasma transfusion may be warranted.

CONTRAINDICATIONS

- Do not use kaolin and pectin as use may increase electrolyte loss.
- Meat and milk withdrawal time periods must be maintained.

FOLLOW-UP

PATIENT MONITORING

- Monitor attitude, suckling response, appetite, fecal color and consistency, and hydration status.
- Monitor age cohorts for signs of diarrhea.

POSSIBLE COMPLICATIONS

Hypovolemic shock and death

PREVENTION/AVOIDANCE

- Reduce exposure, clean maternity areas, move to a clean area after birth. Those handling sick neonates should practice biosecurity measures to reduce exposure to healthy neonates, wash hands and disinfect boots, maintain clothes free of fecal material.
- Vaccination of dams prepartum according to manufacturer's recommendations with a coronavirus vaccine may increase colostral antibody; results are variable.
- Oral vaccination of neonate with a modified-live oral vaccine will produce IgA and IgM. This vaccine is cumbersome for management as it is to be given prior to colostrum consumption and colostrum must be withheld for several hours after vaccination. This may increase the opportunity for bacterial infections and failure of passive transfer.
- In the case of dairy animals, feed neonates colostrum for 30 days if coronavirus is an endemic problem.
- Eliminate areas of fecal buildup.
- Keep environment dry and draft free.

EXPECTED COURSE AND PROGNOSIS

- In uncomplicated infections, diarrhea is present for 2 to 3 days. Prognosis is good, as this infection tends to be self-limiting and generally requires minor supportive care.
- Duration of diarrhea may be 4–6 days with secondary bacterial infections. Prognosis is dependent on the degree of pathology produced by the secondary bacteria.
- Prognosis is good to fair with supportive care. It may take a couple of weeks for animals to fully recover.

MISCELLANEOUS

ASSOCIATED CONDITIONS

A mild respiratory infection may occur simultaneously.

AGE-RELATED FACTORS

- Most cases occur at 7 to 14 days of age.
- Range is 1 day to 3 weeks.

ZOONOTIC POTENTIAL

None

PREGNANCY

COWPOX

BASICS

OVERVIEW

- Cowpox is caused by an orthopoxvirus that is closely related to but distinguishable from the human orthopoxviruses vaccinia and variola.
- Animals develop poxlike lesions commonly on the teat and udder.

SIGNALMENT

- The virus tends to spread through a naïve herd rapidly particularly during times of the year when the teats and udders are likely to have abrasions on the surface.
- Heifers as they are introduced to the milking string are more likely to become involved in endemic herds.

SIGNS

- Incubation period is between 3 and 10 days.
- Typical pox lesions are usually noted only on the teats and udder. However, in severe cases, the pox lesions can be identified on the thin skin of the inside of the inguinal region and occasionally on the perineum.
- Bulls can get lesions on the scrotum.
- Nursing calves can get oral lesions similar to bovine papular stomatitis.
- Lesions usually progress from circular raised reddened areas of erythema and edema to firm 1–2 cm nodules that form a central vesicle. The vesicle eventually ruptures or collapses forming a central crater in the raised circumscribed area. The central area undergoes further necrosis and scab formation if the animal is not being milked.
- Milked animals develop a raised circumscribed lesion with a central umbilicated ulcer that is slow to heal.

CAUSES AND RISK FACTORS

Disease is endemic in rodents of Europe and Asia with the virus occasionally infecting cattle.

- Voles are a common rodent that is infected with the virus.
- Domestic cats are commonly infected in endemic areas by hunting and eating infected rodents and are believed to act as a means of spreading the disease to humans and cattle.
- Being milked by infected hands of herdsmen or by inoculation with contaminated fomites such as teat dipping cups and milking equipment can infect cattle.
- Insects are also suspected of transferring the virus from cow to cow.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pseudocowpox (milkers nodules): Pseudocowpox is a parapoxvirus with lesions similar to cowpox. Virus is similar to bovine papular stomatitis.
- Herpes mammillitis: Small ulcers develop on teats and udders that are slow healing. Viral culturing will assist in differentiating poxviruses from herpesviruses.
- Vesicular stomatitis: Lesions are often also prevalent in the mouth and feet.
- Foot-and-mouth disease: Lesions in the mouth and on the feet are also present in infected animals.
- Caustic substances that are placed on the teat
- *Staphylococcus aureus* infections on the teats can cause vesicles, which may spread to the udder resulting in furunculitis and boils.

CBC/BIOCHEMISTRY / URINALYSIS

N/A

OTHER LABORATORY FINDINGS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Biopsies of the lesions will identify typical poxvirus intracytoplasmic inclusions on the epithelium.
- Electron microscopy of the infected epithelium identifies characteristic poxvirus present in infected keratinocytes.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- The pox lesions are circumscribed raised firm nodules that are blanched usually with a circular area of hyperemia around the base. These raised nodules eventually form a vesicle and then a pustule in the center of the raised nodules. Lesions eventually undergo necrosis and collapse causing a cavitory depression in the center of the nodules. A scab will form over the necrotic tissue, which, once removed, identifies an ulcerated surface that is slow to heal.
- Lesions are seen primarily on the teats and udder but can also be seen in the peritoneal region and on the scrotum of bulls.
- Suckling calves can have similar lesions in the oral cavity.

HISTOPATHOLOGIC FINDINGS

- The pox lesions consist of edema, congestion, and lymphocytic infiltration of the superficial dermis.
- The associated epithelium becomes hyperplastic with ballooning degeneration and necrosis of the affected epithelium in the stratum spinosum.
- Eosinophilic intracytoplasmic inclusion bodies are seen in the swollen keratinocytes in the stratum spinosum.
- Epithelial cells of the stratum spinosum separate forming small vesicles that fill with neutrophils forming a pustule. Later, the associated epithelium beneath the pustules becomes necrotic forming an ulcerated epidermis with serocellular debris overlying the lesion.
- Variable numbers of neutrophils are present in the dermal connective tissues.

TREATMENT

- There is no treatment for the pox-associated lesions.
- One needs to keep the lesions clean and free of secondary bacterial infections.
- Debris or scabs from wounds should be picked up and disposed of to insure that contaminated materials do not contact other animals.
- Antibacterial ointments may assist in healing.

MEDICATIONS

N/A

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING

- Lesions are usually self-limiting.
- Keeping the lesions clean and free of contamination is important in preventing bacterial infections.

PREVENTION/AVOIDANCE

- Herdsmen with lesions should limit involvement in milking since this is a major method of spreading the disease.
- Cleaning cloths, teat dipping cups, and milking machines should be disinfected thoroughly before use on noninfected animals.
- Quaternary ammonia compounds and other teat-dipping compounds with viricidal activity should be adequate for preventing the spread of the disease.
- Currently, no vaccine is available for use in outbreaks.

POSSIBLE COMPLICATIONS

Secondary bacterial infections of the lesions can occur with the development of mastitis in affected quarters or a severe dermatitis involving the skin of the affected udder.

EXPECTED COURSE AND PROGNOSIS

Cowpox is considered a mild disease and should cause little discomfort to affected cattle. Most cases resolve without complications.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Young animals, particularly naïve heifers coming into an endemic herd, are most susceptible.

ZOONOTIC POTENTIAL

People handling infected material can get lesions on their hands and face. The lesions are usually mild and self-limiting.

CRYPTOCOCCOSIS

BASICS

OVERVIEW

- Cryptococcosis is a mycotic infection caused by the basidiomycete *Cryptococcus (Filobasidiella) neoformans*.
- Usually rare, sporadic cases of respiratory disease and/or meningitis or mastitis
- Worldwide distribution
- Important risk factor is exposure to soil/dust enriched with pigeon excreta.

PATHOPHYSIOLOGY

- Animals infected by inhaling dust carrying basidiospores/yeast forms
- Contaminated udder infusions can cause outbreaks of mastitis.
- Thick polysaccharide capsule of *Cryptococcus neoformans* inhibits phagocytosis
- Most infections are mild, subclinical lung infections.
- May cause formation of lung abscess/nodule or diffuse pulmonary infiltrates
- Nodules, or “cryptococcoma,” vary in size and have a gummy, gelatinous consistency
- Solitary pulmonary nodules may be confused with carcinoma.
- Occasional hematogenous spread of *Cryptococcus neoformans* from lungs/udder
- Most frequent secondary site of colonization is meninges, leading to meningitis.
- Lymph nodes, skin, bone, liver, kidneys, and other organs may also be involved.

INCIDENCE/PREVALENCE

- Rare, sporadic
- Outbreaks of mastitis may occur in a herd if contaminated udder infusions are used.
- True prevalence is unknown, as infections normally are subclinical and lack a reliable skin test.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

- *Cryptococcus neoformans* can infect most animals, especially debilitated or immunocompromised animals.
- Host species include cattle, sheep, goats, horses, dogs, cats, zoo animals, and humans.
- Debilitated/immunocompromised animals are at higher risk for disseminated disease.
- Birds may carry *Cryptococcus neoformans* in the intestinal tract but do not suffer clinical disease.

SIGNS

- Upper or lower respiratory disease
- Fever
- Weight loss
- Neurological changes: stiffness, hyperesthesia, blindness, incoordination
- Skin lesions
- Lymphadenitis
- Mastitis

CAUSES AND RISK FACTORS

- *Cryptococcus neoformans* can survive in dry, nitrogen/creatinine-enriched, alkaline environments.
- Contaminated soil is the reservoir for *Cryptococcus neoformans*.
- Exposure to soil/dust enriched with pigeon excreta increases risk of inhalation of *Cryptococcus neoformans*.

- Debilitated/immunocompromised animals may be at higher risk for disseminated disease.
- No known animal-to-animal transmission
- No known animal-to-human transmission

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Respiratory disease: viral, bacterial or other fungal respiratory pathogens
- Bacterial mastitis
- Neurological disease: viral (e.g., rabies, arboviruses), bacterial pathogens

OTHER DIAGNOSTIC PROCEDURES

- Serological tests; latex agglutination tests to detect cryptococcal antigens in serum/CSF
- Culture of tissues/fluids
- Identification of thickly encapsulated yeast forms via India ink wet mounts and microscopic exam

TREATMENT

- Frequently self-limiting
- Surgical removal of lung nodules
- Disseminated disease frequently fatal if not treated
- In humans, combination therapy of amphotericin B and 5-flucytosine for 6–10 weeks has been successful.
- Drug withdrawal periods must be determined and maintained.
- Mortality rates in humans with treated disseminated cryptococcosis is approximately 30%.

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

CRYPTOSPORIDIOSIS

BASICS

OVERVIEW

- Cryptosporidiosis is caused by a nonhost-specific and widely distributed coccidian parasite *Cryptosporidium parvum*.
- *C. parvum* is an important cause of neonatal diarrhea that is clinically similar to other causes of calfhood scours.

PATHOPHYSIOLOGY

- Shed oocysts are sporulated and immediately infective.
- The primary route of transmission is typically fecal-oral; however, environmental contamination can spread the pathogen.
- Sporozoites from the oocysts primarily infect the brush border of the distal small intestine and large intestine.
- A vacuole is formed between the cytoplasm and cell membrane that causes villous atrophy, villous fusion, and, later, inflammatory changes of the mucosa.
- Clinical diarrhea develops on average 4 days after infection as a result of a combination of malabsorption and maldigestion.

SYSTEMS AFFECTED

Gastrointestinal

GENETICS

N/A

INCIDENCE/PREVALENCE

C. parvum was found in 22.4% of calves in one nationwide survey of dairy farms.

GEOGRAPHICAL DISTRIBUTION

Worldwide distribution

SIGNALMENT

Species

Cryptosporidiosis causes diarrhea in mammals (including cattle, sheep, goats, and humans) but it can also affect birds and reptiles.

Breed Predilections

N/A

Mean Age and Range

Highest frequency of infection is seen in calves aged 0–3 weeks.

Predominant Sex

N/A

SIGNS

GENERAL COMMENTS

- Diarrhea, dehydration, anorexia, and tenesmus are nonspecific findings for enteric infections in calves, including cryptosporidiosis.
- Diarrhea in uncomplicated cryptosporidiosis in immunocompetent individuals usually resolves in one week without anorexia.
- Infection without clinical signs can occur.

PHYSICAL EXAMINATION FINDINGS

- Diarrhea, dehydration, anorexia, and tenesmus are evident on physical examination.
- Mixed bacterial or viral etiologies should be considered in severe presentations with acid-base abnormalities, electrolyte

disturbances, hypothermia, and weight loss.

CAUSES

- Cryptosporidiosis is caused by coccidian parasites of the phylum Apicomplexa called *Cryptosporidium* spp.
- The pathology in most domestic mammals is due to *Cryptosporidium parvum*.
- Recent evidence has shown some strain or genotype variability in *C. parvum*.

RISK FACTORS

- Poor hygiene in calf management can increase pathogen exposure from the environment and calf to calf.
- Immunocompromised calves are at greater risk for severe infections.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bovine viral diarrhea (BVD)
- *Clostridium perfringens* infection
- Coccidiosis
- Coronaviral infection
- *Escherichia coli* infection
- Feeding error (incorrect formulation of milk replacer, over/under feeding, etc.)
- Giardiasis
- Rotaviral infection
- Salmonellosis

CBC/BIOCHEMISTRY/URINALYSIS

- The CBC may show evidence of dehydration, hyperkalemia, and hypoglycemia.
- Blood gas analysis may show acidosis.

OTHER LABORATORY TESTS

High-power magnification with acid fast staining can be used on mucosal scrapings or after fecal flotation for identification of the organism.

IMAGING

N/A

GROSS AND HISTOPATHOLOGICAL FINDINGS

- Gross necropsy findings reveal hyperemic intestinal mucosa with yellow degraded intestinal contents.
- Histology reveals atrophy, fusion, and inflammation of the intestinal villi with circular, intramembranous, extracytoplasmic organism in the brush border.

TREATMENT

- There is no specific therapy for cryptosporidiosis but the diarrhea is usually self-limiting (7 day course in uncomplicated cases).
- Treatment is supportive including nutritional support, fluid and electrolyte replacement, and correction of acidosis and hypothermia.
- Antimicrobial therapy may be indicated in cases with secondary bacterial infections.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

ACTIVITY

N/A

DIET

- Electrolyte and rehydration therapy do not provide nutritional support so milk replacer needs to be fed.
- Electrolyte/fluid product may inhibit milk clot formation in the abomasum so it should be administered 1–2 hours after milk feedings.
- Decreasing the volume but increasing the number of feedings may help reduce the osmotic effects in the gut.

CLIENT EDUCATION

Cryptosporidiosis is a zoonotic pathogen so appropriate hygiene precautions should be taken when dealing with infected individuals.

MEDICATIONS

- Antimicrobial therapy if there is evidence of secondary bacterial infection
- Nonsteroidal anti-inflammatory therapy may be used to reduce pain and discomfort in some cases.

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

CONTROL

- *Cryptosporidium* organisms are very resistant to temperature and chemical disinfection. Ammonia products (5%) and desiccation have been demonstrated to help disinfect the environment.
- Individual housing and sanitation of feeding equipment between calves can help control exposure.
- Adherence to hygienic practices in maternity area and in cleaning manure from calf areas can also help decrease environmental exposure.

MISCELLANEOUS

Gastric cryptosporidiosis: *Cryptosporidium andersoni* (formerly categorized as *C. muris*) causes nonzoonotic gastric cryptosporidiosis by infecting the glands of the abomasum in a small percentage of adult cattle. Animals appear clinically normal but inhibition of acid production in the abomasum can lead to decreased milk production in chronically affected cattle. Histopathology, fecal floatation, and acid fast staining can be utilized for identification of the organism.

CULLING STRATEGIES

BASICS

DEFINITION

For the purpose of this discussion, the culling rate will be the number of animals removed divided by the average number of animals at risk for removal. This is really a proportion as it does not have time in the denominator, but it is a commonly used term of herd improvement associations.

OVERVIEW

Successful replacement strategies focus on removing animals because newly arriving animals allow for a higher economic return to the enterprise than the animal leaving (expected average profit of the new animal exceeds the remaining average profit of the animal replaced). Primary variables in replacement strategies are:

- Value of replaced animal (e.g., for meat or sale to another herd)
- Potential production (milk, meat, wool, offspring) and stage of production (lactation, pregnancy status, rate of gain, and weight for age)
- Expected fertility
- Health/expected survivorship (age)
- Cost of treatment or intervention
- Genetic value, phenotype, or conformation (i.e., udder, feet and legs, reproductive efficiency, milk/meat/wool production)
- Cost, availability, and quality of replacements
- Capacity of facility or ability to expand
- Operating goals of the owner/management team

SYSTEMS AFFECTED

Any, depending on condition

GENETICS

Dependent on herd needs and goals:

- Milk production or milk components
- Specific proteins (as cloned into transgenic animals)
- Mastitis or other disease resistance
- Conformation (head length or width, feet and leg conformation, vulvar conformation, udder conformation, teat size, rumen capacity, top line, etc.)
- Color, wool quality, fiber length or crimp, etc.
- Production trait (frame size, pelvic size, muscling, etc).

INCIDENCE/PREVALENCE

- Highly variable depending on herd, markets, value of products, disease incidence, etc. Incidence will vary from the high teens to an excess of 100%.
- Herds with excellent management that control disease well will have low cull rates when expanding, but can approach 50% if they are stable in size and have an excellent heifer or purchasing ability.
- It can make sense to sell the entire herd when the value of animals is high and the replacement costs are low or expected to be low in the near future. For example, cows bought inexpensively in the sale ring or from herds with poorly conditioned, low-producing cows can be managed in another facility in a way that cows can gain weight and produce modest levels of milk at a low cost. Not many managers can accomplish this, but after cows increase their body condition, their value can increase from a low \$0.15–\$0.20/pound live weight to \$0.35–\$0.45/pound live weight, and they may gain weight (200–300 pounds) as well. Milk production can pay for a cow's feed and profit is generated from her sale for meat. In such herds, the cull rate can exceed 100% with cows being replaced within 6 or 7 months of purchase.

GEOGRAPHIC DISTRIBUTION

Worldwide, depending on species and management

SIGNALMENT

Species

All ruminant species

Breed Predilections

Only if the herd is changing from one breed to another because of specific production traits or costs of production.

Mean Age and Range

All ages are susceptible, but older animals are usually more likely than younger. This is because as animals age, their productive potential decreases and/or the probability of disease increases over time.

Predominant Sex

- Dependent on the facility's business priorities. For example, herds with high genetic merit will have bulls, heifers, and cows removed depending on their value to supply genetics to the herd compared to their value for sale to other herds.
- Commercial herds may keep a few bull calves for replacing their herd bulls in low production strings, but herds that use all-bull breeding will often buy seedstock from high genetic value herds. Other bull calves will be sold immediately after birth for meat production.
- Herds with a reputation for high genetic merit (usually measured as milk production, wool, or weaning weights) can sell their less-desirable animals to commercial herds at a value above sale for meat, but often close to their cost of rearing their own heifer. In these high genetic merit herds, owners will often calve out all their heifers, keeping all female offspring. These herds often have a large excess of heifers available to replace animals that are least desirable for their production and management goals.

SIGNS

PHYSICALEXAMINATION FINDINGS

Animals can be healthy, but replacements have higher value compared to animals currently in the herd.

CAUSES AND RISK FACTORS

- Several models examining factors influencing decision making by managers for replacing animals have been developed.
- Dairy cows will be used in several examples of factors identified as important to predicting reasons and mechanisms for culling.

Value of Replaced Animal

This will vary depending on market effects, proximity to markets, transportation costs, breed, genetic value, and condition/production at sale. For example, a heifer can be purchased for \$1500 and is expected to produce 22,000 pounds of milk. A third lactation cow that is 35 days pregnant, 300 days in milk, and 60 pounds of milk using rBST has a value of \$600 if sold for meat; the milk price is \$9/cwt and the cost of making that milk is \$5.85/cwt. The dairy is losing \$2/cwt milking this dairy cow. Compare this cow to a second lactation cow that is 210 days pregnant, has produced 25,000 pounds of milk, but can be fed in the dry lot for \$1.25 per day. Assuming the dairy is full and the milk price is likely to rise to \$12/cwt in the next 3 months, the first cow should be sold for meat, the second cow dried, and the fresh heifer should replace the first cow.

Potential Production

The likelihood of an animal to produce at age adjusted herd average or better, including conceiving within accepted goals (i.e., a 13-month calving interval), what stage of production they are in (i.e., days lactating), and, in the case of dairy animals, whether they conceived a heifer or bull calf (ultrasound diagnosis). For example: compare a first lactation dairy cow who is 200 days in milk, carrying a 120-day heifer, and producing 100 pounds of milk without use of rBST to a herd mate that is 35 days pregnant, 200 days in milk, and 80 pounds of milk using rBST. The second cow can be sold to a neighbor for \$1200 and the cost of raising replacement heifers on the dairy is \$1200. If the herd were expanding, all these animals would likely be kept. If the herd is not expanding, then the second cow is sold and the cost of rearing the heifer is paid for by the sale of the second cow.

Expected Fertility

In general, younger animals have a higher likelihood of conceiving than an older cow, and as age increases, the likelihood of fetal loss increases. In pregnant cows, culling is highly associated with inflammatory disease. As a cow's age increases, and the age at conception increases, her likelihood of culling also increases. Fetal loss, cystic ovarian disease, dystocia, metritis, retained placenta, lack of expression of estrus or anestrus will increase likelihood of a cow being culled, because of their effect on fertility.

Health/Expected Survivorship (Age/Stage of Lactation)

Unhealthy cows make less milk than healthy cows and are at an increased risk for removal because of their low milk production. However, a cow with severe perimetritis leading to infertility may remain in the herd until her production drops below her costs of production, while a cow with an uncomplicated left displaced abomasum 1 week after calving may have no change in her likelihood of staying in the herd compared to healthy herd mates, as long as she has a good production potential. In other words, a cow's milk production potential is still the largest determinant for risk of replacement, and a cow that becomes low producing and unhealthy or fails to conceive is much more likely to be replaced.

Cost of Treatment or Intervention

As cost of treatment/intervention exceeds the potential profitability of the cow, the more likely she is to be sold. Using decision tree analysis for a specific disease, the likelihood of treatment success and failure and the cost of intervention allow for better decision making.

Genetic Value, Phenotype, or Conformation (e.g., Udder, Feet, and Legs, Reproductive Efficiency, Milk/Meat/Wool Production)

Decisions for genetic improvement are quite varied, but principally focus on production traits. Selection on a single trait (i.e., milk production) is often at the expense of fertility, mastitis control, feet and leg conformation, or other traits related to longevity in the herd. Arguably, the current genetic value for milk production in today's bull studs is sufficient to maintain or increase milk production in most commercial dairies. Selection on other important traits is probably more critical to increasing longevity. Although disease per se may not be associated with an increase in culling, it will limit choices as to which animals must remain in the herd.

Cost, Availability, and Quality of Replacements

Keeping replacement costs low is principally achieved by reducing feed cost/unit of gain. Animals entering the herd at a younger age can reduce costs of heifer production and reduce total animal units on the facility (lower generation time). Cost and success at raising replacement heifers is directly related to the ability of a dairy to supply heifers for replacement. Several approaches to acquiring replacements for a dairy are taken. One end of the spectrum is the sale of all calves born with the subsequent purchase of primiparous heifers just before calving. This reduces the number of animals on a facility, which can be important for facilities with limited land facing environmental constraints. Alternatively, dairies with high conception rates using high-quality bulls, good success in delivering live calves, low calf mortality rates, and low to modest rearing costs will have an excess of young stock to replace animals of lower value in their milking herd. However, a milking herd with high losses (death, disease, infertility) can exceed the heifer replacement capacity of the dairy, requiring purchase of replacements if the herd is to remain at current herd capacity.

Capacity of Facility or Ability to Expand

Simply, this is the desire or ability of the management to add cows to the herd. Environmental constraints can be one factor limiting growth, but availability of affordable land, willingness to relocate, quality of available land, or the desire to add more cows are decisions that management must consider when deciding whether to raise their heifers, sell cows, retain cows, or purchase replacements.

Operating Goals of the Owner/Management Team

It is critical that members of management set goals for themselves and their employees and advisors. Without this, decision making can be unfocused or capricious. Whether the goal is the highest milk production, maximum profitability, highest quality genetics, more time off, maximum use of the facility, or something else, defining replacement strategies for the production goals is critical.

TREATMENT

DIET

Appropriate for the maintenance of body condition and health

CLIENT EDUCATION

Teaching your clients the value of their replacement animals and the value of keeping cows healthy is critical for understanding costs involved in maintaining a profitable business.

MEDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

MISCELLANEOUS

PREGNANCY

Typically, nonpregnant cows are culled.

RUMINANT SPECIES AFFECTED

All ruminant species are affected.

BIOSECURITY

Lack of disease control can greatly affect culling risk.

CUTANEOUS MYIASIS OF SHEEP AND GOATS

BASICS

OVERVIEW

- Myiasis is parasitism of living animals by the larvae of dipteran flies.
- Blowfly strike is facultative cutaneous myiasis caused by members of the family Calliphoridae (blowflies).
- Sheep worldwide are affected by blowfly strike, but the causative species of blowfly vary by region.
- Goats are rarely affected by blowfly strike.
- Blowfly strike is seasonal, with peak occurrence during warm, humid periods.
- Primary flies can initiate fly-strike on intact skin. First instar larvae must have a protein meal on the skin surface; second and third instar larvae penetrate intact skin.
- Secondary flies extend already struck areas, and initiate strike in wounds.
- Three distinct forms of fly-strike occur: breech strike, body strike, and wound strike.

SYSTEMS AFFECTED

Skin and musculoskeletal

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

- Blowfly strike is the most economically significant animal health issue in the main sheep raising areas of the Southern Hemisphere.
- Screwworm infestation is a form of wound myiasis. *Chrysomya bezziana* “Old World screw-worm” is distributed throughout Sub-Saharan Africa, and across South and East Asia to Melanesia. *Cochliomyia homnivorax* “New World screw-worm” is distributed from southern Mexico to the southern subtropical Americas, having been eradicated from the southern USA and most of Mexico.
- Both screwworm species are obligate parasites.

SIGNALMENT

Species

Sheep of all ages can be affected, but weaned lambs are particularly susceptible to blowfly strike.

Breed Predilections

N/A

Mean Age and Range

Sheep of all ages can be affected, but weaned lambs are particularly susceptible to blowfly strike.

Predominant Sex

N/A

CAUSES AND RISK FACTORS

Blowfly Strike

Primary Flies Green bottles *Lucilia sericata* (worldwide), *Lucilia cuprina* (Southern Africa and Australasia), *Lucilia illustris* (North America); black blowflies *Phormia regina* and *Phormia terrae-novae* (Northern Hemisphere); and the brown blowfly *Calliphora stygia* (New Zealand).

Secondary Flies

- Many *Chrysomya* species, particularly *Chrysomya rufifacies*, and *Sarcophaga* species where they occur

- The primary risk factor for fly-strike is the size and activity level of the blowfly population, which depends on high ambient temperature, high humidity, and availability of susceptible sheep and carrion.
- Susceptibility to primary strike depends on bacterial dermatitis of water-macerated skin providing serous exudate for the first instar larvae to have a protein meal, and shaded areas for oviposition.
- Breech strike is facilitated by soiling of the wool and perineal skin by urine and wet feces.
- Body strike is facilitated by constant fleece wetness, and especially by fleece-rot or dermatophilosis.
- The fetid odor of struck sheep attracts secondary flies.
- Fetid exudate from foot rot smeared on the body when the sheep lie down attracts flies.
- Open wounds oozing serous exudate are attractive to flies as a source of moisture and protein. Rams with head lacerations from fighting are prone to poll strike.
- Balanoposthitis predisposes to prepuce strike.

DIAGNOSIS

- Breech strike is the most common, but body strike has more severe consequences because detection is delayed.
- Initially, struck sheep twitch the tail, stamp their feet, attempt to bite at the affected part, and are generally distracted.
- The wool about the struck area is wet, discolored grey, and malodorous.
- Many maggots infest the affected area, and there may be covert strikes elsewhere populated by a few maggots.
- As the strike progresses, affected animals separate from the mob, reduce feed intake, and tend to lie down for extended periods.
- The body temperature rises to around 41°C. Pulse and respiratory rates increase in concert with the development of toxemia.

DIFFERENTIAL DIAGNOSIS

N/A

CBC/BIOCHEMISTRY/URINALYSIS

PATHOLOGIC FINDINGS

N/A

TREATMENT

MEDICATIONS

DRUGS OF CHOICE

- Apply liquid larvicidal insecticide to the struck area, and thoroughly saturate a wide margin of surrounding wool.
- Wet but do not remove the wool covering the wound. The wool takes up insecticide and dries out once the maggots are dead. Thus, the treated wool provides a protective covering against further strike, and against sunburn.

CONTRAINDICATIONS / POSSIBLE INTERACTIONS

Insure that meat and milk withdrawal periods are monitored for treatment programs.

FOLLOW-UP

PATIENT MONITORING

Frequent careful monitoring of sheep at pasture is critical during the fly challenge period to identify and treat struck animals before they succumb.

PREVENTION/AVOIDANCE

- Dock tails to the correct length to avoid fecal soiling of the perineal wool. When the animal defecates, the stump of tail should lift the wool clear, but should not be so long that it becomes soiled. The tail should reach beyond the tip of the vulva, and this length is achieved by docking at the third joint, which is located at the distal extremity of the ventral caudal folds.
- Dock early in the season before the fly challenge period.
- Control gastrointestinal parasitism to prevent diarrhea.
- Clip the wool around the breech short, or if necessary shear the sheep.
- Topically apply chemoprophylactic insecticide or insect growth regulator. At docking, apply to the wool around tail docking / castration wounds / rings, and the wool around the breach.
- Older animals can be treated either by jetting targeted at the tail and breech, or by saturation dipping.
- Pesticide categories marketed for fly-strike prevention include organophosphates, pyrethroids, macrocyclic lactones (topical and intraruminal), benzoyl ureas, triazine, and pyrimidine carbonitrile.
- Great care must be taken to match: the pesticide formulation, the application method, the wool type and length, the anticipated period of protection, withholding period, operator safety, and cost.
- Control fleece-rot and dermatophilosis by saturation dipping with zinc sulphate added at 0.5% w/v.
- In Australia, the Mules operation is performed to remove skin folds from the perineum of Merino and Merino-derived breeds of sheep.

POSSIBLE COMPLICATIONS

- Failure to prevent flystrike
- Reasons are any one or a combination of factors including: an inappropriate formulation of pesticide was used, insufficient volume of chemoprophylactic was applied, constant rain leached pesticide from the wool resulting in an abbreviated period of protection, the fly population was resistant to the pesticide (diazinon), climatic conditions favored an intense fly challenge of susceptible sheep, or fecal soiling of the breech was not prevented.

EXPECTED COURSE AND PROGNOSIS

- With treatment: full recovery
- Without treatment: some animals may self-cure mild blowfly strikes especially early in the season; severe infestations are invariably fatal.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Young animals with gastrointestinal parasite burdens are more prone to diarrhea, and therefore fecal soiling of the breech.

CYANIDE TOXICOSIS

BASICS

OVERVIEW

- Cyanide poisoning is characterized by the abrupt onset of severe neurologic signs.
- Cyanogenic glycosides are commonly known as amygdalin, prunasin, dhurrin, linamarin, and triglocinin.
- Many *Prunus* spp. are cyanogenic, but only a few present a serious risk to livestock: choke cherry (*P. virginiana*), black cherry (*P. serotina*), and cherry laurel (*P. laurocerasus*).
- Other cyanide-containing plants associated with livestock toxicosis are Sudan grass and Johnson grass (*Sorghum* spp.), arrow grass (*Triglochin* spp.), vetch (*Vicia* spp.), corn (*Zea mays*), clover (*Trifolium* spp.), California holly (*Heteromeles arbutifolia*), June berry (*Amelanchier* spp.) and eucalyptus (*Eucalyptus* spp.).
- Hydrogen cyanide is readily absorbed from the gastrointestinal tract and acts by inhibiting cytochrome oxidase.
- Ruminants are more susceptible to the toxic effects than monogastric animals because rumen microorganisms produce enzymes that facilitate rapid hydrolysis of cyanogenic glycosides.
- All parts of the plants have cyanogenic potential. The highest concentrations of cyanogenic glycosides are found in the leaves, but concentrations are subject to many influences and may vary considerably.

SIGNALMENT

- All ruminant species are very susceptible. Most reported cases involve goats and cattle.
- Losses in sheep and deer have also been reported.

SIGNS

- Abrupt onset of apprehension and distress occurs within 10 to 15 minutes of ingestion.
- This is quickly followed by weakness, ataxia, hyperventilation, and hypotension. In severe cases, the animals become recumbent and develop cardiac arrhythmias and tetanic-type seizures.
- Death may occur within 15 to 60 minutes of exposure.
- Mucous membranes are initially bright cherry red due to the well-oxygenated venous blood.
- Cyanosis may be observed at a later stage of poisoning.

CAUSES AND RISK FACTORS

- Young and rapidly growing plants have the highest concentration of cyanide.
- Plant trimmings remain toxic as long as the leaves are green and have not completely dried.
- Insect-, frost-, and drought-damaged cyanogenic plants have been associated with a greater risk for cyanide poisoning.
- Concentrations of greater than 200 μ g/g of cyanide in plant material are considered potentially toxic.
- Cyanide in mill tailing ponds at gold mines can present a risk to wild ruminants.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nitrate/nitrite toxicosis—chocolate-colored blood
- Nonprotein nitrogen toxicosis—exposure to NPN supplements, toxic levels of ammonia in rumen content and blood
- Organophosphorus or carbamate insecticide exposure—gastrointestinal irritation and neurological signs, evaluation of cholinesterase activity, detection of pesticides
- Lead poisoning—determination of blood lead concentration
- Neurotoxic plants (poison hemlock, water hemlock, tree tobacco, lupine)—analysis for plant toxins in gastrointestinal

contents, history of exposure

- Cardiotoxic plants (oleander, milkweeds, and azaleas)—analysis for plant toxins in gastrointestinal contents, history of exposure
- Neurotoxic blue-green algae—identification of algae material in rumen contents
- ABPE—onset of clinical signs usually 1–4 days after an abrupt change to lush pasture, pathological evaluation of lung

CBC/BIOCHEMISTRY/URINALYSIS

No specific changes occur.

OTHER LABORATORY TESTS

- Detection of cyanide in blood, rumen content, liver, and skeletal muscle
- Samples must be collected promptly and stored frozen in airtight containers until analysis.
- Concentrations in tissues from lethal exposures may be reduced to one-third of the initial values within 1 hour of death.
- If liver is not collected within 4 hours of death, skeletal muscle is the preferred sample for analysis.
- Because of the volatility of hydrogen cyanide in biological samples, “toxic” thresholds are not established.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- There are no clearly distinctive changes.
- Cherry red blood immediately after death, but the color of blood darkens as postmortem time increases
- Hemorrhages may occur in the subendocardium, subepicardium, and abomasums.
- There may be mild congestion and edema of the lungs.

TREATMENT

- Immediate removal of the cyanogenic plant material
- Avoid stress
- General supportive care in nonsevere cases
- Administration of antidotes as soon as possible in severe cases

MEDICATIONS

DRUGS OF CHOICE

- The primary antidote for ruminants is thiosulfate. Thiosulfate (20%–40% solution) administered IV at a dose of 25–50 mg/100 kg bodyweight
- Sodium nitrite can be given concurrently, but may not be of additional benefit in ruminants. If given, the recommended dose is 10–20 mg/kg bodyweight IV.
- Cobalt compounds, such as cobalt chloride or hydroxycobalamin, have been used successfully in the treatment of cyanide poisoning in Europe, but have not been approved for use in animals in the United States.

CONTRAINDICATIONS

- Do not administer methylene blue, as it is ineffective as a producer of methemoglobinemia.
- If there is suspicion that cyanide poisoning is combined with nitrate poisoning, administration of sodium nitrite is contraindicated.
- Meat and milk withdrawal periods for drugs given must be determined.

FOLLOW-UP

PATIENT MONITORING

Clinical signs

PREVENTION/AVOIDANCE

- Delaying grazing until cyanogenic forage has matured.
- Slow and thorough drying of forage reduces the cyanide concentration.
- Avoid exposure of animals to frost- or insect- damaged cyanogenic plants. After a killing frost, wait for at least 4 to 6 days before grazing.
- Do not allow hungry cattle to graze cyanogenic plants.
- Feeding material as silage will reduce the risk of poisoning, as correct ensilage for 3 weeks reduces levels of toxin by approximately 50%.
- Suspect forage should be analyzed for cyanide concentrations.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Animals poisoned with cyanide are often found dead.
- Cyanide poisoning progresses so rapidly that treatment is often too late. In most cases, the affected animals have a poor-to-grave prognosis.
- If treatment is initiated promptly, the prognosis is fair.
- Animals that live beyond 1 hour following intake are likely to survive.

MISCELLANEOUS

DAIRY BUCK MANAGEMENT

BASICS

OVERVIEW

- Buck management is the most overlooked program in goat production worldwide.
- Body-condition scoring of breeding bucks on a regular basis is important to the reproductive health of the herd.
- The performance of herd bucks is dependent upon their health, nutrition, and proper management.
- Buck-management programs should start with breed-specific genetic selection considerations for the important traits necessary for each herd.
- Bucks should be housed separately from does and brought together for breeding only.
- Buck success is measured by overall reproductive efficiency and the performance of the offspring.
- A buck must be prepared for the breeding season with good nutrition, vaccination, and parasite control as well as foot trimming/care.
- Breeding soundness examination should be carried out annually prior to the breeding season.
- A 1 to 2 year old buck should make 25–50 services in a year. More services are common for older bucks.
- Body condition, structural correctness of feet and legs, and general soundness are also important factors for new breeding buck prospects.

SYSTEMS AFFECTED

Production management, nutrition, musculoskeletal, immune, gastrointestinal, reproductive, skin

GENETICS

- Intersex condition is linked to the polled gene in many breeds of goats and the use of phenotypically polled bucks should be discouraged.
- Selection and progeny test programs should be developed for the buck herd. Important traits include: multiple birth numbers, milk production, carcass quality, environmental adaptability, and feet and leg scores.
- Testicular diameter is directly correlated with fertility.
- Meat breeds generally require growth rate, carcass quality, and feed conversion traits to be superior.

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

- Worldwide; over 90% of the world's goats are in developing countries.
- Goats are important in developing countries as subsistence food producers.

SIGNALMENT

- Specific meat and dairy goat breeds
- Angora and pygmy goats have been reported to be sensitive to copper supplementation.

Mean Age and Range

N/A

Predominant Sex

Male

MEDICATIONS

DRUGS OF CHOICE

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

MISCELLANEOUS

MANAGEMENT EVALUATION

- Producers should be concerned with the body condition of their breeding bucks especially during breeding season. Goats should not be allowed to become too thin or too fat. Body condition score directly affects libido.
- The buck pasture should be far enough from the breeding doe herd that scent emitted by glands located behind the base of the buck's horns will not induce estrus in does. This allows the "buck effect" to occur. Does will come into estrus approximately 7–10 days after the introduction of the buck (buck effect).
- Trimming the hooves of breeding animals is extremely important to buck health and reproductive performance. Bucks with poor hoof health may breed only sporadically or even not at all.

BUCK MANAGEMENT PROGRAMS

- Buck management programs begin with the purchase of new herd sire(s).
- The genetic direction of the herd is of obvious importance in trait/sire selection.
- In addition to inherent genetic traits, bucks must be healthy, fertile, and capable of expressing their desirable traits.
- Bucks tend to lose weight during the progression of the breeding season. Breeding soundness exams should be performed monthly and energy deficiencies rectified. Bucks should enter the breeding season with a body condition score (BCS) of 3.0. It should be remembered that high levels of concentrates fed to bucks may stimulate urolithiasis and ruminal acidosis.
- Foot care is essential in breeding bucks. Though it is often overlooked due to buck hygiene, it is imperative that the feet and legs be cared for on a scheduled regular basis.
- Bucks should be purchased from seed-stock breeders that have documented herd health programs that minimize the likelihood of infectious diseases.
- Herd bucks should be immunized against common diseases and, if necessary, treated for parasites or tested for diseases indicated from a biosecurity standpoint.
- All bucks should undergo a complete breeding soundness evaluation (BSE) to assess their general physical and reproductive soundness. Important components include: physical examination, libido check, examination of genitalia, and a semen evaluation.
- Each component of the BSE such as scrotal circumference (SC) should be accurately measured and utilized within the context of age, weight, nutritional status, and contemporary group. It should be noted that semen quality and testicle size fluctuates seasonally.

Behavior

- Goats are natural climbers and jumpers. Bucks are intelligent animals and are quick to learn and like attention.
- Bucks commonly spray urine on their forequarters during the breeding season as an attractant. Clipping beards and coat hair prior to the breeding season can reduce the overall offensiveness of smell for the handler.
- Bucks can also acquire annoying habits and owners should be careful how goats are handled, especially kids (e.g., pushing on a kid's head will encourage it to butt). Treat all bucks with the respect necessary to maintain social order.
- Bucks are oftentimes housed in groups and a social order develops. Introduction of new bucks into this hierarchy can be dangerous. This is especially true with younger, smaller, or more timid animals.

Reproduction

- Goats are seasonally polyestrous (seasonal anestrus) breeders. Gestation length is 5 months.
- The breeding season typically runs from August through January (in the Northern Hemisphere), with an 18–23-day estrous cycle.

- The typical buck to doe ratio is 1 buck to 20–30 does. A 1:50 ratio is not uncommon in mature bucks.
- A buck should not be expected to breed more than 50 does in a 6-week period.
- Does usually remain in heat for 1 to 2 days. Puberty occurs at 6–8 months of age with breeding at 7–10 months of age or when doelings reach 60%–75% of mature body weight.
- Conception is highest from the middle to the latter part of the heat period. Therefore, if estrus is detected in the afternoon, goats should be bred late the following morning.
- Individual buck breeding variation:
 1. Age
 2. Body condition
 3. Fertility
 4. Libido
 5. Social behavior
 6. Injury
- Phomonal communication plays an important role in goat behavior. Bucks have a strong odor during the breeding season. Pheromones are air-borne chemical substances released in the urine or secreted from cutaneous glands that are perceived by the olfactory system and elicit both behavioral and endocrine responses in females.
- The buck has a strong characteristic seasonal odor and a buck jar containing the odor of the buck can be used as an aid in the detection of estrus in does.
- In goats, exposure of seasonally anestrous females to sexually active males results in activation of luteinizing hormone (LH) secretion and synchronized ovulation. This phenomenon is named “the buck effect” and constitutes the major control of reproductive events. The sudden introduction of bucks to a group of anestrous does will stimulate them to naturally synchronize (assuming the does have not heard or smelled a buck prior). The does generally cycle within 3 days.
- Keeping bucks apart from does for the first 2 days will stimulate buck semen production. Does bred to bucks that are “warmed-up” will have increased fertility rates and may breed successfully the first cycle.
- Conduct a breeding soundness evaluation on all bucks. Select bucks that are above average in scrotal circumference, motility, and percent normal sperm morphology.
- Breeding soundness evaluations should be done yearly, preferably just before breeding season begins.
- Develop a method to identify some progeny of each sire for sire trait evaluation.

Disease Control

- Obstructive urolithiasis is a major concern in breeding bucks. Nutritional management is important in its prevention (see Urolithiasis in Small Ruminants.).
- Urine scald can be common secondary to the males’ tendency to chronically urinate on themselves during the breeding season. Secondary bacterial dermatitis is a common sequela on the caudal aspect of the forelimbs.
- Horn scour trauma is common in group-housed males. These animals can bleed extensively and owners should become concerned with wound myiasis in warmer climates.
- Parasites can be a substantial problem in some breeding schemes. Fecal examination should be performed twice yearly.
- In certain parts of the world, venereal disease can be an important impediment to fertility (e.g., brucellosis, Q-fever, *Chlamydia* sp.).
- Lameness and foot disease can be sequelae to poorly managed and trimmed feet.
- Arthritis can be common in older bucks.
- Breeding bucks should be found negative for CAE and Johne’s disease.

Facilities

- Escape-proof fences are important due to the goat’s climbing capabilities.
- Goats should be provided with dry, clean bedding in a draft-free enclosure (15 sq ft/goat). Buck barns/sheds should be well ventilated.
- A well-drained outside pen large enough for the bucks to get ample exercise should be provided.
- Placement of large objects such as tree stumps, rocks, and wooden spools in the pen provides goats with climbing exercise and social diversion.
- Buck fences should be at least 42 inches in height and predator proof. When using woven (net) wire fence, use a 12 inch by 6 inch wide opening to prevent goats from getting their heads caught in the fence.

- Place feeders at least 6 inches off the ground.
- To help reduce disease transmission, raise hay and mineral feeders off the ground.
- Feed troughs should be designed so that goats cannot stand in them (they may defecate or urinate on the feed).
- Fresh water is essential. Check water availability on a daily basis and regularly drain and clean water troughs.
- Keep water cool during warm weather and, if possible, locate water source in the shade.
- Goats may drink large amounts of water during hot weather. It is very important to encourage water intake to help prevent formation of urinary calculi.

Dehorning

- It is preferable to dehorn (disbud) kids when they are a few days old. Dehorning animals becomes more stressful as horn size increases.
- Dehorning mature bucks is a SUBSTANTIAL venture requiring general and local anesthesia and the removal of the cornual tissue into the sinuses. The healing process takes 6–8 weeks and myiasis is a common sequela in warmer months.
- Horned bucks can be extremely dangerous and require constant observation. Always exercise caution around breeding bucks.

Hoof Trimming

- Rough terrain generally will wear down a goat's hooves in pastured animals.
- Goats kept in pens or on smooth terrain require regular hoof trimming/care approximately every 6 weeks.

ASSOCIATED CONDITIONS

- Obstructive urolithiasis
- Urine scald
- Horn scour trauma
- Wound myiasis
- Parasites can be a substantial problem
- Lameness, infertility, nutritional deficiencies, behavioral issues

AGE-RELATED FACTORS

Bucks are often housed in groups and a social order is developed. Introduction of new bucks into this hierarchy can be dangerous. This is especially true with younger, smaller, or more timid animals.

ZOONOTIC POTENTIAL

Several goat diseases are zoonotic. Care must be taken in the collection of laboratory samples and the diagnosis/treatment of affected animals.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Dairy and meat goats

BIOSECURITY

- Isolation and quarantine of new stock entering the herd
- Treat and/or cull new animals for disease conditions prior to herd introduction.
- Herd bucks should be immunized against common diseases and, if necessary, treated for parasites or tested for diseases indicated from a biosecurity standpoint.

PRODUCTION MANAGEMENT

Production systems:

- Monitor body condition of bucks and supplement feed if necessary.
- Evaluate bucklings and cull unsound or inferior animals.
- Monitor internal parasites through regular fecal samples.
- Treat for internal and external parasites as indicated.
- Replacement bucks should have good conformation, structural correctness, muscling, and increased weight for their age.
- Buck breeding ratio of 1 buck per 20–30 does is dependent on management and on pasture size/conditions.
- After the breeding season, remove bucks and feed to regain body condition.

DAIRY BULL MANAGEMENT

BASICS

OVERVIEW

- Efficient reproductive performance is a critical element in the profitability and ultimately the survival of any dairy operation.
- The performance of any natural-service breeding program depends on the fertility of the bulls and cows and the influences of the management system that we create for them to work in.
- These management systems range from a health-conducive environment with clean, dry pasture to free-stall housing with slippery concrete floors and poor sight lines.
- Ideally, bulls used for natural service would be physically sound, highly fertile transmitters of desirable genetic traits and would not create a safety hazard for people or other cattle of the dairy.
- In the real world, natural-service sires usually fall far short of this ideal.
- The breeding soundness examination (BSE) of bulls as recommended by the Society for Theriogenology is a valuable tool for preventing breeding problems or solving them once they have occurred.
- A BSE should be conducted on every sexually mature dairy bull before purchase, every 6 months during his service life, and whenever a problem with his performance is suspected.

SYSTEMS AFFECTED

Reproductive

GENETICS

N/A

INCIDENCE/PREVALENCE

More than half of dairy producers use natural-service sires either as their primary breeding method or for “clean-up” after a variable number of AI services or days postcalving have elapsed.

GEOGRAPHICAL DISTRIBUTION

Worldwide distribution

SIGNALMENT

Species

Dairy cattle

Breed Predilections

All breeds

TREATMENT

BULL MANAGEMENT PROGRAMS

Sire Selection

- Dairy farmers will often select bull calves from “superior” cows to serve as natural-service sires.
- This approach is almost certain to fail as a means of improving either milk production or other inherited aspects of cow performance or conformation.
- The reality is that the AI industry has access to highly selected bull calves from the elite cows in the national dairy herd and even these bulls routinely fail to transmit genetic superiority to their offspring.
- Calving ease is also a desirable trait in bulls used for natural service, especially those used to breed heifers.

- No reliable calving ease information is available for dairy bulls used in natural service.
- Small bulls may be the result of poor nutrition and may have associated problems with fertility while offering no real advantage in calving ease for the cows or heifers that do become pregnant when bred by them.
- Only healthy, fertile bulls from dairy herds with a high health status should be considered as natural-service sires.

Sire Evaluation

- The breeding soundness examination (BSE) consists of a thorough physical examination of the bull with a special focus on the systems that most dramatically influence reproduction.
- Bulls rely on many cues to detect estrus in cows but visual identification of the sexually active group is probably the most critical so the eyes should be carefully examined.
- The physical ability to mate is primarily a function of the musculoskeletal system.
- Sound feet and legs are essential with special attention paid to conformational problems in the hooves and hind legs.
- Physical examination of the genital tract should follow the guidelines as set forth by the Society for Theriogenology.
- Scrotal circumference, sperm motility, and sperm morphology are critical elements of the BSE and a bull must meet minimal standards for all three criteria to be considered a satisfactory potential breeder.
- In addition, the bull must be free of physical defects that would interfere with his ability to breed cows. More than half the bulls rejected by a BSE are rejected because of problems detected during the physical examination before semen is collected and evaluated.
- Libido, or desire to breed, is also important but is difficult to predict or evaluate as part of the BSE.
- Dairy clients should be advised to monitor bulls carefully during use to ascertain that they are aggressively seeking out cows in estrus and mating with them.

Bull to Female Ratio (BFR)

- Serving capacity, or the ability to provide a fertile mating for every cow eligible to be bred, is an important consideration when evaluating a natural breeding system.
- Serving capacity is a function of the bull's libido, physical mating ability, and fertility and all three of these factors play a role in determining the number of bulls required to breed a group of cows or heifers.
- Breeding efficiency is a function of the bull's age or breeding experience, his fertility, and the fertility of the cows he is bred to, as well as the breeding environment.
- Selecting the correct BFR is often a matter of trial and error.
- A 1:20 BFR is a reasonable starting point and can be adjusted up or down based on herd reproductive performance.
- A BFR of 1:10 or 1:15 may be more realistic for yearling bulls.
- More bulls will be required if estrus synchronization programs that result in concentrated breeding activity are used on the farm.
- Adding more bulls during warm weather may help with fertility problems caused by heat stress but supplementing the bulls with AI is probably more efficient.
- Rotating groups of bulls through strings of open cows or heifers on a 7–14-day schedule will minimize the impact of a group of subfertile bulls.

Monitoring Performance

- Palpation per rectum or ultrasonographic diagnosis of pregnancy in cows and heifers exposed to the bull is the most timely and effective method for monitoring reproductive performance.
- Typical 21-day pregnancy rates for bull-bred dairy cows range from 12% to 17%.
- Special attention to performance is required during hot, humid weather.
- For most dairy producers who are using bulls, there is little economic justification for treating the infertile bull.
- The usual solution is to identify him, cull him, and replace him with another more fertile bull.

CLIENT EDUCATION

Clients should be made aware that the reproductive performance of natural-service bulls is usually poorer than AI and generates additional costs associated with loss of genetic progress, feed consumption, and the creation of health and safety hazards.

MISCELLANEOUS

AGE-RELATED FACTORS

- Older, sexually experienced bulls are more likely to harbor and transmit venereal diseases.
- Older bulls are also larger and therefore more likely to injure cows or themselves during copulation.
- Older bulls are more aggressive and are more likely to cause aggression-related injuries to other bulls or people.

RUMINANT SPECIES AFFECTED

Dairy bulls

BIOSECURITY

- All males to be used as breeding animals should be subject to the same parasite control and vaccination procedures as the cows and heifers in the herd except that bulls should not be vaccinated for brucellosis.
- All bulls entering a herd should undergo a breeding soundness examination and an appropriate period of quarantine followed by reexamination.
- Specific testing for venereal diseases (campylobacteriosis and trichomoniasis) should be conducted as necessary.

DAIRY GOAT DERMATOLOGY

BASICS

OVERVIEW

- Many of the same skin diseases found in cows and sheep also affect dairy goats.
- The most important skin diseases of dairy goats are those that are contagious, zoonotic, and/or affect production.
- The most common skin diseases of dairy goats are dermatophytosis, tick and mange infestations, lice, keds, screwworm infestations, contagious ecthyma, caprine herpes virus, and staphylococcal infections.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS (BASED UPON BODY REGION)

Lips, Face, and Neck

- Contagious ecthyma
- Capripox
- Staphylococcal folliculitis
- Dermatophytosis
- Dermatophilosis
- Peste des petits ruminants (morbillivirus)
- Sarcoptic mange
- Zinc deficiency
- Selenium deficiency
- Pemphigus foliaceus

Ears

- Dermatophytosis
- Dermatophilosis
- Sarcoptic mange
- Ear mites
- Photodermatitis
- Frostbite
- Pemphigus foliaceus

Feet

- Contagious ecthyma
- Foot and mouth disease
- Staphylococcus folliculitis
- Interdigital fusiform infection
- Dermatophilosis
- Sarcoptic mange
- Chorioptic mange
- Pelodera dermatitis
- Besnoitia dermatitis
- Zinc deficiency
- Contact dermatitis
- Pemphigus foliaceus

Udder

- Contagious ecthyma
- Staphylococcal folliculitis
- Zinc deficiency
- Hyperpigmentation from exposure to sun
- Cutaneous papillomas in white Saanens

Perineum

- Contagious ecthyma
- Caprine herpes virus
- Staphylococcal dermatitis
- Ticks
- Neoplasia
- Ectopic mammary gland

DIFFERENTIAL DIAGNOSIS (BASED UPON DERMATOLOGIC PROBLEM)

Pruritus

- Lice
- Sheep keds
- Fleas
- Ticks
- Mites: Psoroptes (ear mange), Sarcoptes, Chorioptes
- Migrating helminthes (*Metastrongylus* and *Parelaphostrongylus tenuis*)
- Flies: *Musca* (bush fly), *Stomoxys calcitrans* (stable fly), *Culicoides* (no-see-ums), *Tabanus* (March flies)

Pustular/Papular/Vesicular Lesions

- Impetigo caused by *Staphylococcus*
- Contagious ecthyma
- Pemphigus foliaceus
- Capripox
- Foot and mouth disease

- *Pelodera*
- Caprine herpesvirus

Crusting and Scaling

- Dermatophytosis
- Dermatophilosis
- Malassezia dermatitis
- Protozoal: *Toxoplasma* sp., *Besnoitia* sp.
- Hypothyroidism
- Contagious ecthyma
- Zinc deficiency
- Selenium deficiency and undetermined vitamin E uptake
- Pemphigus foliaceus
- Capripox
- Mites
- *Pelodera*

Hair Loss

- Hypothyroidism
- Dermatophytosis
- Contact dermatitis
- Mites
- *Pelodera*
- Selenium deficiency and undetermined vitamin E uptake

Nodules With or Without Ulcers

- Demodicosis
- Staphylococcal dermatitis
- Mycetoma (fungal tumors)
- Abscesses (caseous lymphadenitis)
- Cutaneous papillomas
- Squamous cell carcinoma
- Melanoma
- Tuberculosis

Erythema

Sunburn: erythema of skin

Sloughing of Affected Area

Frostbite

CBC/BIOCHEMISTRY/URINALYSIS

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Mite infestations and *Pelodera* can be diagnosed based upon positive skin scrapings and/or response to miticidal therapy (e.g., ivermectin).
- Bacterial skin infections can be diagnosed based upon skin cytology, impression smears of intact pustules, and/or bacterial culture and sensitivity testing.
- Dermatophytosis can be definitively diagnosed by dermatophyte culture or skin biopsy.
- Dermatophilosis can be diagnosed based upon biopsy, impression smears of skin beneath an avulsed crust, culture, or

cytological exam of avulsed crusts.

- Skin biopsy is the most cost effective diagnostic aid for skin diseases where the diagnosis cannot be made clinically or with the above diagnostic tests.

SELECTED SKIN DISEASES

Most diseases listed above are discussed in detail elsewhere in this book. Selected diseases are discussed below.

Interdigital Fusiform Infection

- Benign interdigital dermatitis due to *Fusiformis* infection
- Clinically presents as mildly malodorous condition
- Readily responds to single injection of penicillin/streptomycin or to topical application of antibacterials such as copper sulfate or sulfonamide powder

Ectopic Mammary Gland

- Affects individual animals
- Ectopic mammary glands are extra teats.
- These should be removed from kids before they develop.
- If not removed, they are problematic because they interfere with normal milking procedures and, although somewhat developed, are not productive.

Pelodera

- Parasitic disease caused by invasion of the skin by larvae of a free-living nematode, *Pelodera strongyloides*.
- Larvae live in decaying organic material and exposure occurs from contact with damp, filthy bedding.
- Larvae cannot invade healthy skin; moisture and microtrauma to the skin are predisposing factors.
- Lesions are confined to areas in contact with bedding.
- Affected skin has any combination of erythema, alopecia, pustules/papules, crusts, erosions, or ulceration.
- Pruritus is common.
- Larvae are easily found on skin scrapings and are large $600 \times 38 \mu\text{m}$.
- *Pelodera* is a disease of poor management.
- Treatment: clean environment, move animals to clean dry bedding, disease is self-limiting but ivermectin may speed resolution.

Parelaphostrongylus Tenuis

- Pruritic parasitic infection
- Clinically presents as vertically oriented pruritic excoriations over body wall or shoulders
- It is proposed that migrating larvae irritate dorsal nerve roots causing pruritus in the dermatome.
- Treatment includes corticosteroids and anthelmintics.

Selenium Deficiency

- Selenium deficiency and undetermined vitamin E intake in young goats causes periocular hair loss and generalized scaling and brittle hair coat.
- Affected animals respond in 2–4 weeks to vitamin E/selenium injections.
- Continued supplementation is needed if diet is not corrected.

Mycetoma

- Caused by fungi or actinomycetes bacteria
- Classic clinical presentation is a painless, slowly developing mass with draining tracts and “tissue grains.”
- Skin biopsy and special stains will demonstrate organisms; nodular to diffuse pyogranulomatous inflammation is classic.
- Surgical excision is the treatment of choice, if possible.
- Affected animals acquire lesion via traumatic inoculation of skin.

Pemphigus Foliaceus

- Affects individual animals
- Can occur at any age but most common in goats less than 3 years of age
- PF is a rare immune-mediated skin disease caused by the production of autoantibodies against the intercellular bridges and cell-cell detachment (acantholysis).

- Clinically characterized by pustules, scales, crusting, and patchy alopecia.
- Presumptive diagnosis can be made via clinical signs and acantholytic cells and neutrophils on cytological examination of pustule contents.
- Definitive diagnosis is made by skin biopsy revealing intraepidermal and subcorneal vesiculopustules, neutrophils, and acantholytic cells.
- Affected animals require lifelong immunosuppressive therapy with oral prednisone (2–3 mg/kg divided q 12 hrs), aurothioglucose (1 mg/kg IM q 48 hrs) until clinical remission and then weekly or biweekly as needed.
- Immunosuppressive therapy will predispose affected animals to mastitis, secondary infections, and mite infestations.

Caprine Herpesvirus

- Cutaneous viral skin disease caused by a herpesvirus.
- Clinical signs include vesicles, ulcers, and crusts on the muzzle, feet, oral mucosa.
- Similar lesions can be found in the esophagus, rumen, and intestines.
- Can be the cause of abortions in pregnant does, high fevers accompany these infections
- Diagnosis is based upon history, clinical signs, and virus isolation.
- Skin biopsy reveals acidophilic intranuclear inclusion bodies in epithelial cells; these findings are typical of all herpesvirus infections.
- There is no treatment; disease must run its course.

Cutaneous Aspects of Peste Des Petits Ruminants

- This disease is caused by a morbillivirus and is an important disease of sheep and goats especially in Africa.
- It is also known as pseudorinderpest, pest of small ruminants, goat plague, pest of sheep and goats, Kata, stomatitis-pneumoenteritis syndrome, contagious pustular stomatitis, and pneumoenteritis.
- Cutaneous symptoms include dry hair coat, dry muzzle, edema, and brown crusts on lips; lesions may ulcerate and become crusted.
- Systemic symptoms of respiratory disease rapidly develop.
- This disease is discussed in detail in the Peste Des Petits Ruminants chapter.

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

The most common skin diseases of dairy goats are dermatophytosis, tick and mange infestations, lice, keds, screwworm infestations, contagious ecthyma, caprine herpesvirus, and staphylococcal infections.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

Several of these pathogenic conditions are caused by zoonotic agents. Care should be exercised in the collection and evaluation of samples.

PREGNANCY

Steroids should not be used in pregnant animals.

RUMINANT SPECIES AFFECTED

Caprine

BIOSECURITY

Quarantine new animal arrivals to prevent ectoparasitic infestation in a herd.

PRODUCTION MANAGEMENT

Ectopic mammary glands, if not removed, are problematic because they interfere with normal milking procedures and,

although somewhat developed, are not productive.

SYNONYMS

- Orf
- Sore mouth

DEATH CAMAS (ZYGADENUS)

BASICS

OVERVIEW

- *Zygadenus* spp., or death camas, has a steroidal veratrum-type alkaloid, zygacine or zygadenine, which causes arteriolar dilatation and hypotension. It is similar to the toxin in *Veratrum californicum* and *Schoenocaulon* spp.
- Alkaloids occur as glycosides, aglycones or in the form of esters with various acids.
- The entire death camas plant is toxic but the seeds are the most toxic followed by the bulb. The leaves and stems lose toxicity as the plant matures.
- The mechanism of action of the toxin is that it increases cell permeability to sodium ions. There is increased reflex activity and repetitive discharge in response to stimuli of the afferent nerve pathways.

GEOGRAPHIC DISTRIBUTION

Death camas grows in the western United States in wet meadows and along streams.

SIGNALMENT

- Sheep are the most susceptible ruminant species, then cattle.
- *Zygadenus* is most toxic in spring when other forage is not available.

SIGNS

- High fatality in sheep
- Signs include profuse, frothy salivation, GI upset, hypotension, and death.
- There can be muscle weakness, depression, ataxia, recumbency, and coma.
- Hypotension is experienced due to arteriolar dilation, venous constriction, and bradycardia from A-V dissociation.
- Death occurs from central respiratory depression.

CAUSES AND RISK FACTORS

The major risk factor is grazing on pastures containing *Zygadenus* in the spring.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Toxicity from *Asclepias* spp. (milkweed) and other cardiac glycoside-containing plants such as *Apocynum* (dogbane), *Adonis* (summer pheasant eye), *Digitalis* (foxglove), *Taxus* (yew), and *Rhododendron* (azalea). *Gossypium* (cotton seed meal) can cause similar signs. Also consider pulmonary toxicants such as *Medicago* (alfalfa), *Perilla* (purple mint), Brassicaceae, and *Fusarium*.

CBC/BIOCHEMISTRY/URINALYSIS

NA

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Presence of *Zygadenus* seeds or plant materials in the forage or rumen upon necropsy is most diagnostic.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- There are no distinctive lesions.
- There may be gross severe pulmonary congestion and subcutaneous hemorrhage.

HISTOPATHOLOGICAL FINDINGS

Minimal lesions consisting of GI tract and liver congestion

TREATMENT

Atropine sulfate (2 mg) can be administered to sheep.

MEDICATIONS

N/A

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING

Monitor and treat symptomatically.

PREVENTION/AVOIDANCE

Control *Zygadenus* in pastures through spraying as burning does not eliminate the plant; it regrows from the roots.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

High fatality in sheep

MISCELLANEOUS

DERMATOLOGIC MICROBIOLOGY

BASICS

OVERVIEW

- Diseases of the skin may be categorized as primary in which the lesions are primarily on the skin and may then spread to organ systems. Disease of the skin may be secondary in which the organ systems are initially infected and then cutaneous lesions will appear on the skin.
- In order to distinguish if the skin disease is primary or secondary, a complete clinical examination is necessary. Careful examination and knowledge of the patient's history can lead to accurate diagnosis.
- Normal microbial flora of the skin includes but is not limited to:
 - Some *Staphylococcus* spp.
 - *Dermatophilus congolensis* (can be pathogenic)
- Some of the most common skin diseases include but are not limited to:
 - Dermatitis (*Staphylococcus aureus*, *Strongyloides* spp., protozoan *Besnoitia* spp.)
 - Fibropapillomas (warts) (Bovine papilloma virus—BPV)
 - Impetigo (*Staphylococcus* spp.)
 - Ringworm (*Trichophyton verrucosum*)
 - Bluetongue (*Orbivirus*)

SIGNALMENT

N/A

SIGNS

- Dermatitis: increased warmth and erythema, diffuse weeping or discrete vesicular lesions, and may lead to more serious symptoms that include: edema, necrosis, gangrene, cellulites, lesions, shock, and toxemia
- Fibropapillomas: pedunculated or sessile epidermis outgrowths; in cattle, the warts can be > 1 cm in size and are found on the head, near the eyes, and on the shoulders and neck; warts are dry and crusty, and are white to gray in color; may lead to urinary bladder tumors
- Impetigo: A zone of erythema surrounds 3–6 mm lesions, small vesicles; pustules develop due to the eruption of vesicles and form scabs; acne and more extensive lesions develop in areas of hair.
- Ringworm: exudation, alopecia, and crusted lesions
- Bluetongue: fever, mucosal lesions, swelling of lips and gums, alopecia, diarrhea

CAUSES AND RISK FACTORS

- Dermatitis: in calves, bacteria can be excreted in the dam's milk.
- Fibropapillomas: direct contact with infected animals, virus enters through minor abrasions, use of contaminated instruments.
- Impetigo: bacteria enter through minor abrasions; spread to other animals can easily occur.
- Ringworm: use of contaminated instruments, contaminated environment
- Bluetongue: vector-borne disease transmitted by *Culicoides*

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dermatitis: culture on swab or skin scraping

- Fibropapillomas: biopsy of a lesion, ELISA, histological examination
- Impetigo: culture of vesicular fluid
- Ringworm: culture of hair from the lesion, scrapings of lesions, skin biopsies
- Bluetongue: serological examination

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Dermatitis: if possible, decrease bacteria levels in the immediate environment and add protein supplement for efficient skin repair.
- Fibropapillomas: surgical removal of warts may be indicated in valuable stock.
- Impetigo: daily bath 2x/day with germicidal skin wash
- Ringworm: brush off infective crusts; use topical antifungal and disinfective agents to improve dermatophyte contact.

MEDICATIONS

DRUGS OF CHOICE

- Dermatitis: antihistamines may be useful if there are allergies present or if there is tissue destruction; topical antibiotics or antifungals, autogenous vaccine
- Fibropapillomas: intradermal injected vaccine made from warts from infected animal 1–2 weeks apart; commercial wart vaccines are available.
- Impetigo: erythromycin or dicloxacillin may be helpful; suggest culture and sensitivity to determine effective treatment options
- Ringworm: griseofulvin (7.5 to 60.0 mg/kg orally for 7 or more days) or topical treatment:—2–5% lime sulfur, 1% iodophor, 0.5% sodium hypochlorite, 3% orthocide
- Bluetongue—no treatment
- It is important in choosing treatment options that appropriate drug withdrawal periods be determined and maintained for treated animals.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

- Local anesthetic ointments to prevent further pruritus may be helpful.
- Use absorptive dressing when large areas are affected.
- Addition of protein to marginal diets may augment skin repair.
- Use sterile or disinfected instruments when working herd or flock.
- Make sure living quarters are clean, disinfected; sunlight is helpful with dermatophytes.

DERMATOPHILOSIS

BASICS

DEFINITION

Common pustular/crusting disease of ruminants caused by *Dermatophilus congolensis*

PATHOPHYSIOLOGY

- Caused by aerobic, gram-positive filamentous bacteria *Dermatophilus congolensis*
- Moisture and damage to the skin cause organism to be attracted to stratum corneum where it germinates and bacterial filaments proliferate and invade the epidermis.
- Damage to the skin via shearing, insect bites, or ticks may predispose animal to microtrauma.
- Neutrophilic infiltrate creates serous/crusting exudation resulting in matting of wool or hair.
- Rewetting of the skin results in release of packets of zoospores that escape to the surface of the skin and start the cycle over again of invasion of tissue, exudating, and further matting.
- Incubation can be as short as two weeks.

SYSTEMS AFFECTED

Skin

GENETICS

- Breed variability with respect to susceptibility
- Zebu cattle are considered more resistant than *Bos taurus*.
- West African N'dama, and Muturu breeds are highly resistant.
- Fine wool breeds of sheep are more susceptible.

INCIDENCE/PREVALENCE

- Disease most common in regions with wet weather
- Morbidity can reach 100%.
- Subclinical infections can be present in endemic areas.
- Lambs less than 5 weeks of age are most susceptible.
- Mature animals and males are more commonly affected in Africa.
- Young animals are more commonly infected in South America.

GEOGRAPHIC DISTRIBUTION

- Worldwide distribution
- The disease is of particular importance in Africa, the Americas, the Middle East, and Mediterranean Europe.

SIGNALMENT

- All ruminants are susceptible.
- Can occur in any age, but more often in young animals

SIGNS

- Clinical signs correspond to the predisposing factors: moisture and microtrauma of the skin.
- Hallmark clinical sign is crusting and matting of hair/wool.
- Cattle: paintbrush-like lesions, crusts, or scabs, and/or marked accumulations of “wart-like lesions” on the head, dorsum, upper lateral surface of neck and chest. Lesions are found on legs of cattle that stand in water, mud, or lush pasture; lesions may be localized to udder in dairy cow and to the scrotum in bulls.
- Sheep: early lesions start as serous exudate at base of wool that results in matting of fleece, lumpy masses of wool may result (i.e., “lumpy wool disease”), lameness and proliferative inflammation on feet (strawberry foot rot), crusts in areas where fleece has been shorn, chronic lesions can persist as crusts on face, nose, ears.

- Lambs can rapidly develop generalized infection on back and dorsum, severe serous exudate can make movement difficult; lambs can die from severe secondary bacterial infections or fly-strike.
- Goats: ears first affected with wartlike scabs on inner pinnae; nose, muzzle, feet, scrotum, and tail may be affected; areas most commonly affected are those exposed to trauma.
- Buffaloes and bulls can develop erosive and/or granulomatous lesions on palate, lips, and tongue.
- Subcutaneous and lymph node abscesses can be seen in cattle, sheep, goats.
- “Strawberry foot rot” is an infection of distal extremities in sheep in which large crust formation around carpus, tarsus, and coronary bands is seen. Clinical cases in flocks are most severe in young stock (less than 1 year old). Lesions heal by granulation, which is observed with forced removal of crusts (hence, the strawberry appearance).

CAUSES AND RISK FACTORS

- Most important predisposing factors are chronic wetting (rain, snow) and maceration of the skin and microtrauma to the skin as organism is thought not to be able to invade healthy skin.
- Outbreaks most common after periods of heavy rain and/or high humidity
- Long hair may predispose animals to infection.
- Ectoparasites are important causes of microtrauma.
- Mechanical transmission of the organism can occur via flies and ectoparasites, in animal to animal contact, and during dipping practices.
- Pastures can be contaminated.
- Dried scabs from infected animals are important potential sources of infection for susceptible animals and for reinfection.
- Sheep may carry the infection subclinically and serve as carriers of the disease.
- Infective stage is a motile zoospore that can remain viable in crusts at temperatures of 28 to 31°C for up to 42 months.
- Zoospores in crusts can remain viable when dried and after being heated to temperatures of 100°C.

DIAGNOSIS

Most commonly diagnosed based upon seasonality, history of chronic wetting, and clinical signs

DIFFERENTIAL DIAGNOSIS

- Dermatophytosis, staphylococcal infections, zinc responsive skin disease, pemphigus foliaceus
- Fleece rot, crusted mange lesions
- Muzzle lesions can resemble *peste des petits ruminants* in sheep or contagious ecthyma in goats.
- Malignant catarrh or mucosal lesions in cattle

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTING

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Cutaneous impression smears of underside of moist scabs—Giemsa, Gram stain, or Diff Quik will demonstrate coccoid and branching filamentous organisms (use oil immersion magnification).
- Cytologic examination of the deep layer of the crusts (adjacent to the granulation tissue) reveals coccoid bacteria branching into the formation similar to “railroad tracks.”
- Mince preparations of crusts: mince crusts in sterile water on glass microscope slide; allow to dry; stain and examine oil immersion; may be helpful when only older crusts are available.
- Skin biopsy: folliculitis, intraepidermal pustular dermatitis, intracellular edema, surface crusting characterized by alternating layers of ortho and/or parakeratotic hyperkeratosis and neutrophilic exudate; organism seen within keratinous debris.
- Bacterial culture: organism can be grown on blood agar in increased carbon dioxide atmosphere; organism can be grown

from crusts or skin biopsy.

- Indirect fluorescent antibody and ELISA tests are available for herd investigations.

PATHOLOGICAL FINDINGS

Skin biopsy: folliculitis, intraepidermal pustular dermatitis, intracellular edema, surface crusting characterized by alternating layers of ortho and/or parakeratotic hyperkeratosis and neutrophilic exudate; organism seen within keratinous debris.

TREATMENT

- Separate clinically affected animals from normal animals.
- Provide shelter from rain.
- Improve nutrition (protein, energy, mineral) and ectoparasite control.
- Remove infected crusts from skin.
- Protect animals from fly-strike.
- Infections often resolve spontaneously over several weeks if affected animals can be kept dry. Remove tufts of crusted hair or clip matted hair to reduce number of organisms present.
- Tick control is very important in preventing the disease.

MEDICATIONS

- Procaine penicillin G (20,000 to 70,000 units/kg body weight) every 12 to 24 hours
- Oxytetracycline 20 mg/kg SQ or IM q 72 hrs
- Copper sulfate (0.2%), zinc sulfate (0.2% to 0.5%), or potassium aluminum sulfate (1%) can be used as topical dips or sprays.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

- Disease usually self-cures in 2–4 weeks when animals are removed from wet, moist conditions.
- Key preventative measures: provide shelter from excessive moisture and minimize ectoparasite infestations.
- Other preventive measures: isolate infective animals, cull chronically infected animals, and disinfect environments.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Lameness in sheep
- Mastitis in dairy cows, sheep, and goats

AGE-RELATED FACTORS

Disease more prevalent in young and debilitated animals

ZOONOTIC POTENTIAL

- Possible zoonotic disease, handle infected animals with care.
- Wear gloves when handling infected animals or hair/wool or crusts.
- Dispose of all infected materials (hair, wool, crusts) properly and disinfect all items in contact with affected areas (grooming materials, clippers, etc.).

- Wear gloves and wash hands with disinfectant soaps.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Cattle, sheep, goats, llamas, buffalo, camels

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Can cause decreased milk production in dairy cows and goats
- Severe infections may result in decreased fertility.
- Severely infected animals may die from cachexia.
- Can impair heat resistance in camels
- Hides and skin from infected animals are often unsuitable for leather.
- Fleece with scabs is often downgraded.
- May predispose animals to fly-strike

DERMATOPHYTOSIS

BASICS

DEFINITION

- Superficial infection of the cornified regions of hair, nails, and stratum corneum.
- The most commonly involved organisms are *Trichophyton* spp. and *Microsporum* spp.

PATHOPHYSIOLOGY

- The naturally infective state is an arthrospore.
- Exposure to infective spores occurs from direct contact with an infected animal and/or exposure to a contaminated environment. Contaminated environments are overlooked sources of exposure.
- Rodents may be reservoirs of infection for *Trichophyton* spp.
- Exposure does not guarantee infection as the organism must evade natural host defenses; infective spores may be brushed off or fall off; organism may trigger inflammation, which will eliminate the infection.
- Moisture and microtrauma to the skin allow for the organism to gain entry and germinate; organism invades actively growing hairs (keratin) making them fragile.
- Incubation takes 1–3 weeks.
- Recovery from infection occurs when the host develops a cell-mediated immune response.
- Animals will generally self cure.
- Duration of immunity is unknown.

SYSTEMS AFFECTED

Skin

GENETICS

No evidence of a genetic predisposition to infection has been shown in large animals, but there is evidence of this in small animals.

INCIDENCE/PREVALENCE

- In the United States, this is not a reportable disease; prevalence is unknown.
- Dermatophytosis is one of the most common infectious/contagious skin diseases of large animals.

GEOGRAPHIC DISTRIBUTION

- Worldwide distribution
- More common in warm subtropical/tropical geographic regions

SIGNALMENT

- Can occur in any age, sex, or breed
- Most common in young, old, or debilitated animals

SIGNS

- Clinical signs are highly variable in presentation and may be affected by palliative treatments administered by the owner.
- Classic lesions include any combination of the following:
 - Variable pruritus: none to severe
 - Variably sized annular rings of hair loss
 - Erythema
 - Scaling, crusting, to mounded thick adherent crusts
- Cattle: lesions are well demarcated, tightly adherent, grayish crusts that may develop into severe areas of alopecia, crusting, exudation, and ulceration. Lesions in calves are most common around the eyes and on the head and neck. In cows and heifers, lesions are most common on the udder. Bulls commonly have lesions on the dewlap and intermaxillary spaces.

- Goats: lesions are common on the face, ears, neck, udder, and limbs. Lesions are circular to diffuse areas of alopecia with scaling, crusting, and erythema.
- Sheep: lesions are most common on face, neck, thorax, and back and appear as circular areas of alopecia and thick, gray crusts.
- Lesions around coronary band may lead to lameness.
- Kerion reactions are inflammatory reactions, particularly to *M. gypseum*, that can look like an abscess.

CAUSES

- *Trichophyton* spp.: *T. verrucosum*, *T. mentagrophytes*, *T. equinum*
- *Microsporum* spp.: *M. canis*, *M. gypseum*

RISK FACTORS

- Age extremes, preexisting illness and debilitation, immunocompromised hosts
- Poor nutrition
- Overcrowding and lack of exposure to sunlight
- Exposure to excessive moisture and warmth leading to maceration and damage of skin.
- Adult animals become infected/reinfected when new animals are introduced to herd.
- Parasitic infestations may predispose animals to infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dermatophilosis
- Staphylococcal infection
- Demodicosis
- Zinc responsive skin diseases
- Pemphigus foliaceus

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Wood lamp examination is not useful in large animals as *M. canis* is the only pathogen that regularly fluoresces and this is an uncommon cause of dermatophytosis.
- KOH examination of hair and scale may reveal ectothrix spores. This is not cost effective and many artifacts can occur; invasion of hair shafts is most easily seen with *M. canis*.
- Dermatophyte culture—suspect lesions should be wiped with alcohol and allowed to dry. Remove crusts or pluck infected hairs/scale. Gently embed in fungal culture media. Microscopic examination of fungal culture colony is mandatory.
 - Sab-Duets fungal culture plates are recommended.
 - Easy to inoculate
 - Dual plate has plain Sabouraud's dextrose agar and Dermatophyte Test Medium.
 - Color change (red) on DTM does NOT indicate that there is a pathogen present, only that the rapidly growing colony is suspect.
 - Potential pathogens: pale to cream colonies that develop red color change as they grow; *Microsporum* spp. colonies usually grow within 7 to 10 days but *Trichophyton* spp. may take up to 21 days.
 - Pathogens are never grossly or microscopically pigmented.
 - Use lactophenol cotton blue stain and clear cellophane tape to identify colonies.

- Skin biopsy is the most cost-effective diagnostic tool. Do not scrub or prep the lesion prior to biopsy. Be sure to include the crust.
- In many cases, dermatophytosis, especially in cattle, is diagnosed based upon history and clinical signs; it may not be cost-effective to make a definitive diagnosis in all cases.

PATHOLOGIC FINDINGS

- Folliculitis, furunculosis, hyperkeratosis, intraepidermal pustules, nodular to diffuse pyogranulomatous infiltrates
- Definitive diagnosis requires finding fungal hyphae in nodular reactions, in hair shafts, or in hair follicles. Fungal elements may be seen with H&E stain, but special stains may allow for easier identification.
- Skin biopsy is recommended in any animal in which lesions are atypical and/or where the animal does not respond to appropriate therapy.

TREATMENT

- Infected animals should be isolated from other animals.
- Crusts and scales should be removed from lesions and burned.
- Ideally, infected hairs should be clipped from the lesions.
- Nutrition and housing should be improved; allow animals to go outside, decrease crowding.
- Infective spores will contaminate the environment; debris should be removed from the environment and burned.
- Areas that can be scrubbed should be cleaned with soap and water and copiously rinsed. Bleach 1:10 is the most cost-effective disinfectant; enilconazole is an alternative but is expensive and appropriate drug withdrawal periods may not be determined. Consult FARAD.
 - Enilconazole spray (Clinafarm EG)
 - Enilconazole smoke bombs (Clinafarm SG)
- Gross cleaning and disinfection needs to be done repeatedly as infective spores are hard to kill and eradicate.

MEDICATIONS

- Topical treatments are the most cost-effective in large animals.
- First remove crusts and scales, and then wash the animal in an inexpensive shampoo. Towel dry.
- Twice weekly, topical application of an antifungal solution
- The entire animal must be treated either as vat dip or via a sprayer that thoroughly soaks the hair coat/wool. The solution is not rinsed off. Recommended treatments include
 - Lime sulfur, 8 oz/gal twice weekly
 - Enilconazole 0.2% (Imaverol emulsion) twice weekly (not licensed in United States)
 - Enilconazole (Clinafarm EC in United States ONLY) 55.6 ml/gal twice weekly; off label use
- Ineffective products that should not be used: thiabendazole, betadine, captan, chlorhexidine. Treat infected animals until cured; clinical cure will occur before mycological cure is obtained. Minimum treatment period is 4–6 weeks or 8–12 topical applications.

ALTERNATIVE DRUGS

Systemic Antifungal Drugs

- Efficacy of systemic antifungal drugs is unknown, but based upon what is known, in small animals they are likely to be effective.
- Griseofulvin 50 mg/kg orally once daily until cure
- Itraconazole 5–10 mg/kg orally once daily until cured, or use as pulse therapy (week on-week off)
- Systemic therapy is cost prohibitive in most animals.
- Prior to use of antifungal agents, appropriate withdrawal periods for meat and milk should be determined.

FOLLOW-UP

PREVENTION/AVOIDANCE

Antifungal Vaccines

- Antifungal vaccines are not available in the United States.
- Live antifungal vaccines in eastern Europe and Scandinavia have been shown to decrease clinical symptoms.
- Use of vaccines is controversial and there is no evidence that they are protective against challenge exposure.

POSSIBLE COMPLICATIONS (CONTRAINDICATIONS)

- Lime sulfur will discolor white hair coats.
- Systemic antifungals (especially griseofulvin) are teratogenic and should not be used in pregnant animals.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

EXPECTED COURSE AND PROGNOSIS

- All animals need to be treated to prevent reinfection and/or spread of the disease.
- Infected animals will generally self-cure within 70 to 100 days.
- New animals should be isolated before being added to the herd. Prophylactic dipping with lime sulfur may be useful in preventing introduction of organism in “clean” herd.
- Provide good nutrition, good housing, and adequate exposure to dry, well-ventilated housing.

DIFFERENTIAL DIAGNOSIS OF LUMPS AND SWELLINGS

BASICS

OVERVIEW

- Lumps and swellings are common dermatological problems.
- These lesions can be a cause of great anxiety because they may be due to neoplasia.
- Causes include: infections, trauma, foreign bodies, allergic reactions, parasitic migration, granulomas, and tumors.

SYSTEMS AFFECTED

Production management, skin

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide depending on species and environment

SIGNALMENT

Species

All ruminant species

Breed Predispositions

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Lumps and swellings can be described by any number of the following terms:
 - Papule—small red mass less than 1 cm in diameter
 - Nodule—firm mass up to > 1 cm in diameter caused by infiltration of inflammatory or neoplastic cells
 - Tumor—solid mass of tissue caused by infiltration or expansion of neoplastic cells
 - Abscess—firm to fluctuant cavity in the skin filled with exudate
 - Hematoma—a blood-filled cavity in the skin, usually caused by trauma
 - Seroma—a serum-filled cavity in the skin
 - Cyst—epithelial lined cavity in the skin filled with keratin, corneocytes, hair, sebum, or clear fluid
 - Urticaria or wheal—well-circumscribed raised area of skin caused by edema in the dermis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

[Table 1](#) summarizes the common causes of lumps and swellings by contents.

[Table 2](#) summarizes common causes of infectious, granulomatous, or neoplastic masses.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Cytology and biopsy are the two most useful diagnostic tests.
- Cytology
 - Fine-needle aspirate of the mass
 - Impression smear of cut surface of a biopsy or from surface of the mass
- Biopsy
 - Excisional diagnostic biopsies should be performed, if possible.
 - Deep-wedge biopsies with scalpel blade should be performed if excisional biopsy cannot be done.
 - Do not use punch biopsy instrument, as this will obtain a superficial sample.
 - Blot blood from surface of specimen before placing in 10% neutral buffered formalin.
 - Special stains for infectious agents should be requested.
- Culture and sensitivity should be performed if either cytology and/or biopsy samples reveal infectious agent.
 - Wedges of tissue in sterile saline are more useful for culture in the case of firm, hard masses or if a culture swab is negative for growth.
 - Sterile culture swabs can be used to obtain cultures, if pus is present culture.
 - Cultures cannot be performed on formalinized samples.

TREATMENT

- Specific treatment depends upon definitive diagnosis.
- Surgical treatment is the most cost-effective approach to the management of tumors in ruminants.

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

AGE-RELATED FACTORS

N/A

[Table 1](#)

Differential Diagnosis of Lumps and Swellings		
Contents of Lump/Swelling	Diagnosis	Comments
Edema	Urticaria/angioedema	Allergic reactions, milk allergy, drug allergy; trypanosomiasis
Serum	Seroma	Common cause, tissue reaction to foreign body
Pus	Infection	Subcutaneous infection with or without draining tracts; see Table 2

Blood	Hematoma, vascular tumor parafilariasis	Trauma most common cause of hematoma; seasonal hemorrhagic nodules
Anuclear proteinaceous debris	Cutaneous cyst	
Fat	Lipoma	
Hyperplastic tissue	Nevus, dermatofibroma, scar tissue	
Inflammatory cells		See Table 2
Neoplastic epithelial, spindle or round cells		See Table 2
Melanocytes	Melanoma	
Demodex mites	Demodicosis	Can occur in any animal, most common in goats

Table 2

Differential Diagnosis of Lumps and Swellings Containing Pus, Inflammatory Cells, and/or Neoplastic Cells			
PUS			
Disease	Common Name	Major Dermatological Sign	Species
<i>Corynebacterium pseudotuberculosis</i>	Caseous lymphadenitis	Abscesses of lymph nodes	Sheep and goats
Clostridial infections	Gas gangrene	Pitting edema with erythema	All ruminants
Fungal kerion <i>Trichophyton</i> spp. <i>Microsporum</i> spp.	Subcutaneous dermatophyte	Nonhealing wound	All
Mycetoma	"Fungal tumor"	Cold swelling with draining tracts and "tissue grains"	All
Actinomycosis	Lumpy jaw		All
Nocardiosis			
Actinobacillosis	"Big head," "wooden tongue"		
Phaeohyphomycosis			
Dermatiaceous fungi		Chronic, subcutaneous painless swelling	All
Abscesses			
INFLAMMATORY CELLS/GRANULOMA			
Disease	Common Name	Major Dermatological Sign	Species
Follicular cyst		Single or multiple, firm or hard, containing hair, sebum, cells; frequently rupture	All
Wattle cyst		Round, smooth fluctuant masses, at neck	Goat
Panniculitis	Fat necrosis	Firm to fluctuant mass, may drain yellow-brown fluid	
Eosinophilic granuloma <i>Theileria parva</i>	East coast fever	Hard pruritic mass	Cattle
Hypoderma	Cattle grub	Firm, pruritic nodules	Cattle in Africa
		Firm mass with breathing pore	Cattle
NEOPLASIA			
Disease	Common Name	Major Dermatological Sign	Species
Papillomatosis	Warts	Hyperkeratotic pedunculated, cauliflowerlike lesions	Cattle, sheep, goats
Squamous cell carcinoma		Ulcerative to proliferative masses	Cattle, sheep, goats
Hemangioma		Purple plaques progressing to verrucous masses that bleed	Cattle
Mast cell tumor		Multiple firm to fluctuant masses; in young cattle 6–7 months of age	Cattle
Lymphosarcoma		Multiple lesions, anywhere but especially over trunk, young 1–4 years of age.	Cattle
Melanoma		Single to multiple lesions pigmented	All species

ZOONOTIC POTENTIAL

Several of these diseases are zoonotic. Care must be taken in the collection of laboratory samples and the diagnosis/treatment of affected animals.

DIFFERENTIAL DIAGNOSIS OF PRURITUS

BASICS

OVERVIEW

- Pruritus is an unpleasant sensation that triggers the host to scratch.
- A specific end organ of itch has not been found.
- The sensation of itch is carried from nerve endings to the spinal cord via the ventrolateral spinothalamic tract via the thalamus to the cortex.
- Pruritus is not a disease, but rather a clinical sign.
- The most common causes of pruritus in ruminants include parasites, infections, and allergies.
- Mediators of pruritus include histamine and proteolytic enzymes (proteases).

SYSTEMS AFFECTED

Skin and adnexa

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide distribution

SIGNALMENT

Species

All ruminant species

Breed Predilections

Varies by specific disease entity

Mean Age and Range

Varies by specific disease entity

Predominant Sex

Varies by specific disease entity

SIGNALMENT

- Highly variable, depending upon the cause
- History is very important. Multiple animals affected suggests infectious or contagious agent. Single animal involved suggests allergy, neoplasia, or other cause.

SIGNS

- Symptoms of pruritus can include any combination of the following:
 - Scratching
 - Biting
 - Rubbing
 - Restlessness
 - Excoriations
 - Hair loss characterized by broken hairs
 - Inflammation of the skin, erythema, scaling, crusting
- Decreased production commonly accompanies pruritic skin diseases.

- Evidence of pruritus can be obtained via the history and physical examination.
- Owners may or may not be aware the animal is pruritic; part of the exam should include visual observation of the animal's behavior for a period of time.

CAUSES AND RISK FACTORS

- The most common causes include ectoparasites, superficial skin infections, and allergies.
- Crowding and poor management will enhance the spread of parasites and contagious skin infections.
- Poor management may also predispose animals to irritant reactions and secondary infections, which are often pruritic.
- Contact allergies from fly sprays, wipes, powders, or shampoos can also cause pruritus.
- Ectoparasites and superficial skin infections usually involve more than one animal.
- Allergic causes do not involve multiple animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- See [Tables 1, 2, 3, and 4](#) for differential diagnoses.
- Also see specific chapters for detailed information on clinical signs, diagnosis, and treatment.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Visual examination with handheld magnifying lens and flashlight aids in locating fleas, ticks, lice, etc.
- Skin scrapings for finding mites
- Superficial fungal cultures for identification of dermatophytosis
- Impression smears of exudate or open wounds may reveal eosinophilia, which suggests allergic or parasitic skin disease.
- Skin biopsy is useful when lesions are abnormal or a cause cannot be identified.
- Response to treatment is a common diagnostic test.

TREATMENT

- Specific treatment for pruritus depends upon the definitive diagnosis.
- Palliative topical treatment for pruritus may include cool water soaks, bathing in a mild cleansing shampoo (i.e., grooming shampoo), and topical oatmeal soaks.
- Topical lime sulfur is antibacterial, antifungal, antiparasitical, and antipruritic.

MEDICATIONS

DRUGS OF CHOICE

- Glucocorticoids block all the pathways that cause itch.
- Systemic glucocorticoids can be used for palliative relief; use short term.
 - Palliative systemic treatment is best done with glucocorticoids (i.e., prednisone 0.5 mg/kg PO q 24 hrs).
- Glucocorticoid-containing topical ointments are practical for focal application but not if the pruritus is widespread.
- Antihistamines are of limited use as a sole agent for relief of pruritus.

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

Table 1

Differential Diagnosis of Common Causes of Pruritus in Ruminants: Parasites			
Disease	Etiology	Clinical Signs	Diagnosis
Lice*	<i>Hamatopinus (sucking)</i> <i>Linognathus (sucking)</i> <i>Solenopotes (sucking)</i> <i>Damalina (biting)</i>	Location of lice depends upon species, sucking lice produce anemia; irritability, poor hair coat, selftrauma	Visual identification, response to treatment
Mange mites*	<i>Sarcoptes scabiei</i> (all) <i>Psoroptes</i> (C, S, G) <i>Chorioptes</i> (all) <i>Psorobia ovis</i> (S, C) <i>Demodex</i> (all) <i>Trombiculiasis</i> (all)	All mange mites cause moderate to severe pruritus, scaling, papular eruptions. Chorioptes starts on legs and becomes generalized.	History and clinical signs, skin scrapings, and/or response to treatment
Fleas	Many species, not host specific, can affect all ruminants	Varying pruritus, rubbing, chewing, scratching, self-trauma, broken wool, crusts, anemia in heavy infestations	Visual exam
Rhabditic dermatitis	<i>Pelodera strongyloides</i> (all)	Papular, pustular, ulcerative, alopecic pruritic lesions on skin in contact with moist, filthy environment, most common in fall and winter	History, clinical signs, skin scrapings, and skin biopsy
Migrating helminths	<i>Metastrongylus</i> and <i>Parelaphostrongylus tenuis</i>	Focal linear, vertically oriented lesions, unilateral, pruritic, neurological symptoms common	History, clinical signs, skin biopsy, CFS analysis
Ticks	<i>Otobius</i> <i>Dermatocentor</i> <i>Amblyomma</i> <i>Boophilus</i> <i>Ixodes</i>	Most commonly problem in spring, extent of discomfort related to species and severity of infestation: crusts, erosions, alopecia, nodular reactions	Visual identification
Stephanofilariasis	<i>Stephanofilaria</i> (C, G)	Nonseasonal dermatitis, papules, crusts, ulcers, alopecia, variable pruritus on distribution of clinical signs depends upon geographic region	History, clinical signs, skin scrapings, and skin biopsy
Elaeophoriasis	<i>Elaeophora schneideri</i> (S)	Usually first noticed in winter, unilateral lesions on poll, forehead, face most commonly, hair loss, ulceration, crusting, and intense pruritus	History, clinical signs, and biopsy
Keds	<i>Melophagus ovinus</i> (S)	Severe pruritus, broken wool, excrement-stained wool, alopecia, excoriations	Visual examination
Flies*	Mosquitoes, <i>Culicoides</i> , <i>Simulans</i> , <i>Tabanus</i> , <i>Chrysops</i> , <i>Stomoxys</i> , <i>Hematobia</i> , <i>Musca</i> , <i>Hydrotaea</i>	Small biting insects cause pruritus and papular eruption; large biting flies cause painful pruritic nodules.	Clinical history and physical examination findings

Note: C-cattle, S-sheep, G-goats, L-llama.

*Most common.

Table 2

Differential Diagnosis of Common Causes of Pruritus in Ruminants: Infectious Diseases			
Disease	Etiology	Clinical Signs	Diagnosis
Dermatophytosis	<i>Trichophyton</i> spp. <i>Microsporum</i> spp.	Variable pruritus, focal to multifocal to severe alopecia and crusting	History, clinical signs, fungal culture, possibly skin biopsy
Dermatophilosis	<i>Dermatophilosis congolensis</i>	Paintbrushlike matting of hair coat in areas of chronic wetting; lesions most common on dorsum but may be found on any area where there is chronic moisture and maceration of tissue	History, clinical signs, cytological demonstration of organisms, skin biopsy
Staphylococcal infections	<i>Staphylococcus</i> spp.	Variable pruritus, intact pustules, papules, epidermal collarettes, scaling	History, clinical signs, cytological demonstration of cocci, culture and sensitivity
Pseudorabies	<i>Herpesvirus</i>	Intense, localized, unilateral pruritus, violent licking, biting, and chewing, severe excoriations	History, clinical signs, exposure to infected pigs, necropsy
Scrapie	Slow virus (S)	Most common in 2–5-year-old sheep, intermittent, bilaterally symmetrical severe pruritus that often begins on tail head and progresses cranially; chronic rubbing and biting lead to severe hair loss and excoriations, serpentine tongue movements.	History, clinical signs, necropsy

Note: Diseases can occur in all ruminants unless otherwise indicated.

Table 3

Differential Diagnosis of Common Causes of Pruritus in Ruminants: Allergic Diseases and Miscellaneous Causes

Disease	Etiology	Clinical Signs	Diagnosis
Urticaria and angioedema	Immune-mediated reaction, type 1	Acute or chronic, localized or generalized wheals and bumps that "pit" with dermal pressure, may ooze serum; Jerseys and Guernseys can become sensitized to their own casein (milk allergy).	History and clinical signs, biopsy usually not necessary
Allergic contact dermatitis	Immune-mediated type 4 reaction	Pruritic lesions in area where offending allergen contacts skin, disease of individual animals; moisture is a predisposing factor as it allows allergens to penetrate skin.	History, clinical signs, skin biopsy, provocative challenge with suspect compound
Atopic dermatitis	Immune-mediated type 1 and type 4 reactions to environmental allergens (rare in ruminants)	Recurrent, seasonal or nonseasonal pruritus on face, ears, ventrum, and legs	History, clinical signs, biopsy, and intradermal skin test
Erythema multiforme	Immune-mediated disease (C)	Maculopapular eruptions, urticarial plaques with central depression; annular to polycyclic shapes, unlike urticaria lesions, persist for days to weeks; scaling and crusting may occur.	History, clinical signs, and skin biopsy that shows hydropic interface degeneration

DIFFERENTIAL DIAGNOSIS OF SCALING AND CRUSTING

BASICS

OVERVIEW

- Scaling and crusting are common presenting dermatological problems.
- There are two major types of scaling and crusting diseases: primary and secondary.
- “Primary” diseases are caused by a genetic or heritable defect in the production of the stratum corneum and/or skin lipids. This is commonly referred to as “primary seborrhea.”
- Primary seborrhea (primary disorder of keratinization) is rare in ruminants.
- “Secondary” diseases are caused by any skin or metabolic disease and are more common in ruminants. Ectoparasites, infections, allergies, neoplasia, nutritional diseases, immune-mediated disorders, metabolic disorders, and other environmental factors may cause secondary skin disease.
- Secondary seborrhea is common.

GEOGRAPHIC DISTRIBUTION

Worldwide distribution

SIGNALMENT

Species

All ruminant species

Breed Predilections

Varies by specific disease entity

Mean Age and Range

Varies by specific disease entity

Predominant Sex

Varies by specific disease entity

SIGNS

Scaling and crusting diseases may present with any combination of the following signs:

- Scale—gross visible accumulation of corneocytes (dandruff)
- Oily seborrhea—excessively greasy skin
- Epidermal collarette—circular ring of scale with central area of alopecia and/or hyperpigmentation; erythema may be present.
- Exfoliation—shedding of large amounts of scale over the body
- Matting/exudate—pustular diseases can cause exudate that results in matting of the hair coat.
- Hyperkeratosis—thick, adherent keratin
- Comedome—accumulation in hair follicle; “blackhead”
- Follicular—adherent sheath of scales surrounding a hair shaft just above the hair follicle opening

- Lichenification—marked thickening of the skin over large areas with exaggerated skin ridges “elephantlike skin”
- Plaque—localized patch of thickened skin that is raised with a flat surface
- Callus—focal, alopecic, lichenified plaque over pressure point

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- See [Table 1](#).
- The most common dermatological problem of ruminants is pruritus; pursue pruritic causes of skin disease first.

CBC/CHEMISTRY/URINALYSIS

Laboratory tests are rarely helpful in identifying underlying cause except in cases where the cause is suspected to be metabolic (e.g., malnutrition, toxicity, etc.).

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Skin scrapings to look for mites, lice, and other ectoparasites
- Dermatophyte culture to rule in or out superficial fungal disease
- Bacterial culture and sensitivity in patients with primarily pustular diseases
- Skin biopsy—most useful diagnostic test; do not prep or scrub skin. Submit full thickness biopsy with crust adhered to surface. Submit multiple biopsy specimens.

PATHOLOGIC FINDINGS

Skin biopsy findings depend upon the underlying causes.

[Table 1](#)

Differential Diagnosis of the More Common Causes of Crusting and Scaling in Ruminants

Disease	Etiology	Signs	Diagnostic Tests	Treatment	Miscellaneous
Dermatophytosis	Superficial fungal infection caused by <i>Trichophyton</i> spp. and <i>Microsporum</i> .	Any combination of hair loss, crusting, scaling, with or without pruritus	Fungal culture Skin biopsy	Isolate infected animals Remove crusts Twice weekly topical sponge-or dips to entire body with lime sulfur or enilconazole See chapter "Dermatophytosis"	All species Zoonotic Highly contagious
Dermatophilosis	Bacterial infection of skin caused by <i>Dermatophilus congolensis</i>	Paintbrushlike matting of hair coat with moist erythematous skin beneath avulsed crust	Impression smear Mince prep of crust Skin biopsy	Isolate infected animals Move to dry area Gently remove crusts and scales via warm water soaks. Bathe in antibacterial shampoo (benzoyl peroxide, chlorhexidine) Systemic antibiotics for 3–10 days See chapter "Dermatophilosis"	All species
Staphylococcal infections	<i>S. aureus</i> is primary pathogen, others possible.	Impetigo (pustules) and/or epidermal collarettes	Cytology Culture and sensitivity Biopsy	Topical antibacterial therapy with benzoyl peroxide or chlorhexidine shampoo, iodine shampoos least effective	All species
Malassezia dermatitis	Superficial yeast infection caused by overgrowth of <i>Malassezia</i>	Oily seborrhea and/or dry seborrhea, pruritus common	Impression smear Biopsy	Topical therapy twice weekly with lime sulfur, chlorhexidine/ ketoconazole shampoo, miconazole shampoo, selenium disulfide shampoo	Goats and cows
Malnutrition/ malabsorption	Any disease that causes loss of protein or body condition	Signs of systemic debilitation, scaling, poor hair coat	Rule out other causes Clinical signs Evidence of underlying metabolic disease	Identify underlying disease and treat Wash hair coat to remove excessive scales and crusts	All species
Irritant reactions	Most common feces, urine, wound secretions, caustic agents, inappropriately applied insecticides	Crusting and scaling are late findings, early findings include erythema, pain, vesicles.	History, clinical signs, biopsy sometimes helpful	Identification and removal of the offending agent is key. Residual material is removed via copious amounts of water and mild cleansing soap. Topical antibiotic creams/ointments may be helpful.	All species, true irritants cause reactions in all in-contact animals
Mite infestations	Sarcoptes, Chorioptes, Psoroptes,	Pruritus and scaling	Skin scrapings, response to treatment	Ivermectin, doramectin, amitraz See chapter mite infestation	All species
Zinc responsive skin disease	Primary deficiency or related to poor nutrition	Mild to marked scaling that can be localized to face and pressure points or generalized	Skin biopsy AND response to treatment	Oral zinc supplementation See chapters on nutritional supplementation.	All species, but especially goats, sheep, llamas
Bovine exfoliative erythroderma	Suspect immune-mediated etiology	Early lesions start as erythema and vesicles on muzzle and progress to generalized erythema and crusting, easily epilated hair.	Biopsy	Affected animals recover without treatment	Rare disease in cattle Reported in cattle
Epitheliotropic lymphoma	Cutaneous lymphoma	Erythema, scaling, pruritus, nodules in late stages	Skin biopsy	Cull animal, no successful treatment	
Pemphigus foliaceus	Immune-mediated disease	Primary lesion is pustule; pustules coalesce to thick adherent scaling and crusting on head, neck, face, ears, and eventually whole body.	Skin biopsy	Treatment practical only in single animals or pet goats Systemic glucocorticoids or gold salts Lifelong therapy required; quality of life can be good. Treatment is expensive.	Goats
Chemical toxins	Arsenic Chlorinated naphthalene Polybrominated and polychlorinated biphenyl Iodism	Varying degrees of scaling and crusting	Identification can be difficult and may require multiple samplings of serum, hair, skin biopsy, feed samples, etc.	Treatment depends upon individual agent. See chapters on specific toxicities.	
Photosensitization	UV light induced inflammation of the skin Exposure may be primary or secondary.	Symptoms occur in light skin areas; scaling and crusting are late-stage findings after initial erythema and inflammation.	History, clinical signs	Remove animal from sunlight. Supportive care for lesions to prevent infection; treatment may include glucocorticoids. See chapter "Photosensitization."	

TREATMENT

- Treatment depends upon identification of the underlying cause.

- Removal of crusting and scaling may be necessary for recovery of animal.
- Collect all diagnostic specimens before initiating topical therapy.
- Topical hydrotherapy with warm water and a mild antimicrobial shampoo is recommended.
- Shampoos containing tar should be limited to cases where the scaling and crusting are primarily greasy.
- Sulfur- and salicylic-acid-containing shampoos will remove crusts and scales but require 10–15 minutes of contact time.
- Topical antibiotic ointment (e.g., triple antibiotic, Nolvasan cream/ointment) should be applied to areas where the removal of crusts results in denuded, eroded, or ulcerative skin.

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

FOLLOW-UP

Appropriate follow-up depends upon underlying skin disease.

DIFFERENTIAL DIAGNOSIS OF SKIN DISEASES OF THE UDDER

BASICS

OVERVIEW

- Skin diseases of the udder are common and causes include parasitic, infectious, and/or opportunistic agents; poor management and milking practices; milking machines; exposure to environmental factors; and trauma.
- Skin diseases can occur in any species, but are most common in lactating animals.
- Skin diseases of the udder can predispose animals to mastitis and result in decreased milk production.

[Table 1](#)

Skin Diseases That Affect the Udder				
Disease	Etiology/Predisposing Factors	Lesions	Diagnosis	Treatment/Miscellaneous
Impetigo	Staphylococcal infection (<i>S. aureus</i>) Predisposing factors include stress, poor housing, wet environment, trauma.	Pustules, circular brown-crusts lesions, may become ulcerative.	Culture Cytology	Topical washes with chlorhexidine or betadine; systemic therapy not usually needed Milk affected animals last. Mechanical transmission via milkers is common.
Conditions Associated with Swelling of Udder				
Udder edema	High milk production, low blood protein at calving, related to feed intake	Diffuse swelling of udder	Clinical signs	Frequent milkings, massage, diuretics, anti-inflammatory drugs
Necrotic dermatitis	Udder edema causes ischemia and necrosis of opposing skin sites.	Pain, fold pyoderma necrosis located between wall of udder and medial thigh	Occurs several weeks postcalving and udder edema episode, first-calf heifers most commonly affected	Reduce edema with diuretics, topical antibiotics, pain medications, and glucocorticoids.
Udder intertrigo	Fold pyoderma caused by moisture and chronic maceration of udder wall against another skin surface	Moist exudative, painful dermatitis	Clinical signs; cytological exam of exudate will help determine if bacteria and/or yeast are present. Impression smears	Treat topically using antibacterial/antifungal shampoo.
Udder cleft dermatitis	Most common in older cows; sarcoptic mites believed to be part of the etiology	Lesions most common on cranial edge of cleft between two cranial quarters; moist exudative; malodorous dermatitis	Clinical signs Skin scrapings	Topical antibiotics; improve milking procedures; hydrotherapy to remove exudate; treat herd for mites to minimize outbreaks.
Nodular Lesions				
Contusion or hematoma	Trauma: milking machines and/or poor milking practices	Painful swelling	Clinical signs Needle aspirate Biopsy	Cold compresses for acute lesions, followed by warm compresses and massage Gentle milking Do not incise hematoma unless infected
Disease	Etiology/Predisposing Factors	Lesions	Diagnosis	Treatment/Miscellaneous
Abscesses	Secondary to trauma, wounds, mastitis, infected hematoma, contusion	Painful mass with or without exudate	Clinical signs Needle aspirate	Incise and drain lesions, flush with antiseptic solution (e.g., dilute betadine or chlorhexidine)
Teat spiders	Occurs during dry period caused by accumulations of butterfat, minerals, and/or tissue	Small masses in skin of teat	Clinical signs	Forced manual expression via teat canal or removal by forceps of mass through teat canal
<i>Demodex</i> mites	<i>Demodex</i> mites	Small haired sub-cutaneous nodular lesions in skin	Examine exudate; all ruminants, especially goats	Lance nodule
Urticaria	Immunologic or allergic trigger	Multifocal soft swelling, "hives"	Clinical signs	Identify underlying trigger, antihistamines corticosteroids
Scar tissue	Common posttrauma	Hard irregular swellings	Biopsy	None needed unless scar tissue interferes with milkings
Macular, Vesicular/Bullous, and or Ulcerative Lesions				
Poxvirus	<i>Orthopoxvirus</i> cowpox, vaccine <i>Capripoxvirus</i> sheep pox, goat pox <i>Parapoxvirus</i> pseudocowpox, orf	Macular-papular-vesicular lesions that crust and leave a raised "pock" lesion	Clinical signs and biopsy Virus isolation	Supportive care to prevent secondary infections
Bovine herpesvirus	Herpesvirus 2	Usually on teats; vesicular to ulcerated lesions on teats; linear to ulcerative plaques, sloughing of skin	Clinical signs Biopsy Virus isolation Paired viral titers	Worldwide distributions. Predisposes animal to mastitis, causes marked production drop Mammillitis Isolate infected cows, supportive care to prevent secondary infections and mastitis
Bovine herpesvirus	Herpesvirus 4	1–10-mm vesicles and pustules on lateral and ventral udder	See above	See above
Bovine malignant catarrhal fever	Herpesvirus	Scaling crusting of udder; ulcerative lesions on coronary band, may have udder lesions	See above	No treatment; disease highly contagious; disease is usually fatal.
Foot-and-mouth disease	Picornavirus	Vesicles and bulla, lesions may occur on udder.	See above	No treatment; disease highly contagious; disease is usually fatal.
Vesicular exanthema	Picornavirus	Vesicles and bulla, lesions on udder may be seen.	See above	

DIGITAL (PAPILLOMATOUS) DERMATITIS

BASICS

OVERVIEW

- Digital (papillomatous) dermatitis [(P)DD, footwarts] is a relatively recently described condition seen almost exclusively in dairy cattle. It is an extremely painful condition resulting in severe lameness and reduced milk production.
- It is highly contagious and can rapidly spread through a dairy herd. Fortunately, the disease can be easily treated.
- Discussion of the condition is hampered by the great variety of names that are used to describe the condition including:
 - Hairy heel wart
 - Mortellaro's disease
 - Spirochetal dermatitis
 - Strawberry foot rot
- Affected cattle will often have lameness and will tend to walk on the toes of the feet with lesions. Lesions occur most commonly on the palmar surface of the rear feet near the interdigital ridge.
- Most commonly found in confined dairy cattle, although it has been reported in grazing dairy cattle and beef cattle.
- It is an animal welfare concern.

PATHOPHYSIOLOGY

- Transmission of (P)DD requires constant moisture (hydropic maceration) and low oxygen tension.
- Early lesions are erosive and clearly circumscribed. More chronic lesions can be proliferative and papillomatous.
- Most commonly, lesions are 2–6 cm in diameter, are circular to oval, and have clearly demarcated, raised borders.
- Lesion borders are often surrounded by true hairs that are 2–3 times the length of normal hairs.
- Lesion surfaces may have filiform papillae varying in length from 1 mm to longer than 2 cm (hence, the name “hairy footwarts”). Lesions without the filiform papillae can have a granular appearance.
- Washed lesions are varied in color from bright red to gray or brown and are generally very painful to the touch or spray from a water jet.
- Histopathologically, lesions are characterized by ulcerative and proliferative changes consisting of ulceration of the tips of dermal papillae, epidermal hyperplasia with parakeratosis and hyperkeratosis, colonization by profuse numbers of spirochetes (*Treponema* spp.), and inflammation.

SYSTEMS AFFECTED

Skin, production management and musculoskeletal

GENETICS

N/A

INCIDENCE/PREVALENCE

- Infection spreads rapidly in susceptible cows, once introduced into a naïve herd.
- (P)DD will often affect the majority of cows within the first year of infection. When established in a herd, lesions and lameness are more common in lactation 1 and 2 cows. Prevalence in endemic herds can vary from low (< 5%) to very high (>70%) depending on conditions and control programs on the dairy.

GEOGRAPHIC DISTRIBUTION

Worldwide distribution; mostly found in cows on confinement dairies but has been reported on pasture-based dairies and in beef cattle.

SIGNALMENT

- Although digital dermatitis is a disease that is predominately seen in dairy cattle, it has also been described in beef cattle and sheep.

- The disease commonly occurs in herd outbreaks.

Species

Dairy cattle, occasionally beef cattle, and rarely sheep

Breed Predilections

Most often reported in Holstein dairy cattle, less often in Jersey cattle, other dairy, and beef breeds

Mean Age and Range

- Anecdotal evidence suggests that older animals may develop immunity to the condition, consequently in herds, which are endemically affected with digital dermatitis the disease is most commonly seen in heifers when they are introduced to the milking group.
- Younger cows, lactation 1 and 2, are seen with lesions more often than older cows.

Predominant Sex

Cows are seen most often; bulls are susceptible but not seen as often, possibly due to their low numbers on most dairies.

SIGNS

HISTORICAL FINDINGS

- Lameness is a common herd sign with cows walking on their toes. Affected cows may have “club feet” (i.e., heels will grow longer than nonlame cows since cows are reticent to put weight on their heels).
- The main sign of digital dermatitis is extremely severe lameness in one or more limbs; affected animals are extremely reluctant to bear weight on an affected limb. Such animals are prone to recumbency and often also show a precipitous drop in milk production. The disease is highly contagious and outbreaks are common.
- Lesions have a characteristic “sour” smell and many producers with experience of the disease may detect the disease in the early stages by identifying the smell while milking the herd.
- Diagnosis of digital dermatitis should always be made on close examination of the foot.
- The classical lesion is found on the caudal aspect of the skin above the heel.
- Lesions are typically on the midline between the heel bulbs and below the accessory digits (dew claws) and are covered in a friable layer of grey fibrinlike material.
- The area should be carefully cleaned to remove any debris so that the lesion can be clearly seen.
- Cleaning should be attempted with great care, as the lesion is extremely painful. In some cases an intravenous and/or regional anesthetic may be necessary.
- Two distinct forms of the disease have been described:
 - Erosive form: a reddened raw area of granulation tissue with a “strawberry” appearance
 - Proliferative form: in some chronic cases there may be proliferation of the epithelial tissue to form hairy, frondlike projections.
- Although the majority of cases is seen affecting the heels, lesions may on occasion be found on the skin in the interdigital cleft and on the coronary band on the abaxial aspect of the foot.
- Regardless of the position of the lesion, the severe pain associated with what appears to be a mild lesion is almost diagnostic for digital dermatitis.

CAUSES AND RISK FACTORS

- The causative agent for digital dermatitis has been recently identified as the spirochete bacteria *Treponema brennaborensis* sp. nov.
- The disease is highly contagious between housed dairy cattle. It is typically brought into a herd through the purchase of an affected animal. However, the veterinarian or lay foot trimmers may also transmit it through contaminated hoof trimming equipment.
- Once the disease is in the herd it is thought to spread through unsanitary conditions in the barn.
- The disease is less common in cattle housed in stanchion barns as the animals do not move around and the disease cannot spread.
- The disease is most common in free stall barns particularly when there is freestanding water and fecal material in the passageways.
- On occasion, digital dermatitis may be diagnosed in beef cattle. This is a rare occurrence and is only seen when animals are kept in wet conditions.
- Muddy or wet conditions and purchasing animals from off premises are the two most common risk factors.

- Poor freestall and bedding management will exacerbate the problems since cows will spend more time standing in the manure slurry for longer periods of time, not allowing the feet to dry out periodically.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- There are few conditions that can be confused with digital dermatitis, as there is really nothing else that is as contagious or as painful.
- Laminitis, foot rot, interdigital dermatitis and heel horn erosion, interdigital fibroma, traumatic injury, and thin soles from excessive wear or improper hoof trimming
- The following may be confused with the condition:
 - Slurry heel
 - Interdigital fibroma
 - Traumatic injury to the distal limb
 - Foot rot—interdigital necrobacillosis

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Serology may be helpful but not necessary and is not readily available.
- Culture and sensitivity may be indicated if the lesions appear to be infectious.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- In most cases, the clinical signs of digital dermatitis are all that is required to make a diagnosis.
- If a definitive diagnosis is required, this is best achieved by taking a skin biopsy using a biopsy punch.
- Histopathology using an appropriate stain can demonstrate the presence of spirochete bacteria within the tissue.
- Culture of the proposed etiological agent *Treponema brennaborense* sp. nov is extremely difficult and not recommended.

PATHOLOGIC FINDINGS

Histopathology is helpful but not necessary for diagnosis. Histopathological findings include a combination of ulcerative and proliferative changes consisting of ulceration of tips of dermal papillae, epidermal hyperplasia with parakeratosis and hyperkeratosis, colonization and invasion by profuse numbers of spirochetes, and inflammation.

TREATMENT

One should approach the treatment of digital dermatitis from two different standpoints: (1) treatment of the individual animals that are clinically affected and showing signs of severe discomfort, and (2) treatment of the entire herd, which is probably subclinically affected.

Individual Animal Treatment

- The affected area should be thoroughly cleaned with a suitable disinfectant scrub solution and any underrun heel horn should be removed.
- The area should then be treated with topical oxytetracycline (either 3cc injectable oxytetracycline or a small volume of oxytetracycline water additive powder) and a light dressing applied to keep the antibiotic in contact with the lesion.

Herd Treatment.

There are essentially two ways to mass treat a group of animals with digital dermatitis:

- A solution of either 8 g/L oxytetracycline (made using water additive powder) or 1.5 g/L lincomycin/spectinomycin (Linco-spectin water additive powder) may be prepared and applied to the heel of all cattle using a “garden sprayer.” To be effective, the feet should first be cleaned using a high-pressure hose. Many producers like to treat the feet in

conjunction with milking.

- A footbath may be prepared using either 4–6 g/L oxytetracycline or 0.75–1g/L Linco-spectin and cattle forced to walk through the solution. In order to be effective, it is preferable that cattle have their feet cleaned with either a hose or a primary foot bath containing free-flowing water prior to the medicated footbath. Costs may be kept lower by using a minimum solution footbath (MSFB) with a sponge base that keeps the volume of solution required to a minimum.

CLIENT EDUCATION

Clients should be educated regarding diagnosis, risk factors, and treatment strategies.

MEDICATIONS

DRUGS OF CHOICE

- The most effective treatments are oxytetracycline HCl or lincomycin HCl, applied as a paste under a bandage, or as an aqueous spray applied to the lesions after washing the feet with clear water.
- If applied as an aqueous spray, lesions should be treated once per day for 7 to 14 days. Common dosages for bandage treatments are 10 g of oxytetracycline or lincomycin mixed with approximately 3 ml water to form a paste. Cows must be restrained on a hoof-trimming chute. Common concentrations for the aqueous sprays are 25 g/L for oxytetracycline or 8 g/L for lincomycin, mixed with deionized or distilled water.
- Recurrence is common, so control must be ongoing. Monitoring herd prevalence will help to determine how aggressive the control program needs to be.
- Footbaths are also used as treatment/prevention.
- Most common footbath products are copper or zinc sulfate or formalin (5%–10%).
- Footbaths must be maintained to keep the treatment solution clean and active.
- They should be drained, cleaned, and refilled every 100–300 cow passages depending on the dairy.
- Copper and zinc are problematic due to their heavy metal content and formalin is a carcinogen and respiratory irritant.
- Some commercial companies are developing automated footbaths and proprietary treatment solutions, which may overcome some of the present limitations.

Drugs

- Anecdotal reports indicate that in animals that are not lactating and may be hard to handle, systemic treatment with a long-acting oxytetracycline preparation may be indicated.
- In severe cases, clinicians may consider the use of systemic NSAIDs due to the level of discomfort shown by the animals.

CONTRAINDICATIONS

- The drugs used for treating digital dermatitis are not licensed for this use and great care must be taken to avoid contaminating the udder or the milking machine with the antibiotic aerosol and causing violative residues in the milk. Drug withdrawal times for meat and milk must be maintained.
- Great care must also be taken to ensure that cattle do not drink the footbath solutions as this will also result in residue violation and in the case of Linco-spectin possible toxicity.

PRECAUTIONS

When using aqueous antibiotic sprays in the parlor, care must be taken to avoid spraying the udder or milking machine. Antibiotic residues have not been reported from treatment.

ALTERNATIVE DRUGS

- Various proprietary products are available but have not been demonstrated to be as consistent or efficacious as antibiotics.
- Vaccination: A vaccine for the condition has been developed but its efficacy has been questioned.

FOLLOW-UP

PATIENT MONITORING

- The dressings should be removed within 24 hours of their application. Otherwise, bandage material becomes contaminated and the bandage then creates a good environment to incubate reinfection.
- Most animals will show rapid recovery. Animals that still have significant lameness after 72 hours should be reexamined for an additional cause of lameness.
- Cows should be monitored for recurrence and retreated as necessary.

PREVENTION/AVOIDANCE

- Vaccination: A vaccine for the condition has been developed but its efficacy has been questioned.
- Due to the high costs associated with the disease, prevention is the goal (see Biosecurity below).
- Once digital dermatitis has become endemic within a herd, good hygiene within the barn (regular scraping of passageways and maintaining clean dry stalls) will minimize the spread of the condition.
- It may also be necessary to use prophylactic footbath treatments every 4–6 weeks.

POSSIBLE COMPLICATIONS

Some (P)DD lesions will undermine the horn of the heel or wall, which will necessitate removing the horn overlying the active lesion and treating it with topical antibiotics.

EXPECTED COURSE AND PROGNOSIS

- Animals typically show increased discomfort immediately after treatment but lameness should resolve almost fully within 48 hours.
- Most animals do not require any further treatment and the disease has no long-lasting effects.
- In rare cases where the disease affects the coronary band, it appears that the coronary band may be disrupted and there may be a failure of normal horn production resulting in a full thickness vertical fissure that grows down from the coronary band causing great pain.
- This lesion should not be confused with the classical vertical fissure (sand crack) and treatment is rarely successful.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Lameness, decreased milk production, decreased life in the herd
- Erosive form: a reddened raw area of granulation tissue with a “strawberry” appearance.
- Proliferative form: in some chronic cases, there may be proliferation of the epithelial tissue to form hairy, frondlike projections.

AGE-RELATED FACTORS

More common in younger cows (lactation 1–2).

ZOONOTIC POTENTIAL

The (P)DD-associated spirochetes are similar to those that cause periodontal disease in humans but zoonotic potential is unknown.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Bovine; potentially all ruminant species can be affected.

BIOSECURITY

- All new animals to the dairy herd should be quarantined and have their feet prophylactically treated, especially if there is any suspicion that they come from a herd that is affected with digital dermatitis.
- Any individual involved in foot care should take great care to ensure that equipment is suitably disinfected between farm visits.
- (P)DD-free herds should not buy replacements from off premises.
- Herds with endemic (P)DD should isolate and treat new animals before introducing them to the herd.

PRODUCTION MANAGEMENT

- Recommendations that pertain to cow comfort, including well-designed and bedded freestalls or open housing
- Prompt and aggressive treatment of active lesions will help control (P)DD.

Authors: Chris Clark and Steven L. Berry

DISPLACED ABOMASUM

BASICS

OVERVIEW

- Displacement of the abomasum (DA) is very common in lactating dairy cattle, but has also been reported in sheep, goats, beef cattle, and calves.
- The abomasum is the fourth or “true” stomach in the cow and normally lies in a ventral position in the right cranial quadrant of the abdomen between the 7th and 11th ribs.
- Displacement may occur when the muscular stomach wall loses tone, fills with gas, and is displaced dorsally along the left side (~90% of the time) or to the right side (~10% of displacements).
- In right side displacements, a life-threatening volvulus or torsion may develop in some cases. Much has been written regarding the cause, effects, and treatment of both left and right side displacement.
- This chapter will assist veterinarians in the investigation of increased incidence or risk of displaced abomasums on dairies.

SYSTEMS AFFECTED

Production management, gastrointestinal

GENETICS

There appears to be a genetic component, with some cow lines showing an increased risk.

INCIDENCE/PREVALENCE

- In high-producing, well-managed herds, risk for abomasal displacement should be less than 3%, where risk is calculated as # of cases/# of calvings. In most dairy herds, over 85% of the cases of LDA occur within the first 6 weeks of calving.
- Prevalence varies depending upon herd and nutritional management practices, geographical location, and climate.

GEOGRAPHIC DISTRIBUTION

Worldwide in dairy cattle

SIGNALMENT

Species

Bovine

Breed Predilections

Dairy breeds

Mean Age and Range

N/A

Predominant Sex

Female

SIGNS

Most common clinical signs: abrupt decrease in feed intake and a concurrent drop in milk production or a failure of postparturient cows to increase in feed intake and milk production

PHYSICAL EXAMINATION FINDINGS

- High-pitched ping during simultaneous percussion and auscultation over the ipsilateral paracostal area
- Mild to moderate tachycardia
- Ketonuria
- Scant, pasty manure, but at times may see diarrhea, constipation, or even normal manure consistency depending on duration of the displacement and the presence of concurrent disease
- Dehydration may be present but is usually mild unless the displacement is to the right side. Cows experiencing a right

side displacement with a volvulus may demonstrate tachycardia, rapid dehydration, and metabolic alkalosis due to the tapping of hydrogen ions in the abomasums.

- +/- abdominal distension, especially in the paralumbar fossa corresponding to the side of displacement
- In some cases, a hollow viscus may be palpable during a routine rectal examination depending upon the size of the cow and the amount of gaseous distention.

CAUSES

- The precise cause of abomasal displacement is unknown, but most will agree that it is a multifactorial syndrome, with the highest risk period for abomasal displacement being the immediate postparturient period.
- Feed intake normally drops during last 2 weeks of the dry period and the lower intake carries over into early lactation.
- In addition, hypocalcemia, a known risk factor, is also common during this period of time, especially in multiparous cows.
- This period of altered feed intake leads to three major changes that occur in the GI tract:
 - Decrease in ruminal fill
 - Altered gastrointestinal motility and abomasal distention
 - Gas production within the abomasum
- A partially empty rumen creates a void in the abdominal cavity and if the abomasum fills with gas, it may float up and fill the empty space. Escape of either fermentation end products or the raw substrates (starch, sugars, silage acids) from the forestomachs may lead to an alteration in pH, additional bacterial fermentation, altered motility, and gas production.
- Most DAs occur early in lactation, but it is possible to see mid- to late-lactation occurrences as well. Typically, the ones that occur past the periparturient period are associated with alterations in feed quality, feed intake, fermentation within the cow, or combinations of these problems and are most common in high corn-silage-based rations.

RISK FACTORS

- Reduced feed intake is normally found during the periparturient period (3 weeks before and after calving).
- Cows calving with either clinical or subclinical hypocalcemia are at increased risk for abomasal displacement due to the altered GI motility and reduced feed intake.
- Reduction in intake is greater in fat cows or in cows that experience periparturient conditions, such as milk fever, dystocia, metritis, ruminal acidosis, mastitis, or that deliver twin calves. These cows are also at greater risk for primary or secondary ketosis and endotoxemia, which may potentiate the development of abomasal displacement.
- Stress has also been suggested as a risk factor, especially during the immediate periparturient period when feed intake is already reduced. Stress may be caused by excessive pen changes; mixing of primiparous and multiparous cows; overcrowded housing and feeding systems; prolonged confinement in individual maternity pens; environmental problems such as heat, mud, or extreme cold; and inappropriate calving assistance or general cow handling.
- There appears to be a genetic component, with some cow lines showing an increased risk.
- Ration-based risk factors:
 - Inadequate effective fiber levels
 - Overabundance of rapidly fermentable feeds
 - Easily sortable rations that allow cows to pick through the ration
 - Silages that contain abnormal levels of butyric or propionic acid
- Weather-related risk factors:
 - Periods of rainfall: (1) Forages exposed to rain will change in dry-matter content; (2) certain feed bunk designs may not allow water to properly drain and may lead to ration problems such as molds, yeasts, and lower total intakes; (3) resulting mud may decrease willingness of cows to approach bunk to eat.
 - Heat stress: (1) Lower total dry-matter intake per day; (2) higher risk of large swings in dry-matter intake.

DIAGNOSIS

- Diagnosis of a displaced abomasum involves simultaneous percussion and auscultation of the thoracic and abdominal walls above and below an imaginary line extending from the hip to the elbow on each side of the animal.

- Cattle with an abomasal displacement will have gas trapped within the hollow viscus that yields a “pinging” sound from the gas/fluid interface that can be heard with a stethoscope.
- The size of the ping may vary from only 3–4 inches to over 24 inches in diameter and can be located over the 10th, 11th, and 12th rib. In some cases, larger distensions will result in the sound extending past the 13th rib and into the paralumbar fossa on the side of the displacement. As there are other causes of pings, the clinician should be careful to distinguish a DA ping from gas in the spiral colon, rumen gas cap, or collapsed rumen and other causes of gas-fluid interfaces that may be less commonly found.

CBC/BIOCHEMISTRY/URINALYSIS

- Clinical findings are consistent with other intestinal flow abnormalities and may include hypochloremia, hypokalemia, hypocalcemia, metabolic alkalosis, ketonemia, and elevated levels of beta-hydroxybutyrate and nonesterified fatty acids.
- These changes are due to a combination of depressed feed intake and sequestration of hydrochloric acid within the abomasum

TREATMENT

- There is a variety of treatments. The most common and successful strategies include replacing and securing the abomasum in its normal position using surgical abomasopexy or omentopexy via laparotomy, or casting and rolling the cow before applying 1–2 toggle-pin sutures via an external ventral approach.
- The results of surgery are usually good for survival immediately postsurgery and most cows that survive return to a similar production level as before, regardless of approach; however, follow-up studies have shown that cows with DAs have a higher risk for culling during the current and following lactation, even after a successful short-term recovery and that surgically corrected cows, on average, produce less milk.
- Laparotomy approaches have traditionally been the treatment of choice and complete recovery from surgery (including a return to normal production levels) has been reported to range from approximately 60% to 90%.
- More recently, the roll and toggle technique is reported to have similar or slightly less successful recoveries, but with a greater risk of culling in the follow-up period.
- Supportive therapies are used to correct underlying metabolic changes and more promptly return cows to production. They include IV calcium and dextrose, oral fluids containing electrolytes and glucose precursors, anti-inflammatories such as flunixin meglumine for pain management and preexisting fever, systemic antibiotics for 3–5 days, and IV fluids, depending on the cow's acid-base status and whether fluid was removed from the abomasum during surgical correction.
- Due to costs associated with surgical correction and differences in survival and production following surgical correction, treatment is not recommended for every case when examined economically.
- Each case should be evaluated independently and the decision based on the surgeon's skill and experience, probability of successful recovery and return to lactation, cost of the procedure, and repayment potential (current lactation number, previous/predicted production level, and milk price).
- Younger animals that are average or above in production are predicted to have the best opportunity for economic payback from the surgical intervention, while older animals with a shorter expected future productive life, or lower producing animals, have a lower predicted return and are often culled instead.

MEDICATIONS

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food producing animals.
- Steroids should not be used in pregnant animals.

FOLLOW-UP

PREVENTION/AVOIDANCE

- While the precise cause for LDA is unknown, high-producing dairy cows that experience some type of abnormal periparturient event are most commonly affected.
- Management of LDA problems in herds typically centers on decreasing the known predisposing factors by improving periparturient nutritional management and decreasing the risk for additional declines in feed intake.
- A variety of factors including excessive body condition; stressful housing conditions such as overcrowding, heat, cold, or mud; and improperly balanced or managed rations can increase the risk of larger than normal declines in intake prior to calving and predispose cattle to ketosis. From calving until approximately 4 weeks in lactation, the high-producing dairy cow is susceptible to hypocalcemia, ketosis, and negative energy balance, metritis, and acidosis.
- Management should be addressed to (1) limiting the risk for development of these problems and (2) providing prompt, appropriate therapy as soon as they are diagnosed.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Most common clinical signs: abrupt decrease in feed intake and concurrent drop in milk production or failure of postparturient cows to increase in feed intake and milk production

AGE-RELATED FACTORS

Younger animals that are average or above in production are predicted to have the best opportunity for economic payback from surgical intervention; older animals with a shorter expected future productive life, or lower producing animals, have a lower predicted return and are often culled instead.

DISSEMINATED INTRAVASCULAR COAGULOPATHY (DIC)

BASICS

DEFINITION

A syndrome characterized by hemorrhage and thrombosis, which results from the systemic activation and consumption of coagulation and fibrinolytic proteins, consumption of platelets and vascular injury.

PATHOPHYSIOLOGY

- Any primary disease or disorder that activates the coagulation system and circulating platelets and causes vascular injury has the potential to result in coagulopathies.
- If not treated or corrected, the acquired coagulopathy may proceed to DIC. Clots forming within the small vessels and microvasculature result in ischemic injury, which may become irreversible.
- As the naturally circulating anticoagulants ATIII and proteins C&S are consumed in response to the hypercoagulable coagulopathy, the patient advances to a prothrombotic state.
- As clotting factors are consumed in the diffuse microvascular thrombotic process, hemorrhagic diathesis ensues.

SYSTEMS AFFECTED

All body systems can become affected by microvascular thrombosis initially and subsequently by hemorrhaging as the condition progresses. The severity and duration of the underlying disease or disorder influences the procoagulant stimulus and the associated clinical manifestation(s).

- Cardiovascular—early stages appear as thrombosis, as condition progresses hemorrhaging predominates.
- Pulmonary—thrombosis of the pulmonary vessels can result on hypoxia and respiratory distress.
- GI—microvascular thrombosis results in ischemic condition and irreversible mucosal injury or hepatobiliary dysfunction.
- Lymphatic/immune—thrombosis in early stages progressing to uncontrolled hemorrhaging as condition worsens
- Renal/urologic—microvascular thrombosis may result in acute renal ischemia, hematuria, oliguria, and failure.

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

SIGNALMENT

N/A

SIGNS

General Comments

- DIC is secondary to a primary underlying disease process or syndrome.
- Almost any body system is prone to microvascular thrombosis and consequently a wide variety of clinical signs are described.

Historical Findings

Depends on the underlying disease process or condition

Physical Examination Findings

- Microvascular thrombosis and hemorrhage may cause colic, oliguria, dyspnea, respiratory distress, or altered mentation.
- Large vessel thrombosis is commonly associated with catheter sites and venipuncture.
- Petechial or ecchymotic hemorrhaging, prolonged bleeding following venipuncture, may be noticed, but this is relatively uncommon.

CAUSES

- Most commonly, DIC occurs secondary to inflammatory or ischemic GI disorders and gram-negative infections, resulting in circulating endotoxemia.
- Less commonly associated with viral, rickettsial, protozoal, or parasitic diseases; heat stroke; burns; neoplasia; or severe trauma.

RISK FACTORS

Any disease or event that activates coagulation or causes significant blood loss can result in DIC if left untreated.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Early detection in the hypercoagulable phase is a diagnostic challenge but important with respect to prognosis.
- Patients with primary disorders that have the potential to progress into DIC should be monitored closely.
- Hypercoagulation or DIC should be suspected in patients who fail to respond to appropriate therapy of the primary disease or develop diminished renal, hepatic, or cardiopulmonary function.
- Decreased tissue perfusion as a result of microthrombosis is evidence of specific organ failure.

CBC/BIOCHEMISTRY/URINALYSIS

- Laboratory examination is crucial for determining the systemic hematologic and biochemical alterations but is not pathognomonic for diagnosing altered hemostasis.
- Leukopenias with neutropenia, lymphopenia, or thrombocytopenia are common CBC abnormalities associated with severe sepsis and shock.
- Hypofibrinogenemia is uncommon because most DIC-associated disorders are associated with severe inflammation.
- Altered electrolytes or biochemical parameters may reflect renal azotemia or hepatobiliary injury.

OTHER LABORATORY TESTS

- Laboratory tests of hemostasis are most beneficial when performed serially and should always be interpreted with respect to patient clinical assessments.
- Proper venipuncture technique and sample handling are important to avoid spurious laboratory results.
- Increased fibrin degradation products ($> 40 \mu\text{g/mL}$) and decreased antithrombin III activity ($>60\%$ of control)
- Prolongation of the clotting time tests [prothrombin time (PT) and activated partial thromboplastin time (APTT)] occurs as a late event in DIC and are not sensitive enough to diagnose the preceding phase of hypercoagulation.

IMAGING

Arterial thrombosis can be imaged by vascular digital subtraction contrast angiography.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Generally reflect the primary disease process and focal to diffuse thrombosis, and petechial and ecchymotic hemorrhages may be evident grossly or histologically.

TREATMENT

Hospitalization and intensive care are required to address the needs of this life-threatening condition.

SUPPORTIVE CARE

- Constant monitoring of coagulation parameters is necessary to avoid a recurrent event.
- Frequent patient assessment and monitoring catheter and venipuncture sites are imperative.

ACTIVITY

Limited

DIET

Total or partial parenteral may be required to meet increased energy and metabolic demands due to shock.

CLIENT EDUCATION

DIC is associated with a poor prognosis.

SURGICAL CONSIDERATIONS

If the primary disorder is a surgical lesion, compounded with DIC the prognosis is grave.

MEDICATIONS

DRUGS OF CHOICE

- Treatment of the underlying disease process, which is driving the coagulopathy, is the primary concern.
- Immediate and aggressive fluid administration to maintain tissue perfusion and correct balance of acid-base and electrolyte levels
- Fresh whole plasma transfusion (15–30 mL/kg) to restore the consumed coagulation proteins and platelets. If available, hyperimmune plasma with a higher titer of antiendotoxin antibody may be beneficial.
- The use of heparin is controversial and, if used, should be administered in combination with plasma to assure adequate activity of coagulation proteins.

CONTRAINDICATIONS

- Drugs that cause or may exacerbate preexisting hypotension (e.g., acepromazine) should be avoided.
- Avoid potentially nephrotoxic drugs and those requiring hepatic metabolism.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

- Physical examination every 2 to 4 hours with particular attention to heart and respiratory rate, temperature, urine output, presence of arrhythmias, pulse intensity, and mucous membrane coloration.
- Laboratory tests of hemostasis (platelet count, PT, APTT, FDPs, and ATIII) are most beneficial when performed serially and should always be interpreted with respect to patient clinical assessments.
- Check PCV and TP every 12 hours during the initial treatment with IV fluid to expand the intravascular fluid volume and during equilibration with the extravascular pool.

PREVENTION/AVOIDANCE

Early detection, treatment, and monitoring patients with disorders known to result in DIC are critical.

POSSIBLE COMPLICATIONS

Multiple organ failure and cardiovascular shock

EXPECTED COURSE AND PROGNOSIS

The diagnosis of DIC is based on a prolongation of the clotting times, decreased platelet count and ATIII activity, and increased fibrinogen degradation products, which are not normally present until the condition has progressed to a terminal stage when life threatening hemorrhage and multiple organ and circulatory failure are present.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Large and small-vessel thrombosis
- Ecchymotic and petechial hemorrhage, epistaxis
- Multiple organ failure, death

AGE-RELATED FACTORS

Only if associated with the underlying primary disorder

ZOONOTIC POTENTIAL

DOWN CAMELID

BASICS

DEFINITION

Inability to stand and/or remain standing without assistance

SYSTEMS AFFECTED

- Musculoskeletal
- CNS

GENETICS

N/A

INCIDENCE/PREVALENCE

Worldwide; can occur wherever camelids are raised

GEOGRAPHIC DISTRIBUTION

- Depends on cause.
- Meningeal worm occurs in warmer climates wherever white-tailed deer are in contact with camelids.
- GI parasitism is more common in subtropical and tropical climates.

SIGNALMENT

Species

Camelid

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

General Considerations

Llamas and alpacas will sit in sternal recumbency (“cush”) and resist standing when agitated or stressed. The clinician needs to distinguish between refusal to stand and inability to stand.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Neurologic Disease

- *Parelaphostrongylus tenuis*
- Listeriosis
- Polioencephalomyelasia
- EHV-1
- Tick paralysis
- Rabies
- Trauma
- Neoplasia of CNS or spinal cord

- Abscess of CNS or spinal cord

Alimentary Disease

- Debilitation due to severe gastrointestinal parasitism: Coccidiosis; *Haemonchus contortus*
- Debilitation due to social starvation

Musculoskeletal Disease

- Peripheral nerve damage
- Trauma

Hematologic

Mycoplasma haemolama (formerly Eperythrozoonosis)

Parelaphostrongylus tenuis (meningeal worm)

- Nematode found in white-tailed deer and carried by snails and slugs.
- Llama ingests snail or slug carrying larvae.
- Larvae are released in stomach and migrate to spinal cord and mature in gray matter; migrate to brain through the spinal subdural space.

Clinical Signs

- The parasite does not cause clinical signs in white-tailed deer.
- Infection in camelids can cause signs of neurologic disease including ataxia, paresis, lameness, circling, blindness, and recumbency.

Diagnosis

- There is no reliable antemortem diagnostic test.
- A peripheral eosinophilia may be seen or an eosinophilia in CSF.

Treatment

- Ivermectin (2.5 ml/75 lbs SQ) for 3 days followed by fenbendazole at a dose rate of 30 mg/kg PO for 3 days
- Supportive care is indicated including intravenous fluids and/or parenteral nutrition, as necessary, in addition to anti-inflammatory medication such as flunixin meglumine or corticosteroids or DMSO.
- Flotation therapy and/or physical therapy may be beneficial.

Prevention

Monthly deworming with ivermectin (1 ml/75 lb body weight SQ) to eliminate parasite larvae as they migrate through the body.

Listeriosis

Acute meningoencephalitis caused by gram-positive bacterium *Listeria monocytogenes*

Clinical Signs

Listeriosis can cause a wide range of neurologic signs including cranial nerve deficits, circling, ataxia, paresis, fever, depression, recumbency, and death.

Diagnosis

- Diagnosis is based on clinical signs and elimination of other differential diagnoses.
- Additionally, analysis of CSF may reveal elevated protein (>40 mg/dl) and >12 mononuclear cells/ μ l.

Treatment

- Oxytetracycline (10 mg/kg IV twice daily) or high doses of penicillin (40,000 U/kg three to four times daily or 60,000 U/kg twice daily) in addition to supportive care.

Polioencephalomyelacia

Necrosis of cortical gray matter associated with thiamine deficiency

Clinical Signs

Neurologic signs are variable depending on which area of the brain is affected including blindness, depression, muscle tremors, anorexia, opisthotonus, recumbency, and seizures.

Diagnosis

A range of laboratory diagnostic tests are available (Smith, 1969); however, diagnosis is usually based on history, signalment, and clinical signs.

Treatment

Administration of thiamine (10 mg/kg) once daily intramuscularly or intravenously for 3–5 days is recommended. Thiamine hydrochloride can cause anaphylaxis if given intravenously, therefore it is recommended that the thiamine dose be diluted and administered slowly.

Equine Herpes Virus-1

- A virus similar to EHV-1 has been identified in camelids and may be associated with blindness and encephalitis, which may lead to recumbency.
- Treatment includes NSAIDs and supportive care.

Tick Paralysis

Caused by a neurotoxin from female

Dermacentor variabilis or *D. andersoni*. The condition is observed more commonly in western states.

Clinical Signs

- Ataxia, paresis, and paralysis can progress over a few hours or more slowly over 24–48 hours.
- Ascending paralysis can result in dysphagia and death due to asphyxia due to respiratory paralysis.

Treatment

- Resolution of signs will not occur until the tick is removed.
- Recommended treatment includes topical administration of pyrethrin insecticides and ivermectin (0.2 mg/kg). Signs can reverse within 2–12 hours of removing the tick.

Rabies

Invariably fatal neurologic disease caused by rabies virus

Clinical Signs

- Neurologic signs are variable and include depression, ataxia, and anorexia, and can progress to recumbency, salivation, coma, and convulsions among many other signs.
- Rabies should be considered in any case of nonresponsive central nervous system disease.

Diagnosis

- No clinical diagnostic test is available.
- Postmortem diagnosis is confirmed by histopathology of brain tissue and indirect fluorescent antibody testing of brain sections.

Trauma

- Differential diagnoses to be considered include musculoskeletal or peripheral nerve injury or head trauma.
- A complete physical exam should include palpation of extremities for crepitus and/or muscle atrophy, testing of reflexes, and palpation and manipulation of joints.

Neoplasia or Abscess of CNS or Spinal Cord

- A neurologic exam should be performed to attempt to localize the lesion.
- Diagnosis can be achieved in some cases with head or spinal radiographs, magnetic resonance imaging, or computed tomography.

Coccidiosis

A heavy gastrointestinal burden of coccidia, specifically the pathogenic species *Eimeria macusaniensis*, can be debilitating in camelids.

Clinical Signs

Camelids with heavy infections can present in poor body condition with diarrhea, weight loss, poor hair coat, weakness, and recumbency in severe cases.

Diagnosis

- Diagnosis is based on clinical signs and presence of large numbers of coccidia on fecal floats.
- Camelids can carry nonpathogenic species of coccidia, therefore speciation of oocysts is recommended.

Treatment

- *E. macusaniensis* can be difficult to treat. Ponazuril at 10–20 mg/kg PO can be effective.
- Daily oral doses of amprolium until fecal floats are clear have also been effective.
- In severe cases, supportive care including intravenous fluids and/or parenteral nutrition may also be indicated.

Prevention

Effective preventative measures include addition of coccidiostats to feed or water for camelid herds, reducing stocking densities, regular doses of coccidiostats such as amprolium or sulfadimethoxine, prevention of fecal contamination of feed and water, and proper manure disposal.

Haemonchus Contortus

A blood-sucking gastrointestinal strongyle parasite

Clinical Signs

Camelids infected with this parasite can present with generalized weakness, anemia, depression, anorexia, and diarrhea.

Diagnosis

Diagnosis is based on clinical signs and presence of large numbers of strongyle eggs on fecal float.

Treatment

- Elimination of *Haemonchus contortus* burdens can be difficult due to widespread resistance to commonly used dewormers.
- Ivermectin has been effective against the adult and hypobiotic larval stages, but resistance is occurring.
- Combinations of ivermectin and fenbendazole or ivermectin and pyrantel can be effective.
- Fecal egg count reduction tests are recommended to determine the effectiveness of treatment.
- Moxidectin has been used in salvage situations, but widespread use is leading to development of resistance in some populations.
- Blood transfusions may also be necessary depending on the degree of anemia.

Mycoplasma Haemolamae

A hemoparasite that can cause clinical disease in immunosuppressed or stressed camelids. It can also be found in low numbers in healthy camelids.

Clinical Signs

Infected camelids can present with anemia, depression, acute recumbency, weight loss, and death.

Diagnosis

- The presence of *M. haemolamae* on blood smears with concurrent clinical signs supports diagnosis.
- A PCR-based assay is available from Oregon State University for definitive diagnosis.

Treatment

- Various regimens of tetracycline have been recommended including oxytetracycline at a rate of 10 mg/kg intravenously once or twice a day.
- Supportive care and blood transfusions may also be necessary depending on the degree of anemia.

Other Differential Diagnoses to Consider

- C3 ulcers
- Rickets
- Toxoplasmosis
- Sarcocystosis
- Bacterial, viral bacterial or fungal encephalitis or meningitis
- Intervertebral disk extrusion
- Vertebral osteomyelitis
- Myelitis

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food producing animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

DOWNER COW

BASICS

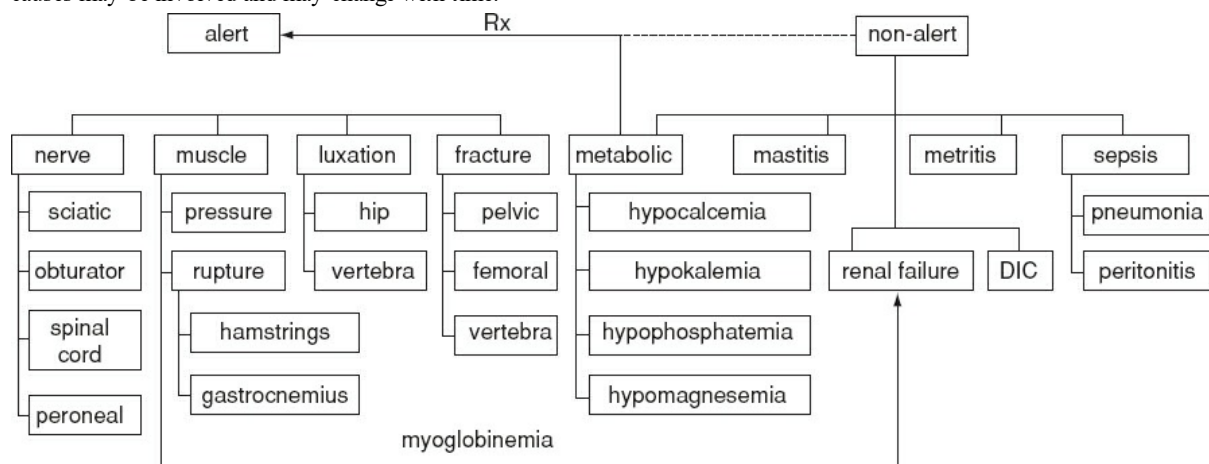

DEFINITION

- Persistent sternal recumbency with no apparent cause
- Usually associated with the periparturient period and often follows parturient paresis
- Some animals may crawl (“creepers”).
- Two forms: alert and nonalert

PATHOPHYSIOLOGY

- Primary recumbency may be due to muscle weakness resulting from metabolic disturbances such as parturient paresis or hypokalemia.
- Nerve damage due to intrapelvic trauma during calving may be a factor contributing to primary recumbency.
- Other causes are toxic substances from metritis or mastitis.
- Primary recumbency not associated with calving may be due to sepsis from peritonitis or pneumonia.
- Regardless of the cause of primary recumbency, pressure damage of muscle and nerves leads to secondary recumbency. Experimentally, this can occur within 6 hours.
- Tertiary recumbency due to muscle tearing occurs in some cases as a result of struggling to move. The hamstring muscles are most often affected.
- Muscle damage can cause severe myoglobinemia leading to renal damage.
- Hip luxation and fractures of the pelvis and femoral head or neck are additional, contributing secondary or tertiary factors in some cases.
- Pain due to muscle damage is another contributing factor. Dermatitis due to urine scalding leads to more pain and hence reluctance to move.
- Massive tissue destruction can lead to DIC.

Figure 1. Diagnostic algorithm for downer cattle. Only the most common causes are shown. In any particular case, multiple causes may be involved and may change with time.

SYSTEMS AFFECTED

Musculoskeletal, CNS, production management

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Usually a periparturient cow and typically a mature, high-producing dairy animal housed on concrete

SIGNS

- Inability to stand. Typical downers maintain sternal recumbency. Those in lateral recumbency are dying animals rather than typical downers.
- Appetite of alert downers is better than that of nonalert downers.
- Movement decreases as the duration of recumbency increases. Alert downers are more active.
- Dry stools are common. Dark urine, especially brown urine, is a grave sign.
- Knuckling (digital flexion) of hind limbs when attempting to stand

CAUSES AND RISK FACTORS

- Metabolic problems such as parturient paresis
- Intrapelvic trauma as a result of dystocia
- Toxic metritis and mastitis
- Wet, slippery concrete
- Large size and excessive weight

DIAGNOSIS

HISTORY

- What is the age, parity, and production level of the cow?
- How long has the cow been down and has it been moved to present location?
- Did calving occur recently? If so, when and was there dystocia? What was the duration of dystocia and how was it managed? Was the calf dead or alive? What was the size?
- Did retained placenta occur and how was it managed?
- Did parturient paresis occur and how was it treated? What was the response to treatment?
- How has recumbency been managed? Has the patient been lifted?

DIFFERENTIAL DIAGNOSIS

- The goal is to identify specific causes of recumbency in order to determine whether treatment is justified and what the management plan should be (see [Figure 1](#)).
- Alert downers commonly suffer from local nerve and/or musculoskeletal damage.
 - Pressure damage to peripheral nerves such as the sciatic, obturator, and common peroneal, will have broad locomotor consequences. Less commonly, vertebral lymphoma can cause local nerve damage.
 - Muscle damage can be due to compression or rupture. Most often the hamstring muscles are involved but pressure damage of the crural region and gastrocnemius rupture may occur also. When massive, muscle damage can have severe systemic effects that may lead to a nonalert downer.
 - Fracture of the pelvis or proximal femur. Less commonly, vertebral fracture
 - Hip luxation or less commonly vertebral or sacroiliac luxation
- Nonalert downers usually suffer from systemic problems, which broadly include metabolic, toxic, and septic problems. As mentioned above, massive muscle damage can cause systemic failure. Kidney damage and a cascade leading to DIC may be involved.
 - Toxic metritis or mastitis
 - Unresolved hypocalcemia, hypophosphatemia, and hypokalemia

- Sepsis due to pneumonia or peritonitis. These can be the result of many things such as “hardware disease,” rupture of lung or liver abscess, or perforation of an abomasal ulcer.

LABORATORY TESTS

- CBC and chemistry panel may reveal signs of underlying disease.
- Serum creatinine kinase (CK), a marker for muscle damage, is elevated significantly in the early stages but has a short half-life and is not reliable for prognosis in clinical cases.
- Serum calcium and potassium levels may point to metabolic problems
- Urine should be examined for color and if dark or brown, myoglobin levels may be evaluated.

IMAGING

Impractical in most cases; radiology could be used to confirm pelvic fracture or hip luxation.

DIAGNOSTIC PROCEDURES

- TPR, examination of the udder and uterus for signs of mastitis and metritis
- Cutaneous testing of hind limbs for evidence of sensory reflexes
- Palpation of limbs for luxation or fractures
- Rectal palpation for pelvic fractures or hip luxation, evidence of crepitus
- Lifting with hip clamps is useful for musculoskeletal and neurologic examination but should be very brief to avoid pressure damage of muscles in the tuber coxae region. The clamps should be well padded to minimize tissue damage.
- Some cows may be able to stand unassisted once lifted but most will not. As support of the hip clamps is released, muscle strength can be determined.
- Response to treatment in a floatation tank is useful but labor intensive.

TREATMENT

- The first goal is to prevent further muscle and nerve damage due to recumbency.
- Provision of soft, clean, and dry bedding is essential. Sand is easier to keep clean than straw bedding. Hard, slippery concrete should be avoided.
- Frequent repositioning will reduce pressure damage.
- Floatation therapy is the best way to reduce pressure damage and enhance vascular supply to compressed tissues. Hot water (body temperature) is essential for hydrotherapy to be beneficial. A side effect is to cleanse the skin and reduce dermatitis.
- Hobbles on the hind limb pasterns have been used to prevent limb abduction into the so-called spread-eagle (splay-legged) position but the practice can be dangerous and is unnecessary on good nonslip bedding.
- Hind limb knuckling (digital flexion) can be managed with a cast on the affected lower limb.
- Surgical amputation or hemiamputation of a toxic udder by ligation of one or both external pudendal arteries.

MEDICATIONS

- Antibiotic treatment is indicated in the case of metritis, mastitis or generalized sepsis.
- Pain medication will make the patient more willing to attempt to move and improve appetite.
- Topical ointments for dermatitis and pressure sores
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING

- Successful treatment of downer cows is labor intensive and requires frequent monitoring of the patient.
- Keeping the bedding clean and dry is important.
- Providing a constant supply of fresh drinking water is important but difficult when animals move continually. A large rubber tub that is not easily turned over works best.
- Frequent skin cleansing is important to prevent urine scalding.
- Frequent repositioning is helpful to minimize pressure damage.
- Floatation therapy requires frequent monitoring to prevent drowning. Keep the water close to body temperature.

POSSIBLE COMPLICATIONS

- Hamstring or gastrocnemius muscle tearing due to struggling to stand
- Hip luxation during ataxic attempts to move, especially when hind limbs are abducted in the so-called “spread eagle” or “splay-legged” position.
- Muscle damage due to excessive use of hip clamps by owners. Some owners may use hip clamps to facilitate milking. They should be advised that it is better to dry the cow off and save the cow rather than lose the cow while trying to save the lactation.
- Drowning or chilling due to improper use of a floatation tank.
- Rope burns of the udder or pasterns due to improper use of hobbles

MISCELLANEOUS

- Prevention is more important than therapy.
- Dry cow feeding should be aimed at prevention of parturient paresis.
- Provision of clean, well-bedded calving stalls is essential.
- Periparturient cows should be monitored frequently so that problems can be treated before they get worse.
- Owners should know that a down cow is an emergency case because irreversible pressure damage can occur in as short as 6 hours of recumbency.

DRUG INTERACTIONS

BASICS

DEFINITION

A drug interaction can be defined as the influence of one drug on the biological activity of another drug administered to the same animal simultaneously.

OVERVIEW

- Drug interactions lead to drug(s) producing unexpected effects that may be harmful, inconsequential, or even beneficial.
- Can occur in vitro due to physical or chemical incompatibilities or in vivo as a result of pharmacokinetic or pharmacodynamic interactions.
- Drug interactions may result in a fatal outcome.
- Employment of relatively large doses, using multiple-drug therapy, and a debilitated state of the patient can increase the probability of severe drug interactions.
- Consider the possibility of drug interaction, evaluate laboratory testing parameters, evaluate and notify pharmaceutical companies of adverse reactions.

SYSTEMS AFFECTED

Production management, metabolic, immune

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Worldwide depending on species and drugs utilized

SIGNALMENT

- All animals susceptible if more than one drug is administered simultaneously.
- Possibility of higher prevalence in young animals or animals kept under intensive conditions due to higher level of drug use.

Species

Potentially all ruminant species

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Drug toxicity
- Augmented or decreased drug effect
- Changes in onset or duration of drugs' effect(s)
- Unexpected effects or side effects

CAUSES AND RISK FACTORS

- Can occur whenever two or more drugs are administered concurrently.
- Likelihood of interactions increases as number of drugs administered concurrently increases.

In Vitro Incompatibilities

Combination of two or more drugs in solution may lead to physical or chemical changes in one of the active ingredients with resultant inactivation.

Semisynthetic penicillins, barbiturates, benzylpenicillin, diazepam, promethazine hydrochloride, sulfonamides, and vitamin B complex should not be mixed with other drugs, as they have many incompatibilities.

In Vivo Interactions

- Interactions that affect drug absorption
 - Increased solubility of lipophilic drugs when coadministered orally with surfactants
 - Decreased oral availability of drugs due to adsorption or chelation (divalent ions and tetracyclines, kaolin and lincomycin, activated charcoal)
 - Changes in gut motility (e.g., coadministered cholinergic drugs)
- Interactions that affect drug distribution: displacement of highly plasma-protein-bound drugs when coadministered (e.g., sulfonamides, phenylbutazone, other NSAIDs, and warfarin)
- Interactions that affect drug metabolism
 - Induction of metabolizing (e.g., phenobarbitone, diphenhydramine, griseofulvin, phenylbutazone, cortisol, and some inhalation anesthetics).
 - Inhibition of metabolizing enzymes (e.g., chloramphenicol).
- Interactions that affect renal excretion of drugs
 - Competition for nonspecific carrier proteins affects the excretion of weak organic acids or bases by tubular secretion (e.g., probenecid prolongs the action of penicillins).
 - Urinary acidification or alkalization will affect the tubular reabsorption of drugs that are either weak organic acids or weak organic bases (e.g., alkalization of urine promotes the excretion of sulfonamides).
- Effects at receptor sites
 - Two drugs acting at the same effector site or different sites but with related effects (e.g., organophosphates and carbamates, neuromuscular blockade caused by anesthetics and aminoglycosides)
 - Decreased efficacy of bactericidal antibiotics when coadministered with bacteriostatic antibiotics
 - Synergistic effects of tranquilizers, sedatives, and anesthetics for balanced anesthesia

DIAGNOSIS

- The signs of a drug interaction are highly variable and dependent on the dose and types of drugs administered as well as the type of interaction.
- Be aware of potential interactions when administering more than one drug simultaneously, particularly if the effect is not acute/obvious.

TREATMENT

- Discontinue treatment
- Use alternatives if available
- Adjust doses according to effect
- Avoid coadministering drugs with known interactions
- Keep number of drugs administered to a minimum
- Supportive therapy as needed

MEDICATIONS

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

DYSTOCIA

BASICS

DEFINITION

- Dystocia occurs when the first or second stage in the parturition process is interrupted or prolonged, necessitating artificial assistance for delivery of the fetus.
- The main objective when assisting a dystocia case is to deliver the fetus without causing trauma to the dam, and if possible to deliver a live fetus.

PATHOPHYSIOLOGY

- Expulsive forces may be weakened in cases of hypocalcemia.
- The most common causes for dystocia are related to fetal/maternal size disproportions, as well as malposition, malpresentation and malposture of the calf.

SYSTEMS AFFECTED

Reproductive, musculoskeletal, production management, endocrine/metabolic

GENETICS

- Sires whose daughters have reduced pelvic diameter
- Those animals whose offspring are oversized in comparison to the breed average

INCIDENCE/PREVALENCE

The incidence of dystocia is about 15% of all parturitions with a reported range from 3% to 25%.

GEOGRAPHIC DISTRIBUTION

Worldwide distribution

SIGNALMENT

Species

Potentially all ruminant species

Mean Age and Range

The incidence of dystocia is higher in primiparous than multiparous animals.

Predominant Sex

Female

Breed Predilection

- The overall incidence of dystocia varies by species and breed.
- The bovine is most often affected but ewes and does when carrying twins may show a high incidence of dystocia.

SIGNS

GENERAL COMMENTS

Defects in the components of the parturition process such as expulsive force, birth canal diameter, fetal size, and uterine torsion must be considered when assessing a dystocia case.

HISTORICAL FINDINGS

- Lack of delivery progress after initiation of parturition
- Continuous violent abdominal contractions without visualization of fetal parts
- Unsuccessful attempts by either an owner or herdsman to deliver the calf

PHYSICAL EXAMINATION FINDINGS

In cattle:

- Prior to assisting a dystocia, the minimal requirements are an ample supply of clean warm water, disinfectant, buckets, lubricants (petroleum jelly or methylcellulose-derived products), two obstetrical chains with handles, and the hormone

oxytocin.

- When there has been little progress for 2 hours after the amnionic sac is presented at the vulva, the animal should be examined manually to determine the cause of the dystocia and assess the most appropriate route of delivery.
- The calf can live up to 10 hours within the birth canal after the amnionic sac is ruptured.
- The purpose of the vaginal exam is to determine the presentation, position, and posture of the calf within the birth canal.
- If the calf is in an anterior presentation (cranial), it must first be determined if the head, neck, and front legs are extended.
- In a posterior presentation, it must be determined if the hind legs are extended. At the same time, calf viability must be ascertained.
- If the head is accessible in an anterior presentation, the swallowing reflex may be elicited by inserting a finger into the mouth; if the calf is alive, swallowing will occur.
- The pedal reflex may be applied by putting pressure on the hooves in an anterior or posterior presentation; a responsive calf will retract its leg.
- During the evaluation process, the position and posture must also be considered.
- The position is related to the dorsum of the calf in relation to the maternal sacrum, pubis, and ileal shafts.
- The posture is related to the fetal extremities (neck and legs) and can be either extended or flexed. These considerations are important because prior to extraction, the calf must be in normal position and posture to prevent trauma to the dam.
- If the fetal head or neck is flexed backward or to a side, this abnormal fetal posture must be corrected prior to extraction.
- Before attempting to extract the calf, it must be ascertained that the presentation, position, and posture are normal.
- The position of the calf must be dorsosacral with a normal posture prior to extraction.
- The final step is to determine whether or not there is sufficient space and lubrication to deliver the calf vaginally.

Anterior Presentation (Cattle)

- The head of the calf should rest on both knees of the front limbs with the legs fully presented in the birth canal.
- There will be sufficient room to pull the calf, if one person can pull the first leg presented until the pastern is 6 inches (12 cm) outside the vulva and, if next while holding the first leg in this position, again one person can pull the second leg equally far outside the vulva.
- At these distances, both shoulders of the calf will have passed the bony entrance of the maternal pelvis.

Posterior Presentation (Cattle)

- About 10%–15% of parturitions occur when the calf is in a posterior presentation.
- Again after applying chains below the dewclaws of the calf and having two persons pull, if both hocks can be presented at the vulva, it indicates that the fetal pelvis has passed through the maternal pelvis and there is sufficient room to deliver the calf vaginally.

RISK FACTORS

- Obesity
- Twins
- Hypocalcemia
- Small frame size
- Large calf

TREATMENT

APPROPRIATE HEALTH CARE

- Observation for appetite, vaginal discharge, and temperature
- Certain cases may require systemic antibiotic treatments if they develop metritis.

NURSING CARE

Administration of antibiotics, NSAIDs, and energy and calcium supplements may be indicated.

ACTIVITY

Walking or movement should be limited in those animals that are weak after parturition.

DIET

No limitations

CLIENT EDUCATION

- Management practices to prevent risk factors for dystocia.
- Training in observational strategies and techniques for prompt and correct diagnosis of dystocia.

SURGICAL CONSIDERATION

- Cesarean section may be indicated if a live calf cannot be delivered vaginally.
- Conversely, dead emphysematous calves may require a fetotomy.

MEDICATIONS

DRUGS OF CHOICE

- Oxytocin 2–3 times/day after parturition. Reassess in 24 hours.
- Systemic antibiotics in prolonged cases may be indicated.

CONTRAINDICATIONS

- Sedatives are contraindicated because they may cause recumbency.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

Care should be taken that the dam is handled safely.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Cows should be monitored for signs of toxic metritis.

PREVENTION/AVOIDANCE

- Proper management of the prepartum cow

- Genetic considerations to help reduce fetal size
- Training of farm personnel in proper observation of preparturient animals.

POSSIBLE COMPLICATIONS

- Trauma and lacerations to the genital tract
- Downer cow (nerve damage)
- Toxic metritis

EXPECTED COURSE AND PROGNOSIS

The majority of assisted dystocia cases properly recover.

ECONOMICS OF BEEF CATTLE REPRODUCTIVE DECISIONS

BASICS

OVERVIEW

Economics is the management of “material wealth.” Beef cattle “material wealth” is difficult to quantify, and the return on investment (ROI) varies and depends upon many factors including:

- Ranch business dynamics (family vs. cooperate)
- Geography—United States beef cattle operations are divided roughly by the Mississippi River. Western states have a higher percentage of ranches (27.4%) with ≥ 50 animals than eastern states (13.8%).
- Goals—Financial gain from beef cattle production may be diluted by “off-farm” income, which can account for over half of total income in small- and medium-sized operations.
- Philosophy—Economic decisions should be followed and reviewed consistently in order to realize progress and goal accomplishment.
- Level of investment—A variety of reproductive tools is available, which range from low to high management intensity and financial involvement. Independent analysis and ROI should be evaluated for each.

PATHOPHYSIOLOGY

N/A

SYSTEMS AFFECTED

Endocrine/metabolic, reproductive, gastrointestinal/nutritional

SIGNALMENT

Some breeds may be more productive in specific geographic locations and require special consideration of:

- Heat tolerance
- Parasite resistance
- Disease resistance
- Native forage availability
- Water availability
- Cattle growth dynamics

SIGNS

Knowledge of beef markets essential

CAUSES AND RISK FACTORS

Financial risks associated with economics of beef cattle reproductive decisions are considerable and are based on:

- Labor—Labor is the single largest cost associated with beef cattle reproductive decisions. Even low-input reproductive decisions such as estrus synchronization requires gathering and handling of cattle, which may be difficult or cost-prohibitive depending upon the geography and dynamics of the operation.
- Record keeping—Although considerable genetic gain can be accomplished using AI or superovulation and ET, this gain may not be readily recognized and, therefore, may be undervalued. Keeping consistent and valid records is an invaluable tool that can help the producer make the appropriate decision about the future and understand the impact of the reproductive decisions made over the last few years.
- Culling of nonproductive beef cattle—The primary consideration to cull cattle should be lack of productivity. Although the scope of this decision is broader than reproduction, focusing reproductive decisions on cattle that have strong opportunities to become pregnant, rather than on cattle that are available only as a result of inconsistent culling patterns, will reflect a more legitimate view of the reproductive status of the herd (See [Table 1](#)).

DIAGNOSIS

Reproductive decision costs: direct and indirect

Direct Costs

- Labor/specialized training
- Estrus synchronization techniques and drugs
- Semen, semen tanks, liquid nitrogen, artificial insemination gun, etc.
- Embryo transfer fees (drugs, professional fees, equipment, etc.)
- Miscellaneous (needles, syringes, palpation sleeves, lube, etc.)
- Vaccines, parasite or predator control

Indirect Costs

- Facility modifications (more frequent animal handling)
- Safety devices (added protection/reduced liability, for animals and handlers)
- Enhanced/additional nutrition (minerals, vitamins, etc., for high-value genetics)
- Depreciation on equipment/facilities
- Consultation fees
- Interest on capital improvement expenditures

DIFFERENTIAL DIAGNOSIS

A variety of unforeseen factors may be considered diagnostic factors associated with reproductive decisions.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

Table 1

Costs-Benefits Analysis of Some Reproductive Decisions in Beef Cattle
Technique—Estrus Detection
• Costs = \$15–50/cow
• Benefits = ↓ calving season
• Other = ↑ labor intensity during breeding and calving
Technique—AI
• Costs = \$10–75/cow
• Benefits = ↑ genetic gain, ↑ pounds weaned, ↑ calf value, ↓ bull maintenance
• Other = ↑ semen costs and specialized labor
Technique—ET (donors)
• Costs = \$200–350/cow
• Benefits = ↑ visibility, and market scope, international sales
• Other = Few cattle (< 10%) have marketable genetics
Technique—ET (recipients)
• Costs = \$50–100/cow
• Benefits = Promotes partnerships, ↑ visibility, market potential
• Other = ↑ facility costs, ↑ labor intensity (calving)
Technique—IVP embryos

• Costs = \$2000–3000/calf
• Benefits = Niche market for genetics of geriatric or dying cattle
• Other = Sex ratio skewed to produce more males, large calves, ↑ labor, ↑ lab fees
Technique—Cloning
• Costs = \$20,000/calf
• Benefits = Genetic preservation, ↑ market potential
• Other = ↑ labor, ↑ death loss, ↑ maintenance costs

Note: ↓ = decrease; ↑ = increase; AI = artificial insemination; ET = embryo transfer; IVP = in vitro embryo production.

DIAGNOSTIC PROCEDURES

- Concerned record keeping efforts
- Accessing available information and advice (university extension service, consultants, beef journals, etc.)
- Comparisons among beef operations
- Goals/accomplishments

TREATMENT

Economic decisions should be:

- Based on best-available information
- Strictly adhered to
- Consistently reevaluated
- Compared based upon ROI

MEDICATIONS

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS

N/A

PRECAUTIONS

The size and scope of *all* economic decisions should be based on:

- Farm income
- Financial return of “added value”
- Debt-to-income ratio
- Current (and future) agricultural markets and economics

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

The ROI for the economics of beef cattle reproductive decisions should be quantified and consistently evaluated to determine the quality (and the cost) of the individual decisions.

ECTROPION

BASICS

OVERVIEW

- Ectropion is an eversion or rolling out of the eyelid. This condition can be congenital or acquired. Ectropion allows exposure of the globe and buildup of debris in the ventral conjunctival sac, which can predispose to chronic keratitis or conjunctivitis. Deformed or notched upper eyelid may also be present.
- Irritation of the eyeballs often results from this condition.
- It can be corrected by surgery, if necessary.

Types of Ectropion

- Developmental
- Cicatricial ectropion
- Traumatic
- Postoperative iatrogenic secondary to entropion surgery
- Neurological
- Senile ectropion—connective tissue loses elasticity as it ages.
- Anatomic ectropion—usually congenital, but may intensify as animal ages; can be heritable in some breeds.

PATHOPHYSIOLOGY

Hereditary, congenital, or secondary to trauma/postoperative

ORGAN SYSTEMS AFFECTED

Ophthalmic

GENETICS

- May be an inherited eye defect
- Congenitally rare: reported in piebald sheep

GEOGRAPHIC DISTRIBUTION

Worldwide

INCIDENCE/PREVALENCE

Rare

SIGNALMENT

Lambs are most commonly affected. But depending on the predisposing cause, all ruminant species may be affected.

SIGNS

Blepharospasm, ocular discharge, drooping eyelid, keratoconjunctivitis, eye irritation epiphora, secondary infections are common, exposure keratoconjunctivitis

CAUSES AND RISK FACTORS

Congenital in piebald sheep; the upper eyelid is notched and there is ectropion at the notch. Entropion generally occurs at either side of the notch.

DIAGNOSIS

Clinically obvious, eyelid is abnormally rolled outward.

DIFFERENTIALS

Foreign body, neoplasia, ophthalmic debris, secondary epiphora

CBC/BIOCHEMISTRY/URINALYSIS

NA

OTHER LABORATORY TESTS

NA

IMAGING

NA

TREATMENT

- Culling individuals (records)
- Surgical techniques to shorten lids and/or roll the lid inward
- Topical antibiotic/steroid combos to temporarily ease discomfort of secondary infections; surgical repair if conjunctivitis, keratitis, epiphora present

Surgical Technique

- There are numerous procedures available, but most of these are for minor cases of ectropion and include procedures such as V to Y, or trephine.
- Surgery is indicated in only those animals deemed valuable enough to warrant intervention. Surgery should not be attempted on breeding animals with a genetic predisposition.
- If the ectropion is moderately extensive, a full-thickness wedge resection may be indicated.
- If the ectropion is severe and is complicated by notching or other malformation of the eyelid, considerable reconstructive surgery may be necessary.
- The full-thickness wedge removal technique involves taking a full-thickness triangular wedge out of the lateral eyelid area. This procedure has a relatively high rate of dehiscence of the marginal portion of the incision. Close the conjunctiva first, using 6-0 absorbable suture and bury the knots under the conjunctiva, then close the skin with 4-0 or 5-0 silk. Use a “figure of 8” suture for the skin margin.
- May be wise to do a temporary tarsorrhaphy to minimize eyelid movement and stress on the incision site; sutures removed in 10-14 days
- Can use topical antibiotics and steroid afterward, but probably unnecessary

MEDICATIONS

DRUGS OF CHOICE

Topical antibiotics and steroids may be indicated.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PATIENT MONITORING

PREVENTION/AVOIDANCE

Cull affected animals that appear as genetic carriers. Avoid ophthalmic trauma and, if at all possible, do not perform entropion surgery on immature animals.

POSSIBLE COMPLICATIONS

Keratoconjunctivitis, dehiscence after surgery, recurrence

EXPECTED COURSE AND PROGNOSIS

Fair to good with surgery

MISCELLANEOUS

ASSOCIATED CONDITIONS

This condition may predispose to keratoconjunctivitis.

AGE-RELATED FACTORS

Generally found in young animals or postsurgical patients

EDEMA, PERIPHERAL

BASICS

OVERVIEW

- Edema is an abnormally increased accumulation of fluid in the interstitium.
- Edema in ruminants is most often caused by either increased intravascular hydrostatic pressure or decreased intravascular colloid osmotic (oncotic) pressure.

SYSTEMS AFFECTED

Multiple systems affected depending on underlying disease

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

All ruminant species affected

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

Edema can nearly always be distinguished from other causes of tissue swelling based upon whether or not a “pit” is left following firm, digital pressure applied to the tissue over several seconds. It is important to maintain the pressure over time to allow the excess fluid time to escape between the cells.

CAUSES AND RISK FACTORS

- Increased intravascular hydrostatic pressure:
 - Traumatic reticulopericarditis (“hardware disease”) leading to cardiac tamponade
 - Bacterial endocarditis
 - Adult/enzootic/BLV associated lymphosarcoma affecting the right heart base
 - Severe current or previous pneumonia or other primary lung disease leading to cor pulmonale
 - High altitude disease/brisket disease
 - Congenital heart defect
 - Thymic/adolescent lymphosarcoma
- Decreased intravascular oncotic pressure:
 - Protein losing enteropathies:
 - (a) Clinical parasitism.
 - (b) Johne’s disease/*Mycobacterium avium* subspecies *paratuberculosis*
 - (c) Bovine viral diarrhea

- (d) Salmonellosis
- Protein losing nephropathies:
 - (a) Pyelonephritis
 - (b) Renal amyloidosis

- Failure of the liver to produce adequate albumin:

This is rare in ruminants but can occur (e.g., in cases of severe protein or caloric malnutrition).

- Other causes:
 - Increased capillary permeability (e.g. insect or snake bite).
 - Obstruction of lymphatic return (e.g. thymic/adolescent lymphosarcoma).
 - Monensin or lasalocid toxicity.
 - Copper deficiency.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

- Cellulitis
- Urolithiasis
- Caval syndrome
- “Normal” edema in primiparous cows
- Neck chain or leg band applied too tightly restricting venous return
- Overzealous IV fluid administration

CBC/BIOCHEMISTRY/URINALYSIS

- Packed cell volume/total protein concentration
 - A PCV/TP is simple to run and can quickly help to distinguish between cardiac and oncotic causes of edema.
 - The TP must be interpreted with caution:
 - (a) Oncotic causes of edema are typically due to low albumin. Total serum protein includes other proteins (primarily globulin) in addition to albumin and may be within normal limits despite hypoalbuminemia.
 - (b) Dehydration can lead to the spurious conclusion that the total protein level is within normal limits in an animal with true hypoproteinemia. A PCV run on the same sample provides at least some reference for interpretation of the test vis-à-vis the animal’s hydration status.
- CBC/chemistry profile
- Hypoalbuminemia is suggestive of the low oncotic pressure causes of edema.
- Hyperglobulinemia is suggestive of a chronic inflammatory problem such as traumatic reticulopericarditis.
- Urinalysis
- Proteinuria is highly suggestive of a protein losing nephropathy.
- *Important note:* The pH of ruminant urine is often quite alkaline (high pH). At high pH, the protein indicator on urine test strips may be falsely positive.

OTHER LABORATORY TESTS

- Fecal flotation for parasite ova
- Johne’s test

IMAGING

Ultrasound may help to distinguish between edema and cellulitis.

OTHER DIAGNOSTIC PROCEDURES

- Cardiac auscultation. Note rate, rhythm, and the presence of any murmur. If a cardiac cause of edema is suspected, then the heart rate will generally be at least mildly elevated.
- Observation and palpation of venous (primarily jugular) distension. Note that the head must be elevated above the scapulohumeral joint. The jugular vein is normally moderately distended ventral to the level of the scapulohumeral joint.

- Palpation of peripheral lymph nodes

PATHOLOGICAL FINDINGS

Findings will be dependent upon the underlying disease.

TREATMENT

- Edema is not a disease but rather a manifestation of disease. In general, the treatment for edema is to treat the underlying disease.
- Animals receiving intravenous fluid therapy (e.g., neonatal diarrhea) sometimes over time develop edema due to decreased intravascular oncotic pressure. In these cases, it is necessary to switch to plasma (preferred) or colloids for volume expansion.

MEDICATIONS

DRUGS OF CHOICE

- Furosemide: 0.05 to 1.0 mg/kg IV or IM
- Dexamethasone: Approximately 0.04 mg/kg IV or IM
- Naquasone (dexamethasone 5 mg and trichlormethiazide 200 mg) bolus: 1 to 2 boluses initially followed by 1/2 to 1 bolus daily for udder edema

CONTRAINDICATIONS/POSSIBLE INTERACTIONS

- Dexamethasone should be used cautiously when a concurrent infectious process is or may be present.
- Drug withdrawal time periods for meat and milk need to be followed.

FOLLOW-UP

N/A

MISCELLANEOUS

- Some degree of udder edema in primiparous dairy cows is normal. This is secondary to the changes that occur in the vascular system of the udder when the first calf is born.
- Severe edema can have deleterious effects (mastitis, increased susceptibility to herpes mamillitis, etc.).
- Investigations of herd problems with abnormally severe udder edema in first calf cows should initially focus upon the immediate prefresh diet of the heifers, specifically levels of minerals (sodium particularly), readily fermentable carbohydrate (starch), and protein.

EMBRYO CRYOPRESERVATION

BASICS

OVERVIEW

Embryo cryopreservation (or freezing) is a method of holding embryos in a suspended metabolic state for a number of reasons.

- Transfer into recipients at a more suitable time
- Transport embryos to a distant location
- Market high value genetics
- Schedule embryo transfer (ET) when recipients are available.
- Embryo cryopreservation is also a primary reason that bovine ET is a large industry in the United States (over half of the bovine embryos collected in 2003 in the United States were cryopreserved).

PATHOPHYSIOLOGY

Advantages of embryo cryopreservation compared to ET of fresh embryos:

- Allows calves to be born during a favorable season of the year
- Allows many embryos to be transferred at a single location
- Allows synchronized recipients to be utilized if few fresh embryos are collected on a given day

SYSTEMS AFFECTED

Endocrine/metabolic, reproductive

SIGNALMENT

Embryos from some breeds of cattle (i.e., *Bos indicus* and Jersey) may exhibit a low pregnancy rate following ET, perhaps due to lipid content in the cytoplasm of embryo cells.

SIGNS

N/A

CAUSES AND RISK FACTORS

The bovine uterus is highly immunocompetent; however, introduction of foreign material during ET (of fresh or frozen embryos) is possible.

DIAGNOSIS

In order to recover embryos for cryopreservation, the uterus of the donor female is lavaged (usually 7 days after estrus) with a simple isotonic salt solution. Donor females are generally stimulated with FSH to produce multiple ovulations and are then inseminated (usually via AI) to allow for fertilization. Embryos are recovered and staged (according to the IETS) as the following (on day 7):

- Stage 3 = Degenerate
- Stage 4 = Morula
- Stage 5 = Early blastocyst
- Stage 6 = Full blastocyst
- Stage 7 = Expanding blastocyst
- Stage 8 = Hatched blastocyst

There may also be unfertilized ova. Within each stage classification embryos are graded (grade 1, 2, or 3 with 1 being the highest quality). Grade 3 embryos are usually not cryopreserved due to poor conception rates post thaw.

DIFFERENTIAL DIAGNOSIS

N/A

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

Bovine embryos are approximately 150 μm in diameter and must be visualized with the aid of a microscope ($\geq 60\times$ magnification).

DIAGNOSTIC PROCEDURES

Grading embryos is a subjective process.

**TREATMENT*****Cryopreservation Technique***

- Embryos can be equilibrated and cryopreserved in a variety of medias that contain different cryoprotectants usually involving a gradual cooling process:
 - Glycerol (1.0–1.5 M)
 - Ethylene glycol (1.0–2.0 M)
- Embryos can also be rapidly cryopreserved (vitrification) using a much higher concentration of cryoprotectants (Gly = 5.0–7.0 M, EG = 3.0–8.0 M). Regardless of technique, embryos are usually cryopreserved in 1/4 or 1/5 ml plastic straws and housed in properly identified goblets and canes.
- Gradual cooling protocols initiate freezing at -7.0°C and cool at a rate of about 0.5°C per minute to -35°C . Before the embryos begin the cooling ramp, they are “seeded” to initiate ice crystal formation and prevent negative effects of latent heat. Embryos are plunged into liquid nitrogen (-196°C) after reaching -35.0°C . Vitrification is a protocol in which the embryos in the highly concentrated cryoprotectant media are introduced into liquid nitrogen after a short time (1–10 minutes).

Thawing Technique

Most thawing protocols employ a 5–10 second air thaw, and then a 20–30 second submersion in a 30°C water bath. In order to slowly replace the Gly with water and prohibit embryo cells from rupturing, embryos cryopreserved in Gly require a stepwise removal of the Gly usually buffered with varying sucrose concentrations. Embryos cryopreserved with EG can be thawed and transferred directly (DT) to the waiting recipient. Depending upon concentration and type of cryoprotectants, vitrified embryos can be slowly rehydrated during the thawing process or transferred directly.

**MEDICATIONS****DRUGS OF CHOICE**

N/A

CONTRAINDICATIONS

N/A

PRECAUTIONS

Some cryoprotectants can be absorbed through the skin, and possibly the uterine endometrium following ET. Exposure effects of small amounts of cryoprotectants are not described.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Pregnancy rates of embryos following cryopreservation, thawing, and ET are variable and related to many factors.

- Embryo/recipient synchrony
- Embryo quality
- Stage of embryo development
- Recipient quality

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Advantages of DT embryos
 - No microscope needed
 - Limited assistance needed
 - Reduced thaw time
- Advantages of Gly embryos
 - Enables postthaw grading and evaluation of embryos
 - May be required by some breed registries
- Advantages of vitrified embryos
 - No intercellular ice crystals
 - Enables many embryos to be frozen in a short time

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Pregnancy rates following ET of cryopreserved/thawed bovine embryos range (40%–60%).

RUMINANT SPECIES AFFECTED

Cattle

BIOSECURITY

Embryos should be frozen in sealed straws regardless of protocol to prevent viral/bacterial contamination.

PRODUCTION MANAGEMENT

DT embryos have distinct time and resource management advantages.

EMESIS

BASICS

OVERVIEW

- Emesis, or vomiting, is a centrally mediated event originating in the medulla.
- The medullary vomiting center can be stimulated by visceral afferent stimuli or by stimulation of the chemoreceptor trigger zone.
- In ruminant species, activation of the chemoreceptor trigger zone most often results from stimulation via toxins.
- Emesis is an unusual occurrence in ruminant species.

GENETICS

No genetic factors have been identified in animals that vomit, however management factors may play a significant role when vomiting is observed in calves.

SIGNALMENT

Species

- All ruminant species may be affected.
- Sheep and goats may be more affected than cattle due to their dietary indiscretions but signs may be observed in any adult ruminant.

Breed Predilection

N/A

Mean Age and Range

- Emesis can occur in any age animal.
- In young animals, emesis may result from congenital anomalies such as persistent right aortic arch or esophageal diverticula.
- Young animals are also more prone to diseases such as meningitis and may suffer trauma to the central nervous system.
- It is very rare to observe vomiting in animals less than 6 months of age due to lack of exposure to agents that cause vomiting.

Predominant Sex

N/A

SIGNS

- Signs of anorexia and hypersalivation typically precede emesis.
- Emesis involves coordinated contractions of the abdominal and diaphragm muscles with concurrent relaxation of the cardia.

CAUSES AND RISK FACTORS

- Workup of a case involving emesis (true vomiting) must include attainment of an appropriate history, physical examination, and examination of the environment in which the animal or animals reside.
- History most commonly associated with signs of emesis includes potential exposure to various toxins or poisonous plants. This is especially pertinent when multiple animals are showing signs.
- Toxins that can result in emesis include methanol or ethanol, copper, phosphorus, arsenic, nitrates, snakebite, and petroleum products.
- Numerous poisonous plants can cause emesis and exposure is clearly dependent on plant availability. A partial list of plants includes
 - Castor bean
 - Cocklebur

Cyanogenic plants (Arrow grass, Johnson grass, Sudan grass, chokecherry, elderberry, etc.)

Delphinium (larkspur)

Laurel

Melia (chinaberry)

Nitrate accumulators (pigweed, lamb's quarter, Jimson weed, fireweed, dock, Johnson grass, oats, millet, rye, corn, sorghum, etc.)

Oleander

Solanum spp.

Veratrum (hellebore)

Zigandenus spp. (death camas)

- Other conditions that have been associated are difficult dental eruptions or tooth root abscesses, late-stage hypocalcemia, grain overload, traumatic reticuloperitonitis, diaphragmatic hernia, abomasal impactions, and vagal indigestion.
- Outbreaks of vomiting in a herd situation are likely due to ingestion of spoiled corn silage or ingestion of toxic plants such as azaleas, rhododendrons, lily of the valley, or sneezeweed. A report of a flock outbreak in sheep was attributed to gram-negative endotoxins that had contaminated a shipment of prepared feed.

DIAGNOSIS

Based on history and clinical signs

DIFFERENTIAL DIAGNOSIS

- Most cases of feed returning to the mouth of ruminants is due to regurgitation (i.e., reflux of esophageal or rumen contents into the mouth or nose).
- Excessive regurgitation typically results from physical blockage of the esophagus, cardia, or rumenoreticular outflow.
- Common conditions resulting in regurgitation include foreign bodies, tumors, papillomas, granulomas, abscesses, diaphragmatic hernia, or esophageal irritation.
- Pharyngeal lesions (e.g., balling gun injury) may also cause gagging or retching, but this is not true emesis.
- Passage of a stomach tube may aid in determining if the normal passage of ingesta from mouth to cardia is impeded.

CBC/BIOCHEMISTRY/URINALYSIS

In chronic cases, a CBC may be of benefit to identify elevated fibrinogen levels if the cause is associated with an esophageal abscess. Clinical signs of hypocalcemia will be confirmed with a biochemistry profile. Electrolyte profiles can be helpful in correcting bicarbonate deficits and hydration status.

OTHER LABORATORY TESTS

N/A

IMAGING

- None directly applicable to emesis; however, ultrasound, radiology (plain or contrast), and endoscopy may be considered to assist in ruling out pharyngeal or esophageal disease.
- Contrast radiography of the cervical and thoracic regions is beneficial in defining obstructive lesions associated with the esophagus. Barium studies can be helpful in small ruminants.

PATHOLOGICAL FINDINGS

- Toxins or toxic plants present in forestomachs
- CNS lesions involving medulla

TREATMENT

- Removal of animals from offending toxin or toxic plants
- Specific antidotes or treatments for various toxins may be indicated.
- Rumenotomy may be indicated.

- The use of laxatives or ruminotorics to increase forestomach motility and passage of ingesta is unlikely to be of practical benefit in an animal that is actively vomiting.
- Transfer of fresh rumen fluid from a healthy donor is likely to restore rumen flora and function once the vomiting has ceased.

MEDICATIONS

DRUGS OF CHOICE

Magnesium oxide, activated charcoal and mineral oil are indicated as an aid in removing or limiting absorption of toxins. Antibiotics may be used to prevent bacterial sepsis associated with rumenitis.

CONTRAINDICATIONS

- The use of anti-emetics (e.g., phenothiazines, antihistamines, metaclopramide) in ruminant species is not well documented.
- It may be contraindicated to chemically block the elimination of toxicants from the forestomach of an animal actively vomiting
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food producing animals.

FOLLOW-UP

PATIENT MONITORING

Monitor patient for continued signs of emesis and possible complications.

PREVENTION/AVOIDANCE

Avoid exposure to poisonous plants or toxic compounds.

POSSIBLE COMPLICATIONS

- Complications associated with emesis (or regurgitation) include aspiration pneumonia, dehydration, electrolyte derangements, or acid-base abnormalities.
- The term “internal vomiting” has been used to describe a form of vagal indigestion whereby abomasal outflow is blocked and the abomasal contents are refluxed into the reticulorumen.
- Hypochloremic metabolic alkalosis often results from internal vomiting, conceivably could occur with emesis.

EXPECTED COURSE AND PROGNOSIS

- Depending on the dose and duration of a toxic insult, prognosis is guarded to good if animals are immediately removed from the source of the toxin.
- Complications including metabolic derangements and aspiration pneumonia worsen the prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- In young animals, emesis may result from congenital anomalies such as persistent right aortic arch or esophageal diverticula.

ENDOMETRITIS

BASICS

DEFINITION

- Endometritis is inflammation of the lining of the uterus (endometrium) without systemic illness. It is associated with chronic bacterial infection of the uterus beyond 3 weeks postpartum and is characterized by purulent uterine discharge and delayed involution of the reproductive tract.
- Endometritis has clinical importance to the extent that it causes impaired fertility in the breeding period.
- There are few clinical trials with validated diagnostic criteria, economically meaningful outcomes, and correct analyses, resulting in controversy over the optimum methods of diagnosis and treatment.

PATHOPHYSIOLOGY

- Contamination of the uterus with a wide variety of bacteria is nearly universal after calving.
- The key element in the pathophysiology of endometritis is the immune response of the uterus to effect uterine involution and to clear bacterial infection.
- The central mechanism of bacterial clearance is nonspecific immunity (phagocytosis by neutrophils). By 3 to 4 weeks postpartum, the number of bacteria and the variety of species have diminished substantially in healthy cows.
- In cows with clinical endometritis, the most common isolates are *Arcanobacterium pyogenes*, *Streptococcus* spp., and *E. coli*.
- The only bacterium that is consistently associated with uterine inflammation is *A. pyogenes*. This opportunistic, gram-positive facultative anaerobe is commonly present in mixed culture with a wide variety of organisms, but most often with the gram-negative anaerobes *Fusobacterium necrophorum* and *Prevotella melaninogenica* (formerly *Bacteroides melaninogenicus*).
- Toxins and enzymes from these bacteria cause inflammation of the endometrium, which may impair ovarian function and inhibit establishment of pregnancy.

SYSTEMS AFFECTED

Reproductive

GENETICS

No known association

INCIDENCE/PREVALENCE

- The reported prevalence of postpartum endometritis varies widely, depending on the case definition and method of diagnosis, and the interval postpartum at examination. Unfortunately, in many studies, the case definition was not explicit, and in most cases was not validated as being associated with reproductive performance.
- The incidence of endometritis in a review of 43 studies ranged from 2% to 37.3%, with a median of 10%.
- Using validated diagnostic criteria, between 3 and 5 weeks postpartum the prevalence was 17%, varying among herds from 5% to 26%.

GEOGRAPHIC DISTRIBUTION

Worldwide, in intensively managed dairy cattle

SIGNALMENT

Species

Cattle; predominantly dairy cattle; 3 to 8 weeks after calving

Breed Predilections

None known

Mean Age and Range

Lactating adults; all parities affected, but more common in older (\geq third parity) than younger cattle

Predominant Sex

Females only

SIGNS

Mucopurulent or purulent discharge from the vulva, but this sign is frequently not observed by chance alone. Internal examination is required.

HISTORICAL FINDINGS

Cows with endometritis will frequently have been affected with one or more risk factors early in the current lactation.

PHYSICAL EXAMINATION FINDINGS

- It is important to interpret physical exam findings in light of normal postpartum involution of the reproductive tract, and to allow time for involution to occur in healthy cattle before making a diagnosis of endometritis.
- Although data on normal involution are piecemeal, on average, healthy cows achieve a stable uterine horn diameter of 4–5 cm by 25–30 DIM, and cervical diameter < 5 cm by 40 DIM.
- Lochia is normally passed until 14–23 DIM and, over the course of involution, lochia changes from thin red-brown fluid to more viscous sanguineous-purulent to yellow-white mucous liquid. Complete microscopic involution takes until approximately 40 DIM. Therefore, examination of cattle for endometritis should be done no sooner than 3 weeks postpartum. Practically, diagnosis and treatment should only be initiated 4 weeks after calving (i.e., > 28 to 30 DIM).
- Examination should include visual inspection of the perineum for fresh mucopurulent or purulent discharge. Vaginoscopy is recommended to improve both the sensitivity and specificity of diagnosis. Insertion of a clean-gloved hand after wiping the vulva with a paper towel is an alternative to vaginoscopy. At 4 weeks postpartum, mucopurulent or purulent discharge (but not mucus with flecks of pus) from the cervix, and cervical diameter > 7.5 cm are significantly associated with increased time to pregnancy.
- Transrectal palpation of the uterus has traditionally been the means of diagnosis of endometritis, but this method is subjective and has poor sensitivity and specificity for identifying cows with impaired fertility.
- Given knowledge about cervical discharge and size, palpation of uterine size, symmetry, and texture had no predictive value for reproductive performance.
- There is some evidence to suggest that blanket treatment of cows with RP, dystocia, or purulent vulvar discharge noticed by the herd manager after 13 DIM, without any examination to specifically diagnose endometritis, may be economically advantageous at the herd level. However, the value of the effort for individual diagnosis and treatment depends on the sensitivity and specificity of the diagnostic criteria, the prevalence of endometritis, and the cost and efficacy of treatment.
- Additionally, there are cows without these risk factors that have clinical endometritis (detectable by examination of vaginal discharge).

CAUSES

- Failure of uterine immune defenses resulting in chronic bacterial infection of the uterus that persists beyond 3 weeks postpartum
- The central etiologic agent is *Arcanobacterium pyogenes*, although there is commonly a mixed infection with anaerobes (*Fusobacterium necrophorum*, *Prevotella melaninogenica*).

RISK FACTORS

RP, dystocia, twins, metritis, and clinical ketosis are risk factors for endometritis, the greatest of which is RP. However, in one large field trial with a validated case definition, over half the cows with clinical endometritis did not have any of the significant risk factors (twins, RP, or metritis).

DIAGNOSIS

For reproductive examinations before the breeding period to have value, they must identify cows at increased risk of failure to become pregnant in a timely way and that may benefit from treatment.

DIFFERENTIAL DIAGNOSIS

Pyometra (uterus filled with pus, with a CL present); metritis (more severe uterine infection with systemic signs including fever; occurs in the first week postpartum)

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Uterine bacteriologic culture (collected transcervically using a guarded swab) or uterine biopsy (using mare biopsy forceps) might be useful to investigate unusual cases or epidemics but are not useful for routine diagnosis.
- Subclinical endometritis can be diagnosed by uterine cytology, either by transcervical cytobrush, or flush and aspiration of 20–60 ml of saline, centrifugation, and staining of smears. This technique is novel in cattle, but cows with > 5% or > 18% neutrophils at 5 weeks postpartum, or > 1% at 40–60 DIM in the absence of clinical signs (see below) had reduced reproductive performance.

IMAGING

Subclinical endometritis can be diagnosed by transrectal ultrasonography on the basis of fluid in the uterine lumen.

DIAGNOSTIC PROCEDURES

Inspection of uterine/vaginal discharge by vaginoscopy or manual examination with a clean glove, as well as transrectal palpation of the diameter of the cervix; palpation of the diameter of the uterine horns (>8cm diameter) may be useful in the absence of inspection of vaginal discharge, but is an insensitive method.

PATHOLOGIC FINDINGS

Histologically, disruption of the endometrial epithelium, infiltration of inflammatory cells, and accumulations of lymphocytes, vascular congestion, and stromal edema

APPROPRIATE HEALTH CARE

Outpatient medical

NURSING CARE

N/A

ACTIVITY

As usual

DIET

As usual

CLIENT EDUCATION

See Prevention/Avoidance below.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

- The general principle of therapy for endometritis is to reverse inflammatory changes that impair fertility by reducing the load of pathogenic bacteria and enhancing the processes of uterine defense and repair.
- Well-designed, appropriately analyzed, large-scale field studies of the diagnosis and treatment of endometritis with both an objective case definition and economically meaningful outcomes are lacking. Many therapeutic trials suffer from a lack of negative controls, small numbers of animals resulting in little statistical power, or both. Most investigations have used diagnostic criteria that were not validated as to their effect on reproductive performance, making it difficult or impossible to discern a true treatment effect.

DRUGS OF CHOICE

- IU Antibiotic—the principle is to reduce the load of pathogens. There are two valid studies showing that one treatment of 0.5 g cephalixin benzathine IU at approximately 30 DIM reduced time to pregnancy relative to untreated cases.
- PGF—the principle is to induce luteolysis and in turn, estrus. Reducing or removing the influence of progesterone on the

uterus and causing myometrial contractions should enhance resolution of endometritis. There is controversy over whether PGF causes myometrial contraction or other benefits for treatment of endometritis in the absence of a CL. On balance, PGF is most effective when a CL is present. Although clear-cut data are lacking, IM injection of PGF (0.5 mg cloprostenol or 25 mg dinoprost) after approximately 30 DIM is likely beneficial as treatment for endometritis. A second administration of PGF 14 days later may provide additional benefit, although clinical trial data are lacking.

CONTRAINDICATIONS

Use of PGF before approximately 26 DIM is controversial. Some studies suggest beneficial effects, many suggest no benefit, and a few report a deleterious effect on subsequent reproductive performance among cows with endometritis.

PRECAUTIONS

- Cephapirin benzathine is approved for use in lactating cows in Canada and the European Union, but not in the United States. IU tetracycline and other antibiotics may result in violative drug residues in milk.
- Drug withdrawal times need to be determined and maintained for all treated food animals.

POSSIBLE INTERACTIONS

None known

ALTERNATIVE DRUGS

There are reports of treatment of endometritis by IU infusion of oxytetracycline, crystalline penicillin G, and numerous other antibiotics, as well as Lugol's iodine, povidone iodine, and other disinfectants, and systemically administered estradiol, tetracycline, penicillin, and ceftiofur. There is little evidence that any of these improve reproductive performance, and several of the IU substances may cause damage to the endometrium or to uterine defenses.

FOLLOW-UP

PATIENT MONITORING

Follow-up examination and repeated treatment 2 weeks after initial diagnosis and treatment (i.e., at approximately 45 DIM) might be useful to identify refractory cases. However, in almost 80% of cases, clinical signs will be resolved by this time, even if untreated.

PREVENTION/AVOIDANCE

- The key element in establishment of chronic uterine infection appears to be the effectiveness of uterine defense mechanisms in clearing the inevitable infection. However, there is little information on preventive measures specific to endometritis.
- Management and nutritional practices that prevent dystocia, RP, and metritis by favoring peripartum immune function (e.g., transition diet to meet or exceed NRC 2001 for > 3 weeks prepartum with average DMI > 12 kg/cow/day, > 60 cm manger space/cow, calving at BCS = 3.5 out of 5) will plausibly reduce the incidence of endometritis.

POSSIBLE COMPLICATIONS

- Given the case definition of a localized uterine condition, there is no mortality attributable to endometritis, and no direct loss of milk production. Reports have shown an increase in the mean calving to pregnancy interval from 7 to 48 days for cows with endometritis compared to unaffected herd mates, despite various treatments administered to affected animals.
- A meta-analysis of 23 studies found that endometritis increased mean days open by 15, decreased the relative risk of pregnancy by 150 DIM by 31%, and reduced the rate at which cows became pregnant by 16%.
- Cows with mucopurulent or purulent cervical discharge or cervical diameter > 7.5 cm at approximately 4 weeks postpartum had an increase of 32 days in median time to pregnancy over unaffected cows.

EXPECTED COURSE AND PROGNOSIS

Affected cows take longer, and are at increased risk of failure to become pregnant. Clinical signs will be resolved by 60 DIM in > 95% of cases after one (or in a minority of cases, two) treatment with cephapirin IU or PGF. The issue is how many of these are truly cured as opposed to cases of ongoing subclinical endometritis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Cows with endometritis may be at greater risk of pyometra.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Bovine (common), caprine, ovine, camelid (uncommon)

BIOSECURITY

The bacteria that appear to be a necessary cause of endometritis are ubiquitous opportunists and there is no evidence that they are contagious; their presence on the farm or even in the reproductive tract is not by itself sufficient to cause disease. Therefore, prevention of new cases should be directed as nonspecific enhancement of immunity in peripartum animals.

PRODUCTION MANAGEMENT

N/A

SYNONYMS

Uterine infection (commonly but incorrectly referred to interchangeably with metritis)

SEE ALSO

Metritis

Pyometra

ABBREVIATIONS

BCS = body condition score

CL = corpus luteum

DIM = days in milk (days after calving)

DMI = dry matter intake

IM = intramuscular

IU = intrauterine

NRC = National Research Council

PGF = prostaglandin F₂ γ

RP = retained placenta

ENTROPION

BASICS

DEFINITION

Entropion is an inversion or rolling in of the eyelid, most commonly the lower lid. The condition can be congenital or acquired, and usually leads to trichiasis, which can cause severe corneal damage. This in turn causes blepharospasm, which aggravates the entropion.

PATHOPHYSIOLOGY

Hereditary, congenital, or secondary to trauma/irritation; causes pain and damage to the cornea when the eyelashes, skin, and hair rub on the cornea

SYSTEMS AFFECTED

Ophthalmic: may cause blindness if chronic

GENETICS

Hereditary; entropion can be either congenital or acquired. Congenital entropion may not manifest itself initially, and it may be inherited in certain breeds.

INCIDENCE/PREVALENCE

Can range from 1 to 80% in a given flock

GEOGRAPHIC DISTRIBUTION

Worldwide depending on species

SIGNALMENT

Species

- Common in lambs, uncommon in cattle, usually dehydrated neonates. Has been observed in camels.
- Potentially, all ruminant species

Breed Predilections

N/A

Mean Age and Range

Common in lambs, usually the lower eyelid; uncommon in cattle, usually dehydrated neonates.

Predominant Sex

N/A

SIGNS

HISTORICAL FINDINGS

Types

- *Spastic entropion*— Due to painful lesion of the globe (e.g., keratitis, corneal ulcer); almost always a complication of entropion due to other causes
- *Cicatricial entropion*— Following inflammation, trauma, or surgery of eyelids
- *Anatomic entropion*— Usually congenital, but may become worse as postnatal development progresses and is often heritable; many of these animals have an abnormally long eyelid, particularly on the lower lid margin.

PHYSICAL EXAMINATION FINDINGS

- Blepharospasm, ocular discharge, corneal ulceration in chronic cases
- The eyelids are examined for abnormalities of position, function, and structure, such as lagophthalmos, ptosis, trichiasis, ectropion, entropion, blepharitis, lid neoplasms.
- Clinical signs seen with entropion include epiphora, blepharospasm, conjunctivitis, and keratitis. The amount and type of signs varies with the extent of involvement and duration.

- Medial entropion may occlude the lower lacrimal punctum.

CAUSES AND RISK FACTORS

May be secondary to keratoconjunctivitis; inflammation causes a predisposed eyelid to roll inward.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Clinically obvious, rolling the thumb under the eye and seeing the lid unroll confirms presence of entropion.
- *Chlamydia psittaci* is unilateral, becoming bilateral in 7 to 14 days. Early in the disease, the conjunctiva is chemotic, glistening, and grayish-pink, and the ocular discharge is serous. Sneezing is present early in the disease.

Severe blepharospasm occurs and may cause a secondary spastic entropion.

- Differentiate between primary and secondary entropion, however, need to treat either way.
- Differential for persistent corneal ulcer: entropion, KCS, foreign bodies, ectopic cilia, and infection

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Culture and cytology of ocular secretions if underlying cause suspected
- Cultures of the external ocular structures must be done before extensive cleaning is done and before drugs are instilled.
- Sterile swabs are used to collect material for culture. The swab should be moistened. The moistened swab is rubbed over the area to be cultured taking care to avoid skin, hair, and other nearby structures.
- Bacterial identification and disc sensitivity tests aid in the choice of antimicrobial therapy.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

- Examination of the cornea is incomplete without utilization of topical ophthalmic stains.
- Fluorescein is used to demonstrate the presence or absence of corneal ulcers. For topical use, fluorescein-impregnated paper strips are preferred to fluorescein solution to insure sterility.
- The corneal epithelium is lipid selective and prevents any appreciable corneal penetration by fluorescein. In the presence of a corneal epithelial defect, the dye rapidly diffuses into the corneal stroma.

PATHOLOGIC FINDINGS

N/A

TREATMENT

- In lambs, the eyelid often needs to be everted long term, until maturity normalizes the conformation.
- Always evaluate the problem after topical anesthesia to decrease the spastic component. Surgical correction should only involve the anatomic or cicatricial component.
- Medical treatment of entropion involves ocular lubricant ointments, such as Lacrilube, Dura Tears, or Hypotears.
- There are many methods of correction, but the simplest and usually most effective is the skin and muscle resection.
- With large flocks of affected lambs, it may be impractical to do surgery. In this case, 0.5–1.5 ml of 70% ethanol injected subcutaneously in the affected eyelid in the area of the entropion (about 0.5–1.0 cm below eyelid margin) will usually cure the entropion. Penicillin can be substituted for the ethanol.

ACTIVITY

N/A

DIET

N/A

CLIENT EDUCATION

Due to the hereditary nature of this condition, the client should be discouraged from breeding the same lines of sheep to prevent the occurrence in the future.

SURGICAL CONSIDERATIONS

- If the cause of the entropion is excessive eyelid length, the treatment involves shortening the eyelid. You may choose to do a simple full-thickness wedge resection; the resection should be within the lateral one-third of the eyelid.
- Surgical Technique: under anesthesia, a modified Hotz-Celsus resection can be performed in which a section of skin is removed from under the eyelid and the resulting sutures pull the eyelid out. Towel clamps or forceps can be used to initially decide how much tissue needs to be removed, and then the incisions are made parallel to and 2 mm from the eyelid to remove a strip of tissue. Nonabsorbable interrupted sutures close the defect and hold the lid out. Slight undercorrection is advised due to wound contracture. Be sure loose ends of the stitches do not rub the cornea.

MEDICATIONS

DRUGS OF CHOICE

Broad-spectrum antibiotics are usually administered if corneal ulceration is present; culture and sensitivity tests can guide selection in recurring, nonhealing, or infected ulcers.

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Topical corticosteroids and anesthetics are contraindicated when the cornea retains fluorescein stain.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

Concurrent corneal disease (e.g., ulcer from eyelid rubbing) also should be treated.

POSSIBLE COMPLICATIONS

Corneal ulcers, dehiscence of sutures/staples, recurrence

FOLLOW-UP

EXPECTED COURSE AND PROGNOSIS

Immediate relief from pain and epiphora unless there is underlying infection. Prognosis is good as long as lid eversion is maintained.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Secondary to or predisposes to keratoconjunctivitis

AGE-RELATED FACTORS

Young most commonly affected (lambs by day 2 or 3 of age).

ZOONOTIC POTENTIAL

Chlamydia psittaci may cause disease in humans.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Sheep most commonly; potentially all ruminant species are affected.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

Remove mothers and offspring from the breeding program, as the condition is hereditary.

ENZOOTIC ATAXIA

BASICS

OVERVIEW

Enzootic ataxia is a disease of newborn or young lambs. It is most frequently associated with lambs born of ewes with a deficiency of copper in the diet.

PATHOPHYSIOLOGY

- Abnormal bone growth and increased fragility of bones predisposing to fractures of long bones is apparently due to defects in development of connective tissue and growth plates.
- Hypomyelinogenesis occurs in utero or shortly after birth in affected kids and lambs resulting in a progressive ataxia, muscle atrophy, paresis, and paralysis.
- Affected animals have stiffness of the back and legs and are reluctant to rise. When individuals do stand, there is a characteristic swaying of the hindquarters.
- Other neurologic signs can include blindness, obtundation, and head tremor.
- There may be persistent diarrhea, unthriftiness, and poor fleece in lambs.
- The pathogenesis is not known.

SYSTEMS AFFECTED

Musculoskeletal, CNS, hair/wool, production management

GENETICS

There is a possible familial predisposition.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide distribution

SIGNALMENT

Species

Sheep, goats, blesbok (*Damaliscus dorcas phillipsi*), black wildebeest (*Connochaetes gnou*), sika deer (*Cervus nippon Temminck*), bactrian camels, red deer, *Cervus elaphus*, beef cattle, and piglets may be affected.

SIGNS

- Affected animals may appear normal at birth.
- Clinical signs usually occur within the first 6 months of life.
- Ewes are often asymptomatic, but may have “stringy” appearance to the wool or osteoporosis.
- Depigmentation of hair coat is noticeable in darker colored animals. Commonly occurs around the eyes giving a “spectacled” appearance.

CAUSES AND RISK FACTORS

- Copper deficiency in the dam’s diet is responsible for the clinical signs; however, the pathogenesis is not known. It is speculated that copper deficiency results in altered cellular respiration and reduced synthesis of myelin. It may also result in reduced synthesis of noradrenaline and increase dopamine in tissues.
- Animals raised on pasture with copper deficient soil are at greater risk of disease.
- There is a possible familial predisposition.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Molybdenum toxicity causes improper copper metabolism and causes the same clinical signs as copper deficiency.
- Sulfur
- In young kids, signs resemble the neurologic form of caprine arthritis and encephalitis (CAE) virus infection.
- The diarrhea associated with enzootic ataxia is commonly mistaken for internal parasitism, although it is possible for both conditions to be present, especially in animals raised on pasture.

CBC/BIOCHEMISTRY/URINALYSIS

Ewes may be anemic.

OTHER LABORATORY TESTS

There may be decreased copper levels in blood and liver.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Generally diagnosed based on clinical signs with possible decreased blood or liver copper levels.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- Possible symmetric cavitations in the subcortical white matter can lead to secondary hydrocephalus.
- In severe cases, little is left of the hemispheres except the cortical shell of gray matter.

HISTOPATHOLOGICAL FINDINGS

- White matter neuronal degeneration or necrosis can be found in the central portions of the cerebral hemispheres, brain stem, and spinal cord.
- Demyelination occurs in the brain stem and spinal cord. Myelinated tracts may have a spongy appearance with some collections of gitter cells.
- Chromatolysis of neurons in the red nucleus may occur.

TREATMENT

Evaluate copper status of the herd and soils where animals are pastured. Copper supplementation should be provided as needed.

MEDICATIONS

None

CONTRAINDICATIONS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

Provide appropriate copper/mineral supplements. Supplements can be administered in various forms such as a top dressing to pasture or feed, or a weekly drench given to individual animals.

POSSIBLE COMPLICATIONS

None

EXPECTED COURSE AND PROGNOSIS

- Prompt supplementation with copper may improve signs.
- Severely affected animals may have permanent neurologic deficits.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Copper supplementation can be toxic to treated animals.

AGE-RELATED FACTORS

The onset of clinical signs usually occurs between 1 week and 6 months of age.

ZOONOTIC POTENTIAL

None

PREGNANCY

Maternal copper deficiency is cause of clinical disease in lambs and kids.

SYNONYMS

Swayback

ENZOOTIC PNEUMONIA OF CALVES

BASICS

DEFINITION

Respiratory disease complex of young calves less than 6 months of age caused by multiple etiologic agents, a decreased host defense system, and environmental risk factors such as poor ventilation and overcrowding.

PATHOPHYSIOLOGY

- The bacterial pathogens involved with this disease are normal inhabitants of the nasal and pharyngeal mucosa.
- Host and environmental factors combine to weaken the normal pulmonary defense mechanisms.
- Viral infections cause damage to the mucosal lining of the upper respiratory tract and may reduce the production of secretory defenses.
- Viral infections may also have an effect on alveolar macrophages or neutrophils, which can enhance bacterial adherence.
- Factors such as failure of passive transfer, stressors such as overcrowding and mixing, poor ventilation, and high relative humidity also allow the proliferation of these opportunistic bacteria.

SYSTEMS AFFECTED

Respiratory

GENETICS

N/A

INCIDENCE/PREVALENCE

- Based on producer diagnosis, 7.4%–11% of dairy calves
- Based on veterinary diagnosis, 25.6%–29% of dairy calves

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Species

- Most common in housed dairy calves and veal calves
- Beef calves in crowded conditions

Breed Predilections

N/A

Mean Age and Range

- Calves less than 6 months of age
- Peak incidence at 5–6 weeks of age

Predominant Sex

N/A

SIGNS

N/A

HISTORICAL FINDINGS

- Multiple animals depressed and febrile
- Partial anorexia
- Increased respiratory rates
- Coughing
- Nasal discharge

- Lacrimation
- Decreased weight gains
- Rough hair coats
- High morbidity
- Low mortality

PHYSICAL EXAMINATION FINDINGS

- Fever (39.5°C–40.5°C)
- Polypnea
- Mild to severe dyspnea
- Abnormal cranioventral lung sounds such as loud harsh breath sounds, crackles, and wheezes
- Harsh, dry, cough response on tracheal compression
- Intensity of heart sounds is increased dorsal to heart base.

CAUSES

Multifactorial etiology

Primary Infectious Agents

- *Mycoplasma bovis*
- *Mycoplasma dispar*
- Other *Mycoplasma* spp.
- Bovine respiratory syncytial virus
- Parainfluenza-3 virus
- Bovine herpesvirus-1
- Bovine viral diarrhea virus
- Bovine adenovirus
- Bovine coronavirus

Secondary Agents

- *Mannheimia haemolytica*
- *Pasteurella multocida*
- *Histophilus somnus*
- *Arcanobacterium pyogenes*

RISK FACTORS

- Inadequate housing
- Poor ventilation
- Housing calves together in large groups
- Grouping calves together of various ages
- Direct contact with older animals
- Low colostral immunity
- Birth outside the maternity pen
- Overcrowding
- High relative humidity
- Large daily temperature range

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pneumonia caused by *Mannheimia haemolytica*
- Aspiration pneumonia
- Congenital cardiac defects

- *Histophilus somnus* pneumonia

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Isolation and identification of organisms

- Nasopharyngeal swabs
- Transtracheal washes
- Lung lavage samples
- Serological tests for confirmation of BRSV infections
- Immunohistochemistry, virus isolation or antigen capture ELISA for identification of persistently infected BVDV calves

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Extensive anteroventral lung consolidation
- Fibrinous pleuritis
- Suppuration and abscessation of lungs
- Severe interstitial pneumonia associated with BRSV infections
- Inflammation of nasal mucosa

TREATMENT

APPROPRIATE HEALTH CARE

- Medical management: use and selection of appropriate antibiotics
- Appropriate selection and treatment of cases
- Consider mass medication of calves in outbreak situations.
- Sick calves should be isolated from healthy calves.

NURSING CARE

- Fluid therapy such as oral electrolyte solutions or intravenous fluids may be indicated in dehydrated animals.
- Well-ventilated, draft-free environment provided

ACTIVITY

N/A

DIET

N/A

CLIENT EDUCATION

- Discuss probable causes and risk factors.
- Warn that viral or *Mycoplasma* pneumonias may not respond to antimicrobial therapy.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

Any antimicrobials labeled for use in the bovine for undifferentiated respiratory disease would be suitable. These may include:

- Short-acting or long-acting oxytetracyclines
- Tilimicosin
- Trimethoprim-potentiated sulfonamides
- Ceftiofur
- Florfenicol
- Enrofloxacin (beef calves only)

CONTRAINDICATIONS

N/A

PRECAUTIONS

- Failure to respond to treatment may indicate predominantly viral infections, *Mycoplasma* infections, or late selection and treatment of cases.
- Drug withdrawal times must be determined and maintained for treated animals.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

Efficacy of NSAIDs in these cases is questionable.

FOLLOW-UP

PATIENT MONITORING

Pyrexia may be utilized as a measure of response to therapy. Calves that are still febrile after 3 days of therapy could be categorized as a relapse and considered for an alternative antimicrobial.

PREVENTION/AVOIDANCE

- Improving air quality is an important criterion for control.
- Dairy calves should not share the same air space as adult animals.
- Rearing dairy calves in calf hutches is an excellent method for reducing the potential risk factors associated with enzootic calf pneumonia.
- Alternatively, use group housing in cold well-ventilated facilities.
- Humidity levels between 55% and 75% are optimal.
- Avoid mixing of various age groups of calves.
- Utilize all-in–all-out approach in group housing, if possible.
- Avoid overcrowding.
- Ensuring calves have high levels of passive immunity by ensuring adequate colostrum ingestion shortly after birth.
- There is lack of evidence to support that vaccines administered to young calves are beneficial in preventing enzootic pneumonia.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Response to antimicrobial therapy should be evident within 48 hours if the primary pathogen is bacterial.
- *Mycoplasma* and viral infections may not respond to antimicrobial therapy.
- Calves that are selected early in the course of the disease for treatment will generally have a very low case fatality rate.
- Case fatality rates have been reported at 2.25%.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Neonatal diarrhea may be associated with enzootic pneumonia, as many of the same risk factors are shared.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Cattle

BIOSECURITY

- Keeping age groups of calves separate is a significant preventive measure.
- Avoid mixing of calves from various sources.
- Purchased calves may be persistently infected with bovine viral diarrhea virus, which may predispose infected animals to enzootic pneumonia.

PRODUCTION MANAGEMENT

- Heifers that do not experience enzootic pneumonia are twice as likely to calve and will calve 6 months earlier than heifers that did have enzootic pneumonia.
- Enzootic pneumonia cases are at an increased risk of culling.

SYNONYMS

N/A

SEE ALSO

Aspiration pneumonia

EPERYTHROZONOSIS

BASICS

DEFINITION

- Eperythrozoonosis (Candidatus *Mycoplasma* spp.) is often considered to be a subclinical disease of cattle, small ruminants, and camelids. However, it can be a significant cause of hemolytic anemia in immunologically naïve, immunosuppressed, or debilitated individuals.
- Current nomenclature recommendations are as follows: *Mycoplasma* (*Eperythrozoon*) *wenyoni* in cattle, *Mycoplasma* (*Eperythrozoon*) *ovis* in sheep, and *Mycoplasma haemolamae* in camelids.

PATHOPHYSIOLOGY

- Eperythrozoonosis is contractible via inoculation of infected blood. Biting insects are considered vectors, though a specific insect has not been identified as the principal vector. Transmission may also occur vertically and via blood-contaminated needles or instruments.
- Parasitemia develops within days of inoculation, but the rapid onset of an effective immune response curtails proliferation, halting further progression. Thus, latent infection can be common in endemic herds and the organism often coexists symbiotically within the host without causing clinical signs of anemia.
- The recent development of highly sensitive PCR assays have detected the organism in the blood of otherwise apparently healthy individuals.
- Debilitated, immunosuppressed, or immunologically naïve individuals are susceptible to uncontrolled parasitemia and clinical signs of disease develop. The organism is found on the surface of erythrocytes, which are primarily removed from the circulation by the mononuclear phagocytes in the spleen and liver.
- Icterus without hemoglobinemia or hemoglobinuria is a cardinal clinical sign. In sheep, intravascular hemolysis may also occur. Anemia develops, and in severe cases, death from hypoxemia may ensue.

SYSTEMS AFFECTED

- Hemic/lymphatic: anemia, extravascular hemolysis, icterus; dependent edema in cattle
- Cardiovascular: hypoxemia
- Skin: poor wool quality in sheep
- Reproductive: scrotal edema and reduced fertility in bulls

GENETICS

N/A

INCIDENCE/PREVALENCE

The disease is often subclinical, and widely used diagnostic methods (examination of blood smears or serology) are not sensitive enough to detect latent infection. Thus, it is difficult to actually determine the prevalence of the disease. The use of a recently developed and highly sensitive PCR assay has thus far detected latent infection in approximately 20% of New World camelids in the United States, Canada, and Australia. Use of PCR assays in other species will be helpful in determining the true prevalence of the disease.

GEOGRAPHIC DISTRIBUTION

Cases have been reported worldwide.

SIGNALMENT

Species

Cattle, small ruminants, camelids, mule deer, elk

Breed Predispositions

N/A

Mean Age and Range

Any age may be affected but younger immunosuppressed or immunologically naïve ruminants may be more susceptible.

Predominant Sex

N/A

SIGNS

GENERAL COMMENTS

- Eperythrozoonosis rarely causes clinical signs of disease and its presence may be a coincidental finding. Severely debilitated or immunosuppressed individuals are more susceptible to clinical eperythrozoonosis.
- The signs of the primary disease process that are responsible for immunosuppression often overshadow the clinical signs of eperythrozoonosis.

HISTORICAL FINDINGS

Concurrent illness, progressive depression, weakness and lethargy, poor growth or chronic weight loss, poor coat quality, anorexia, and icterus

PHYSICAL EXAMINATION FINDINGS

- Clinical signs of disease infrequently occur in cattle and the presence of *Eperythrozoon* species may be a coincidental finding in some individuals.
- Immunosuppression from concurrent systemic disease may predispose individuals to eperythrozoonosis; however, the primary disease process may conceal the signs of eperythrozoonosis.
- Sheep appear to be most susceptible.
- Fever, weakness, and recumbency are expected if the condition progresses. In severe cases, tachycardia, tachypnea, pallor of the mucous membranes, lack of episcleral vessels, and icterus develop.
- Although hemolysis is primarily extravascular, intravascular hemolysis can occur in sheep and thus hemoglobinuria may be present.
- In chronic infection, signs of anemia may be present without signs of active hemolysis (e.g., icterus). In cattle, dependent edema, reduced fertility, and lymphadenopathy may be the predominant signs.

CAUSES

- Eperythrozoonosis is caused by a small (0.5 μm) coccoid prokaryotic organism that lacks a cell wall and cannot be cultivated. Although historically classified as a rickettsial organism, recent studies suggest that it is more closely related to mycoplasma.
- Current nomenclature recommendations are as follows: *Mycoplasma (Eperythrozoon) wenyonii* in cattle, *Mycoplasma (Eperythrozoon) ovis* in sheep, and *Mycoplasma haemolamae* in camelids.

RISK FACTORS

Eperythrozoonosis is most commonly considered to be an opportunistic infection that infrequently results in clinical disease, unless an individual is severely immunosuppressed or systemically compromised.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any cause of extravascular hemolysis in cattle would cause similar signs including anaplasmosis and autoimmune hemolytic anemia.
- The absence of hemoglobinemia and hemoglobinuria distinguishes eperythrozoonosis from causes of intravascular hemolysis in cattle.
- With the occasional occurrence of intravascular hemolysis, leptospirosis and copper toxicity should be considered as differential diagnoses in sheep.

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia: regenerative anemia 5 to 7 days after onset (signs of regeneration include an increased MCV, anisocytosis, polychromasia, basophilic stippling, reticulocytes, Howell Jolly bodies, nucleated red blood cells); nonregenerative anemia may occur in chronic cases.
- Hemoglobinemia (pink plasma, MCH, and MCHC increased) and/or hemoglobinuria may occur in sheep.

- Hyperbilirubinemia (unconjugated)
- Hypoglycemia
- Acidosis

OTHER LABORATORY TESTS

- Eperythrozoon species may be seen in a peripheral blood smear on the surface of erythrocytes as a coccoid, rod, or ring-shaped organism.
- Giemsa, Romanowsky, and acridine orange stains are particularly helpful to highlight the organisms. Parasitemia is often low, or affected cells are removed from the circulation by the mononuclear phagocytic system, therefore absence of visible *Eperythrozoon* species does not preclude the diagnosis.
- Complement fixation and indirect fluorescent antibody tests are positive within a few days of onset of clinical disease but, in some cases, may remain positive for only a short period of time. Unless paired serology is used, a single positive titer cannot distinguish between recent infection and previous exposure.
- A PCR test has been developed to detect the organism in camelids and cattle and is more sensitive in detecting the organism than examination of blood smears.
- The evolution of an immune attack directed at the organism on the surface of red blood cells may lead to a positive Coomb's test.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Splenomegaly, edema, body cavity effusion, and widespread icterus

TREATMENT

APPROPRIATE HEALTH CARE

Inpatient or outpatient care

NURSING CARE

- If anemia is severe and clinical or laboratory evidence of hypoxemia is evident (intense lethargy or weakness, profound tachycardia or tachypnea, severe anemia, acidosis, increased anion gap), a whole blood transfusion is indicated.
- The normal total blood volume is approximately 8% of the body weight (i.e., 0.08 x body weight in kilograms equals the total blood volume in liters). Typically, transfusing one-fourth to one-third of the total blood volume is adequate.

ESCHERICHIA COLI O157:H7, CHALLENGES IN FOOD SAFETY

BASICS

OVERVIEW

- Shiga-toxicogenic *Escherichia coli* O157:H7 emerged as a significant enteric pathogen following a human outbreak in 1993 due to undercooked hamburgers.
- It may be transmitted by food, water, or direct contact.
- The infectious dose is considered to be very small; even one organism is believed to cause disease especially in children and the elderly or immunocompromised. These populations are more susceptible and may succumb to hemorrhagic colitis and hemolytic uremic syndrome.
- Humans have been reported to contract *Escherichia coli* O157:H7 from petting zoos, contaminated and undercooked ground meat, raw milk, water, as well as inadequately pasteurized apple cider and various fruits and vegetables.
- Cattle and most ruminants are considered a reservoir of *Escherichia coli* O157:H7.
- In 1997, this significant pathogen was declared an adulterant in ground beef by the U. S. Department of Agriculture because the infectious dose is very low and common cooking practices may not kill the organism.

SYSTEMS AFFECTED

Production management, gastrointestinal

GENETICS

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

CAUSES AND RISK FACTORS

- *Escherichia coli* O157:H7 is a ubiquitous organism and is prevalent in ruminant feces.
- Beef and dairy cattle and other infected animals are asymptomatic.
- Fecal shedding is greater in summer months.
- The organism can be found in water and feed and can survive for extended periods (13 weeks in cold water such as lakes, wells, and rivers).
- Disabled, nonambulatory “downer” cattle have been reported to have a higher prevalence than healthy cattle.
- Seasonal variation in infectivity occurs in the summer months, with an increase in fecal shedding in cattle and corresponding increase in human illness.

- The CDC reported that risk factors for human illness from *Escherichia coli* O157:H7 are eating undercooked ground beef and contact with farms or farm animals.
- Cooking ground beef to 160°F internal temperature, hand washing, and separating food and animal areas are protective practices that reduce human exposure.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Escherichia coli O157:H7 may be best isolated by selective enrichment and immunomagnetic separation (IMS) to enhance sensitivity due to the low prevalence of the organism.

PATHOLOGIC FINDINGS

N/A

TREATMENT

- Potential animal production practices that reduce *Escherichia coli* O157:H7 include cleaning and disinfecting water troughs, feeding probiotics or competitive exclusion products, administering bacteriophages, vaccines, genetically modified feeds, sodium chlorate in feed or water, manure treatment, and good management practices to reduce fecal contamination.
- Chlorination of water troughs does not seem to significantly decrease *Escherichia coli* O157:H7 due to the amount of organic material present and constant recontamination.
- Most experts believe there will be no single magic bullet, but that multiple interventions will need to be applied.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Humans have been reported to contract *Escherichia coli* O157:H7 from petting zoos, contaminated and undercooked ground meat, raw milk, water, as well as inadequately pasteurized apple cider and various fruits and vegetables.
- Cattle and most ruminants are considered a reservoir of *Escherichia coli* O157:H7.
- Hemorrhagic colitis and hemolytic uremic syndrome in humans

AGE-RELATED FACTORS

- The infectious dose is considered to be very small; even one organism is believed to cause disease especially in children and the elderly or immunocompromised. These populations are more susceptible and may succumb to hemorrhagic colitis and hemolytic uremic syndrome.
- Prevalence of *Escherichia coli* O157:H7 varies with stages of production: unweaned dairy calves approximately 2%, weaned calves 5%, and adult cattle at slaughter 13–28%.
- Children, the elderly, and immunocompromised people are more susceptible and may succumb to hemorrhagic colitis and hemolytic uremic syndrome (HUS).

ZOONOTIC POTENTIAL

- Shiga-toxigenic *Escherichia coli* O157:H7 emerged as a significant enteric pathogen following a human outbreak in 1993 due to undercooked hamburgers.

- It may be transmitted by food, water, or direct contact.
- Humans have been reported to contract *Escherichia coli* O157:H7 from petting zoos, contaminated and undercooked ground meat, raw milk, water, as well as inadequately pasteurized apple cider and various fruits and vegetables.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Potentially, all ruminant species can be affected.

BIOSECURITY

The CDC reported that risk factors for human illness from *Escherichia coli* O157:H7 are eating undercooked ground beef and contact with farms or farm animals.

PRODUCTION MANAGEMENT

Research in potential animal production practices that reduce *Escherichia coli* O157:H7 include cleaning and disinfecting water troughs, feeding probiotics or competitive exclusion products, administering bacteriophages, vaccines, genetically modified feeds, sodium chlorate in feed or water, manure treatment, and good management practices to reduce fecal contamination.

Author: Bonnie Buntain

ESOPHAGEAL DISORDERS

BASICS

DEFINITION

- Choke, megaesophagus, stricture, rupture
- Esophageal disorders refer to any disorders that disrupt the normal function of the esophagus.
- Most common is esophageal obstruction (*choke*), which is defined as the partial or complete obstruction of the esophageal lumen resulting in the inability to swallow effectively. The obstruction may be caused by an intraluminal obstruction such as feed material or foreign body, or by an extraluminal obstruction such as abscess or neoplasia. In addition to obstruction, the esophagus may be affected by stricture, rupture, or megaesophagus.

PATHOPHYSIOLOGY

- Intraluminal esophageal obstruction occurs most commonly in areas of decreased dilation such as the cranial cervical esophagus, thoracic inlet, or base of the heart.
- Ingested feed is the most common cause of obstruction, particularly large objects such as apples, corn cobs and potatoes, or dry materials such as pelleted feed.
- Ruminants are notoriously indiscriminant eaters and esophageal obstruction can also be caused by ingestion of foreign bodies.
- Esophageal obstruction can be potentiated by the presence of an extraluminal space-occupying lesion such as an abscess or neoplasia or by underlying neurologic dysfunction.

SYSTEMS AFFECTED

Gastrointestinal

- Esophageal obstruction causes dysphagia and ptyalorrhea.
- Bloat results from complete obstruction of the esophagus, as gas produced by reticulorumen fermentation is unable to escape.
- Esophageal damage from obstruction may result in rupture, fibrosis, or stricture formation.

Endocrine/Metabolic

Esophageal obstruction may cause metabolic acidosis if unrelieved due to a persistent loss of sodium bicarbonate and sodium phosphate in the saliva.

Cardiovascular

Tachycardia may be present due to stress or dehydration. Ruminants frequently become dehydrated due to loss of saliva and the inability to drink.

Respiratory

Aspiration pneumonia may result secondary to esophageal obstruction.

Skin/Exocrine

Cellulitis may be present in the cervical region if the obstruction has resulted in esophageal rupture.

GENETICS

None

INCIDENCE/PREVALENCE

- Esophageal obstruction is rare in cattle, sheep, and goats. Of the ruminants, it is most common in cattle due to their indiscriminant eating habits.
- Megaesophagus is rare in ruminants.

GEOGRAPHIC DISTRIBUTION

None

SIGNALMENT

- May be seen in cattle as well as sheep and goats
- There does not appear to be any age, breed, or sex disposition.
- Any ruminant exposed to solid feedstuff, pelleted feed, or foreign objects is susceptible.

SIGNS

GENERAL COMMENTS

- The most consistent clinical signs of esophageal obstruction are ptyalism, rumen tympany, coughing, and repeated extension of the head and neck.
- The presence of clinical signs varies with the duration (acute to chronic) and severity of the obstructive lesion (partial to complete).

HISTORICAL FINDINGS

- Ptyalism
- Extension of the head and neck
- Anxiety and restlessness
- Frequent swallowing
- Nasal discharge containing feed material

PHYSICAL EXAMINATION FINDINGS

- Ptyalism
- Dysphagia
- Coughing
- Nasal discharge
- Anxiety
- Tachycardia/tachypnea
- Respiratory distress
- Bruxism
- Bloat
- Repeated attempts to swallow
- Staggering
- Dehydration

CAUSES

- Esophageal obstruction is usually caused by impaction of feed material in the esophagus or ingestion of foreign bodies.
- Eating large items such as corn cobs, apples, and potatoes, whole or in large pieces, can be the sole cause of the obstruction without any underlying disease.
- Foreign material (e.g., glass or metallic objects) can also be consumed and lodge in the esophagus.
- Consuming dry or pelleted feeds can also cause esophageal obstruction if the bolus is not moist enough to allow passage through the esophagus. Of the ruminants, this is most common in sheep.
- Esophageal obstruction may be secondary to other disorders of the esophagus such as strictures, diverticula, neoplasia such as squamous cell carcinoma, or abscesses.

RISK FACTORS

- Gluttony
- Ingestion of dry or pelleted feed
- Incomplete mastication of feedstuffs
- History of esophageal obstruction or stricture
- Dehydration

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Various infectious agents may cause dysphagia similar to that seen with esophageal obstruction.
- Botulism, tetanus, and rabies can all cause bloat, dysphagia, and ptyalism. Toxic plants—such as milkweed, larkspur, sneezeweed, and *Rhizoctonia leguminicola*—infected red clover—also cause ptyalism.
- Traumatic damage to the pharynx can also cause ptyalism and cellulitis.
- Bloat can be caused by vagal indigestion or trauma and inflammation associated with the vagal nerve.

CBC/BIOCHEMISTRY/URINALYSIS

- Packed cell volume and serum protein level may be elevated due to dehydration.
- Metabolic acidosis, hyponatremia, and hypokalemia may be present due to the loss of saliva.
- The leukogram and fibrinogen levels may be altered due to inflammatory changes associated with the primary disease process or secondary aspiration pneumonia.

IMAGING

Radiography

- Both survey and contrast radiography may be helpful to determine the etiology and severity of esophageal obstruction.
- Both the cervical and thoracic esophagus can be visualized by radiography.
- Diagnosis of stricture, perforation, and diverticula can also be made by contrast esophageal radiology.
- Contrast media can be easily administered via oroesophageal or nasoesophageal tube.
- Fluoroscopy may be helpful to diagnose motility disorders although restraint in the ruminant can be frustrating.

DIAGNOSTIC PROCEDURES

- In small ruminants, the object may be palpated in the cervical esophagus. This is often not possible in the bovine patient and passage of a nasogastric tube is necessary to establish the location of the obstruction. The tube should be passed through an oral speculum and should be advanced gently to avoid damage to affected mucosa.
- The overall condition of the patient should be evaluated.
- The thorax should be carefully auscultated for evidence of aspiration pneumonia.

Endoscopy

- Esophagoscopy will aid in localizing and characterizing the lesion as well as determining the severity of esophageal damage.
- Strictures and diverticula can also be visualized with esophagoscopy. A 2–3-m endoscope may be necessary to visualize the extent of the bovine esophagus, however a 1-m or pediatric endoscope is adequate for the small ruminant. The animal should be restrained in a head gate or stanchion and the head should be controlled. Use of an oral speculum is necessary to prevent damage to the endoscope. Insufflation with air will help to visualize the esophagus especially in cases where a large amount of saliva is present.

TREATMENT

MEDICAL MANAGEMENT

- Some cases of esophageal obstruction will resolve spontaneously but each should be treated as quickly as possible to decrease inflammation and reduce the incidence of complications.
- In cases where the obstruction is palpable within the cervical esophagus, it may be manually extracted by applying gentle and steady pressure in the jugular groove aboral to the obstruction and pushing it in an oral direction.
- Sedation is usually necessary, but once the object is in the proximal esophagus it may be propelled into the pharynx or grasped and removed. A speculum and manipulation of the tongue will be helpful with this technique.
- If the obstruction is in the thoracic esophagus, an attempt can be made to push the object into the rumen as the esophagus widens as it courses toward the cardia. Then, if it is a foreign body, it can be retrieved via rumenotomy. This should not be performed if the object has sharp edges as identified by endoscopy, as it could potentially lacerate the esophagus.
- Objects in the cervical esophagus should not be pushed aborally due to the narrowing of the esophagus at the thoracic inlet.

- Sedation should be given to reduce anxiety and promote esophageal relaxation around the object. A nasogastric tube can be passed to the level of the obstruction and the obstruction, if it is feed material, may be broken down with a gentle lavage of warm water.
- The use of lubricants such as mineral oil or surfactants (DSS) is controversial due to the risk of aspiration.
- The animal should be sedated (see Medication below) to allow the head to drop as low as possible, preventing aspiration of lavage material. Additionally, a large-bore endotracheal tube can be inserted into the esophagus, cuff inflated, and the smaller oroesophageal tube inserted through the larger tube. This allows lavage material and fluid to pass through the ET tube and reduce risk of aspiration. If available, progress can be evaluated with endoscopy. Several attempts may need to be made to break down the obstruction, and it may take several hours to do so. Breaks should be taken to allow the animal to rest and breathe without risk of aspiration.
- If the obstruction cannot be relieved with the animal standing, general anesthesia may be required. The patient is placed in lateral recumbency with the head lowered and the same lavage techniques are used. If this does not allow relief of the obstruction, esophagotomy may be required.
- If there is evidence of esophageal rupture based on clinical signs, endoscopy, or radiography, surgical management may be necessary. If the rupture is acute, survival with surgery is possible.
- If the rupture is long-standing, involves contamination of the thorax, or involves extensive soft tissue contamination, the prognosis is extremely guarded and slaughter is recommended.

SURGICAL MANAGEMENT

- If the obstruction cannot be alleviated with sedation, lavage, and manual extraction, or if the object is sharp or irregular, surgical correction by esophagotomy becomes necessary.
- Perforation or rupture of the esophagus requires surgical intervention. Due to the risk of contamination of the surgery site, general anesthesia is usually required. Alternatively, the procedure has been performed under sedation and local anesthesia. Preoperative antimicrobials should be given and continued after surgery. An esophageal tube should be placed at the level of the obstruction for easier identification of the esophagus.
- Cervical esophagotomy is considerably easier to perform than transthoracic esophagotomy, as rib resection and positive pressure ventilation are required for the latter.
- If damage to the esophagus is severe, resection and anastomosis may be required. Detailed description of each of these surgeries is beyond the scope of this text and can be found elsewhere.
- Esophageal surgery carries a high complication rate and includes contamination of soft tissues, dehiscence of the incision, stenosis or diverticulum formation, pleuritis, and aspiration pneumonia.

NURSING CARE

- The animal should be held off feed and water until the obstruction is resolved. In cases of dehydration, the patient may require intravenous fluid therapy.
- The type of intravenous fluid used should be based on electrolyte and acid-base imbalances.

DIET

- Diet associated with esophageal disorders is dependent on type and severity of the disease present.
- Ruminants with resolved esophageal obstruction and minimal mucosal damage with no decrease in motility can be fed frequent small amounts for the first 24–72 hours.
- More severe esophageal damage, decreased motility, or surgical correction will require alternative alimentation.
- Placement of an esophagostomy tube distal to the obstruction site is one option. This is best reserved for calves that are not yet functional ruminants, as the regurgitated food material and saliva will leak around the tube. Daily passage of an orogastric tube can be used for feeding if done cautiously to avoid damage to the already compromised esophagus.
- Ideally, ruminants can be fed through a temporary rumenostomy cannula. This allows a complete bypass of the damaged esophagus while maintaining an acceptable level of nutrition.

CLIENT EDUCATION

- The practice of feeding poor-quality feed or whole food items should be discouraged.
- Due to the indiscriminant eating habits of ruminants, producers should be encouraged to keep pastures free of foreign objects that could pose a risk if consumed.

MEDICATIONS

DRUGS OF CHOICE

- Xylazine (.01–.02 mg/kg/IV) can be given for sedation and esophageal relaxation.
- Broad-spectrum antimicrobials should be given in cases of esophageal necrosis, aspiration pneumonia, or esophageal surgery.
- Flunixin meglumine can be given (1.1 mg/kg q 24h) for inflammation and pain but withdrawal times should be followed.
- Oxytocin is not effective for treatment of esophageal obstruction in ruminants (unlike its possible use in Equidae) due to the presence of striated muscle for the length of the esophagus.

CONTRAINDICATIONS

The use of lubricants, such as mineral oil or surfactants (DSS) to relieve an esophageal obstruction, is controversial due to the risk of aspiration.

PRECAUTIONS

- Antibiotic and nonsteroidal anti-inflammatory (NSAIDs) choices should be made with regard to meat and milk withdrawal times.
- NSAIDs should be given judiciously to the dehydrated patient due to the risk of nephrotoxicity.

FOLLOW-UP

PATIENT MONITORING

PREVENTION/AVOIDANCE

POSSIBLE COMPLICATIONS

- Esophageal perforation
- Esophageal stricture
- Recurrent obstructions
- Aspiration pneumonia
- Altered esophageal motility
- Esophageal diverticulum
- Pleuritis
- Incisional dehiscence (surgery cases)

EXPECTED COURSE AND PROGNOSIS

- Prognosis is dependent on duration and severity of the lesion as well as occurrence of complications.
- Prognosis is good if resolution of the obstruction occurs spontaneously or with minimal manipulation and mucosal damage.
- Prognosis is guarded with more aggressive manipulation or if surgical correction is required, and grave to poor with prolonged obstruction and rupture of the esophagus.

FACIAL ECZEMA

BASICS

OVERVIEW

- Facial eczema is a hepatogenous photosensitization.
- Hepatotoxic sporidesmins A to H are produced by the fungus *Pithomyces chartarum*, a saprophyte of pasture leaf litter.
- Sporidesmins are pyrrolidiones.
- All grazing ruminants can be affected.

PATHOPHYSIOLOGY

SYSTEMS AFFECTED

Liver and lightly pigmented skin are affected, typically: ears, eyelids, face, lips, and dorsum of the trunk, vulva, mammary gland, and coronets.

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Sporidesmin toxicosis occurs primarily in autumn, but only in warm humid coastal areas of northern New Zealand, and sometimes Australia, South Africa, and Europe.

SIGNALMENT

- Only ruminants and camelids grazing at pasture are affected.
- Fallow deer, New World camelids, and sheep are most susceptible. Cattle and red deer are moderately susceptible. Goats are least susceptible.
- Morbidity can approach 50%; mortality is typically < 5%.
- Subclinical effects are of great economic importance.
- Merino sheep are less susceptible to liver damage than British breeds. In sheep, the heritability of susceptibility to facial eczema is 0.42.
- Pastures predominantly made up of ryegrass are more hazardous than pastures of other plant species.

SIGNS

- Exposed nonpigmented and lightly pigmented skin is affected, typically: ears, eyelids, face, lips, and dorsum of the trunk, vulva, mammary gland, and coronets.
- Direct sunlight elicits cutaneous hyperaesthesia. Signs include: restlessness, head shaking, rubbing or scratching the affected part, and seeking shade.
- Initially, there is cutaneous erythema and edema of the ears, face, udder, and escutcheon. The ears droop, and there is copious lacrimation.
- Affected patches of skin have superficial necrosis that exudes serous fluid, and scabs form.
- Rubbing often results in self-trauma and secondary suppurative dermatitis.
- When affected sheep with short wool or open fleeces are exposed to direct sunlight, they often assume a characteristic posture with exaggerated lordosis and run to seek shade. The abnormal behavior appears to be a pain response.
- The milk production of affected cows drops dramatically. Cattle are restless, seek shade, and lick at the peeling skin.
- Affected fallow and red deer have mild skin lesions, but are more restless and irritable than other species, and actively seek shade. Deer deteriorate rapidly; some become temporarily blind (keratosis), and compared with other species, a greater proportion die.

- Severely affected animals of all species develop jaundice.

CAUSES AND RISK FACTORS

- Sporidesmin toxicosis from grazing the spores of the leaf litter fungus *Pithomyces chartarum*.
- The amount of sporidesmins on pasture is directly proportional to spore numbers. Spore production peaks when humidity approaches 100%, at temperatures between 20 and 24 degrees C, with night minimum temperatures > 14 degrees C. Spore numbers increase within 48 hours after > 4 mm of rain followed by grass minimum temperatures of > 12 degrees C, typically 16 to 18 degrees C for two consecutive nights.
- Several such periods are necessary for spore numbers to exceed the “danger level” of >100 000 spores per gram of grass.
- Other risk factors include; stocking rate, closeness of grazing, class of livestock, time spent grazing, and previous recent exposure to sporidesmins.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

All other causes of photosensitivity include rape scald (*Brassica napus*); musky storksbill toxicosis (*Erodium moschatum*); lupinosis from phomopsin mycotoxins produced by *Diaporthe toxica*; pyrrolizidine alkaloid poisoning; lantadene poisoning; ngai poisoning (*Myoporum laetum*); hypericism (*Hypericum* sp.); trefoil dermatitis following ingestion of bur medic (*Medicago polymorpha*), hay made from flood-damaged alfalfa (*Medicago sativa*) or Alsike clover (*Trefolium hybridum*); fagopyrin toxicosis from seeds and dried plants of buckwheat (*Polygonum fagopyrum*); ergotism (*Claviceps purpurea*); mycotoxicosis from *Periconia* sp. on Bermuda grass; blue-green algal poisoning (*Microcystis* sp.); heritable porphyria; postpartum photosensitivity; ovine white liver disease; and toxicosis from administration of synthetic chemicals such as carbon tetrachloride.

CBC/BIOCHEMISTRY/URINALYSIS

Liver damage is reflected by elevated serum gamma glutamyltransferase (GGT).

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Sporidesmins are nonspecific toxins that in sufficient concentration cause permeability changes in many tissues.
- Grazing animals absorb ingested sporidesmins from the intestine.
- Unconjugated sporidesmins are excreted and concentrated in bile. Initially there is dose-dependent degeneration/necrosis of the biliary epithelium. Leakage of bile into mesenchymal tissue of portal triads initiates pericholangitis.
- Severe or repeated insults result in progressive obliterative cholangitis, with biliary and periportal fibrosis. The reparative phase is characterized by bridging periportal fibrosis and proliferation of many small-diameter bile ducts.
- The liver lesions are asymmetrically distributed.
- The left lobe is primarily affected due to portal streaming. After repeated or chronic poisoning, there is fibrosis and atrophy of the left liver lobe and compensatory hypertrophy of the right and caudate lobes, which gives the liver a typical “boxing glove” gross appearance.
- Consequent to cholestasis, phylloerythrin, which is a photoactive metabolite of chlorophyll, cannot be excreted via the biliary system and accumulates in tissues. Similarly, endogenous photoactive porphyrins accumulate in tissues, resulting in mild jaundice.
- Accumulated photoactive metabolites in superficial tissues undergo a photodynamic reaction with sunlight and adjacent tissue is damaged.

TREATMENT

Remove from toxic pasture and provide shade. Allow animals to graze outside at night.

MEDICATIONS

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

Spore count monitoring is actively pursued at regional level. Farmers can monitor individual paddocks.

POSSIBLE COMPLICATIONS

Death

EXPECTED COURSE AND PROGNOSIS

- Once removed from toxic pasture, if provided with adequate shade, food and water, both the skin and liver heal within 1 to 3 weeks.
- Recovery of lost weight takes longer. Chronic ill thrift is a sequel of severe outbreaks.

MISCELLANEOUS

ASSOCIATED CONDITIONS

The milk production of affected cows drops dramatically. Cattle are restless, seek shade, and lick at the peeling skin.

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Ewe fertility and fecundity can be markedly reduced, because the facial eczema danger period coincides with the mating season of sheep.

RUMINANT SPECIES AFFECTED

- All ruminant species grazing at pasture.
- Merino sheep are less susceptible to liver damage than British breeds. In sheep, the heritability of susceptibility to facial eczema is 0.42.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Manage pasture to minimize the amount of leaf litter substrate in the sward.

- Plan grazing management so that warm, humid paddocks are grazed before the danger period, and exposed, cool paddocks are reserved for the danger period.
- Avoid grazing to the base of pastures by ensuring light grazing pressure.
- Zinc administration before exposure reduces liver damage. Intraruminal slow-release zinc capsules of various sizes are available for cattle and sheep.
- Oral dosing of sheep and cattle with zinc oxide slurry, at frequencies ranging from daily to weekly, is progressively less effective as the interval is increased.
- Zinc sulphate in the drinking water is effective only for dairy cattle with no alternate source of water.
- Pastures can be sprayed with fungicides before spore counts rise, to provide safe pastures for 4 to 6 weeks.

FAILURE OF PASSIVE TRANSFER

BASICS

DEFINITION

- Newborn ruminants are born hypogammaglobulinemic due to the nature of their placentation.
- Although immunocompetent at birth, neonatal ruminants are immunonaïve and thus dependant on maternally derived immunoglobulin and other factors absorbed from colostrum.
- Neonates that fail to acquire adequate passive immunity are said to suffer failure of passive transfer.

SYSTEMS AFFECTED

Immune system, gastrointestinal system, musculoskeletal system, and respiratory system; also production management

GENETICS

N/A

INCIDENCE/PREVALENCE

- Unknown but in many instances of poor colostrum management extremely high
- An association exists between higher IgG (or protein) levels and lower disease incidence.
- This association appears to have a greater influence in herds with high disease incidence compared to herds with low disease incidence.

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNS

HISTORICAL FINDINGS

These animals are at increased risk for the development of diseases such as septicemia, enteritis, diarrhea, omphalitis, arthritis, and respiratory disease.

CAUSES AND RISK FACTORS

Factors to consider in assessing disease risk include general hygiene, pathogen virulence, pathogen concentration, the physical environment (e.g., temperature, humidity, wind chill), nutritional status, and miscellaneous stresses (e.g., transportation, handling, surgery).

Composition and Formation of Colostrum

- Colostrum is a complex fluid that in addition to immunoglobulins contains various immune cells, immunoactive substances such as cytokines, and nutritional elements.
- The concept of failure of passive transfer has largely been used to describe situations in which neonates do not absorb adequate levels of colostrum immunoglobulin.
- This narrowly focused concept is due to the fact that immunoglobulins are such a large constituent of colostrum and they have been the most thoroughly studied component.
- Immunoglobulin G1 (IgG₁) is the primary immunoglobulin in bovine colostrum, making up > 85% of the total colostrum immunoglobulin mass.
- Colostral IgG₁ originates from maternal serum and is transferred into colostrum during the last 4 to 6 weeks of gestation.
- Transfer involves active, IgG₁-specific, Fc receptors located on the basolateral membrane of mammary secretory epithelial cells.
- These receptors appear to be under the control of lactogenic hormones as well as local mechanisms within the mammary gland.

Colostrum Cellular Makeup

- Colostrum contains greater than 1×10^6 cells per milliliter.

- Although the particular cell types present in colostrum vary between species, time of lactation, and other physiologic conditions, it is clear that neonates receive a significant number of immune cells via colostrums.
- In sheep and cattle, lymphocytes make up approximately 20%–30% of colostrum cells.
- Studies in cattle suggest that these colostrum lymphocytes differ from those in maternal circulation and that they function by modulating the neonatal immune system and the secretion of various cytokines, as well as the secretion of immunoglobulin A.
- Macrophages and neutrophils make up the remainder of colostrum cells.
- Macrophages are thought to serve as cytokine-producing and antigen-presenting cells.
- The neutrophils are likely involved in the protection of the mammary gland rather than the neonate.
- While interleukin-2 (IL-2) and tumor necrosis factor (TNF) have been found in colostrum, their role as yet is unknown.
- Colostrum is rich in insulinlike growth factor-1 (IGF-1), which helps regulate newborn growth and may enhance the early neonatal immune response.
- Finally, transforming growth factor is present in high concentrations in bovine colostrum but decreases by 30 days postpartum.

Absorption of Colostrum

- Whereas the transfer of immunoglobulin from maternal circulation into colostrum involves an active, specific, receptor-mediated process, absorption across the gut wall of the neonate is nonselective and in fact does not appear to differentiate between macromolecules.
- Absorption and transfer across intestinal epithelial cells occur via nonselective pinocytosis initiated by the presence of macromolecules.
- The efficiency of immunoglobulin absorption effectively declines to zero over the first approximately 24 hours of life.
- The term “closure” is used to define the point at which absorption by the gut of immunoglobulins ceases.
- NOTE: the absorptive process across the gut epithelium appears to be saturable. That is, a finite capacity exists for the absorption of all macromolecules.
- The presence of high levels of nonimmunoglobulin molecules fed during the first 24 hours of life may adversely compete with the absorption of colostrum immunoglobulins.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Determination of Passive Transfer Status

- Many methods are available to measure immunoglobulin concentrations in calf serum after absorption from colostrum.
- In conjunction with specific guidelines, these techniques are used to define if a neonate has attained adequate passive transfer or suffers failure of passive transfer.
- By convention, serum IgG₁ concentration of 10 mg/ml at 48 hours of age is the objective value for defining the threshold between adequate passive transfer and failure of passive transfer.
- The various tests for immunoglobulin concentration vary in their speed, accuracy, and equipment required for operation. The first step of all tests involves the acquisition of serum from the calf.
- Single radial immunodiffusion (SRID) and the enzyme-linked immunosorbent assay (ELISA) are the only tests that directly measure serum IgG concentration. Other tests including zinc sulfate turbidity, sodium sulfite precipitation, whole blood glutaraldehyde coagulation, total serum solids by refractometry, and gamma-glutamyl transferase activity indirectly estimate serum IgG concentration based on colostrum total proteins.
- The techniques for performing these tests and the values used for their interpretation can be found in numerous texts (e.g., Bovine neonatal immunology, see below).
- NOTE: results of the various testing methods on any particular operation must be kept in perspective and their use not overinterpreted.

Assessing Disease Risk

- An association exists between higher IgG (or protein) levels and lower disease incidence.
- This association appears to have a greater influence in herds with high disease incidence compared to herds with low disease incidence.
- The rate of disease occurrence is obviously a balance between a calf’s ability to resist disease and the severity of disease

challenging the calf.

- Serum immunoglobulin concentration is only one factor that contributes to disease resistance, yet it provides no information regarding the degree of disease challenge.
- Additional factors to consider in assessing disease risk include general hygiene, pathogen virulence, pathogen concentration, physical environment (e.g., temperature, humidity, wind chill), nutritional status, and miscellaneous stresses (e.g., transportation, handling, surgery).
- Furthermore, other factors that influence disease resistance might include the less-studied nonimmunoglobulin components of colostrum (cells, cytokines, etc.).

Test Accuracy

- Accurate measurement of serum immunoglobulin in a particular calf does not necessarily guarantee protection from disease for the following reasons:
 - First, the tests described only quantify a calf's serum immunoglobulin concentration. They do not determine specific protective capabilities of the absorbed immunoglobulins.
 - Second, these tests cannot determine if the absorbed immunoglobulins will reach the appropriate site of challenge in a calf in sufficient concentrations to neutralize a particular pathogen.
- These two points are not meant to conclude that there is no benefit in measuring serum immunoglobulin levels as an indicator of passive transfer of immunity. Rather, they illustrate the potential limitations of measuring immunoglobulin levels.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

CLIENT EDUCATION

- The efficiency of immunoglobulin absorption effectively declines to zero over the first approximately 24 hours of life.
- The term “closure” is used to define the point at which absorption by the gut of immunoglobulins ceases.

TREATMENT

Transfusions may prove helpful.

MEDICATIONS

FOLLOW-UP

PREVENTION/AVOIDANCE

Proper colostrum management

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Clinical course and prognosis vary and are associated with the underlying disease conditions. Without additional quality colostrum or transfusions, typically failure of passive transfer warrants a guarded to poor prognosis.

**MISCELLANEOUS****ASSOCIATED CONDITIONS**

Septicemia, enteritis, diarrhea, omphalitis, arthritis, and respiratory disease

AGE-RELATED FACTORS

First 24–48 hours of life

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

All domestic and wild ruminant species can be affected.

BIOSECURITY

Selection of donors:

- Identify on-farm disease problems that can be influenced by colostrum management.
- Do not pool colostrum. Feed colostrum from an individual preselected dam to individual young stock.
- Minimize disease transfer via colostrum (e.g., Johne's disease, CAE, BLV) by preselecting negative dams.
- Only first milking colostrum should be fed to the newborn during the first 12 hours of life.

PRODUCTION MANAGEMENT

- Young stock whose dam produces inadequate colostrum, should be fed colostrum from a preselected donor.
- Frozen colostrum should be stored from individual donors, identified, and marked prior to freezing.
- Maintain a bank of frozen, high-quality colostrum for use in emergency situations.
- Feed young stock first within 2 hours of birth and again within 12 hours of birth.

SYNONYMS

Failure to thrive

ABBREVIATIONS

CAE = caprine arthritis encephalitis

ELISA = enzyme-linked immunosorbent assay

Fc = IgG₁-specific Fc receptors

IGF-1 = insulinlike growth factor-1

IgG₁ = immunoglobulin G1

IL-2 = interleukin-2 (IL-2)

SRID = single radial immunodiffusion

TNF = tumor necrosis factor

FASCIOLIASIS (LIVER FLUKE)

BASICS

OVERVIEW

- Liver flukes are platyhelminths (flatworms) of the class Trematoda. They have a long, complex life cycle that requires a snail intermediate host. Stages in the snail are not infective to mammalian hosts.
- After the fluke completes a complex asexual development within the snail, the stage called cercaria penetrates out of the snail onto pasture and develops into metacercariae. Livestock can become infected only if they ingest the free-living metacercariae while grazing pasture.
- There are two species of liver fluke that infect livestock: *Fasciola hepatica* and *Fascioloides magna*.

Fasciola hepatica

- *Fasciola hepatica*, the common liver fluke, is the most important liver fluke species of ruminants, but also will infect horses, swine, rabbits, and humans.
- Distribution of *F. hepatica* is strictly limited by the distribution of its snail's intermediate hosts and is most common in the Gulf Coast and the Pacific northwest regions of the United States.
- Cattle infected with *F. hepatica* rarely demonstrate clinical disease, but subclinical impairment of feed efficiency, growth, and fertility can have an important impact on productivity
- Though bovine fascioliasis is most often a subclinical disease, where extremely high fluke burdens rapidly accumulate, outbreaks of acute disease can occur
- Ovine/caprine fascioliasis may present with severe clinical symptoms such as anemia, anorexia, weight loss, submandibular edema, ascites, and death.
- Life cycle of *F. hepatica* does not change, but seasonal transmission profiles differ for each geographic region and these differences mean that treatment programs also differ by region.
- Only two flukicidal drugs are labeled for use in the United States, and both are extremely limited in their ability to kill the immature migrating stages less than 8 weeks old.

Fascioloides magna

- *Fascioloides magna*, the large American fluke, is a normal parasite of deer, but also infects cattle, small ruminants, and swine.
- Distribution of *F. magna* parallels that of *F. hepatica* but also is present in many areas where *F. hepatica* is not found.
- *F. magna* is considered to have low pathogenicity in deer, cattle, and swine, but will cause severe disease in small ruminants.
- Infections with *F. magna* do not become patent in nondeer hosts, so definitive diagnosis is possible only at necropsy.
- Treatments effective against *F. hepatica*, are poorly effective against *F. magna*, making treatment and control in ruminants/swine difficult.

SIGNALMENT

Fasciola hepatica

- All ages of ruminants; disease rare in other hosts
- Young animals are more susceptible to infection and more likely to demonstrate clinical disease.
- Small ruminants are more likely than cattle to develop clinical disease.

Fascioloides magna

- Cattle and swine may become infected, but symptoms of disease are very unlikely.
- Small ruminants of any age may become infected and may demonstrate severe disease.

SIGNS

Fasciola hepatica

Cattle

- Usually no clinical symptoms
- Major impact is decreased animal productivity.
- May see poor growth, weight loss, unthriftiness
- Calves with heavy infections may demonstrate anemia, submandibular edema, ascites.

Sheep/Goats

- Clinical symptoms are more severe than in cattle.
- May be none in light infections
- Anemia, anorexia, weight loss, submandibular edema, ascites, and death in moderate to heavy infections
- May see acute disease caused by large numbers of juvenile flukes. Symptoms resemble acute haemonchosis; may see as outbreak.

Complications

May include:

- Infectious necrotic hepatitis (Black disease, *Clostridium novyi*)
- Bacillary hemoglobinuria (*C. haemolyticum*)

Fascioloides magna

- Cattle and swine—symptoms of disease are very uncommon.
- Sheep and goats—weight loss, lethargy, sudden death

CAUSES AND RISK FACTORS

- *Fasciola hepatica*, *Fasciola gigantica*, *Fascioloides magna* and *Dicrocoelium dendriticum*.
- *Fasciola hepatica* is present worldwide.
- *Fasciola gigantica* is restricted to warmer climates including Africa and Asia.
- *Fascioloides magna* is present only in parts of North America and Europe.
- *Dicrocoelium dendriticum* is common in Europe and Asia, but is infrequently diagnosed in North America and the United Kingdom.
- *Dicrocoelium dendriticum* is substantially less pathogenic than the other fluke species.

Fasciola hepatica

- Snails of the genus *Fossaria* serve as the primary intermediate host in the United States. Characteristics of *Fossaria*
 - Amphibious; lives in wet mud along edges of shallow water
 - Typically inhabits semipermanent ponds and temporary pools (e.g., tire ruts)
 - Found in areas with neutral soils (pH 6–8) and poor drainage
 - Has the ability to aestivate (burrow in mud and enter arrested state)
- Ruminants grazing low-lying wet pastures in enzootic regions. Major enzootic areas: Gulf Coast states, California/Northwest/Pacific Northwest, Puerto Rico, Hawaii. Sporadic cases diagnosed elsewhere
- Ruminants in enzootic regions not on a liver fluke control program
- Years with above-normal rainfall provide increased risk of infection.

Fascioloides magna

- In addition to *Fossaria*, there are a number of other snail species that serve as intermediate hosts for *F. magna*.
- Ruminants/swine grazing low-lying wet pastures or pastures containing lakes/ponds in enzootic regions.
 - Major enzootic areas: everywhere in the United States where *F. hepatica* is enzootic, plus additional areas in southeast United States in moist lowland and swampy areas, Great Lakes states, especially Minnesota, Wisconsin, Michigan, Adirondack Mountains of New York, western United States
 - Enzootic regions where there are large populations of deer

Life Cycle (*Fasciola hepatica*, *Fasciola gigantica*, *Fascioloides magna*)

- Adult flukes reside in either the bile ducts (*Fasciola hepatica*, *Fasciola gigantica*) or thin-walled cysts of the definitive host, which communicate with the bile ducts (*Fascioloides magna*) producing operculated ova, which are passed in the feces.

- The most common definitive host of *Fasciola hepatica* and *Fasciola gigantica* are cattle and sheep; however, other species may be affected.
- The definitive hosts of *Fascioloides magna* are wild cervidae including deer and moose. Fluke eggs hatch releasing miracidia, which seek out, invade the tissues of *Lymnaea* spp. or *Galba* spp. snails, and undergo asexual replication.
- Flukes escape from snails as cercariae, attach to pasture forage, and mature to metacercariae. Metacercariae are ingested by the definitive or aberrant host and immature flukes are released in the intestine, migrate across the intestinal wall and peritoneal cavity reaching the liver. Flukes migrate through the liver parenchyma and finally take up residence in either the bile ducts or hepatic cysts.
- In sheep and goats, *Fascioloides magna* will tend to migrate continuously rather than becoming encysted; hence, small numbers of these flukes may cause sufficient hepatic damage to result in the patient's demise.

Life Cycle (*Dicrocoelium dendriticum*)

- The lifecycle of *Dicrocoelium dendriticum* exhibits substantial pattern differences from that of *Fasciola* or *Fascioloides*. The intermediate hosts are land snails with broad distribution. Additionally, cercariae that leave snails infect a second intermediate host (*Formica* spp. ants) where they mature to metacercariae. Ants are ingested by grazing herbivores.
- Flukes migrate up the common bile duct and there is no significant or destructive tissue migration phase.

Environmental and Host Factors Affecting the Life Cycle

- In general, fluke eggs hatch only at temperatures above 40°F. Intermediate hosts (snails) are able to replicate only at temperatures above 50°F.
- Immature fluke forms fail to mature at cool environmental temperatures; however, these forms will overwinter within snails and replicate and are released with the advent of more temperate conditions in the spring.
- Metacercariae present on pastures are readily destroyed by severe cold (harsh winters) or hot, dry conditions. Consequently, the risk of infection is impacted by both seasonal and geographic risks producing a distinct local pattern.

DIAGNOSIS

Fasciola hepatica

- Based on clinical signs (if present), time of year, grazing history, and knowledge of herd history and area
- Demonstration of eggs in feces; with acute disease, there may be no eggs in feces; caused by juvenile flukes
- Characteristic liver lesions and/or demonstration of liver flukes in bile ducts

Fascioloides magna

- Premortem diagnosis very difficult—eggs are rarely shed in the feces livestock hosts
- Cattle, pigs—no clinical signs, eggs not passed in feces, usually incidental finding at slaughter/necropsy
- Sheep, goats—tentative diagnosis by clinical signs (similar to acute fascioliasis) and history of area/geography. Definitive diagnosis at necropsy—no eggs in feces

DIFFERENTIAL DIAGNOSES

- Gastrointestinal nematodes, particularly *Haemonchus contortus*
- *Taenia hydatigena* larvae in hepatic parenchyma (when helminths found in liver at necropsy)

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia
- Hypoproteinemia
- Elevated GGT and/or GLDH

OTHER LABORATORY TESTS

- Fecal sedimentation technique—eggs will not float. Eggs are large, golden brown, operculated (140 × 80 μ).
- Flukefinder modified sedimentation method improves ease of fecal diagnosis and is recommended.
- ELISA for *F. hepatica* if available (few labs perform this test)
- A PCR-RFLP assay for the distinction between *Fasciola hepatica* and *Fasciola gigantica* has recently been developed.

IMAGING

Ultrasound findings can aid in the diagnosis after 9 weeks postinfection. Ductal dilatation is shown by ultrasound, and

moving echogenic forms in the dilated bile ducts can be observed after 9 weeks postinfection in sheep.

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

Fasciola hepatica

Most lesions due to chronic infections

- Hyperplastic cholangitis—bile duct dilation, thickening, and fibrosis. In cattle, get calcification of bile ducts so-called pipe-stem lesion
- Hepatic fibrosis—Liver is pale and firm with irregular outline.
- In acute disease
 - Enlarged liver with hemorrhagic tracts
 - Surface of liver covered with a fibrinous exudate
 - Serosanguineous fluid in abdominal cavity
 - Flukes may be too small to see with naked eye.

Fasciola magna

- Cattle and pigs—young flukes migrate in liver parenchyma, but adult flukes become encapsulated in thick-walled cysts that do not communication with bile ducts. Necrotizing tracts in the liver containing black hematin pigmentation
- Sheep and goats—young flukes migrate extensively through liver causing severe damage to liver parenchyma (adults do not encyst). Necrotizing tracts in the liver containing black hematin pigmentation. Black pigmentation also may be present in other organs.

TREATMENT

Available flukicidal drugs (see below) do not kill juvenile and/or immature liver fluke stages. Therefore, timing of treatments is critical and is based on local patterns of transmission.

Table 1

Source: Table modified from Kaplan (2001).

Drugs Available in the United States for Treatment of Liver Flukes			
	Curatrem (clorsulon)	Ivomec-Plus (clorsulon + ivermectin)	Valbazen (albendazole)
Dose	7 mg/kg	2 mg/kg + 200 g/kg	10 mg/kg
Kills adult flukes	+ (> 99%)	+ (97–99%)	+ (76–92%)
Kills immature flukes (8–12 weeks)	+ (85–95%)	—	—
Kills juvenile flukes (0–8 weeks)	—	—	—
Route of administration	Oral drench	Subcutaneous injection	Oral drench
Spectrum	Narrow (flukes only)	Broad (flukes, nematodes, ectoparasites)	Broad (flukes, nematodes, tapeworms)
Meat withdrawal times	8 days	49 days	27 days
Other information	Treatment of choice if treating at a time of year when it is expected that juvenile and/or immature stages will be present		Withholding feed for 24 hr prior to treatment will improve efficacy.

Suggested treatment times:

- Gulf Coast region—Treat in late summer or early fall; supplemental treatment in the spring in unusually wet years and on properties with a history of problems with liver fluke.
- Northwest United States (where winters are cold, e.g., Idaho, Montana)—Treat in late winter or early spring.
- Pacific Northwest/California (mild winters)—Fluke transmission may occur year round; no strategic treatment plan has been developed.

MEDICATIONS

DRUGS OF CHOICE

Only two drugs are available to treat liver fluke infections in the United States. (See [Table 1](#))

- Clorsulon: two products available (Curatrem, Ivomec-Plus)
- Albendazole (Valbazen) No drugs have FDA label approval for treatment of *F. magna* and effectiveness of treatments has not been well established. It is suggested to use albendazole at twice the recommended label dose for 2 or 3 consecutive days.

CONTRAINDICATIONS

- Drug withdrawal times for meat must be monitored and followed.
- None of the drugs are approved for use in lactating dairy cattle.

FOLLOW-UP

N/A

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Improve pasture drainage
- Fence off ponds
- Move cattle off of “fluky” pastures during high transmission periods

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Prognosis is very good in chronic infections.
- Prognosis is guarded in acute disease.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Infections with gastrointestinal nematodes will almost always be present in fluke-infected animals, which will exacerbate the impact on the host.
- Associated conditions include anorexia, lethargy, pale mucous membranes, peripheral edema, weight loss, ill thrift, poor performance, and sudden death.

AGE-RELATED FACTORS

All ages are susceptible, but young animals are more likely to suffer severe disease.

ZOONOTIC POTENTIAL

- Metacercariae of *F. hepatica* are infective to humans, but this parasitic stage is found only on pasture.
- There is no possible zoonotic transmission directly from animals to humans.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

All ruminants are susceptible to infection.

BIOSECURITY

- *F. hepatica* can be spread between farms by infected rabbits and deer, making eradication almost impossible.
- Fencing of pastures (and ponds) with “deer-proof” fencing should prevent *F. magna* infections in livestock in enzootic areas.

PRODUCTION MANAGEMENT

- Fence off marshy areas from grazing ruminants.
- Strategic deworming of cattle and sheep in the spring or early summer may limit the degree to which snail populations become infected with immature stages of flukes and limit amplification of infection.
- Deworming prior to introduction of livestock into low-lying pastures will have a long-term beneficial effect.

Authors: Ray M. Kaplan and Jeff W. Tyler

FATTY LIVER

BASICS

OVERVIEW

- Hepatocellular accumulation of fat results from overfeeding of dry dairy cows in the preparturient period; by the postparturient period, a damaging amount of fat has accumulated in the liver. It may appear as an individual case or as a herd problem in dairy cows. It is uncommon in beef cattle where it appears as an individual case prepartum.
- Fatty liver often appears in association with other diseases of the postparturient cow such as ketosis, retained placenta, metritis, milk fever and displaced abomasum.
- The development of fatty liver is a slow, insidious process and may range from progressively decreased milk production to a full-blown liver injury.
- The fundamental metabolic-nutritional defect is in the livers of cows where triglycerides (TG) are synthesized in excess of the liver's ability to synthesize the proteins of very low density lipoprotein (VLDL).

PATHOPHYSIOLOGY

- Overfeeding during the dry period induces excessive body fat stores.
- In the postparturient period, development of a negative energy balance leads to an intense mobilization of lipid from these stores.
- In the process, stored lipids are hydrolyzed by lipolytic enzymes to their constituent fatty acids and glycerol, which are then transported to the liver via the circulation as nonesterified fatty acids (NEFA) and glycerol.
- NEFA are taken up by the liver and enter the lipid metabolic pathways and glycerol enters the carbohydrate metabolic pathways. NEFA is resynthesized into TG or further metabolized.
- Normally, TG are transported out of the liver as components of lipoproteins of which VLDL is the major TG transporter. When there is insufficient lipoprotein synthesis, the TG cannot be transported out of the liver and they accumulate in the hepatocyte.
- These stores of TG physically damage the hepatocytes and/or disturb their normal metabolic pathways to induce the clinical syndrome of fatty liver.

SYSTEMS AFFECTED

Hepatic, metabolic, production management, nutrition

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

- Fatty liver is seen primarily in the high-producing dairy cow that is in its second to fourth lactation and is recognizably overconditioned.
- The more severely affected cows with depression and anorexia may be poorly conditioned. It may appear in individual cows or as a herd problem.
- When fatty liver appears in beef cattle, it occurs prior to calving and as an individual case.

Species

Bovine

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Clinical signs of fatty liver are related to the degree of liver damage and/or to the associated diseases of parturition that may be present.
- Affected cows have a history of overfeeding during the dry period, possibly with difficulties in calving or postparturient disorders such as metritis, retained placenta, parturient paresis, ketosis, or displaced abomasum.
- They are characterized by being overly fat, anorexic, depressed, and weak with decreased milk production. Clinical signs of liver injury such as icterus are not usually apparent.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- All diseases of the high-producing dairy cow in early lactation are included in the differential. The more important differentials are ketosis, parturient paresis, retained placenta, metritis, and displaced abomasum. These are often seen concurrently with fatty liver.
- Secondary differentials include toxic hepatitis, biliary cholangitis, cholestasis, hepatic encephalopathy, and hepatoma.

CBC/BIOCHEMISTRY/URINALYSIS

- The CBC often has a leukopenia, neutropenia, lymphopenia, and degenerative left shift. Fibrinogen and Hp may also be increased. These are nonspecific signs of general inflammation and do not point directly to fatty liver.
- The common biochemical profiles are variable regarding the standard indices for liver injury.
- These include serum bili and serum liver enzymes such as AST, GD, GGT, ID, and AIP. The bile acids, urea, proteins, albumin, or NH_3 are also variable so judicious interpretation of any positive results correlating with history and clinical signs are required to arrive at a diagnosis.
- BSP or ICG clearance $\text{T}_{1/2}$ are generally increased but both tests are time consuming, BSP is not generally available, and ICG is expensive.
- Serum lipid analyses including NEFA, TG, Chol, and LP fractions are definitive, noninvasive tests but are time and equipment expensive. NEFA increase; TG, Chol, and VLDL decrease.
- Urine ketones will be present in concurrent ketosis and urobilinogen may be absent if there is advanced cholestasis.
- Liver biopsy with compatible serum lipid analyses is the definitive diagnostic test for fatty liver. The specimen is distinctly yellow, is extremely friable, and floats in water. Microscopically, excessive hepatocyte accumulation of fat is seen.
- At necropsy, there is excessive abdominal and omental fat with some degree of icterus throughout the abdominal cavity. The liver is enlarged with rounded edges, greasy to the touch, extremely friable, and yellow.

TREATMENT

- Concurrent diseases, which may be present, must be treated.
- Restore anorexia or decreased rumen motility by transfaunation and provide good-quality, highly palatable hay.
- Correct the nutritional energy imbalance, restore carbohydrate metabolism, and promote liver protein synthesis.
- The therapy of fatty liver is supportive with the goal of correcting the negative energy balance, reducing fat mobilization, promoting carbohydrate metabolism, and increasing transport of TG out of the liver by promoting LP synthesis. All therapeutic approaches are empirical and largely symptomatic.

MEDICATIONS

DRUGS OF CHOICE

- Give an initial bolus of 250–500 ml of 50% glucose followed by a continuous intravenous infusion of glucose at 50–60 g/h to restore energy balance.
- Glucose precursors such as propylene glycol may be given per os initially at 250 mg bid for 2 days followed by 125 mg per os bid for 2 more days.
- Glucose is monitored two to three times per day using a portable glucose meter. Urine ketone is monitored at the same time using dipsticks.
- Choline, a component of LP, may be given at 50 g/d S.C. with some success in promoting the movement of TG out of the liver.
- PZI may be given at 200 U bid for several days to promote glucose utilization and hepatic LP synthesis, which will aid the movement of TG out of the liver.
- Glucocorticoids as used for bovine ketosis may be used to promote gluconeogenesis.
- Glucagon at 10 mg/day has been used experimentally at a constant intravenous infusion for 14 days and shown to be effective in increasing plasma glucose, and decreasing NEFA and TG. When given S.C. at 2.5 or 5.0 mg/day every 8 hours for 14 days, similar results were obtained in older cows but not in younger cows.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PREVENTION

- The most effective means of preventing fatty liver is to avoid overfeeding during the dry period. The goal is to prevent the positive energy balance, which results in an overly fat or overconditioned cow with excess fat stores. In these cows, shortly postpartum, the demands of lactation create a marked negative energy balance, which then calls upon the fat stores for energy.
- As a result of the lipolysis, NEFA and glycerol are delivered to the liver in excess of its ability to transport the reformed TG out of the liver. These TG accumulate in the hepatocyte to eventually cause liver injury.

EXPECTED COURSE AND PROGNOSIS

The prognosis is generally poor in the advanced and complicated cases of fatty liver. Early diagnosis and rapid corrective measures will markedly improve the outcome.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Clinical signs of fatty liver are related to the degree of liver damage and/or to the associated diseases of parturition that may be present.
- They are characterized by being overly fat, anorexic, depressed, and weak with decreased milk production. Clinical signs of liver injury such as icterus are not usually apparent.

AGE-RELATED FACTORS

Generally, animals in their second through fourth lactation

FESCUE TOXICITY

BASICS

OVERVIEW

- Fescue toxicosis is a disease affecting primarily the cardiovascular and endocrine systems.
- Tall fescue (*Festuca arundinacea* Schreb.) is a cool season perennial grass grown worldwide.
- Noninfected varieties of tall fescue are available but they do not withstand extreme environmental conditions (overgrazing, drought, heat, etc.) as well as the endophyte-infected varieties.
- The fungus has a symbiotic relationship with the fescue, which makes the plant hardier.
- *Neotyphodium coenophialum* is present within the seed and throughout the plant.
- *N. coenophialum* produces several ergot-type and pyrrolizidine-type alkaloids, which cause the clinical signs associated with fescue toxicity.
- Three syndromes are seen in ruminants: fescue foot, summer slump, and fat necrosis.
- Another syndrome causing severe reproductive abnormalities in pregnant mares is not generally seen in ruminants.

PATHOPHYSIOLOGY

- The grass itself is not believed to be the cause of toxicity, but rather an endophytic fungus that infects it, *Neotyphodium coenophialum* (endophyte-infected).
- These toxins primarily cause peripheral vasoconstriction.

SYSTEMS AFFECTED

Cardiovascular and endocrine systems.

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Tall fescue (*Festuca arundinacea* Schreb.) is a cool season perennial grass grown worldwide.

SIGNALMENT

- This toxicosis affects cattle, sheep, and goats, as well as horses.
- Any animal that is grazing or consuming fescue hay can be affected.

Species

- Summer slump (most common syndrome—seen in all ruminants)
- Fescue foot (only in cattle)
- Fat necrosis in cattle/lipomatosis/abdominal necrotic fat (only in cattle)

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Fescue foot (only in cattle)
 - Early: mild lameness particularly in rear limbs, walking with back arched

- Redness and swelling around coronary band
- Limb edema may be present.
- Cold extremities
- Hair on pastern easily rubbed off
- With progression, a sharp line of demarcation appears at the level of the pastern or fetlock.
- Skin below line becomes dry and gangrenous.
- Hoof wall and skin may necrose.
- Tips of ears and switch of tail may also necrose.
- Affected animals are generally underweight and have dull hair coat.
- Summer slump (most common syndrome—seen in all ruminants)
 - Hirsutism
 - Elevated temperature and respiratory rate
 - Poor weight gain
 - Heat intolerance
 - Diarrhea
 - Hypersalivation
 - Photosensitization
 - Delayed puberty in heifers
 - Decreased conception and pregnancy rates
 - Decreased milk production
- Fat necrosis in cattle/lipomatosis/abdominal necrotic fat (only in cattle). Signs are related to obstruction of abdominal organs: bloat, colic.

CAUSES AND RISK FACTORS

- Consumption of tall fescue that is infected with *N. coenophialum*
- Fescue foot is more commonly seen in cold ambient temperatures.
- Summer slump is seen in warm to hot ambient temperatures.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

- Fescue foot
 - Ergot toxicosis/*Claviceps purpurea* toxicity (history of consuming nonfescue forages, examination of forage for fungus)
 - Trauma (examination of foot)
 - Foot rot (examination of foot)
 - Frostbite (history of ambient conditions)
 - Selenium toxicosis (elevated serum selenium, history of consuming nonfescue forages)
- Summer slump
 - Internal parasites (fecal examination)
 - Nutritional deficiencies (analysis of feeding practices—including trace mineral supplements)
 - Chronic organophosphate toxicity—particularly in sheep (history of exposure, clinical signs of neurologic disease/axonal degeneration)
 - Molybdenum toxicity (located in an area of high molybdenum soil; signs attributable to copper deficiency: hypotrichosis, diarrhea, joint swelling, low serum or liver copper, and high liver molybdenum)
- Fat Necrosis
 - Lymphosarcoma (necropsy)
 - Intestinal obstruction (exploratory laparotomy, inflammatory leukogram, abdomenocentesis)
 - Peritonitis (inflammatory leukogram, abdomenocentesis)

- Intussusception (exploratory laparotomy, inflammatory leukogram, abdominocentesis)
- Intestinal torsion (exploratory laparotomy, inflammatory leukogram, abdominocentesis)

CBC/BIOCHEMISTRY/URINALYSIS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Clinical signs matching syndromes noted above
- History of consuming fescue (pasture or hay) for weeks or months
- Microscopic examination of fescue for fungus
 - Should examine many tillers or seeds of the grass
- Clinical signs have been seen in animals consuming fescue with as little as 20% if the grass is infected with *N. coenophialum*.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- All syndromes
 - Poor body condition
 - Rough hair coat
- Fescue foot: gangrenous tissue on extremities, particularly rear limbs, with a line of demarcation from normal tissue.
- Fat necrosis: presence of calcified fat in abdomen, particularly the omentum

HISTOPATHOLOGICAL FINDINGS

Fescue foot: vascular thrombosis, tissue necrosis in lower limbs

TREATMENT

- Fescue foot: if disease is recognized early (before tissues necrose), remove fescue from diet or dilute with forage source that is not infected.
- Summer slump: remove from fescue
- Fat necrosis—none

MEDICATIONS

DRUGS OF CHOICE

Fescue foot: broad-spectrum antibiotic therapy for secondary bacterial infections (observe appropriate withdrawal times).

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

POSSIBLE INTERACTIONS

FOLLOW-UP

N/A

MISCELLANEOUS

- Recent research suggests that treatment of fescue or direct feeding of seaweed extract (*Ascophyllum nodosum*) may decrease the toxic effects of endophyte-infected fescue.
- Nontoxic varieties of endophyte-infected fescue have been developed and appear to be hardier than noninfected fescue but with a much lower potential to cause the untoward effects seen with toxic endophyte-infected varieties.

FLOPPY KID SYNDROME

BASICS

OVERVIEW

- A floppy kid syndrome (fading kid syndrome, FKS) case is defined as one that is normal at birth but develops a sudden onset of profound muscular weakness (flaccid paresis or paralysis) or ataxia at 3–10 days of age.
- Kids with this clinical syndrome were first reported in the spring of 1987, although there were anecdotal reports of herds with this syndrome several years earlier.
- First recognized in herds in Canada and the west coast of the United States, this syndrome has since been diagnosed throughout the United States and Canada.

SIGNALMENT

- Affected kids have been found in dam-reared, pasteurized milk hand-reared, and unpasteurized milk hand-reared herds.
- There does not seem to be a breed predilection.

SIGNS

- Profound muscular weakness (flaccid paresis or paralysis) or ataxia
- Affected kids cannot use their tongues to suckle but can swallow.
- Affected kids have no other signs of illness such as diarrhea or respiratory disease.

CAUSES AND RISK FACTORS

- *Clostridium botulinum*, *E. coli*, and caprine herpes virus have been incriminated as possible etiologic agents.
- Cases tend to occur most commonly late in the kidding season.
- Herd morbidity ranges from 10%–50%.
- No specific management or goat-related risk factors have been identified.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diagnosis is made on the basis of clinical signs of paresis/paralysis in 3–10-day-old kids with metabolic acidosis.
- These cases may be confused with white muscle disease, abomasal bloat, colibacillosis, septicemia, or enterotoxemia.

CBC/BIOCHEMISTRY/URINALYSIS

- A marked metabolic acidosis with an increased anion gap and decreased bicarbonate is present.
- Chloride levels are normal.
- Some affected kids are hypokalemic.
- There are no other detectable, repeatable serum biochemical abnormalities.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

N/A

TREATMENT

- Early recognition of the syndrome and immediate treatment of the base deficit as well as supportive care are critical.
- If clinical chemistries are available, the base deficit can be calculated and the kid can be given fluids spiked with bicarbonate.
- Less severely affected kids can be treated with sodium bicarbonate (baking soda) at the rate of teaspoons in a small amount of water given orally.
- In addition, kids may need supportive therapy such as tube feeding.

MEDICATIONS

DRUGS OF CHOICE

Oral or intravenous sodium bicarbonate

CONTRAINDICATIONS

N/A

FOLLOW-UP

N/A

MISCELLANEOUS

- Spontaneous recovery without treatment has been reported in a few cases; however, case fatality rates have been as high as 30%–50% in untreated animals.
- Because the etiology is not known, no preventative measures can be specifically recommended.
- Necropsy of dead kids is encouraged to rule out other causes of neonatal mortality.

Assessing Hydration Status in Ruminants

% Dehydration	Demeanor	Sunken Eye	Skin Tenting
<6%	Normal	—	—
6–8%	Depressed	+	+/-
8–10%	Depressed	++	2–5 sec
10–12%	Comatose	+++	5–10 sec
>12%	Dead	++++	>10 sec

DIAGNOSIS

CLINICAL EXAMINATION

- The degree of patient dehydration is typically determined by physical examination.
- Skin turgor and elasticity, position of the eye within the orbit, tenacity of mucus within the oral cavity, capillary refill time, and patient demeanor are all indicators of patient hydration status.

- As a general rule of thumb, fluid deficits less than 6% of body weight cannot be detected on clinical examination and deficits greater than 12% of body weight are generally fatal. The following table provides attempts to summarize expected clinical signs of dehydration in cattle.
- Clinical demeanor also has been associated with acid/base status in neonatal calves with diarrhea.
- The following table summarizes expected base deficits in calves of varying ages. It should be emphasized that this information is relevant only in neonatal calves with primary uncomplicated gastrointestinal disease.
- Calves with septicemia will have highly variable acid/base status. Furthermore, these rules of thumb are not appropriate in adult ruminants.
- Under ideal circumstances fluid and electrolyte disorders are confirmed by inexpensive, minimally invasive laboratory procedures.

CBC/BIOCHEMISTRY/URINALYSIS

- Hematocrit and serum protein concentration are readily determined in most veterinary practices.
- These procedures are useful adjuncts to physical examination in confirming the presence of dehydration.
- Serum chemistry analyzers suitable for clinic and ambulatory practice are becoming more common.
- Although panel composition varies with instrument and test kit, patient side confirmation of azotemia, acid/base status, and serum calcium and potassium is now possible. It should be noted that many of these instruments have not been validated for use in ruminants; however, most practitioners find them useful adjuncts in the development of fluid therapy protocols.

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

GENERAL PRINCIPLES OF FLUID THERAPY

1. Oral fluids are generally preferred unless medically contraindicated. Oral fluids are inexpensive and safe and can be administered rapidly in field conditions.
2. Hypoglycemia is rare in adult ruminants, but occurs occasionally in neonates. Diseases of adult ruminants, which result in hypoglycemia, include fatty liver, ketosis, and pregnancy disease.
3. Mild hypocalcemia is common in anorectic adult cattle.
4. Mild metabolic alkalosis is common and expected in anorectic adult cattle.
5. Metabolic alkalosis and increased serum concentrations of albumin may decrease serum-ionized calcium. Metabolic acidosis and hypoalbuminemia may increase serum-ionized calcium. Many laboratories measure total calcium; however, animals recognize and regulate serum-ionized calcium. Correction factors developed for companion animals are inaccurate.

in ruminants.

6. Sodium bicarbonate administration is appropriate only for correction of metabolic acidosis. Metabolic acidosis is common in neonates with diarrhea, grain engorgement, and salivary loss, but rare in most other conditions of ruminants.

7. Maximum short-term IV fluid administration rates should not exceed 80–90 ml/kg/hr (20 ml/kg/hr in llamas).

8. Maximum long-term IV fluid administration rates for cattle should not exceed 20 ml/kg/hr.

9. Hypokalemia is common in anorectic adult cattle.

10. Neonates with diarrhea often have hyperkalemia (increased serum potassium concentrations); however, body stores of potassium (intracellular potassium) are often very low.

11. Potassium administration rates should not exceed 0.5 mmol/kg/hr unless the patient is severely hypokalemic, or glucose and/or bicarbonate are administered concurrently. Glucose and bicarbonate administration will cause extracellular potassium to shift to the intracellular space.

12. Near isotonic (300 mOsm/L) fluids should be used under most conditions.

13. Fluid deficit is generally calculated as follows: $\text{Body weight (kg)} \times (\% \text{ dehydration}/100) = \text{deficit (L)}$.

14. Estimates of daily maintenance requirements vary from 60–120 ml/kg/day, depending on severity of ongoing losses (diarrhea, renal losses). The values above include ongoing losses. Maintenance requirements are calculated as follows: $\text{Body weight (kg)} \times [(60\text{--}120 \text{ ml/kg/day})/1000 \text{ ml/kg}] = \text{(L)}$.

15. Total daily fluid needs are calculated by adding deficits and daily maintenance requirements.

16. Base deficit is typically calculated as follows: $\text{Body weight (kg)} \times [\text{measured deficit (mmol/L)}] \times [\text{bicarbonate space}]$. Bicarbonate space is typically estimated as 0.5 to 0.6 in cattle. Bicarbonate replacement is used to replace 50–100% of base deficit. Higher percentages of deficit replacement, approaching 100%, are appropriate in neonates with diarrhea.

17. The core electrolyte abnormalities in calves with diarrhea include dehydration, acidosis, low systemic potassium with serum hyperkalemia due to acidosis, and occasionally hypoglycemia.

18. Isotonic = 300 mOsm/L, Isotonic sodium bicarbonate = 1.3% = 1.3 g/100mL = 13 g/L, Isotonic sodium chloride = 0.9% = 0.9 g/100 mL = 9 g/L

19. Do not withhold milk from calves with diarrhea. Do not feed beef calves more than 1 L/feeding. Beef calves are acclimated to small, frequent meals.

20. Oral fluids are probably adequate in mildly dehydrated calves ($\leq 8\%$). Severely dehydrated calves probably require at least short-term intravenous fluids.

TREATMENT

In general, fluid therapy can be reduced to the following set of questions:

1. What is the fluid deficit?
2. What is the daily maintenance requirement for fluids?
3. What will the total fluid needs be over the next 24 hrs?
4. What is the base deficit?
5. What volume of isotonic sodium bicarbonate will replace this deficit?
6. How would you prepare this volume of isotonic sodium bicarbonate solution?
7. What is the maximum rate of fluid administration in the first hour?
8. How much 50% dextrose will we add to the first hour's fluids to create a 1% solution?
9. What is the theoretical maximum concentration of potassium for fluids administered in the first hour of therapy?
10. Based on the above answers, design a fluid therapy protocol for the patient.

EXAMPLE

You are examining a 50-kg Holstein heifer calf with profuse diarrhea. The calf is 15 days old. On physical examination, the calf is severely dehydrated (estimate 10%) and is comatose.

1. What is the calf's fluid deficit?

Body weight (kg) \times (% dehydration)/100 = 50 kg \times 10/100 = 5L

2. What is the calf's daily maintenance requirement for fluids?

Body weight (kg) \times 100 ml/kg = 50 kg \times 100 ml/kg = 5000 ml = 5L

3. What will the calf's total fluid needs be over the next 24 hrs?

Deficit + Maintenance = 5L + 5L = 10 L

4. What is the calf's base deficit?

Body weight (kg) \times (estimated base deficit) \times bicarbonate space = Estimated deficit based on the calf's demeanor (comatose) and age (>8 days) is 20 mmol/L 50 kg \times 20 mmol/L \times 0.6 = 600 mmol HCO_3^- . Alternatively, base deficit can be calculated from measured blood bicarbonate. For purposes of this calculation, we will assume the calf has a pure metabolic acidosis and serum bicarbonate of 5 mmol/L, and that normal is 25 mmol/L. Body weight (kg) \times (normal bicarbonate - measured bicarbonate) \times 0.6 = 50 kg \times (25 - 5) \times 0.6 = 600 mmol/L HCO_3^-

5. What volume of isotonic sodium bicarbonate (1.3%) will replace this deficit?

Each liter of an isotonic solution has 300 mOsm/L. In the case of isotonic sodium bicarbonate, half the particles in solution are Na^+ and half are HCO_3^- . Therefore, each liter of isotonic sodium bicarbonate contains 150 mmol/L of HCO_3^- . [Calculated deficit (mmol)]/150 mmol/L = [600]/150 = 4 L 1.3% sodium bicarbonate (NaHCO_3)

6. How would you prepare this volume of isotonic sodium bicarbonate solution?

1.3% = 1.3 g/100 ml = 13 g/L Volumes required \times 13 g/L = 4L \times 13 g/L = 52 g NaHCO_3 in 4 L sterile water It is important that base deficit be corrected using isotonic solutions.

7. What is the maximum rate of fluid administration in this calf for the first hour?

Calves may be administered as much as 40 to 80 ml/kg during the first hour of therapy without creating an inordinate risk of pulmonary edema. Thereafter, administration rates should not exceed 20 ml/hr. Maintenance fluid rates in calves are approximately 4 ml/kg/hr. Body weight (kg) \times 80 ml/kg/hr = 50 kg \times 80 ml/kg/hr = 4000 ml = 4L

8. How much 50% dextrose will we add to the first hour's fluids to create a 1% solution?

We desire a 1% dextrose solution. Standard solutions, which we carry in our truck, are 50% solutions. Consequently, we will need to make a 1:50 dilution to create a 1% solution. 1L = 1000 mL, 1000 mL/50 = 20 mL Therefore, we add 20 mL of 50% dextrose to each of the 4L we administer in the first hour. Remember, not all calves with diarrhea are hypoglycemic and excessive glucose supplementation will cause serum glucose to exceed the renal threshold, causing an osmotic diuresis, an undesirable effect in a dehydrated patient.

9. What is the theoretical maximum concentration of potassium for fluids administered in the first hour of therapy?

Generally, we limit potassium administration to a maximum of 0.5 mmol/kg/hr. (Body weight (kg) \times 0.5 mmol/kg)/volume administered (50 \times 0.5)/4 = 6.25 mEq/L Having performed this calculation, we recognize that the concurrent administration of bicarbonate and glucose will cause potassium to move intracellular, resulting in a precipitous decline in serum potassium. Consequently, we will typically administer 8 to 12 mmol/L potassium in bicarbonate-containing fluids.

10. Based on the above answers, we design a fluid therapy protocol for a calf.

Obviously, these are not exact calculations. Here is a rough plan.

a. Hour 1: 4 L isotonic sodium bicarbonate, each liter supplemented with 10 mmol K/L. Each of the first 2 L is supplemented with 20 ml 50% dextrose.

b. Hour 2: 2 L of a commercially available oral electrolyte solution (total volume 6 liters)

c. Hour 8: 2 L whole milk (total volume 8 liters)

d. Hour 14: 2 L of a commercially available oral electrolyte solution (total volume 10 liters)

If the calf is readily nursing, alternate oral electrolytes and milk at 6-hour intervals. If hydration appears normal, one or both daily electrolyte feedings may be discontinued. Do not use stool characteristics as a criteria for administration of milk.

FOLLOW-UP

In animals receiving extensive fluid therapy, the need to reassess hydration and acid base at frequent intervals should be considered.

MISCELLANEOUS

- Many practitioners use hypertonic fluids. These solutions can be rapidly administered in an ambulatory setting.
- As general rule, 7–8% sodium chloride solution is administered at a rate of 5 ml/kg IV.
- When using such protocols, oral fluids should be provided or administered.

FLUORIDE TOXICITY

BASICS

OVERVIEW

- Fluoride (F^-) is absorbed by the gastrointestinal tract and lungs.
- Clinical signs associated with chronic F^- exposure are manifest primarily in skeletal and dental abnormalities and may take months to years to become apparent depending on the solubility of the fluoride compound, amount of F^- absorbed, and duration of exposure.
- Chronic fluorosis is commonly due to ingestion of mineral supplements with high F^- content or consumption of contaminated forage and water by industrial emissions containing F^- .
- Acute toxicity is rare but may result from inhalation of gases containing fluoride or ingestion of highly toxic rodenticides containing fluoride. In acute cases, clinical signs are referable to the nervous system and death results from respiratory or cardiac failure.

SIGNALMENT

Dairy cattle are considered more at risk of chronic toxicity due to their longer lifetime in production. There is no breed, sex predilection, or genetic basis for fluorosis.

SIGNS

- Dental abnormalities occur only if animals are exposed during permanent tooth development prior to eruption and include dullness, mottling, pitting, and discoloration of tooth enamel, and abnormal tooth wear and loss, particularly in pairs of teeth that erupt at the same time.
- Dental problems may result in decreased feed and water intake, difficulty with mastication, weight loss, and general unthriftiness.
- Other clinical signs include decreased milk production and skeletal abnormalities; lameness, arthritis, fractures of the pedal bones; bilateral enlargement and roughening of metatarsals, metacarpals, ribs and mandible; and abnormal hoof wear resulting from altered gait with elongated toe, especially on hind feet.

CAUSES AND RISK FACTORS

- $> 40\text{--}100\text{ mg } F^-/\text{kg feed cattle}$, $> 60\text{ mg } F^-/\text{kg feed ewes}$, $> 150\text{ mg } F^-/\text{kg feed lambs}$
- Rock phosphate deposits, nondefluorinated or inadequately defluorinated mineral supplements, monoammonium, diammonium, and gypsum phosphate fertilizers or other sources of phosphorus containing less than 100:1 parts phosphorus to fluoride, contaminated forage and water from industrial aerial emissions, deep well and thermal spring water, fluorinated municipal water, sewage effluent from municipalities using fluorinated water, forage and water contamination by volcanic gas and ash pose a risk.
- Forage usually has a low level of fluoride but levels are variable and should be considered.
- A calcium deficient diet may increase F^- accumulation. Animals in poor body condition may be more susceptible.
- Rodenticides containing sodium monofluoroacetate (1080) or fluoroacetamide are highly toxic and may account for acute toxicity. Due to the highly lethal nature of these compounds, their use is restricted in the United States.
- Fluoride absorption is related to solubility; sodium fluoride $>$ rock phosphate $>$ dicalcium phosphate $>$ defluorinated phosphate

DIAGNOSIS

Clinical signs, history of exposure/mineral supplementation, radiography and feed/bone/urine F^- levels

DIFFERENTIAL DIAGNOSIS

Arthritis; osteoporosis; deficiencies in calcium, phosphorus, or vitamin D; traumatic injury

CBC/BIOCHEMISTRY/URINALYSIS

Eosinophilia, anemia, hypoglycemia, increased ALP

OTHER LABORATORY TESTS

- F^- , Ca^{2+} , P concentrations in forage, mineral supplements, soil, and water
- F^- content in bone (normal content will vary with bone selected), antler, kidney, serum
- > 10 ppm F^- in urine
- T_4 , T_3 hypothyroidism

IMAGING

Radiography: periosoteal hyperostosis, exostosis, sclerosis in metacarpals, metatarsal, mandible, and ribs

DIAGNOSTIC PROCEDURES PATHOLOGICAL FINDINGS

- Gross—teeth: pitting, discoloration, chalkiness of enamel, irregular wear, and tooth loss
- Skeletal—exostoses, sclerosis, arthritis, stunted growth
- Histopathological—abnormal remodeling of bone, atrophy of osteoblasts and bone marrow cells, retardation of cartilage cell differentiation

TREATMENT

Remove from source. Provide feeds that are easily masticated, symptomatic treatment for osteoarthritis/lameness

MEDICATIONS

DRUGS OF CHOICE

None

CONTRAINDICATIONS

.

POSSIBLE INTERACTIONS

N/A

FOLLOW-UP

PATIENT MONITORING PREVENTION/AVOIDANCE

- Aluminum sulfate, aluminum chloride, calcium aluminate, and calcium carbonate reduce absorption of fluorides.
- Use only feed grade sources of phosphorus supplements.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

In mild cases, improvement may be seen over weeks to months as fluoride body stores are depleted. In severe cases of lameness or inability to consume adequate forage, euthanasia may be required as some bony lesions are irreversible.

MISCELLANEOUS

ASSOCIATED CONDITIONS AGE-RELATED FACTORS

Young animals with growing bones are most severely affected. Exposure of adult animals will result in normal dentition with skeletal lesions.

ZOONOTIC POTENTIAL

None

PREGNANCY

Congenital fluorosis has been reported in calves born to fluoride-intoxicated cows.

RUMINANT SPECIES AFFECTED

All ruminants are susceptible.

BIOSECURITY

None

FOOT-AND-MOUTH DISEASE

BASICS

OVERVIEW

- Foot-and-mouth disease (FMD) is a very contagious, viral disease of cloven-hoofed livestock and some wild animals, characterized by fever and vesicular lesions with subsequent erosions of the epithelium of the mouth, tongue, nostrils, feet, and teats.
- Sheep and goats are considered “maintenance” hosts. They can have very mild signs; therefore, diagnosis may be delayed allowing time for aerosol and contact spread as well as environmental contamination.
- Compared to other species, pigs produce extremely high concentrations of virus particle in aerosols. They are considered “amplifying” hosts.
- Cattle are considered “indicators” of this disease because they generally are the first species to show signs of infection. Their lesions are more severe and progress more rapidly.
- Recovered or vaccinated cattle exposed to diseased animals can be healthy carriers for 6–24 months. Sheep can be carriers for 4–6 months. Pigs are not carriers of FMDV.

PATHOPHYSIOLOGY

- FMDV is a single-stranded RNA virus and a member of the family Picornaviridae, genus *Aphthovirus*.
- There are seven immunologically and serologically distinct types of FMDV: O, A, C, Southern African Territories (SAT) -1, SAT-2, SAT-3, and Asia-1. Currently there are more than 60 subtypes.
- FMDV usually enters the host via the respiratory tract and can be transmitted by aerosols, ingestion, direct contact, artificial insemination, and meat products.
- Feeding of infected animal products such as meat, milk, bones, glands, and cheese can also spread the disease.
- Incubation of the virus is from 1 to 14 days and clinical signs usually develop in 3 to 5 days.
- The disease usually runs its clinical course in 1 to 3 weeks.

SYSTEMS AFFECTED

Skin, herd health, reproductive, cardiovascular, renal

GENETICS

There is no particular mode of inheritance for this disease.

INCIDENCE/PREVALENCE

- The morbidity rate may approach 100% in susceptible populations, particularly when the disease or serotype is not endemic to the population.
- Mortality is usually between 1% and 5%, although may be higher in young animals or in certain wildlife populations exposed to certain strains.

GEOGRAPHIC DISTRIBUTION

- Generally, endemic areas include Asia, Africa, and parts of South America. In South America, Chile and Guyana are free of the disease without vaccination.
- North and Central America, Australia, and New Zealand have been free of FMD for many years. Despite the 2001 outbreak in the United Kingdom, it and most European countries are recognized as free without vaccination.
- The OIE designates member countries as being in one of five categories: (1) free without vaccination, (2) free with vaccination, (3) having free zones without vaccination, (4) free zones with vaccination, and (5) having endemic FMD. This list is updated each May and can be accessed at www.oie.int.
- Serotypes are somewhat geographically represented. O and A occur in many parts of the world, serotypes SAT-1, 2, 3 are generally limited to Southern Africa, and Asia-1 is generally found in Asia.

SIGNALMENT

Species/Host Range

- Cloven-hoofed domestic livestock (e.g., cattle, pigs, sheep, goats, water buffalo) and cloven-hoofed wild animals (e.g., deer, elk, bison, antelopes, wildebeest) predominant. Other susceptible animals include elephants, nutrias, armadillos, and hedgehogs and may serve as sources of transmission to ruminants.
- South American camelids have low susceptibility to FMDV, whereas camels are resistant to natural infection.
- FMDV does not discriminate on the basis of breed, age, or sex, although mortality may be higher in younger animals.
- Immunity to one virus serotype is not protective against other serotypes.

SIGNS

- Initial clinical signs are fever, lethargy, salivation, lameness, blanching of the coronary bands, and inappetence.
- Foot-and-mouth disease is characterized by vesicles (blisters), which progress to erosions in the mouth, nares, muzzle, feet, or teats.
- Vesicles on the tongue, dental pad, gums, soft palate, nostrils, or muzzle characterize oral lesions. Severe oral lesions may lead to complete sloughing of the epithelial lining of the tongue.
- Hoof lesions are in the area of the coronary band and interdigital space. Severe lesions may lead to complete sloughing of the hoof.
- Infection with FMD is accompanied by a high fever in the range of 103–106°F.
- Depression, anorexia, excessive salivation, serous nasal discharge, decreased milk production, lameness, and reluctance to move are commonly observed.
- Abortion may occur in pregnant animals.
- Young animals may die acutely without clinical signs.

CAUSES AND RISK FACTORS

- Contact with infected animals; spread from aerosols; exposure to contaminated meat, milk, cheese, blood, etc.; contact with mechanical vectors (e.g., contaminated people's hands, footwear, etc.).
- It is important to note exposure to infected pigs can spread the disease very rapidly because they are efficient amplifiers of FMDV and that sheep can produce infectious aerosols while not displaying pronounced clinical signs.
- Risk factors include naïve population exposed to exotic FMD virus or serotype, unvaccinated population in endemic areas, poor biosecurity, and feeding contaminated feed to susceptible animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Vesicular stomatitis
- Papular stomatitis
- Bovine viral diarrhea-mucosal disease
- Malignant catarrhal fever
- Foot rot
- Herpes mammillitis
- Pseudocowpox
- Rinderpest
- Bluetongue
- Contagious ecthyma (orf) in sheep
- Infectious bovine rhinotracheitis
- Chemical and thermal burns

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Antigen detection: virus isolation (gold standard), complement fixation, ELISA
- Nucleic acid detection: PCR
- Antibody detection: virus neutralization, ELISA

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- In the United States, contact the authorities immediately upon suspicions of a vesicular disease. Only under the direction of a foreign animal disease diagnostician (FADD) will samples be collected in the initial case. All samples must be sent to the Foreign Animal Disease Diagnostic Laboratory (FADDL) in Plum Island, New York.
- Vesicular fluid, the epithelium that covers vesicles, whole blood, serum (acute and convalescent), and esophageal-pharyngeal fluid from convalescent animals (probang test) in cell culture fluid are important samples for diagnosis.

GROSS FINDINGS

- The diagnostic lesions of foot-and-mouth disease are single or multiple vesicles from 2 mm to 10 cm in size.
- Lesions may be seen in any stage of development from a small white area to a fluid-filled blister, sometimes joining with adjacent lesions. The vesicles rupture, leaving a red, eroded area, which is then covered with a gray fibrinous coating. This coating becomes yellow, brown, or green, and is then replaced by new epithelium.
- “Tiger heart” lesions may also be seen; these lesions are characterized by a gray or yellow streaking in the myocardium caused by degeneration and necrosis. These are most commonly seen in young animals that die acutely.
- Denuded rumen papillae

TREATMENT

In endemic areas, generally supportive treatment of infected individuals is warranted. Milking time hygiene is of utmost importance. In areas where FMD is exotic, health care is usually swift and terminal.

MEDICATIONS

N/A

FOLLOW-UP

PREVENTION/AVOIDANCE

- FMD is prevented thru the implementation of stringent biosecurity procedures.
- It is possible for humans to act as vectors of the disease with virus surviving for 24 to 48 hours on oral mucosa.
- At the farm level, basic animal husbandry practices that limit spread of endemic organisms (e.g., restriction of high-risk visitors, quarantine of high-risk animals and animal products, etc.) will aid in the exclusion of FMD.
- At the country level, control of importation of animals and products, decontamination of at-risk garbage, and a strong animal health infrastructure will mitigate the risk of FMD transmission.
- The virus is inactivated when exposed to pH below 6.5 or above 11; however, it can survive for extended periods (days to weeks) when protected in milk, meat, serum, or other organic material.
- Sodium hydroxide (2%), sodium carbonate (4%), and citric acid (0.2%) are effective disinfectants. FMDV is resistant to iodophors, quaternary ammonium compounds, hypochlorite, and phenol, especially in the presence of organic matter.

PRODUCTION MANAGEMENT

Vaccination

- Vaccines against FMD are available and are used primarily in endemic areas or as an aid in eradicating the disease.

POSSIBLE COMPLICATIONS

Secondary bacterial infection of eroded foot-and-mouth lesions are common as is low milk production, failure to thrive,

mastitis, and reproductive inefficiency.

EXPECTED COURSE AND PROGNOSIS

- The disease usually runs its course in 1 to 3 weeks.
- Some animals may become carriers. Cattle may carry the virus for a few years, while sheep and goats usually carry it for less than a year.
- The duration of immunity from naturally occurring disease is relatively short and is serotype, and often subtype, specific.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

All ages of animals are susceptible to infection with FMD. Neonates are more susceptible to fatal cardiac disease related to FMD infection.

ZOONOTIC POTENTIAL

FMD has been isolated from only about 40 human cases, despite widespread occurrence of the disease in animals. Vesicular lesions can be seen, but signs are mild. Because of this, FMD is not considered a public health concern.

PREGNANCY

Some pregnant animals may abort.

RUMINANT SPECIES AFFECTED

Domestic and wild, even-toed ungulates: cattle, goats, sheep, bison, South American camelids, water buffalo, deer, reindeer, elk, mouse, antelopes, chamois, gazelles, impala, giraffe, wildebeest

FOOT ROT IN CATTLE

BASICS

DEFINITION

- Interdigital phlegmon (foot rot) is an acute or subacute necrotizing infection of the interdigital skin in cattle that extends into the underlying tissues and results in diffuse digital swelling and lameness.
- A second form of the disease has been reported in the UK and the United States, “superfoul,” “super foot rot,” or peracute foot rot, which is much less responsive to antimicrobial therapy than the normal form.
- Super foot rot will have a peracute onset (i.e., less than 12 hours after infection).

PATHOPHYSIOLOGY

- Trauma to the interdigital skin causes a local dermatitis and allows the infection from *Fusobacterium necrophorum* and *Prevotella levii* or other synergistic bacterium to get established.
- The early infection produces dermal and hypodermal necrosis with subsequent involvement of the whole interdigital skin. The necrotizing dermatitis spreads to the underlying tissues and causes an inflammatory response, which leads to generalized digital swelling and acute lameness due to pain. The foot becomes swollen from the fetlock to the coronary band.

SYSTEMS AFFECTED

Skin (primary), musculoskeletal (secondary)

GENETICS

Incidence may be higher in *Bos taurus* than *Bos indicus*.

INCIDENCE/PREVALENCE

Usually sporadic but can be epidemic under some conditions

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Bovine

Breed Predilections

Jersey cattle are reported to have lower risk than other dairy breeds.

Mean Age and Range

More common in younger animals but found in all age groups

Predominant Sex

None

SIGNS HISTORICAL FINDINGS

- Sporadic occurrence of lameness with swelling around the coronary band

PHYSICAL EXAMINATION FINDINGS

- Swollen, painful foot with necrotic, foul-smelling interdigital lesion; usually only one foot involved, more common in rear feet

CAUSES

- *Fusobacterium necrophorum* is always present and *Porphyromonas levii* is the most common secondary organism. Other *Porphyromonas* species are also found as secondary invaders as well as members of the genera *Prevotella*, *Peptostreptococcus*, and other *Fusobacterium*.
- Isolates of *Fusobacterium* have been found to have great differences in virulence, with isolates from “super foot rot”

being at the higher end of the virulence scale.

- *Fusobacterium necrophorum* and *Prevotella levii* are considered to be part of the normal flora of bovine intestinal tracts. Spirochetes are occasionally isolated from lesions.

RISK FACTORS

Major risk factor is trauma to the interdigital skin, which can be due to mechanical trauma (e.g., stones, stubble, frozen ground, etc.) or hydropic maceration due to constant moisture (e.g., wet ground or manure slurry); may be more common during warmer weather.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Septic arthritis as a sequel to sole ulcer, white line abscess, or vertical fissure. Septic arthritis will usually have swelling of only one digit and will not have the necrotizing interdigital lesion unless the cellulitis has become more diffuse.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Acute to peracute onset of lameness, symmetrical swelling around the coronary band and in the interdigital space
- Usually only found on one foot and is more common on rear feet
- Pyrexia and decreased feed intake are commonly seen in both beef and dairy cattle and decreased milk production is common in dairy cattle.
- Microbiological culture is seldom used due to the time and expense involved in culturing anaerobic organisms.
- In herd outbreaks, culture may be useful to confirm the presence of *F. necrophorum*.

PATHOLOGIC FINDINGS

- Necrotizing, usually caseous, necrosis of the interdigital skin with a characteristic foul odor and swelling of the foot around the coronary band
- Extensive inflammation of the skin and underlying tissues

TREATMENT

APPROPRIATE HEALTH CARE

- Currently, there are two vaccines licensed for prevention of interdigital phlegmon but this author is unaware of any peer-reviewed studies on vaccine efficacy.
- Hoof trimmers will commonly treat lesions with a topical antimicrobial and wrap the foot with a bandage.
- Sometimes it is necessary to remove the interdigital fat pad to facilitate healing of the interdigital skin.

NURSING CARE

- If bandages are applied, they should be removed after 3–4 days.
- Affected cattle should be given the full course of parenteral antimicrobials and be monitored for improvement and clinical cure.

ACTIVITY

Should be limited during recovery

DIET

Nutrition is sometimes blamed, but there is little or no evidence of any specific nutritional deficiency or excess that causes

the skin to be invaded by bacteria more easily.

CLIENT EDUCATION

- If wet conditions are associated with an outbreak, cattle should be moved to drier areas, if possible.
- Good corral and freestall management and removal of any trauma inducing objects should attenuate the incidence.
- During an outbreak, it would be prudent to isolate affected animals from the remainder of the herd.

SURGICAL CONSIDERATIONS

Amputation of a claw may become necessary if septic arthritis occurs secondary to the interdigital phlegmon.

MEDICATIONS

DRUGS OF CHOICE

- The following drugs have labels specifically for foot rot and can be used on all dairy cattle as well as beef cattle:

Amoxicillin (Amoxi-inject): 3–5 mg/lb IM or SC for ≤ 5 days (withdrawal: meat 25 days; milk 96 hours)

Ceftiofur HCl (Excenel): 1.1–2.2 mg/lb IM or SC once per day for 3–5 days (withdrawal: meat 2 days; milk 0 days)

Ceftiofur HCl (Naxcel): 1.1–2.2 mg/lb IM once per day for 3–5 days (withdrawal: meat 0 days; milk 0 days)

Sulfadimethoxine bolus (Albon bolus): 25 mg/lb PO once per day for first day, 12.5 mg/lb once per day, should not exceed 5 days (withdrawal: meat 7 days; milk 60 hours)

Sulfadimethoxine injectable, 40% solution (several manufacturers): 25 mg/lb IV once per day as initial dose, 12.5 mg/lb IV once per day; continue for 2 days after clinical signs are gone.

Penicillin or oxytetracycline can be used for treatment of susceptible bacterial infections in nonlactating dairy cattle and beef cattle. Check label for dosage and withdrawal times.

Nonsteroidal anti-inflammatory drugs (NSAIDs) may be helpful on a case-by-case basis.

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

Do not treat for longer than period stated on label.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

Extralabel antimicrobials might be used but practitioners would have to show that labeled products were not efficacious.

FOLLOW-UP

PATIENT MONITORING

Monitor affected cattle during treatment for indications that pain and swelling are abating.

PREVENTION/AVOIDANCE

- Footbaths with antiseptic solutions are commonly used on dairies to prevent new cases of infectious foot diseases including interdigital phlegmon.
- Commonly used footbath compounds are CuSO_4 or ZnSO_4 (5%–10%) or formalin (3%–5%).
- Footbaths require good management to be effective since contamination of the footbath solution with feces and urine will render the solution ineffective.
- It is commonly recommended that the footbath be drained, cleaned, and refilled after every 100–300 animals pass through.
- Footbath programs have to be carefully monitored and tend to be site specific.

POSSIBLE COMPLICATIONS

Suppurative arthritis, septic tenosynovitis, rupture of the flexor tendon, abscessation of the interdigital space, and phalangeal

osteomyelitis

EXPECTED COURSE AND PROGNOSIS

Recovery is usually uneventful if the disease is diagnosed and treated promptly. “Super foot rot” is usually not responsive to antibiotics.

MISCELLANEOUS

Other infectious causes of lameness exacerbated by poor foot hygiene or wet or muddy conditions, such as interdigital dermatitis, digital dermatitis, and heel horn erosion

AGE-RELATED FACTORS

Found in all ages but more common in younger animals

ZOONOTIC POTENTIAL

No

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Bovine, both dairy and beef

BIOSECURITY

Introduction of new cattle onto a facility may introduce new, highly virulent strains of the bacteria and cause outbreaks of interdigital phlegmon.

FRACTURES AND LUXATIONS

BASICS

DEFINITION

- Luxation: complete dislocation or displacement of a joint
- Subluxation: partial dislocation (displacement) of a joint
- Fractures are classified as *complete* or *incomplete:closed* (simple), when the overlying tissue is intact;*compound*, when the fracture site communicates with the skin surface;*comminuted*, when the bone is splintered; or *displaced*, when the ends of the bone are no longer aligned.

PATHOPHYSIOLOGY

Luxations and Subluxations

- Subluxations/luxations of the fetlock joint are rare.
- Generally, both fetlock joints of a foot are affected and displacement may occur dorsally or laterally, with dorsal subluxation being more common.
- Luxation of the patella may occur dorsally, laterally, or medially and may be intermittent or permanent.
- When luxated dorsally (intermittent upward fixation), the patella is hooked over the proximal aspect of the medial trochlear ridge of the femur during flexion.
- This has been associated with desmitis of the patellar ligament as well as ligamentous laxity.
- Dorsal luxation generally occurs unilaterally; it may however be bilateral.
- Lateral and medial luxations are rare.
- Lateral luxation is congenital or may be associated with trauma to the medial femoropatellar ligament.
- The llama has a single patellar ligament; all other ruminants have three distal patellar ligaments. Patellar luxation in goats and llamas is usually congenital in origin.
- Coxofemoral luxations occur when an animal slips or falls.
- Excessive traction during dystocia may cause coxofemoral luxation in calves.
- Craniodorsal luxations are most common.
- Luxation of the sacroiliac joint is rare and is usually associated with calving.

Fractures

- Fractures of the distal phalanx are usually closed and intra-articular and involve the palmar (plantar) third of the bone.
- The inside claws of the forelimbs and the outside claws of the hind limbs are affected most commonly.
- P2 fractures are rare and are generally compression fractures associated with jumping on hard ground.
- Transverse and oblique fractures of P1 may not involve the pastern or fetlock joint.
- Sagittal, comminuted, and avulsion P1 fractures are usually intra-articular.
- Trauma is the most common cause of long-bone fractures in both ruminants and llamas.
- Capital physal fracture of the femur can occur during forced extraction, in particular in breeds of beef cattle with a large birth weight and muscle mass.
- In young bulls, the shear forces associated with their pushing against one another may cause physal fractures of the head of the femur.
- Fractures of the pelvis are rare and are caused by severe traumatic insult with the wing of the ileum fracturing most commonly.
- Fractures of the mandible and maxilla are usually traumatic in origin and occur more commonly in younger animals.

SYSTEMS AFFECTED

Musculoskeletal, production management, nervous, skin

GENETICS

- The Brahman breed has been associated with an increased risk of upward fixation of the patella.
- Heritability of patellar luxation in llamas has not been established but owners should be advised against using a llama with congenital patellar luxation as breeding stock.

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

All ruminant species are affected.

Breed Predilections

- Potential heritability of patellar luxation in llamas
- The Brahman breed has been associated with an increased risk of upward fixation of the patella.

Mean Age and Range

Animals of all age groups are affected.

Predominant Sex

There is no sex predilection.

SIGNS

- Fetlock subluxation/luxation is characterized by severe alteration of the axis of the distal limb, buckling of this joint, moderate to severe lameness, abnormal range of motion, and effusion of this joint as well as pain on rotation and flexion of the distal limb.
- Upward fixation of the patella is characterized by a sudden locking of the extremity in extension (the distal limb is flexed and dragged along).
- In lateral patellar luxation, the patella is palpable on the lateral aspect of the joint and the quadriceps muscle loses its extensor function so that the stifle and hock are permanently flexed.
- Congenital lateral patellar luxation can affect both legs, and a crouching stance with inward rotation of the stifles is characteristic.
- Clinical signs of patellar luxation in small ruminants and llamas are similar to those described in cattle and a click may be audible as the patella is disengaged from a locked position.
- Signs of ileosacral luxation/subluxation range from ataxia and knuckling of the hind limbs (due to fibular nerve paresis) to recumbency.
- With ileosacral luxation the sacral region appears dropped, the head of the tail elevated, and rectal palpation reveals a dorsoventral narrowing of the pelvic canal.
- Craniodorsal coxofemoral luxations cause lameness with minimal weight bearing.
- Caudovernal and cranioventral luxations are associated with a recumbent animal.
- In order to compensate for fracture of P1 of the inside claw of the forelimb, crossing of the legs may be seen. In the hind limb the outside claw is more commonly affected and a strong abduction of the limb is noted.
- Long-bone fractures present as sudden onset non-weight bearing lameness, the patient may be recumbent and an unphysiological angle to the limb may be evident.
- With a slipped capital physis, the animal will bear weight but is noticeably lame, crepitus may be palpable over the greater trochanter, and, in chronic cases, muscle atrophy and varus deformity of the contralateral limb are evident.
- Fractures of the tuber coxae are characterized by the “knock down hip” appearance associated with the bony displacement and a slow anterior phase to the stride.
- With pelvic wing fractures, a dragging of the toe as it is advanced and the anterior and ventral location of the fracture segment may also be appreciated.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnoses for the presenting signs include:

- Subsolar abscess
- Laminitis
- Sprain (distorsion)
- DJD
- Septic arthritis
- Hip dysplasia (young bulls)
- Neurological deficits
- Spastic paresis (Differentiate from upward fixation of patella: with spastic paresis the limb is held in extension but passive flexion is possible.)
- Neurogenic atrophy of the quadriceps femoris muscle (due to femoral nerve damage at birth) resulting in lateral patellar luxation (Differentiate from congenital lateral luxation as surgery will not correct this lesion.)
- Soft-tissue trauma (joint capsule, ligament, muscle tears)
- Cranial cruciate ligament rupture
- Medial and lateral collateral ligament injury to the stifle
- OCD/subchondral bone cysts
- Angular limb deformities

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

- High quality radiographs are often required in order to localize and confirm the presence of a luxation/subluxation or fracture and to determine the prognosis.
- Imaging of the upper limb and pelvis can be challenging and requires a high-output machine.
- The large udder in adult cows complicates radiography of the pelvis.
- If general anesthesia is not practical, sedation may be sufficient to obtain a ventral-to-dorsal image of the affected limb in lateral recumbency.

DIAGNOSTIC PROCEDURES

- External palpation of the pelvis and upper limb for crepitus (both standing and at a walk) provides valuable information in localizing a lesion
- Use of a stethoscope for audible crepitus in the upper limb may also prove helpful.
- Rectal palpation of the bony pelvis is necessary if a pelvic fracture is suspected.

PATHOLOGIC FINDINGS

- In fetlock luxation/subluxation, the medial or lateral collateral ligament is usually completely torn with the other being detached from the bone.
- Soft-tissue trauma at the site of fracture may cause pain, swelling, and a hematoma that palpates as a fluctuant mass.
- Crepitus may be evident
- In large animals with femoral and humeral fractures, crepitus may only be detectable on auscultation.

TREATMENT

See Surgical Considerations below.

APPROPRIATE HEALTH CARE

N/A

NURSING CARE

N/A

ACTIVITY

- With any of the conditions described isolated strict stall confinement of the affected animal, in order to minimize movement is desirable
- Upward fixation of the patella in small ruminants and calves is an exception where restricted exercise is advocated in order to strengthen the muscles that stabilize the stifle joint.

DIET

In general no change in diet is necessary.

CLIENT EDUCATION

- The client must be informed that activity should be kept to a minimum.
- In the case of cast application, it must be monitored for signs of strike-through (drainage) and foul odor, and the animal's degree of lameness must be followed closely.

SURGICAL CONSIDERATIONS

- Subluxations/luxations of the fetlock joint can be treated by repositioning the joint and applying a cast (usually for a period of 6–8 weeks).
- Arthrodesis of the fetlock joint may be considered in the case of compound luxations.
- Successful use of collateral ligament prosthesis has been described in the fetlock.
- Upward fixation can be corrected through standing desmotomy of the medial femoropatellar ligament.
- Desmotomy of the lateral and imbrication of the medial patellar ligament are appropriate for lateral luxation of the patella.
- Osteotomy and relocation of the tibial crest and trochleoplasty (deepening of the trochlear groove) have been described in ruminants.
- In adult cattle, simple, closed fractures of the digit can be managed with stall rest, application of a block on the other claw, and cast application.
- Comminuted or open fractures may require amputation of the digit.
- In small ruminants, young cattle, and llamas, phalangeal fractures and those of the long bones may be treated with cast application alone or transfixation pins in combination with a cast.
- Tibial and radial fractures may be stabilized using the Thomas splint.
- Internal fixation using dynamic compression plates, intramedullary pins, or interlocking nails may be successfully implemented for the repair of metacarpal/tarsal, tibial, radial, humeral, and femoral fractures.
- External support for transport to a referral center should involve the placement of two sections of PVC pipe (positioned at right angles to one another) secured firmly over a bandage.
- Internal fixation with pins or screws is advocated for the treatment of a slipped capital physis of the femur.
- Closed reduction of coxofemoral luxations may be attempted in acute injury (within 24 hours) whereby the affected limb of the sedated, recumbent animal is secured by a heavy rope running through the inguinal region, and traction is applied to a second rope attached to the distal metatarsal area.
- The aim of open reduction for coxofemoral luxation is to remove the debris, preventing relocation of the femoral head, from within the acetabulum.
- Sequestrum formation associated with fracture of the tuber coxae may require surgical removal of the bony fragment.
- Rostral fractures of the mandible and maxilla can often be treated conservatively or through circumdental wire placement.
- More caudal jaw fractures may require external or internal fixation.

MEDICATIONS

DRUGS OF CHOICE

- In the case of open luxation/subluxation or fracture or if surgery is performed, broad-spectrum antibiotic coverage is indicated.
- For all conditions described, nonsteroidal anti-inflammatory medication is indicated to provide pain relief and a reduction in inflammation.

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

- Monitor for degree of lameness, joint effusion, soft-tissue swelling, problems in the contralateral limb, muscle atrophy, ability to feed and drink.
- In the case of cast placement, this should be monitored for strike-through and foul odor.
- Surgery sites should be closely monitored for incisional infections.

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

Those commonly associated with surgical procedures especially fracture repair

EXPECTED COURSE AND PROGNOSIS

- In young animals with fetlock subluxation, the prognosis is good, with luxation it is guarded. In adult animals, the prognosis is guarded to poor.
- With upward fixation of the patella and the appropriate surgical treatment, the prognosis is fair.
- In the case of lateral and medial patellar luxation, the prognosis is guarded to poor.
- Mild subluxations of the sacroiliac joint are associated with a good prognosis however may pose problems during parturition in the future.
- Prognosis for fractures of the digit depends on fracture configuration and the degree of joint involvement.
- Mild residual lameness is to be expected following long-bone fracture repair.
- Prognosis for successful repair of a long-bone fracture deteriorates with increasing complexity of fracture and increasing age and weight of animal.
- Stall rest alone for slipped capital physis of the femur is associated with a poor prognosis.
- Fractures of the tuber coxae generally have a good prognosis.
- Fractures of the bony pelvis are associated with callus formation and a narrowing of the birth canal.
- The prognosis for animals with coxofemoral luxation depends on their ability to stand, the direction of the luxation, and the time that passes before correction.
- Mandibular/maxillary fractures are generally associated with a good prognosis.

FREEMARTINISM

BASICS

OVERVIEW

- A freemartin is a XX/XY chimera that results from the fusion of the placental circulation of at least one male and one female fetus.
- Freemartinism most commonly occurs when a single female twin calf is born with a single bull calf twin, but in cattle, sheep, and goats, it can occur with triplets or quadruplets provided there are dual-sex fetuses present.
- Affected female twins most commonly appear phenotypically female at birth but may demonstrate masculinization of external genitalia peripubertally.

SYSTEMS AFFECTED

Reproductive

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide distribution

SIGNALMENT

Female calves, lambs, or goat kids that are born with at least one male sibling

Species

Cattle, sheep, and goats; more common in cattle

Breed Predispositions

N/A

Mean Age and Range

Newborn

Predominant Sex

N/A

SIGNS

- The only clinical signs of relevance relate to androgenization of the gonadal and genital phenotype
- Elongation of the hair at the ventral vulva
- Exaggerated prominence to the clitoris
- Short blind ending vagina
- Absence of ovaries and uterine structures
- Inguinal, abdominal, or paranephric testes

DIAGNOSIS

- In postpubertal heifers: palpation of pelvis for absence of normal uterine anatomy and absent ovaries
- Physical appearance of vulva and clitoris
- Karyotyping of peripheral blood sample to demonstrate XX/XY intersex status and/or demonstration of male cells in

blood or tissues of heifer by PCR

- Vaginal length less than 12 cm and the absence of an external os to the cervix on vaginoscopy can be used to assist in the diagnosis of suspect freemartinism at 3–6 weeks of age.

Author: Simon F. Peek

FROSTBITE

BASICS

DEFINITION

Damage or injury to the skin and body tissues resulting from their freezing following exposure to excessive cold or windchill.

OVERVIEW

- Severe frostbite is a grave physiological condition with potentially life-threatening consequences.
- All species are susceptible.
- Uncommon injury in well-nourished animals when environmental temperatures are above 10° F (–12.22° C)
- Frostbite is not uncommon when temperatures are at or below 0° F (–17.78° C) or windchill lowers the temperature to those low temperatures.
- Neonates are at greatest risk due to wet, thin skin at birth, lack of substantial quantities of subcutaneous fat, high surface area: volume ratio.
- Frostbite may be primary or secondary to debilitating disease or malnutrition.
 - Sick calves may suffer frostbite despite adequate housing and nutrition.
 - Frostbite may occur at higher environmental temperatures in compromised animals.
- Cold injury most commonly affects ears, tail, teats, scrotum, and distal extremities (feet; hind limbs more than forelimbs).
- May be associated with systemic disease
- Tissue damage is substantially exaggerated if thawing is followed by refreezing (freeze-thaw-freeze-thaw syndrome).
- Tissue previously damaged by freezing is more prone to injury on subsequent exposure to cold temperatures.

PATHOPHYSIOLOGY

- Exact mechanism of tissue damage is difficult to define.
- Multiple pathologic mechanisms occurring concurrently
- Frostbite involves direct cellular injury from freezing, injury from progressive vasoconstriction and subsequent arterial thrombosis, and ischemic necrosis.
- Four phases describe mechanisms of cell damage during freezing:
 - Phase I (prefreeze phase): congestion and leakage of fluid from vascular compartment due to arterial constriction and venous dilation
 - Phase II (freeze-thaw phase): extracellular ice crystal formation causes cell membrane rupture or cellular dehydration.
 - Phase III (vascular stasis phase): more severe and persistent arterial spasm and venous dilation leading to arteriovenous shunting and tissue hypoxia
 - Phase IV (ischemia phase): neural tissue damage due to prolonged tissue hypoxia
- Additional injury occurs during rewarming:
- Return of blood flow and warming of affected tissue
- Interstitial edema due to capillary hyperpermeability following release of histamine and bradykinin from damaged mast cells; edema persists for about a week.
- Subcutaneous hemorrhage
- Skin develops vesicles or raised, red-purple lesions.
- Thromboxane and norepinephrine release cause severe vasoconstriction at line of demarcation between viable and damaged tissue; prostaglandin I₂ release has a membrane stabilizing effect.
- Specific enzymes (NADH-diaphorase, alkaline phosphatase, esterase) are found in dermal fibroblasts, sebaceous glands, and hair follicles and at high concentrations in viable tissue; may help to define line of demarcation of viable and nonviable

tissue in dermis.

- During frostbite, inappropriate upregulation of neutrophil-endothelial cell adhesion results in sequestration of granulocytes in damaged tissue. Hypoxia and inflammation result in release of their cytoplasmic granules and additional cellular damage.
- Altered elasticity of granulocytes and vasoconstriction lead to trapping of cells in capillary beds and microthrombi formation.
- Direct cellular destruction, release of catecholamines, and tissue anoxia have potentially significant secondary effects in severe frostbite resulting in damage to other organs.
- Affected skin is usually anesthetic.
- Rapid rewarming is painful but results in less cellular and tissue damage than does slow rewarming.

SIGNALMENT

- Neonates
- Debilitated, sick, or dehydrated animals
- Animals with heavily pigmented skin
- Milking cattle and goats turned outside in cold weather with inadequately dried udders and teats
- Animals with preexisting vascular damage (e.g., ergotism, fescue toxicosis, vasculitis)
- Malnourished animals with reduced metabolic heat generation

SIGNS

- Signs of chilling including piloerection, shivering, peripheral vasoconstriction
- Mild frostbite causes blanching of tissue and reduced sensation followed by painful erythema, scaling, and alopecia.
- Severe frostbite results in necrosis, dry gangrene, sloughing of affected part(s); affected skin is usually anesthetic.
- Death from low core body temperature can result if not treated before vital organs are compromised.
- Frozen teats
 - Initially appear reddened or pale
 - If severe, progress to scab formation over distal half of teat.
 - Scab loosens over days and exposes raw denuded teat end.
 - As second scab develops, duct may become occluded and milking difficult.
- Milk-fed calves may show superficial muzzle sloughing.
- Pain with rewarming of affected area
- Line of demarcation between viable and nonviable tissue usually appears within 3 days of rewarming affected areas.
- Demarcation line is initially diffuse but becomes more distinct within 7 days, but may take weeks before clearly defined.
- Vesicles and blisters develop on affected areas.
- After sloughing, ears are rounded, alopecic, and have pinna of variable length.

CAUSES AND RISK FACTORS

- Exposure to subnormal temperatures and wetness
- Windchill accelerates evaporation and cooling of exposed areas.
- Wet neonates or adults with wet udders, teats, testicles
- Heifers with severe periparturient udder edema and reduced perfusion to teats
- Poor nutrition
- Hypoglycemic neonates
- Previous tissue damage due to cold injury

DIAGNOSIS

- Diagnosis is based upon history and clinical signs.
- Appearance of skin and tissue of affected area(s)

POSTMORTEM LESIONS

- Decreased subcutaneous and perirenal fat deposits
- Edema
- Subcutaneous hemorrhage of tarsal region
- Edema, vesicles, or bullae over affected tissue
- Skin and tissue necrosis
- Histology: adiposities filled with eosinophilic cytoplasm instead of lipid; tissue microthrombosis, vasculitis

DIFFERENTIAL DIAGNOSIS

- Inherited, small pinna of American La Mancha goat
- Traumatic injury
- Previous tissue damage from ergot toxicosis

CBC/BIOCHEMISTRY/URINALYSIS

- Metabolic acidosis
- Dehydration
- ±Hypoglycemia (primarily neonates)
- ±Reflect secondary infection or organ compromise

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Only amenable to treatment in early stages
- Treatment depends on severity of injury; mild cases may not require therapy.
- Rewarming should be initiated as soon as possible but not until it is known that refreezing can be prevented; thawing and refreezing increases tissue damage.
- Incomplete or partial rewarming decreases chances for successful recovery.
- Move animal to areas (warm housing) where refreezing is not possible.
- Handle frozen tissue gently.
- Rapid thawing reduces physical effects of frostbite without causing further cellular damage.
- Thaw rapidly in warm water (plain or with a dilute antiseptic solution).
 - Recommended water temperature range: 100.2–111.1 °F, 38–44 °C
 - Water should be 104–106 °F.
- Rewarming process should be repeated twice daily for 2 to 3 days.
- Application of lanolin or bland, protective ointment or cream after rewarming completed
- Apply aloe vera topically for its antithromboxane, anti-inflammatory, and analgesic effects.
- Leave damaged area exposed during healing.
- Analgesia
 - Nonsteroidal anti-inflammatory drugs for analgesia and systemic anti-inflammatory effects
 - Flunixin meglumine; 1.1 mg/kg IV, IM every 12 to 24 hours
 - Ketoprofen: 2.2 mg/kg/day IV, IM
 - Hind limb pain: ± use of epidural during rewarming period for analgesia
- Broad-spectrum antimicrobials to prevent secondary infection
- Correction of dehydration and metabolic acidosis by administration of oral or intravenous fluids

- Fluid administration advised even if not dehydrated for vascular support and to help correct hyperviscosity, improve capillary circulation, and prevent hypovolemic shock that may occur after peripheral rewarming and subsequent fluid shifts
- Protect animal from subnormal temperature until healing has occurred.
- Inspect skin for blisters and bullae.
 - Blisters that are filled with clear or opaque fluid should be debrided to prevent further tissue contact with thromboxane and prostaglandin E₂, which may mediate progression of dermal ischemia.
 - Hemorrhagic blisters should be left intact to avoid further damage to microvasculature.
- Supportive care
 - High-protein, high-calorie diet
 - Vitamin supplement
- Tetanus immunization in animals with extensive frostbite
- Use of glucocorticoids is controversial.
 - Short-term use may be beneficial in decreasing capillary permeability, maintaining microcirculation, stabilizing cell membrane, and reducing induced histamine.
 - Long-term use should be avoided.
- Restrain to avoid self-mutilation
- Edges of healthy and gangrenous tissue should be kept clean, protected, and allowed to slough naturally.
- Check daily under sloughing skin for infection.
- If necessary, debride necrotic tissue to facilitate healing and limit secondary infection.
- Postpone debridement or surgical excision of limbs until boundary between viable and nonviable tissue is clearly obvious, which may take 8 weeks (impractical for most large animals).
- Treatment of frostbitten teats:
 - Keep teat duct patent; may require surgery.
 - Prevent development of mastitis.
 - Topical aloe vera
 - Severely affected cows may need to be culled.

MEDICATIONS

N/A

DRUGS OF CHOICE

N/A

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

- Avoid massaging or rubbing tissue during warming as this can prolong resolution of edema and recovery period.
- Do not use occlusive bandages over damaged areas.
- Avoid premature debridement of affected area; more tissue may be viable than initially apparent.

FOLLOW-UP

Full recovery is usually possible after mild to moderate frostbite provided appropriate and proper treatment is given.

PRODUCTION MANAGEMENT

- Change management to avoid occurrence of frostbite.
- Give special attention to drying off calves, kids, and lambs born in cold environments.
- Ensure susceptible body parts remain dry during exposure to subnormal temperatures.
- Provide adequate, clean, dry bedding to neonates to minimize heat loss by convection and evaporation.
- Provide easily accessible shelter.
- Provide consistent feeding management.
- With ambient temperatures below 0° C management should include:
 - Dry udder and teats completely before animal leaves parlor.
 - Provide adequate windbreaks and shelter.
 - Dip just the teat end during very cold weather.
- Provide windbreaks and bedding for calving cow when windchill temperatures are below 10–20° F.
- House calving cows and calves less than 1 day old when windchills are below 10° F and calves cannot be kept dry because of rain or snow.
- Keep dairy animals clean, dry, and out of the wind with adequate dry bedding daily when temperatures are subnormal.

FUNGAL TREMORGENS

BASICS

OVERVIEW

- Tremorgens are mycotoxins that have been reported to cause tremoring conditions in cattle, goats, sheep, deer, horses, and camelids.
- Clinical signs associated with ingestion of these neurotoxins are collectively known as “staggers” and include ataxia, muscle tremors, rigid stance, recumbency, and paddling convulsions. The tremors are accentuated by exercise and can lead to tetany and collapse.
- The mycotoxins are produced by fungal genera such as *Aspergillus*, *Neotyphodium*, *Penicillium*, *Phalaris*, and *Claviceps*, and are often associated with specific grasses, such as dallis grass, bahia grass, canary grass, Bermuda grass, and perennial ryegrass.

PATHOPHYSIOLOGY

- The endophyte *Neotyphodium lolii* is associated with perennial ryegrass (*Lolium perenne*) and produces tremogenic toxins known as lolitrems A, B, C, and D. These toxins are indole compounds that are derivatives of lysergic acid that exert their effects in a similar fashion to paspalitrems in that they inhibit GABA and glycine.
- The seed heads of dallis and bahia grasses can be infected by *Claviceps paspali*. The fungus produces alkaloids including indole compounds derived from lysergic acid known as paspalitrems. These alkaloids include paspalinine, paspalitrem A, and paspalitrem B, which may exert their effects by inhibiting the inhibitory neurotransmitter, gamma-aminobutyric acid (GABA).
- Loss of inhibitory neurotransmitters leads to increased neurotransmission and prolonged depolarization, resulting in the neurologic signs of incoordinated movements, ataxia, and muscle tremors.

SIGNALMENT

Reports of tremogenic mycotoxin intoxication have occurred in cattle, horses, goats, sheep, deer and camelids. There are no age, species, or breed predilections.

SIGNS

As described above

CAUSES AND RISK FACTORS

- Risk factors and inciting conditions vary between tremorgenic compounds.
- Paspalitrems proliferate in warm, humid climates of the southeastern United States. Wet conditions following dallis grass seed head formation result in increased toxin formation.
- Factors that promote formation of *Phalaris* mycotoxin include decreased light intensity, humidity, and high nitrogen levels.
- Outbreaks of ryegrass staggers have been documented in New Zealand, Australia, and North America during the summer and early fall during drought conditions.
- Seventy-five percent of the fungal species associated with mycotoxin production are found in the lower 2 cm of the plant, therefore, outbreaks usually occur on overgrazed pastures. Toxin levels increase within days of heavy dew or light rainfall.

Fungal Varieties

- The seed heads of dallis and bahia grasses can be infected by *Claviceps paspali*. The fungus infects the pistil of the grass flower and produces a sticky fluid, “honeydew,” which hardens into mature sclerotia containing a high concentration of toxin.
- The fungus produces alkaloids including indole compounds derived from lysergic acid known as paspalitrems. These alkaloids include paspalinine, paspalitrem A, and paspalitrem B, which may exert their effects by inhibiting the inhibitory

neurotransmitter, gamma-aminobutyric acid (GABA).

- Loss of inhibitory neurotransmitters leads to increased neurotransmission and prolonged depolarization, resulting in neurologic signs of incoordinated movements, ataxia, and muscle tremors.
- The condition is known as dallis grass staggers or nervous ergotism.
- The fungal genera *Phalaris* can be found in canary grass and produce tryptamine alkaloids (dimethylated indolealkylamines).
- These mycotoxins produce their neurogenic effects by competitively inhibiting the initial step in the breakdown of serotonin by monoamine oxidase. There are two clinical forms of *Phalaris* grass staggers: acute death from cardiovascular collapse and the chronic nervous form. The cardiovascular form often results in sudden death within 12–72 hours of exposure to the toxin.
- Clinical signs prior to death reflect cardiovascular failure (e.g., cardiac arrhythmias, dyspnea, cyanosis, and extreme tachycardia). The nervous form may occur after repeated exposures over 2–3 weeks. Clinical signs include those listed above and a “rabbit hopping” gait seen in sheep, when both rear legs move in unison.
- Bermuda grass is also associated with staggers in cattle, sheep, goats, and horses. The toxic principle has yet to be identified but the clinical signs are similar to those seen in ryegrass staggers and can develop as soon as 36 hours following ingestion or after several days of exposure.
- The toxin endures through the drying process and may be found in hay several years after the initial cutting.
- The endophyte *Neotyphodium lolii* is associated with perennial ryegrass (*Lolium perenne*) and produces tremorgenic toxins known as lolitrems A, B, C, and D. Lolitrem B is most commonly associated with clinical signs of ryegrass staggers in ruminants and horses.
- These toxins are indole compounds, which are derivatives of lysergic acid that exert their effects in a similar fashion to paspalitrems in that they inhibit GABA and glycine. Signs may be mild until the animal is stimulated or excited when the prominent clinical sign becomes muscle tremors of the head and neck.
- Signs may progress to ataxia, stiffness, hypermetria, generalized tremors, or seizures.
- Other mycotoxins that may contribute to ryegrass staggers include those produced by the genera *Penicillium* and *Aspergillus*. The mycotoxins produced by *Penicillium* spp. include penitrem A, verruculogen, and fumitremogin B. *Aspergillus* spp. produces verruculogen and penitrem A.
- These toxins are produced by fungus in the soil and are absorbed by plant roots and accumulate in vegetation. The toxic mechanism on the CNS is as described above.

DIAGNOSIS

- Diagnosis is based on clinical signs and history of exposure.
- Analysis of forage to identify specific mycotoxins can be performed by most state diagnostic laboratories; but it is not commonly performed, and obtaining a forage sample with adequate mycotoxin levels is difficult.
- Extracts of the fungus-infected feed material can be analyzed by thin-layer chromatography, high-performance liquid chromatography, or bioassay.

DIFFERENTIAL DIAGNOSES

- Other plants that may contain mycotoxins and cause tremorgenic conditions include white snakeroot, rayless goldenrod, jimmy fern, and mountain laurel.
- Other conditions that can cause similar neurologic signs include hypomagnesemia in ruminants, rabies, yew (*Taxus* spp.) poisoning, and selenium poisoning.

CBC/BIOCHEMISTRY/URINALYSIS

Tremorgens cause no changes in clinical pathology. An elevation in serum creatinine kinase or aspartate aminotransferase may be seen due to muscle cell damage from ataxia or incoordination.

PATHOLOGIC FINDINGS

TREATMENT

- There is no specific treatment or antidote for tremorgenic mycotoxin intoxication.
- Removal from affected pastures or contaminated forages and supportive care may allow for recovery in 3–14 days.

GASTROINTESTINAL MICROBIOLOGY

BASICS

OVERVIEW

- Diseases of the digestive tract of ruminants are common among farm animals.
- GI tract infections are primarily spread throughout the population by means of fecal to oral transmission.
- Many of the pathogens are zoonotic and pose both a herd safety issue as well as a food safety concern.
- The digestive tract of ruminants is a complex environment composed of normal microflora, which provide both a defense mechanism against colonization of pathogens and a major source of nutritional and metabolic components for the ruminant.
- Normal microflora of the ruminant digestive tract include but are not limited to:

Bacteroides spp.

Butyrivibrio spp.

Candida spp.

Clostridium spp.

Eubacterium spp.

Lactobacillus spp.

Methanobacterium spp.

Ruminococcus spp.

Selenomonas spp.

Streptococcus spp.

Trichosporon spp.

Vibrio spp.

- Some of the most common pathogens associated with ruminant digestive tract infections include but are not limited to:

Campylobacter jejuni

Cryptosporidium spp.

E. coli O157:H7

Listeria monocytogenes

Mycobacterium avium paratuberculosis

Salmonella spp.

CAUSES AND RISK FACTORS

- Transmission is primarily fecal to oral.
- Risk factors include anything contaminated with feces such as water, feed, equipment, or the environment.
- Newborn calves can be infected by coming in contact with the mother's udders that have been contaminated with feces, or in some instances through the mother's colostrum.
- Neonates are most susceptible due to lack of an established GI tract microflora.
- Neonates are most susceptible due to lack of a fully established immune system.
- Pathogenic strains of *Escherichia coli* recovered from the intestinal tract of animals fall into categories called enterotoxigenic, enteropathogenic, enterohemorrhagic, and necrotoxicogenic. Two categories—enteroaggressive and enteroinvasive—have not been reported in domestic livestock.
- The pathogenicity of bacterial strains is determined by the genetic presence of adhesins and toxins.
- The genes encoding for these adhesions and toxins are generally organized in chromosomes, large plasmids, or phages, and are often transmitted horizontally between strains. Bacterial antibiotic resistance is passed on in this way.

Neonatal Diarrhea

- Numerous pathogens are implicated in the occurrence of neonatal diarrhea, but only a limited number is commonly involved in the infection process. Most bacteria are actually secondary opportunists and not primary pathogens. Most of these bacteria are present within the gastrointestinal tract of many healthy, mature adults.
- Infectious diarrhea is an important cause of neonatal calf morbidity and mortality that results in significant economic losses in the sheep, dairy goat, beef, and dairy cattle industries.
- The immune status of the newborn (the level of passively acquired immunity through colostrum) is the major risk factor related to the occurrence of diarrhea.
- The environmental conditions in which neonates may reside vary tremendously between facilities.
- Numerous risk factors related to the occurrence of neonatal diarrhea have been identified. These factors can be categorized as: those that are related to the neonate, the pathogens involved in the infection, and the environment of the neonate.
- Risk factors related to bacterial pathogens associated with neonatal calf diarrhea include the occurrence of multiple infections and the size of the infective inoculum.

OTHER LABORATORY TESTS

Common techniques for identifying digestive tract pathogens:

Selective Growth

Depending on the type of pathogen suspected in the disease, one can use selective media and growth conditions specific to the pathogen in order to select for the growth of the pathogen over other organisms. This technique should help to reduce the presence of normal microflora.

Antibiotic Susceptibility

Various organisms can be identified based on their resistance or susceptibility to specific antibiotics.

Biochemical Assays

Once a pure culture is isolated from a fecal sample, there exist numerous biochemical assays that identify biochemical and metabolic properties that are unique to the organism or group of organisms in question.

Serology

Employs the use of antibodies in order to identify the presence of antigenic factors, which may be unique to a specific pathogen. Antibodies can cross react with other organisms resulting in false-positive test results. Pathogens can also undergo mutations involving antigenic factors, which can lead to false negative results.

Verotoxin Assays

Gene-probe methods directed at toxin gene sequences

Polymerase Chain Reaction (PCR)

DNA extractions can either be performed after the organism has been cultured and selected for growth, or in some cases DNA extractions can be performed directly on the fecal samples without the need for culture. PCR utilizes primers and/or probes, which identify organisms by targeting specific genes, DNA sequences, or polymorphisms unique to the organism.

Enzyme-Linked Immunosorbent Assay (ELISA)

The use of ELISA and immunoblotting assays to examine the serum antibody response of cattle to bacteria is another diagnostic tool. Evidence of infection utilizing an LPS-based ELISA in association with an immunoblotting procedure, can be used to supplement existing bacteriological procedures. ELISA can also be employed to examine cell-free broth filtrates for enterotoxin production and cytotoxin production. Viable bacteria can be examined for invasive properties by an ELISA with the immunoglobulin fraction of antiserum to formalin-killed bacteria of an invasive strain.

PREVENTION

Farm management practices can reduce digestive tract related diseases:

- Waste management practices in order to reduce active pathogens
- Managing the calving season so that it overlaps as little as possible with the rainfall season
- Manipulating grazing so that fecal deposition occurs away from the water
- Setting up fencing to keep livestock away from the water
- Established milking, feeding, and calving practices that limit exposure to feces
- Proper storage of feed
- Keeping neonates and calves away from feces
- Keeping the housing clean and disinfected, and monitoring the housing
- Monitoring of the herd through diagnostics and clinical signs of illness
- Isolating infected ruminates once they have been identified
- Monitoring critical control points such as: carrier cows, replacement stocks, feces of sick cows, dirty environments, recycled flush water, feedstuffs, feed commodities, infected rodents and birds, and rendering trucks

GASTROINTESTINAL PHARMACOLOGY

BASICS

OVERVIEW

- The importance of motility modifiers in ruminants is for the treatment of a myriad of gastrointestinal dysmotilities or malfunctions of the esophageal groove reflex, or as an aid in placement of reticular magnets.
- Diseases of ruminants that are caused by motility disorders and could potentially benefit from motility modification include paralytic ileus, cecal dilatation, and displacements of the abomasum.
- Paralytic ileus frequently occurs with the presence of severe hypocalcemia, but is rarely observed postoperatively.
- Well-documented data about modifiers of gastrointestinal (GI) motility in ruminants are sparse due to the complex nature of the control systems responsible for motility in the bovine.

PATHOPHYSIOLOGY

- Gastrointestinal motility is known to be regulated by myogenic, neural, and chemical systems, with a fourth regulatory system involving the interstitial cells of Cajal believed to have a function in establishing the pacemaker activity of the GI cells.
- It is important to recognize that the neural control of GI motility refers to the extrinsic system that includes the vagus nerve and the sympathetic pelvic, lumbar colonic, and hypogastric nerves and the intrinsic system. This system consists of ganglia with efferent axons to the smooth muscle cells, afferent sensory axons, and the interconnective nerve strands located in the myenteric and submucosal plexuses.
- Chemical control of GI motility is performed by various hormones and neurotransmitters. These compounds are released from nerve endings of both the extrinsic and intrinsic nervous systems that supply the GI tract.

Gastrointestinal Pharmacology

- Pharmacologic compounds capable of influencing GI motility either imitate or antagonize the effects of endogenous transmitters.
- Motility modifiers are categorized as cholinergics, adrenergics, antidopaminergics, serotoninergics, motilin agonists, opioid receptor-blockers, or lidocaine based upon their mechanism of action and their main target receptor. A key factor in

the cascade of smooth muscle contractions is the serum calcium concentration of the affected animal.

- Correction of preexisting hypocalcemia and other electrolyte imbalances and rehydration is crucial to every protocol dealing with the treatment of GI motility disorder.

Cholinergics

- Acetylcholine (ACh) is the natural cholinergic neurotransmitter released from cholinergic axonic terminals.
- In the GI tract, ACh binds to the muscarinic receptors released from nerve terminals that originate from the intrinsic nervous system of the gut. All of the compounds that follow have an effect on either the release or breakdown of ACh and provide some ability to affect GI motility.

Bethanechol

- Bethanechol mimics the effect of ACh and is classified as a directly acting parasympathetic agonist. This compound has high affinity to muscarinic receptors of the GI tract with a much lower affinity for the smooth muscle cells of the vascular system.
- When dosed at 0.07 mg/kg subcutaneously (SC), this compound was found to increase overall myoelectric spiking activity in cows.

Neostigmine

- Neostigmine is classified as an indirectly acting parasympathetic agonist due to its ability to inhibit acetylcholinesterase, which hydrolyzes ACh. The effect of neostigmine is less restricted to the GI tract than that of bethanechol.
- This compound dosed at 0.02 mg/kg SC increased myoelectric activity but the effect was most pronounced upon uncoordinated spikes.

Metoclopramide

- Metoclopramide represents a first-generation prokinetic compound. Prokinetics have the ability to stimulate, coordinate, and restore gastric, pyloric, and small intestinal motility. Metoclopramide works by enhancing the release of ACh from postganglionic cholinergic nerve terminals, sensitizing muscarinic receptors and reducing hydrolysis of ACh by inhibiting acetylcholinesterase.
- Numerous studies at varied dosages have discovered that this compound alone does not affect GI motility and have identified that it does have the ability to cross the blood-brain barrier leading to restlessness and excitement. However, when metoclopramide (0.1 mg/kg SC) was used in combination with bethanechol (0.07 mg/kg SC), increased spike rates were reported.

Atropine and Scopolamine

- Atropine and scopolamine are naturally occurring alkaloids. They bind competitively to muscarinic receptors and are classified as parasympathetic antagonists.
- Atropine (0.04 mg/kg IV) completely eradicates abomasal myoelectric activity for up to 3 hours. Adverse effects are ruminal bloat and tachycardia.

Adrenergics

- Norepinephrine is the naturally occurring neurotransmitter of most sympathetic postganglionic nerve terminals, binding to both alpha and beta adrenergic receptors. These terminals are located postsynaptically on intestinal smooth muscle cells.
- Presynaptic stimulation by inhibition of ACh release is more important than postsynaptic stimulation because smooth muscle cells receive little postganglionic sympathetic innervation.

Xylazine and Detomidine

- Xylazine and detomidine have potent alpha-2 agonistic properties; yohimbine represents an alpha-2 receptor blocker; tolazoline is an alpha-1 and -2 receptor blocker and D1-propranolol is a beta-receptor blocker. Stimulation of adrenergic receptors results in inhibition of GI motility.
- The stimulating effect of adrenoceptor blockers is restricted to disease processes accompanied by a hyperactive state of the sympathetic nervous system.
- D1-propranolol has been shown to have no significant effect on contractility in vitro on bovine colonic tissue or in vivo on the ileoceocolic area of healthy cows when dosed at 0.2 mg/kg IM.
- Xylazine induces widespread reduction in GI motility when dosed at 0.2 mg/kg IM, and adverse effects have included salivation, ruminal bloat, hypothermia, and bradycardia.
- Yohimbine (0.125 mg/kg IV) or tolazoline (0.25–0.5 mg/kg IV) may be used for xylazine reversal.

Antidopaminergics

Dopamine is the precursor of norepinephrine and epinephrine. Dopaminergic receptors have been demonstrated in the GI tract of laboratory animals and sheep but not cattle.

Domperidone

Domperidone is a potent and specific dopamine-receptor antagonist that binds to dopaminergic receptors and does not cross the blood-brain barrier. The effect of this compound on the rumen and forestomachs of goats is to block the stimulatory effects of dopamine.

Serotoninerics

Serotonin is stored in the GI tract mainly in the enterochromaffin cells and is involved in regulation of GI motility by either enhancing or inhibiting it by binding to the receptors.

Cisapride

Cisapride represents a prokinetic drug that has been studied as a potential excitatory agent that would exert its effects by increasing the release of Ach at postganglionic nerve terminals. However, cisapride did not affect myoelectric activity at the ileoceccocolic area of healthy cows in vivo or produce any increased contractility of smooth muscle preparations in vitro at a dose of 0.08 mg/kg IV.

Other Compounds

- Motilin is a hormone that initiates contractile activity by binding to specific receptors situated on smooth muscle cells.
- Erythromycin lactobionate has been demonstrated to bind to motilin receptors situated on smooth muscle cells. This compound increases myoelectric activity in the abomasum and duodenum for up to 8 hours following either IV or IM injections in healthy cattle.
- Opioid peptides in the gut are represented by met-enkephalin and leu-enkephalin. Receptors for these peptides are present in the myenteric plexus and activation causes inhibitory effects by hyperpolarization of neurons, preventing neuronal excitation.
- Naloxone did not affect myoelectric activity of the ileoceccocolic area of experimental cows when given at 0.05 mg/kg IV.
- Lidocaine blocks voltage-gated channels and this blockade is thought to contribute to a motility-promoting effect in postoperative ileus in other species. However, lidocaine does not have significant effects on in vitro abomasal or duodenal tissues of healthy cows.

TREATMENT

- Most cases of paralytic ileus, cecal dilatation/dislocation, and displacement of the abomasum are multifactorial diseases.
- Treatment protocols should not be restricted to the administration of motility modifiers and should always include treatment of the concurrent metabolic disorders, infectious diseases, and supervision of management practices.
- Many of the compounds described in this chapter do not have veterinary-approved products available for use in cattle in the United States. In this area of study, well-documented results are rare and intensive research in this field is warranted in the future.

MEDICATION DRUGS OF CHOICE CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

GOSSYPOL TOXICOSIS

BASICS

OVERVIEW

- Gossypol is a bi-naphthyl-aldehyde that occurs naturally in the cotton plant (*Gossypium* spp.).
- Whole cottonseed (WCS) and cottonseed meal (CSM) are a good source of energy, fiber, and protein in diets of adult cattle, calves, and sheep.
- Because gossypol has been recognized since the turn of the century to be toxic to animals, a limiting factor of whole cottonseed and cottonseed meal as feed sources to ruminant livestock is their gossypol content.

SYSTEMS AFFECTED

Reproductive, musculoskeletal, respiratory, hepatic

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide in areas feeding cottonseed meal

SIGNALMENT

- Ruminants have been reported to detoxify gossypol in the rumen by binding to soluble proteins. However, the protein-binding detoxifying mechanism in adult cattle can be overwhelmed if the total gossypol content is excessive, or low protein content is present in the rumen.
- Preruminant cattle such as lambs and calves are commonly affected.

Species

Potentially all ruminants feeding on cottonseed meal

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- The clinical signs of gossypol toxicity seen in ruminants and preruminant cattle include sudden death as well as physiological and reproductive effects without death.
- Adult cattle reduced milk production and respiratory stress
- Preruminant calves show respiratory signs and congestive heart failure.
- Infertility in cows
- Reduced spermatogenesis and impaired sperm motility associated with morphological aberrations of the sperm midpiece. Damaged spermatogenic epithelium with an increase in sperm cell midpiece abnormality and erythrocyte fragility.

CAUSES AND RISK FACTORS

- Consumption of diets containing excessive amounts of gossypol from whole cottonseed and cottonseed hulls or meal is the route of exposure that causes toxicity.
- The level predisposing the animal to toxicity depends on the species, rumen function, level of protein in the diet, and duration of consumption.

DIAGNOSIS

History of Feeding Cottonseed Products

- Young calves—cottonseed meal or cottonseed hulls in starter or grower rations
- Ruminants—whole cottonseed fed above recommended levels

Table 1

Given	To obtain	Multiply by
Percent (%)	Parts per million (ppm)	10,000
Parts per million (ppm)	mg/kg	1.0

Clinical Picture

- Multiple animals involved
- Sudden death syndrome
- Chronic respiratory problems, unresponsive to antibiotics
- Animals not doing well, depressed
- History of infertility

DIFFERENTIAL DIAGNOSIS

- Monensin toxicity
- Vitamin E and selenium toxicity
- Toxic plants such as coffee, senna, bracken fern, white snakeroot, lantana, and milkweed

CBC/BIOCHEMISTRY/URINALYSIS

There are minimal changes in blood chemistry and erythrocyte parameters during toxicity. However, changes such as an increase in erythrocyte fragility, hemoglobinuria, anemia, and a decrease in hemoglobin content have been reported.

OTHER LABORATORY TESTS

Estimation of Gossypol Intake from Rations Containing Cotton Products

- Send representative samples of the cotton by-product (WCS or CSM) to a qualified laboratory for total and free gossypol analysis. Note that the standard analytical method will not give accurate results of gossypol levels in a total mixed ration (TMR) sample, therefore, the cotton by-products should be analyzed individually
- Laboratory results will be in percent (%). Convert to mg/kg, as shown in [Table 1](#). For example, a typical result from a sample of WCS may be 1.1% total gossypol. According to [Table 1](#), this would be equivalent to 11,000 ppm, or 11,000 mg/kg.
- To calculate the amount of gossypol in the seed kernel of the whole seed, the result must be multiplied by 0.55 to get an accurate gossypol level as fed. In the above example, this would lead to a value of $(11,000 \text{ mg/kg}) \times (0.55) = 6050 \text{ mg/kg}$.
- Estimate the amount of each cotton by-product fed per cow on a daily basis. For example, a TMR might contain 15% WCS on a dry matter basis. If a cow consumes 22.5 kg/day of this TMR on average, then she consumes $(22.5 \text{ kg}) \times (0.15) = 3.4 \text{ kg}$ of WCS daily.
- Multiply the amount of cotton by-product consumed by the amount of gossypol in mg/kg. In the example, this would be $(3.4 \text{ kg}) \times (6050 \text{ mg/kg}) = 20,570 \text{ mg}$ (20.5 g) of gossypol per cow from WCS on a daily basis.
- Add the gossypol from each source to calculate the animal's total daily gossypol intake.

PATHOLOGIC FINDINGS

Gross Necropsy Findings

- Lesions are compatible with failure of the cardiovascular and respiratory system similar to those reported for swine.
- Hepatomegaly
- Cardiomegaly
- Gelatinous, yellow-brown color fluid in the thoracic and peritoneal cavity

Histopathology

Centrilobular hepatic congestion and necrosis related to hepatic anoxia

TREATMENT

N/A

MEDICATIONS

FOLLOW-UP

PREVENTION/AVOIDANCE

- Stage of rumen development is critical in detoxifying gossypol. While the young ruminant is being fed milk, rumen development and function are minimal. During this time, the animal functions essentially as a preruminant and tolerable levels of free gossypol in the diet are similar to nonruminant species, which is 200 ppm.
- When considering toxicity levels of free gossypol in ruminants, the source—whole cottonseed vs. cottonseed meal—should be considered. Detoxification of free gossypol in the rumen appears to be more efficient with whole cottonseed.
- Guidelines for safe levels of gossypol intake should not exceed 20 g/day for lactating dairy cows, 8 g/day for breeding bulls.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- The clinical signs of gossypol toxicity seen in ruminants and preruminant cattle include sudden death as well as physiological and reproductive effects without death.
- Adult cattle reduced milk production and respiratory stress.
- Infertility in cows
- Reduced spermatogenesis and impaired sperm motility associated with morphological aberrations of the sperm midpiece. Damaged spermatogenic epithelium with an increase in sperm cell midpiece abnormality and erythrocyte fragility.

GRASS TETANY/HYPOMAGNESEMIA

BASICS

OVERVIEW

- Magnesium (Mg) deficiency affects the central nervous system of ruminants.
- Mg is absorbed from the rumen and excreted in urine.
- High dietary potassium decreases absorption of Mg.
- Rapidly growing grasses contain relatively high concentrations of potassium and low concentrations of Mg.

PATHOPHYSIOLOGY

- Mg is necessary for most major cellular metabolic pathways and is vital to maintenance of resting membrane potentials at synapses.
- Because adenosine triphosphate (ATP) requires Mg to form the high-energy bond between phosphates, Mg is required for all enzymatic reactions requiring ATP.
- Mg is also necessary for ATPase activity; therefore, myofibril contractions are sustained in hypomagnesemia, leading to tetanic spasms.
- Most Mg is present in teeth and bones, which is not readily mobilized.
- There is no direct hormonal control of Mg uptake, so daily intake is necessary.

SYSTEMS AFFECTED

CNS, musculoskeletal, production management

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide in distribution

SIGNALMENT

- Most commonly seen in lactating beef cattle within the first 2 months of calving, particularly if grazing cool season grasses.
- Lactating dairy cattle are affected less commonly because of differences in nutritional management. Grazing dairy cattle would be at greater risk.
- Ewes and dairy goats are also susceptible.
- Calves on all milk diets without added Mg may develop the disease as well.

Species

Potentially, all ruminant species

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

- Affected animals are often found dead.
- Anorexia and separation from the herd

- Early in the course, ears will be erect and twitching and hyperesthesia will be noted.
- Alert, hyperexcitable, may charge
- Muscle fasciculations and head tremors may be noted.
- Nystagmus and fluttering of the eyelids
- Ataxia
- Recumbency
- Clonic convulsions, opisthotonus, or tetanic muscle spasms
- Elevated body temperature because of excess muscle activity
- Increased heart and respiratory rate

CAUSES AND RISK FACTORS

- Mature ruminants just prior to calving and during early lactation have the highest demand for Mg.
- Periods of rapid grass growth, particularly cool season grasses and cereal crops, are the most common time for clinical signs to occur (spring and/or fall).
- Heavy fertilization of pastures increases the risk of grass tetany. Use of recycled poultry bedding as a feed supplement or fertilizer has commonly been associated with an increased incidence of hypomagnesemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypocalcemia (serum Ca)
- Nervous ketosis (urine ketones)
- Nervous coccidiosis (fecal float)
- Heavy metal toxicities: for example, arsenic and lead (history of exposure to heavy metals, elevated blood, kidney or liver concentration of heavy metal)
- Salt poisoning (history, necropsy)
- Tetanus (response to therapy, necropsy)
- Rabies (necropsy)
- Viral encephalitides (history of herd and surrounding area, increasing antibody titers)

CBC/BIOCHEMISTRY/URINALYSIS

- Serum Mg less than 1.2 mg/dl
- Cerebrospinal fluid Mg less than 1.45 mg/dl
- Urine Mg less than 2.5 mg/dl
- Postmortem ocular Mg less than 1 mg/dl (within 24 hours of death)
- Affected animals are often hypocalcemic.
- After episodes of tetany, animals will often have elevated potassium, aspartate aminotransferase (AST), and creatinine phosphokinase (CK) due to muscle damage.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Diagnosis is most often made on the basis of clinical signs or history because of the need for immediate treatment.
- Decreased serum, CSF, ocular or urine Mg concentrations are confirmatory.

PATHOLOGIC FINDINGS

.

GROSS FINDINGS

- May note evidence of thrashing on ground around where the animal died.
- No gross findings directly attributable to hypomagnesemia
- Trauma and bruising are common findings because of seizures.

- Rumen contents may be aspirated into lungs.
- Ecchymotic hemorrhages
- Agonal pulmonary emphysema

HISTOPATHOLOGICAL FINDINGS

Calves dying of hypomagnesemia may have microscopic calcium deposits in arterial walls of the heart, lungs, and spleen.

TREATMENT

- Minimize handling to decrease the chance of initiating tetanic seizures.
- It may be necessary to administer intramuscular sedation prior to initiating Mg therapy to control seizure activity. Avoid intravenous sedative administration.
- Heart rate should be monitored closely while administering Mg solutions and treatment should be slowed or discontinued if heart rate drops substantially.
- Respiratory failure may occur if Mg solutions are given too quickly due to medullary depression.

MEDICATIONS

DRUGS OF CHOICE

- Animals with hypomagnesemia are often hypocalcemic as well and should receive therapy containing calcium.
- Administer intravenous calcium borogluconate solution containing 5% Mg (500 ml for adult cattle; 50–100 ml for calves and small ruminants).
- Many animals relapse several hours after treatment, so an additional source of Mg should be provided with initial treatment.
 - Oral Mg salts: (1) 50% Mg sulfate solution (125–150 ml for adult cattle). (2) Mg oxide (60 g in gelatin capsule for adult cattle).
 - Subcutaneous injection of 100–200 ml (for adult cattle) of a 20%–50% Mg sulfate solution. Limit to 50 ml per site to avoid tissue damage.
 - Mg enema—60 g of Mg in 250–500 ml of water. Solution should not be more concentrated than this to avoid mucosal sloughing.

CONTRAINDICATIONS

- Avoid potassium-containing solutions for therapy because they will interfere with Mg absorption.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

- Allowing animals access to only hay or mature grass for a portion of the day will increase Mg in the diet and may prevent further cases.
- Mg is unpalatable and will not be consumed in significant quantities unless mixed with some other dietary component.
- Mg can be added to feed or water to encourage intake
 - If feeding Mg in water, animals must be given access to only supplemented water to ensure intake of Mg.
 - Spraying or dusting pastures with Mg fertilizers in the spring will increase dietary Mg.
 - Mg will be readily consumed in concentrate mixtures or molasses licks.

MISCELLANEOUS

Therapy is often unrewarding, especially in cases where seizures have already occurred.

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- Most commonly seen in lactating beef cattle within the first 2 months of calving, particularly if grazing cool season grasses.
- Lactating dairy cattle are affected less commonly because of differences in nutritional management. Grazing dairy cattle would be at greater risk.
- Calves on all-milk diets without added Mg may develop the disease as well.
- Calves dying of hypomagnesemia may have microscopic calcium deposits in arterial walls of the heart, lungs, and spleen.

ZOONOTIC POTENTIAL

Hypomagnesemia is neither contagious nor zoonotic.

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

Cattle, sheep, and goats

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Periods of rapid grass growth, particularly cool season grasses and cereal crops, are the most common times for clinical signs to occur (spring and/or fall).
- Heavy fertilization of pastures increases the risk of grass tetany. Use of recycled poultry bedding as a feed supplement or fertilizer has commonly been associated with an increased incidence of hypomagnesemia.

SYNONYMS

Hypomagnesemia, tetany

HAEMONCHOSIS

BASICS

OVERVIEW

- Haemonchus is a voracious blood-sucking parasite that causes anemia, hypoproteinemia, and death losses especially in small ruminants.
- Diarrhea and weight loss are seldom important in haemonchosis.
- In warm moist environments, *Haemonchus* is by far the dominant gastrointestinal nematode.
- *Haemonchus* species tend to be host specific but there is some host cross infection.
- Populations of *Haemonchus contortus* have become resistant to all currently available anthelmintics.

SIGNALMENT

- All ages of sheep, goats, camelids, deer, and cattle may become infected, but young and lactating adult small ruminants are at greater risk of disease.
- Until young animals have been exposed to *Haemonchus* and are older than 4 to 7 months of age, they do not develop resistance to the parasite.
- Hosts adversely affected may vary with environment and vegetation consumed. Where sheep and goats graze on short grass and legumes, the disease is seen most often in goats. When there is plentiful browse, goats are unlikely to be exposed to large numbers of infective larvae.
- Adult females are unable to mount a protective immune response against helminths during the periparturient period.
- Breeds and species that evolved in humid tropical areas are more likely to have the genetic traits that make them resistant to infection.

SIGNS

- The primary signs of disease are those of anemia and hypoproteinemia.
- The onset of disease can be sudden with apparently healthy animals becoming weak and lying down unable to rise.
- Diarrhea is seldom seen in haemonchosis although the stool may be soft.
- In chronic cases, there may be a loss of wool, decreased fiber diameter, and weight loss.
- Depending on the physiologic status of the host and the number of parasites with which it is infected, the disease may present differently.

Peracute Disease

Sudden death, very few clinical signs, the PCV falls to less than 10. Only a few individuals in the flock will be affected. The anemia is responsive and immature erythrocytes will be seen in the survivors. There may be a soft stool.

Acute Disease

- More individuals in the flock will be affected. Anemia, pale mucous membranes, and hypoproteinemia (bottle jaw) are the most common clinical signs. May be constipated.
- A common sequela to acute haemonchosis is wool break, in which wool breaks off weeks following the acute signs of disease.

Chronic Disease

Anemia becomes unresponsive—ill thrift with poor-quality wool, weight loss, or failure to gain

Host Immunity

- Immunity to *Haemonchus* infections is slow in development and fragile when exposed to large numbers of larvae.
- Disease is seen in all ages but more in young and during the periparturient relaxation of resistance.
- There is genetic resistance to haemonchosis, which is usually manifest as an acquired protective immunity, with fewer worms establishing and those worms producing fewer eggs.

- There may be an allergic response to massive larval exposure known as self-cure. Adult worms are expelled and the larvae that triggered the response may eventually take their place or are lost.

Parasite Survival Strategies

- Adult females produce 5000–6000 eggs per day.
- Larvae feed on fecal bacteria, molts do not shed the cuticle. This sheath protects the L3 infective larva from desiccation.
- The L3 larvae are infective to the host. It takes 5 to 10 days from the eggs being passed for development to the infective stage.
- The larvae can only exit the fecal pellet then ascend vegetation in a film of moisture.
- The ruminant, while grazing, ingests larvae.
- The L3 exsheaths in rumen, moves to abomasum, enters gastric pits, and molts to L4.
- The L4 feeds on blood and molts to the adult, who mates and produces eggs approximately 3 weeks after being acquired.
- Adult worms live for months in susceptible hosts.
- The worms produce so many eggs that some offspring will survive unfavorable conditions within or outside the host.
- During prolonged periods of drought or winter weather conditions, ensheathed larvae survive in the fecal pellet. They are inactive and apparently do not utilize stored energy. When rains occur, they rapidly exit the fecal pellet.
- Following dry periods, the livestock graze closer to the fecal pat than normal and their chances of becoming infected are increased.
- Hypobiosis, or arrested development within the host's abomasum during the early fourth stage. These larvae are in a state of inactivity and are not affected by the host's immune system. They survive until conditions either within the host or in the environment are more favorable.
- *Haemonchus contortus* have such a rich genome that some individuals in populations have genes that enable them to resist the effects of anthelmintics.
- With the extreme fecundity of the worm, it has rapidly adapted to the use of anthelmintics and some populations have become resistant to every anthelmintic currently available.

CAUSES AND RISK FACTORS

- *Haemonchus* is a tropical parasite that does well in warm, humid, temperate climates during the warm season.
- Young or lactating animals
- Heavily stocked and grazed pastures
- Breeds that evolved in arid or cold climates are at greater risk.
- Grazing pastures a few days following rains increases the likelihood of acquiring infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anemia due to other parasites and bacteria such as *Fasciola*, *Fascioloides*, *Bunostomum*, *Ostertagia*, *Teladorsagia*, *Babesia*, *Anaplasma*, *Mycoplasma (Eperythrozoon)*, fleas, lice, and biting flies.
- Chronic copper poisoning in sheep may be differentiated by time of the year, age of affected animals, icterus, and access to sources of copper.
- Poisoning caused by sweet clover, pokeweed, or plants that cause intestinal or other bleeding may resemble haemonchosis. Age of animals and time of year may help differentiate.

CBC/BIOCHEMISTRY/URINALYSIS

- Erythrocyte and hemoglobin levels will be depressed.
- At first strictly blood loss, low packed cell volume with normal erythrocytes. Surviving animals quickly mount a response as the body attempts to replace lost erythrocytes.
- A macrocytic normochromic anemia is the most common finding with acute haemonchosis.
- In chronic haemonchosis with iron, cobalt, copper levels depleted, a microcytic, hypochromic anemia will be seen.
- Serum protein levels are low.
- Protein loss occurs through the gastrointestinal tract so both albumen and globulin levels are lowered by a similar

amount.

OTHER LABORATORY TESTS

- Fecal flotation using a saline or sugar flotation media with a specific gravity of 1.18 or greater will float the eggs of *Haemonchus* and other nematodes.
- Fecal examination will reveal strongylid thin-shelled segmented eggs.
- A quantitative test such as the modified McMaster method will aid the clinician in determining if there are sufficient numbers of worms to cause disease.
- There is a more or less linear relationship between the egg count and the number of adult worms. Fecal egg counts of more than 4000 eggs per gram of feces are associated with haemonchosis.
- Measuring before and after treatment egg counts can be vital in determining if anthelmintics used are actually effective in specific herds and flocks.
- Eggs are not diagnostic for *Haemonchus*, as other genera of strongylids produce identical eggs.
- In humid areas during the warm portion of the year, *Haemonchus* is usually the dominant parasite especially where it is resistant to anthelmintics.

PATHOLOGIC FINDINGS

GROSS FINDINGS

- Postmortem examination demonstrating the presence of adult worms in the abomasum is the most accurate diagnostic method.
- The body cavities may be fluid filled.
- Intermandibular edema, pallor of the mucous membranes are indicative of haemonchosis.
- The fecal material will be of normal consistency, dark, and dry, or an unformed stool may be seen.

HISTOPATHOLOGICAL FINDINGS

- The histological findings are those associated with anemia due to erythrocyte loss.
- Bone marrow changes will be a function of the duration of the disease.
- There will be no specific changes in the abomasum, however, in hosts undergoing an immunologic response, there may be increased cellularity with mast cells, eosinophils, or globular leukocytes.
- None of these findings are consistent or diagnostic.

TREATMENT

- Broad-spectrum safe anthelmintics are the primary means of treatment and control.
- Early after the development of broad-spectrum anthelmintics, many *Haemonchus contortus* populations became resistant to anthelmintics. Resistance has become common in many geographic regions.
- Selection by treatment not mutation appears to be the driving force in the establishment of resistance.
- *Haemonchus* in cattle and in small ruminants in cooler climates is susceptible to some benzimidazoles, levamisole/morantel, or macrocyclic lactones if administered in an adequate dose to the specific host.
- In warmer climates with elevated precipitation, worm populations have been selected for resistance.
- Tolerant or resistant worms often accompany livestock being introduced into new areas. The worms accompanying their hosts are likely to be those with resistant features; clinical disease thus happens more rapidly than in areas where there may still be susceptible worms.
- Underdosing: Either by underestimating weight or by selecting a dose for the average size of animal in a flock, worms will be exposed to a less than lethal level of anthelmintic.
- Goats and cervids metabolize anthelmintics more quickly than do cattle or sheep. Therefore, a sheep dose is an underdose in a goat.
- Injecting anthelmintics may be a form of underdosing. When persistent anthelmintics are used, the injectable formulation will maintain a blood level over a prolonged period of time. As long as the blood level is sufficient to kill all incoming worms, this may be an advantage rendering the host largely free of parasitism for weeks. As the blood levels drop, only those worms with some level of tolerance of the drug will be able to establish in the host.

- Cattle pour-on formulations are not absorbed as well by many other species, and when used are a form of underdosing in other species.

Anthelmintic Resistance

- Treating to keep parasite levels at the minimum is selecting for resistance if every worm is not killed. Treating every 3 to 4 weeks year-round or during the transmission season insures that only those worms with tolerance to an anthelmintic have only similar worms to mate with.
- Strategic worming practices, such as treat and move if the new pasture has few if any parasitic larvae in them, insure that the survivor worms can mate only with survivors.
- Anthelmintic resistance by *Haemonchus* has few apparent drawbacks; the benzimidazole-resistant worms are larger, produce more eggs, and therefore suck more blood than the susceptible worms.
- Macrocyclic lactone resistant *Haemonchus* may not be as cold tolerant as larvae in the pasture and may die out over winter if exposed to sufficient chilling.
- At least some of the levamisole/morantel-resistant *Haemonchus* revert to susceptibility, as the resistance gene trait is linked to the sex gene.
- Almost without exception, the anthelmintics labeled for use in small ruminants in North America are not effective against *Haemonchus* in the southern states.
- The most important aspect of the use of anthelmintics is to determine if the product is actually effective on the farm on which a control program is contemplated.
- Fecal egg count reduction test: Animals are administered what is believed to be an adequate dose of anthelmintic after collection of feces to determine the quantity of eggs present. A reevaluation of egg counts 7 to 14 days later will determine if there has been an adequate reduction in egg counts.
- Because of the natural variation of the number of worms in individual hosts, the average difference must be determined in 12 to 20 individual animals within a herd or flock to be certain that the test is valid.
- From a practical aspect, 6 to 10 individuals who are identified and resampled may be sufficient especially if they are younger animals.
- Allowing some animals to remain as untreated controls increases the value of the test but is often impractical under field conditions.
- In some instances, an anthelmintic cannot be identified that is effective against the worm population on a farm.

Enhancement of Anthelmintics

- The effectiveness of benzimidazoles may be enhanced by dividing the dose over several days or by fasting the animals overnight in a dry lot.
- Combining anthelmintics by administration of two or more drugs each from a different family of anthelmintics simultaneously
- Which two or three drugs should be used on an individual farm? The answer is what works on that farm. Proprietary drugs using all three families of anthelmintics are being used in other countries with *Haemonchus*-resistance problems.

Rotation of Anthelmintics

- Fast rotation: use a drug in a different family each time an anthelmintic is utilized. This method selects for resistance to all the compounds in the rotation.
- Slow rotation: use a product for a year then switch to a compound in another family. May work for a while but resistance will occur.
- There may be nothing to rotate to.
- Some rotation systems are not rotation at all, just other compounds in the same family all of which affect the worm in the same fashion.
- Use a product until it fails, then switch to something in a different family.

Effective Use of Anthelmintics

- Once an anthelmintic is identified that is effective on the farm in question, then decide what is desired in a control program.
- In the early spring, reduced pasture contamination is the most important aspect. The ewe or doe in the periparturient relaxation of resistance phase, even if she has the genetic capacity for resistance, will be a source of eggs for the environment.

- Strategic deworming to remove arrested or recently emerged larvae before they contaminate the pasture may have the greatest impact on pasture contamination.
- A few individual animals will have a much greater number of worms and worm eggs than the remainder of the population.
- If the worm-wealthy individuals can be identified, treating them rather than the entire host population can have as much impact on lessening the number of larvae subsequently on pasture as treating the entire flock.
- Identification of wormy individuals can be made by determining egg counts or by measuring the color of the ocular mucous membranes.
- Treating these animals will reduce the worm population but will not ensure the survival of only resistant worms, as those in the untreated animals will not be selected.
- A corollary to individual treatment is the culling of those animals that are treated most often. They are not resistant to worms and their offspring will likely have similar traits.
- Another approach is treatment of hosts after they have been exposed to large numbers of worms. Treatment 2 weeks following rain should remove much of that acquired population of worms before they can begin passing eggs.
- Zero grazing for a period of time after a disease outbreak may enable the host to recover both in terms of reestablishment of a protective immune response and production of erythrocytes and serum protein levels.

Prevention Management

- Management systems that lower the exposure of hosts to parasites can be devised. These systems may not optimize the value of forages but they result in healthier livestock.
- Rapid pasture rotation systems where pastures are vacated for as few as 30 days before returning animals may be of value in warm, humid climates, during the hottest time of the year in high rainfall areas or on irrigated pastures.
- Rapid pasture rotation otherwise will insure that the worms are waiting for the hosts when they return to the pasture.
- Utilizing pastures that have been used for cropping, especially in the last half of the grazing season, is grazing parasite-free pastures and, by the following year, any larvae deposited on the cropland will not survive until the next grazing.
- Alternate or cograzing with other species or classes of livestock may harvest *Haemonchus* larvae from the pasture.
- In general, the *Haemonchus* in sheep and goats do not do well in cattle. Recent observation questions this assumption, as some populations of *Haemonchus contortus* may thrive in calves.
- Horses do not share *Haemonchus* and can be safely grazed in areas dangerous to ruminants.
- Older cattle may become infected but are highly resistant to effects of the worms and can be used to clear larvae from a pasture.

Nutrition

- In general, *Haemonchus* does not cause weight loss and animals may appear to be thrifty up to the time they become extremely anemic.
- Providing sufficient protein is vital with haemonchosis as that is what is being lost.
- During the periparturient period, increased protein, not energy levels will lessen egg production by gastrointestinal nematodes.
- To be sure, you cannot feed animals through the disease but it is vital in recovery, especially for those whose immune response is compromised.

Natural Biological Control

- Pastures containing plants high in condensed tannins are safer grazing for hosts as the incoming larvae are adversely affected.
- The physical structure of some plants is also a challenge for larvae to ascend the vegetation.
- If animals browse, their chances of acquiring larvae diminish as the distance from the ground increases. Most infective larvae are found within 2 inches (50 mm) of the soil surface.
- Predaceous fungi have been evaluated as agents that kill larvae in pastures. One species, *Duddingtonia flagrans*, is able to traverse the digestive tract and is present in the fecal pat when the larvae hatch. Feeding spores or incorporating them in ruminal boluses has the capacity to lower pasture contamination.

Vaccination

- Vaccination is an approach deemed likely to be successful because animals naturally develop resistance to *Haemonchus*. However, the requirement for multiple exposure and maturation of the host immune system appears to be important in natural immunity and also appears to be the case with whole-worm antigens, selected antigens, or irradiated larval

vaccines.

- A different approach—the production of vaccines directed against antigens the host normally never encounters (cryptic antigens)—has shown promise. Antigens derived from the intestinal lining of the worm were identified, and vaccinated sheep produce antibody against these antigens. When the worm begins to suck blood, the antigen-antibody reaction destroys the intestinal lining of the worm.
- As with anthelmintics, the ability of the worm to rapidly select populations with possible different antigenic determinants is a concern.
- Cryptic antigen-vaccinated animals are not boosted by natural infection, so vaccination will have to be repeated frequently.

Genetics

- The selection of individual animals with a level of resistance to the parasite or those that have the capacity to rebound from the effects of parasitism seems to be a logical approach. The offspring of resistant hosts are likely to also be resistant. Therefore, resistance to *Haemonchus* could be a selection criterion used in a flock.
- The genetic aspect of resistance to gastrointestinal parasites is not well understood. It appears that multiple genes are involved in aspects of the protective response and that different genes may be more important at different times in the course of infection.
- Some breeds have more individual animals with sufficient factors, and they are more likely to survive exposure levels that would kill other animals.
- Even in resistant breeds, all animals are not equal, and factors such as lactation, age, or nutritional status may influence the course of disease.
- When animals are producing at their genetic maximum, they are at greater risk of parasitic disease because they are immunologically and nutritionally challenged.
- Other phenotypic characteristics such as production of milk, fiber, multiple births, and resistance to other agents may be at odds with resistance to helminths. Research does not indicate that the traits, which lead to increased production, are linked to those of increased susceptibility.
- To determine if genetic resistance is the answer to the problem of haemonchosis, as currently appears to be the case, much more knowledge is needed.

Summary

- There is no overall approach that fits with the environment—and management practices—that will control haemonchosis.
- Schemes that recognize that some animals are much more at risk than others and that strive to assure that the at-risk population is exposed to fewer worms or, if exposed, is treated differently may have a chance of success.
- Programs based on chemical control alone will likely fail unless the season of transmission is very short or new anthelmintics with completely different modes of action are discovered.
- Effective vaccines may be produced but will not likely be practical in young animals at highest risk. However, they may lessen pasture contamination and subsequent exposure.

HAEMOPHILUS SOMNUS COMPLEX

BASICS

DEFINITION

- *Haemophilus somnus* is a small, pleomorphic, gram-negative bacteria.
- It was first identified in 1960 as the cause of thrombotic meningoencephalitis (TME) in feedlot cattle. Since this time, it has been confirmed as contributing to or causing disease involving multiple organ systems.

PATHOPHYSIOLOGY

- *H. somnus* can be isolated from respiratory and reproductive tracts of healthy animals.
- Method of transmission is unclear, possibly spread via respiratory secretions, urine, or venereal contact.
- Organism can survive in biologic fluids for several weeks in the environment.
- *H. somnus* initially colonizes mucous membranes. It then invades the circulatory system leading to vasculitis and septicemia with localization in various tissues and organs.
- Entry via the respiratory tract is the probable route of respiratory infection.
- Reproductive disease is possibly spread through venereal contact or respiratory route.

SYSTEMS AFFECTED

- Respiratory—important bacterial pathogen in bronchopneumonia/pleuropneumonia (bovine respiratory disease complex, BRDC); also associated with pleuritis, laryngitis, otitis media
- Nervous—TME
- Reproductive—abortion, infertility (due to endometritis), vaginitis, orchitis, mastitis
- Cardiovascular—myocarditis, pericarditis, septicemia
- Musculoskeletal—infectious polyarthritis
- Ophthalmic—conjunctivitis, retinal hemorrhage

GENETICS

N/A

INCIDENCE/PREVALENCE

- Culture of normal animals and serologic evidence suggests infection is widespread. Clinical disease is less common.
- In Canada and the northern United States, *H. somnus* infection is considered to be a significant cause of morbidity and mortality in feedlot cattle.

GEOGRAPHIC DISTRIBUTION

- Commonly isolated in Canada, western and midwestern United States. Rarely isolated in northeastern and southeastern United States.
- Identified in South America, Europe, Australia, New Zealand, Russia, Israel, and Japan

SIGNALMENT

Species

Bovine—similar disease syndromes seen in sheep infected with *Haemophilus agni* and *Histophilus ovis*.

Breed Predisposition

- Systemic disease is seen predominantly in beef cattle.
- Reproductive disease can be seen in both beef and dairy cattle.

Mean Age and Range

- Respiratory, neurologic, and cardiovascular disease are predominantly in feedlot cattle (6–24 months of age).
- Reproductive disease is seen in breeding-age animals.

Predominant Sex

- Systemic disease affects both sexes.
- Reproductive disease is seen predominantly in females.

SIGNS

GENERAL COMMENTS

- Signs will differ based on system(s) affected.
- Combinations of respiratory, nervous, cardiovascular, musculoskeletal, and/or ophthalmic disease can occur in an affected individual or in a group of animals.
- Reproductive involvement typically occurs without other system involvement.

HISTORICAL FINDINGS

- Onset of systemic disease can range from acute death with no premonitory signs to chronic disease.
- Sporadic abortion is the typical reproductive manifestation.

PHYSICAL EXAMINATION FINDINGS

- Systemic disease—fever, depression, possibly a high morbidity
 - Respiratory—dyspnea, nasal discharge, lacrimation; similar to other causes of bacterial pneumonia
 - Nervous—severe depression, partially closed eyes, muscle weakness, ataxia, recumbency
 - Occasionally, opisthotonus, nystagmus, strabismus, unilateral or bilateral blindness, hyperesthesia, and/or convulsions can occur.
 - Ophthalmic—retinal hemorrhage with accumulation of exudates. Typically seen with other system involvement.
 - Musculoskeletal—swelling, heat, and pain in one or multiple joints
 - Myocarditis—typically, cattle that have had prior case of respiratory disease. Often found acutely dead. May present as congestive heart failure.
- Reproductive disease—sporadic abortion with little to no clinical signs in the dam

CAUSES

Infectious disease: organism—*Haemophilus somnus*

- Pathogenic and commensal strains
- Pathogenic strains are resistant to complement and serum antibodies.
- Pathogenic strains can survive within macrophages and PMNs.

RISK FACTORS

- Disease typically seen during the first 3–4 weeks following feedlot arrival.
- Immunologically naïve cattle experience higher morbidity and mortality following feedlot entry.
- Possible seasonal effect (increased diagnostic lab submissions during November, December, and January)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Respiratory

- Clinically indistinguishable from other differentials; requires culture, virology, serology, and/or histopathology for differentiation
- Other bacterial pathogens in BRDC—*Manheimia haemolytica*, *Pasteurella multocida*
- Primary viral respiratory infection—IBR, BVDV, BRSV, etc.

Neurologic

- Polioencephalomalacia—high sulfate/sulfur level in feed and/or water, typically afebrile, cortical blindness, different pathologic lesions
- Listeria meningoenkephalitis
- Hypovitaminosis-A—insufficient levels of vitamin A in feed, low plasma and liver vitamin A levels
- Salt toxicity—history of water deprivation, typically afebrile, cortical blindness, high serum and CSF sodium levels, different pathologic lesions

- Lead toxicity—opportunity for exposure to lead, typically afebrile, cortical blindness, high blood lead level, different pathologic lesions
- Viral encephalomyelitis—rabies, malignant catarrhal fever, etc.
- Cranial trauma

Reproductive

- Indistinguishable clinically from other causes of abortion. Requires culture, virology, and/or histopathology of abortus and placenta for differentiation.
- Other bacterial causes of abortion—*Leptospira* spp., *Listeria monocytogenes*, *Brucella abortus*, etc.
- Protozoal causes of abortion—*Neospora caninum*
- Viral causes of abortion—IBR, BVDV
- Other causes of abortion—Mycotic infection, idiopathic, toxicity (plant, nitrate, etc.), trauma

CBC/BIOCHEMISTRY/URINALYSIS

No unique or specific changes. Nonspecific changes associated with inflammation could be seen—increased fibrinogen, leukocytosis, increased neutrophil:lymphocyte ratio, increased serum globulin

OTHER LABORATORY TESTS

- Bacterial culture
 - Slow-growing nature can lead to overgrowth of contaminants
 - Requires blood-containing media for growth
 - Requires an atmosphere containing increased CO₂
 - Previous antibiotic treatment may decrease ability to isolate organism.
- Serology—requires acute and convalescent samples for accurate interpretation
- Other testing modalities—immunohistochemistry and PCR testing developed, but not commercially available at this time

IMAGING

N/A

DIAGNOSTIC PROCEDURES

CSF tap—Fluid typically contains increased total protein, increased globulin, and increased cell count (predominantly neutrophils).

PATHOLOGIC FINDINGS

- Gross lesions
 - Respiratory—fibrinopurulent bronchopneumonia with a cranioventral distribution. Fibrinous pleuritis may be present with or without pneumonia lesions.
 - Neurologic—multifocal areas of hemorrhage and necrosis throughout all areas of the brain. Meninges may appear cloudy and hyperemic. CSF is typically cloudy.
 - Musculoskeletal—serofibrinous polyarthritis
 - Cardiovascular—Myocarditis lesions are typically found in the papillary muscle of the left ventricle, range from a round area of hemorrhage and necrosis acutely to an exudative abscess.
 - Reproductive—characterized by a necrotizing placentitis. Fetal septicemia may result in petechial hemorrhages.
- Histopathologic lesions: Septic thrombosis and vasculitis are seen in the affected organ(s).

TREATMENT

APPROPRIATE HEALTH CARE

- Clinically affected animals should have constant access to fresh, palatable feedstuffs and clean water.
- Animals should be cared for in a low-stress, low-competition environment.
- If affected individuals become laterally recumbent and are unable to rise, or if their condition has severely deteriorated, euthanasia is appropriate.

NURSING CARE

Normal

ACTIVITY

Physical activity should be minimized.

DIET

Normal

CLIENT EDUCATION

None

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

Respiratory Disease

- Typically treated as undifferentiated BRDC
- Several antibiotics are specifically labeled for treatment of *H. somnus*:
 - Ceftiofur (1.1–2.2 mg/kg SQ for 3–5 days)
 - Enrofloxacin (7.5–12.5 mg/kg SQ)
 - Florfenicol (40 mg/kg SQ)
- Many other antibiotics labeled for treatment of BRDC may be effective as well.

Neurologic Disease

- No drugs are labeled for this use in the United States. Extralabel use requires that the practitioner provide an appropriate drug withdrawal time.
- Antibiotic must pass blood-brain barrier:
 - Florfenicol
 - Oxytetracycline

CONTRAINDICATIONS

None

PRECAUTIONS

Appropriate drug withdrawal time should be followed before slaughter.

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUGS

None

FOLLOW-UP

PATIENT MONITORING

Typically involves evaluation of improvement or deterioration of clinical signs (attitude, appetite, rectal temperature, system-associated signs).

PREVENTION/AVOIDANCE

- Many nonspecific control measures for BRDC (viral vaccination, stress reduction, etc.) would be effective in control of *H. somnus*.
- Commercial *H. somnus* bacterin is available.
 - Requires two doses at 2- to 3-week interval.
 - Results of trials to evaluate clinical efficacy have yielded conflicting results.

- Postarrival mass medication with antibiotics can be used when high BRDC morbidity is expected.

POSSIBLE COMPLICATIONS

Poor response to therapy may require euthanasia.

EXPECTED COURSE AND PROGNOSIS

- Generally, cattle treated in the early stages of disease have a better chance of recovery than those with more advanced disease regardless of the affected system.
- Cattle with advanced neurologic disease have a poor to grave prognosis even with aggressive treatment.
- Polyarthritis often has a poor response to therapy leading to chronic lameness.

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

- Systemic disease typically is seen in feedlot cattle (age 6–24 months).
- Reproductive disease is seen in breeding age animals.

ZOONOTIC POTENTIAL

None

PREGNANCY

Organism can cause abortion.

RUMINANT SPECIES AFFECTED

- Bovine
- Ovine—affected by similar disease caused by *Haemophilus agni* and *Histophilus ovis*

BIOSECURITY

Biosecurity is difficult to attain in a feedlot setting due to movement of cattle from multiple sources onto the premises.

PRODUCTION MANAGEMENT

H. somnus plays a role in BRDC, which is the most economically significant disease in the beef industry.

SYNONYMS

Neurologic disease—“brainer,” “sleeper”

SEE ALSO

- Bovine respiratory disease complex
 - BRDC—*Mannheimia haemolytica*, *Pasteurella multocida*
 - Primary viral respiratory infection—IBR, BVDV, BRSV
- Neurologic: polioencephalomalacia, *Listeria* meningoencephalitis, hypovitaminosis-A, salt toxicity, lead toxicity, viral encephalomyelitis, rabies, malignant catarrhal fever
- Reproductive
 - Bacterial causes of abortion—*Leptospira* spp., *Listeria monocytogenes*, *Brucella abortus*
 - Protozoal causes of abortion—*Neospora caninum*
 - Viral causes of abortion—IBR, BVDV
 - Other causes of abortion—mycotic infection, idiopathic, toxicity (plant, nitrate, etc.), trauma

ABBREVIATIONS

BRDC = bovine respiratory disease complex

BRSV = bovine respiratory syncytial virus

BVDV = bovine viral diarrhea virus

CSF = cerebrospinal fluid

IBR = infectious bovine rhinotracheitis (bovine herpesvirus-1)

PCR = polymerase chain reaction

PMNs = polymorphonuclear leukocytes

HEARTWATER (COWDRIOSIS)

BASICS

DEFINITION

- A tick-borne rickettsial disease of domestic and wild ruminants is caused by *Ehrlichia* (formerly *Cowdria*) *ruminantium*. This rickettsial agent is transmitted by ticks of the genus *Amblyomma*, particularly the tropical bont tick (*A. variegatum*).
- The disease is enzootic throughout sub-Saharan Africa, Madagascar, and the Caribbean islands of Guadeloupe, Marie-Galante, and Antigua. The disease is exotic to the United States.
- At least two *Amblyomma* species found in North America are potential vectors and this poses the threat of the disease introduction. Introduction of the vector is also possible through importation of wildlife from endemic areas.
- It is colloquially called “heartwater” due to the common finding of hydropericardium in infected cattle.

SIGNALMENT

- Most domestic ruminants are susceptible.
- Sheep and goats are more susceptible. Among sheep breeds, Persian and Afrikaner are more tolerant than European breeds. Angora goats are highly susceptible.
- *Bos indicus* breeds are more tolerant than *Bos taurus* breeds.
- Among wild ruminants, water buffalo and bison are highly susceptible. Infection has been observed in eland, wildebeest, blesbuck, and Cape buffalo.
- Age resistance, or a reduction in severity of clinical signs after infection, occurs in very young animals (calves < 4 weeks of age, lambs and goat kids < 1 week), and results in immunity to reinfection with the same strain and a carrier state.

SIGNS

- Incubation period following bite from infected tick is 9–29 days in cattle, 5–35 days in sheep.
- Signs can be peracute, acute (most common), subacute, or subclinical.
- Peracute signs include rapid development of fever, hyperesthesia, lacrimation, convulsions, and sudden death. This form occurs in susceptible breeds introduced into endemic areas and is the rarest form.
- Acute signs include several days of high fever, anorexia, depression, exaggerated gait, excessive blinking, chewing movements, circling, aggression, and most animals die. This is the most common form.
- Subacute form is characterized by mild fever and mild nervous signs and occurs in animals with some natural resistance.
- The subclinical form has been reported in animals with natural resistance including neonates.
- Hydropericardium (hence the name heartwater) and hydrothorax are some of the pathological findings observed on necropsy.

CAUSES

- Cowdriosis is caused by *Ehrlichia* (formerly *Cowdria*) *ruminantium*, a rickettsial agent transmitted by ticks of the genus *Amblyomma*.
- Important tick species that transmit the organism are *A. variegatum*, *A. habraeum*, and *A. pomposum*.

RISK FACTORS

- Naïve animals introduced to endemic areas are highly susceptible. Introduction of vectors carrying *E. ruminantium* may also result in outbreaks.
- In endemic areas, reduced tick populations may lower herd immunity through less-frequent challenge and thereby put herds at greater risk for an epidemic of illness when tick populations rebound.
- In the United States, Gulf Coast states from Florida to Texas are at risk for introduction of the tropical bont tick, and possibly *E. ruminantium*, from the Caribbean.
- Zebu breeds of cattle appear more resistant to infection than European breeds.

- Animals 3–18 months are most susceptible, while young calves, lambs, and goat kids exhibit age resistance.

DIAGNOSIS

- Cowdriosis should be suspected when an animal is infested with *Amblyomma* ticks and develops fever and nervous signs and dies.
- In fatal cases, presence of characteristic gross lesions and demonstration of *E. ruminantium* colonies using Giemsa stain on endothelial cells of brain smears.

DIFFERENTIAL DIAGNOSIS

- Includes diseases that cause sudden death (peracute form) or cortical signs. These include anthrax, lightning strike, polioencephalomalacia, salt poisoning, lead poisoning, and rabies.
- The acute form may resemble babesiosis, theileriosis, and trypanosomiasis especially in endemic areas.
- Nervous system abnormalities may suggest other diseases such as rabies, hypomagnesemia, nervous ketosis, listeriosis, tetanus, meningitis or encephalitis, or poisoning by some toxins.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

Serologic assays (e.g., ELISA) are available but suffer from cross-reactions with other rickettsiae.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

May be definitively diagnosed by observation of organisms in smears of affected tissue, usually brain.

PATHOLOGIC FINDINGS

- Pathogenesis is the result of damage to vascular endothelium and subsequent increased vascular permeability.
- Gross lesions include hydrothorax, hydropericardium, pulmonary edema, splenomegaly, petechiae, and ecchymoses of mucosa.

TREATMENT

- Tetracyclines are the treatment of choice but must be given early in the course of the disease.
- Chemoprophylaxis with tetracyclines has been suggested in animals introduced to endemic areas.
- Short-acting formulations of oxytetracycline, 10–20-mg/kg body weight, given two times at 24-hour intervals
- Various vaccines are available in endemic areas with varying successes.
- Tick control is essential.
- Exposure of young animals may permit development of resistance.

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Young animals are more resistant to infection.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

N/A

RUMINANT SPECIES AFFECTED

- Sheep and goats are more susceptible. Among sheep breeds, Persian and Afrikaner are more tolerant than European breeds. Angora goats are highly susceptible.
- *Bos indicus* breeds are more tolerant than *Bos taurus* breeds. Among wild ruminants, water buffalo and bison are highly susceptible.

BIOSECURITY

Heartwater is a foreign animal disease in the United States. Contact appropriate animal health officials (e.g., USDA—APHIS Veterinary Services <http://www.aphis.usda.gov/vs>) for suspected cases.

HEAT STRESS IN SOUTH AMERICAN CAMELIDS

BASICS

OVERVIEW

DEFINITION

Disease syndrome in South American camelids secondary to exposure to conditions of excessively high ambient temperature or combinations of high ambient temperature and high humidity.

PATHOPHYSIOLOGY

- The preoptic area of the anterior hypothalamus receives and processes information from thermosensors throughout the body.
- Hyperthermia arises from thermoregulatory malfunction. In cases of heat stress, malfunction arises due to an elevated thermal burden that the body is incapable of handling.

SYSTEMS AFFECTED

- Cardiovascular, respiratory, digestive, hemic/lymphatic, hepatobiliary, renal/urologic, reproductive, nervous.
- The extent of body system damage is dependent upon the severity of the exposure.
- Animals that have undergone prolonged severe heat stress may have systemic complications that far outlast the inciting hyperthermic incident.

GENETICS

N/A

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Heat stress can occur in any part of the world where ambient temperature rises above 80°F.

SIGNALMENT

Species

Potentially all camelid species

Breed Predilections

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

Fever, widely fluctuating rectal temperature, tachycardia, tachypnea, anorexia, weakness, sweating, open mouth breathing, cyanosis, droopy lip with froth at commissures, ventral edema, scrotal edema in males, depression, marked weakness, colic, recumbency, DIC, hypovolemic shock, multiorgan failure (kidney, liver)

HISTORICAL FINDINGS

Exposure to high ambient temperature or a combination of high heat and high humidity is required for animals to become heat stressed.

PHYSICAL EXAMINATION FINDINGS

- Physical examination findings vary based on the severity of disease.
- Elevated rectal temperature is typically present. If animals are examined early in the course of disease or at a cooler time of day, rectal temperature may not be excessively high.

- Increased heart and respiratory rates are often present.
- Sweating and open mouth breathing are common as disease progresses. Weakness and incoordination become marked and can progress to recumbency.
- Ventral edema, particularly scrotal edema in males, is common in affected individuals.
- In severely affected animals, petechial and ecchymotic hemorrhages associated with the onset of DIC, uremic smell to the breath and ulcers in the mouth associated with renal failure may also be seen.

CAUSES

Breakdown of thermoregulatory function due to exposure to periods of high heat \pm high humidity

RISK FACTORS

Environmental Factors

- Temperature
- Humidity
- Air movement

Animal Factors

- Dehydration
- Exercise
- Heavy, dark fleece
- Obesity
- Pregnancy
- Lactation
- Current or recent illness

Nutritional Factors

- High concentrate diet
- High protein hay
- Selenium deficient diets
- Vitamin and mineral deficient diets
- Salt-deficient diets

Management Factors

- Availability of fresh drinking water
- Availability of shade
- Availability of cooling water
- Presence of fans
- Timing of stressful activity

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnosis varies depending on observed clinical signs:

- Infectious diseases that generate fever
- Polioencephalomalacia
- Tick paralysis
- Parelaphostrongylosis
- GI causes of colic
- C3 ulcers
- Urethral rupture (animals with severe ventral edema)
- Testicular abscess (males with scrotal swelling)
- Testicular hydrocele (males with scrotal swelling)

CBC/BIOCHEMISTRY/URINALYSIS

- CBC often shows a mature neutrophilia with no left shift, platelet count may decrease with time.
- Biochemistry—abnormalities vary depending on organ systems involved. Increases can be seen in creatinine, urea nitrogen, AST, CK, bilirubin, and SDH. Hypoproteinemia may be present. Electrolytes (Na, and Cl) may be decreased. Whole body potassium is often decreased, but serum levels may be increased in the presence of academia. Metabolic and respiratory acidosis also may be present.
- Urinalysis—initially increased specific gravity that may become isosthenuric if renal failure ensues, tubular casts may be present in individuals with severe disease, positive blood and protein also may be present.

OTHER LABORATORY TESTS

Clotting profiles—clotting times may be increased.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

CSF—used to rule out other causes of neurologic disease

PATHOLOGIC FINDINGS

Gross Postmortem

- Autolysis beyond what is expected for time of death
- Hemorrhages and other signs consistent with DIC
- Serous atrophy of fat

Histologic Changes

- Renal necrosis
- Hepatic necrosis
- Coagulation necrosis of neurons
- Vascular congestion in the lungs, liver, spleen, and myocardium

TREATMENT

SUPPORTIVE CARE

- Cooling to within a normal rectal temperature—care should be taken as these animals may lack the ability to warm themselves if overcooled. Focus of cooling efforts should be on the ventral body surface because evaporative cooling is best here. Intact fleece will help insulate the animal even when wet, so water must soak through to the skin.
- IV fluids—correction of dehydration, electrolyte disturbances and acidosis. Adult camelids require 30–40 ml/kg/day and crias require 80–120 ml/kg/day. Camelids are prone to pulmonary edema at rapid infusion rates. Administration rate should not exceed 20 ml/kg/hr.
- Intranasal oxygen therapy if indicated.
- Shearing—if not already shorn will increase area for heat loss.

ACTIVITY

Limit activity as muscle activity increases heat production.

DIET

- High-quality forages should be fed during warmer times of the year. This will decrease the heat increment of digestion.
- It is important to ensure that overfeeding does not occur as it predisposes to obesity and the necessity to process the excess energy at a metabolic level.
- Mineral supplements that contain salt or an additional salt supplement should always be available.

CLIENT EDUCATION

- Clients should be educated on risk factors and prevention techniques as well as early recognition of affected animals.
- Use the comfort index (ambient temperature + % humidity) to anticipate problems.

CI < 120—Problems are unlikely.

CI 120–180—Caution. Problems are possible.

CI > 180—Danger. Problems are likely, observe animals closely.

MEDICATIONS

DRUGS OF CHOICE

Anti-inflammatory Agents

- Steroids—for shock
 - Dexamethasone—0.1 mg/kg IV
 - Prednisolone sodium succinate—0.5–1.0 mg/kg
- Nonsteroidal anti-inflammatory agents—flunixin meglumine 1.1 mg/kg. NSAIDs should be used cautiously as many heat-stressed animals may have severe renal compromise at presentation.

Antimicrobial Agents—for Prevention of Secondary Infection

- Ceftiofur hydrochloride—1.1–2.2 mg/kg IM or SC q 24 hours. Ceftiofur sodium can be used IV at the same dose.
- Ampicillin trihydrate—10 mg/kg IM q 24 hours. Sodium ampicillin can be used q 8 hours at the same dose.
- Penicillin—22,000 IU/kg IM or SC q 12 hours. Potassium penicillin can be used IV q 6 hours at the same dose.

Antioxidant Agents

- Vitamin E—immediate antioxidant activity: 1 ml/100 lbs SC or IM (300 IU/ml)
- Selenium—antioxidant activity will take 7–10 days for effect:
 - Bo-Se—1 ml/50 lb
 - Mu-Se—1 ml/200 lb

CONTRAINDICATIONS

- NSAIDs should be used with caution because severe renal compromise is often present at presentation.
- None of the drugs listed are approved for use in camelids and none have an established withdrawal time.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

FOLLOW-UP

PATIENT MONITORING

- Rectal temperature should be monitored regularly (every 0.5 hours) until stabilized, then several times daily.
- Serum biochemistry should initially be monitored every 1 to 2 days depending on severity of disease to assess progress and provide a basis for alteration in fluid therapy.

PREVENTION/AVOIDANCE

- Shear animals for hot humid months.
- Adequate access to clean drinking water.
- Adequate access to a mineral and salt supplement.
- Provide shade, fans, and other cooling mechanisms for animals during high heat and humidity.
- Observe animals and institute immediate treatment at signs of trouble.

POSSIBLE COMPLICATIONS

- Affected animals are more predisposed in the future.
- Infertility:

Male—excessive heat is spermicidal to primary spermatocytes.

Female—ovarian activity will decrease in times of high heat.

- Pregnancy loss
- Congenital abnormalities in the fetus

EXPECTED COURSE AND PROGNOSIS

- Prognosis varies from good to grave depending on condition at the time of admission.
- Early heat stress with no systemic complications will often resolve with cooling and several days in a cooler environment.
- Individuals with organ failure and other serious manifestations may not survive despite aggressive therapy.

MISCELLANEOUS

ASSOCIATED CONDITIONS

HEAT STRESS IN DAIRY CATTLE

BASICS

OVERVIEW

- The thermoneutral zone for dairy cattle is between 41°F and 77°F.
- When dairy cattle are exposed to ambient temperatures above 77°F or a temperature-humidity index (THI) greater than 72, physiological changes occur that affect milk production, reproduction, and general health.

PATHOPHYSIOLOGY

- Total body heat load is the sum of metabolic heat production and heat from solar radiation.
- Cattle are able to dissipate heat by nonevaporative mechanisms such as conduction, convection, or radiation, or evaporation of water from the skin and respiratory tract.
- If high temperature and humidity prevent the dissipation of heat through either evaporative or nonevaporative mechanisms, the cow's body temperature will rise resulting in:
 1. Reduced DMI to lower endogenous heat production with subsequent reduction in milk production of 10%–20% or more.
 2. The shift of blood flow from internal organs to the skin surface. Alterations in blood flow to the uterus and ovaries and changes in maternal-fetal hormone levels lead to reduced follicular activity, early embryonic death, and reduced milk yield in the following lactation.
 3. Panting and respiratory alkalosis with compensatory output of bicarbonate in urine leading to acidosis and contributing to laminitis, sole ulcers, and white line disease.

SIGNALMENT

Cattle of any age or stage of production; however, high-producing dairy cows will experience heat stress before dry cows or youngstock due to the increase in metabolic heat production associated with high milk production and dry matter intake (DMI).

SIGNS

Individual Cows

- Standing in stall, decrease in activity including activity during estrus
- Will seek shade and wind
- Increased respiratory rate, open-mouth breathing
- Sweating, increased rectal temperature
- Increased saliva production
- Reduced DMI
- Increased water intake

Herd

- Decreased milk production
- Decreased conception rate

CAUSES AND RISK FACTORS

- Climate—air temperature greater than 77°F or high relative humidity combined with high ambient temperature resulting in THI greater than 72
- Inadequate shade structure

TREATMENT

Modify the Environment

- Shade: Provide 60 sq ft of shade per cow. Provide feed and water in shaded areas.
- Ventilation: Avoid overcrowding. Raise the roof and open the sides of the shade structure. Install a ridge vent. Allow 50 ft between structures.
- Reduce air temperature: In arid environments, the use of evaporative cooling pads and fans, high-pressure foggers, and misters cool air by using energy from the air to evaporate water.
- Cool the cow: Forcing air over a wet hair coat cools the cow by evaporating water from the hair and skin. Sprinkler and fan systems may be used in holding areas and shade structures. Human-made cooling ponds and sprayers have been shown to reduce body temperature.

Modify the Ration

- Forage: Feed high-quality forage with an ADF no less than 18%.
- Protein: Feed a ration of 18% protein (or less) on a DM basis with RDP not to exceed 61% of dietary CP. Excess protein requires energy to excrete; do not feed excess N.
- Energy: Fat can be added to a ration up to 6%–7% on a DM basis.
- Buffer: Sodium bicarbonate may be fed at a rate of 0.75% of DMI.
- Minerals: Increase K to 1.5% DM, Na to 0.45%, and Mg to 0.35% DM for lactating cattle.
- Feeding smaller quantities of feed more frequently at cooler times of the day may help to maintain DMI. Provide a minimum of one watering station per 20 cows and maintain water temperature between 70°F–86°F.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Panting and respiratory alkalosis with compensatory output of bicarbonate in urine leading to acidosis and contributing to laminitis, sole ulcers and white line disease.

HEATH FAMILY: GRAYANOTOXIN

BASICS

OVERVIEW

- Laurels (*Kalmia*), pieris (*Pieris*), and rhododendrons and azaleas (*Rhododendron*) are all members of the Ericaceae (Heath) family.
- Usually an evergreen shrub or small tree, but may be a climber
- Leaves are tough, leathery, glossy, smooth margined, and alternate.
- Flowers are large and showy in terminal clusters and have five white or colored petals.
- Due to domestication for ornamentation, the geographical distribution is worldwide
- Grow in acidic habitats
- Toxicity occurs with ingestion of 0.15%–0.6% of body weight of the green plant.
- Dried plant is toxic

PATHOPHYSIOLOGY

- Grayanotoxins are principal toxins.
- Andromedotoxin, acetylandromedol, rhodotoxin, and asebotoxin are all names for grayanotoxin I.
- Deacetylanhydroandromedotoxin is grayanotoxin II.
- Deacetylandromedotoxin is grayanotoxin III.
- Grayanotoxin I and III are the most potent with grayanotoxin I being the most common.
- The grayanotoxins increase Na⁺ permeability resulting in increased resting membrane potentials of heart and nervous tissue although this may not be the mechanism of all clinical signs.
- Pyrethroid intoxication has a similar mechanism of action, but a different site of action on the sodium channels.
- Grayanotoxin has digitalislike cardiac effects, but is structurally different from digitalis.
- Grayanotoxin III prolongs ventricular depolarization.
- Intoxication causes upper GI abnormalities such as, colic, excessive salivation, odontoprisis, vocalization, and projectile vomiting.
- Onset of clinical signs is acute ~6 hours.
- First clinical sign is GI related.
- May cause irregular heart rate
- Cardiovascular deficits may cause weakness and depression.

SIGNALMENT

- Seen frequently in camelids and small ruminants
- Any animal ingesting the plant is at risk.

SIGNS

- Colic
- Depression
- Weakness
- Anorexia
- Rumen atony
- Frequent swallowing
- Excessive salivation
- Bloat

- Irregular heart rate; initially bradycardia, then tachycardia
- Dullness
- Dyspnea
- Vomiting, may be projectile
- Nasal discharge
- Frequent defecation
- Ataxia
- Recumbency
- Loss of PLR
- Coma
- Sudden death

CAUSES AND RISK FACTORS

Any ruminant ingesting a plant from the Ericaceae family is at risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other plant toxicities
- Pyrethroid toxicity

CBC/BIOCHEMISTRY/URINALYSIS

- Hemoconcentration
- Hyperkalemia
- Hyperchloremia
- Prerenal azotemia
- Elevations in glucose

OTHER LABORATORY TESTS

- Hypoxemia
- Acidemia

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Evidence of leaves in rumen
- Analysis for grayanotoxin in rumen, vomitus, urine, and fecal samples

PATHOLOGIC FINDINGS

- Nonspecific gastrointestinal irritation and hemorrhage
- Liver damage
- Kidney damage
- Evidence of regurgitated ruminal contents in mouth and pharynx
- Aspiration pneumonia
- Sheep may develop a secondary pasteurellosis.

TREATMENT

- Supportive care
- Rumenotomy to remove plant parts and prevent continuing toxicity

MEDICATIONS

DRUGS OF CHOICE

- Analgesics
- Activated charcoal (AC) (2–5 g/kg PO in a water slurry)
- Evidence in other species of recycling through gastrointestinal system; repeat doses of AC may be beneficial.
- Atropine 1 mg/kg given IV to effect
- Cathartics
- Antibiotics for treatment of aspiration pneumonia

CONTRAINDICATIONS

- Avoid fluids with calcium and potassium.
- Aspiration pneumonia is a possible complication that may be worsened by aspiration of oral administered drugs.
- Drug withdrawal times must be determined and maintained.

FOLLOW-UP

PATIENT MONITORING

- Monitor acid/base.
- Monitor potassium levels.

PREVENTION/AVOIDANCE

- Animals do not normally ingest plants, but will when there is little else to eat.
- Camelid poisoning commonly occurs from tying pack animals within reach of plant.
- Limit exposure to toxic plants.

POSSIBLE COMPLICATIONS

- Aspiration pneumonia
- Ischemia secondary to hypoperfusion
- Respiratory failure

EXPECTED COURSE AND PROGNOSIS

- With supportive care, mortality is low.
- Animals that survive recover completely.
- Aspiration pneumonia may occur and lead to respiratory failure.
- Neurologic abnormalities may lead to respiratory failure.
- Depending on amount ingested, may present as sudden death.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Aspiration pneumonia

AGE-RELATED FACTORS

HEAVY METAL TOXICOSIS

BASICS

OVERVIEW

- Toxicity arising from exposure (mostly by ingestion) to heavy metals.
- The term “heavy metals” has been given a wide range of inconsistent meanings and has not been defined by any authoritative body such as IUPAC.
- Here “heavy metals” describes a group of metals and metalloids (semimetals), specifically arsenic (As), copper (Cu), lead (Pb), molybdenum (Mo), and zinc (Zn), which have been associated with toxicity in ruminants under natural conditions.

PATHOPHYSIOLOGY

- Arsenic (As)—exists in trivalent and pentavalent forms. Trivalent arsenicals bind to sulfhydryl (–SH) groups leading to inactivation of enzymes and enzyme cofactors including those involved in cellular respiration (TCA cycle). They also impair capillary integrity resulting in plasma transudation into the GI tract. Pentavalent arsenicals uncouple oxidative phosphorylation leading to cellular energy deficits.
- Copper (Cu)—acute exposure causes irritation and coagulative necrosis of GI mucosa. Chronic toxicity occurs when the capacity of the liver to regulate Cu (by sequestration and excretion) is exceeded. Excess Cu undergoes redox cycling ($\text{Cu}^+ \rightleftharpoons \text{Cu}^{++}$) and generates reactive oxygen species that cause membrane lipid peroxidation and necrosis of hepatocytes. Cu is then released from necrotic hepatocytes to blood circulation and damages RBC causing intravascular hemolysis and release of hemoglobin. Damage to RBC causes anoxia, more centrilobular hepatic necrosis, and more release of Cu, which accumulates in and damages the kidney. Cu also inactivates proteins and enzymes by binding to –SH groups and may displace other essential trace metals (e.g., Zn) from their proteins.
- Lead (Pb)—binds to –SH groups and inactivates several enzymes including those involved in heme synthesis, impairs nerve and muscle transmission by competing with calcium (Ca), displaces Ca in bone and Ca-binding proteins (e.g., calmodulin), impairs membrane-bound enzymes (e.g., Na^+, K^+ -ATPase) leading to RBC fragility and renal tubular injury, impairs vitamin D metabolism, and interferes with GABA production and activity in the CNS. Pb is also irritating (GI mucous membrane), gametotoxic, teratogenic, and immunosuppressive.
- Molybdenum (Mo)—interferes with Cu metabolism leading to Cu deficiency—Mo and sulfur (S) form insoluble thiomolybdates in the rumen, which bind and reduce absorption of Cu—and stimulate urinary loss of Cu. Some thiomolybdates increase hepatobiliary excretion of Cu, decrease blood Cu availability, and directly inhibit Cu-dependent enzymes. Mo may also alter Zn metabolism and impair myelin maintenance and function leading to enzootic ataxia in lambs.
- Zinc (Zn)—exact pathophysiology of Zn toxicity in ruminants is unknown. However, Zn irritates the GI tract; antagonizes Ca, Cu, and iron (Fe) metabolism; and injures the pancreas and pancreatic ducts.

SYSTEMS AFFECTED

- As—virtually all (GI, renal, hepatic, CNS, respiratory, cardiovascular, etc.)
- Cu—GI, hepatic, renal, hematic, cardiovascular
- Pb—CNS, GI, hematic, skeletal, renal
- Mo—GI, hematic, musculoskeletal, CNS, cardiovascular, dermal
- Zn—hepatic, hematic, renal, pancreas, GI

GENETICS

Compelling scientific evidence supports genetic predisposition of certain breeds of sheep to Cu toxicity (see Breed Predispositions below).

INCIDENCE/PREVALENCE

- Incidence of heavy metal toxicosis is to some extent influenced by nutrition and other management factors, age, sex, and

breed (see Species and Breed Predilections below for specifics).

- As toxicity is now less frequent because of reduced use of As-containing compounds as pesticides.
- Peak incidence of Cu toxicity occurs in the fall and winter while most cases of Pb toxicity are associated with seeding and harvesting activities.

GEOGRAPHIC DISTRIBUTION

- Heavy metal toxicoses can occur virtually anywhere.
- In the United States, Cu toxicosis is more common in western states.
- Mo is naturally high in soils in some U.S. states (Florida, Oregon, California, Utah, Hawaii, Montana, Colorado, and Nevada) and in several areas of other countries around the world.

SIGNALMENT

Species

- All ruminants are susceptible to heavy metal toxicosis.
- Sheep are very sensitive to Cu, while Pb most commonly poisons cattle.
- Ruminants are more sensitive than nonruminants to Mo.

Breed Predilections

- As, Pb and Zn toxicities have no breed predilections.
- Cu—British breeds of sheep (i.e., Suffolk, Oxford, and Shropshire), Texel sheep, and Jersey cattle are more susceptible.
- Mo—Scottish Blackface and Finnish Landrace sheep are apparently more prone to develop swayback.

Mean Age and Range

Young and old animals are more susceptible to heavy metal toxicosis.

Predominant Sex

N/A

SIGNS

- As—abdominal pain, weakness, staggering, ataxia, watery diarrhea, ruminal atony, weak rapid pulse and shock, oliguria, proteinuria, dehydration, uremia, and acidosis.
- Cu—*acute toxicity*: vomiting, anorexia, hypersalivation, abdominal pain, greenish diarrhea, dehydration, shock, collapse, and death. *Chronic*: sudden onset of hemolytic crisis with weakness, anorexia, thirst, depression, hyperventilation, trembling, anemia, hemoglobinemia, methemoglobinemia, hemoglobinuria (port wine urine), icterus, dyspnea, and death.
- Pb—depression, hyperesthesia, muscle tremors, convulsions, blindness, ataxia, seizures, incoordination, aggression, head pressing, spastic twitching of eyelids, bloat, tenesmus, diarrhea, teeth grinding, jaw champing, and death
- Mo—sudden death, anorexia, severe diarrhea with gas bubbles, emaciation, reduced growth, anemia, lameness, ataxia, swayback in lambs, recumbency, protrusion of nictitating membrane, blindness, achromotrichia (depigmentation of hair/wool), rough hair coat, alopecia, deformity of limbs, muscular degeneration, decreased milk production, and decreased reproductive performance
- Zn—green-colored diarrhea, dehydration, anemia, jaundice, weakness, paresis, anorexia, reduced weight gains, decreased milk yield, subcutaneous edema, polydipsia, polyuria, polyphagia, depression, listlessness, chemosis, exophthalmia, convulsions, and death

CAUSES AND RISK FACTORS

- As—grazing in areas around As mining and smelting sites, exposure to herbicides or old pesticides that have been improperly discarded or stored
- Cu—excessive administration of Cu formulations or ingestion of improperly formulated rations, feeding sheep feeds formulated for other animals, consumption of vegetation or water contaminated with Cu (e.g., near mining/smelting operations or pastures amended with poultry or swine manure), consumption of forage/feeds low in Mo and S and grazing animals in areas containing hepatotoxic plants (e.g., plants containing pyrrolizidine alkaloids). Chronic toxicity is precipitated by stress (e.g., shipping, bad weather, deteriorating plane of nutrition or lactation).
- Pb—consumption of forages contaminated by airborne emissions near Pb smelters or along roadsides, consumption of contaminated water or feed from Pb-lined pipes and drinking/feeding utensils, ingestion of Pb-containing products (automotive batteries, farm machinery grease or oil, paints, putties, and pesticides). In cattle, many cases are associated with seeding and harvesting activities when used oil and batteries are likely to be improperly disposed. Toxicity is exacerbated in animals deficient in Ca, Zn, iron (Fe), and vitamin D. The restricted use of leaded gasoline and oils has

significantly reduced environmental contamination of Pb.

- Mo—consumption of contaminated pastures (near mining or metal production plants) or forage grown with heavy application molybdc or phosphate fertilizers and lime. Low dietary Cu and high dietary S exacerbate the toxicity. High soil pH increases Mo absorption and decreases Cu absorption.
- Zn—consumption of improperly formulated diets or zinc-contaminated forage (e.g., near galvanizing factories and mines), access to substances containing Zn, and careless use of Zn sulfate as a prophylactic and treatment of diseases (e.g., ovine foot rot, facial eczema, and lupinosis)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- As—Pb toxicity, insecticide poisoning, selenium (Se) toxicity, Mo toxicity, Cu toxicity, bovine viral diarrhea
- Cu—infectious gastroenteritis, leptospirosis, arsenic or selenium toxicoses, phenothiazine and other anthelmintic poisonings, bacillary hemoglobinuria, nitrate/nitrite poisoning, postparturient hemoglobinuria, babesiosis, *Corynebacterium renale* infection
- Pb—other diseases with nervous signs including rabies, PEM, TME, listeriosis, ammoniated feed toxicosis, hepatic encephalopathy, nervous coccidiosis, tetanus, hypovitaminosis A, thiamine deficiency, sodium (Na) ion toxicosis, hypomagnesemic tetany, nervous acetonemia, As poisoning, brain abscess or neoplasia, *Haemophilus meningoencephalitis*.
- Mo—primary Cu deficiency, enzootic ataxia, infectious gastroenteritis, internal parasitisms, leptospirosis, anthelmintic poisoning, As toxicosis, Se toxicosis
- Zn—other causes of diarrhea or anemia, such as acute autoimmune hemolytic anemia

CBC/BIOCHEMISTRY/URINALYSIS

- As—elevated hematocrit, BUN and urine specific gravity, and proteinuria
- Cu—hemoglobinemia, methemoglobinemia, reduced blood glutathione, reduced PCV, increased WBC, AST, LDH, AP, GGT, SDH, and bilirubin
- Pb—microcytic hypochromic to normocytic normochromic anemia, basophilic stippling, high nucleated RBC counts, mature leukocytosis, decreased myeloid/erythroid ratio, increased RBC fragility leading to anisocytosis, polychromasia, echinocytosis, poikilocytosis, and target cells. Also urinary ALA levels are elevated; RBC ALAD and porphyrin levels are reduced and elevated, respectively.
- Mo—microcytic hypochromic anemia, elevated AST, GGT, GDH, CK, SDH, bilirubin, creatinine, and Ca, and increased or decreased BUN (depending on the stage of the toxicosis)
- Zn—anemia, neutrophilia, immature RBCs, uremia, reduced erythrocyte ALAD, elevated blood Na, glucose, LDH, GGT, AP, and SDH

OTHER LABORATORY TESTS

- As—analyze for As concentration in liver, kidney, urine, GI contents, feces, and in suspected feeds.
- Cu—analyze for Cu concentration in serum, liver, kidneys, and in suspected feed.
- Pb—analyze for Pb concentration in whole blood (>0.6 ppm is diagnostic), kidney, and liver as well as urinary ALA.
- Mo—determine Mo concentration in blood, liver, and kidney. Blood levels that result in toxicity depend on dietary intake of Cu and S. Quantify Mo and Cu in feeds and forage.
- Zn—analyze for Zn concentration in serum and tissues (e.g., kidney, liver, pancreas) and urine. Special royal-blue top tubes are recommended for blood collection to avoid contamination.

PATHOLOGIC FINDINGS

- As—abomasum and intestines show redness and congestion of mucosa, submucosal edema, and epithelial necrosis.
- Cu—acute toxicity results in severe gastroenteritis with hemorrhage, edema, erosions, and ulcerations in the abomasum, faint-blue color of GI contents, generalized icterus, and swollen friable livers. In chronic toxicity, livers appear yellowish, swollen, and friable; kidneys are dark-red or bluish-black (gunmetal blue kidneys); and gall bladders are distended with greenish bile. Histopathology reveals centrilobular coagulative necrosis with fibrosis of portal areas and lymphocytic inflammation in liver, proliferation and apoptosis of bile ducts with bile stasis, necrosis of renal tubular and glomerular

cells and hemoglobin in renal tubules, brown-black and enlarged spleen with numerous fragmented RBCs, and status spongiosus in the CNS white matter.

- Pb—emaciation, muscle wasting, and degenerative changes in the nervous system and kidney. Histopathology reveals laminar cortical cerebral necrosis, necrosis of renal tubules with high numbers of mitotic figures, and osteoporosis.
- Mo—emaciation, coarse and poorly pigmented hair/wool, osteoporosis and fractures, swollen friable livers, and swollen kidneys with perirenal edema. Histopathology shows hydropic hepatocellular degeneration and periacinar hemorrhagic necrosis, hydropic renal degeneration with tubular necrosis, lysis of cerebral white matter, and demyelination and degeneration of motor tracts in the spinal cord and neurons (in lambs with swayback).
- Zn—poor body condition, abomasitis and duodenitis with greenish mucosa, submucosal edema in the rumen and abomasum, catarrhal enteritis and congestion of small intestines, subcutaneous edema, hydrothorax, hydropericardium, and pancreatic atrophy. Cattle also show pulmonary emphysema, pale flabby myocardium, severe hepatic degeneration, and lesions in the pancreas. Histopathology reveals fibrosing pancreatitis, renal glomerular and tubular lesions, multifocal granulomas in the liver, and proliferation of neck cells of gastric glands.

TREATMENT

General Principles

Stabilize the patient, eliminate source of heavy metal, decontaminate (e.g., by physical removal through rumenotomy, washing off topically or by administration of cathartics), administer antidote (chelation therapy), enhance elimination, and provide symptomatic and supportive care.

MEDICATIONS

- As—dimercaprol (BAL) 3 mg/kg IM q8h (before clinical signs) or 6 mg/kg IM q8h (after onset of clinical signs) for 3–5 days; sodium thiosulfate (30–60 g PO q6h for 3–4 days)
- Cu—ammonium molybdate (50–500 mg PO sid per head) and sodium thiosulfate (300–1000 mg PO sid per head) for 3 weeks (an aqueous mixture of the two salts can be sprayed on the feed to reduce labor); three treatments of ammonium tetrathiomolybdate (sheep, 1.7–3.4 mg/head IV or SC) on alternate days; D-penicillamine (52 mg/kg/day PO for 6 days), but it is expensive for treating on a flock basis.
- Pb—diazepam (0.55–1.5 mg/kg IM) for seizures; Ca-EDTA (73.3 mg/kg slow IV, divided sid or tid) for 3–5 days; BAL (3–6 mg/kg IM q8h for 3–5 days). Thiamine 250–1000 mg q12h is a useful adjunct to Ca-EDTA.
- Mo—copper glycinate (60 mg/calf and 120 mg/adult cattle SC); 1000 mg copper sulfate per adult cow; copper sulfate (1–5% depending on Mo levels in the feed) in salt-mineral mix
- Zn—chelation therapy with Ca-EDTA as for Pb and supplementation of ration with Cu.

CONTRAINDICATIONS

- Ca-EDTA and BAL—use with extreme caution and adjust dose in patients with impaired renal function.
- Ca-EDTA and BAL should not be used in patients with anuria and impaired liver function, respectively.
- Exercise extra caution when using Cu compounds in sheep (very sensitive to Cu).
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

POSSIBLE INTERACTIONS

- Ca-EDTA—use with caution with nephrotoxic drugs (e.g., aminoglycosides) and glucocorticoids.
- BAL—do not administer with Fe and Se salts (forms toxic complexes).
- Chelation therapy can cause depletion of essential minerals (e.g., Zn and Fe).

FOLLOW-UP

PREVENTION/AVOIDANCE

Prevent access to sources of heavy metals and ensure correct mineral nutrition and proper pasture management.

EXPECTED COURSE AND PROGNOSIS

- Generally favorable in animals with mild to moderate signs provided that the source of the heavy metal can be identified and removed from the animal's environment.
- Guarded to poor in animals with severe signs (e.g., hemolytic crisis, severe CNS signs)

MISCELLANEOUS

ASSOCIATED CONDITIONS

As and Pb toxicities—none; Cu toxicity—Zn deficiency, possibly Mo deficiency; Mo and Zn toxicities—Cu deficiency

ZOONOTIC POTENTIAL

- None. However, organ meat may contain levels of heavy metals that pose a risk to humans (e.g., livers containing > 500 mg/kg Cu are considered a risk to public health).
- Lead and Mo are secreted in milk and can present a risk to humans.

PREGNANCY

- Pb crosses placental barrier and is secreted in milk and thus can cause fetal and neonatal poisoning.
- Zn exposure in ewes can cause fetal and/or neonatal Cu deficiency.
- Pregnant ruminants are more susceptible to Zn toxicity.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Nutrition—Ca, Zn, S, Fe, and vitamin D supplementation can reduce incidence of heavy metal toxicity. For example, the maintenance of correct Cu-to-Mo-to-S ratio in feeds is imperative to reduce incidence of Mo toxicity.
- Pasture management—use of some fertilizers may induce mineral imbalances in forage, hepatotoxic plants increase toxicity of Cu, and some plants may reduce bioavailability of essential heavy metals such as Cu.

SYNONYMS

As toxicity—arsenic toxicosis. Other names for As-containing compounds include arsenicals, arsenites, arsenates, arsine. Cu toxicity—enzootic icterus of sheep, copper toxicosis, copper poisoning, copper sulfate poisoning Pb toxicity—plumbism, saturnism, lead intoxication, lead poisoning, lead toxicosis Mo toxicity—molybdenosis, molybdenum toxicosis, teart disease, peat scours Zn toxicity—zinc poisoning, new wire disease (in birds), zincalism (in humans)

HEMORRHAGIC BOWEL SYNDROME

BASICS

DEFINITION

- Hemorrhagic bowel syndrome (HBS) is a severe, highly fatal disease that presents as acute intestinal dysfunction in dairy cattle characterized by submucosal hemorrhage of the jejunum and often intraluminal blood clots.
- The syndrome can be diagnosed by history, clinical signs, and consistent diagnostic findings, and definitively by exploratory laparotomy or necropsy. Efforts to treat the disease are supportive coupled with surgical intervention.

PATHOPHYSIOLOGY

- The complete etiology and pathogenesis of HBS have not been completely elucidated, however, the consistent identification of *Clostridium perfringens* type A, and its associated alpha and beta 2 toxins provides evidence for their role in the syndrome.
- Dietary factors are also thought to be a contributory factor in the development of HBS.

SYSTEMS AFFECTED

- Gastrointestinal: Findings most frequently include hemorrhagic enteritis, devitalized or ischemic portions of the small intestine, distended loops of bowel, dark red to purple discoloration of the serosa of the bowel, and intraluminal blood clots that are closely adherent to the mucosal surface.
- Cardiovascular: Inflammatory mediators released during necrosis of the small intestine secondarily affect the cardiovascular system. Tachycardia and cool extremities due to decreased peripheral perfusion are the most common findings.

GENETICS

N/A

INCIDENCE/PREVALENCE

Reports of HBS have increased in frequency in the United States. Fifty percent of respondents to a survey of Minnesota dairy farms had reported at least one case of HBS in the previous 12 months. Greater than half of these respondents reported multiple cases. Ninety-four percent of the affected herds contained greater than 50 cows, and 83% of these affected herds were being fed a total mix ration.

GEOGRAPHIC DISTRIBUTION

N/A

SIGNALMENT

Hemorrhagic bowel syndrome is most commonly diagnosed in high-producing, adult, female dairy cattle.

SIGNS

HISTORICAL FINDINGS

Reports suggest cattle consuming a total mixed ration are more likely to be affected. In addition, affected cattle tend to be approximately 3 months postpartum.

PHYSICAL EXAMINATION FINDINGS

Signs include acute anorexia, decreased milk production, scant feces, and abdominal pain. Abdominal distention, tachycardia, bloody stool, cool extremities, and pale mucous membranes are often observed as well.

CAUSES

The specific cause of HBS is undetermined. However, the beta 2 toxin liberated by *Clostridium perfringens* type A has been incriminated in the development of the syndrome.

RISK FACTORS

High-producing dairy cows fed total mix rations high in energy and low in fiber appear to be at greater risk. One study found that larger herds (>50 cows) were more likely to have cases of HBS than smaller herds.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Intussusception

Intussusception is the most likely rule out in cases of HBS due to similarities in presentation. Cattle with intussusception often have a history of a more prolonged progression of illness and gradual abdominal distention than those with HBS. Cattle with HBS often present with more severe depression and higher heart and respiratory rates than those with intussusception.

Abomasal Lymphosarcoma/Pyloric Outflow Obstruction

Tumors, foreign bodies, or abscesses that obstruct the outflow of the pylorus could present with clinical signs similar to HBS. Occult blood tests may or may not be positive in this instance, depending on the nature of the obstruction. Serum biochemical findings, however, may mimic HBS. Clinicians should look for other signs of enzootic lymphosarcoma. Cattle with pyloric outflow obstruction do not present with acute onset of signs and are not as depressed as those with HBS. In addition, the characteristic “papple”-shaped abdominal contour observed from the rear in cases of pyloric obstruction is not a consistent finding in HBS.

Abomasal Ulcer

Occult blood tests may be positive and the animal may present with some degree of abdominal pain with abomasal ulceration. Ultrasonography is useful to differentiate between HBS and abomasal ulcers; however, exploratory laparotomy may be required to make a definitive diagnosis.

Salmonellosis

The depression, acute onset, anorexia, and passage of blood in the feces associated with salmonellosis can be suggestive of HBS. Leukopenia and the continued passage of stool, albeit abnormal, aids in the differentiation of salmonellosis from HBS.

Mesenteric Root Volvulus/Intestinal Incarceration

Exploratory laparotomy may be the only means to definitively differentiate between these conditions and HBS.

CBC/BIOCHEMISTRY/URINALYSIS

Complete Blood Count/Fibrinogen

Cattle with HBS frequently have a leukocytosis accompanied by a left shift. Packed cell volume and total protein vary depending on the hydration status of the animal.

Serum Chemistry

- Results of a serum chemical profile reflect the gastrointestinal stasis associated with the disease.
- Findings include a metabolic alkalosis, hypochloremia, hypokalemia, azotemia, hypo- or hypercalcemia, hypo- or hyperphosphatemia, and hyperglycemia. Hyperglycemia is thought to be a result of endogenous release of steroid and epinephrine due to the stress of disease.
- Serum enzymes including creatinine, AST, GGT, and SDH tend to be elevated.

Urinalysis

Ketonuria is a common finding in cows with HBS due to anorexia and potentially negative energy balance.

OTHER LABORATORY TESTS

Fecal Occult Blood

Fecal occult blood tests are positive in cases of HBS due to the submucosal hemorrhage associated with the disease.

Rumen Chloride

Elevation in rumen chloride (>30 mEq/dL) is a consistent finding in HBS due to the tendency for obstruction of the proximal jejunum with clotted blood. However, rumen chloride levels may be within the normal range if complete obstruction of the jejunum does not occur, or if the obstruction is more distal in the jejunum and the test is performed prior to backflow of gastrointestinal content into the rumen.

IMAGING

Ultrasound: Transabdominal ultrasonography in the ventral region of the right paralumbar fossa consistently reveals dilatation of small intestinal bowel loops. Often, homogenous echogenic material consistent with clotted blood is evident within the dilated loops of intestine.

DIAGNOSTIC PROCEDURES

Abdominocentesis

Cytologic examination of abdominal fluid is often unremarkable in cases of HBS; however, this diagnostic tool can be of benefit to rule out other causes of acute gastrointestinal stasis, hemorrhage, and obstruction.

Rectal Exam

Rectal findings may reveal distended bowel loops, however, inability to palpate these does not rule out the disease.

Exploratory Laparotomy

Exploratory right-sided laparotomy, in most cases, should serve as the definitive diagnostic tool.

PATHOLOGIC FINDINGS

- Necropsy findings include segmental necrosis with hemorrhage of the jejunum. Frequently, a large blood clot that may or may not be adhered to the mucosa occludes the lumen of the affected segment of bowel.
- Occasionally, fibrinous peritonitis is discovered in addition to the jejunum lesions.

TREATMENT

APPROPRIATE HEALTH CARE

Hemorrhagic bowel syndrome requires intensive inpatient management coupled with surgical exploration and intervention to identify and remove affected jejunum.

NURSING CARE

Nursing care of HBS cases requires intravenous fluids to correct the electrolyte derangements associated with the disease.

ACTIVITY

Due to the severity of the disease, the activity level of cattle with HBS will be depressed; therefore, altering activity is not a factor in the management of HBS.

DIET

Animals with HBS are anorexic, therefore, the goal of the clinician is to stimulate intake of its normal diet. Rumen transfaunation is often a helpful tool to restore active rumen bacteria and protozoa. The diet of the herd should be examined to ensure adequate fiber content and reduce excessive energy intake.

CLIENT EDUCATION

- Clients should be instructed to examine the ration of the herd to ensure adequate fiber length and content.
- Animals with HBS that recover from the disease should be monitored, and owners should expect continued passage of feces and increases in appetite and milk production as the animal convalesces.

SURGICAL CONSIDERATIONS

- In cases of HBS, a right-sided exploratory laparotomy is indicated not only to arrive at a definitive diagnosis, but also to remove the offending segment(s) of bowel. Intestinal resection of affected areas and anastomosis appear to provide the best postoperative prognosis.
- Enterotomy, with either manual removal of the blood clot or intraluminal lavage, is a reported means of relieving the intestinal obstruction. Manual dissolution of the clot without enterotomy has also been described, but is associated with a poor prognosis.

MEDICATIONS

DRUGS OF CHOICE

- Antibiotics are indicated in cases of HBS due to the assumption that *Clostridium perfringens* plays a role in the syndrome. Specifically, procaine penicillin G at 40,000 IU/kg once a day IM is active against clostridial species and also serves as supportive therapy postoperatively to guard against the development of peritonitis.
- Currently, FARAD recommends a 45-day slaughter withdrawal on extralabel use of procaine penicillin G and a 96-hour milk withdrawal.

CONTRAINDICATIONS

N/A

PRECAUTIONS

Animals with a history of allergic reaction to penicillin should not be treated with procaine penicillin G.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

- The most important sign indicating successful surgical treatment is the passage of a normal amount of feces within 24 hours postoperatively. However, the consistency of the stool may be abnormal for some time and some blood may pass for an additional 48 hours or so.
- Rumen motility should also be monitored daily and should gradually return to normal function. The heart rate and respiratory rate should be observed every 4 hours until they are within normal limits.
- Rectal temperature should be recorded daily for at least 1 week following recovery in an attempt to detect postoperative peritonitis.

PREVENTION/AVOIDANCE

- Due to the fact that the pathogenesis of HBS is still under investigation, efforts to prevent or reduce the number of cases of HBS are primarily centered on providing immunity to *Clostridium perfringens* type A and carefully monitoring dietary factors.
- Currently, there are no commercially available vaccines that contain *Clostridium perfringens* type A or its beta-2-toxin gene, and vaccines containing *Clostridium perfringens* types C and D are not apparently protective against HBS. However, autogenous vaccines using farm-specific isolates are available from various laboratories and are being used in the herd of origin as a preventative measure.
- Preliminary results suggest these vaccines have some efficacy in the prevention of HBS.
- Diets high in energy and low in fiber have been incriminated as risk factors in the development of HBS. Therefore, dietary adjustments may also benefit herds experiencing cases of HBS.

POSSIBLE COMPLICATIONS

Peritonitis is a potential complication of cattle that recover from HBS. Peritonitis may develop due to rupture or leakage of necrotic bowel or following resection and anastomosis of compromised sections of jejunum. Postoperative ileus of the gastrointestinal tract is also a frequent complication.

EXPECTED COURSE AND PROGNOSIS

- The prognosis for HBS is poor to grave. The more quickly the condition is recognized and subjected to surgical treatment, the better the chances for survival. In addition, more aggressive surgical management (resection and anastomosis) is associated with a better survival rate.
- Often, the progression of the syndrome is so rapid that even the most astute managers fail to appreciate the severity of the disease, and damage to the jejunum is beyond repair or intervention.

HEPATITIS (FUNGAL, TOXIC, AND INFECTIOUS)

BASICS

OVERVIEW

- Many agents can cause diffuse degenerative and inflammatory diseases of the liver in ruminants, categorized under the general term “hepatitis.”
- Fungal agents include *Aspergillus* and *Fusarium*. Toxic agents include inorganic and organic poisons and poisonous plants.
- Infectious agents include clostridia and liver flukes.

PATHOPHYSIOLOGY

- Fungal and toxic agents—typically cause centrilobular swelling, decreased hepatic blood flow, lysosomal damage, and decreased mitochondrial function, leading to liver cell death and necrosis. Necrosis leads to decreased gluconeogenesis and eventually to fibrosis.
- Infectious agents—*Clostridium* spp. are normally found in the ruminant gastrointestinal tract, including the liver. Anaerobic conditions (e.g., from migrating liver fluke larvae) can cause clostridia to multiply and release exotoxins, which cause coagulative necrosis in the liver.
- Large numbers of migrating liver flukes may cause enough liver damage to cause an acute hepatic insufficiency, with decreased production of serum proteins causing submandibular edema.

SYSTEMS AFFECTED

Hepatic system

SIGNS

HISTORICAL FINDINGS

Exposure to fertilizers or presence of poisonous plants on the farm

PHYSICAL EXAMINATION FINDINGS

Icterus (may not be visible even with hyperbilirubinemia in ruminants), hepatic encephalopathy signs (dullness or hyperexcitability, muscle tremors, convulsions, weakness, head pressing), emaciation, edema, diarrhea or constipation, photosensitization, liver enlargement (the liver is normally palpable in ruminants, on the right side behind the costal arch, only if it is enlarged).

CAUSES AND RISK FACTORS

- Causes—fungal causes include toxins from *Aspergillus* and *Fusarium*. Toxic causes include inorganic poisons (i.e., copper, arsenic, phosphorus) and organic poisons (i.e., gossypol, creosol, coal tar).
- Toxic causes also include poisonous plants (i.e., the weeds senecio and crotalaria), pasture plants (i.e., Alsike clover [*Trifolium hybridum*], water-damaged alfalfa hay), and trees and shrubs (i.e., lantana).
- Infectious causes include clostridia, chlamydia, liver flukes, and ascarid infections.
- Risk factors—include inadvertent exposure to toxic causes in the form of fertilizers, cottonseed oil, or industrial waste.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Encephalomyelitis—liver enzymes normal
- Encephalomalacia—liver enzymes normal
- Cerebral edema—liver enzymes normal

CBC/BIOCHEMISTRY/URINALYSIS

Biochemistry

Liver enzymes, bilirubin, and bile acids. Liver enzymes (e.g., SDH, GGT, Alk phos, AST) are important measures of disease. SDH is liver specific, found in cytoplasm of hepatocytes; short half-life therefore elevated in acute liver disease but may be normal in chronic liver disease.

- GGT, Alk phos, and AST are not liver specific, are membrane bound, are found in liver but also in other tissues like muscle, bone, kidney. Long half-life therefore elevated in chronic liver disease but may be normal in acute liver disease.
- GGT is found mainly in the biliary tract, so it is a good indicator of biliary obstruction.
- Serum bilirubin is not a sensitive indicator of liver function in ruminants, since it is only slightly elevated in liver disease. However, in the absence of hemolytic anemia, a bilirubin level > 2 mg/dl (mainly conjugated bilirubin in ruminants) indicates impaired liver function in ruminants.
- Bile acids are a specific liver function test in ruminants. A bile acid concentration > 60 micromol/L indicates liver dysfunction in ruminants.

OTHER LABORATORY TESTS

Liver biopsy/histopathology

IMAGING

Ultrasound can visualize the gallbladder and a portion of the liver on the right side of the abdomen, high up and caudal to the last rib and between the ribs.

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Enlarged liver with swollen edges
- In toxic hepatitis, tend to see pronounced generalized lobulation due to engorged centrilobular vessels, icterus, edema, possibly photosensitization
- In infectious hepatitis, tend to see more focal lesions, with necrosis, lobulation, fatty infiltration. In parasitic hepatitis, tend to see focal hemorrhages under the liver capsule, and necrotic tracks.

TREATMENT

ACTIVITY

N/A

DIET

Ideal diet for animals with hepatitis is low in protein and fat, due to the diminished ability of the liver to detoxify ammonia

and other nitrogenous substances, and high in carbohydrates and calcium, but affected animals are usually anorexic.

CLIENT EDUCATION

Applying fertilizers safely and correctly to avoid exposing animals to toxic levels, recognizing and eliminating poisonous plants on pasture, clostridial vaccination, liver fluke control

MEDICATIONS

- Oral antibiotics to control protein digestion and putrefaction (works better in monogastric animals than in ruminants)
- Supplement feed or inject with multivitamins and minerals.
- Oral or intravenous glucose to maintain blood glucose levels
- Activated charcoal 500 g PO as a laxative if acute intoxication suspected

DRUGS OF CHOICE

Oral neomycin or chlortetracycline

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

Oral antibiotics tend to alter rumen microflora, often resulting in indigestion and acidosis.

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

N/A

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

See Client Education above.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

Prognosis poor if hepatic fibrosis seen on liver biopsy/histopathology; otherwise prognosis guarded.

HEREDITARY CHONDRODYSPLASIA: OVINE

BASICS

Ovine hereditary chondrodysplasia (spider lamb syndrome)

- *Heritable* congenital defect that produces multiple, severe skeletal deformities in young lambs. “Spider” relates to severe valgus limb deformities that create a “spider legged” appearance.
- *Genetic defect* disrupts normal ossification processes involving transformation of cartilage to bone.
 - Semilethal—affected lambs seldom survive past 6 months of age.
 - Most common in black-faced breeds of sheep
 - First described in United States in 1980s in popular lines of Suffolk and Hampshire sheep
 - Documented in Suffolk, Hampshire, Shropshire, Oxford, Southdown, and associated crossbred sheep
 - Entered non-black-faced breeds (e.g.: *Southdown*) through crossbreeding programs
 - Prior to availability of DNA testing, *white* and *gray* pedigrees used to define carriers. *Grey* individuals—pedigrees linked to suspected carriers. *White* individuals—pedigrees with no apparent incidence of carriers. Pedigrees often inaccurate—now DNA testing a better option.
 - Inheritance pattern—simple autosomal recessive. NN = normal; NS = carrier; SS = clinically affected lamb.

PATHOPHYSIOLOGY

Genetic defect linked to fibroblast growth factor receptor 3 (FGFR3)

- FGFR3 normally down regulates chondrocyte growth in bone development process.
- Homozygous SS disrupts down regulation of process resulting in excessive and disorderly proliferation and transformation of chondrocytes to bone.

SYSTEMS AFFECTED

Musculoskeletal

INCIDENCE/PREVALENCE

United States and Canada (also other countries where carrier sheep have been imported)

- Regions where black-faced breeds are common (Midwest)
- Rare but not uncommon

RISK FACTORS

- Breeds commonly associated with the problem
- Mating carrier sheep—(NN X NN = 100% NN), (NS X NS = 25% SS + 50%NS + 25% NN)

DIAGNOSIS

- DNA isolated from blood or semen can identify NN, NS or SS status
- Clinical signs (suggestive), radiological and necropsy findings (supportive)
- Clinical presentation
 - Two distinct clinical entities can confuse practitioners.
 - *Affected lambs that appear grossly normal at birth.* While subtle deformities are present at birth, typical limb deformities and muscle atrophy associated with SLS may not be readily apparent until the lamb is 4 to 6 weeks old.
 - *Affected lambs with visible deformities at birth.* Severe skeletal deformities obvious at birth, may affect neonatal survival.
- Clinical description of skeletal deformities observed in both groups include

- Abnormally long, thin-boned legs with a long fine neck (extreme type for breed)
- Small rounded head (Roman nose) with occasional lateral deviation to the nose
- Moderate to severe muscle atrophy—progresses with age
- Scoliosis (usually) and/or kyphosis (less common) of the spine
- Wide, flattened appearing sternum with small palpable “dimple”
- Moderate to severe valgus deformities distal to the hock and/or carpus; severity increases with age and growth.

DIFFERENTIAL DIAGNOSIS

- AGH syndrome (arthrogryposis hydranencephaly syndrome) and/or limb deformities
- Cache Valley virus—joints feel “frozen,” lack of articulation; die at birth
- Plant toxicities—*Veratrum californicum*, locoweed (*Astragalus* or *Oxytropis* sp.)

DIAGNOSTIC PROCEDURES

- Radiographic findings—abnormal areas of ossification observed throughout skeleton.
 - Live animal or postmortem: flexed lateral of the elbow reveals multiple irregular “islands” of ossification in the olecranon.
 - Postmortem: VD or DV view sternum (disarticulated from ribs) reveals multiple irregular islands of ossification instead of normal symmetrical bipartite pattern.
- Blood or semen can be submitted for DNA testing to confirm genotype.
- Laboratory findings—Nondiagnostic: slightly increased alkaline phosphatase activity associated with bone lesions

GROSS FINDINGS

- *Skull*: rounding of dorsal silhouette (Roman nose appearance) with elongation and erosion of cartilage on the occipital condyles
- *Sternum*: sternbrae irregular shape and size, failure to fuse, malalignment and dorsal deviation of second to sixth sternbrae
- *Vertebrae*: consistent scoliosis, misshapen, excessive amounts and abnormal configuration to vertebral body cartilage
- *Appendicular skeleton*: excessive cartilage in olecranon and scapula, lateral “bowing” of distal radius and ulna, hind limbs usually less severely affected, erosion of articular cartilage in most joints

TREATMENT

None. Euthanasia suggested once diagnosis confirmed

FOLLOW-UP

PREVENTION/AVOIDANCE

Where appropriate, DNA test and utilize only NN rams in the breeding program.

HIGH MOUNTAIN DISEASE

BASICS

DEFINITION

This disease is right-heart failure secondary to hypoxic pulmonary vasoconstriction associated with living at high altitudes where the oxygen content of the air is lower than at lower altitudes. This is a form of cor pulmonale, which is right-heart failure secondary to pulmonary hypertension due to disease of the pulmonary vasculature.

PATHOPHYSIOLOGY

- Chronic pulmonary hypertension is the primary cause of this condition. In cattle, a hypoxic (high altitude) environment leads to pulmonary vasoconstriction, the severity of which depends on the amount of smooth muscle in the arterial and arteriolar walls.
- Altered myocardial metabolism and chemoreceptor activity may be contributory factors. There also may be phenotypic changes in smooth muscle cells with hypoxic or pressure-induced injury causing the deposition of elastin and collagen in pulmonary vasculature. A pressure overload on the right ventricle results from chronic pulmonary arterial hypertension. Depending on the rapidity of the development of the hypertension, the right ventricle may respond with failure, dilation, or hypertrophy. If acute failure does not occur and the animal remains in a hypoxic environment, the disease is progressive and right-heart failure will result when the right ventricle dilates and is unable to compensate.
- Ingestion of locoweed (*Oxytropis* and *Astragalus* spp.) can worsen the disease due to myocardial damage caused by the plant toxins.
- Other chronic pulmonary diseases, such as lungworm infestation and bronchopneumonia, can lead to cor pulmonale in ruminants by causing pulmonary hypertension, and these conditions can exacerbate the effects of high mountain disease.

SYSTEMS AFFECTED

- Cardiovascular—Right-heart dilation or hypertrophy leads to right-heart failure, which causes increased venous blood pressure due to diminished return of blood through the right heart. The increased pressure causes vascular leakage, which leads to ventral subcutaneous edema, ascites, and pulmonary/pleural effusion.
- Gastrointestinal—Diarrhea is a common finding.
- Hepatobiliary—Hepatic congestion is common because of decreased return of blood to the right heart.
- Musculoskeletal—Affected animals are usually weak and exercise intolerant. This is secondary to heart failure.
- Respiratory—Pneumonia, emphysema, and atelectasis are commonly found in addition to pleural and pulmonary effusion.

GENETICS

The predisposition to this condition appears to be heritable, as calves from affected cows are more likely to have the disease. The mode of inheritance is unknown.

INCIDENCE/PREVALENCE

- The incidence is estimated at 0.5 to 2.0% in cattle pastured at elevations greater than 6000 feet in the western United States and South America.
- The incidence is increased in areas or conditions where locoweed ingestion is a problem. In addition, the incidence can be increased in certain herds if proper selection pressures are not applied because there is a heritable component of the disease.

GEOGRAPHIC DISTRIBUTION

- The disease is most common in the western United States and in South America, although it has been reported in other mountainous regions of the world. It most commonly occurs at altitudes greater than 6000 feet, although similar conditions have been reported at lower elevations.
- Areas where locoweed grows are more likely to have the condition reported.

SIGNALMENT

Species

Cattle are most commonly affected, although the disease has been reported in sheep and deer under extreme stress. Acquired heart failure in small ruminants is most commonly attributed to other sources.

Breed Predilections

None.

Mean Age and Range

The disease is more common in calves than adult cattle, but all ages are affected.

Predominant Sex

None

SIGNS

- The most common primary sign is subcutaneous edema of the brisket, ventral thorax, and sometimes limbs and submandibular region.
- Increased distension and/or pulsation of the jugular vein, dyspnea, tachypnea, cyanosis, weakness, and exercise intolerance are usually evident and usually precede the formation of edema.
- Ascites and diarrhea may be present also.
- Occasionally marked subcutaneous edema does not form and instead the animals become emaciated in conjunction with the presence of the other signs.

HISTORICAL FINDINGS

Affected animal are usually first noted to be depressed or lethargic, followed by the slow onset of the above-mentioned signs. Often a stressor such as movement or extremely cold weather precedes the onset of clinical signs.

PHYSICAL EXAMINATION FINDINGS

1. Ventral subcutaneous edema (thorax, limbs, brisket, and submandibular)
2. Jugular venous distension and/or pulsation
3. Lethargy, exercise intolerance, weakness
4. Tachypnea, dyspnea
5. Heart murmur
6. Diarrhea
7. Ascites
8. Cyanosis

CAUSES

- The cause of this condition is a hypoxic environment. The disease can be exacerbated by concurrent lung disease, severe stress, or locoweed ingestion.
- There is a genetic predilection.

RISK FACTORS

- Living at altitude greater than 6000 feet
- Pulmonary disease
- Stress
- Cold weather
- Availability of locoweed
- Genetic predisposition (the animal's sire or dam was affected)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Any other cause of right-heart failure, such as tricuspid insufficiency, cardiac lymphosarcoma, other thoracic neoplasia, bacterial endocarditis, pulmonic stenosis, and dilative cardiomyopathy can be difficult to differentiate.

- Pericarditis, traumatic pericarditis—Heart sounds may be muffled or a “washing machine murmur” may be heard with these conditions. Animals with traumatic reticulopericarditis are likely to be painful (positive grunt test, expiratory grunt, abducted elbows) febrile, and toxemic. Pericardiocentesis or ultrasound may differentiate these conditions.
- Chronic pneumonia—Thoracic auscultation may differentiate, as harsh lung sounds or areas of consolidation may be heard with pneumonia. Transtracheal wash cytology and culture can rule in or out, and a neutrophilia on a CBC rules in an infectious process.
- Parasitic bronchitis—A fecal exam (Baerman sedimentation technique) will rule in or out. Eosinophilia in transtracheal wash cytology is indicative of larval migrans.
- Left-heart failure—This causes weak peripheral pulses, pulmonary edema, and pleural effusion. Pulmonary edema is evidenced by crackles on thoracic auscultation.
- Pleuritis—This is almost always a secondary condition in ruminants. Thoracic auscultation reveals pleural friction rubs and a horizontal fluid line. Ultrasound can be helpful. Evaluation of pleural fluid is diagnostic (total protein greater than 2 g/dl or greater than 10,000 cells/ml is abnormal).

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Transtracheal wash—Cytology and culture can rule in or out parasitic bronchitis or primary bronchopneumonia.
- Fecal sedimentation can diagnose parasitic bronchitis.
- Cardiac catheterization—With cor pulmonale there are increased pressures in the right ventricle, right atrium, and pulmonary artery. Right-heart failure is indicated by increased right ventricular end diastolic pressure.

IMAGING

Radiology and ultrasound are useful only to rule out other primary lung disease, pleuritis, and pericarditis. An echocardiogram can verify right-heart dysfunction.

OTHER DIAGNOSTIC PROCEDURES

None

PATHOLOGIC FINDINGS

- On necropsy, there are findings indicative of right-heart failure such as ventral subcutaneous edema, ascites, hepatic congestion (nutmeg liver), and myocardial damage (dilation and/or hypertrophy of the right ventricle).
- The lungs may have lesions of bronchitis, pneumonia, emphysema, or bronchiectasis. Lesions of locoweed toxicosis may be present in other organs.

TREATMENT

APPROPRIATE HEALTH CARE

- The disease is reversible if caught early on and the affected animals are treated appropriately.
- Moving affected animals to lower altitudes (less than 5000 feet) and treating any primary or secondary pulmonary disease are most important.
- Animals may be treated on an inpatient or outpatient basis but should be confined in a suitable low-stress environment to minimize the need for exercise.
- If locoweed ingestion is a problem for the herd, it should be moved, or supplemental feed should be provided to minimize ingestion of locoweed.

NURSING CARE

- Oxygen therapy is beneficial if economically feasible as reversal of hypoxia helps relieve the pulmonary hypertension.
- Diuretics are beneficial. Avoid overhydration, stress, and exercise. Large effusions can be removed via paracentesis.
- Digitalis and digoxin can be used if heart failure is present; however, the prognosis is poor once signs of heart failure are present, and there are economic considerations with the use of these drugs.

ACTIVITY

The patient's activity should be restricted as much as possible.

DIET

Avoid locoweed.

CLIENT EDUCATION

- Affected animals that recover should not return to high altitude or be used for breeding.
- Prognosis for recovery of individual animals is good unless heart failure is present.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

- Broad-spectrum antibiotics should be used if pneumonia is present. Examples are florfenicol at 40 mg/kg sub-Q once (slaughter withdrawal 38 days), oxytetracycline at 20 mg/kg IM q 48 hours (200 mg/ml product, cattle dose, or 10 mg/kg IM q 24 hours for sheep and goats).
- Nonsteroidal anti-inflammatory drugs may be beneficial (i.e., flunixin meglumine at 1.1–2.2 mg/kg IV q 24 hours for up to three days; 4-day slaughter withdrawal).
- Diuretics such as furosemide (500 mg once daily for 1–2 days in cattle) may help speed up the resolution of edema but should be avoided in patients with diarrhea or if aspirin is used.
- Digoxin may be used to treat heart failure if economically feasible (0.25 mg/100 lb, the titrate dose to achieve normal atrial rate; cattle dose, no withdrawal time available).
- Drug withdrawal times must be determined and maintained for all treated food-producing animals.

CONTRAINDICATIONS

- Avoid overhydration.
- Do not use diuretics in patients with possible electrolyte or acid/base disturbances, such as diarrhea, or in patients on aspirin therapy.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

None

POSSIBLE INTERACTIONS

None

ALTERNATIVE DRUGS

- There are many broad-spectrum antibiotics for treatment of bacterial pneumonia in ruminants.
- Other NSAIDs, such as aspirin, may be used if necessary.

FOLLOW-UP

PATIENT MONITORING

Frequency of monitoring is dependent upon the severity of the patient's condition, but once-daily monitoring of clinical signs should give an indication of the animal's progress.

PREVENTION/AVOIDANCE

- Do not breed recovered animals, as there is a heritable component to this disease. Recovered animals should not be moved back to high altitude.
- Avoidance of primary lung disease such as pneumonia and lungworm infestation (via biosecurity, judicious vaccination, deworming protocols, etc.) can prevent secondary cor pulmonale and decrease the severity of clinical signs in animals that become affected with brisket disease.
- Avoid locoweed ingestion by avoiding locoweed or providing supplemental feed in pastures where locoweed exists.

(Locoweed is not a first-choice forage, generally.) Cattle can become addicted to locoweed, however, so if locoweed ingestion becomes a problem, cattle may have to be moved.

- Avoid severe stress, especially during extremely cold weather.

POSSIBLE COMPLICATIONS

Complications that could occur with any serious disease or stressor are likely in affected animals (such as abortion).

EXPECTED COURSE AND PROGNOSIS

Onset of the disease takes 1 to 2 weeks. Prognosis for recovery is good unless heart failure is present. Full recovery may take several days to more than a week.

MISCELLANEOUS

ASSOCIATED CONDITIONS

None

AGE-RELATED FACTORS

The disease is most common in young animals but all ages may be affected.

ZOONOTIC POTENTIAL

None

PREGNANCY

Abortion is possible in pregnant animals due to fetal stress.

RUMINANT SPECIES AFFECTED

Cattle are by far the most susceptible, but the disease has been reported in sheep and deer under extreme stress.

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

See “Avoidance” section above. In addition, measurement of pulmonary arterial pressures may be useful in selection of breeding stock (mean arterial pressure should be less than 35 mm Hg at elevations of 5000 feet or greater).

HORNER'S SYNDROME

BASICS

OVERVIEW

Horner's syndrome is a group of clinical signs associated with interruption of ocular sympathetic nerve pathways.

SIGNALMENT

Can occur in any species

SIGNS

- Miosis
- Ptosis
- Enophthalmos
- Protrusion of the third eyelid
- Anisocoria
- Cattle manifest miosis, enophthalmos, and loss of sweat on the ipsilateral side of the muzzle, unlike horses where there is excessive sweating of the face and neck to the level of C2 on the affected side.
- Sheep and goats generally only exhibit mild ptosis.
- Visual deficits do not usually occur.

CAUSES AND RISK FACTORS

- Lesions anywhere along the preganglionic or postganglionic ocular sympathetic nerve fibers result in the characteristic clinical signs known as Horner's syndrome.
 - Preganglionic sympathetic nerve fibers:
 1. Originate from the mesencephalic tectum in the brain stem.
 2. Descend through cervical spinal cord.
 3. At the level of T1–T3 spinal cord segments, they enter the gray matter of the spinal cord.
 4. Exit the ventral spinal nerves and run through the brachial plexus.
 5. Ascend the neck in the vagosympathetic trunk.
 6. Continue to the cranial cervical ganglion under the tympanic bulla where they synapse with postganglionic sympathetic nerve fibers.
 - Postganglionic sympathetic nerve fibers:
 1. Pass through the petrous temporal bone area.
 2. Follow the ciliary nerve and innervate the following:
 - a. Periorbital smooth muscles that are responsible for pulling the globe toward the surface of the orbit
 - b. Eyelid muscles and third eyelid muscles in some species
 - c. Dilator muscle of the pupil
 - d. Periarteriolar musculature
 - e. Sweat glands of the head
 - f. Ciliary muscles
- Specific injuries or disease that can result in Horner's syndrome include:
 - Trauma to the neck or avulsive injuries
 - Abscesses in the periorbital, mediastinal, or thoracic region
 - Compressive lesions in the T1 – T3 spinal segments
 - Neoplasms that have been associated with Horner's syndrome include lymphosarcoma, melanoma, squamous cell

carcinoma, neurofibroma, and respiratory epithelial carcinoma

- Esophageal perforation
- Otitis interna and otitis media
- Complications associated with surgical ligation of the carotid artery
- Necrotizing perivascular drug injections
- Transient Horner's syndrome can occur after IV injection of drugs. It has been associated most frequently with xylazine, but can also occur after IV injection of vitamin E/selenium or phenylbutazone.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anisocoria may be caused by ocular diseases such as abnormalities of the iris, cornea, lens, or retina.
- Miosis can be caused by ocular pain especially if uveitis is present.
- Paralysis of the eyelid(s) can be caused by trauma or injury to the palpebral branch of the facial nerve as it crosses the zygomatic arch. This can occur in cattle that struggle in stanchions.
- Facial paralysis can be caused by injury to the buccal branches of the facial nerve on the side of the jaw.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

- Cervical and/or thoracic radiographs may reveal abnormalities such as vertebral fracture or luxation, abscesses or other space occupying masses, esophageal perforation or other abnormalities that would result in injury to the sympathetic pathway.
- Ultrasound may be useful in identifying retrobulbar masses.

DIAGNOSTIC PROCEDURES

Localizing the site of injury can be attempted using the following methods:

- Evaluate associated clinical signs that may be present such as concurrent neurologic signs that can be localized to particular areas of the CNS.
- Application of epinephrine (0.1 ml of 1:1000 epinephrine) topically to the eye to cause mydriasis
 - Postganglionic lesions demonstrate onset of dilation in < 20 minutes.
 - Preganglionic lesions demonstrate onset of dilation in 30–50 minutes.
- Evaluate response to application of direct-acting vs. indirect-acting agents.
 - Indirect-acting agents (1% hydroxyamphetamine) cause good dilation of a normal eye or one with a preganglionic or a central pathway lesion.
 - Direct-acting agents (1% phenylephrine) cause good dilation of an eye with a postganglionic lesion.

PATHOLOGIC FINDINGS

GROSS FINDINGS

Depend on the underlying cause

HISTOPATHOLOGICAL FINDINGS

No findings are considered specific for Horner's syndrome.

TREATMENT

- Treat the underlying cause of denervation.
- Drain abscesses when possible.

- Lavage perivascular drug injection sites and administer systemic NSAIDs or dexamethasone to prevent tissue necrosis.

MEDICATIONS

Depend on the underlying cause of denervation

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

N/A

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Signs are often irreversible even when the underlying cause is successfully treated.
- IV administration of xylazine causes Horner's syndrome but resolves spontaneously; however, necrotizing perivascular injections can result in permanent neurologic deficits if not treated immediately.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Transient Horner's syndrome can occur after IV injection of drugs. It has been most frequently associated with xylazine but also can occur after IV injection of vitamin E/selenium or phenylbutazone.

HYPOCALCEMIA: BOVINE

BASICS

DEFINITION

Hypocalcemia, also known as milk fever and postparturient paresis, is an afebrile disease characterized by acute-to-peracute flaccid paralysis in lactating dairy cows. It occurs most commonly in high producing dairy cows within 72 hours after parturition.

PATHOPHYSIOLOGY

- Muscular contraction is impaired several ways by hypocalcemia: (1) loss of the membrane-stabilizing effect of calcium on peripheral nerves resulting in hyperesthesia and mild tetany, and (2) impaired role of calcium in the release of acetylcholine at the neuromuscular junction resulting in paralysis due to blockade of the transmission of nerve impulses to the muscle fibers.
- Increased disease susceptibility has been observed around the time of parturition. Low extracellular calcium in vitro decreases phagocytosis and intracellular killing by polymorphonuclear neutrophils.

SYSTEMS AFFECTED

Metabolic and musculoskeletal

GENETICS

N/A

INCIDENCE/PREVALENCE

- Postparturient paresis occurs commonly in older dairy cows. The condition is uncommon in second-calf cows and rare in first-calf heifers. The effect of age and parity is likely related to capacity for milk yield and mobilization of calcium.
- The incidence of parturient paresis is 3%–8% of cows, but may be as high as 25%–30% in individual herds. Jersey cattle appear to be the most susceptible breed.

Calcium and Phosphorus Homeostasis

- Circulating concentrations of calcium and phosphorus are precisely regulated by parathyroid hormone (PTH) secreted by the parathyroid glands, calcitonin secreted by the C cells of the thyroid gland, and 1, 25-dihydroxycholecalciferol (1,25-[OH]₂D; vitamin D) produced by the kidney. Phosphorus is less strictly controlled than is calcium. Both minerals are absorbed in the small intestine, with phosphorus being absorbed in the proximal small intestine.
- Hypocalcemia stimulates production of PTH, which in turn stimulates synthesis of vitamin D by the kidney. The efficiency of calcium absorption is increased by vitamin D.
- When excess calcium is present, calcitonin inhibits resorption of calcium by the kidney leading to urinary loss.
- Plasma concentrations of calcium and phosphate are maintained during periods of dietary deficiencies. The early lactation period in dairy cattle is characterized by hypocalcemia, which stimulates the synthesis of PTH. The increased concentrations of PTH enhance resorption of calcium from bones and from the renal tubules. Low plasma concentrations of phosphorus trigger production of vitamin D, which in turn increases the uptake of phosphorus.
- With adequate dietary concentrations of phosphorus, active absorption of the mineral becomes saturated, and passive absorption predominates.
- In contrast to most species, ruminants must secrete excess phosphate in the saliva, and to a lesser extent, in the urine. A fraction of phosphate excreted in saliva is resorbed in the small intestine, while the remainder is eliminated from the body in the feces.
- Cows with chronic hypomagnesemia also have profound alterations in calcium homeostasis. Hypomagnesemia prevents production or secretion of both PTH and 1,25-(OH)₂.

GEOGRAPHIC DISTRIBUTION

Worldwide, depending on species and environment

SIGNALMENT

Species

Potentially all ruminant species

Breed Predilections

Jersey cattle appear to be the most susceptible breed.

Mean Age and Range

- Postparturient paresis occurs commonly in older dairy cows. The condition is uncommon in second-calf cows and rare in first-calf heifers.
- The effect of age and parity is likely related to capacity for milk yield and mobilization of calcium.

Predominant Sex

Female

SIGNS

HISTORICAL FINDINGS

- Parturient paresis occurs in cows with the combination of hypophosphatemia (~2.1 mg/dl), hypermagnesemia (2.2–2.7 mg/dl), and hyperglycemia (95–130 mg/dl). In contrast to parturient paresis, nonparturient hypocalcemia is often associated with hypomagnesemia and hyperphosphatemia.
- Common clinical pathologic findings in cows with parturient paresis are neutrophilia, lymphopenia, and eosinopenia, along with moderately increased serum concentrations of creatinine phosphokinase.
- There are three discernible stages of milk fever:
 - Stage I is short in duration and animals exhibit hypersensitivity, excitability, and muscle tremors. Head bobbing, ear twitching, and fine tremors over flank will be seen. Affected animals have a reduced appetite and most resist walking. If affected animals are willing to move, they tend to be ataxic and fall easily. Animals will proceed into stage II, if treatment is not instituted.
 - Stage II milk fever is characterized by sternal recumbency and the inability to rise. Many cows appear drowsy with a characteristic kink (S-curve) in their neck. The muzzle is dry, and ears and other extremities are cold with a body temperature of 97°F to 101°F (36.1°C to 38.3°C). Most affected cows have a faint pulse and the heart rate is increased (80/min). Constipation and rumen stasis are common findings in stage two milk fever.
 - Stage III milk fever is characterized by lateral recumbency and progression to a comatose state. Bloat may result due to an inability to eructate gas. Cardiac output decreases, the heart rate may reach 120 beats/min, and the pulse is nearly undetectable. If treatment is not instituted quickly, affected cows will die from cardiac arrest or respiratory failure within a few hours.

CAUSES AND RISK FACTORS

- The increase in milk yield capacity and ability to mobilize calcium stores are likely the reasons why age and parity are associated with an increased incidence of milk fever in older high-producing cows.
- The most consistent abnormality of milk fever is the acute hypocalcemia in which the plasma calcium concentration decreases from approximately 10 mg/dl to 3–7 mg/dl (see [Table 1](#)).

Table 1 Blood Serum Analysis of Normal Dairy Cows and Dairy Cows with Milk Fever

Condition	Mineral (mg/ml)		
	Calcium	Phosphorus	Magnesium
Normal	9.4	4.6	1.7
Normal at parturition	7.3	3.9	
Milk fever			
Stage I	6.2+/-1.3	2.4+/-1.4	3.2+/-0.7
Stage II	5.5+/-1.3	1.8+/-1.2	3.1+/-0.8
Stage III	4.6+/-1.1	1.6+/-1.0	3.3+/-0.8

Note: Mean+/-standard deviation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Metritis, mastitis, grass tetany, acute indigestion, traumatic gastritis, coxofemoral luxations, obturator paralysis, lymphosarcoma, spinal compression and fracture of the pelvis, aspiration pneumonia, degenerative myopathy

CBC/BIOCHEMISTRY/URINALYSIS

Common clinical pathologic findings in cows with parturient paresis are neutrophilia, lymphopenia, and eosinopenia, along with moderately increased serum concentrations of creatinine phosphokinase.

OTHER LABORATORY TESTS

Parturient paresis occurs in cows with the combination of hypophosphatemia (~2.1 mg/dl), hypermagnesemia (2.2–2.7 mg/dl), and hyperglycemia (95–130 mg/dl). In contrast to parturient paresis, nonparturient hypocalcemia is often associated with hypomagnesemia and hyperphosphatemia.

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

TREATMENT

- Treatment efforts are intended for returning serum calcium to within the normal range. The treatment should be administered as soon as possible to avoid muscular and nerve damage.
- Calcium borogluconate is commonly administered IV but can be administered via subcutaneous and IP routes. Subcutaneous administration allows for slow calcium absorption, which may reduce the risk of cardiac arrest. Animals that relapse or fail to respond should be reexamined and treated in 8 to 12 hr.
- Calcium is directly cardiotoxic; any calcium-containing solution should be administered slowly (over about 10 to 20 min) during cardiac auscultation. Administration of calcium should be discontinued if dysrhythmias develop. To eradicate cardiac dysrhythmias associated with administration of calcium, atropine can be given intravenously. The cardioexcitatory consequences of intravenous calcium can be reduced by rapid administration of $MgSO_4$.
- In the case of mild parturient paresis, oral calcium can be administered. Oral calcium administration will decrease the risk of cardiotoxicity. The best combination of calcium preparation is calcium propionate in a propylene glycol gel. Reaching a 4 g rise of calcium in the blood requires oral administration of about 50 g soluble calcium. Calcium propionate is a better alternative than calcium chloride.
- The administration of calcium chloride has a tendency to cause a slight metabolic acidosis.

Chronic Cases

- For the 15% of parturient paresis cows that do not react to calcium therapy, administer 1 α -hydroxycholecalciferol, 1 α -(OH)₃, a synthetic analog of vitamin D₃. It should be administered at 1 μ g/kg of body weight, half IV and half IM.
- The advantages and disadvantages of vitamin D₃ in treating milk fever have been reported elsewhere.

ACTIVITY

N/A

DIET

- Dietary manipulation of the dry cow ration with the addition of anionic salts has been used routinely to prevent milk fever.
- The acid-base status of a cow dictates the sensitivity of the tissue to PTH stimulation, and metabolic alkalosis is responsible for the blunting of PTH responsiveness.
- Formulation of rations to reduce this metabolic alkalosis and/or induce a compensated metabolic acidosis in prepartum

cows is widely used.

CLIENT EDUCATION

- Reduced feed intake before calving, due to palatability of anionic salts, may reduce caloric intake creating problems other than milk fever, such as displaced abomasums.
- Prophylactic use of calcium and vitamin D preparations demands a lot of labor and is costly. Use of vitamin D metabolites to prevent hypocalcemia, may result in postparturient paresis that is more clinically severe than normal postparturient paresis.

Figure 1 Mean urine pH of Jersey cows fed 2 Eq of anion using hydrochloric acid, ammonium chloride, calcium chloride, calcium sulfate, magnesium sulfate, or elemental sulfur as a source of anions (n = 6). (Adapted from Goff and Horst, 2004).

Control/Prevention

- Dietary manipulation of the dry cow ration with the addition of anionic salts has been used routinely to prevent milk fever. The acid-base status of a cow dictates the sensitivity of the tissue to PTH stimulation, and metabolic alkalosis is responsible for the blunting of PTH responsiveness. Formulation of rations to reduce this metabolic alkalosis and/or induce a compensated metabolic acidosis in the prepartum cows is widely used.
- Feeding of anionic salts in the prepartum dairy ration results in a negative dietary cation-anion difference diet (DCAD), which causes a mild acidosis. This mild acidosis mobilizes calcium and may enhance absorption of Ca from gut.
- Anions are usually added as anionic salts, such as CaCl_2 or MgSO_4 . Urine pH is routinely monitored to assess the degree of metabolic acidification. A urine pH of 8.25 has been proposed as the basis for the screening of milk fever within 48 hr of parturition.
- Prepartum diets supplemented with commercial preparations of HCl mixed into commercial feed appears to lower the urine pH over anionic salts ([Figure 1](#)).

DCAD Guidelines

- Dietary cation-anion differences (DCAD: $\text{mEq}[(\text{Na} + \text{K}) - (\text{Cl} + \text{S})]/100 \text{ g}$).
- Assess the prefresh ration for added cations, such as sodium from sodium bicarbonate.
- Urine pH is a practical indicator of metabolic pH status and reflects the effectiveness of anionic products. Urine pH should be 6.0–6.5 for Holsteins and 5.5–6.0 for Jerseys for optimal effect.
- An incremental introduction of anionic products may reduce palatability problems of supplemental rations.
- Low dietary calcium administration has been considered a method to reduce the incidence of milk fever. The method of low dietary calcium administration, however, has been almost abandoned. It has been difficult to keep calcium administration low with commercially available feeds. The addition of 1 kg/d of zeolite (sodium aluminum zeolite, Dedima 100, Degussa-Huls AG, D-60287, Frankfurt am Main, Germany) to the diet during the last month of pregnancy has been considered as a prevention of postparturient paresis. The zeolite prevented postparturient paresis as well as subclinical hypocalcemia in Jersey cows.

Precautions and Considerations

- The aim of feeding a diet with a DCAD of -10 to -15 mEq/100 g dry matter to dry cows may raise the levels higher than the optimal level required to control or prevent hypocalcemia. This DCAD range may be difficult to achieve when dietary potassium exceeds 1.2% of dietary dry matter.
- Reduced feed intake before calving due to palatability of anionic salts may reduce caloric intake creating problems other

than milk fever, such as displaced abomasums.

- Prophylactic use of calcium and vitamin D preparations demands a lot of labor and is costly. Use of vitamin D metabolites to prevent hypocalcemia may result in postparturient paresis that is more clinically severe than normal postparturient paresis. These preparations are best used only in high-risk cases.

HYPOCALCEMIA: SMALL RUMINANT

BASICS

DEFINITION

- Hypocalcemia in ewes is most common during the last 4 to 6 weeks of gestation. The developing ovine fetus has a relatively high demand for calcium compared to the bovine fetus. However, hypocalcemia may occur during the first 6 weeks of lactation even in the face of relatively low milk yield.
- In dairy goats during lactation, hypocalcemia may occur and can be diagnosed several weeks into lactation.
- Sheep and goats are affected less frequently by hypocalcemia than are dairy cows.
- Plasma calcium tends to be higher during pregnancy and peaks at 5 to 7 weeks prepartum in cervidae. Hypocalcemia can be observed 1–2 weeks postpartum.
- Nonparturient hypocalcemia makes up a higher proportion of cases in small ruminants.
- Clinical signs of hypocalcemia in sheep and goats include hyperesthesia and tetany rather than flaccid paralysis that occurs in dairy cattle.
- Prompt hypocalcemia therapy reduces the incidence of secondary complications (e.g., muscle damage and mastitis).

PATHOPHYSIOLOGY

- Muscular contraction is impaired several ways by hypocalcemia: (1) loss of the membrane-stabilizing effect of calcium on peripheral nerves resulting in hyperesthesia and mild tetany, and (2) impaired role of calcium in the release of acetylcholine at the neuromuscular junction resulting in paralysis due to blockade of the transmission of nerve impulses to the muscle fibers.
- Increased disease susceptibility has been observed around the time of parturition. Low extracellular calcium in vitro decreases phagocytosis and intracellular killing in polymorphonuclear neutrophils.
- In contrast to most species, ruminants must secrete excess phosphate in the saliva and, to a lesser extent, in the urine. A fraction of phosphate excreted in saliva is resorbed in the small intestine while the remainder is eliminated from the body in the feces.
- Sheep with chronic hypomagnesemia also have profound alterations in calcium homeostasis. Hypomagnesemia prevents production or secretion of both PTH and 1,25-(OH)₂.
- Physiological hyperparathyroidism in pregnant deer has been observed during the last trimester of pregnancy.
- The hyperparathyroidism of pregnant deer is manifested by increased concentration of alkaline phosphatase (AP), parathyroid hormone (PTH), and estradiol-beta (E2).

SYSTEMS AFFECTED

Production management, metabolic, nutritional, and musculoskeletal

GENETICS

N/A

INCIDENCE/PREVALENCE

- During late gestation, 25% of the sheep flock may have hypocalcemia.
- The incidence of hypocalcemia is increased in does carrying multiple fetuses during late lactation.
- In one study of the hypocalcemic cases that recovered, approximately 25% required more than one treatment. Ewes that developed hypocalcemia before lambing and that recovered, lost 22% of their lambs, the main reason probably being premature birth.

GEOGRAPHIC DISTRIBUTION

Worldwide depending on species and environment

SIGNALMENT

Species

Small ruminant species

Breed Predilections

Mean Age and Range

- The effect of age and parity is likely related to capacity for milk yield and mobilization of calcium.
- In sheep, the tendency to develop hypocalcemia increases with increasing age.

Predominant Sex

Female

SIGNS

Ovine Hypocalcemia

Incidence/Prevalence

During late gestation, 25% of the flock may have hypocalcemia.

Clinical Signs

- Tetany is detected in sheep and goats more often than in cattle where flaccid paralysis is the primary sign of hypocalcemia.
- Hypocalcemia may be difficult to differentiate from pregnancy toxemia, so assessment of urine for ketones may be helpful.
- Transit tetany may occur in pregnant ewes and lambs following the stress of transportation. Lambs will present with muscle tremors and tetany rather than flaccid paralysis.

Treatment

The administration of intravenous calcium solutions (1 g Ca/45 kg of BW) will usually resolve hypocalcemia. However, ewes are more likely to relapse than cows after calcium treatment.

Dietary Prevention

A continuously increasing plane of nutrition during the last 6 weeks of gestation will increase calcium intake and prevent hypocalcemia and pregnancy toxemia in most cases.

Caprine Hypocalcemia

In dairy goats during lactation, hypocalcemia may occur and can be diagnosed several weeks into lactation.

Incidence

The incidence of hypocalcemia is increased in does carrying multiple fetuses during late lactation.

Clinical Signs

Hyperexcitability or mild depression and ataxia are the most common signs of hypocalcemia. Goats do not often exhibit signs of recumbency or coma.

Treatment

The administration of intravenous calcium solutions (1 g Ca/45 kg of BW) will usually resolve hypocalcemia.

Prevention

Limiting calcium intake for 30 days before parturition is helpful in prevention programs. The removal of alfalfa hay from the diet will lower the concentration of calcium in the diet, which may reduce hypocalcemia.

Cervidae Hypocalcemia

- Plasma calcium tends to be higher during pregnancy and peaks at 5 to 7 weeks prepartum in cervidae. Hypocalcemia can be observed 1–2 weeks postpartum.
- Elevated concentrations of plasma calcium and phosphorus are observed during lactation.
- Physiological hyperparathyroidism in pregnant deer has been observed during the last trimester of pregnancy.
- The hyperparathyroidism of pregnant deer is manifested by increased concentration of alkaline phosphatase (AP), parathyroid hormone (PTH), and estradiol-beta (E2).
- An increase in calcium absorption and mobilization during pregnancy may be facilitated by increased AP and PTH.
- Elevated plasma E2 may function to block excessive bone resorption. After parturition, lowered E2 and elevated calcitonin may protect the skeleton against excessive bone resorption.

MEDICATIONS

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Subclinical hypocalcemia in ewes is probably a consequence of vaginal prolapse rather than a cause.
- Sheep with chronic hypomagnesemia also have profound alterations in calcium homeostasis. Hypomagnesemia prevents production or secretion of both PTH and 1,25-(OH)₂.
- Physiological hyperparathyroidism in pregnant deer has been observed during the last trimester of pregnancy.
- The hyperparathyroidism of pregnant deer is manifested by increased concentration of alkaline phosphatase (AP), parathyroid hormone (PTH), and estradiol-beta (E2).

AGE-RELATED FACTORS

- The effect of age and parity is likely related to capacity for milk yield and mobilization of calcium in heavily lactating dairy goats.
- In sheep, the tendency to develop hypocalcemia increases with increasing age.

HYPODERMATOSIS

BASICS

DEFINITION

Infestation with and lesions caused by the larvae of two *Hypoderma* species

OVERVIEW

Hypodermatosis in Cattle

- Common parasitic disease of economic importance in cattle; also reported in goats, sheep, horses, and humans
- *Hypoderma* spp. widely distributed in Northern Hemisphere (North America, Europe, Africa, and Asia). Southern limit is reached in Punjab India, Libya, northern Mexico, and Hawaii
- Not reported south of the equator
- *Hypoderma bovis* (northern cattle grub, bomb fly) and *Hypoderma lineatum* (common cattle grub, heel fly) parasitize cattle.
- *H. bovis* occurs in northern United States and Canada. *H. lineatum* occurs in southern, warmer areas of United States.
- Adult are hairy, beelike flies without functional mouth parts so they do not sting or bite host.
- Complete life cycle is about 1 year, but adult flies are short-lived (7–8 days), being active in spring to early summer.
- Female fly can lay as many as 100 eggs on a single host; total egg production is 500 to 800 eggs per female.
- First-stage larval migration through connective tissue initially leads to inflammation and edema; final migration to dorsum of animals results in formation of warbles (nodules with breathing pores containing larvae).
- Cattle may be infected with 1 to 300 warbles.
- Infections are most severe in younger animals.
- Larvae are most pathogenic during two phases of their development: (1) Late autumn and winter when larvae in epidural fat and esophagus: if large numbers present or if animal treated and larva killed in situ, the anaphylactic reaction may cause damage to spinal tissue or difficulty swallowing or eructating. (2) Preemergence phase when damage occurs in subdermal tissue, skin of back, and subsequently hide and carcass
- In species other than cattle, the life cycle of *Hypoderma* spp. is rarely completed; aberrant migration may result in neurologic disorders.

Hypoderma in Goats

Przhevalskiana silenus

- Synonyms: *Hypoderma silenus*, *H. crossi*, *P. crossi*, *P. aegagi*
- Parasitizes goats, sheep, and occasionally horses in Europe, Mediterranean countries, and Asia
- Goats frequently have numerous lesions, sheep often only minor infestation.
- *Przhevalskiana silenus* flies lay eggs on hairs of leg and chest in spring. Larvae migrate directly to dorsum of animal.
 - First-stage larvae reside under cutaneous trunci muscle causing muscle necrosis and neutrophilic infiltration.
 - Larvae migrate through overlying muscle, penetrate skin, and molt to second stage.
 - Wall of granulation tissue forms around larvae and creates nodule.
 - Third-stage larvae drop to ground and pupate.
 - Damages leg and back muscles and hides
- *Hypoderma aeratum* parasitize goats in Cyprus, Crete, and Turkey.
- *H. crossi* infest goats in India.
- *H. lineatum* is not documented to infest goats.
- Sheep also parasitized by *H. aeratum*,

H. crossi, and occasionally *H. diana*.

- *H. diana* parasitizes deer.

PATHOPHYSIOLOGY

Life cycles of cattle *Hypoderma* are similar except stages of *H. lineatum* occur 3 to 8 weeks earlier than *H. bovis*.

- Geographic and climatic conditions cause the life cycle of these parasites to vary as to specific time of year for the appearance of various stages.
- In the United States in spring or early summer, adult *H. lineatum* appear 3–4 weeks before *H. bovis*.
- Female *H. lineatum* deposit eggs in linear rows on hairs associated with the heels of forelegs, dewlap, or lower body of cattle.
- Female *H. bovis* deposit eggs singly on hairs of the rump or upper parts of the hind limbs of cattle.
- Tiny first-stage larvae hatch from eggs within 3–7 days, crawl down the hair, penetrate the skin, and migrate through the connective tissue.
- Larvae release enzymes to break down tissue and facilitate movement as they migrate to the host's back. Tissue through which larvae travel becomes greenish-yellow.
- *H. bovis* larvae migrate directly toward the spinal canal.
- *H. lineatum* larvae migrate to the subcutaneous connective tissues along the esophageal wall.
- Larvae remain at these sites for the winter and molt to second stage of development.
- During later winter months (January and February), both species resume migration through the connective tissues to the subdermal tissue of the host's dorsum and cut a breathing hole through the hide.
- Larvae form warbles (swellings) between the layers of the hide and undergo two molts within a cystlike structure in nodules during a 4–6-week period.
- Third-stage larvae (grub) emerge from the breathing pore in the skin, causing a disease called cutaneous myiasis.
- Larvae fall to the ground and burrow into the soil to pupate; metamorphosis from grub to adult fly takes 2 to 8 weeks.
- Adult flies emerge from the pupae and mate soon after. Adults active from late May through August with peak activity during June and July.
- Life cycle takes about a year, 8 to 11 months of which are spent as grubs in the bodies of cattle.
- Healing occurs after emergence of grub but carcass and hide remain damaged.
- Allergic reactions may occur if larvae die naturally or are damaged during attempts to remove them manually.

SIGNALMENT

- Younger animals are most severely affected.
- Older animals develop a degree of immunity to the grub larvae.
- Infections become lighter with age.
- No sex or breed predilection

SIGNS

- Cattle bothered by adult flies during spring and summer demonstrate a behavior called “fly worry” or “gadding.”
 - Stampeding behavior
 - Running back and forth with tails in air
 - Stamping feet
 - Decreased feeding and production
 - May inflict self-injury
- Larvae cause irritation, rashes, sores as they penetrate skin.
- Heavy infestations result in poor growth, condition, and production.
- Signs and lesions due to first-stage larvae migration
 - *H. bovis*: fat necrosis, inflammation, and edema of connective tissue around spinal canal, posterior paresis, and/or paralysis, secondary periostitis, osteomyelitis
 - *H. lineatum*: inflammation and edema around esophagus may interfere with swallowing and eructation, weight loss, bloat, and respiratory compromise.
- Signs and lesions due to third-stage larvae
 - Firm to fluctuant, ~ 3 cm, raised nodules (warbles) with breathing pore along dorsum of animal
 - Lesions are painful to touch.

- Yellowish fluid may exude from breathing pore.
- Surrounding tissue is necrotic.
- Secondary infection of cysts and abscess formation
- *Przhevalskiana silenus* flies lay eggs on hairs of leg and chest in spring. Larvae migrate directly to dorsum of animal.
 - First-stage larvae reside under cutaneous trunci muscle causing muscle necrosis and neutrophilic infiltration.
 - Larvae migrate through overlying muscle, penetrate skin, and molt to second stage.
 - Wall of granulation tissue forms around larvae and creates nodule.
 - Third-stage larvae drop to ground and pupate.
 - Cause muscle and hide damage
- Anaphylactic reaction
 - Response to larvae killed in situ in treated animals or crushed during removal from cyst on back
 - Depression, salivation, lacrimation, defecation, edema of head and anus, dyspnea and death

CAUSES AND RISK FACTORS

- Warble flies present in Northern Hemisphere between 25 and 60 degrees latitude in North America, Europe, Africa, and Asia.
- Local climate and geographic factors affect life cycle of *Hypoderma*

DIAGNOSIS

- Season, location, and presence of characteristic lesion
- Cystlike bumps on cattle's backline with visible breathing hole
- Extraction of larvae after enlarging breathing hole
- ELISA test to detect antibody to migrating larvae

DIFFERENTIAL DIAGNOSIS

- Trauma
- Infectious granulomas
- Parafilaria in cattle
- Epidermoid or dermoid cysts
- Neoplasia
- Other causes of spinal cord disease
- Other causes of esophageal dysfunction and bloat

CBC/BIOCHEMICAL/URINALYSIS

N/A

OTHER LABORATORY TESTING

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

Skin biopsy

- Larvae in a subcutaneous and dermal cyst
- Cyst walls contain dense connective tissue with neutrophilic and eosinophilic infiltrate.
- ± suppurative pyogranulomatous or granulomatous reactions containing eosinophils and larval segments

TREATMENT

- If small number of lesions are present, carefully remove entire grub and cyst manually by aseptically enlarging breathing

hole.

- Breaking of cyst or larvae by trauma, squeezing nodule, or manual removal may result in severe systemic reaction.
- Protect ruptured nodular lesions from fly strike and secondary bacterial infections with topical ointments.
- Fly control measures to minimize environmental factors that favor propagation of fly numbers include fly repellents or tags and dust bags
- Systemic insecticides (pour-ons, spot-ons, injectable, drench, boluses, dipping vat, pressure spray, feed additives) for nonlactating cattle; proper timing is essential for safe, effective treatment and control.
 - Ideal time for treatment varies with geographical area, temperatures, and species of *Hypoderma* involved.
 - Treat after adult heel fly activity ceases but before migrating larvae reach the esophagus or spinal cord.
 - In the United States, administer drugs in early autumn (after eggs hatch) to eliminate first-stage larvae during early phase of migration.
 - In the northern United States and Canada, do not treat between November 1 and March 1.
 - Treatment after November 1 may cause severe allergic reactions in animals, resulting in bloat, paralysis, and death.
 - Third-stage larvae are less susceptible to treatment.
 - Further treatment in spring (after March 1)
- Organophosphates
 - Not approved for use in lactating cattle
 - Trichlorphon, crufomate, fenthion, phosmet, bromphos, coumaphos, fenclorphos
 - Observe dosage recommendations and precautions.
 - Observe withdrawal periods for meat and milk.
- Ivermectin, moxidectin, doramectin (pour-ons, injectables, sustained release bolus); not approved for lactating cattle
- Treatment in goats
 - Ideal treatment time varies with geographical locations.
 - 2% trichlorfon backwash
 - Ivermectin
- Topical application of rotenone directly on grub; repeat every 4 weeks as needed—will kill grub but not protect hide from damage
- Ear tags impregnated with organophosphorous compound or synthetic pyrethroid may help reduce egg disposition by adults.
- No approved cattle grub treatment for lactating animals
- Heifers and dry cows may be treated only if the days to freshening exceed that period listed on product label.
- Apply treatments only as recommended for given geographical area and latitude.

MEDICATIONS

N/A

DRUGS OF CHOICE

Ivermectin: cattle

- 200 ug/kg SQ
- Topical 5% solution poured along back at dosage of 500 ug/kg

CONTRAINDICATIONS

- Organophosphate toxicosis
 - Signs: lacrimation, pollakiuria, diarrhea, muscle fasciculations, ptialism, bloat
 - Antidotal therapy: atropine if needed; caution—may exacerbate bloat
- Anaphylactic reaction if animals treated when grub are in situ or during removal from cyst
 - Anti-inflammatory drugs
 - Antimicrobials

- Death of *H. lineatum* in wall of esophagus or of *H. bovis* in spinal canal
 - Esophagitis, bloat
 - Meningitis, periostitis, osteomyelitis, posterior paresis or paralysis
- Do not treat cattle with systemic insecticides when larvae are in their overwintering sites as death in situ and subsequent lysis may result in anaphylaxis.

PRECAUTIONS

- Do not treat cattle after November 1.
- Before using any pesticide, read label and follow all precautions.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

- Lesions can persist for up to 12 weeks.
- Recovered cattle have immunity for months.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Secondary bacterial infections or abscess formation
- Spinal cord inflammation and neurologic signs
- Esophageal dysfunction

ZOONOTIC POTENTIAL

N/A

RUMINANT SPECIES AFFECTED

Cattle, goats, sheep, deer

BIOSECURITY

N/A

PRODUCTION MANAGEMENT

- Confine cattle to barns from May to August; heel flies are unlikely to enter barn to lay their eggs.
- Develop regional, community-based fly control program through treating all nonlactating cattle with systemically active insecticide
- Monitor for grub infection
 - Inspect backs of cattle in March and April for presence of warbles.
 - Most important to examine animals under 5 years of age
 - Calves born after fly season and those kept indoors during summer are unlikely to have cattle grubs.
 - Observe for gadding behavior in cattle during late spring and summer.
- Examine pastured animals for eggs on hairs of animal's legs, udder, escutcheon, and rump.
- Economic losses due to decreased milk production, loss of body condition, and injury during "gadding" behavior
- Beef cattle infected with grubs do not finish well and sell at lower prices than grub-free cattle.
- Devaluation loss: devalued carcass due to damage to tissue from tunneling of grub larvae
- Trim loss: meat around warbles is discolored and must be discarded • Hide loss: breathing holes damage valuable portion of hide
- Heavy infestation in replacement cattle can result in poor weight gain, delayed time to first lactation, and long-term production losses.

HYPOTHYROIDISM AND IODINE DEFICIENCY- INDUCED HYPOTHYROIDISM

BASICS

OVERVIEW

- Naturally occurring hypothyroidism is rare in large animals.
- Etiologies in large animals include iodine deficiency and inherited abnormalities.
- Characterized by an array of clinical signs associated with a decrease in thyroid hormone activity
- Goiter is a subacute or chronic disease characterized by thyroid gland enlargement resulting from a deficiency of biologically active iodine
 - Inadequate iodine intake in feedstuffs or water
 - Excessive intake of goitrogenic plants interfering with iodine metabolism
- Deficiency may be an absolute iodine dietary deficiency or from a decrease in iodine absorption from the intestine due to high nitrates or other minerals in diet or water.
- Dietary deficiency results in low plasma iodine concentrates with a subsequent decrease in the normal accumulation and trapping of iodides in the thyroid gland causing suppression of thyroid hormone synthesis (induced-hypothyroidism).
- Low plasma thyroid hormone levels triggers the anterior pituitary to release thyroid-stimulating hormone (TSH), which stimulates thyroid gland activity resulting in follicular hyperplasia and glandular enlargement.
- Geographically, goiter occurs commonly in areas with iodine-deficient soil
 - Western Canada
 - Northeast or northwest (Pacific coast) United States
 - Great Lakes, Great Plains, Rocky Mountains
 - Western states of Latin America, Venezuela, Colombia
 - Himalayas
 - Highland regions of the continents

Hereditary Congenital Goiter

- Inherited congenital goiter with hypothyroidism reported in Merino and Polled Dorset sheep and in Dutch (mixed seaman and dwarf goats), pygmy, Boer, and Nubian goats, and Afrikaner cattle
- Afrikaner cattle
 - Abnormality of the basic RNA
 - May have concurrent inherited grey coat color
- Dutch goats and Merino sheep due to defect in thyroglobulin synthesis
 - Affected Merinos sheep may develop a lustrous, fine, straight, (silky) wool.
 - Lambs have impaired development of wool-producing follicles, thick, scaly skin, sparse wool, goiter, ± respiratory difficulty.
- Autosomal recessive trait in Dutch goats
 - Thyroid weights: affected 15–300 g, unaffected 1–4 g
 - Decreased plasma T₃ and T₄
 - On necropsy, thyroid was hypertrophic and hyperplastic, colloid was almost absent.
 - Signs in kids included sluggishness, poor growth, recurrent bloat, thick and scaly skin, sparse, rough haircoat. If not supplemented with iodine, haircoat disappeared and skin thickened and became scaly
 - Responded to iodide (1 mg per day orally)

Iodine Deficiency (Induced Hypothyroidism)

- Iodine deficiency results in hypothyroidism and goiter.
- Sheep are more susceptible to iodine deficiency than cattle.
- Referred to as “endemic goiter” in goats
- Primary iodine deficiency or goiter is caused by an inadequate dietary intake of iodine, which often reflects low iodine content in soil.
 - Especially affects unborn fetus and neonates
 - Associated with increased calf mortality rates
 - Clinical signs range from dry skin and sparse hair coat in mild cases to diffuse alopecia, myxedema, ± goiter in more severely affected animals.
- Secondary goiter due to decreased uptake of dietary iodine may be due to interference by high calcium, nitrates, goitrogens, or goitrogenic plants in the diet.
- Goitrogens are compounds that interfere with the intestinal uptake of dietary iodine or with its metabolism during thyroxine formation.
- Overall, goitrogens increase the iodine requirement.
- Iodine deficiency is most commonly seen in neonates of dams that consumed goitrogenic plants during gestation.
- Goitrogenic plants disrupt iodine metabolism.
 - Impaired uptake of iodine by thyroid gland by thiocyanates, nitrate type in *Brassicas* or legume crops
 - Impaired iodination of tyrosine residues within the gland by thiouracil in brassica seeds
- Iodine supplementation may overcome deficiency signs from thiocyanate-type goitrogens but can only partially suppress those caused by thiouracil-type goitrogens.

Neonatal Hypothyroidism (Cretinism, Iodine Deficiency)

- Hyperplastic goiter in neonates is the most common thyroid disorder in small ruminants and horses.
- Due to excess consumption of iodine (e.g., kelp-feed supplements) or goitrogenic plants by dam during gestation
- Few “idiopathic” cases reported in western Canada.
- Neonatal hypothyroidism in Angora goats
 - Signs included retarded growth, shortened heads, droopy eyelids, dullness, weight gain, prognathism, bilateral goiter.
 - Probable cause was ingestion of a thiocyanate goitrogen by dams during gestation.
 - Iodine responsive
- In neonatal hypothyroidism, the thyroid glands are abnormal and pituitary gland is normal.
- Inadequate circulating thyroid hormone concentrations result in release of thyroid stimulating hormone (TSH) from the pituitary gland and subsequent thyroid enlargement.
- Goiter is the most consistent, but not always present, clinical sign.
- In sheep, plasma thyroxine of < 20 nmol/l and pasture content of iodine of < 0.09 mg/kg are associated with high incidence of congenital goiter.
- High incidence of neonatal hypothyroid cases reported in western Canada.
- In affected herds or flocks, neonatal mortality rate is greatly increased.
- Animal surviving initial period after birth may recover except for partial persistence of the goiter.

SIGNALMENT

- May occur in all ages, sexes, and breeds
- Most commonly see hypothyroid signs in
 - Fetuses and neonates more than yearlings
 - Young and growing lambs and kids
 - Geriatric animals
 - Heavily producing goats and ewes
- Adult ewes affected more frequently than rams
- Polled Dorset, Dorset horn, and Merino sheep and Boer and Angora goats appear more susceptible to iodine deficiency (induced hypothyroidism).

SIGNS

Signs of Inherited Goiter

- Sheep: high mortality rate, goiter, “silky” appearance to wool, edema, floppiness of ears, enlarged and inwardly bowed carpi, dorsoventral flattening of the nose, dyspnea
- Goats: goiter, growth retardation, sluggishness, rough sparse hair coat that worsens with age, thick scaly skin, respiratory distress
- Afrikaner cattle: high incidence of stillbirths and neonatal deaths, tracheal compression from enlarged gland, ± coat color defect

Neonatal Hypothyroidism

- Thyroid enlargement or goiter
- Late abortion, stillborn, or weakness in newborns
- Dry skin
- Poor quality and sparse wool and hair
- In one outbreak, affected Angora kids showed no hair or skin abnormalities.
- Tendon laxity or failure to form normal bone insertions
- Retarded central nervous system development (hypomyelination)
- Behavioral abnormalities
- Incoordination
- Poor suckling and right reflexes
- Hypothermia
- Tendon contraction
- Skeletal defects
- Lambs have impaired development of wool-producing follicles, thick, scaly skin, sparse wool, goiter, ± respiratory difficulty.
- Death due to weakness, hypothermia, hypoglycemia

Signs of Iodine Deficiency

- Goiter
- Affected adult goats generally show no skin changes ± dry skin
- Poor wool growth
- Poor quality wool
- Rough and matted fleece
- Weight loss or obesity
- Subcutaneous edema
- Routine activities reduced
- Hypolactia
- Decreased weight gain
- Infertility in both sexes
- Poor libido in male
- Low semen quality
- Irregular estrus
- Abnormal conception rates
- Resorption of embryos; abortion; fetal hydrops
- Prolonged gestation

Goiter May Be Associated With

- Respiratory distress
- “Thyroid thrill” due to increased arterial supply to thyroid gland and heard or felt over jugular furrow
- Pulsation of gland concurrent with arterial pulse
- Edema of the neck

CAUSES AND RISK FACTORS

- Goitrogenic plants: Cruciferae family
 - *Brassica* spp. contain glucosinolates that are hydrolyzed to thiocyanates and include rape, kale, turnips, Chinese cabbage, cauliflower, broccoli, cole, rutabaga, swede
 - Legume family including white clover (cyanogenic glycosides), subterranean clover, soybeans, and peanuts (thiocyanates)
 - Plant goitrin (in kale), thiourea, and thiouracil interfere with iodination of tyrosine.
- Other goitrogenic plants
 - Prune family (cherries, apricots)
 - Some grains (sorghum, flaxseed, linseed meal, rapeseed meal)
 - Mimosine in *Leucaena leucocephala* is metabolically broken down into a goitrogen in ruminants.
 - Stargrass (*Cynodon nlemfuensis*) contains cyanides, act through effects of thiocyanate,
 - Turnip weed, radish
 - Rapeseed oil cake
- High dietary calcium or nitrates
- Selenium deficiency
 - Associated with susceptibility to goiter
 - Essential for deiodinase activity during thyroxine metabolism
- Cereal grains and hay are low in iodine.
- Winter or heavy rainfall
- Heavily fertilized pastures
- Bacterial pollution of water or feedstuffs
- Feeding sewage sludge
- Interrelationships that affect iodine metabolism include high arsenic, fluorine, or calcium; deficient or high cobalt, and low manganese concentrations in diet.

DIAGNOSIS

- Diagnosis of iodine deficiency may be difficult.
- History of intake of excess iodine (e.g., kelp, seaweed supplement), low dietary iodine, or goitrogenic plants by dam during gestation
- Clinical signs of hypothyroidism/iodine deficiency
- Aborted fetus, stillborn or dead neonate with appropriate clinical signs/lesions
- Decreased plasma-bound iodine (PBI) concentrations in blood (normal 2.4–14 μ g of PBI/dl of plasma)
- Decreased iodine concentration in blood, serum, plasma, milk, urine, and forage content
 - Blood iodine concentrations normally between 5 and 10 μ g/dl
 - Serum iodine concentrations normally between 2.1 and 9.3 μ g/dl
 - Decreased plasma and serum thyroxine concentrations
 - Normal serum thyroxine: Ewes: > 60 nmol/l, Lambs: > 90 nmol/l
 - Normal serum thyroxine concentrations for goats: 5.0–7.0 μ g/dl; 6.1–8.3 μ g/dl
 - Normal serum thyroxine concentrations for 2-week to 6-year-old goats: mean 6.53 μ g/dl, range 2.0–17.0 μ g/dl 5.0–7.0 μ g/dl; 6.1–8.3 μ g/dl
 - Normal T₃ levels in goats 124–151 ng/dl
- Iodine levels in blood and milk are reliable indicators of thyroxine status of the animal
- In ewe, milk iodine concentration below 8 μ g/L is indicative of dietary iodine deficiency.
- Blood thyroxine concentrations affected by level and stage of production. Level may drop as much as 30% in the first week after parturition.
- In ewes, premating and during pregnancy, thyroid hormone concentrations were not reliable indicators of iodine

deficiency.

- Urinary iodine concentration is good marker of iodine intake.
- Pasture iodine content is not helpful if problem is due to intake of goitrogenic plants.
- Heterozygous Afrikaner cattle can be identified by blot hybridization analysis.
- Skin biopsy reveals orthokeratotic, hyperkeratosis, follicular keratosis and atrophy, telogenization of hair follicles, sebaceous gland atrophy, and diffuse dermal mucinous degeneration (myxedema)
- Necropsy lesions

Necropsy Lesions

- Gross lesions
 - Adult sheep: Bilateral enlargement of thyroid gland (most cases) with edema in and around thyroid gland
 - Lambs: Enlarged thyroid (up to 10 times or more of normal size) and edema
 - Transudates in body cavities
- Histologic lesions
 - Epidermal atrophy, sebaceous gland hypoplasia, diffuse mucinous degeneration (myxedema)
 - Scarce hair follicles that are hypoplastic,
 - Absence of colloid in follicles
 - Hyperplasia of follicular lining cells, which invaginate into lumen
- Sheep: Thyroid gland-to-body weight ratio of more than 0.46:1 or greater than 0.9 g/kg fresh weight indicates goiter (0.4–0.9 g/kg indicates marginal iodine deprivation)
- Total thyroid gland weight of > 2.8 g for congenital goiter in lambs
- Characteristic histologic lesions in thyroid gland of normal or increased weight

DIFFERENTIAL DIAGNOSIS

- Thymic gland enlargement in newborn
- Abscesses
- Wattles cyst
- Cobalt and vitamin B₁₂ deficiency
- Causes of infectious abortion
- Hypovitaminosis A

CBC/BIOCHEMISTRY/URINALYSIS

- ± increased plasma protein, serum triglyceride, cholesterol, phospholipid
 - CBC and serum chemistry panels are nondiagnostic.

OTHER LABORATORY TESTS

- TSH or TRH response test
- ± increased plasma protein, serum triglyceride, cholesterol, phospholipid
- CBC and serum chemistry panels are nondiagnostic.
- Basal serum levels of T₃ and T₄ are unreliable for diagnosing hypothyroidism.

DIAGNOSTIC PROCEDURES

Skin biopsy

TREATMENT

- Developmental lesions cannot be reversed because thyroid hormone therapy is effective only during period of low plasma concentrations of thyroid hormone.
- Treatment of clinically affected neonates is seldom undertaken due to high case fatality rate.
- Clinical and subclinical effects of simple iodine deficiency may respond to iodine supplementation during pregnancy.
- Iodine supplements are effective against thiocyanate- and nitrate-type goitrogens but not effective against thiouracil-type goitrogens.

- Iodine supplementation
 - Iodized poppyseed oil IM (1 ml per ewe) 7–9 weeks before lambing; may provide iodine for up to 2 years
 - Mineral blocks or loose mineral with iodine
 - Iodized salt containing 0.007% to 0.01% iodine in iodate form (as only salt source)
 - Supplement with organoiodine or periodates
 - Drench in potassium iodine (200–300 mg orally) once in late gestation
 - Lugol's in the drinking water (one drop of Lugol's in 1 gallon of water)
 - 7% iodine applied sparingly one time along the topline (7% iodine may be irritating, avoid sunlight after application)
 - Weekly application of tincture of iodine (1 ml) along back of goats during gestation
 - Weekly application of tincture of iodine (4 ml for cattle, 1–2 ml for sheep) to inside of flank during gestation
 - Monitor for signs of iodine toxicity
- Iodine supplementation for beef cattle
 - Recommended level of supplementation of iodine is 0.5 ppm.
 - ppm iodine supplement is required for diets containing 25% goitrogenic feeds.
 - Sources of supplemental iodine that are highly available to the ruminant but are unstable because of oxidation include calcium iodide, sodium iodide, and potassium iodide.
 - More stable forms of iodine supplement include potassium iodate or pentacalcium orthoperiodate.
 - Organic iodide, ethylenediamine dihydroiodine (EDDI) used as feed supplement.
 - Current Food and Drug Administration (FDA) regulations set the maximum limit of iodine supplementation at 10 mg/head/day.
- Treatment for affected neonates or young stock
 - Lugol's iodine (3–5 drops) in milk
 - Potassium iodine (20 mg) orally

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

- Potassium iodide is potentially toxic and abortogenic.
- Oversupplementation with iodine may induce iodism.
- Signs of iodism include coughing, seromucoid nasal discharge, excessive lacrimation, and generalized scaling of the skin, partial alopecia, variable appetite, and joint pain.
- Iodine is rapidly metabolized and excreted by the body so removal of supplement generally results in rapid recovery from iodism.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- May be relationship between inherited dwarfism and hypothyroidism
- May be relationship between stillbirth/perinatal weak calf syndrome and hypothyroidism

RUMINANT SPECIES AFFECTED

- Sheep
- Goats
- Cattle

PRODUCTION MANAGEMENT

- Economic losses due to

- Abortion
- Increased perinatal mortality
- Infertility problems
- Poor growth
- Poor wool quality
- Maintain adequate amounts of iodine in the diet
 - Lactating cow and dry cow need 0.6 to 0.8–1.0 mg/kg dry weight feed.
 - Nonpregnant cows and calves require 0.1 to 0.3 mg/kg dry weight feed.
 - Sheep need from 0.1 to 0.4 mg iodine/kg dry matter.
 - Lactating does require 0.8 mg/kg dry matter.
 - Nonlactating goats require 0.2 mg/kg dry matter.
 - Cruciferous plants increase ration iodine requirement up ~2 mg/kg.
- Amount of iodine required in diet is effected by many factors
 - Geographic region
 - Weather, rainfall
 - Season
 - Access to goitrogenic plants
 - Degree of pasture fertilization

INDIGESTION

BASICS

DEFINITION

- Simple indigestion is a form of gastrointestinal upset causing transient anorexia and minimal symptoms of systemic illness.
- Defined as being a less-severe illness than other forms of rumen indigestion
- Results from an abrupt change in feed

PATHOPHYSIOLOGY

- Animals are exposed to feedstuffs to which they are previously unaccustomed in either type or amount.
- This results in a change in the rumen environment by the presence of unusual substrates.
- The rumen microflora change in population as a result of change in feed substrate.
- Microflora then produce fermentation products that have deleterious effects on rumen motility, digestion, and nutrient absorption.

SYSTEMS AFFECTED

Gastrointestinal

GENETICS

There is not generally thought to be a genetic predilection for simple indigestion.

INCIDENCE/PREVALENCE

Simple indigestion is a common disease of nongrazing animals and is the most common sequela of an abrupt change in ration.

GEOGRAPHIC DISTRIBUTION

Distributed in areas in which conditions or production systems limit grazing

SIGNALMENT

Species

Any ruminant species is susceptible.

Breed Predilections

No breed predilection exists.

Mean Age and Range

- Any age animal is susceptible.
- Primary animals affected are young animals being intensively fed for growth and adult dairy cattle being fed for production.

Predominant Sex

No sex predilection exists

SIGNS

GENERAL COMMENTS

- Signs are generally less severe and more transient than other rumen indigestion disorders.
- May present as an individual animal or herd problem
- Due to adaptability of rumen flora, different animals may respond variably to management changes.

HISTORICAL FINDINGS

- Acute onset
- Anorexia of 1–2 days duration
- Decrease in milk production

- Malodorous diarrhea 12–24 hours after onset

PHYSICAL EXAMINATION FINDINGS

- General lack of evidence of significant systemic illness
- Rumen motility reduced, but often present
- Rumen fill is nearly normal, but contents are fluid.
- Bloat is mild, if present.
- Malodorous diarrhea may be noted.

CAUSES

- Abrupt change in feed type or amount
 - Rumen microflora are exposed to substrates to which they are not accustomed or in greater quantities than that to which they are acclimated.
 - Production of inhibitory substances directly from feed presence or as a result of fermentation and its products
- Implicated feeds
 - Moldy, overheated feed
 - Frosted forages
 - Incompletely fermented, spoiled, sour silage
 - High-quality feeds fed at a suddenly high rate or a change in one or more components

RISK FACTORS

- Lack or complete absence of grazing time
- Provision of large amounts or accidental exposure to novel feeds

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Traumatic reticuloperitonitis
- Left displaced abomasum
- Ketosis
- Lactic acidosis
- Rumen alkalosis
- Rumen putrefaction
- Vagal indigestion
- Peritonitis
- Any systemic illness early in development causing anorexia

CBC/BIOCHEMISTRY/URINALYSIS

May indicate mild dehydration: Elevations in total serum protein, hematocrit, BUN, and creatinine

OTHER LABORATORY TESTS

Rumen fluid analysis

- Microflora inactive under light microscopy
- Rumen fluid pH may be slightly acid or alkaline, depending on nature of offending feedstuff

IMAGING

Not required to diagnose simple indigestion, but survey radiography may be useful in diagnosing traumatic reticuloperitonitis

DIAGNOSTIC PROCEDURES

Diagnosis generally based on physical examination excluding more-severe sources of indigestion

GROSS FINDINGS

Uncomplicated cases of simple indigestion are transient and rarely result in death.

HISTOPATHOLOGICAL FINDINGS

N/A

TREATMENT

APPROPRIATE HEALTH CARE

- Patients with simple indigestion may be treated as outpatients.
- Valuable animals may warrant hospitalization for monitoring of their condition for timely improvement and intervention should their condition worsen.
- Remainder of herd should be closely monitored by producer for further incidence.
- Treatment of affected animals
 - Transfaunation of 8–16 L of healthy rumen fluid: may be obtained from healthy donor or from slaughter house
 - Provide good quality grass hay or straw
 - If rumen pH alterations confirmed:
 - Acidosis: magnesium hydroxide or magnesium oxide (450 g per adult cow) PO
 - Alkalosis: Acetic acid (4–10 L) PO

NURSING CARE

Oral or parenteral polyionic fluid therapy may be indicated depending on severity of dehydration or electrolyte imbalances.

ACTIVITY

Activity may be limited in order to allow close monitoring of the animal's condition.

DIET

- Offending feedstuffs should be removed from the affected animals and the herd.
- Animals should be provided unlimited access to good quality grass hay or straw.
- Unless the offending feedstuff is inherently damaged (i.e., moldy, spoiled, contaminated), it may be reintroduced in small, graduated amounts, along with good-quality hay or other forage source.

CLIENT EDUCATION

- Animals being fed for production should be introduced to concentrated feeds gradually and provided quality forage.
- When new feedstuffs are incorporated into a production system, they should be incorporated prior to full depletion of previous feedstuffs, in order to allow gradual introduction.
- Feed should be inspected immediately prior to feeding for signs of damage or contamination.
- Silages and other stored feeds should be properly protected from environmental damage (moisture, oxygen, feces).

SURGICAL CONSIDERATIONS

In cases of simple indigestion, surgery such as rumenotomy is rarely required.

MEDICATIONS

DRUGS OF CHOICE

- Medication outside of supportive care and dietary management rarely required in uncomplicated cases of simple indigestion
- Ruminatorics are of limited use in simple indigestion
 - Nux vomica
 - Ginger
 - Tartar
 - Parasympathomimetic agents:
 - Neostigmine—may be of value if motility is reduced but still present; requires vagal tone to produce action; atonic animals are unable to respond.
 - Carbamylcholine—induces forestomach contractions, which are not productive and uncoordinated

CONTRAINDICATIONS

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Important to confirm rumen pH before administering corrective substances: Magnesium oxide contraindicated in absence of rumen acidosis

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

- Monitor closely for return to feed in 24–48 hours.
- May require additional transfaunations or additional diagnostics if not responding

PREVENTION

- Provide animals on feed with smaller meals more frequently, more closely mimicking grazing.
- Add buffers to feed (NaHCO_3).
- Avoid rapid changes in feeding practices.

POSSIBLE COMPLICATIONS

Rumen environment may further deteriorate and require more intensive therapy.

EXPECTED COURSE AND PROGNOSIS

- Typical course of anorexia is 1–2 days, with diarrhea occurring 12–24 hours after onset.
- If uncomplicated and managed by removal of offending feed, prognosis is good.
- Animals return to normal once rumen microflora and fermentation products achieve homeostasis and inhibitory products have been eliminated.
- Transfaunation encourages more rapid return of stable rumen environment.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Lactic acidosis; rumen alkalosis

AGE-RELATED FACTORS

Young animals may be more inclined to overindulge in concentrated feeds.

ZOONOTIC POTENTIAL

None

PREGNANCY

If condition is mild and has a short course, it is unlikely to result in loss of pregnancy.

RUMINANT SPECIES AFFECTED

Any ruminant species may be affected.

BIOSECURITY

PRODUCTION MANAGEMENT

- Silage and other processed feeds should be properly prepared and stored to prevent spoilage.
- Animals should be gradually introduced to increasing amounts or different types of feeds.
- New feedstuffs should be ordered and introduced prior to depletion of previous feed to allow for mixing and gradual

introduction.

INFECTIOUS BOVINE RHINOTRACHEITIS

BASICS

DEFINITION

- Infectious bovine rhinotracheitis (IBR) is a mild to severe upper respiratory disease in cattle caused by bovine herpesvirus-1 (BHV-1). IBR viral infection is one of the viral factors in bovine respiratory disease complex (BRDC).
- BHV-1 can also cause conjunctivitis, reproductive disease, and abortion. A variant of BHV-1, bovine herpesvirus-5 (BHV-5) can cause viral encephalitis.
 - The virus may remain latent in tissues and be reactivated after stress. Genomes of several different viral strains may be latent in the same animal at the same time.
- Infection with BHV-1 may occur simultaneously with other bacterial and viral infections (e.g., *Mannheimia* [*Pasteurella*] *haemolytica*, bovine viral diarrhea [BVD] virus, and parainfluenza virus type 3) leading to severe respiratory infection.
- Infection with IBRV may also enhance bovine keratoconjunctivitis (IBK) caused by *Moraxella bovis*.

PATHOPHYSIOLOGY

- BHV-1 is spread through nasal exudate, droplets, genital secretions, semen, frozen embryos, and fetal fluids.
- Cattle are the only significant source of viral spread. Although other species may become infected, they probably do not contribute to the spread of BHV-1.
- BHV-1 multiplies in the nasal cavities and upper respiratory tract resulting in rhinitis, laryngitis, and tracheitis. The virus spreads from the nasal cavity to the ocular system by the lacrimal gland. BHV-1 induces damage to the upper respiratory tract (URT) epithelium and conjunctiva of the eye. The damage to URT epithelium coupled with inflammatory changes increases the susceptibility of the lung to secondary bacterial infection.
- Conjunctivitis results from inflammation and edema of the conjunctiva. BHV-1 can induce late-term abortions in pregnant cattle by causing a viremia that results in BHV-1 infection of the ovary, placenta, and corpus luteum.
- In Europe, BHV-1 is associated with genital tract infections of both the male (infectious pustular balanoposthitis, IPB) and female (infectious pustular vulvovaginitis, IPV). BHV-5 infections spread rapidly up the peripheral nervous system to the brain and cause encephalitis.
- Once animals are infected with BHV-1 or BHV-5 in the URT, the virus spreads to the nervous system becomes latently infected in the nervous and lymphoid system, and the animals are a life-long source of infectious virus.
- Airborne transmission of the virus is believed to be of minor importance.

SYSTEMS AFFECTED

Respiratory, reproductive, ocular, immune, gastrointestinal, central nervous system

GENETICS

N/A

INCIDENCE/PREVALENCE

- BHV-1 is endemic in cattle.
- IBR is seldom seen in calves less than 6 months of age and is most prevalent and severe in animals between 6 and 18 months of age.
- Nonvaccinated pregnant cattle are highly susceptible to BHV-1 infection and up to 25% can abort (so-called abortion storm).

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Widely present in bovines and many wild species, American bison (*Bison bison*), African buffalo (*Syncerus caffer*), and sheep

SIGNS

- Symptoms in BHV-1 infected calves can vary from subclinical to severe disease with 100% morbidity and 10% mortality.
- Clinical signs of rhinotracheitis can occur within 1 or 2 days of infection with an increased rectal temperature of 104–108°F (40–42°C).
- Respiratory signs may consist of pink muzzle, nasal discharge (initially serous and later mucopurulent), inappetance, fever, depression, salivation, drop in milk production, red conjunctiva, and ocular discharge.
- In the presence of secondary bacterial infections (*Mannheimia haemolytica*, *Pasteurella multocida*, *Haemophilus somnus* or *Mycoplasma bovis*) respiration becomes labored followed by hyperpnea, open-mouth breathing, and death.
- Conjunctivitis can occur with respiratory disease or it may appear alone. Conjunctivitis originates from the cornenoscleral line and is usually bilateral.
- Abortion occurs in the last trimester of gestation.
- In calves, both respiratory and digestive tracts are involved.
- IPV, also known as coital exanthema, is characterized by small pustules on vulva and vagina. These pustules may later enlarge and spread over the whole epithelium and cause edema and hyperemia. The loss of epithelium encourages secondary infections.
- Lesions in IPB are limited to the prepuce, penis, and urethra.
- In Europe, BHV-1 is mainly responsible for genital tract infections. The respiratory tract disease varies in intensity and prevalence. In Belgium, digestive disorders are common in calves.
- Virus strains causing abortion, encephalitis, and mastitis are present only in a few countries. Dermatitis and lesions in the interdigital space are also rare.
- Infection becomes latent and may recrudesce with stress. The virus may be shed intermittently or continuously after recrudescence.

CAUSES

- BHV-1 is an enveloped double-stranded DNA virus of the genus *Varicellovirus*, in the subfamily Alphaherpesvirinae, family Herpesviridae.
- The virus is easily inactivated by desiccation, heat, and disinfectants.

RISK FACTORS

Stress (e.g., weaning, shipping, etc.) will increase the risk. Maternal antibody will inhibit vaccine response.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Respiratory

- Pneumonia
 - Shipping fever
 - Enzootic calf pneumonia
 - *Haemophilus somnus* pneumonia
 - Atypical interstitial pneumonia
 - Early bacterial pneumonia
 - Verminous pneumonia
- Septicemia—neonates
- Virus
 - Bovine coronavirus (BCV) has also been associated with respiratory disease. In younger calves, it is also seen with enteritis and diarrhea. BCV in 5- to 13-month-old cattle causes symptoms of dyspnea, nasal discharge, and increased respiratory rate.

- Infectious bovine rhinotracheitis (IBR)
- Bovine respiratory syncytial virus (BRSV) is characterized by increased harshness in respiratory sounds to severe with dyspnea, forced expiration, and open-mouth breathing. Spontaneous cough can be easily induced and can vary from dry and nonproductive to moist.
- Parainfluenza-3 virus (PI-3) infection is usually a mild, lower respiratory disease.
- Bovine viral diarrhea virus (BVDV) is associated with oral ulcers, mucopurulent discharge, and upper respiratory disease.

Abortion—Infectious

- Anaplasmosis
- Bluetongue
- Bovine viral diarrhea virus (BVDV) mucosal disease
- Brucellosis
- Campylobacteriosis
- Epizootic bovine abortion
- Leptospirosis
- *Mycoplasma*
- Mycotic abortions
- Q fever
- Salmonellosis
- Trichomoniasis

BHV-5 Encephalitis

The differential diagnoses include listeriosis, pseudorabies, rabies, and *Haemophilus somnus*.

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Other procedures that have proved useful in detection of BHV-1 are fluorescent antibody tests of fresh tissue and immunohistochemistry staining of cell cultures or formalin-fixed paraffin embedded tissues.
- Intranuclear inclusion bodies are often present in the liver of BHV-1–infected fetuses.
- A rise in serum neutralizing antibody titer also can be used to confirm BHV-1 infection. Paired serum samples collected 2 to 3 weeks apart are necessary; a single sample, even if it has a high titer, is of little value. It is not possible to detect a rising antibody titer in abortions, because infection generally occurs a considerable length of time before the abortion, and titers are already maximal.
- BHV-1 ELISA antibody detection tests are also available.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- BHV-1 is readily detected by virus isolation. Clinical specimens should be collected during the febrile, acute phase of infection. Respiratory and ocular specimens can be collected antemortem using swabs. Swabs can also be used for the detection of genital infections.
- On postmortem, virus isolation samples from IBR animals can be collected from the upper respiratory tract and trachea.
- From aborted fetuses, the liver, adrenal, kidney, and lung are the preferred tissues. In animals with encephalitis, several regions (olfactory lobes, midbrain, cortex, etc.) should be sampled. BHV-1 can also be detected using polymerase chain reaction (PCR).

PATHOLOGIC FINDINGS

Gross Lesions

- Gross lesions of uncomplicated IBR are restricted to the upper respiratory tract and trachea.
 - Petechial to ecchymotic hemorrhages with edema are found in the mucous membranes of the nasal cavity and the sinuses. There may be focal areas of necrosis in the nose, pharynx, larynx, and trachea that may coalesce to form plaques. The sinuses may be filled with a serous or serofibrinous exudate.

- As the disease progresses, the pharynx becomes covered with a serofibrinous exudate, and blood-tinged fluid may be found in the trachea.
- The pharyngeal and pulmonary lymph nodes may be acutely swollen and hemorrhagic. The tracheitis may extend into the bronchi and bronchioles; when this occurs, epithelium is sloughed in the airways.
- In animals with bacterial bronchopneumonia, the viral lesions are often masked.
- Aborted fetuses may have pale, focal, necrotic lesions in all tissues, which are especially visible in the liver.
- In digestive tract infection, one can see erosions and ulceration of buccal mucosa, lips, gums, hard palate, esophagus, and abomasums.
- In IPV and IPB, inflammatory lesions can be seen in vulva, vagina, cervical mucosa, prepuce, and penile mucosa.

Histologic Examination

- Histologic examination of IBR tissues reveals acute catarrhal inflammation of the mucosa with rare inclusion bodies as well as lymphocytic infiltration in the mucosa, edema in the lamina propria, and type A eosinophilic inclusion bodies can be seen.
- In BHV-5 encephalitic calves, histological changes consist of a widespread nonsuppurative meningoencephalitis, more severe in the anterior cerebrum, the dorsolateral cortex and, to a lesser extent, the posterior cerebrum and the midbrain.
- The lesions are characterized by gliosis, disruption of the neutrophil and perivascular cuffing, consisting of macrophages, histiocytes, and lymphocytes. In aborted fetuses, intranuclear inclusion bodies are often present in the liver.

TREATMENT

APPROPRIATE HEALTH CARE

The therapy for IBR is supportive. Severely diseased animals that are dehydrated may receive oral and/or intravenous fluids.

ACTIVITY

Handling of BHV-1-infected animals should be minimal to decrease the risk of secondary bacterial infections.

DIET

N/A

CLIENT EDUCATION

Minimize handling of animals and use preventative vaccines.

SURGICAL CONSIDERATIONS

N/A

MEDICATIONS

DRUGS OF CHOICE

Nonsteroidal anti-inflammatory drugs (NSAIDs) may have some benefit to lessen the severity of BHV-1 disease. Antimicrobial treatment is used to reduce secondary bacterial infections.

CONTRAINDICATIONS

N/A

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

Respiratory characteristics along with rectal body temperature should be frequently monitored to assess IBR clinical progression and also the development of secondary bacterial infections that would result in bovine respiratory disease complex (BRDC).

PREVENTION/AVOIDANCE

Immunity and Vaccination

- Infection leads to the development of humoral and cell-mediated immunity. The humoral immunity and not the cellular immunity can be transmitted to neonates via colostrum.
 - Both modified-live virus (MLV) and inactivated virus BHV-1 vaccines are on the market. The MLV vaccines are available as either a parenteral (intramuscular, IM or subcutaneous, SC) or intranasal (IN) vaccine.
 - Use of MLV vaccines is not without risk due to persistence of the virus and its potential for reactivation.
- Although conventional vaccines can prevent clinical signs of IBR, their use has not resulted in reduction of the prevalence of infection. Similarly, marker vaccines can prevent disease but not infection and/or subsequent latency. The continued excretion of virus from vaccinated animals results in environmental contamination making the control of the disease more difficult.
- No vaccine has been shown to overcome viral latency.
- BHV-1 vaccines are cross-reactive and should be efficacious against BHV-5.

Control and Eradication

- Marker vaccines can be used in conjunction with companion diagnostic tests to differentiate between infected and vaccinated cattle, a property that is useful in eradication and control programs.
- Eradication of herpesviruses is extremely difficult because of their ability to establish latent infections. In addition, these viruses have a wide range of genes and proteins (envelope glycoproteins and cytokine inhibitors, for example) that can counteract host immune response.
- Many European countries were forced to eradicate BHV-1 because of international trade restrictions on the import/export of seropositive cattle whereby importing countries consider only vaccinated animals for import and require that the animals be seronegative prior to vaccination.
- Eradication programs in Austria, Denmark, and Switzerland have removed most of the seropositive cattle from their bovine populations. The Swiss program consisted of four phases (e.g., prevention of virus transmission by restrictions on trade of bovines, slaughter of antibody-positive animals in breeding herds, detection and eradication of BHV-1 reservoirs, and enforcement of monitoring program by legal action). Currently, a similar program is being tried in Germany.

POSSIBLE COMPLICATIONS

- IM MLV BHV-1 vaccines may cause abortion in pregnant cattle.
- Maternal antibodies in calves interfere with development of an effective IBR immune response with parenteral MLV vaccines.
- Maternal antibodies have no effect on IN MLV vaccines.

EXPECTED COURSE AND PROGNOSIS

- Uncomplicated BHV-1 respiratory infections will resolve in 5–7 days.
- Animals that have secondary infections usually will develop bronchopneumonia with varying levels of morbidity and mortality.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- BRDC is a frequent sequela to IBR.
- Retained placenta and metritis are possible sequelae to BHV-1 abortion.

- Virus strains causing abortion, encephalitis, and mastitis are present only in a few countries. Dermatitis and lesions in the interdigital space are also rare.

AGE-RELATED FACTORS

A rare, generalized disease may occur in neonatal calves less than 2 weeks of age. Most IBR and BHV-5 disease is seen in animals > 6 months of age.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

BHV-1 infections result in late-term abortions that occur as long as 100 days following infection.

RUMINANT SPECIES AFFECTED

Bovine

BIOSECURITY

- BHV-1 survives very poorly in the environment and is susceptible to UV light, desiccation, heat, and disinfectants. The virus will survive better in the winter.
- Animals exhibiting clinical signs of IBR or BHV-5 should be isolated from other cattle as transmission of these viruses occurs by the oronasal route.

PRODUCTION MANAGEMENT

- In herds with a history of IBR, BHV-1 abortion, or BHV-5 encephalitis, a BHV-1 vaccine program should be implemented.
- Although conventional vaccines can prevent clinical signs of IBR, their use has not resulted in reduction of the prevalence of infection. Similarly, marker vaccines can prevent disease but not infection and/or subsequent latency. The continued excretion of virus from vaccinated animals results in environmental contamination making the control of the disease more difficult.

INFECTIOUS NECROTIC HEPATITIS

BASICS

DEFINITION

Infectious necrotic hepatitis is a disease affecting mainly animals on pasture and causing sudden death.

PATHOPHYSIOLOGY

- *Clostridium novyi* type B is a gram-positive spore-forming anaerobic bacteria, and is a normal inhabitant of soil. Spores are ingested by animals in the process of grazing, and occasionally cross the intestinal mucosa and are carried through the lymphatic drainage by the mononuclear macrophage system to the Kupffer cells of the liver.
- Liver damage, typically from larval migration of the common liver fluke *Fasciola hepatica*, and occasionally from other liver parasites such as *Fascioloides magna*, *Dicrocoelium dendriticum*, and *Cysticercus tenuicollis*, can cause localized anaerobic conditions, allowing the clostridial spores to germinate and proliferate. This releases exotoxins (mainly lethal alpha toxin and necrotizing and hemolytic beta toxin), which cause coagulative necrosis in the liver. The exotoxins enter the general circulation, damaging vascular endothelium and neurons in multiple organs, causing sudden death.

SYSTEMS AFFECTED

Hepatic

GENETICS

N/A

INCIDENCE/PREVALENCE

- Tends to be a seasonal disease related to the liver fluke life cycle, occurring in the warmer months when fluke transmission is active.
- Incidence in affected sheep flocks 5%–10%; incidence in cattle difficult to determine.

GEOGRAPHIC DISTRIBUTION

- Worldwide, wherever liver flukes are present.
- Important problem in Australia and New Zealand, lesser importance in Europe, the United Kingdom, and the United States

SIGNALMENT

Species

Mainly sheep and cattle. Disease appears to progress more rapidly in sheep.

Breed Predilections

N/A

Mean Age and Range

Age: 2–4 years; adult animals in good body condition

Predominant Sex

N/A

SIGNS HISTORICAL FINDINGS

- Sudden death in a liver-fluke-endemic area during the warmer months of the year in animals unvaccinated against clostridia
- History of liver fluke infestation in the past

PHYSICAL EXAMINATION FINDINGS

- Animals most often found dead, in lateral recumbency with no signs of struggle and in apparently advanced decomposition even if death was recent.
- Signs nonspecific before death occurs (e.g., depression, anorexia, dyspnea, fever initially but subnormal temperature

before death)

CAUSES AND RISK FACTORS

- Causes—toxins produced by the gram-positive anaerobic bacteria *Clostridium novyi* type B proliferating in liver tissue damaged by migrating liver flukes
- Risk factors—failure to vaccinate against clostridia; exposure to liver flukes

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other clostridial diseases (e.g., bacillary hemoglobinuria)—see red urine, bleeding from nose or rectum
- Anthrax—see bleeding from orifices
- Acute fascioliasis in sheep

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

- Anaerobic culture
- Fluorescent antibody
- Gram-stain and microscopic inspection of an impression smear of the liver shows numerous large gram-positive rods.
- Specific toxin identification

IMAGING

N/A

OTHER DIAGNOSTIC PROCEDURES

N/A

PATHOLOGIC FINDINGS

- Generalized autolysis of all body tissues, especially the liver and kidneys
- Foci of coagulative necrosis in the liver
- Migrating fluke channels in the liver
- Engorged and hemorrhagic subcutaneous blood vessels
- Blood-tinged fluid in all body cavities (urine appears normal in color)

TREATMENT

Rarely treated since animals are usually found dead prior to diagnosis

ACTIVITY

Restrict movement of animals being treated, since stress of physical exertion can precipitate sudden death.

DIET

N/A

CLIENT EDUCATION

- Routine vaccination against clostridia
- Control of liver fluke infestation by pasture management, limiting access to streams and ponds, and strategic flukicide treatment.

MEDICATIONS

- Vaccinate herd

- Mass medicate herd with long-acting penicillin or tetracycline. Use-flukicide (e.g., clorsulon).

DRUGS OF CHOICE

- Penicillin: 20,000–40,000 IU/kg IV q 6 hours
- Clorsulon: 7 mg/kg PO

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

N/A

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

N/A

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Vaccination with clostridial toxoid with booster in 4–6 weeks and annual revaccination preferably in early summer at least 1 month before expected fluke exposure
- Use of molluscicides in streams, flukicides in animals, and drainage of marshy areas

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Prognosis is grave in animals showing clinical signs.
- Rapid clinical course in sheep usually found dead before clinical signs noted.
- Short clinical course in cattle, with nonspecific clinical signs (depression, anorexia) seen just before death.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Fascioliasis

INFECTIOUS PUSTULAR VULVOVAGINITIS

BASICS

OVERVIEW

- Infectious pustular vulvovaginitis (IPV) is characterized by vulvitis and vaginitis and it is part of the granular venereal diseases.
- Infectious pustular vulvovaginitis is caused by alphaherpesvirus, bovine herpes virus (BHV) type 1, subtype 2, of the Herpesviridae family.
- Bovine herpesvirus-1 is divided in two subtypes (BHV-1.1 and BHV-1.2) according to genetic differences and the systems that it affects.
- BHV-1.1 affects the respiratory system causing infectious bovine rhinotracheitis (IBR), while BHV-1.2 affects the reproductive system causing IPV in females and infectious pustular balanoposthitis (IPB) in males. Bovine herpesvirus 5 is formerly known as BHV-1.3, which is responsible for the encephalitic form of the disease.
- Rarely IPV and IBR occur concurrently.
- Agent: bovine herpesvirus type-1 subtype-2 (BHV-1.2)

GENETICS

- Bovine herpesvirus 1 is the herpesvirus serologically related to IBR or IPV/IPB, and is divided in two main subtypes according to genetic differences (BHV-1.1 and BHV-1.2).
- The genetic differences may be responsible for the diverse epidemiological and pathological patterns of virus behavior. While BHV-1.1 is related to IBR, the respiratory form of the disease, BHV-1.2 is related to the genital form of the ailment (IPV/IPB).
- Bovine herpesvirus 1.2b is a different strain of the virus and it is usually related to the occurrence of IPV/IPB and outbreaks of low/medium virulence of IBR.
- Some specific genotypes of bovine animals are more resistant to challenges with BHV-1, developing less-severe disease. This is an indication that breeding programs that increase the occurrence of these specific genes may alter the sensitivity of populations to BHV-1 infection.

INCIDENCE/PREVALENCE

Infectious pustular vulvovaginitis was considered endemic in Europe during the 1960s and 1970s. However, due to control measures such as vaccination and elimination of serologically positive animals, its prevalence has been reduced greatly.

- Outbreaks of IPV were frequent in Europe and more specifically in Great Britain in the 1960s and 1970s. However, it has become less common in the past few years due to implemented control measures.
- Seroprevalence surveys have indicated that 10%–50% of cattle may be serologically positive for BHV, but the prevalence depends on vaccination practices.

GEOGRAPHIC DISTRIBUTION

Bovine herpesvirus has been isolated in Africa, Asia, North America, Australia, New Zealand, and Europe.

Transmission

- Infectious pustular vulvovaginitis is transmitted directly by coitus or artificial insemination.
- Mechanical means are also possibilities for the transmission of the causal agent.

Epidemiology

- The incubation period for BHV-1.2 is usually between 1 and 3 days.
- Transmission of BHV-1.2 is rapid and can affect 60%–90% of the herd.

SIGNALMENT

Species

Bovine, ovine, and wild ruminants

Breed Predilections

N/A

Mean Age and Range

- Animals in the breeding age are more likely to be infected.
- Unbred animals can also be affected.

Predominant Sex

Female

- Female: bovine females infected with BHV-1.2 usually develop IPV.
- Male: bovine herpesvirus 1.2 is responsible for IPB in males.

DIAGNOSIS

- Indirect: Serology—ELISA and virus neutralization test; Skin test—delayed-type hypersensitivity (DTH) reaction
- Direct: Fluorescent microscope; polymerase chain reaction (PCR)

DIFFERENTIAL DIAGNOSIS

- Granular venereal disease caused by mycoplasma, ureaplasma, *Haemophilus somnus*, and *A. pyogenes*
- Transmissible fibropapilloma
- Granular vulvitis
- Necrotic vulvitis

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

PATHOLOGIC FINDINGS

- Females develop mucopurulent secretion from the vagina and inflammation of the vulva and vagina.
- Lymphoid follicles present pustules that develop from small-sized ulcers to coalescing erosions.
- Male bovines infected with BHV-1.2 that develop infectious pustular balanoposthitis (IPB) are reluctant to mate.
- The animals tend to recover within 10 to 30 days of the beginning of signs and remain transiently immune.

TREATMENT

Although, lavage of the vagina with antiseptic solutions and emollients has been recommended, treatment is usually not required. Animals usually recover within 30 days of the initial infection.

MEDICATIONS

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Vaccination can be of benefit. However, in the face of an outbreak, vaccination has little effect.
- Avoid mating among infected animals to decrease the risk of dissemination of the disease.
- BHV-1.2 can survive cryopreservation. Therefore, semen donors and semen should be tested and free of BHV-1.2.
- Eradication of the disease requires vaccination and often elimination of animals that are carriers of the genital form of BHV.

POSSIBLE COMPLICATIONS

- Not uncommonly, female bovine infected with BHV-1.2 that develop IPV have an increased rate of return to estrus after insemination. This can have a major impact in the breeding programs and consequently to the profitability of dairy and beef operations.
- Rarely IPV is followed by abortion outbreaks.

EXPECTED COURSE AND PROGNOSIS

- Animals usually develop signs of infection within 1 to 3 days after exposure.
- Initial signs are mucopurulent vaginal secretion and vulvar/vaginal inflammation.
- Lymphoid tissue develops pustules that become small ulcers (< 3 mm) and may result in coalescing erosions. The vulvar mucosa in the latter stages of the disease presents small but numerous necrotic focal areas.
- Within 10 to 30 days of infection, animals recover spontaneously.
- Infectious pustular vulvovaginitis has a very good prognosis.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- During the initial phases of the disease, animals may present less-specific signs such as pyrexia and milk drop.
- Animals in the breeding age infected with BHV-1.2 may present increased rate of return to estrus.
- Conjunctivitis with serous discharge and bilateral nasal discharge are signs of BHV-1.2 when the respiratory tract is affected.

AGE-RELATED FACTORS

Although, breeding-age animals are more likely to develop the condition, unbred heifers can also be infected.

ZOONOTIC POTENTIAL

N/A

PREGNANCY

Infectious pustular vulvovaginitis is rarely related to abortion outbreaks.

RUMINANT SPECIES AFFECTED

Bovine, ovine, wild ruminants

BIOSECURITY

- Vaccination
- Testing of bulls and frozen semen
- Avoid the use of shared hired bulls

INHALATION PNEUMONIA

BASICS

DEFINITION

Inhalation or aspiration pneumonia is caused by inhalation of large amounts of foreign material.

PATHOPHYSIOLOGY

- Inhalation of large amounts of foreign material into the lungs sets up an inflammatory reaction.
- Irritation of the lung tissues results in infection by a mixed population of organisms (e.g., *Corynebacterium* spp., *Fusobacterium* spp., *E. coli*, *Klebsiella* spp., etc.) leading to cell and tissue death and a gangrenous pneumonia.

IODINE DEFICIENCY AND TOXICITY

BASICS

OVERVIEW

- Iodine is essential for normal formation and function of the thyroid hormones thyroxine (T_4) and triiodothyronine (T_3). Inadequate intake of iodine results in the formation of inactive thyroid hormones. In a negative feedback system, the pituitary responds to decreased serum thyroid hormones by increasing secretion of thyroid stimulating hormone (TSH) resulting in a compensatory hypertrophy and hyperlasia of the thyroid gland (goiter) especially in neonates.
- Goiter is usually the first clinical sign of an iodine deficiency. The concentration of iodine in water, soil, and plants is highly variable but is readily absorbed from the gastrointestinal tract as iodide (I^-). The body stores iodide in the thyroid gland, salivary glands, gastric mucosa, and mammary glands.
- Short periods of decreased intake rarely results in clinical signs of deficiency in adult animals.
- Toxicity (iodinism), a result of prolonged ingestion of plants or supplements containing iodine (0.4 mg/kg–2.2. mg/kg), also produces clinical signs of goiter. Iodine is excreted in urine and to a lesser degree in milk, sweat, and feces.

SYSTEMS AFFECTED

- Cardiovascular—tachycardia
- Endocrine/metabolic—hyperthermia, hypothermia, goiter
- Gastrointestinal—anorexia, weight loss
- Musculoskeletal—enlarged neck
- Nervous system—depression
- Respiratory—persistent cough, naso-ocular discharge, bronchopneumonia
- Reproductive—decreased milk yield, reproductive disorders, abortion, increased mortality of neonates
- Skin/exocrine—dermatitis, alopecia, flabby edematous skin

GENETICS

Familial dys hormonogenetic goiter—an autosomal recessive trait affecting mRNA for thyroglobulin in goats, Afrikaner cattle, and Corriedale, Dorset horn, Merino, and Romney Marsh sheep

INCIDENCE/PREVALENCE

N/A

GEOGRAPHIC DISTRIBUTION

Geographic areas known to be deficient in soil iodine include the Great Lakes region, Pacific Northwest, Central Plains, Rocky Mountains, and northeastern United States; parts of eastern Europe, Swiss Alps, parts of the Andes, and Himalayas

SIGNALMENT

All ruminants and all ages are susceptible but newborns are at greater risk of deficiency as well as toxicity. Sheep may be more tolerant of higher doses of iodine than are cattle.

Species

Potentially all ruminant species

Breed Predilections

Afrikaner cattle and Corriedale, Dorset horn, Merino, and Romney Marsh sheep may be more affected by goiter

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

Deficiency

Enlargement of the thyroid gland, skin of the neck may be thickened and edematous, calves and lambs may be born without hair or wool, may be born weak, or die shortly after birth; iodine deficiency in cows may result in reproductive disorders characterized by decreased conception rates, fetal resorption, abortions, and stillbirths. In bulls, decreased libido and semen quality are observed.

Toxicity

- Signs are highly variable depending on dose, nature of the compound ingested, and length of time of exposure.
- Clinical signs may take months to more than a year to develop in adults, and adults may not exhibit clinical signs unless stressed or have concurrent disease.
- Symptoms include enlarged thyroid gland; lacrimation; salivation; dry, flaky skin; cough; naso-ocular discharge; bronchopneumonia; decreased feed consumption; decreased weight gain; decreased milk production; tachycardia

CAUSES AND RISK FACTORS

Deficiency

- Geographic areas known to be deficient in soil iodine include the Great Lakes region, Pacific Northwest, Central Plains, Rocky Mountains, and northeastern United States; parts of eastern Europe, Swiss Alps, parts of the Andes, and Himalayas
- Consumption of goitrogenic plants increases the dietary need for iodine 2–4x. Goitrogenic substances alter the uptake of iodine by the thyroid gland or the incorporation of iodine into the thyroid hormone producing clinical signs of iodine deficiency.
- Known goitrogenic plants include soybean, soybean meal, cottonseed, cassava, millet, sweet potatoes, cabbage, rape, kale, turnips, white clover, onions, garlic (heating or processing usually destroys goitrogenic substances). An increase in dietary iodine will compensate in most cases.

Toxicity

- In newborns, goiter is usually a result of ingestion of excess iodine by the cow/ewe/doe.
- Sources include excess mineral supplements containing ethylenediamine dihydroiodide (EDDI), calcium iodate, kelp, potassium iodide, and sodium iodide. Iodine is widely used for its antibacterial properties. Treatment doses of EDDI for therapy or prevention of infectious pododermatitis are higher than recommended daily requirements and pose a risk.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Consumption of goitrogenic plants, abscess, trauma, hematoma, foreign body, neoplasia of thyroid gland (especially in older bulls), familial dysmorphogenetic goiter—an autosomal recessive trait affecting mRNA for thyroglobulin in goats, Afrikaner cattle, and Corriedale, Dorset horn, Merino, and Romney Marsh sheep. Selenium deficiency aggravates iodine-deficient goiter, diets high in nitrates inhibit iodine uptake by the thyroid gland.

CBC/BIOCHEMISTRY/URINALYSIS

Biochemical changes are inconclusive for iodine deficiency/toxicosis.

OTHER LABORATORY TESTS

- Iodine levels in serum, milk, and urine (Lactating animals will have lower serum iodine and higher milk iodine levels due to iodine excretion in milk.)
- Iodine levels in soil, forage, and water
- Serum T₃ and T₄ levels

IMAGING

Ultrasonography or radiography may rule out other causes of swelling in neck region.

DIAGNOSTIC PROCEDURES PATHOLOGIC FINDINGS

Gross Pathology

- Uniformly enlarged thyroid gland may be twice normal size.
- Respiratory system: tracheitis, bronchopneumonia, inflammatory exudate

Histopathology

Histopathology of thyroid gland is variable.

TREATMENT

- In cases of deficiency, diet may be supplemented with stabilized iodized salt containing 0.007% iodine.
- In cases of toxicosis, removal from source of excess iodine is the only treatment.

MEDICATIONS

DRUGS OF CHOICE

None

CONTRAINDICATIONS

FOLLOW-UP

PATIENT MONITORING PREVENTION/AVOIDANCE

- Forage analysis in iodine deficient areas and supplementation with a stable iodized salt
- Species requirements
 - Dairy cows 0.33 mg I/kg DM for nonlactating, 0.45 mg I/kg DM for lactating animals
 - Sheep 0.10–0.80 mg I/kg DM the higher range for pregnant and lactating animals
 - Goats 0.2–0.8 mg I/kg DM the higher range for lactating animals
 - Beef cattle 0.5 mg I/kg diet

POSSIBLE COMPLICATIONS EXPECTED COURSE AND PROGNOSIS

In mild cases, goiter will resolve with supplementation/removal, but young animals affected in utero may not survive.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Hypothyroidism

AGE-RELATED FACTORS

Newborns are at greatest risk.

ZOONOTIC POTENTIAL

None

PREGNANCY

- If dietary iodine levels are marginal or deficient during pregnancy, developmental abnormalities, neonatal weakness, signs of goiter at birth or shortly thereafter, and death of the neonate may result even though pregnant females may not show any clinical signs of iodine deficiency.
- Clinical signs in the neonate depend on the stage of development at the time of deficiency and are not usually reversible.

RUMINANT SPECIES AFFECTED

All species susceptible

BIOSECURITY

JIMSONWEED TOXICITY (DATURA STRAMONIUM)

BASICS

OVERVIEW

- Caused by ingestion of jimsonweed (Jamestown weed or *Datura stramonium*) and its toxic tropane alkaloids.
- All parts of the green or dried plant are toxic including the seeds. Plants become more toxic as they mature. Seeds are considered to be the most toxic part of the plant.
- Contain two tropane alkaloids: (1) L-hyoscyamine (atropine) and (2) scopolamine (L-hyoscine)
- Tropane alkaloids act as a competitive antagonist of acetylcholine at muscarinic cholinergic receptors of the parasympathetic nervous system.
- Clinical signs are attributable to this receptor blockade and are manifest as (1) blockage of contraction of the muscles of the iris and mydriasis, (2) decreased smooth muscle contraction of the gastrointestinal system, (3) decreased salivary secretions, and (4) increased vagal tone.
- Jimsonweed is commonly found in fencerows, barnyards, and roadsides throughout much of the United States.
- The green plant is generally unpalatable due to its strong odor. Thus, lack of other forage, drying of the plant in hay, or contamination of cereal grains or feed with the seeds are the primary routes of ingestion and toxicity.
- Toxicity is often somewhat self-limiting as anorexia is induced early in the toxic process limiting ingestion of further toxins.
- Signs predominantly involve the neuromuscular, ophthalmic, and gastrointestinal systems.

SIGNALMENT

- All ruminant species and swine can be affected.
- Cattle appear to be more susceptible than other ruminants.
- No sex, age, or breed predilection among animals consuming the plant

SIGNS

- Mydriasis
- Depression
- Restlessness
- Anorexia
- Sinus tachycardia
- Weakness
- Photophobia
- Dry mucous membranes
- Constipation/ileus
- Rumen atony

CAUSES AND RISK FACTORS

Associated with ingestion of toxin-containing plant. Consumption of feed or cereal grains containing 1000 seeds/kg can be toxic in cattle.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other toxic plants with tropane alkaloids including moonflower, angel's trumpet, deadly nightshade, belladonna, black

henbane, horse or bull nettle, Texas thistle, tropical soda apple, and ground cherries.

- Parenteral or topical atropine therapy

CBC/BIOCHEMISTRY/URINALYSIS

No changes specific for jimsonweed toxicity

OTHER LABORATORY TESTS

- Urine and gastrointestinal contents can be tested for tropane alkaloids.
- Test administration of parasympathomimetic drugs *may not* cause appreciable improvement.

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- If acute consumption is suspected, a rumenotomy with confirmation of plant material or seeds in the ingesta would be diagnostic and may be indicated.
- Urine from affected animal is said to induce mydriasis if applied topically to the eye of a test animal.

PATHOLOGIC FINDINGS

- Identification of seed or plant material in the rumen
- No distinct lesions
- May see hemorrhages of the liver or kidney or effusions of the pericardium

TREATMENT

- Remove animals from source of toxin (plants or seed).
- If acute ingestion of large volumes of toxin are suspected, rumenotomy with evacuation of the ingesta may be beneficial.
- Often self-limiting due to anorexia, an early sign.

MEDICATIONS

DRUGS OF CHOICE

- Orogastric administration of mineral oil or activated charcoal may decrease absorption of the toxin.
- Rarely administration of a cholinergic drug (such as physostigmine, pilocarpine, or arecoline) is used, however, no clear benefit to the use of these drugs has been demonstrated.

CONTRAINDICATIONS

Atropine

POSSIBLE INTERACTIONS

FOLLOW-UP

PATIENT MONITORING

Monitor for signs of continued ileus or intestinal obstruction secondary to ileus.

PREVENTION/AVOIDANCE

Do not pasture animals on fields with jimsonweed or feed hay or grain containing the plant or seed.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Often self-limiting due to decreased ingestion of the toxin after initial signs of toxicity.
- Most have a good prognosis with supportive care

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

N/A

ZOONOTIC POTENTIAL

N/A

PREGNANCY

- Some studies have demonstrated teratogenic properties of tropane alkaloids, however more recent studies have not been able to clearly demonstrate a cause and effect relationship.
- Until further work is done, tropane alkaloids should be considered possible teratogens.

RUMINANT SPECIES AFFECTED

- All ruminant species and swine
- Cattle appear to be most susceptible.

JOHNE'S DISEASE

BASICS

OVERVIEW

- Johne's disease (pronounced Yo-nees) is a serious disease of most ruminants that can cause significant economic loss if not controlled.
- Species affected by Johne's disease include cattle, sheep, goats, and camelids.
- It is estimated that greater than 50% of the dairy and 20% of the beef cow-calf operations in the United States have at least one animal infected with Johne's disease.
- Johne's disease is caused by the bacteria *Mycobacterium avium* subsp. *paratuberculosis*.
- Animals less than 6 months of age are most susceptible to infection. Older animals are less susceptible to infection.
- The primary source of infection is feces that contain the causative bacteria. Infected animals can produce large amounts of the bacteria and shed this organism in their feces.
- Most infected animals do not begin shedding the Johne's organism until they are adults.
- Any method by which young stock become exposed to fecal material from adult animals may serve as a source of infection with the Johne's disease organism.
- This may include being born in a dirty maternity pen, nursing a dirty teat, being housed in direct contact with adult animals, using common feeding/manure handling equipment (skid-loader), or having manure run-off from mature cow areas going through the environments of young stock.
- Another important source of transmission is milk and colostrum. About one-third of cows infected with Johne's disease, whether they are showing clinical signs or not, will shed the bacteria in their colostrum or milk.
- Approximately 20% of cows with Johne's disease will pass the causative bacteria across their placenta to the developing fetus. The risk of this happening increases dramatically in cows with clinical signs of Johne's disease.

SIGNALMENT

- Newborn animals are most susceptible to infection with Johne's disease. As they get older, risk of infection decreases. In cattle, most infections likely occur in the first 6 months of life.
- Following a long incubation period of months to years, clinical disease typically occurs in an adult animal.
- All breeds of cattle, sheep, and goats are susceptible to Johne's disease.

SIGNS

- There is a long incubation period between infection and the appearance of clinical signs. In cattle, this period of time may range from 1 year to several years.
- Prior to the development of observable clinical signs, animals may be affected subclinically. Syndromes that have been associated with subclinical Johne's disease in cattle include reduced milk production, reduced reproductive performance, and increased disease susceptibility.
- The classical clinical sign of Johne's disease in cattle is chronic, watery diarrhea. This diarrhea may be intermittent at first, but eventually progresses to chronic and unrelenting. Diarrhea is not as evident in sheep and goats.
- The diarrhea has no distinguishing characteristics such as blood, mucus, or foul odor. It is often referred to as "pipe stream" in nature because of its watery and projectile appearance.
- Secondary to diarrhea, animals lose weight despite the maintenance of a good appetite. Weight loss is the primary clinical sign in sheep and goats.
- Depending on concurrent metabolic loads (milk production, pregnancy), weight loss may occur gradually over months or very rapidly over the course of a few weeks.
- In advanced cases, the development of submandibular edema may occur secondary to a decrease in total serum protein.

CAUSES AND RISK FACTORS

Johne's disease is caused by the bacteria *Mycobacterium avium* subsp. *paratuberculosis*.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Parasitism
- Copper deficiency
- Bovine leukosis
- Salmonellosis
- Amyloidosis
- Chronic reticuloperitonitis/peritonitis

CBC/BIOCHEMISTRY/URINALYSIS

Hypoproteinemia, characterized by low serum albumin, may be present in advanced clinical cases of Johne's disease.

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Fecal culture—standard culture methods require 10–16 weeks to complete. New rapid culture methods can shorten the culture time to 8–10 weeks.
- PCR/DNA probe—organism detection assay used on feces or tissue
- ELISA, immunodiffusion, complement fixation—antibody detection assays
- Acid-fast stain—direct visualization of organism in appropriate tissue samples such as ileum or ileal cecal lymph nodes

GROSS FINDINGS

- In cattle, lesions are primarily found in the distal jejunum, ileum, cecum, proximal colon, and associated lymph nodes.
- Thickening of the intestine three to four times normal thickness is characteristic.
- Affected mucosa takes on a corrugated appearance.
- The ileocecal valve is typically thickened and often reddened in color.
- In sheep, intestinal mucosal may be thickened, but it does not typically become corrugated.
- Mesenteric lymph nodes are enlarged and edematous in cattle. In sheep, they have areas of necrosis and calcification.

HISTOPATHOLOGICAL FINDINGS

- The earliest cellular changes are increased numbers of macrophages and lymphocytes.
- As the infection progresses, the mononuclear inflammatory infiltrate becomes pronounced and giant cells become more numerous. The inflammation is diffuse; the lesions are not walled off or circumscribed by fibrous connective tissue.
- Acid-fast bacteria will be present in areas of mononuclear inflammation.

TREATMENT

- There are no chemotherapeutic agents approved for use in food-producing animals for the treatment of *Mycobacterium paratuberculosis*.
- Use of antimycobacterial chemotherapeutic agents has largely been ineffective. Isoniazid, rifampin, Clofazimine, dapsone, aminoglycosides, and ethambutol may result in transient reduction in clinical signs and slowing of disease progression, but response is inconsistent and they have failed to cure the disease.
- Drug withdrawal times must be determined and maintained for food-producing animals.

MEDICATIONS

N/A

CONTRAINDICATIONS

N/A

FOLLOW-UP

PATIENT MONITORING

N/A

PREVENTION/AVOIDANCE

- Stopping the transmission from infected cattle that are shedding the bacteria (generally adult animals) to susceptible animals (generally young animals) is key to controlling the disease.
- Specific recommendations include making sure newborns are born into and housed in a clean environment, reducing the chance of spread through colostrum and milk by not sharing colostrum and milk between multiple young stock or feeding only pasteurized sources of milk or milk replacers, making sure that weaned young stock are separated from adult animals.
- Infected animals should be identified and either culled or managed so as to reduce the chance they are spreading the disease to susceptible animals.

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Johne's is a chronic progressive disease.
- Progression of Johne's disease typically occurs over a 2–3-year period.
- Johne's disease progression can be divided into four stages. Stage 1 is the period of inapparent infection that occurs early in the disease progression. Stage 2 is a subclinical phase where shedding of the organism is intermittent. Stage 3 is characterized by consistent heavy shedding. Stage 4 is the clinical stage of the disease.
- Johne's disease is inevitably a fatal disease if allowed to progress.

MISCELLANEOUS

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

- Calves are most at risk for becoming infected with Johne's disease. As cattle get older, infection becomes less likely.
- Because of the long incubation period, clinical signs of disease typically do not appear until adulthood.

ZOONOTIC POTENTIAL

There has been some association of *Mycobacterium paratuberculosis* with Crohn's disease in humans, but no definitive link has been made.

PREGNANCY

Mycobacterium paratuberculosis can cross the placenta and infect the fetus. This occurs about 20% of the time in Johne's-infected cows. The risk of fetal transmission in utero increases as the disease progresses in the dam.

SYNONYMS

Paratuberculosis

JOHNE'S DISEASE—SMALL RUMINANTS AND EXOTICS

BASICS

OVERVIEW

- Johne's disease (paratuberculosis) is an insidious, chronic, diarrheal disease of domestic and wild ruminant species that occurs worldwide.
- Ruminant species infected include domesticated cattle, sheep, goats, and camelids, as well as several species of deer (white-tailed, sika, red, axis, roe, fallow), moose, Rocky Mountain bighorn sheep, Rocky Mountain bighorn goats, tule elk, American buffalo, antelope, aoudad, mouflon, water buffalo, yak, gnu, and wild rabbits.
- Monogastric animals infected include mules, horses, swine, chickens, monkeys, and mandrills.
- The causative agent is *Mycobacterium avium* subsp. *paratuberculosis* (*Map*)
- Based on culture characteristics and molecular typing, two strains of *Map* have been described. These include the cattle (C) strain, which predominantly affects cattle as well as goats, camelids, and wildlife; and the sheep (S) strain, which primarily affects sheep.
- Cross-species transmission of *Map* between cattle and sheep can occur.
- The role of wildlife in maintaining infection cycles in domesticated ruminants is unknown. Natural transmission of *Map* from wildlife to domesticated animals has not been documented, however, domesticated animals have been implicated in natural outbreaks of Johne's disease in wildlife populations.
- The majority of information available regarding the epidemiology, biology, pathology, and diagnosis of Johne's disease is based on studies performed on cattle. While many of the features of Johne's in small ruminants and exotics are likely similar to those found in cattle, differences do exist.
- Transmission studies in most species indicate the primary route to be fecal-oral. Transmission can also occur via colostrum and milk, as well as across the placenta (intrauterine).
- Though age-related resistance has been primarily studied in cattle, it is believed that young animals (< 30 days) are most susceptible to infection.

SYSTEMS AFFECTED

Production management, nutrition, gastrointestinal, musculoskeletal

GENETICS

N/A

INCIDENCE/PREVALENCE

Unknown

GEOGRAPHIC DISTRIBUTION

Worldwide, depending on species and environment

SIGNALMENT

Species

Many domestic and wild ruminant species as well as monogastric species

Breed Predilection

N/A

Mean Age and Range

2–7 years

Predominant Sex

N/A

SIGNS

- Chronic weight loss is the most consistent finding in sheep, goats, camelids, and deer.
- Diarrhea or softening of stool is observed at the end stages of disease in the minority (10%–20%) of cases.
- Hypoproteinemia with intermandibular edema (bottle jaw) can be seen in sheep, camelids, and deer.
- Wool break and poor fleece condition can be observed in sheep.
- Patchy alopecia can be observed in deer.
- Clinical signs often appear with, or are exacerbated by, periods of stress (parturition, etc.).

CAUSES AND RISK FACTORS

- Manure management
- Water contamination
- Acid soils
- Colostrum feeding
- Milk feeding and pasteurization
- Note: Bacterial shedding in feces, milk, colostrum, as well as transplacental transmission is more common in animals displaying clinical signs of disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Parasitism
- Internal abscessation (*C. pseudotuberculosis*)
- Caprine arthritis and encephalitis (CAE)
- Ovine progressive pneumonia (OPP)
- Protein/energy malnutrition
- Copper deficiency
- Cobalt deficiency
- Other diseases causing chronic weight loss

CBC/BIOCHEMISTRY/URINALYSIS

Hypoproteinemia and hypoalbuminemia are typically manifest in the later stages of disease.

OTHER LABORATORY TESTS

N/A

DIAGNOSTIC PROCEDURES

- Fecal culture—Test sensitivity is dependant on the *Map* strain and stage of infection. The S strain of *Map* is difficult to grow in culture and can take up to 12 months. In all small and wild ruminants, test sensitivity is increased in the later stages of disease.
- Serologic testing (AGID, ELISA)—Test sensitivity is increased in the later stages of disease. Cross-reacting antibodies to *Corynebacterium pseudotuberculosis* can affect test specificity.
- Polymerase chain reaction (PCR)
- Histopathologic examination of ileocecal lymph nodes, mesenteric lymph nodes, and ileocecal junction

PATHOLOGIC FINDINGS

- Variable weight loss or cachexia
- Variable thickening (mild to severe corrugation of mucosa) of distal small intestine and cecum
- Enlargement and edema of associated lymph nodes
- Lymphangectasia
- Histology: epithelioid cell infiltration into mucosa and submucosa with presence of acid-fast organisms, caseous necrosis, sinus histiocytosis of intestinal lymph nodes.
- Note: severity of pathologic findings may not correlate with disease severity.

TREATMENT

While supportive therapy may prolong life, no practical treatment is available.

MEDICATIONS

N/A

CONTRAINDICATIONS

N/A

FOLLOW-UP

N/A

PREVENTION/AVOIDANCE

- Control fecal/oral transmission (sanitation, hygiene, etc.).
- Prevent feeding of colostrum and milk from test-positive animals.
- Purchase replacement animals from Johne's-free herds or herds with no evidence of infection.
- Annual serologic testing of herd
- Segregation and culling of test-positive animals or clinical cases
- Culling of offspring from known Johne's-infected dams

POSSIBLE COMPLICATIONS

N/A

EXPECTED COURSE AND PROGNOSIS

- Animals exposed to *Map* can either clear the infection or proceed to develop chronic diarrheal disease.
- Animals diagnosed with and displaying signs of Johne's disease are expected to continue to suffer decreased production, ill thrift, and weight loss, and finally succumb to the disease.

MISCELLANEOUS

N/A

ASSOCIATED CONDITIONS

N/A

AGE-RELATED FACTORS

Young animals (< 30 days of age) are believed to be most susceptible to infection. Infection of older animals is possible, however, definitive proof of susceptibility is hampered by limitations of current diagnostic techniques.

ZOONOTIC POTENTIAL

While humans can be infected with *Map*, currently insufficient evidence exists to determine if *Map* is a pathogen of real significance. Concern also exists whether or not *Map* is associated with Crohn's disease, a chronic granulomatous ileocolitis of humans. Again, there is currently insufficient evidence to determine if *Map* is a cause of Crohn's disease.

BASICS

DEFINITION

- JLIDS is a syndrome in young llamas characterized by failure to grow/gain weight as expected and generalized ill thrift, which routinely progresses to multiple and/or chronic systemic infections and eventually to death.
- Recent research suggests an inherited impairment in B-cell development as a potential primary cause.

PATHOPHYSIOLOGY

- Poorly understood
- The specific immunodeficiency has not been determined, but an autosomal recessive defect in B-cell development has been proposed.
- Immunodeficiency leads to opportunistic or overwhelming systemic infections, and failure of the animal to respond to appropriate therapies, ultimately resulting in death.

SYSTEMS AFFECTED

Primarily the immune system is affected. Secondary infections can affect the respiratory, hematologic, gastrointestinal, musculoskeletal, urogenital, and/or ocular systems.

GENETICS

An autosomal recessive inherited basis is suspected but not proven for JLIDS.

INCIDENCE/PREVALENCE

Not well established. One report suggests immune dysfunction is responsible for 7% or greater of llama deaths.

SIGNALMENT

- Juvenile llamas, usually between the ages of 6 and 18 months, of either sex
- Not documented in alpacas

SIGNS

- There are no pathognomonic signs—signs vary with the organ system(s) involved and the stage of the disease, including respiratory signs, lameness, dermatitis, ocular signs, or CNS signs/ataxia.
- Common reported complaints include:
 - Poor body condition and/or poor growth as compared to herdmates
 - Recurring infections or infections that fail to respond to treatment
 - Anemia, with pale mucous membranes, tachycardia, and mild heart murmur
 - Lethargy, depression
 - Occasionally, peracute infection may lead to rapid weight loss and death without prior signs.

RISK FACTORS

- No specific risk factors have been identified.
- A hereditary component to the development of the clinical disease is likely, but a specific inheritance pattern has not been elucidated.

DIAGNOSIS

DIFFERENTIAL DIAGNOSES

Malnutrition, nutritional deficiency (copper, zinc, or selenium), iron deficiency, intestinal parasitism, and hypothyroidism

CBC/BIOCHEMISTRY/URINALYSIS

- Anemia—usually mild, normocytic, normochromic, and nonregenerative, though if the animal is infected with the erythrocyte parasite *Eperythrozoon* spp., the anemia can be severe and mildly regenerative.
- Hypoproteinemia with hypoalbuminemia and low to low-normal globulin levels, even in the face of infection
- Low serum iron concentration with low to low-normal total iron binding capacity

IMAGING

Radiography may be indicated if clinical signs of lower respiratory tract disease and/or septic arthritis is present.

OTHER DIAGNOSTIC PROCEDURES

- *Clostridium perfringens* C and D antibody ELISA: paired serum samples are collected prior to and 2 weeks after vaccination with *C. perfringens* C and D toxoid, and antibody levels are measured. Healthy llamas show at least a twofold increase in titers, while JLIDS llamas have a low initial titer and fail to show any significant rise in titer after vaccination.
- Lymph node biopsy: affected llamas show regions of paracortical lymphocyte depletion.
- Immunologic testing: lymphocyte blastogenesis assays, serum protein electrophoresis, and flow cytometry can be used to characterize the specific immunodeficiency in an affected llama. Although these tests are still in the process of being validated for camelids, initial reports suggest consistent findings in JLIDS llamas include low levels of serum IgG and low numbers of B-lymphocytes.

TREATMENT/PREVENTION

- In the early stages, rule out intestinal parasitism as a cause for ill thrift with appropriate anthelmintic therapy.
- Antimicrobial therapy is indicated to treat systemic infections, with the caveat that infections in llamas with JLIDS routinely fail to respond to therapy and ultimately are fatal.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

MISCELLANEOUS

ASSOCIATED CONDITIONS

- Eperythrozoonosis is a common incidental finding in camelids in North America, but is rarely associated with clinical anemia except in animals with underlying immune dysfunction. The detection of the organism in the blood smear in an animal with severe anemia with or without hemolysis is suggestive of immunodeficiency, such as JLIDS.
- Secondary infections with typically nonpathogenic organisms, such as *Pneumocystis carinii*, *Bordetella* sp., or fungal organisms, are commonly associated with JLIDS.

AGE-RELATED FACTORS

KERATOCONJUNCTIVITIS/CONJUNCTIVITIS

BASICS

OVERVIEW

- Infectious bovine keratoconjunctivitis (IBK) is the inflammation/infection of the cornea and conjunctiva.
- Interactions between the animal, its environment, season, vector availability, physical abrasions, and concurrent infection influence the prevalence of IBK.
- IBK vaccination has in many cases been less than successful.
- Affected animals must be separated from the herd/flock. Vector transmission is important in the longevity of the disease state.
- Carrier animals are common and must be identified and removed from the flock/herd.
- Conjunctivitis: inflammation of the conjunctiva, the membrane that covers the eyelids, and the exposed surface of the eyeball

PATHOPHYSIOLOGY

- Primary: infectious, allergic, foreign body, irritation
- Secondary: underlying disease, deep eye disease, and systemic disease
- *Moraxella bovis* may utilize host iron sources for growth. Iron-repressible outer membrane proteins may accomplish this.
- *Mycoplasma* spp. or infectious bovine rhinotracheitis (IBR) virus may exacerbate the disease process.
- Virulent strains of *M. bovis* produce hemolysin
- *Moraxella bovis* pili antigen cross-reactivity, variable bacterial strains, and uncontrolled environmental factors influence vaccine efficacy.

SYSTEMS AFFECTED

Ophthalmic, musculoskeletal, reproductive, production management

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

- All species, all ages
- Seen most often in young animals

SIGNS

HISTORICAL FINDINGS

- Blepharospasm, epiphora, conjunctival vessel injection, chemosis, lymphoid follicles, corneal opacity, neovascularization, and ulceration
- IBK symptoms may range from mild conjunctivitis to severe corneal ulceration. Chronic corneal perforation and blindness may occur.
- Intense redness of the conjunctival tissues occurs unilateral or bilateral often associated with discomfort and epiphora. Epiphora can be serous, sanguineous, purulent, mucoid, and/or a combination of these.
- Severe cases are often associated with photophobia, blepharospasm, and corneal ulcers, with or without partial or complete loss of vision.

CAUSES AND RISK FACTORS

- Seen most often in young animals. Dust and shipping exacerbate the condition. Flies irritate the eyes further and help spread disease. Tall grass and dusty feeds may physically irritate corneal surfaces.
- In most common outbreak situations where infectious agents are involved, ruminant species are predisposed to

Moraxella bovis (in cattle), *Chlamydia psittaci*, and *Mycoplasma* spp. (in sheep and goats).

Bacteria

- *Chlamydia psittaci*—may cause abortions and polyarthritis in addition to ocular signs, most common during lambing
- *Branhamella ovis* (*Neisseria*)—aerobic bacteria found in one or both eyes, may be normal flora, found with concurrent mycoplasmal and chlamydial disease and in normal eyes. Can also be cultured from cattle. *Mycoplasma*
- May show neovascularization, corneal ulceration, hypopion, and anterior uveitis; is usually unilateral.
- Goats generally do not develop hypopion and ulceration but can have corneal opacification and blindness.
- Camelids have not been reported to be infected by mycoplasmal conjunctivitis.
- *Moraxella* spp. infections in llamas, spread by flies from infected cattle, can occur.
- Neonatal septicemia of all species.

Virus

- Parainfluenza virus, adenovirus, and other respiratory viruses can cause ocular discharge.
- Equine herpesvirus type 1—in llamas, causes blindness and retinal degeneration.

Foreign Body

Foreign objects—seeds or awns of plants, grasses, windblown debris

Entropion

Infolding of eyelid causing abrasion to the corneal surface and tissue irritation; predisposing to ulceration and bacterial infections

Ectopic Cilia

Eyelashes grow inward toward the corneal surface causing irritation to the cornea predisposing to ulcers and infections.

Parasites

- *Oestrus ovis*—nasal bot of sheep can migrate from the nasal passages through the nasolacrimal duct into the eye.
- *Elaeophora schneideri* (sore head)—usually found in deer, spread by biting flies, is most common in the western United States and Canada. Can cause cataracts and blindness due to migration of the parasite.
- *Thelazia californiensis*—ophthalmic parasite seen in ruminants and camelids.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Distinguish primary eye lesions from secondary systemic and parasitic conditions.

Cattle

- Pink eye/infectious bovine keratoconjunctivitis caused by *Moraxella bovis* with acute herd outbreaks of up to 90% morbidity, especially in young.
- Foreign bodies—grass awns, thistle thorns, tall pasture grass
- Allergic, physical, chemical, or smoke irritation
- Cancer—squamous cell carcinoma with predisposition in white faced breeds and unpigmented conjunctiva/adnexa
- IBR—infectious bovine rhinotracheitis associated with respiratory signs, cough
- Phytotoxicity—ingestion of photosensitizing plants and materials such as lush clover, lupinosis, lantana, lucerne. Other toxic agents include: mycotoxins, phenothiazines, motor oil, lubricating oils, and timber preservatives.
- Entropion—congenital defect usually of the lower eyelid
- Eye worms—*Thelazia* sp., habronemiasis
- Vitamin A deficiency—lack of green, fresh, feedstuffs, drought, calves on skim milk
- Cobalt deficiency—unthrifty, poor coat, anemia
- Riboflavin deficiency
- Dermoid cysts
- Toxic ingestion—vitamin D, iodine, phenothiazines, polybrominated biphenyls, chlorinated naphthalenes
- Listeriosis—neurological signs

- Other causes—East coast fever, besnoitosis, lumpy skin disease, bluetongue, actinomycosis, mucosal disease, cholangitis, ephemeral fever, moniliasis, transfusion reaction, respiratory syncytial virus, angioneurotic edema, theileriosis (caused by *Theileria parva* and *T. annulata*), ant bite, rinderpest, trypanosomiasis, malignant catarrhal fever, pneumonic pasturellosis.

Sheep and Goats

- Pink eye—outbreaks of conjunctivitis and corneal ulcers of one or both eyes most often associated in sheep with *Chlamydia psittaci* and in goats with *Mycoplasma* sp.; either agent can be the primary causative infecting organism in both species.
- Chlamydial outbreaks are highly infectious striking up to 90% in herd/flock; often associated with abortion outbreaks in does and lameness/arthritis of stifle, carpal, and tarsal joints. Chlamydiosis is also usually associated with severe eyelid edema and marked conjunctival lymphoid hyperplasia.
- Mycoplasma-related conjunctivitis often associated with less-severe conjunctivitis, but more severe nasal discharge, coughing, and pneumonia.
- *Mycoplasma* sp. also associated with mastitis and arthritis, but much less severe conjunctivitis
- *Neisseria ovis*
- Entropion/ectropion
- Foreign body/grass awn
- Cancer
- Cobalt deficiency
- Fly-strike
- Photosensitization—St. John's wort, heliotrope
- Vitamin A deficiency
- Listeriosis
- Sepsis

CBC/BIOCHEMISTRY/URINALYSIS

Changes consistent with possible underlying disease

OTHER LABORATORY TESTS

- Cornea staining with fluorescein (corneal ulcers exam)
- Topically applied anesthesia, evaluate orbit and adnexa for foreign bodies
- Microbial culture/sensitivity of eye fluids or conjunctival scrapes
- Conjunctival scrapings with cytologic evaluation—show inflammatory cells
- New methylene blue, Wright's, or Giemsa stains may show intracytoplasmic inclusions in epithelial cells. This occurs in one-third of chlamydial cases. Giemsa or Gram stain may show intracytoplasmic coccobacillary/ring-shaped bodies with mycoplasma.

Serology

- IFA for chlamydia, ELISA with mycoplasma to detect carrier animals
- Milk cultures in dairy goats for *M. mycoides* spp. *mycoides*

IMAGING

N/A

TREATMENT

- Isolation of affected animals and fly control.
- For parasitic external infections, mechanical removal and flushing may prove helpful; antibiotics topically or systemically for secondary infections; topical or systemic organophosphates (products approved for ophthalmic use only); steroid ointment may help with inflammation (cases without concomitant ulceration).
- Uncomplicated mycoplasmal and chlamydial eye infections are generally self-limiting without treatment; however, treatment may shorten course and decrease carrier state.

- Treatment of IBK is determined by economic considerations, drug efficacy, and withdrawal times, and feasibility of drug administration.

MEDICATIONS

DRUGS OF CHOICE

- Culture and sensitivity are indicated for appropriate therapeutic choice. Antibiotic therapy should be aimed at achieving drug concentrations in titers at a level high enough to meet or exceed the minimum inhibitory concentration (MIC) for an adequately sustained time period.
- Oxytetracycline ophthalmic ointment 3–4 times daily for 3–4 weeks
- Steroid ophthalmic ointment 2–3 times daily to decrease inflammation (cases without concomitant ulceration)
- Neomycin/polymyxin-B/bacitracin ophthalmic ointment 3–4 times daily for sensitive organisms
- Oxytetracycline systemically for mycoplasmal or chlamydial infections
- Tylosin systemically where culture and sensitivity indicate use for *Branhamella*.
- Atropine 1% ointment 1–2 times daily. If uveitis is present, provide shade from the sun. Llamas are very sensitive to atropine and may need atropine once every 3 days. Monitor pupil diameter to determine reapplication protocol.
- Treatment of isolated affected animals as early as possible with subcutaneous injections 48–72 hours apart with a long-acting tetracycline drug or florfenicol.
- Severe corneal ulceration cases may be given a subconjunctival injection of a long-acting penicillin or tetracycline. Possibly an eyelid flap procedure using absorbable suture material may be indicated. Similar treatment for sheep and goats may be indicated.

CONTRAINDICATIONS

- Do not use steroid preparations topically or systemically if a corneal ulcer is present.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

FOLLOW-UP

PATIENT MONITORING

Recheck corneal surface for ulceration weekly.

PREVENTION/AVOIDANCE

- Quarantine all new animals when entering the flock/herd, milk screening of dairy goats for mycoplasma, fly, and dust control.
- Mow fields to prevent physical abrasions.
- Decrease environmental stress (e.g., heat, particulate matter, bioaerosol level).
- Asymptomatic carriers can potentiate repeat outbreaks in following years.
- Resistance to repeat infection in the same animals is strong, but wanes after 2 to 3 years.
- Provision for uncrowded, shaded areas, fly control with insecticide bags hung near feeders and pyrethrum ear tags, keeping pastures mowed and free of thistle and grass awns and phytotoxic plants, possible vaccination program to be administered at least 30 days prior to sunny dry seasons.
- Do not vaccinate sheep and goat flocks that are unaffected, as this affects sera titer screens.
- Can vaccinate sheep and goats prior to breeding season, but carriers can maintain presence in flock.

POSSIBLE COMPLICATIONS

Blindness, abortions, lameness, and complications due to systemic disease

EXPECTED COURSE AND PROGNOSIS

- Mycoplasma generally resolves in 10 days, but may have recurring episodes for weeks; carriers possibly develop.

- Chlamydial infection generally resolves in 30 days with recurrence and carriers possible.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Ulceration, blindness, abortions, lameness

AGE-RELATED FACTORS

Generally in younger stock; however, all ages are susceptible.

ZOONOTIC POTENTIAL

- *Chlamydia* sp. can cause flulike symptoms in humans.
- Several of these diseases are zoonotic. Care must be taken in the collection of laboratory samples and the diagnosis/treatment of affected animals.

PREGNANCY

Some causes of keratoconjunctivitis can also cause abortion.

RUMINANT SPECIES AFFECTED

Cattle, sheep, and goats are most commonly affected. Llamas have not been reported with mycoplasmal conjunctivitis

BIOSECURITY

- Isolation and quarantine of new stock entering the herd/flock.
- Treat and or cull new animals for disease conditions prior to herd introduction.

PRODUCTION MANAGEMENT

Many eyelid disorders and ectopic cilia are hereditary problems. Avoid using these animals for breeding.

KETOSIS (ACETONEMIA—DAIRY CATTLE)

BASICS

DEFINITION

- Ketosis is a metabolic disorder of lactating dairy cows resulting from an abnormal buildup of ketones in body tissues and fluids.
- The disorder is generally more common 4 to 6 weeks after calving, but can occur as early as a few days after parturition.
- Ketosis is characterized by hypoglycemia, ketonemia, ketonuria, acetone on breath, inappetance, either lethargy or high excitability, loss of weight, depressed milk production, and occasionally incoordination.

PATHOPHYSIOLOGY

- Contributory factors for ketosis have been attributed to two abnormalities in fatty acid oxidation and ketogenesis. The first abnormality is an insufficiency in carnitine palmitoyltransferase activity, which results in decreased entry of long chain fatty acids into the mitochondria.
- Bovine carnitine palmitoyltransferase is inhibited by lipogenic enzymes, such as malonyl-CoA carboxylase and fatty acid synthetase, which are induced by insulin and inhibited by glucagon.
- Lack of a continual insulin response and the resulting increase in the glucagon-to-insulin ratio in plasma of cows treated with glucagon may have been a factor in the increased rate of oxidation of fatty acids.
- The second contributory factor, oxaloacetate, is necessary for acetyl-CoA to enter the Krebs cycle and be oxidized to carbon dioxide.
- In addition, oxaloacetate is an intermediate in the synthesis of glucose from lactate, propionate, pyruvate and glucogenic amino acids. Oxaloacetate is formed during the conversion of pyruvate to phosphoenolpyruvate by pyruvate carboxylase.
- In dairy cows, glucagon increases expression of messenger RNA for pyruvate carboxylase.
- Administration of glucagon addresses the two factors that contribute to the development of ketosis, namely decreased activity of carnitine palmitoyltransferase and oxaloacetate insufficiency.

SYSTEMS AFFECTED

Hepatic, musculoskeletal

GEOGRAPHIC DISTRIBUTION

Worldwide, depending on production management

SIGNALMENT

Species

Bovine

Breed Predispositions

N/A

Mean Age and Range

N/A

Predominant Sex

N/A

SIGNS

HISTORICAL FINDINGS

- The most commonly encountered clinical signs of ketosis include inappetance, constipation, mucus-covered feces, depression, a staring expression, loss of body weight, decreased milk production, and a humped back posture suggestive of mild abdominal pain. Acetone odor is also detected on the cow's breath. These signs are evident a few days to few weeks after calving in affected cows.
- Other common signs include circling, staggering, licking, chewing, bellowing, hyperesthesia, compulsive walking, and head pressing. These occur in episodes of approximately an hour in duration.

CAUSES AND RISK FACTORS

- Ketosis may occur as either primary or secondary ketosis.
- Primary ketosis is caused either by a negative energy balance due to a reduction in feed intake or absorption of dietary carbohydrate precursors.
- In contrast, secondary ketosis occurs due to a decrease in feed intake, commonly due to a preexisting condition such as metritis, mastitis, traumatic reticulitis, or abomasal displacement.
- The onset of ketosis is triggered by a drain on the cow's glucose reserve. As blood glucose concentrations decrease, body fat is mobilized to meet energy demands.
- A corresponding increase in the concentration of nonesterified fatty acids (NEFA) in blood is indicative of this fat mobilization (see [Table 1](#)). Although NEFA are metabolized in the liver, incomplete β -oxidation of NEFA leads to the formation of ketone bodies.

TREATMENT

Medicinal

- Cows with ketosis can be treated by intravenous infusion of 500 ml of dextrose. However, this treatment is only beneficial for a few hours, as most of the dextrose is excreted in the urine and thus can not be recommended as the sole treatment for ketosis.
- Glucocorticoids, such as dexamethasone (0.04 mg/kg) or betamethasone (0.04 mg/kg), reduce cellular uptake of glucose and are commonly used to extend the duration of the hyperglycemia caused by administration of dextrose.
- Overuse of glucocorticoids may result in a reduction of feed intake and exacerbate problems in cows with fatty liver.
- In addition, the treatment of ketosis is aimed at providing glucose precursors, such as glycerol, propylene glycol, and sodium propionate. Glycerol should be given 180 ml/day for 2 days then 90 ml/day for 2 days.
- Cattle with ketosis also can be drenched with propylene glycol (oral liquid, Crown) at 200 ml for the first day then 100 ml/day for 3 days.
- Sodium propionate should be administered orally at 100–250 g daily. Sodium propionate may be considered a more effective treatment of metabolic acidosis in diseases such as ketosis. The added propionate serves as a source for glucose for the cow.

Therapeutics

The concentration of glucose in the blood is regulated by insulin and glucagon, hormones produced by cells in the islets of Langerhans in the pancreas. The islets contain three major types of cells: alpha, beta, and delta.

Table 1 Blood Changes Associated with Ketosis

Source: Adapted from Schultz (1978).

Blood parameter	Normal	Ketosis
Blood glucose (mg/100 ml)	52	28
Blood ketones (mg/100 ml)	3	41
Plasma NEFA (mg/100 ml) ¹	3	33

¹NEFA = nonesterified fatty acids.

Insulin

- Insulin, a peptide hormone composed of acidic and basic chains attached by disulphide bonds, is produced by beta cells. Insulin is an anabolic hormone and acts to preserve nutrients in their storage forms by stimulating glycogenesis,

lipogenesis, and glycerol synthesis by inhibiting gluconeogenesis, glycogenolysis, and lipolysis.

- In ruminants, insulin can be a potent regulator of feed intake and nutrient partitioning. Therapeutic and physiological effects of coadministration of insulin and glucose have been evaluated for efficacy in treating cows with ketosis.
- The results of one study indicated that circulating concentrations of ketone bodies and nonesterified fatty acids were significantly lower in cows receiving glucose plus insulin (22.1 μ U/ml and 0.79 mEq/L, respectively) than in cows receiving glucose alone (63.8 μ U/ml and 0.98 mEq/L, respectively). Therefore, the concurrent use of glucose and insulin may be useful in the treatment of ketosis.

Glucagon

- Glucagon, a peptide hormone containing 29 amino acids, is a pancreatic hormone produced by the alpha cells of the islets of Langerhan. Glucagon stimulates hepatic gluconeogenesis, glycogenolysis, amino acid uptake, and ureagenesis.
- Continuous, intravenous infusion of glucagon in one study for 14 days beginning 21 days postpartum resulted in decreased liver triacylglycerol concentrations and the incidence of ketosis in dairy cows that were given 1,3-butanediol in the diet to induce fatty liver and ketosis.
- Intravenous infusion of glucagon also improves the carbohydrate status of lactating dairy cows without increasing plasma concentrations of NEFA. Because continuous intravenous infusion of glucagon is not practical for on-farm use, studies have been performed comparing single or multiple 5 mg injections of glucagon over a 14-day period. The results of these studies suggest that this treatment improves the carbohydrate status of dairy cows and decreases plasma concentrations of NEFA and β -hydroxybutyrate. Repeated daily, 15 mg injections of glucagon decreased hepatic concentrations of triacylglycerol in cows older than 3.5 years, but failed to produce similar results in younger cows.
- Glucagon is not currently used in the treatment of ketosis, and it appears that its use would only be effective in animals older than 3.5 years.

DIET

- Because blood and liver concentrations of vitamin B₁₂ decrease in cows after parturition, it has been recommended that niacin (6 g/day) be incorporated into the ration for up to 10 weeks after calving.
- Reduced concentrations of cobalt and vitamin B₁₂ have been implicated as a cause of ketosis. Metabolism of propionate through the Krebs cycle requires vitamin B₁₂. Vitamin B₁₂ can be added to the diet, but the efficacy of this vitamin in the treatment of ketosis has not been proven.

MEDICATIONS

CONTRAINDICATIONS

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

FOLLOW-UP

PREVENTION/AVOIDANCE

- The underlying mechanism responsible for clinical and subclinical ketosis is negative energy balance during the first 8 weeks of lactation.
- During late lactation and the dry period, feeding programs should be designed to promote good body condition scores at the time of calving. The model ration for early lactation cows should be highly palatable and energy dense, and introduced in a stepwise fashion.
- Prophylactic use of slow release insulin at a low dose (0.14 IU/kg of BW) has proven effective in preventing ketosis and hepatic lipidosis.

Energy Substrates

- Inclusion of specific precursors that increase the energy density of the diet during the last 3 weeks prepartum may be warranted.
- An increase in the amount of glucose precursors should promote hepatic gluconeogenesis and increase circulating concentrations of insulin. This should decrease hepatic triglyceride accumulation and NEFA mobilization.

- Supplementation of the diet with propylene glycol increases blood glucose and reduces NEFA mobilization and liver fat accumulation.
- Increasing the amount of starch in the diet may be the most effective strategy to increase energy density, and may increase plasma insulin concentration by as much as 300%.

Dietary Fat

- Altering the energy status of the dry cow by increasing dietary fat has not provided much improvement in the energy status of the dry cow.
- Dietary fat does not decrease plasma concentrations of NEFA, liver triglycerides, or the development of metabolic diseases. In contrast, the results of one research trial indicated that inclusion of fat in the diet resulted in lower liver triglyceride concentrations, despite higher NEFA concentrations.

Pregnancy Toxemia of Beef Cattle: Protein Energy Malnutrition Basics

Definition

- Pregnancy toxemia in beef cattle occurs as a result of a negative energy balance due to concurrent increases in energy demands and decreases in the quality and quantity of feed when caloric requirements are increased.
- The increased energy demand is due to fetal development and cold weather.

Signs

Historical Findings

Affected beef cows are usually thin with long hair coats, and their body temperature often is lower than normal. Affected cows that develop diarrhea die 7–14 days after becoming recumbent.

Diagnosis

Differential Diagnosis

- Hypocalcemia
- Listeriosis
- Polioencephalomalacia
- Hypomagnesemia
- Trauma
- Parasitism

CBC/Biochemistry/Urinalysis

- Serum calcium concentrations, packed cell volume, and insulin may be decreased. The liver is smaller than normal at necropsy, since fatty infiltration of hepatocytes occurs transitorily in protein-energy malnutrition.
- Ketonuria is not a common clinical manifestation of ketosis in beef cattle.

Pathologic Findings

Lesions from concurrent diseases may be observed if protein energy malnutrition is acute. A yellow fatty liver and decreased muscle mass often is present. Atrophy of fat has been observed in the coronary groove, bone marrow, and perirenal region.

Treatment

The administration of glucose precursors, such as propylene glycol (150–200 ml, orally), can be helpful to alleviate symptoms of pregnancy toxemia.

Prevention and Nutritional Control

The key to preventing pregnancy toxemia and hepatic lipidosis in pregnant beef cows is to ensure sufficient body condition (body condition score: 5 to 7) as the cow enters the last trimester of her pregnancy. An environmental temperature, at 0°C increases energy needs by 20%.

Contraindications

Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

Miscellaneous

Associated Conditions

Overuse of glucocorticoids in treatment may result in a reduction of feed intake and exacerbate problems in cows with fatty liver.

LACTATION FAILURE (DYSGALACTIA, AGALACTIA, HYPOGALACTIA)

BASICS

OVERVIEW

- Agalactia is a clinical sign characterized by the absence of milk secretion, or the inability of a dam to lactate after parturition.
- Hypogalactia refers to an abrupt reduction in the normal amount of milk produced, and the term “dysgalactia” is sometimes used as a synonym.
- True agalactia can be present in situations of mammary gland aplasia or endocrinology problems that compromise milk synthesis.
- Secondary agalactia is much more common and is present as one of the clinical signs of infectious diseases, intoxications, or neoplasia.
- Contagious agalactia of small ruminants is a syndrome that principally affects the mammary glands, joints, and eyes. The main causal agents are *Mycoplasma agalactiae* in sheep, and *M. agalactiae*, *M. mycoides* subsp. *mycoides* large colony type, and *M. capricolum* subsp. *capricolum* in goats. In addition, *M. putrefaciens* can produce a similar clinical picture, particularly in goats.

SIGNALMENT

- Females just after parturition are most commonly affected.
- Contagious agalactia occurs on all five continents and is often enzootic.

SIGNS

In secondary agalactia or hypogalactia, some of the specific signs for the primary disease can be present, including:

- Depression
- Inappetence (feed refusal)
- Fever
- Swollen or inflamed quarter(s)
- Conjunctivitis and arthritis (infectious agalactia of small ruminants)

CAUSES

- Mammary aplasia, dysplasia
- Peracute toxigenic mastitis (agalactia)
- Clinical mastitis (hypogalactia)
- *Mycoplasma* mastitis in small ruminants (agalactia)
- Leptospirosis (hypogalactia)
- Self-suckling or others suckling
- Water deprivation
- Intoxication (fungal toxins)
- Nutritional deficiency or imbalance (hypogalactia)
- Injury
- Neoplasia

RISK FACTORS

- Cows affected by peracute toxigenic mastitis caused by *Staphylococcus aureus*, *Escherichia coli*, or *Klebsiella* spp. show signs of severe toxemia, such as high fever (104°F–107°F), rumen stasis, and inappetence. Although not all quarters are usually affected, agalactia as a consequence of severe systemic illness can be present. The lactation curve is compromised

and loss of the affected quarter is not uncommon. However, if treatment is successful, cows can reestablish milk production within 1 to 3 days.

- Contagious agalactia of sheep and goats is caused by *Mycoplasma agalactia* and can manifest in an acute, subacute, or chronic form. The udder shows signs of inflammation at the beginning of infection, milk secretion is watery and becomes purulent as the disease progresses, and agalactia is observed in the latter stages. Herd outbreaks may be accompanied by conjunctivitis and lameness (joint inflammation).
- Dysgalactia and agalactia caused by leptospirosis outbreaks have been described in cow and sheep herds.
- Grazing of tall fescue (*Festuca arundinacea*) that is contaminated with fungus (*Acremonium coenophialum*) has been shown to cause hypogalactia in cows. Feeding of grains contaminated with ergot (*Claviceps purpurea* in rye or *Claviceps africana* in sorghum) has produced clinical symptoms characterized by hypogalactia and eventual gangrene of extremities.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inability to secrete milk needs to be differentiated from inability to release milk from the alveolus or to pass it through the teat canal. Blockages need to be more fully examined.
- Primiparous females after parturition sometimes have trouble adapting to the new environment in the milking parlor and the administration of exogenous oxytocin (20 IU) may be necessary the first few days of lactation to accomplish milk release. This procedure may need to be repeated for some days until the animal has completely adapted.
- Proliferative granulation tissue or fibrosis (pencil obstruction) consequent to teat injury can cause partial or total obstruction of a teat canal, compromising milk flow. This is more common in one or two teats rather than hypogalactia or agalactia of the entire gland.

LAMENESS IN SHEEP

BASICS

OVERVIEW

- Lameness is common in sheep.
- It is an important cause of economic loss due to decreased productivity, decreased fertility, and increased culling as well as the indirect costs associated with treating and managing the lame animals.
- The significant welfare implications of lameness cannot be over overestimated. Lameness in sheep should always be addressed and never ignored.
- Sheep may go lame for any number of reasons and generally it is possible to extrapolate from our knowledge of other species. There are, however, a number of conditions specific to sheep that require special consideration due to their infectious nature, the severity of the disease, and the economic and welfare costs associated with disease.
- Like all ruminants, the hooves of sheep grow continuously. Regular hoof care will decrease the chances of the animals developing severe lameness and will also allow the identification of more serious disease before it spreads throughout the flock.
- The three most important causes of lameness in sheep are: (1) infectious foot rot, (2) interdigital dermatitis, (3) contagious ovine digital dermatitis.

SIGNALMENT

- These conditions are most commonly seen in flock outbreaks of mature sheep, although they may affect all ages and breeds.
- Certain breeds of sheep (e.g., merino) appear to be more susceptible to foot rot.

SIGNS

- Lameness in one leg should be easily recognized by even inexperienced shepherds, however, in most cases, more than one limb are affected.
- Bilateral forelimb lameness often results in the animals flexing their carpi and “walking on their knees” with the development of severe calluses.
- In severe cases, the animal may become recumbent and be unable to reach feed and water resulting in severe loss of body condition.
- In some cases, fly-strike may complicate a foot rot lesion.
- Close examination of the feet is an absolute requirement of the examination of any lame sheep.

Interdigital Dermatitis (Scald)

- Lameness may be severe.
- The lesion is restricted to the interdigital skin especially in the heel region.
- The skin may be reddened or pale; there may be swelling and possible hair loss.
- Although the lesion appears mild, it causes significant discomfort.

Foot Rot

- Lameness is severe.
- There is severe underrunning of the hard horn. The lesion typically starts on the axial surface of the heel and in severe cases may result in complete separation of the axial wall and the sole from the underlying tissues.
- There is a characteristic malodorous exudate from the lesions.

Contagious Ovine Digital Dermatitis (CODD)—Hairy Heel Wart

- This unusual cause of lameness has been recently described in the United Kingdom.
- The lesion typically affects only one limb; there is severe undermining of the hoof wall and extreme pain.

CAUSES AND RISK FACTORS

- Interdigital dermatitis is caused by *Fusibacterium necrophorum* and nonvirulent strains of *Dichelobacter nodosus*.
- Contagious foot rot is caused by a number of virulent strains of *Dichelobacter nodosus* (previously *Bacteroides*).
- Prior infection of the foot with either *Fusobacterium necrophorum* or *Arcanobacterium pyogenes* may make it more susceptible to infection.
- The virulence of *D. nodosus* strains is associated with the production of heat-stable proteases and an increase in keratolytic activity.
- The cause of CODD is unknown. Analysis of samples from the lesions has demonstrated the presence of spirochetes, which appear to be similar to those associated with digital dermatitis in cattle.
- Severe lameness in sheep is generally associated with warm, wet conditions.
- The etiological agents of contagious foot rot and CODD do not survive for long periods in the environment (16 days maximum).
- The main mechanism of spreading the disease is by the purchase and introduction of clinically affected animals or subclinical carrier animals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

There are few conditions that can be confused with these causes of lameness:

- Foot and mouth disease virus
- Laminitis due to excessive carbohydrate consumption
- White line abscess formation
- Postdipping lameness—poorly maintained parasiticide dips resulting in infection with *Erysipelothrix rhusiopathiae* (*E. rhusiopathiae*).

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

- Not usually performed
- *Dichelobacter nodosus* may be cultured but requires special transport media.
- A biopsy of CODD lesions may be used to demonstrate the presence of spirochetes.

TREATMENT

- The mainstay of therapy for any form of lameness is proper hoof trimming.
- All animals should have their feet trimmed. The flock should be separated into clean and affected animals (trimming equipment should be disinfected between animals).
- Move animals through a 15% zinc sulfate footbath (150 g/L). If possible, affected animals should stand in the solution for at least 15 minutes.
- Animals should then be turned out to a clean (previous unused for at least 3 weeks) pasture.
- The process should be repeated at weekly intervals until the disease is controlled.
- Severely affected animals or those responding poorly to treatment should be culled.

MEDICATIONS

DRUGS OF CHOICE

- Animals with severe foot rot should be treated with a long-acting oxytetracycline product (20 mg/kg).
- Anecdotal evidence suggests that an oxytetracycline footbath (similar to that used for cattle) may be of benefit for the treatment of CODD.

CONTRAINDICATIONS

- Most drugs are not licensed for use in sheep, therefore these recommendations constitute an off-label use of the drugs.
- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.
- Steroids should not be used in pregnant animals.

FOLLOW-UP

PATIENT MONITORING

- Dealing with these diseases is extremely costly and time consuming.
- Repeated treatments are necessary.

PREVENTION/AVOIDANCE

- Due to the high costs associated with the disease, prevention is the goal.
- Sheep that are new to the flock from an unknown source should always have their feet trimmed and treated.
- They should then be placed in isolation for 2 weeks prior to introduction to the rest of the flock.
- Multivalent vaccines are available in some parts of the world and are an effective means of control, however, immunity is short lived.

EXPECTED COURSE AND PROGNOSIS

- Foot rot: The majority of animals will recover without incident.
- CODD: The prognosis for this condition is guarded.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Lameness, loss of productivity, and subsequent culling from the flock

AGE-RELATED FACTORS

LAMINITIS IN CATTLE

BASICS

OVERVIEW

- Laminitis is a common, multifactorial disease causing lameness in cattle.
- Laminitis is the most common lameness causing disease in dairy cattle and is often found in beef cattle on high-concentrate diets. Laminitis is a diffuse aseptic inflammation of the dermis (corium) of the claw that can be acute, subacute, or chronic.
- The lesions attributable to laminitis are the result of systemic disease associated with dysfunction of the digital vasculature and/or sinkage of the third phalanx with subsequent production of poor-quality horn in the sole, wall, heel, and white line of the hoof capsule.
- Laminitis rarely occurs as acute laminitis, but when it does it is a medical emergency (grain overload).
- Subacute, or chronic, laminitis is much more common in both dairy and beef cattle.
- Subclinical laminitis is sometimes referred to, and is characterized by soft yellow sole and heel horn with hemorrhages in the sole and white line but no concurrent lameness.

PATHOPHYSIOLOGY

- There is speculation that excess production of histamines from protein sources or endotoxins from gram-negative bacteria occur after feeding high-concentrate diets under acid conditions (subacute rumen acidosis, SARA).
- The histamines or endotoxins may then set up a metabolic cascade resulting in decreased oxygen and nutrient supply to the corium. Once the corium is damaged, poor-quality horn is produced, which leads to further damage from mechanical or environmental conditions (high moisture, manure slurry). If the vascular insult lasts long enough, the distal phalanx sinks within the hoof capsule causing further damage to the corium.
- Sinkage of the distal phalanx is thought to be irreversible. There has been speculation that the vascular insult results in separation of the laminae, which leads to sinking of the third phalanx; however, separation of the laminae has not been found to be a prominent feature in pathological samples examined.
- A more current theory is that laminitis is due to failure of the suspensory apparatus for the third phalanx, which occurs around the time of parturition and allows the distal phalanx to sink.
- It has also been noted that the digital cushion in animals with laminitis has more connective tissue and less fat and provides less protection of the corium from concussion.
- Other researchers have proposed a role of metalloproteinases in allowing the suspensory apparatus to relax with resultant sinking of the distal phalanx.

SYSTEMS AFFECTED

- Dermatologic
- Musculoskeletal (secondary to complicated laminitis lesions)
- There is speculation that excess production of histamines from protein sources or endotoxins from gram-negative bacteria occur after feeding high-concentrate diets under acid conditions (subacute rumen acidosis, SARA).
- The histamines or endotoxins may then set up a metabolic cascade resulting in decreased oxygen and nutrient supply to the corium. Once the corium is damaged, poor-quality horn is produced, which leads to further damage from mechanical or environmental conditions (high moisture, manure slurry). If the vascular insult lasts long enough, the distal phalanx sinks within the hoof capsule causing further damage to the corium.
- Sinkage of the distal phalanx is thought to be irreversible. There has been speculation that the vascular insult results in separation of the laminae, which leads to sinking of the third phalanx; however, separation of the laminae has not been found to be a prominent feature in pathological samples examined.
- A more current theory is that laminitis is due to failure of the suspensory apparatus for the third phalanx, which occurs

around the time of parturition and allows the distal phalanx to sink.

- It has also been noted that the digital cushion in animals with laminitis has more connective tissue and less fat and provides less protection of the corium from concussion.

- Other researchers have proposed a role of metalloproteinases in allowing the suspensory apparatus to relax with resultant sinking of the distal phalanx.

SYSTEMS AFFECTED

- Dermatologic
- Musculoskeletal (secondary to complicated laminitis lesions)

GENETICS

Laminitis has an estimated heritability of 0.14–0.22.

INCIDENCE/PREVALENCE

Variable, from 5%–50% or greater

GEOGRAPHIC DISTRIBUTION

Worldwide

SIGNALMENT

Species

Bovine, both dairy and beef

Breed Predilections

- Laminitis is seen most often in dairy breeds due to long periods of feeding high-concentrate rations to promote milk yield.
- In beef cattle, it is more often seen in feedlot cattle than cattle housed on pasture or range.

Mean Age and Range

First-calf cows are more likely to have subacute lesions (sole and white line hemorrhage) due to factors associated with first calving, such as large change in energy density of feed and change in housing, lactation, and growth, all occurring simultaneously.

Predominant Sex

Seen more in dairy cows

SIGNS

HISTORICAL FINDINGS

Increased lameness as a herd problem with laminitis-associated lesions (see Physical Examination Findings and Risk Factors).

PHYSICAL EXAMINATION FINDINGS

- In acute laminitis, animals are clinically lame and walk with arched backs.
- Affected cattle may shift weight from foot to foot and are reluctant to move.
- Hooves are tender to hoof testers.
- Pyrexia and anorexia are commonly seen.
- There are no visible alterations in the hoof; however, increased warmth and pulsation may be discernable.
- In subacute laminitis, the sole will have hemorrhage or yellow discoloration, which will be visible 6–8 weeks after the initial insult.
- In chronic or recurrent-chronic laminitis, the shape of the claw is altered, where the claw becomes broad with concavity of the dorsal wall (“slipper foot”). *Lesions Related to Laminitis*
- Red and/or yellowish discoloration and softness of sole horn
- Horizontal grooves and fissures on the wall (hardship grooves, thimbles)
- Abnormal shape of the claw—becomes broader and flatter, and dorsal wall becomes furrowed and concave (slipper foot)
- Sole and heel ulcers
- Toe ulcers and abscesses
- Double sole
- White line separation, hemorrhages, or abscesses
- Dropped sole

CAUSES

- A combination of predisposing factors leads to displacement of the third phalanx and/or disruption of digital-vascular system causing production of poor-quality horn.
- Manure slurry and constant moisture will soften the already damaged horn.
- Hard floors will cause increased pressure to the damaged corium, which can lead to full thickness ulcers or allow abscesses to form.

RISK FACTORS

Housing conditions (concrete flooring, wet floors, manure slurry, time standing on concrete, bedding, stall comfort), genetics, breeding, nutrition and feeding management (high-concentrate, low effective fiber, wet feeds, slug feeding, ruminal acidosis), periparturient period (calving, transition to lactating cow rations, hormonal changes)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of lameness: digital dermatitis, interdigital phlegmon, hoof overgrowth due to imbalance of growth and wear, thin soles due to excessive wear

CBC/BIOCHEMISTRY/URINALYSIS

N/A

OTHER LABORATORY TESTS

N/A

IMAGING

N/A

DIAGNOSTIC PROCEDURES

History and clinical observation

PATHOLOGIC FINDINGS

Sinkage of the third phalanx, decreased fat content of the digital cushion, inflammation of the corium and epidermis, exostosis of third phalanx, decreased thickness of corium, abnormal claw shape, overgrowth of lateral, hind claws

TREATMENT

APPROPRIATE HEALTH CARE

- Functional hoof trimming should be performed at least one to two times per year, which will help to redistribute weight bearing and allow normal horn formation to resume.
- Sole ulcers should have the surrounding horn thinned to allow growth of new horn.
- An orthopedic block should be applied to the sound claw to allow the diseased claw to rest and heal.
- White line abscesses will need to be opened and all necrotic tissue removed.
- Lesion borders should be thin so that corium is not pinched during the healing process.

NURSING CARE

Affected dairy cows should be placed in pens close to the milking parlor. If treated cattle are bandaged, the bandages will need to be removed after 3–5 days.

ACTIVITY

Walking should be limited as much as possible for lame cattle.

DIET

Normal

CLIENT EDUCATION

- Clients should understand the relationship between various risk factors and laminitis.
- Nutrition and feeding management as well as cow comfort should be monitored and changes made as necessary to keep laminitis (and lameness) at an acceptable level.

SURGICAL CONSIDERATIONS

Deeper infections (septic arthritis or tenosynovitis) seen as sequelae to sole ulcers or white line disease may require claw amputation as a salvage operation.

MEDICATIONS

DRUGS OF CHOICE

For treatment of acute laminitis (grain overload):

- Flunixin meglumine (1.1–2.2 mg/lb once per day for ≤ 3 days) is not labeled for lactating or dry dairy cows.
- Dexamethasone (see label for dose, withdrawal, and class of animals).

CONTRAINDICATIONS

- Dexamethazone can cause abortion in pregnant cows with possible dystocia, retained placenta, and metritis.

- Appropriate milk and meat withdrawal times must be followed for all compounds administered to food-producing animals.

PRECAUTIONS

See Causes and Risk Factors above.

POSSIBLE INTERACTIONS

N/A

ALTERNATIVE DRUGS

N/A

FOLLOW-UP

PATIENT MONITORING

- Animals with sole ulcers or white line disease should be rechecked after 1–2 weeks. Lesion should be cleaned and the wall or sole thinned again at the edge of the lesion, if necessary.
- If granulation tissue is present, it must be removed.

PREVENTION/AVOIDANCE

- Periodic locomotion scoring of cows will alert management when lameness incidence is increasing and allow timely investigation and action to prevent laminitis (or other lameness-causing diseases).
- Animal comfort with good bedding, comfortable stalls, and yielding walking surfaces will help decrease incidence.
- Proper nutrition and feeding management are critical.
- Make sure that there is a gradual transition from dry cow to lactating rations in dairy cattle and that cows have adequate effective fiber.
- Zinc methionine and biotin have been shown to decrease lesions associated with laminitis.
- Research has shown that the digital cushions in heifers contain less fat and therefore provide less cushion than in cows.
- Heifers should have enough time (i.e., 2 months, if going from dirt to concrete) to adapt to new corrals or freestalls before calving.
- For beef cattle, a gradual transition from high roughage to concentrate feeding should attenuate the incidence of laminitis.

POSSIBLE COMPLICATIONS

Sole or toe ulcers or white line abscesses, if not treated early, can progress into deeper infections with involvement of the bones, joints, tendons, and ligaments of the foot.

EXPECTED COURSE AND PROGNOSIS

- Most cases of laminitis that cause lameness can be treated by functional hoof trimming and treating the lesion and will have a good prognosis for recovery.
- If animals have had chronic or recurrent-chronic laminitis and the pedal bone has dropped in the claw capsule, the prognosis for recovery is worse.
- Sole ulcers, toe ulcers, white line abscesses, and heel ulcers will require follow-up care and may require replacement of orthopedic blocks after several weeks.

MISCELLANEOUS

ASSOCIATED CONDITIONS

Subacute ruminal acidosis

AGE-RELATED FACTORS

First lactation dairy cows are especially prone to laminitis-related lesions (sole and white line hemorrhage).

ZOONOTIC POTENTIAL
